**DIRECT VERSUS INDIRECT REALISM WITH REGARD TO CAUSATION.** Realists with regard to causation either reject the Basic Reductionist thesis concerning causal relations, or else both the Strong and the Moderate Reductionist theses concerning causal laws. But there is a crucial divide within realist approaches, and it concerns the question of whether causal states of affairs are immediately observable. According to direct realism, some causal states of affairs are immediately observable; according to indirect, or theoretical-term realism, no causal states of affairs are immediately observable.

What causal states of affairs are directly observable, according to a direct realist approach to causation? Since it is not at all plausible that one can be directly acquainted with causal laws, the relevant states of affairs must consist of causal relations between states of affairs. Thus direct realism can be defined as a version of realism that claims that the relation of causation is immediately given in experience.

Indirect, or theoretical-term realism rejects this claim, maintaining either that the relation of causation is itself an irreducible, theoretical relation, or, alternatively, that causal laws are irreducible, theoretical states of affairs, or both. Either way, then, the relation of causation is not directly observable.

## DIRECT REALISM

We can now turn to a consideration of the four general types of approaches to causation, beginning with direct realism. This view of causation involves four main theses: first, that the relation of causation is directly observable; second, that that relation is not reducible to non-causal properties and/or relations; third, that the relation of causation is also not reducible to non-causal properties and/or relations together with causal laws—since such a reduction would entail that one could not be directly acquainted with the relation of causation; fourth, that the concept of the relation of causation is analytically basic.

A number of philosophers have claimed that the relation of causation is observable, including David Armstrong (1997), Elizabeth Anscombe (1971), and Evan Fales (1990). Thus Anscombe argues that one acquires observational knowledge of causal states of affairs when one sees, for example, a stone break a window, or a knife cut through butter, while Fales, who offers the most detailed argument in support of the view that causation is observable, appeals especially to the impression of pressure upon one's body, and to one's introspective awareness of willing, together with the accompanying perception of the event whose occurrence one willed.

Suppose that it is granted that in such cases one does, in some straightforward sense, observe that one event causes another. Does this provide one with a reason for thinking that direct realism is true? For it to do so, one would have to be able to move from the claim that the relation of causation is thus observable to the conclusion that it is not necessary to offer any analysis of the concept of causation, that the latter can be taken as analytically basic. But observational knowledge, in this broad, everyday sense, would not seem to provide adequate grounds for concluding that the relevant concepts are analytically basic. One can, for example, quite properly speak of physicists as seeing electrons when they look into cloud chambers, even though the concept of an electron is certainly not analytically basic. Similarly, the fact, for example, that sodium chloride is observable, and that one can tell by simply looking and tasting that a substance is sodium chloride does not mean that the expression 'sodium chloride' does not stand in need of analysis.

But might it not be argued in response, first, that, one can observe that two events are causally related in precisely the same sense in which one can observe that something is red; second, that the concept of being red is analytically basic, in virtue of the observability of redness; and therefore, third, that the concept of causation must, for parallel reasons, also be analytically basic?

This response is open, however, to the following reply. If a concept is analytically basic, then one can acquire the concept in question only by being in perceptual or introspective contact with *an instance* of the property or relation in question that is picked out by the concept. One could, however, acquire the concept of a physical object's being red in a world where there were no red physical objects: It would suffice if things sometimes looked red, or if one had hallucinations of seeing red things, or experienced red after-images. The concept of a physical object's being red must, therefore, be definable, and cannot be analytically basic.

What is required if a concept is to be analytically basic? The answer that is suggested by the case of the concept of redness is that for a concept to be analytically basic, the property or relation in virtue of which the concept applies to a given thing must be such that that property or relation is immediately given in experience, where a property or relation is immediately given in experience only if, for any two qualitatively indistinguishable experiences, the property must either be given in both or given in neither.

Is the relation of causation immediately given in experience? The answer is that it is not. For given any

experience *E* whatever—be it a perception of external events, an awareness of pressure upon one's body, or an introspective awareness of some mental occurrence, such as an act of willing, or a process of thinking—it is logically possible that appropriate, direct stimulation of the brain might produce an experience, *E\**, that was qualitatively indistinguishable from *E*, but which did not involve any causally related elements. So, for example, it might seem to one that one was engaging in a process of deductive reasoning, when, in fact, there was not really any direct connection at all between the thoughts themselves—since all of them were in fact being caused instead by something outside of oneself. Causal relations cannot, therefore, be immediately given in experience in the sense that is required if the concept of causation is to be unanalyzable.

Let us now turn to objections to direct realism. The first has, in effect, just been set out. For if, for any experience in which one is in perceptual or introspective contact with the relation of causation, there could be a qualitatively indistinguishable, hallucinatory experience in which one was not in contact with the relation of causation, it would be possible to acquire the concept of causation without ever being in contact with an instance of that relation. But such experiences are logically possible. So the concept of causation must be analyzable, rather than being analytically basic.

Second, it seems plausible that there is a basic relation of causation that is necessarily irreflexive and asymmetric, even if this is not true of the ancestral of that relation. If either reductionism or theoretical-term realism is correct, one may very well be able to explain the necessary truths in question, since the fact that causal concepts are, on either of those views, analyzable means that those necessary truths may turn out to be analytic. Direct realism, by contrast, in holding that the concept of causation is analytically basic, is barred from offering such an explanation of the asymmetry and irreflexivity of the basic relation of causation. It therefore has to treat these as a matter of synthetic *a priori* truths.

Third, direct realism encounters epistemological problems. Thus, features such as the direction of increase in entropy, or the direction of the transmission of order in non-entropic, irreversible processes, or the direction of open forks, often provide evidence concerning how events are causally connected. In addition, causal beliefs are often established on the basis of statistical information—using methods that, especially within the social sciences, are often very sophisticated. Given an appropriate analysis of the relation of causation, one can show why

such features are epistemologically relevant, and why the statistical methods in question can serve to establish causal hypotheses, whereas if causation is a basic, irreducible relation, it is not at all clear how either of these things can be the case.

## HUMEAN REDUCTIONISM

Humean reductionist approaches to causation are of three main types: first, accounts that analyze causation in terms of conditions that in the circumstances are nomologically necessary, sufficient, or both; second, accounts in which counterfactual conditionals play the crucial role; and third, accounts based upon probabilistic relations of a Humean sort.

**CAUSES AND NOMOLOGICAL CONDITIONS.** This first Humean reductionist approach comes in different forms. According to perhaps the most common version, a cause is a condition that is necessary in the circumstances for its effect. To say that event *c* is necessary in the circumstances for event *e* is roughly to say that there is some law, *l*, and some circumstance, *s*, such that the nonoccurrence of *c*, in circumstance *s*, together with law *l*, logically entails the nonoccurrence of *e*.

It may be held instead that a cause is a condition that is sufficient in the circumstances for its effect. To say that event *c* is sufficient in the circumstances for event *e* is to say that there is some law, *l*, and some circumstance, *s*, such that the occurrence of *c*, in circumstance *s*, together with law *l*, logically entails the occurrence of *e*. Finally, it has also been suggested that for one event to cause another is for its occurrence to be both necessary and sufficient in the circumstances for the occurrence of the other event.

What problems do such approaches encounter? Perhaps the most serious difficulty concerns the direction of causation. Suppose, for example, that our world were a Newtonian one, and thus one where the basic laws were time-symmetric. Then the total state of the universe in 1950 would have been both necessary and sufficient not only for the total state in 2050 but also for the total state in 1850. It would therefore follow that events in 1950 had caused both events in 2050 and events in 1850.

Less general objections are also important. First, if a cause is necessary in the circumstances for its effect, this precludes cases of causal preemption, in which event *d* would have caused event *e* were it not for the presence of event *c*, which both caused *e* and prevented *d* from doing so. In such a case *c* is not necessary for *e* since, if *c* had not occurred, *e* would have been caused by *d*. Second, cases of

causal overdetermination are also ruled out. For if both  $c$  and  $d$  are causally sufficient to bring about  $e$ , and both do so, then neither  $c$  nor  $d$  was necessary in the circumstances for the occurrence of  $e$ .

These objections can be avoided if one holds instead that a cause is sufficient in the circumstances for its effect. But then other objections emerge. In particular, it follows that there can be no causal relations if all the laws of nature are probabilistic. This is a serious difficulty, especially given the indeterministic nature of quantum mechanics.

**COUNTERFACTUAL CONDITIONAL APPROACHES.** A second important reductionist approach attempts to analyze causation using subjunctive conditionals. One way of arriving at this approach is by analyzing causation in terms of necessary or sufficient conditions (or both) but then interpreting the latter, not as nomological connections, as above, but as subjunctive conditionals. Thus one can say that  $c$  is necessary in the circumstances for  $e$  if, and only if, had  $c$  not occurred  $e$  would not have occurred, and that  $c$  is sufficient in the circumstances for  $e$  if, and only if, had  $e$  not occurred  $c$  would not have occurred.

John L. Mackie (1965/1993, 1974) took this tack in developing a more sophisticated analysis of causation in terms of necessary and sufficient conditions. Thus, after defining an INUS condition of an event as an insufficient but necessary part of a condition which is itself unnecessary but exclusively sufficient for the event, and then arguing that  $c$ 's being a cause of  $e$  can then be analyzed as  $c$ 's being at least an INUS condition of  $e$ , Mackie asked how necessary and sufficient conditions should be understood. For general causal statements, Mackie favored a nomological account, but for singular causal statements he argued for an analysis in terms of subjunctive conditionals.

The most fully worked-out subjunctive conditional, or counterfactual approach, however, is that of David Lewis (1973/1986, 1979/1986, 2000). His basic strategy involves analyzing causation using a narrower notion of causal dependence and then analyzing causal dependence counterfactually: (1) an event  $c$  causes an event  $e$  if, and only if, there is a chain of causally dependent events linking  $e$  with  $c$ ; (2) an event  $g$  is causally dependent upon an event  $f$  if, and only if, had  $f$  not occurred  $g$  would not have occurred.

Causes, so construed, need not be necessary for their effects because counterfactual dependence, and hence causal dependence, are not necessarily transitive. Never-

theless, Lewis's approach is closely related to necessary-condition analyses of causation since the more basic relation of causal dependence is a matter of one event's being counterfactually necessary in the circumstances for another event.

What problems arise for such approaches? One objection involves overdetermination, where two events,  $c$  and  $d$ , are followed by an event  $e$ , and where each of  $c$  and  $d$  would have been causally sufficient, on its own, to produce  $e$ . If it is true, in at least some actual or possible cases of this sort, both that  $c$  causes  $e$  and that  $d$  causes  $e$ , then one has a counterexample to Lewis's counterfactual analysis.

A second objection involves cases of preemption; that is, cases where there is some event  $c$  that causes  $e$ , but where there is also some event  $d$  that did not cause  $e$ , but that failed to do so only because the presence of  $c$  prevented it from doing so.

Until the late twentieth century, the discussion of preemption had focused on cases where one causal process preempts another by blocking the occurrence of some state of affairs in the other process, and a variety of closely related ways of attempting to handle this type of preemption have been advanced, involving such notions as fragility of events, quasi-dependence, continuous processes, minimal-counterfactual sufficiency, and minimal-dependence sets (Lewis 1986, Menzies 1989, McDermott 1995, Ramachandran 1997). But none of these approaches can handle the case of trumping preemption, advanced by Jonathan Schaffer (2000), where one causal process preempts another without preventing the occurrence of any of the states of affairs involved in the other causal process.

Third, there is once again the problem of explaining the direction of causation. One possibility is to define the direction of causation as the direction of time, but neither Mackie nor Lewis favors that approach: both think that backward causation is logically possible. Mackie's main proposal appeals to the direction of irreversible processes involving the transmission of order—such as with outgoing concentric waves produced by a stone hitting a pond—and Lewis advances a somewhat related proposal, in which the direction of counterfactual dependence, and hence causal dependence, is based upon the idea that events in this world have many more effects than they have causes. But the problem with both of these suggestions is that the relevant features are at best contingent ones, and it would seem that, even if the world had neither of these features, it could still contain causally related events.

A final objection, and the most fundamental of all, is concerned with the truth conditions of the counterfactuals that enter into the analysis. One familiar approach to counterfactuals maintains that the truthmakers for counterfactuals concerning events in time involve causal facts (Jackson 1977). Such analyses cannot of course be used in an analysis of causation, on pain of circularity. Accordingly, Lewis formulated his analysis of causation in terms of counterfactuals whose truth conditions are a matter of similarity relations across possible worlds (Stalnaker 1968, Lewis 1973). It can be shown, however, by a variant on an objection advanced by Bennett (1974) and Fine (1975), that this account of counterfactuals does not yield the correct truth-values in all cases (Tooley 2003). Moreover, the same type of counterexample also shows an analysis of causation based on such conditionals will generate the wrong truth-values in the cases in question.

**PROBABILISTIC APPROACHES.** Among the more significant developments in the philosophy of causation since the time of Hume is the idea, motivated in part by quantum mechanics, that causation is not restricted to deterministic processes. This has led several philosophers to propose that causation itself should be analyzed in probabilistic terms.

The central idea is that causes must make their effects more likely. This idea can, however, be expressed in two rather different ways. The traditional approach, developed by Hans Reichenbach (1956), I. J. Good (1961/1962), and Patrick Suppes (1970), focuses upon types of events and involves the notion of positive statistical relevance. According to this notion, an event of type *C* is positively relevant to an event of type *E* if and only if the conditional probability of an event of type *E*, given an event of type *C*, is greater than the unconditional probability of an event of type *E*. The basic idea, then, is that for events of type *C* to be direct causes of events of type *E*, a necessary condition is that the former be positively relevant to the latter.

But do causes necessarily make their effects more likely? Consider two types of diseases, *A* and *B*, governed by the following laws. First, disease *A* causes death with probability 0.1, while disease *B* causes death with probability 0.8. Second, contracting either disease produces complete immunity to the other. Third, in condition *C*, an individual must contract either disease *A* or disease *B*. (Condition *C* might be a weakening of the immune system.) Finally, assume that individual *m* is in condition *C* and contracts disease *A*, which causes his death. Given these conditions, what if *m*, though in condition *C*, had

not contracted disease *A*? Then *m* would have contracted disease *B*. But if so, then *m*'s probability of dying had he not contracted disease *A* would have been 0.8—higher than his probability of dying given that he had contracted disease *A*. So the claim that lies at the heart of probabilistic approaches—that causes necessarily make their effects more likely—cannot be true.

## NON-HUMEAN REDUCTIONISM

Traditional probabilistic approaches, in analyzing causation in terms of statistical relations, offered a Humean reductionist account of causation. In the late twentieth century, however, an alternative type of probabilistic approach to causation was suggested, one that involves analyzing causation in terms of propensities, or objective chances. Objective chances, however, do not logically supervene upon the totality of Humean states of affairs, as is shown by the fact, for example, that if atoms of a given type take a certain average time *t* to undergo radioactive decay, that fact is logically compatible with different objective chances of such atoms' undergoing decay within a given period of time. An analysis of causation that involves objective chances is therefore a reductionist account of a non-Humean sort.

**OBJECTIVE CHANCE APPROACHES TO CAUSATION.** A number of philosophers—such as Edward Madden and Rom Harré (1975), Nancy Cartwright (1989), and C. B. Martin (1993)—have both advocated an ontology in which irreducible dispositional properties, powers, propensities, chances, and the like, occupy a central place, and maintained that such an ontology is relevant to causation. Often, however, the details have been rather sparse. But a clear account of the basic idea of analyzing causation in terms of objective chances was set out in 1986 both by D. H. Mellor and by David Lewis and then, in the 1990s, Mellor offered a very detailed statement and defense of this general approach in his book *The Facts of Causation* (1995).

Mellor's approach, in brief, is roughly as follows. First, Mellor embraces an ontology involving objective chances, where the latter are ultimate properties of states of affairs, rather than being logically supervenient upon causal laws together with non-dispositional properties, plus relations. Second, Mellor proposes that chances can be defined as properties that satisfy three conditions: (1) The Necessity Condition: if the chance of *P*'s obtaining is equal to one, then *P* is the case; (2) The Evidence Condition: if one's total evidence concerning *P* is that the chance of *P* is equal to *k*, then one's subjective probability

that  $P$  is the case should be equal to  $k$ ; (3) The Frequency Condition: the chance that  $P$  is the case is related to the corresponding relative frequency in the limit. Third, chances enter into basic laws of nature. Fourth, Mellor holds that even basic laws of nature need not have instances, thereby rejecting reductionist accounts in favor of a realist view. Fifth, any chance that  $P$  is the case must be a property of a state of affairs that temporally precedes the time at which  $P$  exists, or would exist. Finally, and as a very rough approximation, a state of affairs  $c$  causes a state of affairs  $e$  if and only if there are numbers  $x$  and  $y$  such that (1) the total state of affairs that exists at the time of  $c$ —including laws of nature—entails that the chance of  $e$  is  $x$ , (2) the total state of affairs that would exist at the time of  $c$ , if  $c$  did not exist, entails that the chance of  $e$  is  $y$ , and (3)  $x$  is greater than  $y$ .

This approach to causation is open to three main types of objections. First, this account necessarily involves the Stalnaker-Lewis style of counterfactuals, and, as was noted earlier, such a closest-worlds account of counterfactuals is unsound.

Second, there are a number of objections that can be directed against the view that objective chances are ontologically ultimate properties, one of which is as follows. Imagine that the world is deterministic, that every temporal interval is divisible, and that all causation involves continuous processes. Suppose that  $x$  at time  $t$  has an objective chance equal to 1 of being  $C$  at time  $(t + \Delta t)$ . Then there are an infinite number of moments between  $t$  and  $(t + \Delta t)$ , and for every such moment,  $t$ , it must be the case either that  $x$  at time  $t$  has an objective chance equal to 1 of being  $C$  at time  $t$ , or that  $x$  at time  $t$  has an objective chance equal to 1 of not being  $C$  at time  $t$ . But then, if objective chances are ontologically ultimate, intrinsic properties of things at a time, it follows that  $x$  at time  $t$  must have an infinite number of intrinsic properties—indeed, a non-denumerably infinite number of properties.

This view of the nature of objective chances involves, accordingly, a very expansive ontology indeed. By contrast, if objective chances, rather than being ontologically basic, supervene on categorical properties plus causal laws, this infinite set of intrinsic properties of  $x$ , at time  $t$  disappears, and all that one may have is a single, intrinsic, categorical property—or a small number of such properties— together with relevant laws of nature.

Third, there are objections to the effect that, even given this view of objective chances, the resulting account of causation is unsound. Here one of the most important is that, just as in the case of attempts to analyze causation

in terms of relative frequencies, it can be shown that the crucial claim that a cause raises the probability of its effect remains unsound when one shifts from relative frequencies to objective chances.

## INDIRECT, OR THEORETICAL-TERM, REALISM

Direct realism with regard to causation is, as we saw earlier, deeply problematic. There is, however, a very different form of causal realism, according to which causation is a theoretical relation between events. On this view, all knowledge of causal states of affairs is inferential knowledge, and the concept of causation stands in need of analysis. But unlike reductionist accounts, the relevant analysis does not imply that causal states of affairs are logically supervenient upon non-causal states of affairs.

A THEORETICAL-TERM REALIST ACCOUNT OF CAUSATION. This approach to causation involves finding postulates that serve to define implicitly the relation of causation. One suggestion here (Tooley 1990), for example, starts out with postulates for causal laws that say, very roughly, that the *a posteriori* probabilities of effects are a function of the *a priori* probabilities of their causes, whereas, by contrast, the *a posteriori* probabilities of causes are not a function of the *a priori* probabilities of their effects. Then, when one adds the further postulate that causal laws involve the relation of causation, the result is an implicit definition of the relation of causation. That implicit definition can then be converted into an explicit one by using one's preferred approach to the definition of theoretical terms. So, for example, if one adopts a Ramsey/Lewis approach, the relation of causation can be defined as that unique relation between states of affairs that satisfies the relevant open sentences corresponding to the postulates in question.

## REALISM OR REDUCTIONISM?

Reductionist approaches to causation are, as we have seen, exposed to a variety of objections. In addition, however, there are general objections that appear to tell against any reductionist approach. Two especially important ones are, first, that the Basic Reductionist Thesis is unsound, and, second, that reductionism cannot provide a satisfactory account of the direction of causation.

SINGULARISM AND CAUSAL LAWS. According to the Basic Reductionist Thesis, causal relations are logically supervenient upon the totality of instances of non-causal properties and relations, together with causal laws. But

this thesis is exposed to a number of objections, such as the following. Assume that indeterministic laws are logically possible and that, in particular, it is a basic law both that an object's acquiring property *P* causes it to acquire either property *Q* or property *R*, but not both, and that an object's acquiring property *S* also causes it to acquire either property *Q* or property *R*, but not both. Suppose now that some object simultaneously acquires both property *P* and property *S* and then immediately acquires both property *Q* and property *R*. The problem now is that, given that the relevant laws are basic, there cannot be any non-causal facts that will determine which causal relations obtain. Did the acquisition of *P* cause the acquisition of *Q*, or did it cause the acquisition of *R*? On a reductionist approach, no answer is possible. Accordingly, causal relations between events cannot be logically supervenient upon causal laws plus non-causal states of affairs.

**REDUCTIONISM AND THE DIRECTION OF CAUSATION.** What determines the direction of causation? Reductionists have advanced various suggestions, but some arguments seem to show that no reductionist account can work. One such argument appeals to the idea of a very simple world—consisting, say, of a single particle, or of two particles rotating endlessly about one another. Such simple worlds would still involve causation since the identity over time of the particles, for example, requires causal relations between their temporal parts. But since such worlds are time-symmetric, the events in them will not exhibit any non-causal patterns that could provide the basis for a reductionist account of the direction of causation. Accordingly, no reductionist account of the direction of causation can generate the correct answer for all possible worlds. It would seem, then, that only a realist account of causation will do.

## CAUSATION: PHILOSOPHY OF SCIENCE

In *The Critique of Pure Reason* (first published in 1781), the German philosopher Immanuel Kant maintained that

causation was one of the fundamental concepts that rendered the empirical world comprehensible to humans. By the beginning of the twenty-first century, psychology was beginning to show just how pervasive human reasoning concerning cause and effect is. Even young children seem to naturally organize their knowledge of the world according to relations of cause and effect.

It is hardly surprising, then, that causation has been a topic of great interest in philosophy, and that many philosophers have attempted to analyze the relationship between cause and effect. Among the more prominent proposals are the following: Causation consists in the instantiation of exceptionless regularities (Hume 1975, 1999; Mill 1856; Hempel 1965; Mackie 1974); causation is to be understood in terms of relations of probabilistic dependence (Reichenbach 1956, Suppes 1970, Cartwright 1983, Eells 1991); causation is the relation that holds between means and ends (Gasking 1955, von Wright 1975, Woodward 2003); causes are events but for which their effects would not have happened (Lewis 1986); causes and effects are connected by physical processes that are capable of transmitting certain types of properties (Salmon 1984, Dowe 2000).

It often happens, however, that advances in science force people to abandon aspects of their common sense picture of the world. For example, Einstein's theories of relativity have forced people to rethink their conceptions of time, space, matter, and energy. What lessons does science teach about the concept of causation?

### RUSSELL'S CHALLENGE

In 1912, the eminent British philosopher Bertrand Russell delivered his paper "On the Notion of Cause" before the Aristotelian Society. In this paper, he claimed that the notion of cause had no place in a scientific worldview:

All philosophers, of every school, imagine that causation is one of the fundamental axioms or postulates of science, yet, oddly enough, in advanced sciences such as gravitational astronomy, the word "cause" never appears ... To me, it seems that ... the reason why physics has ceased to look for causes is that, in fact, there are no such things. The law of causality, I believe, like much that passes muster among philosophers, is a relic of a bygone age, surviving, like the monarchy, only because it is erroneously supposed to do no harm. (p. 1)

Russell was not alone in this view. Other writers of the period, such as Ernst Mach (the German physicist and philosopher of science), Karl Pearson (the father of mod-

ern statistics), and Pierre Duhem (French physicist, as well as historian and philosopher of science), also argued that causation did not belong in the world of science. This view was shared by the logical positivists, a group of philosophers working primarily in Austria and Germany between the World Wars whose ideas shaped much of philosophy of science in the twentieth century. A general suspicion of causal notions also pervaded a number of fields outside of philosophy, such as statistics and psychology.

### CAUSATION IN SCIENCE

Despite Russell's remark, it is simply false that the word "cause" (and its cognates) does not appear in the advanced sciences. Russell's claim can be readily refuted by perusing any leading science journal. Admittedly, some uses of the word "cause" and its cognates have specific technical meanings—such as talk of "causal structure" in connection with the general theory of relativity—but frequently enough these words are used in their ordinary English sense. To cite just one example, an issue of *Physical Review Letters* from 2003 contains an article titled "Specific-Heat Anomaly Caused by Ferroelectric Nanoregions in  $\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3$  and  $\text{Pb}(\text{Mg}_{1/3}\text{Ta}_{2/3})\text{O}_3$  Relaxors." Moreover, it has become common in physics to classify a variety of phenomena as "effects": there is the "Hall effect," the "Kondo effect," the "Lamb-shift effect," the "Zeeman effect," and so on. But surely "cause and effect" are an inseparable pair: where there are causes, there are effects that are caused by them, and where there are effects, there are causes that cause them.

The person on the street is more likely to encounter causal claims from the medical sciences, such as: "Cholesterol in the bloodstream causes hardened arteries, which in turn causes heart attacks." While the medical sciences may not be as advanced as Russell's example of gravitational astronomy, it is implausible to think that these causal claims are the result of conceptual confusion, or are otherwise scientifically disreputable.

Despite the falsehood of its most provocative claim, however, Russell's paper does succeed in highlighting a number of important and interesting problems about the role of causation in science.

### ANTI-FUNDAMENTALISM

Although the advanced sciences have hardly eschewed talk of causation, it is true that the deepest physical principles—such as Newton's three laws of motion, his law of universal gravitation, Maxwell's equations governing the

electric and magnetic fields, Schrödinger's equation governing the evolution of quantum systems, and Einstein's field equations relating the distribution of mass-energy in the universe with the structure of space and time—make no mention of causation. All of these principles take the form of mathematical equations and act as constraints on possible states of physical systems (under suitable mathematical characterizations). A given sequence of states may be compatible with, for example, Newton's laws of motion, but nothing in those laws explicitly says that certain states (or aspects of those states) cause others. This suggests that the causal relation is not part of the constitution of the world at the deepest metaphysical level, a view that the historian and philosopher of science John Norton labels "anti-fundamentalism" (Norton 2003). Indeed, the world described by fundamental physics is in many ways at odds with the ordinary picture of a world regimented by cause and effect relationships.

### ASYMMETRY

People normally think of causation as both *asymmetric* and *temporally biased*. It is asymmetric in the sense that if  $C$  is a cause of  $E$ , then (always? typically?)  $E$  is not a cause of  $C$ . This claim must be stated with some care. It may be, for instance, that anxiety is a cause of insomnia, which is in turn a cause of anxiety. But it is one's anxiety on Monday evening that causes insomnia on Monday night, which in turn causes anxiety on Tuesday morning. Monday night's insomnia is not both the cause and the effect of one and the same episode of anxiety. Causation is temporally biased in the sense that causes (always? typically?) occur before their effects in time.

By contrast, the fundamental laws of physics mentioned above are all *time-reversal invariant*. That is, if a particular sequence of states of a physical system is consistent with the laws of physics, then the temporally reversed sequence is also consistent with those laws. The laws of physics do not discriminate between the past and the future in the way that causation does, with two possible exceptions. The first exception involves the statistical laws governing the decay of certain mesons. While these laws exhibit a slight temporal asymmetry, the phenomena in question seem too esoteric to be of much help in understanding the asymmetry of causation.

The second exception is the second law of thermodynamics, which states that the entropy of a closed system can increase but never decrease. Thus a closed system whose entropy is increasing is consistent with the second law, while the temporal reverse of this system is not. The second law of thermodynamics is not, however, a funda-

mental law. The entropy of a physical system is determined by the physical state of the particles that make up the system, as characterized in terms of ordinary physical parameters such as position and momentum. These particles are in turn governed by the time-reversal invariant laws already mentioned. It is thus something of a mystery how the asymmetric second law of thermodynamics can arise from the underlying symmetric dynamics governing the constituents of thermodynamic systems. One prominent view is that the second law of thermodynamics is the result of de facto temporal asymmetries in the boundary conditions of the universe.

There have been a few attempts to ground the asymmetry of causation in the second law of thermodynamics. The basic idea is that the best characterization of our physical universe will include not only the fundamental laws of physics, but also the statement that in the past our universe was in a state of very low entropy—the so-called “past hypothesis.” When entertaining various counterfactual suppositions, one conjoins those suppositions with the laws of physics and the past hypothesis to determine what the world would be like if those suppositions were true. Because people hold fixed features of the past, but not of the future, when entertaining contrary-to-fact suppositions, any changes from the actual world introduced in those suppositions will tend to entail significant changes in the future but only insignificant changes in the past. In this way, macroscopic features of the future will counterfactually depend upon what is true in the present, whereas macroscopic features of the past will not. This asymmetric relation of counterfactual dependence can then serve as the basis of an account of causation (such as that of David Lewis in “Causation” [1986]). If this account is correct, then the existence of an asymmetric causal relation is not guaranteed by the laws of physics but is rather the consequence of contingent asymmetries in the boundary conditions of the world.

The best-known attempt to account for causal asymmetry is the common cause principle, first formulated by the German-American philosopher Hans Reichenbach and presented in his posthumously published book *The Direction of Time* (1956). For Reichenbach, temporal order and causal order are conceptually intertwined. Reichenbach defines causation in terms of probabilities and temporal order, but temporal order is itself defined in terms of asymmetries in probabilities. Let  $A$  and  $B$  be two events that are probabilistically *correlated*; in other words, the probability that  $A$  and  $B$  will occur together,  $P(A \& B)$ , is greater than the product of the individual probabilities,  $P(A)P(B)$ . (If the two probabilities are equal, then  $A$

and  $B$  are said to be probabilistically *independent*.) An event  $C$  is said to “screen off”  $A$  from  $B$  if it renders them *conditionally independent*; that is, if  $P(A \& B|C) = P(A|C)P(B|C)$ . If there is an earlier event  $C$  that screens off  $A$  from  $B$ , but no later event that does so, then the trio  $ABC$  forms a *conjunctive fork open to the future*. If there is a later screener-off  $E$ , but no earlier one, then  $ABE$  is a conjunctive fork open to the *past*. Finally, if there is an earlier and a later screener-off, then that is a *closed fork*. According to Reichenbach, the overwhelming majority of open forks are open to the future, and this probabilistic asymmetry provides the basis for the distinction between the past and the future. Reichenbach further held that if two events  $A$  and  $B$  are correlated, and neither is a cause of the other, then there exists a common cause of  $A$  and  $B$  in their mutual past that screens  $A$  off from  $B$ .

Reichenbach believed that his common cause principle was related to the second law of thermodynamics. Think of  $A \& B$  as one possible state of a physical system, the other possible states being  $A \& \sim B$ ,  $\sim A \& B$ , and  $\sim A \& \sim B$ . A probability distribution over these states in which  $A$  and  $B$  are correlated contains *information*, in a sense that is made precise within the mathematical field of information theory. From a formal perspective, information is inversely related to entropy. Thus a correlation between  $A$  and  $B$  is like a low entropy state of a physical system, and it is to be explained in terms of an earlier causal interaction between the system and its external environment.

There are a number of difficulties facing Reichenbach’s common cause principle. The principle seems to fail for certain quantum phenomena involving distant correlations, such as the one featured in the famous thought experiment by the physicists Albert Einstein, Boris Podolski, and Nathan Rosen, in their 1935 paper “Can Quantum Mechanical Description of Reality Be Considered Complete?” In a simplified version of this setup, two particles form a single system in which the total spin is zero. If the particles are separated, and the spin of each particle is measured, they will always be found to have opposite spins. There is thus a correlation between the outcome of the two measurements. Neither measurement result can be a cause of the other, for the measurements can be conducted at such a great distance that not even a light signal could connect the two. Yet a series of mathematical and empirical results, beginning with the work of the physicist John Bell in 1964, show that there can be no earlier state of the two-particle system that screens off the measurement outcomes.

A further problem is that it is unclear why Reichenbach’s fork asymmetry should hold within the physical

framework of classical statistical mechanics. Within this framework, a system possesses a microstate that evolves deterministically according to Newton's laws of motion. An "event"  $A$  is just a coarse-grained characterization of the state of the system at a particular time, consistent with many different microstates. A probability distribution is defined over the possible states of the system. Suppose that the events  $A$  and  $B$  are correlated according to this probability measure, and that there is an earlier event  $C$  that screens off  $A$  from  $B$ . It is possible to take the image of  $C$  under the deterministic dynamics of the system; that is, one can evolve each microstate in  $C$  to some point in time after the occurrence of  $A$  and  $B$  and collect the resulting set of microstates into a new event  $C'$ . By construction,  $C'$  will stand in the same probability relations with  $A$  and  $B$  that  $C$  did. Hence,  $C'$  will be a later event that screens off  $A$  from  $B$ , and  $ABCC'$  will form a closed fork. Because this procedure is fully general, it is not clear how there can be forks open to the future at all. One possible reply to this worry is that in such a closed fork, the later screener-off  $C'$  will just be a heterogeneous collection of microstates, and hence will not qualify as an "event" in the relevant sense. This reply raises two new questions: first, which sets of microstates constitute genuine events? Second, why should we expect that only earlier screeners off will be genuine events?

### FURTHER CAUSAL ANOMALIES

There are a number of further respects in which the world described by fundamental physics seems not to be one ruled by relations of cause and effect. It is well known that certain quantum-mechanical phenomena such as radioactive decay appear to be *indeterministic*. For example, even a complete description of the present state of a carbon-14 atom cannot allow one to predict whether or not it will decay during a certain period of time, but will instead yield only a probability that decay will occur. If the atom does eventually decay, can anything be said to cause the decay event? This kind of indeterminism provides part of the motivation for attempts to analyze causation in terms of probabilities. But even probabilistic theories of causation have difficulties when indeterminism is coupled with the sorts of distant correlations described in the previous section.

Moreover, even classical Newtonian physics admits indeterminism. For example, John Norton, in "Causation as Folk Science," describes a system consisting of a point mass sitting at the apex of a bell-shaped dome. Newton's laws of motion permit the point mass to rest there indefinitely, but they also allow it to begin sliding down the

side of the dome in an arbitrary direction after an arbitrary finite time. No force is necessary to dislodge the mass: the sudden motion of the mass down the side of the dome is fully consistent with the constraint that at every instant, the force acting on the mass (due to the pull of gravity, and the reactive push of the dome's wall) is proportional to its acceleration. Such a motion thus appears to be entirely uncaused.

Einstein's general theory of relativity also gives rise to causal anomalies. For example, the Austrian-American mathematician Kurt Gödel showed that Einstein's field equations permitted solutions in which there were *closed causal curves*. Thus it may be possible for a billiard ball to get knocked, continue rolling along its new trajectory, and then eventually bump into its earlier self, knocking it into that new trajectory in the first place. Such a scenario appears to be at odds with people's ordinary conception of causation as an asymmetric relation, for the collision between the older and younger billiard ball causes the trajectory of the younger ball, which in turn causes that collision.

### CAUSAL INFERENCE

One of Russell's targets in "On the Notion of Cause" was the so-called "law of causality"; indeed, it is this law, rather than the "notion of cause" itself, whose utility is compared to that of the British monarchy. Russell cites a formulation of this principle from the nineteenth-century British philosopher John Stuart Mill: "The Law of Causation, the recognition of which is the main pillar of inductive science, is but the familiar truth, that invariability of succession is found by observation to obtain between every fact in nature and some other fact which has preceded it." (Mill 1856, p. 359.)

According to Mill, science discovers causal relationships by discovering invariable regularities in nature, and the success of science presupposes the pervasiveness of such regularities. Russell was certainly right to challenge the importance of this law to science—not because science is not in the business of discovering causal relationships, but because causal inference in science does not rest upon the discovery of perfect regularities.

Causal inference presents a *prima facie* difficulty, first articulated by the Scottish philosopher David Hume in 1739. Suppose that one billiard ball collides with a second, causing it to move. One can observe the motion of the first billiard ball; and one can observe the motion of the second billiard ball; but one cannot observe the causation that connects the two together. How, then, is a person to acquire knowledge of causal relationships?

Traditionally there have been two main lines of response to this problem. One line that has already been mentioned is to reject the notion of causation on the grounds that it is inaccessible to empirical investigation. The second line, adopted in different ways by Hume, Mill, and a number of twentieth and twenty-first century philosophers, is to try to spell out systematic connections between causation and observable phenomena such as empirical regularities in order to explain how the former can be inferred from the latter. The “law of causation” championed by Mill and attacked by Russell stems from this second line of response to the problem. (A third possibility, defended in the early part of the twentieth century by the French-American philosopher C. J. Ducasse, and in the middle of the twentieth century by the Belgian psychologist André Michotte, is to reject the claim that causation is not subject to direct perception. Even if this is possible in special cases such as billiard ball collisions, however, this hardly seems to be an adequate explanation for causal knowledge generally.) This problem concerning the empirical accessibility of causation has been a driving force behind attempts to banish causation, and also behind attempts to provide causation with a sound philosophical analysis.

In fact, however, causal inference is neither impossible nor a matter of reading causal relations off universal regularities or correlations. Causal inference, like other forms of scientific inference, is broadly “hypothetico-deductive” in character. A causal hypothesis is formulated, and in conjunction with various background assumptions (often involving causal relationships themselves), it is used to derive predictions about what types of correlations will be observed. These predictions are then compared with observations. In this way, causal hypotheses may be subjected to empirical test without the need for a direct reduction of causal claims to claims about regularities and the like.

## EXPERIMENTATION

The most reliable causal knowledge comes not from passive observations, but from controlled experimentation. In the medical sciences, the experiments often take the form of randomized clinical trials. Consider the claim that a particular drug causes lowered blood pressure. How might one test this claim? One possibility would be to make the drug available on the open market and observe hypertension patients who choose to take the drug and those who do not. There is a problem with this methodology. Suppose that the drug is expensive; one might expect that patients who buy the drug will be

wealthier on average than those who do not. Wealthier patients might enjoy any number of other benefits—such as access to better healthcare generally, better diets, and so on—that influence whether or not they experience a reduction in hypertension. If one finds that patients who take the drug do in fact experience greater reduction in blood pressure levels than those who do not, it can still not be known whether this reduction is due to the drug or due to one of the other advantages associated with wealth. In a randomized trial, it is determined randomly which patients will receive the drug and which will be given a placebo instead. Randomization helps to ensure that treatment is not correlated with any other causes that might influence recovery.

This example helps to show the importance of the distinction between genuine causal relationships, on the one hand, and mere regularities or correlations on the other. Suppose that the drug is available only to wealthy patients, and that patients who take the drug fare better, on average, than those who do not. If this correlation is due to the wealth of the patients who use the drug, rather than to any effect of the drug itself on hypertension, then one would not expect the correlation to persist under various policy interventions. For example, if the drug were to be covered by insurance, so that less wealthy patients could also afford to take the drug, then the correlation between use of the drug and lowered hypertension would disappear. As the philosopher Nancy Cartwright puts it in her paper “Causal Laws and Effective Strategies” (1983), causal relationships support “effective strategies,” while mere correlations or regularities do not. It is for this reason, Cartwright argues, contrary to the opinion of Russell, that the notion of cause cannot be dispensed with. It is also for this reason that one often finds the most self-conscious attention to the specific concerns of causal inference in those branches of science that have a practical dimension, such as medicine and agronomy.

In many areas of science, randomized trials are not feasible. This may be due to the inability to produce the putative cause at will, or it may be due to the lack any analog of a control group that receives placebos. Nonetheless, in the experimental setting, it is often possible to isolate the influence of the cause under investigation by preventing other causes from operating. For example, an experiment might be conducted within a metallic container to eliminate external magnetic influences; or the experimental apparatus may be set afloat in a pool of mercury to prevent vibrations from being transmitted through the floor of the laboratory (as was done in the famous Michelson-Morley experiment of 1887, which failed to

detect any effect of the earth's motion on the speed at which light traveled). Sometimes the experimental preparations are more mundane, such as thoroughly dusting the apparatus to eliminate the effects of stray dust particles, or even removing pigeons found nesting in the apparatus (as was required by Arno Penzias and Robert Wilson, who discovered the cosmic microwave background in 1965).

## CAUSAL MODELS

In some fields, such as macroeconomics, epidemiology, and sociology, experimental manipulation is simply not feasible, and causal relationships must be inferred from observed correlations. Beginning around 1990 has been an explosion of interest in developing causal modeling techniques to facilitate such nonexperimental causal inferences. Two important works that have garnered a substantial amount of attention from philosophers are *Causation, Prediction and Search* (2000), by the philosophers Peter Spirtes, Clark Glymour, and Richard Scheines, and *Causality: Models, Reasoning, and Inference* (2000) by the computer scientist Judea Pearl. Both frameworks employ graphs to represent causal relationships among sets of causal variables. The variables in a set  $V$  form the nodes of a graph, and certain pairs of variables are connected by *edges* in the graph. In a *directed graph*, the edges take the form of arrows, which point from one variable into another. If a graph over the variable set  $V$  contains an arrow from the variable  $X$  to the variable  $Y$ , that indicates that  $X$  is a *direct cause* of  $Y$  (also called a *parent* of  $Y$ ): the value of  $X$  has an effect on the value of  $Y$  that is not mediated by any other variable in the set  $V$ .

The causal structure represented by a directed graph is connected to a probability distribution over the values of the variables by the *causal Markov condition*. This condition states that, conditional upon the values of its direct causes, the values of a variable are probabilistically independent of the values of all other variables, except for its effects. In other words, a variable's parents screen off that variable from all other variables, except for its effects. (The causal Markov condition is closely related to Reichenbach's common cause principle, discussed above.)

With the help of the causal Markov condition, as well as other conditions such as the *minimality* and the *faithfulness* conditions, a graph representing causal relationships among a set of variables will serve as a model that makes predictions about probabilistic relationships among the variables. In particular, it predicts that certain variables will be dependent or independent of others, either unconditionally, or conditional upon the values of

other variables. These predictions can then be tested using normal statistical means.

The most obvious use of these methods is to test whether a postulated set of causal relationships among the variables in the set  $V$  is consistent with the statistical data about the values of those variables. But there are other types of problems where these methods can be applied. Even if one does not begin by hypothesizing a specific causal model, it is possible to determine which sets of causal relations among a variable set are consistent with the statistical data. Typically, the data will not single out one causal model, but will only pick out an equivalence class of statistically indistinguishable models. In this case, background knowledge may help to narrow the set of plausible models. In a different sort of problem, one begins with a qualitative causal model and uses it to make quantitative predictions about the effects of interventions that have not yet been performed.

It is important to note that the causal Markov condition is not an a priori constraint on the relationship between causal structure and probability. It can fail, for instance, if a variable set  $V$  omits a variable that is a common cause of two variables included in  $V$ . The causal Markov condition is at best an empirical assumption that holds for a wide variety of causal structures, and hence any application of techniques based on the causal Markov condition to infer causal relationships from probabilistic data carries substantive empirical presuppositions. A number of critics have charged that these presuppositions severely limit the utility of the new causal modeling techniques.

## CONCLUSIONS

Contrary to Russell's claim, causal notions are as pervasive in science as they are in philosophy and everyday life. New scientific techniques continue to be developed for the discovery of causal relationships. Nonetheless, the world as it is described by the deepest physical principles bears little resemblance to a world that is regimented by asymmetrical causal relationships. Thus there remain a number of deep puzzles about how causal relationships can emerge from physical laws that themselves make no mention of causality.

## CAUSATION IN INDIAN PHILOSOPHY

Indian philosophical theories, from their earliest speculative cosmologies and explorations of the nature of human existence—in the Vedas and Upanisads, whose compositions were completed by roughly the first half of the first millennium BCE—emphasized the plight of humans and their struggle towards a soteriological goal. An understanding of the evolution of the world and the place of human beings within it held out the hope of improving their lot, either in some other place after death or in the next life in the round of deaths and rebirths. Or even, as the Upanisads suggested, in the ultimate avoidance of rebirth itself—a theme adopted by much Indian philosophy thereafter.

As in Western metaphysical speculations about the nature of the cosmos and man's place within it, the Indian thinkers made central and vital use of the concept of a cause—*karana* in Sanskrit—and progressively developed a sophisticated understanding of this concept.

### VEDAS AND UPANISADS

The earliest Vedic answers to the question of cosmological evolution suggested a god or gods, variously named and described, as creating and ruling over the human

world. Such views invoked probably the most obscure and difficult application of the concept of causation—that of creation—but had at least the merit of putting men and gods in a continuing relationship. Men could worship their gods, and indeed could wield a degree of control, through religious ceremonies that aimed to elicit benefits from them.

The Upanisads took a more subtle turn, concentrating on a deeper understanding of the nature of man himself. The “inner self,” the *atman*, was distinguished from its physical embodiment and was taken to proceed through a series of rebirths according to a causal law of *karma*—whereby moral merit or demerit dictated the nature of the next rebirth. Ultimately it would hopefully achieve release from rebirths and acquire its final state of bliss (*moksa*).

The period from the fourth to the second century BCE was one of quite subtle developments, with new and deeper ideas of the causal operation of the law of *karma*, of the nature of human existence, and of the nature of and route to the soteriological end for man. The Hindu *Bhagavad Gītā* was composed—a part of the great epic the *Mahabharata* (the actual period of composition is still much disputed)—and two nonorthodox systems of ideas were introduced: Jainism and Buddhism. Interestingly, both Jainism and Buddhism have no place for deities in their systems, human existence and progression to the ultimate state of release from rebirth being said to depend on the efforts of the individual. We will look at these three systems, and at just some of the later developments through the classical period of Indian philosophy.

## BHAGAVAD GĪTĀ

The *Bhagavad Gītā* (Song of the Lord) takes the form of a dialogue between the warrior-prince (*ksatriya*) Arjuna and Lord Krishna, who is a human manifestation (*avatara*) of the god Vishnu. Arjuna hesitates to lead his army into battle against his cousins who have usurped control of the state, suffering a confusion about which duty he should follow: fight to rectify the wrong they have done to society or refrain from fighting to protect his family and caste. Krishna argues that Arjuna should fight. The world is in a final epoch of the cycle of evolution and corruption, a process of dissolution that requires his coming to advise mankind on correct behavior. As Vishnu, he has designed the nature of human society with its hierarchy of castes and their associated socioreligious duties. By the law of *karma*, the *ātman* of each individual goes through the process of birth-death-rebirth (*sāmsara*), gaining merit according to good deeds and

demerit according to bad. *Karma* in this context therefore has moral, religious, and soteriological dimensions. *Moksa*, final release, is achieved through individual effort. And the central theme of the *Bhagavad Gītā* is the doctrine of *karma-yoga*, a route to salvation that involves acting according to established socioreligious duties, for the sake of maintaining the social fabric and for pleasing god.

Quite apart from the question whether *karma-yoga* actually resolves a conflict of duties such as Arjuna’s, there is a further question: whether the *Bhagavad Gītā* really leaves any room for freedom of action for Arjuna, or indeed mankind in general. The text ascribes such enormous powers to Vishnu that individual human effort seems futile. Nature—the world in which the *atman* becomes embodied—is a creation of Vishnu. It involves the interplay between three “strands” (*gunas*), called *sattva*, *rajas*, and *tamas*—which can be translated as “goodness,” “passion,” and “inertia,” respectively. All nature is but the playing out of the interaction between these *gunas* in a mechanistic, deterministic way. The balance of the *gunas* in a particular individual also dictates his character and hence his actions. The *atman* cannot affect the *gunas*, and there seems no chance of choosing to follow the path of *karma-yoga*, much less any other activities.

The *Bhagavad Gītā* adds further worries for its *karma-yoga* theme, for Vishnu has foreknowledge of all that will happen, and retains a tight control over all actions—overt and psychological—of all human beings. “The Lord abides in the hearts of all beings, O Arjuna, causing them to turn round by His power as if they were mounted on a machine,” declares Krishna in the final chapter. So the *Bhagavad Gītā* is a brave but flawed attempt to teach an ethics of engagement in traditional socioreligious duties. The law of *karma* was supposed to allow human beings to strive towards *moksa*, the law itself being a creation of Vishnu to ensure a just outcome for our efforts. The text’s failure to sustain this account perhaps goes a long way toward explaining why a good deal of later philosophical speculation (if not common religious practices), including much of so-called orthodox or Hindu philosophy, found no room for a deity as originating and controlling human existence.

## JAINISM

Jainism was founded in the sixth century BCE by Vardhamana—who became known as Mahavira (Great spiritual hero)—and is named after the Sanskrit word for conqueror (*jina*). (Though Vardhamana left no texts, a particularly important text was composed by Umasvati

some nine centuries later: *Tattvarthadhigama Sutra*, or *Discourse on the Nature of Things*.) It is system that supposedly commends itself to reason. Rejecting the authority of the Vedas, it nevertheless keeps the idea of a spiritual substance, a *jiva*. Entrapment in the round of births and deaths is seen as a consequence of fine polluting karmic dust that restricts the all-knowing ability of the *jiva*. The route to salvation involves the elimination of this pollution, to achieve the state of perfect knowledge (*kevala*). In contrast to the complex interpretation of the workings of the law of *karma* in the orthodox tradition, the Jain account might appear a straightforward theory of physical causation. Yet the process of karmic improvement nevertheless has a serious moral dimension, for it involves a commitment to five “vows of restraint”: nonviolence (*ahimsa*), truthfulness (*satya*), no theft (*asteya*), sexual continence (*brahmacharya*) and nonattachment to worldly pleasures (*apigraha*). By the individual’s own efforts, therefore, the desired end of perfect knowledge is achieved.

## BUDDHISM

Buddhism was founded, also in the sixth century BCE, by Siddhartha Gautama, who became known as the Buddha (the Enlightened One) and spent many years proclaiming his insights into the predicament of the cycle of births and deaths and the route to release into *nirvana*. He left no writings of his own, but his teachings are recorded in the collection known as the *Sutta Pitaka* of the Pali work the *Tripitaka* (Three baskets of tradition). The Buddha taught a system of ideas that was in stark contrast to the earlier orthodox Vedic tradition, rejecting any reliance on those texts, on the priestly caste (the Brahmins), and on the orthodox depiction of salvation. Nothing brings out this contrast more than claim that reality has these three marks: impermanence (*anitya*), no-soul (*anatman*) and suffering (*duhkha*). A standard depiction of reality (*brahman*) by the Hindu tradition is quite the opposite: being as a permanent (*sat*), consciousness (*cit*) and bliss (*ananda*).

The Buddha’s system is supposedly based upon observation, both of the world outside him and of the inner workings of his mental world. Crucially, he could not observe an *atman*. Instead, he reports as his fundamental discovery that all the ingredients observed obey a general principle of “dependent origination” (*pratityasamutpada*). Whatever comes into existence is the causal consequence of previous existents. Causal generation has a complex form where a number of such previous existents produce together the new existent. And

each and every existent is momentary. Applying this general principle to the specific case of a sentient being, he classified all its momentary causal ingredients into five groups (*skandhas*). These can be rendered as these (following their later interpretation in the work *Milindapanha*, or Questions of King Milinda): thoughts (*vijnana*), feelings (*vedana*), volitions (*samskara*), perceptions (*samjna*) and bodily ingredients (*rupa*). And, most crucially, there being a complex interplay between the ingredients both within and across the groups, he identifies as the *fundamental* causal factor driving them all—through this life and through into rebirths—the thought “I am a permanent entity.”

This cognitive error, involved as it is in the Hindu idea of the *atman*, is the root cause of all grasping—for fame, for power, and for all other worldly goods—and therefore the root cause of suffering and rebirths. Only the correction of this error can lead to salvation. Moreover, this correction leads to a general change in motivations for action, whereby selfish desires are replaced by altruistic ones such as compassion, and the adoption of such altruistic desires in its turn helps to achieve the cognitive correction.

Within this new account of the human predicament is clearly embedded a sophisticated theory of causation. Dependent origination, the momentariness of the ingredients of causal chains, and the necessity linking the steps in causal development, together offer an impressive analysis of *karana*. Later Buddhist thinkers further sophisticated these ideas and indeed developed the theme that each new causal product is *genuinely* new, for the effect is not already existent in the cause. Such is the doctrine of *asatkaryavada*, the nonexistence of the effect in the cause.

## SANKHYA

Sankhya is an orthodox school that, in common with Jainism and Buddhism, finds no room for a deity. The earliest authoritative text of the school is the *Sankhyakarika* (Verses on discrimination) of Isvarakrishna. Though this was probably composed in the fifth century CE, it is thought that the system of ideas can be traced back into the Vedic period.

There are, in this system, two kinds of substance: the experiencer and the experienced. The former (comparable to the *atman* of the Upanisads) is *purusa*, an inactive “silent witness” of the latter, *prakrati* or nature. *Purusas* are eternal and numerous, whereas *prakrati* is eternal and singular. The account of *prakrati* in Isvarakrishna’s text is

a complex story about its evolution out of an original state of equipose between the *gunas*.

*Sattva* is the strand of nature that is productive of consciousness or intelligence; *rajas* is the strand productive of activity; *tamas* the strand productive of resistance. The original state of equipose is *pradhana*, meaning “the inferred one” because its existence is claimed on the basis of inference by analogy from experience. The first evolute is *Mahat* (the Great One) or *buddhi* (the subtle material that forms the basis of consciousness). Next comes *ahamkara* (the basis of individuation or self-sense), and then evolution takes two directions where either *sattva* or *tamas* predominates. Through the *sattva* route evolve *manas* (mind, of perhaps better brain), the five organs of perception, and the five organs of action. Through the *tamas* route evolve the five subtle elements (essences of sound, touch, taste, smell, and sight), and the five gross elements (ether, air, light, water, and earth) that are the constituents of all gross matter.

At first sight the process seems to be a cosmic evolution, with at least some roots in the early Vedic tradition. Yet it clearly is also designed to explain the nature of *sāmsara* and *moksa* for individual *purusas*. But why does nature evolve in this way? There is no deity to start it and plan its process. A *purusa* becomes entrapped in *samsara* by becoming engrossed in the play of nature before it, and, losing its awareness of its distinction from *prakrati*, it conceives itself as an embodied self, as an actor within the natural world. To achieve *moksa* it needs to regain its awareness of its distinct status as the pure inactive witness of *prakrati*. The Sankhyans indeed identify the following two purposes behind the evolution of *prakrati*: it evolves to provide experience for *puruṣas* yet at the same time to provide the possibility of this ultimate release from *sāmsara*.

### SANKARA’S CRITIQUE

Sankara, the eighth-century Hindu philosopher, criticizes the Sankhyan system’s explanation of the evolution of *prakrati* as follows: neither *prakrati* nor *puruṣas* can provide the efficient cause (*nimitta karana*) of this evolution, for *prakrati* is insentient—it lacks *cit*, or intelligence—and *puruṣas* are inactive. Such evolution cannot be spontaneous, for no spontaneous activity is evident in experience. However, the Sankhyans believe they can find such cases; but the important issue between them and Sankara seems to be more fundamental. The Sankhyans are working with the idea of the purpose of evolution, as opposed to causation. The evolution of *prakrati* is a natural development that serves the purposes of *puruṣas*, and

no intelligent designer is required contrary to Sankara’s insistence. We might well compare the Sankhyan approach to that of Aristotelian teleological explanation.

Sankara’s criticism comes in his major text, the *Brahma-sutra-bhasya* (Commentary on the verses concerning reality). He is a major figure in the Vedanta school, which takes its inspiration from the ancient Upanishads. Unlike the Sankhyans, he is unwilling to engage in speculative reasoning beyond the words of those texts and claims to be merely restating their essential message. Other figures in the Vedanta tradition also wrote commentaries on the *Brahma sutra*, and we can judge Sankara’s philosophical inventiveness from the quite striking differences in the contents of those commentaries.

Both Sankara and the Sankhyans adopt a view of causation whereby the effect preexists in the material cause (*upadana karana*)—called *satkaryavada*. They differ, however, in the detail. For the Sankhyans the evolution of *prakrati* is a *real* process of natural unfolding out of the potentialities of the *gunas*—a position known as *parinamavada*. Sankara, however, finds difficulties with the notion of potentiality and argues instead for the more extreme position of the identity of the effect with the cause—there is only a *merely apparent* transformation from cause to effect. Applying this claim—known as *vivartavada*—to the case of the emergence of the experienced world out of the one real thing, *Brahman*, which is undifferentiated consciousness, the implication is that the experienced world is but an illusory appearance of *Brahman*. The route to *moksa* is the realisation of this difficult truth.

### NYĀYA

Nyaya is another orthodox school, beginning with the third-century BCE text by Gautama, the *Nyāya Sūtras* (Verses on argument). Important commentaries were written by Vatsyayana and Uddyotakara in about the third and sixth centuries CE, respectively, and substantial developments continued with the Navya-nyāya (or “new Nyāya”) thinkers of the fourteenth to sixteenth centuries. Since argument or reasoning is often concerned with causal relations in the observed world, the Nyāya philosophers gave considerable attention to an analysis of such relations.

Causation, on their understanding, is the real production of new things out of the parts of matter (ultimately atoms). This is another version of *asatkaryavada*, for the effect is a *new* existent. From threads we can make a cloth, and from clay we can make a pot: The cloth and

the pot are new products of the causal process. They do, however, stand in a special relationship to the threads and clay, a relationship called *samavaya* (inherence). The cloth, for example, is said to inhere in the threads as *one in many*, one thing in many things; just as much as the threads are parts of the cloth as *many in one*. The idea of a material cause (*upadanakarana*) is given this new interpretation by this school—the matter or parts out of which something is made is called the “inherent cause” (*samvayikarana*).

Causation also involves an efficient cause (*nimit-takarana*) or causes, such as the work of the weaver and the motions of the loom. Any case of causal production is likely to involve a multitude of factors—actions or material ingredients and all their individual qualities—and the Nyāya philosophers duly classify such factors further in terms of their efficacious or peripheral role in the process. A cause, in the final analysis, is the sum of the causal factors that are the invariant and unconditional antecedent of the effect.

The Nyāya account was criticized by both Buddhists and Sankara. For the Buddhists it is in stark contrast to the aggregate (*skandha*) theory, according to which the “new” product is merely the sum of the parts, and they try to fault the special relation of inherence that the Nyāya theory makes central to its account. Sankara, too, finds this relation logically flawed, since it leads to an infinite regress. If the parts and the new object are related by this *samavaya* relation, what relates *it* to the parts and the object? It seems it would have to be another case of *samavaya*, and then the same question arises again—without end.

## CAUSATION IN ISLAMIC PHILOSOPHY

According to the Qur'anic position, God is the voluntary creator of the universe. In causal theory, one finds an apparently necessary connection between cause and effect. Islamic philosophy experiences a profound tension between these two ideas—the Qur'anic legacy of God's will and the idea of independent causes leading to effects. From this perspective, one may observe four stages in the concept of causation in Islamic philosophy.

### THE FIRST STAGE

The first stage, beginning with the rise of Islam in the seventh century and extending well into the tenth, is dominated by the Qur'anic understanding of cosmos, which assigns God as the fundamental cause of the universe and of the events taking place within it. A cause is thus conceived as a “means” or “way” conditioned or provided by God as a blessing to achieve something, as indicated in the following verses: “Do they not look at the camels how they are created? And at the sky how it is raised? And at the mountains how they are fixed firm? And at the earth how it is spread out?” (Qur'an 88:17–20); “it is God who causes the seed and the date-stone to split and sprout. He brings forth the living from the dead, and brings forth the dead from the living ...” (Qur'an 6:95–104; also 67:3–4; 24:39; 2:118). Early philosophers of the Kalām Theology School attempted to express this Qur'anic understanding by their metaphysics of atoms and accidents. They argue that because each atom is created and annihilated at every instance, no being can subsist by itself and have an effect on another body except through the creation of an omnipotent God. In this scheme, causation is conceived as a creation at every instance, including human actions. Abū'l-Ḥasan 'Alī ibn Isma'īl al-Ash'arī (d. 935) argued that “God wills everything which can be willed” and that every instance of causation is to be conceived within the domain of this all-embracing divine will (1953, p. 33).

## THE SECOND STAGE

In the second stage the Muslim Neoplatonic Aristotelians establish a philosophical theory claiming the necessary connection of cause and effect. Abū Yūsuf Ya‘qūb ibn Ishāq al-Kindī (c. 801–866), Abu Naṣr Muḥammad al-Fārābī (870–950), and Abū ‘Alī al-Ḥusayn ibn Sīnā (980–1037) are the proponents of this school. Al-Kindī and al-Fārābī thus establish an emanationist system of universe that follows from God necessarily. This world system is decidedly necessitarian, neatly elaborated by Ibn Sīnā in a causally deterministic way. In his scheme, the universe is conceived as a hierarchical order of beings, which offers a cosmic pattern for causation in general and a model for all causal interactions. Each being is connected to the next in a necessarily ordered chain of causation beginning with God through the heavenly spheres down to the remote spheres of dark and primitive matter. The philosophers of the Kalām School vehemently objected to this theory claiming that, if accepted, the Qur’anic understanding of God’s absolute will and power becomes vacuous.

## THE THIRD STAGE

Three prominent philosophers represent the third stage: Abū Ḥāmid Muḥammad al-Ghazālī (d. 1111), Abū’l-Walīd Muḥammad ibn Rushd, known as Averroes (d. 1198), and Ṣadr al-Dīn Muḥammad ibn Ibrāhīm al-Shīrāzī, known as Mullā Ṣadrā, or Ṣadrā (d. 1641). Against the philosophers of the Neoplatonic Aristotelian School, al-Ghazālī argues along Humean lines that people observe in existence not a necessity but two things that are contiguous. The connection, therefore, between a cause and its effect is due to the prior decree of God, who creates them side by side. What does not have a free will cannot enter into a temporal relation. When a piece of cotton burns, it is not the fire that is burning, for fire is inanimate and in itself has no action. What proof can be given that the fire is the agent? The only proof is that people observe an act of burning, not any other mediating factor. Therefore, existing contiguously with a thing does not prove causation between two things. Ghazali denies skepticism by arguing that the repeated occurrence of events fixes unshakably in our minds the belief in their occurrence according to past habit.

Ibn Rushd objected to this theory, arguing that in denying the necessity of a causal link, al-Ghazālī’s motive was to defend the exclusive prerogative of God’s sovereignty and efficient causal agency in all events. But the denial of this connection involves the rejection of an agent in an act, and hence, the logical ground for the idea

of God as an efficient cause is destroyed. Moreover, logic implies the existence of causes and effects, and knowledge of these effects can only be obtained through knowledge of their causes. Hence, denial of causes implies the denial of knowledge, which, in turn, implies that nothing can be really known.

Mullā Ṣadrā developed an existential theory of causation based on the primacy of existence. An abstract notion of existence arises in the mind, but that notion cannot yield true reality. For, in each case, existence is a unique individual in an ongoing process of renewal. Essences arise in the mind as a result of this process when existence becomes further diversified into modes. It is existence that moves within this process; both the cause and the caused are existence; the essence is caused to arise in the mind in connection to particular beings. Causation must be considered within that existential process in which the problem of necessary connection does not arise. In each instance of causality there is a temporal emergence in which the temporal emergent, that is, the cause, is not the true cause but only a preparatory condition for it. The true cause in such an emergence is, therefore, the eternal creative act of God. In that case, this process is continuous, not discrete, involving change in the substance of everything that moves within the process.

## THE FOURTH STAGE

In the fourth stage one finds primarily the idea of causal explanation on the basis of the Qur’anic notion that God acts regularly and that there is no change in this regular course of action, called *sunnat Allah*. No thinker in this stage paid more attention to the problem of causation than the twentieth century thinker, Bediüzzaman Said Nursi of Turkey (d. 1960). Nursi uses two arguments to defend al-Ghazālī’s theory of causation. The first is the argument from theodicy that establishes that “might and majesty require causes to be veiling occasions of God’s omnipotence for the human mind” (Nursi 1996, p. 1278). God creates things for certain good ends. If causes are not seen as veils for God’s acts, the human mind will directly infer God in all natural phenomena and attribute the seemingly evil results of these actions to him. This inference harms God’s might and glory. Similarly, we may not be able to see good results immediately and thus blame God for evil. The second argument claims that “God’s uniqueness and glory require causes to withdraw their interference from the actual efficacy” (Nursi 1996, p. 1278). The nature of an effect exhibits a perfection that is the result of a rational planning and omnipotence. These

qualities are not inherent in the causes producing their effect; hence, the true cause is outside the event, deduced by the mind and experienced by the awakened heart. There is thus only one true cause, God, who assures people of the causal nexus through the first argument by theodicy.

## CAVELL, STANLEY (1926–)

Stanley Cavell, American philosopher and long-time professor of philosophy at Harvard University, has written on epistemology, philosophy of language, moral philosophy, and aesthetics; on Shakespeare and Romanticism and

Samuel Beckett; on modernism in the arts, classic Hollywood film comedies and melodramas of the 1930s and 1940s, and opera; on his most direct influences, J. L. Austin and Ludwig Wittgenstein, especially with reference to their attempts to draw words back to their everyday homes; on Friedrich Nietzsche and Martin Heidegger, who articulate our perhaps inevitable ambivalence toward what the latter calls “average everydayness”; on Kant, who in limiting knowledge to make room for faith makes the conditions and boundaries of human understanding and the recognition of our finitude dominant themes for subsequent thought; and also on the Kantian inheritance in the transcendentalism of Thoreau and Emerson, who conceptualize these issues in terms of lost contact with things themselves and the possibility of an intimacy regained that allows for acceptance of the world’s independence from us. Cavell’s circle of interests has its unity: his overarching concern is with philosophy’s aspirations to self-knowledge and with obstacles the intellect erects to self-knowledge, particularly in the form of distortions of self-expression and loss of voice. Cavell links these threats to skepticism, conceived not just as a general doubt about the extent of our cognitive capacities, but as an expression of a tragic condition of withdrawal haunting the present age. Later, he finds acknowledgment of and response to this condition in images of recovery articulated in the dimension of the moral life he calls “Emersonian perfectionism.”

Several essays in *Must We Mean What We Say* (1969) defend the salience of philosophical appeals to ordinary language. In doing so, they prepare for the comprehensive diagnosis of skepticism and the impulses behind it offered in Cavell’s central work, *The Claim of Reason: Wittgenstein, Skepticism, Morality, and Tragedy* (1979). Because appeals to “what we say when” draw on knowledge of native tongues, they do not directly refute the skeptic by convicting him of linguistic mistakes. The skeptic, after all, remains a master of language. On the other hand, because skeptical procedures do not fully fit ordinary ways of raising and responding to doubts about particular claims, Cavell interprets skepticism’s negative conclusions about the limits of human knowledge not as failures of certainty, but as intellectualized disappointment with the sources of our capacities for making sense of the world.

Accordingly, part one of *The Claim of Reason* offers a reading of the later Wittgenstein’s notion of criterion, on which criteria constitute not certainty, but the relevance and applicability of our concepts to worldly circumstances. On this view, our capacity to speak intelligibly is

based on nothing deeper (nor less deep) than our agreement in judgment, which agreement is not secured prior to particular judgments. Criteria are thus subject to repudiation, as our agreements may seem to run thin. The skeptic errs in implying that criteria should be grounded in something deeper, lest our whole conception of things be deemed irredeemably subjective. But because the skeptic reminds us of the repudiability of criteria, the skeptic's progress (or lack thereof) conveys an important moral: our sense of things is not a cognitive accomplishment.

Part two elaborates the external world skeptic's failure to live up to his own self-conception as a perfect knower. This skeptic faces a dilemma: either he fails to specify concrete claims about the external world for scrutiny, or his doubts about the claims he does single out do not generalize to all beliefs about external objects. Here Cavell discerns a truth behind the external world skeptic's efforts—that our relation to the external world as a whole is not a matter of knowledge about an, as it were, all-encompassing object, but rather one of acceptance. While such a conclusion may seem to exacerbate the skeptic's sense that we are cut off from the world, Cavell asks whether this discomfort, expressive of disappointment with ordinary modes of inquiry, criteria—even our manner of involvement with things—is self-imposed.

Part three of *The Claim of Reason* explores the nature of practical reasoning and the limits of both morality and traditional moral theorizing. Cavell sets himself against the “moralization of morality”: the assumption that if morality is genuinely rational, it must rest on rules grounding its verdicts and rendering it competent to assess the value of every action. Much as the skeptic prescind from actual practices of evaluating epistemic claims, so the moralist refuses the concept of morality by failing to locate its role in everyday life.

Part four, exploring symmetries and asymmetries between external world and other minds skepticism, argues that in the case of other minds, acknowledgment of others—not certainty about their inner lives—is in question. The tragic fate of the present age is that for the most part, we live our skepticism, tending, as a matter of historical fact, to shirk our responsibilities in knowing others and in making ourselves known to them. At stake is the voice—our expressiveness, and the barriers we erect to it.

Cavell's later writings explore his sense that responding to our tragically skeptical state, working through the issue of the voice, is a crucial task of modernity. Cavell reads romanticism (exemplified in Wordsworth and Coleridge as well as Emerson and Thoreau, thematized

most explicitly in *In Quest of the Ordinary: Lines of Skepticism and Romanticism* [1998]) as registering both the success of and dissatisfaction with Kant's settlement with skepticism. Acknowledging that the quest for knowledge, at least as conceived by skepticism, blocks our access to the things themselves, romanticism seeks other routes to their recuperation. These lie in the particulars of our ability to make sense of them, despite the lack of philosophical grounding for our ways of doing so. At the same time, in reading the defining texts of moral perfectionism (especially in *Conditions Handsome and Unhandsome: The Constitution of Emersonian Perfectionism* [1990] and *Cities of Words: Pedagogical Letters on a Register of the Moral Life* [2004]), Cavell finds in this openness the potential for the creation or discovery of a self capable of articulating its own identity, its own ideals and possibilities, again without need of a foundation from outside. In large part, recovery from the threat of skepticism lies in everyday uses of words, not because they express a set of commonly-held beliefs, but insofar as they manifest a responsiveness to ourselves and the world that enables us to find our conditions intelligible.

## CAVENDISH, MARGARET

(1623?–1673)

Margaret Cavendish was born into the Lucasses, a family of English gentry. She does not seem to have had an education that was in any way remarkable for a young woman of her time. Indeed, she reports that while she had the usual tutors, her mother “cared not so much for our dancing and fiddling, singing and prating of several languages” (Cavendish 1667), deeming honesty and civility more important. One consequence is that Cavendish was never able to speak or read any language but her native English. In 1643, when she was about twenty, she became a maid of honor to Charles I’s wife, Queen Henrietta Maria, and the next year she followed the queen into exile in Paris.

While at the court in exile, she met and subsequently married William Cavendish, who eventually became the Duke of Newcastle and who was a widower some twenty years her senior. The marriage seems to have been a happy one, and indeed, it is Margaret, a second and childless wife, who lies buried next to William in Westminster Abbey. Margaret Cavendish found a husband who supported her ably in her intellectual endeavors. In marrying into the Cavendish family, she became a member of a family that had been in the forefront of the intellectual life of the time. Newcastle’s cousins, the Devonshires, were patrons of Thomas Hobbes, and Newcastle and his brother, Sir Charles Cavendish, had as part of their circle a number of leading thinkers, including Marin Mersenne, Pierre Gassendi, and René Descartes. It is not clear to what extent this wider circle was available to Cavendish, but both her husband and her brother-in-law were prepared to encourage and to instruct her as she developed her intellectual interests. Cavendish published copiously, in a wide variety of genres, throughout her life, both while she and her husband lived in exile in Holland and after they returned to England in 1660, after the restora-

tion of Charles II. The Newcastles lived on their return at the family estate, Welbeck, in Nottinghamshire, but made visits to London. During one of these visits, Cavendish made a ceremonial visit to the Royal Society, unusual in that they did not otherwise admit women to its meetings. Cavendish died in 1673, at the relatively young age of fifty, some three years before her husband.

Cavendish published over a dozen works, including poetry, plays, epistolary treatises, a life of her husband and a shorter one of herself, a novel, and some six works in natural philosophy. Cavendish reworked her ideas about natural philosophy throughout her life, improving them as she enlarged her reading and altered her vocabulary and her grasp on the issues about which she was writing. Among her works in natural philosophy, probably the best and most interesting are her last, *Grounds of Natural Philosophy* (1668/1996), where she lays out her material in its most organized form, and two slightly earlier works, *Philosophical Letters* (1664/1994) and *Observations upon Experimental Philosophy* (1666/2001). These last two are especially interesting because, in them, Cavendish situates her own views against a commentary on several leading thinkers of her day.

From *Grounds of Natural Philosophy* one learns the basic premises of Cavendish’s approach to natural philosophy. She tells the reader there can be no substance but body, which exists in degrees of purity. While the less pure parts of matter are inert, the purer parts are self-moving and are endowed with self-knowledge. These come in two sorts, again distinguishable by their degree of purity: a sensitive part, which is living, and a rational part, which understands. Natural phenomena are to be explained in terms of the doings of matter, under the guidance of reason and as carried out by sense. Thus, Cavendish’s account of nature is one of a number of accounts that try to explain natural phenomena in terms of the motions that lead to the division and composition of otherwise undifferentiated matter. Cavendish has absorbed and is working within one of the dominant explanatory paradigms of her day.

As *Philosophical Letters* and *Observations upon Experimental Philosophy* make clear, Cavendish developed her own version of this paradigm. *Philosophical Letters* consists of a series of letters to a fictional female correspondent discussing passages of Hobbes, Descartes, Henry More, and Francis Mercury van Helmont, with a final, less focused part answering a number of different questions and mentioning a number of different authors, including Galileo Galilei, Walter Charleton, and Robert Boyle. Unlike Hobbes and Descartes, Cavendish

rejects the idea that there can be purely mechanical explanations for such human functions as sensation, insisting on the self-moving, knowledgeable nature of sensation, which she says “patterns out” or imitates objects sensed. She rejects a mechanical or “transfer” theory of motion as unintelligible and provides an alternative, under which all motion is self-generated action on the basis of self-knowledge, rather than a passive reaction to impact. Thus, while a materialist, Cavendish is not a mechanist, but a vitalist. She energetically distinguishes herself, however, from other contemporary vitalists, like More, on the grounds that More’s immaterial plastic spirit of nature, as immaterial, is impotent to move matter. Cavendish’s vitalism is materialist and not dualist. Cavendish’s position can be seen as developing in conversation with a number of related theorists, with whom she shares a number of views, while carving out her own position.

In *Observations upon Experimental Philosophy* Cavendish takes on the experimenters of the Royal Society, in particular Robert Hooke. She criticizes Hooke for supposing that microscopes provide a unique view into the heart of things, on the grounds that adding a dubious instrument to a dubious sense organ does not improve matters. Her overall approach is to urge the claims of reason to give understanding over the deliverances of the senses. Although arguing for the special virtues of reason, Cavendish does not suppose that reason is a source of certainty in natural philosophy. Instead, her approach is probabilistic. Toward the end of *Philosophical Letters* she writes that

the undoubted truth in Natural Philosophy is, in my opinion, like the Philosophers Stone in Chymistry, which has been sought by many learned and ingenuous Persons and which will be sought as long as the Art of Chymistry doth last; but although they cannot find the Philosophers Stone, yet by the help of this Art they have found out many rare things, both for use and knowledg. (1664/1994, p. 508)

While one cannot attain undoubted truth, to refuse to be guided by it would be like refusing to take medicine on the grounds that one will die eventually.

## CELSUS

Celsus, a Middle Platonist (Origen wrongly called him an Epicurean) critic of Christianity, wrote the *Alethes Logos*

(True doctrine) about 178 CE. We know the work—whose title derives from a Platonic expression (*Meno* 81a)—only through quotations in Origen’s reply, *Contra Celsum*, composed seventy years later. Celsus began his work by assuming the character of a Jew and attacking Christian views from this standpoint. Then he proceeded on his own to demonstrate their inadequacy in relation to the basic axioms of contemporary philosophical theology, especially with regard to the doctrines of God and providence and poetic-philosophical inspiration; as a Platonist he found the Christian idea of the Incarnation both impossible and immoral. At the end of his work he urged the Christians to abandon their irrational faith and join him in upholding the state and its religion. After Christianity was recognized by the Roman government, Celsus’s work was destroyed.

The theology of Celsus is based, in his own view, on an ancient tradition handed down, especially among oriental wise men, from remote antiquity. This tradition, the “true doctrine,” informed him of the existence of one god known by many names and worshiped by all pious men. Such a “polytheistic monotheism,” he believed, had been perverted or misunderstood, first by the Jews and then by the Christians. If they were to return to the tradition, they would abandon their irrational exclusiveness and would recognize the divine right of the one emperor. His work thus culminates in a theology of politics.

Origen’s reply is important not only because in it his philosophical theology, developed earlier, is clearly expressed in relation to Celsus’s views, but also because it shows the extent to which he agreed with Celsus in opposing more literal religious conceptions. Each held, for example, that his own authoritative traditions are to be understood symbolically, whereas the other’s traditions must be meant literally. But Origen finally took his stand on the particularity of the Hebrew-Christian tradition, which Celsus found totally unacceptable.

## CENSORSHIP

“Censorship” is the suppression of speech or symbolic expression for reason of its message. Liberal Western constitutionalism has traditionally condemned censorship on both instrumental and intrinsic grounds, classically articulated by John Stuart Mill in *On Liberty*. In this traditional liberal view, freedom of speech instrumentally serves the ends of truth and self-government. Censorship, by entrenching orthodoxy and suppressing dissent, impedes the advancement of truth and the processes of democratic change. Freedom of speech is also intrinsically valuable, in this view, as an aspect of human autonomy. Censorship illegitimately interferes with that autonomy, because speech, unlike action, typically causes others no harm. The proper response to bad speech is more speech, not government regulation.

Late-twentieth-century and early-twenty-first-century critics have challenged both the instrumental and the intrinsic justifications for freeing speech from censorship. First, some suggest that the power to speak is so unequally distributed that free competition in the marketplace of ideas is unlikely to produce either truth or democracy. For example, advocates of regulating campaign advertisements argue that wealthy voices dominate and thus distort political debate, and advocates of hate-speech regulation argue that racial epithets and invective perpetuate a form of cultural white supremacy in which minority voices are effectively silenced. These critics would turn the traditional free-speech principle on its head. In their view freedom of speech helps to entrench the existing status quo while government regulation of the speech of powerful groups can level the playing field. Redistribution of speaking power would advance truth and political equality better than a regime of *laissez-faire*.

Second, some critics argue that the defense of free speech on autonomy grounds undervalues the harms that speech causes. On this view speech regulation ought to be more widely allowed to protect the countervailing autonomy interests of listeners or bystanders. Liberal constitutional democracies generally permit censorship only to avert a narrow range of material harms. For example, incitement to riot may be forbidden, as may publication of the movements of troops at war. But censorship is rarely permitted on the ground that speech will cause disapproval, anger, alarm, resentment, or offense on the part of the audience. American constitutional law categorically forbids such justifications. Legal systems that permit them do so only in exceptional contexts: For example, British law forbids expressions of racial hatred, and some

international human rights laws forbid advocacy of genocide.

Free-speech critics argue that such exceptions should be more the rule. First, some argue, government should be free to prevent injury, not only to bodies, but also to hearts and minds, including the injury caused by expressions of caustic opinion. Second, others argue, speech should be regulable for its social impact, even in the absence of immediate physical harm. On this view speech is not self-regarding but rather helps to structure social life. Thus, for example, pornography, hate speech, and graphic television violence inculcate attitudes that make society more immoral, sexist, racist, lawless, or violent than it would be if a different rhetoric prevailed. Speech helps construct society by socializing behavior, and reconstructing society, in this view, requires regulating speech.

At stake in these debates is whether speech will continue to be understood, like religious and reproductive practices, as presumptively a matter for private resolution, or instead will be subject to greater government regulation in the pursuit of social ends, including that of maximizing the quantity or diversity of speech itself.

## CHAADAEV, PĚTR IAKOVLEVICH

(c. 1794–1856)

Pětr Iakovlevich Chaadaev was a Russian thinker and writer. He was a member of the old nobility (his mother's father was the celebrated historian Mikhail Mikhailovich Shcherbatov [1733–1790]). He studied at Moscow University and participated in the great war of 1812 and in the subsequent campaign against Napoleon Bonaparte in Europe. In 1816–1817, while an officer in the Hussars, he met and became friends with Aleksandr Sergeevich Pushkin (1799–1837), who in his young years dedicated three letters in verse to Chaadaev. In 1821 Chaadaev resigned from military service, cutting short what had promised to be a brilliant career. From 1823 to 1826 he traveled in Europe (England, France, Italy, Switzerland, and Germany), where he became acquainted with Friedrich Wilhelm Joseph von Schelling and Hugues Félicité Robert de Lamennais, whose religious-philosophical ideas made a profound impression on him. At that time he also became friendly with a number of representatives of certain European religious sects, who were adherents of Catholic socialism. The acquaintance with European culture, social heritage, and ideas precipitated a spiritual crisis in Chaadaev: the transition from Enlightenment deistic beliefs about the universe to a modern version of Christianity, consisting in a syncretic union of religion, philosophy, history, sociology, natural science, art, and literature.

After his return Chaadaev wrote (from 1829 to 1831) his main work: *Lettres philosophiques*. It was written in French and consisted of eight treatises in the form of letters addressed to a lady. This work signified the start of an original Russian philosophy, as well as the formation of a new worldview for Chaadaev. Here, Chaadaev attempted to develop a religious justification for the social process. The establishment of a "perfect order on earth" is possible, in his opinion, only by means of the direct and constant action of "Christian truth," which, through the continuous intellectual interaction of many generations, forms the foundation of "the universal-historical tradition" in the movement of social history and facilitates "the education of the entire human race" (1991 Vol. 1, p. 644). In Chaadaev's view this social idea of Christianity evolved, first, in Catholicism. This idea defined, as Chaadaev points out in the first letter, "the sphere in which Europeans live and in which alone under the influence of religion the human race can fulfill its ultimate purpose" (p. 652).

From this premise Chaadaev infers that European successes in the domains of culture, science, law, and material progress were the fruits of Catholicism as a socially active, political religion; and therefore these successes could serve as the starting point of a higher synthesis. The interpretation of Christianity as a historically progressive social development became for Chaadaev the foundation of a critique of the contemporary Russian situation. In Russia Chaadaev found neither “elements” nor “embryonic indications” of European progress. In his opinion the reason for this was that, when it initially separated from the Catholic West, Russia “erred concerning the true spirit of religion”: Russia did not recognize “the purely historical side,” that is, the socially transformative principle, to be an inner property of Christianity (658). The consequence of this was that Russia lagged behind Europe and had not gathered “all the fruits” of science, of culture, of civilization, of a well-ordered life. Chaadaev believed that, for Russia to achieve the successes of European society, it was insufficient for it simply to adopt the European forms of development: It had to change everything from the beginning, by repeating, under the flag of the salvific Catholic idea, the entire history of western Europe.

The first “Philosophical Letter” was published in the Moscow journal *Teleskop* (1836). This publication produced in thinking Russia an impression similar to a “rifle shot resounding in a dark night” (in the words of Alexander Ivanovich Herzen, 1954–1965). After its publication the journal was prohibited by the government, and its editor-publisher, N. I. Nadezhdin (1804–1856) was arrested and expelled from Moscow, while Chaadaev himself was declared, “by imperial order,” to be insane. This “Philosophical Letter” was the only work of Chaadaev’s to be published during his lifetime. Chaadaev’s conclusions in this letter provoked a serious critique and disputation in circles of the Russian intelligentsia. Despite the official prohibition of the polemic around the *Philosophical Letters*, there were serious responses to them from Pushkin, P. A. Viazemskii (1792–1878), Aleksandr Ivanovich Turgenev (1784?–1846), Filip Filipovich Vigel (1786–1856), D. P. Tatishchev (1974–), Schelling, and others. By and large, these commentators did not agree with Chaadaev, but they recognized that it was legitimate and timely to formulate philosophical problems connected with solving the riddle of “the sphinx of Russian life” (in Herzen’s words). Chaadaev’s publication also provoked a serious split in Russian social life, a split that acquired the character of a dispute that, in principle, could never be resolved.

Although Chaadaev was prohibited from publishing his ideas, he continued his philosophical search. To accusations that he was insufficiently patriotic, he responded with the article “L’apologie d’un fou” (The apology of a madman; written in 1837 but first published in Paris in 1862), in which, speaking about Russia, he affirms that “we are called to solve most the problems of the social order, to answer the most important questions which preoccupy mankind” (1991 Vol. 1, p. 675). Here, he admits that the traditions of Orthodox Christianity possess indisputable merits and have played a beneficial role in the formation of the Russian mind. He is prepared to see Russia’s calling in the fact that “at the proper time [it] would offer a solution to all the questions provoking disputation in Europe.” In the 1840s Chaadaev’s house in Moscow became the center of an important literary and philosophical circle.

Following in Chaadaev’s footsteps, many Russian writers and philosophers became sufficiently bold to pose and ask into fundamentally important but hitherto systematically unexplored problems of social development. This exploration made it possible to clarify conceptions regarding the historical evolution of Russia, and it had a significant influence on the formation of the two fundamental trends in Russian social thought: the Westernizing orientation (Timofei Nikolaevich Granovskii [1813–1855], Vissarion Grigor’evich Belinski, Herzen, and Konstantin Dmitrievich Kavelin) and the Slavophile orientation (Aleksei Stepanovich Khomiakov, Ivan Vasil’evich Kireevskii, Konstantin Sergeevich Aksakov [1817–1860], and Yu. F. Samarin [1819–1876]). Chaadaev himself found a common language with representatives of both camps, although he also critiqued both; at various times he was invited to contribute to journals that held diametrically opposed positions.

Chaadaev’s ideas on the philosophy of history proved to be a stimulus for such different thinkers as Khomiakov, Herzen, Apollon Aleksanrovich Grigor’ev (1822–1864), Konstantin Nikolaevich Leont’ev, Nikolai Iakovlevich Danilevskii (1822–1865), and Vladimir Sergeevich Solov’ev (Solovyov). In essence, these ideas marked the start of the development of an original Russian philosophy.

Chaadaev’s esthetic judgments reflected the influence of his “one idea”; they are subordinate to the moral ideal worked out by him. For Chaadaev, beauty in art is inseparable from truth and goodness. The artist is a guide leading people toward endless perfection; in transient things the artist discerns the milestones on this path. Somewhat paradoxically, Chaadaev condemned the art of

antiquity, in which, he believed, “all the moral elements were chaotically confused” (1991 Vol. 1, p. 359). In contrast, Gothic art was, for Chaadaev, “something sacred and heavenly,” serving as an expression of moral feelings and compelling man “to lift his gaze toward heaven” (p. 359). In contemporaneous letters Chaadaev valued Nikolai Vasil’evich Gogol’s (1809–1852) *Selected Passages from a Correspondence with Friends* (1846), in which “among weak and even sinful pages there are pages of astonishing beauty, full of infinite truth” (1991 Vol. 2, p. 1991). Chaadaev’s aesthetic judgment was defined by his moral creed: “[M]oderation, tolerance, and love for all that is good, whatever form it might take” (p. 200).

Chaadaev’s legacy was most accurately assessed by Khomiakov, who wrote in 1860:

An enlightened mind, an artistic feeling, a noble heart—those are the qualities that attracted everyone to him. But at a time when it appeared that Russian thought had become submerged in heavy and involuntary sleep, he was especially valuable to us because he was awake and awakened others, because in the thickening darkness of that time he did not allow the lamp of truth to go out.

## CHAMBERLAIN, HOUSTON STEWART

(1855–1927)

Houston Stewart Chamberlain, the Anglo-German race theorist and philosophical and historical writer, was born in Southsea, near Portsmouth, England. Despite his English birth and family, his early indifference toward England and all things English developed into a lifelong hatred. Chamberlain was brought up by relatives in France. After being forced to attend schools in England, he returned to England only briefly, in 1873 and 1893. A nervous breakdown determined the course of his physical and mental development. (Frequently ill, hypersensitive, neurotic, he was crippled during the last thirteen years of his life by an incurable paralysis.) He traveled in western and central Europe for nine years seeking a cure. A German tutor inspired him to turn his mind to German literature and philosophy, and eventually he chose Germany as his home. As early as 1876 he wrote, “My belief that the whole future of Europe—that is, of world civilization—is in Germany’s hands has become a certainty” (*Lebenswege meines Denkens*, p. 59).

Chamberlain’s intellectual development began with the study of botany and other natural sciences; this was soon completely supplanted by a preoccupation with philosophy, literature, theology, art, and history. The turning point of his life was his meeting his future father-in-law, Richard Wagner, “the sun of my life,” whom Chamberlain considered the greatest poet and musician of all time. Johann Wolfgang von Goethe inspired the central concept of Chamberlain’s picture of the world and his “theory of life,” the concept of *Gestalt* (form) as the

expression of all that is timeless and unchangeable. The *Gestalt* is encountered as the primary concept in the intuition of everything living (*Anschauung*) and must be grasped and interpreted in thought. It is the key to metaphysics and art, two fields which Chamberlain passionately defended against rationalism and “the coarsely empirical theory of evolution.”

## RACE

Chamberlain’s “*Lebenslehre*” (Theory of life), which he first drafted in 1896 (it was not published until 1928 and was then titled *Natur und Leben* [Nature and life]), presented the position of most of his later writings, a position to which he frequently sacrificed historical truth in *Die Grundlagen des 19. Jahrhunderts* (*Foundations of the Nineteenth Century*), his weakest but best-known work. Chamberlain upheld “Life,” intuition, metaphysics, “holy art” in the Wagnerian sense, and antidemocratic thought against rationalism, biological materialism (of Jewish origin), the superficial belief in progress, and moral decadence. His *Weltanschauung*—a favorite word of Chamberlain’s—is closely related to Wagner’s theory of decadence and regeneration. It carries with it the urge to improve the world, and Chamberlain felt himself called into the battle for moral renewal not of humanity in general (he spoke derogatorily of “the ghost, humanity”), but of the Teutonic culture and people. To save culture from the threat of materialism was also the declared aim of his books on Immanuel Kant and Goethe.

In the *Grundlagen* Chamberlain represented history as a conflict of opposing philosophies of life, represented by the Jewish race on the one hand and by the Germanic-Aryan race on the other. The application of the biological idea of race to the study of cultural phenomena was widespread around the turn of the twentieth century. Under the influence of Charles Darwin, it was used by anthropologists, ethnologists, religious historians, and others. It could serve both as a basis for scholarly interpretation and as a vehicle for racism, following the example of Comte Joseph Arthur de Gobineau. It was natural for Chamberlain to take over the concept of race from his scientific studies, but the significance he gave to it went beyond what was tenable in the light of the scientific knowledge then available and even denied the relevance of scientific criticism: “Even if it were proved that there had never been an Aryan race in the past, we are determined that there shall be one in the future; this is the decisive point of view for men of action” (*Grundlagen*, 1st ed., Vol. I, p. 270). Intuition and instinct, an overwhelming irrationalism, the capacity to sweep away logical con-

traditions—these are the major characteristics of this “historical” work.

Without ever giving a precise definition of “race,” Chamberlain considered it to be the “*Gestalt* in particular, transparent purity” (*Natur und Leben*, p. 152) “Only thoroughbred ‘races,’” he held, “accomplish the extraordinary” (*Rasse und Persönlichkeit*, p. 75). In connection with his race theory, Chamberlain emphasized the significance of nations: “It is almost always the nation as a political entity that creates the conditions for the formation of a race, or at least for the highest expressions of the race” (*Grundlagen*, 1st ed., Vol. I, p. 290). The awareness of racial identity, not physical characteristics, determined a race. Thus Chamberlain could speak of the English or Japanese “races” and also employ the term in a very broad sense, as when he included the Slavs and Celts among the Teutonic peoples.

Race was always dominant in Chamberlain’s thought, whether he was describing the “heritage of the old world” as Hellenic art and philosophy, Roman law, and the coming of Christ; the cultureless chaos of peoples which separated the ancient from the modern world; or the role of the Jews and the Teutonic peoples, who entered Western history as “pure” races and whose antagonism shaped the modern world. He recognized the existence of other historical forces, such as religion or the desire for power, but he placed them far below race in importance. He was thus led to the paradox of trying to prove that the historical Jesus, whose birth he regarded as “the most important date in the entire history of humanity,” was not a Jew. Chamberlain denied that the Jewish people possessed any metaphysical inclinations or philosophical tendencies. Their outstanding characteristics in his view were materialism and rationalism. They were thus incapable of religion and could not have produced the man Jesus. The Jews served Chamberlain as a dark foil for the image of the Germanic peoples, whom he celebrated as the creators of “all present culture and civilization” and whose standard-bearers were the Germans. Paul Joachimsen, in a memorial article, described the aim of the *Grundlagen* as “to demonstrate the elements of Western cultural development in the light of an Aryan theodicy.” But whereas Joachimsen considered Chamberlain’s work as a document already belonging to the past, we know today what terrible consequences his ideas had when they were translated into reality after his death. The chief ideologist of National Socialism, Alfred Rosenberg, showed himself to be Chamberlain’s disciple in his *Mythus des 20. Jahrhunderts* (Myth of the twentieth century).

## GOETHE AND KANT

One must not interpret Chamberlain's personality exclusively by the *Grundlagen*. His philosophical books on Kant and Goethe provide a far more solid basis for judgment and are more representative of his inclination and his intellectual position. His *Goethe* (1912) is a milestone in studies of the poet. Chamberlain was concerned to present "a clear, enthusiastic, and at the same time a critically reflective, grasp of this great personality in its essence and effect." Chamberlain found in Goethe the same polarities which he found in himself: nature and freedom, intuition and concept, poet and scholar, Christian and pagan—in brief, "the juxtaposition of opposed vocations." Jean Réal rightly described *Goethe* as "full of originality, of depth, and of prejudice" ("Houston Stewart Chamberlain et Goethe").

Chamberlain interrupted his studies of Goethe, which he pursued for more than twenty years, in order to write his *Immanuel Kant* (1905). Through Kant's limitation of the possibility of metaphysics Chamberlain came to realize the place of religion in human life. This side of Kant's thought appealed to Chamberlain's antirationalistic, vitalistic tendencies.

During World War I, Chamberlain composed fanatical anti-English propaganda. He was an intimate of Kaiser Wilhelm II from 1901 until well into the kaiser's exile in the Netherlands. He was quite naturally unable to come to terms with the Weimar Republic and turned his sympathies to Adolf Hitler, whom he first met in 1923. *Mensch und Gott* (Man and God), written in Chamberlain's old age, is an impressive attempt at a philosophical synthesis but casts no light on his personality as a whole. One can agree with the judgment of Friedrich Heer in *Europa—Mutter der Revolutionen* (Stuttgart, 1964, p. 6): "H. S. Chamberlain presents himself as a highly significant symbol combining high culture and barbarism."

## CHANCE

Much is asked of the concept of *chance*. It has been thought to play various roles, some in tension, or even incompatible, with others. Chance has been characterized negatively as the absence of causation; yet also positively—the ancient Greek “*tyche*” reifies it—as a cause of events not governed by laws of nature, or as a feature of laws of nature. Chance events have been understood epistemically as those whose causes are unknown; yet also objectively as a distinct ontological kind, sometimes called “pure” chance events. Chance gives rise to individual unpredictability and disorder; yet it yields collective predictability and order: stable long-run statistics and, in the limit, aggregate behavior susceptible to precise mathematical theorems. Some authors believe that to posit chances is to abjure explanation; yet others think that chances are themselves explanatory. During the Enlightenment, talk of chance was regarded as unscientific, unphilosophical, the stuff of superstition or ignorance; yet at the beginning of the twenty-first century it is often taken to be a fundamental notion of our most successful scientific theory, quantum mechanics, and a central concept of contemporary metaphysics.

Chance has both negative and positive associations in daily life. The old word in English for it, “*hazard*,” which derives from French and originally from Arabic, still has unwelcome connotations of risk; “*chance*” evokes uncertainty, uncontrollability, and chaos. Yet chance is also allied with luck, fortune, freedom from constraint, and diversity. And it apparently has various practical uses and benefits. It forms the basis of randomized trials in statistics, and of mixed strategies in decision theory and game theory; it is appealed to in order to resolve problems of fair division and other ethical stalemates; and it is even thought to underpin biological and cultural adaptation. Throughout history, “*chance*” devices have been a source of entertainment, as well as of scorn.

### A BRIEF HISTORY OF THEORIES OF CHANCE

The study of gambling games motivated the first serious mathematical study of chance by Blaise Pascal and Pierre de Fermat in the mid-seventeenth century, culminating in the *Port Royal Logic*. But inchoate ideas about chance date back to antiquity. Epicurus, and later Lucretius, believed that atoms occasionally underwent uncaused, indeterministic swerves—an early doctrine of pure chance. Aristotle, by contrast, believed that all events are necessary and regarded what we call coincidences (as in

“We met at the market place by chance”) as the intersections of independent deterministic causal chains—a view later shared by Thomas Aquinas, Antoine Augustin Cournot, and John Stuart Mill. Augustine believed that God’s will controls everything, and thus that nothing happens by chance. In the middle ages, Averroes had a notion of “equipotency” that arguably resonated with Gottfried Wilhelm Leibniz’s and later Pierre Simon de Laplace’s ideas about “equipossibility,” which undergirded their classical interpretation of probability: The probability of an event is the ratio of the number of equipossible cases in which it occurs to the total number of such cases. Girolamo Cardano, Galileo, Fermat, and Pascal also anticipated this interpretation.

Throughout the development of probability theory during the seventeenth through nineteenth centuries by authors such as Christian Huygens, Jakob Bernoulli, Thomas Bayes, Pierre Simon de Laplace, the Marquis de Condorcet, Abraham de Moivre, and John Venn, the fortunes of chance were at best mixed. De Moivre called chance “a mere word.” David Hume captured the attitude of his time when he wrote, “’Tis commonly allowed by philosophers that what the vulgar call chance is nothing but a secret and conceal’d cause” (Hume 1975, p. 130). The triumphs of Newtonian mechanics engendered great confidence in determinism, personified by Laplace’s image of an intelligent being (the so-called “Laplacean demon”) for whom “nothing would be uncertain and the future, as the past, would be present to its eyes” (Laplace 1951, p. 4). Eliminativism about chance in nature had, moreover, good theological credentials: God’s omniscience apparently made the world safe for determinism. But even the atheist Bertrand Russell insisted that a chance event is merely one whose cause is unknown. F. H. Bradley found the very notion of chance unintelligible.

Nonetheless, other intellectual developments set the stage for a revival of chance. With the burgeoning of social statistics in the nineteenth century came a realization that various social phenomena—births, deaths, crime rates, etc.—while unpredictable on an individual basis, conformed to large-scale statistical regularities. A somewhat analogous pattern of collective order from individual chaos appeared in statistical mechanics. The social sciences and then the physical sciences thus admitted statistical laws into their conceptual repertoire. This culminated in the early twentieth century with the advent of quantum mechanics, which appeared to show that chance was irreducible and ineradicable. Andrey Kolmogorov’s axiomatization of probability came soon after

Werner Heisenberg and Erwin Schrödinger brought quantum mechanics to its apogee.

Meanwhile, chance was also making a comeback in philosophy. Charles Sanders Peirce defended pure chance on the basis of empirical evidence. William James saw the postulation of chance as a way to resolve the apparent conflict between determinism and free will. To be sure, philosophers such as John Stuart Mill, Moritz Schlick, and C. D. Broad thought that capricious chance could provide no ground for genuine freedom. Nevertheless, chance had regained its respectability. In the 1950s Hans Reichenbach's work on probabilistic causation placed chance in the limelight in the philosophy of science.

### THE MATHEMATICS OF CHANCE

The mathematics of chance, unlike its philosophy, is relatively uncontroversial. That mathematics is widely taken to be probability theory. In Kolmogorov's theory (1933/1950), events are assigned numerical values between 0 and 1 inclusive:

$$P(X) \geq 0$$

$$P(\Omega) = 1$$

(Here  $\Omega$  is the universal set of all possible outcomes.) The probability of one of two mutually exclusive events occurring is the sum of their probabilities:

$$P(X \cup Y) = P(X) + P(Y) \text{ if } X \cap Y = \emptyset$$

(This law has an infinite generalization.) And the conditional probability of  $A$  given  $B$  is as follows:

$$P(A|B) = P(A \cap B)/P(B) \text{ for } P(B) > 0$$

While Kolmogorov's theory remains the orthodoxy, some philosophers (e.g., James Fetzer, Paul Humphreys, Karl Popper) question its appropriateness for chance.

### CHANCE IN SCIENCE

Probability was introduced into physics in the late nineteenth century, when James Clerk Maxwell and Ludwig Boltzmann grounded thermodynamics in statistical mechanics. The status of this probability was an important interpretive issue, but it was not universally regarded as objective chance. Statistical mechanics was based on Newtonian particle mechanics, which was apparently deterministic. There are profound and ongoing controversies over the existence and nature of chance in both statistical mechanics and quantum mechanics.

In nonrelativistic quantum mechanics, according to the canonical Copenhagen interpretation, there are two rules for the evolution of a physical system:

- *Schrödinger's equation* prescribes a deterministic evolution for the state of the system. Typically, the state is a superposition (combined state) of the various definite-property states that the system might possess (e.g., definite position, definite momentum, etc.). While the system is in a superposition, it has no single value for such quantities.
- The *collapse postulate* is where chance enters quantum mechanics. Upon measurement of such a superposition, the state instantaneously collapses to one of the quantity's eigenstates (definite-property states). Which one is a matter of chance, the probability for each being derivable by Born's rule.

Albert Einstein considered this intrusion of chance into microphysics an unacceptable violation of causality and hoped for an underlying deterministic theory, with hidden variables, that explains the apparently chancy behavior of quantum systems. In 1935, Einstein, Boris Podolsky, and Nathan Rosen (EPR) insisted that there must be such an underlying theory, arguing that the quantum-mechanical description of a certain two-particle system is incomplete. Neils Bohr and Werner Heisenberg effectively criticized the EPR argument, and since an experimental test of an EPR pair of particles appeared to be physically unrealizable, most physicists quickly forgot the debate.

In 1952 David Bohm proposed a variant of the EPR setup using two coupled particles with correlated spins. Bohm's variant was both immune to the criticisms of Bohr and Heisenberg and physically realizable. In 1965 John Bell proved a now-legendary theorem stating that no local hidden-variable theory, of the type desired by Einstein, could replicate the statistical predictions of quantum mechanics for the correlated spins. Contrary to what the EPR paper had assumed, an underlying hidden-variable theory that assigned definite local values of spin to individual particles was incompatible with the predictions of quantum mechanics. Physicists then realized that a decisive experimental test was possible, and numerous experiments were performed in the 1970s, culminating in Alain Aspect's 1982 experiments, widely regarded as decisive. Nature sided with Bohr and Heisenberg, not Einstein.

Ironically, however, this confirmation of the predictions of quantum mechanics did not definitively show

that God plays dice, to use Einstein's memorable phrase. In 1952 Bohm also formulated a hidden-variable variant of quantum mechanics that ascribes definite positions to all particles at all times, reproduces all the experimental predictions of standard quantum mechanics, and is perfectly deterministic. This is consistent with Bell's theorem. No *local* hidden-variable theory can match the predictions of quantum mechanics for coupled particles, but Bohm's version of quantum mechanics is *nonlocal*: A particle in one place may be affected, instantaneously, by distant events. Einstein would have approved of Bohm's theory for its deterministic microphysics and disapproved of it for violating the even more cherished precept of no nonlocal interactions.

There are other versions of quantum mechanics besides Bohm's that reject chancy collapses. It is thus unclear whether the success of quantum-mechanical theories implies a fundamental indeterminism in nature, and whether future experiments can resolve the issue.

Evolutionary biology is another area of science in which the existence and role of chance has been sharply debated. Evolutionary fitness is held by some philosophers and biologists to be fundamentally chancy, while others disagree.

## PHILOSOPHICAL ACCOUNTS OF CHANCE

Now, at the beginning of the twenty-first century, "chance" is typically taken to be synonymous with "objective probability," as distinguished from epistemic or subjective probability. *Frequentists*, originating with Venn, identify chance with relative frequency. For example, the chance that a particular coin lands heads is the frequency of tosses on which it so lands, divided by the total number of tosses. If we restrict ourselves to actual outcomes, then such frequencies will presumably be finite. A concern is that the outcomes may ill-reflect the true chances; a fair coin may land heads nine times out of ten. At the extreme, the *problem of the single case*, various events are unrepeatable, yet arguably have nontrivial chances (e.g., the outcome of the next presidential election). In such cases, mismatch between chance and relative frequency is guaranteed. Sometimes we might include in the reference class for a given event various other events. For example, regarding your chance of getting cancer, the class might include various other people like you. But there may be competing classes that yield different relative frequencies. You may belong both to the class of smokers and the class of those with no family history of cancer. What, then, is the real chance? This is the *problem of the reference class*.

Some frequentists follow Richard von Mises in requiring the sequences of trials that ground chances to be *infinite*, and thus presumably hypothetical. Then the chance of an outcome type is identified with its *limiting* relative frequency. (Further randomness constraints might also be imposed on the sequences.) Counterintuitively, such "chances" are then sensitive to the ordering of the trials (a sequence with infinitely many heads and tails can be rearranged to give whatever limiting relative frequency we like). Moreover, the appeal to hypothetical trials, let alone infinitely many of them, may betray the empiricist and scientific scruples that made frequentism initially appear attractive, for such "chances" are not constrained by anything in our experience.

Historically associated with Peirce and Popper, *propensity* accounts of chance postulate primitive dispositions, or tendencies, possessed by various physical systems. Propensity theories fall into two broad categories. According to *single-case* propensity theories, propensities measure the tendencies of a system to produce given outcomes; according to *long-run* propensity theories, propensities are tendencies to produce long-run outcome frequencies over repeated trials. The former have been advocated by the later Popper, David Miller, and James Fetzer; the latter by the early Popper, Paul Humphreys, and Donald Gillies.

Adopting a long-run view answers a need for testability of propensity attributions, one arguably found wanting for single-case propensity attributions. A long-run attribution may be held falsified if the long-run statistics diverge too much from those expected. However, defining propensities in terms of long-run relative frequencies may render single-case chance attributions problematic. This poses a dilemma for the long-run propensity theorist. If propensities are linked too closely to long-run frequencies, the view risks collapsing into a variant of frequentism. But if the view is cast so as to make single-case chance attributions possible, it risks collapsing into a variant of the single-case propensity view.

Long-run propensity theories may be motivated by the worry that in a single case there can be factors present that are not part of the description of the chance setup but that affect the chances of various outcomes. If the long-run propensity theorist responds by, in effect, falling back on long-run frequentism, the single-case propensity theorist goes the other way, embracing all causally or physically relevant details as part of the chance setup, determining the single-case chance (though we cannot measure it) for any given trial. The chance of each outcome is determined by everything that might influence

the evolution of the setup. Propensity theories of this type respect some of our physical and causal intuitions, but pay a price epistemically. Since each single-case setup is presumably unique, we cannot use frequencies to estimate the chances or to falsify hypotheses about them.

A final problem, specifically for *conditional* propensities, is *Humphreys' paradox*. If  $\Pr(A|B)$  is a propensity, it seems to have a built-in causal direction, from  $B$  to  $A$ ; the “inverse” conditional probability  $\Pr(B|A)$  can often be calculated, but it appears to get the causal direction wrong. Various authors argue that inverse probabilities cannot be considered propensities, earlier events not having propensities to arise from later events. Thus, not all conditional probabilities may be interpretable as propensities.

While frequentist and propensity theories have dominated philosophical accounts of chance, a recent recurring proposal is that “chance” be viewed as a theoretical term similar to others in the sciences, such as “mass” or “fitness.” In this post-positivist era, philosophers mostly agree that such terms cannot be reduced to non-theoretical terms. Instead, we may view theoretical terms as implicitly defined by their roles in scientific and philosophical theories. This approach avoids many of the difficulties discussed above, but it may not satisfy philosophers who find something troubling about the very notion of chance (see below). It also renounces giving a philosophical account of chance with *normative* status—claiming, for example, that theorists *should* admit objective chances into quantum mechanics but not into economics.

Pioneering work by David Lewis on the connections between chance and *credence* (subjective probability) has inspired *Humean best-system* theories. They share these tenets:

- Chances are defined so that their distinctive connection with credences is rendered transparent (see “Chance and Credence” below).
- Chances supervene on (are determined by) the entire history of actual events, and not on anything modal that does not itself supervene on the actual.
- Chances are determined by the laws of nature: the regularities of a best system (theory) that optimizes the balance of simplicity, strength (covering as many phenomena as possible), and fit (how typical actual events are, given the chances posited by the system).

Humean best-system accounts aim to be as acceptable to empiricists as finite frequentism, while avoiding the defects of that account.

## CHANCE AND CREDENCE

Perhaps the most crucial demand we make of chances is that they guide our bets, expectations, and predictions—that they be guides to life in the face of uncertainty. This role is captured by some chance-credence principle or other, the most common coinage recently being Lewis’s Principal Principle (Lewis 1986, p. 83–132):

$$(PP) Cr(A|ch(A) = x \ \& \ E) = x$$

Here  $Cr$  is one’s credence function,  $A$  is a proposition,  $ch(A)$  is the chance of  $A$  (presumably time-indexed), and  $E$  is further evidence that one may have. For (PP) to be applicable,  $E$  cannot be relevant to whether  $A$  is true or false, other than by bearing on the chance of  $A$ . (PP) codifies something crucial about chance. A touchstone for any theory of chance is that it should underwrite (PP). There is considerable controversy over which theory (if any) can meet this challenge.

## CHANCE AND DETERMINISM

*Determinism* is the thesis that any complete past or present state of the world, conjoined with the laws of nature, entails all future events. In a deterministic world, some insist, chance has no work left to do, the entire future being already determined by past events. Philosophers are divided over whether determinism rules out (nontrivial) chances. Since the definition of determinism says nothing about chance, more is needed to argue that determinism rules out chances.

D. H. Mellor, Popper, and others who view propensities as fundamental physical loci of indeterminism, see an immediate inference from determinism to the nonexistence of chances. Frequentists such as Venn and Reichenbach see no such inference: intermediate frequencies can exist in both deterministic and indeterministic worlds. The Humean best-system approach leaves open whether a deterministic system of laws can include chance laws (although Lewis rejects this possibility). And on the implicit-definition approach, intermediate chances and determinism coexist just in case our fundamental physical theories are deterministic but some scientific theory postulates objective probabilities. Statistical mechanics uses chances, but its underpinnings are deterministic, and typical uses of chance in biology and the social sciences involve no presumption for or against determinism, as Isaac Levi (1990) and others have argued.

Nor does indeterminism guarantee the existence of chances. Fundamental physical laws may fail to entail a unique future without being probabilistic. However, if these laws are probabilistic, as some interpretations of

quantum mechanics contend, then chances are apparently guaranteed on any but a skeptical/subjectivist view.

### SUBJECTIVISM, SKEPTICISM ABOUT CHANCE, AND EXCHANGEABILITY

Chance is meant to play a certain theoretical role. It is a further matter what, if anything, actually *plays* this role. According to Bruno de Finetti, nothing does. “Probability does not exist,” he said (1990, p. x), meaning that *chance* does not exist and that all probability is subjective. Skepticism about chance is easily assimilated to skepticism about kindred modal notions—possibility, counterfactuals, causation, laws of nature—that seem not to be straightforwardly reducible to nonmodal notions, in particular, notions congenial to an empiricist. And skepticism specifically about chance can be based on further arguments, for one can be skeptical not just about its modality, but also about its putative *degrees*. Subjectivists have also argued that chance is redundant, its alleged role being completely discharged by credences. Richard Jeffrey, Bas van Fraassen, Brian Skyrms, and others have developed subjectivist positions in the spirit of de Finetti.

Moreover, the mathematics of chance (unlike the other modal notions) permits a particular eliminativist gloss. A sequence of trials is said to be *exchangeable* with respect to a probability function if the probabilities of trial outcomes are invariant under finite permutations of trials; probabilities may be sensitive to the numbers of outcomes of each kind, but not to their ordering. De Finetti (1990) showed that when this condition is met, there is a unique representation of the probability distribution over the trials as an expectation of simpler probability distributions according to which the trials are independent and identically distributed. For example, if your credences over the results of repeated coin tossing are exchangeable, then it is as if you treat the trials as tosses of a coin of unknown bias, with credences over the possible biases. Subjectivists have argued that this delivers some of the supposed benefits of chance, without any questionable metaphysics.

### CONCLUSION

Many of the perplexities about chance—its controversial metaphysics, its seeming resistance to reduction, its epistemological recalcitrance, etc.—are familiar from other modal notions. But chance has been handled in mathematics and philosophy with more precision than those other notions. In the process, still further perplexities have been born. For the foreseeable future, at least in the

writings of philosophers and philosophically minded scientists, chance is probably here to stay.

## CHANNING, WILLIAM ELLERY

(1780-1842)

William Ellery Channing, America's most famous Unitarian minister, was described by Ralph Waldo Emerson as "one of those men who vindicate the power of the American race to produce greatness." Channing, born in Newport, Rhode Island, was graduated from Harvard in 1798. The following two years he spent as a tutor in Richmond, Virginia, and in private study. During this period he underwent a profound religious experience, and in 1801

he returned to Harvard for theological study. He was ordained the minister of Boston's Federal Street Congregational Church in 1803 and held this pastorate throughout his life. He died in Bennington, Vermont.

Channing was not an original or profound thinker, a systematic philosopher, or a great writer. His significance in the history of ideas lies in his representative influence, his achievement in expressing and synthesizing the diverse strands of thought that appeared in America at the end of the eighteenth and the beginning of the nineteenth centuries.

Although Channing was celebrated in his own lifetime as a man of letters (his critical essays on John Milton, Napoleon Bonaparte, and François Fénelon were widely read both here and abroad), his lasting reputation stands on his attempt to develop an "enlightened" religious faith for the Americans of his generation. Jonathan Edwards had responded to the spirit of the Enlightenment by employing the ideas of John Locke and Isaac Newton to revitalize Calvinist dogma. Channing employed the liberating spirit of eighteenth-century thought to free Christianity from an outmoded theology. "God has given us a rational nature," he said in his famous sermon "Unitarian Christianity" (1819), "and will call us to account for it." Without denying the authority of Scripture, Channing argued that men should "reason about the Bible precisely as civilians do about the Constitution under which we live." This rational approach to revelation led Channing to reject the "irrational and unscriptural doctrine of the Trinity." Substituting the moral perfection of God for the Calvinist conception of divine sovereignty, Channing also repudiated such doctrines as natural depravity and predestination. "It is not because his will is irresistible but because his will is the perfection of virtue that we pay him allegiance," Channing asserted. "We cannot bow before a being, however great and powerful, who governs tyrannically."

As a religious thinker Channing was liberal but not radical. Eighteenth-century skepticism had no place in his thinking. He was influenced considerably by Scottish "commonsense" philosophers, such as Adam Ferguson and Richard Price, and in his discourse "The Evidences of Revealed Religion" (1821) he relied heavily on the traditional arguments of William Paley in attempting to refute David Hume and assert the validity of miracles.

Channing is also important for his influence on the New England transcendentalists. Like Jean-Jacques Rousseau, whose writings he admired, he was partly an Enlightenment figure and partly a romantic. Channing's romanticism is most apparent in the sermon "Likeness to

God" (1828), in which he asserted that humankind discovers God not only through Scripture and rational inquiry but also through consciousness. Long before Emerson's famous essays were published, Channing was preaching that in all its higher actions the soul had "a character of infinity" and describing sin as "the ruin of God's noblest work." Despite the fact that Channing never professed enthusiasm for the "new views," the similarity between his conception of the divine potential in human nature and the later pronouncements of Emerson and Theodore Parker is unmistakable. The path to transcendentalism lay through Unitarianism, and it was Channing who helped to pave the way.

Finally, Channing is significant for his humanitarian influence. His belief in the parental character of God and the dignity of humanity provided an ideological base for humanitarian efforts, and he spoke out in favor of most of the reform causes of his day. His pamphlet against slavery, written in 1835, attracted wide attention. Although Channing always shied away from radical solutions to social disorder, no one was more influential in articulating the gospel of human dignity that nourished most American reformers before the Civil War.

## CHAOS THEORY

A physical system has chaotic dynamics, according to the dictionary, if its behavior depends sensitively on its initial conditions, that is, if systems of the same type starting out with similar sets of initial conditions can end up in states that are, in some relevant sense, very different. But when science calls a system chaotic, it normally implies two additional claims: That the dynamics of the system is rel-

atively simple, in the sense that it can be expressed in the form of a mathematical expression having relatively few variables, and that the geometry of the system's possible trajectories has a certain aspect, often characterized by a strange attractor.

Chaos theory proper, it should be noted, has its home in classical physics (and other kinds of dynamics that share the relevant properties of classical physics). The extent to which chaotic mathematics is fruitful in understanding the quantum realm is still a matter of debate.

### SENSITIVE DEPENDENCE ON INITIAL CONDITIONS

In the popular imagination a chaotic system is one whose future state may be radically altered by the smallest of perturbations—as when the fluttering of a butterfly's wings creates a disturbance whose size is inflated to the point where it tips the meteorological balance on the other side of the globe, creating a tornado where there would otherwise have been none. Though the "butterfly effect" marvelously engages human fear and wonder at the unpredictability of things, it captures rather less completely what is interesting and distinctive about modern chaos theory.

The idea of an inherent unpredictability in human and other affairs due to the inflation of small disturbances is an old one. Swift wrote in *Thoughts on Various Subjects* (1711) that "A Wise man endeavors, by considering all Circumstances, to make Conjectures, and form Conclusions: But the smallest Accident intervening, (and in the Course of Affairs it is impossible to see all) doth often produce such Turns and Changes, that at last he is just as much in doubt of Events, as the most ignorant and unexperienced Person" (p. 415).

Modern mathematics is able to characterize the sensitivity of initial condition dependence in various ways that lie far beyond Swift's means. Notions such as the Liapunov exponent help to quantify the speed at which the trajectories of systems starting out with similar initial conditions will diverge. Measure theory quantifies something like the chance that a small initial difference will lead to a relatively large difference in outcome, in systems where not every small change makes such a difference. There is nothing here, though, that would have astounded Swift.

### SIMPLICITY

The central insight of chaos theory is that systems governed by simple equations, that is, systems whose behav-

ior can be characterized by a small number of variables, called low dimensional systems, are often sensitive to initial conditions. At first blush this realization has a pessimistic cast. Most obviously it leads to the conclusion that even a simple dynamics may be unpredictable in the medium to long term, as which of two significantly different outcomes occurs may depend on such first details of the initial conditions as to lie beyond the resolving power any reasonable observational effort.

Somewhat less obviously certain kinds of sensitivity to initial conditions impede systematic dynamical understanding. A famous example closely connected to the origins of chaos theory is the three body problem, the task of elucidating all the properties of the dynamics of a three body system in Newtonian gravitational theory. In 1890 Henri Poincaré showed that three body systems can tend to chaos in the modern sense of the word, and concluded that a systematic treatment of three body dynamics would be difficult if not impossible.

Chaos can be an impediment to prediction and systematic understanding in low dimensional systems then. However, if low dimensional chaos is bad news for the study of systems known to have low-dimensional dynamics, it is good news for the study of systems known only to have chaotic dynamics. Traditionally such systems were modeled by complex equations, if at all; chaos theory introduces the serious possibility that these systems may be governed by equations with very few variables. Underlying the complex appearances may be a simple reality. The prospect of finding a hidden simplicity in such complex phenomena as turbulent flows, the weather, the movements of financial markets, and patterns of extinction is what most excites proponents of chaos theory. (Much the same prospect animates the advocates of catastrophe theory, the study of cellular automata, “complexity theory,” and so on.)

To what extent can the nature of this hidden simplicity, if it exists, be divined? Given sensitive dependence on initial conditions, it is difficult to find the simple equation that best predicts the observed phenomena, since small errors in measuring initial conditions can make even the true model look like a bad predictor. More feasible is to infer some of the more interesting properties of the putative underlying law, such as the degree of sensitivity to initial conditions and certain geometrical aspects of the dynamics induced by the law (discussed below).

Under favorable conditions this information can be used to model accurately the behavior of chaotic systems to some extent—or at least that is the hope both of aca-

demical chaoticians and of those hoping to use the mathematics of chaos theory to beat the financial markets.

By far the boldest posit made in undertaking such work is the assumption that there is a simple dynamic law lying behind the subject system’s complex behavior. For elaborate systems such as ecosystems and economies, the assumption of dynamic simplicity is often no more than a leap of faith; however, Strevens describes some circumstances in which ecosystems and some other complex systems have a low dimensional macrodynamics.

The Geometry of Chaos Trace the trajectory of a paradigmatically chaotic system through the space of possible states and the result is a complicated tangle of looping paths. It is the geometry of this tangle more than anything else—more even than sensitive dependence per se—that is distinctive of chaos (though there is disagreement as to which feature of the geometry is most important).

One especially striking feature of such trajectory tangles is their often-fractal structure: They cut out a shape in the space in which they are embedded so intricate that mathematicians ascribe it a fractional dimension. Such a shape is a strange attractor (strictly speaking an attractor only if it is a set of trajectories that systems starting from some points outside the attractor eventually join).

Many of the more interesting properties of chaotic systems can be understood as arising from the intricate geometry of the trajectory tangle. One well-known example is the appearance of “period-doubling cascades” in systems that are moving from a periodic to a chaotic regime of behavior: As some parameter affecting the system’s dynamics is tweaked, the system first oscillates between two states, then between four states, then eight states, and so on, with shorter and shorter times between each successive doubling, until it goes chaotic. What is interesting about this behavior is that it turns up in many physically quite different kinds of systems, and that there are certain aspects of the period doubling, notably the rate at which the doubling increases, that are the same (in the limit) in these otherwise rather different systems. This universality in chaotic systems holds out the promise of understanding the behaviors of a considerable range of systems in terms of a single mathematical—in this case, it turns out, a geometrical—fact. So far however the wider significance of this understanding is unclear.

A more practical part of chaotic geometry is the use of limited data about the behavior of chaotic systems to reconstruct to a certain extent the geometry of the system’s trajectory. Suppose that the behavior a chaotic sys-

tem is characterized by three variables, so that the system's "trajectory tangle" is a subset of three-dimensional space. Suppose also that only a single property of the system's dynamics can be observed, a function of the values of the three variables. In favorable conditions, this single set of observations can be used to recover the geometrical structure of the three-dimensional dynamics. Various predictions, quantitative and qualitative, can then be made from the recovered geometry.

This is a powerful technique, as it assumes no knowledge of the number or even the nature of the underlying variables. However its success does depend on, among other things, the simplicity assumption explained above: The technique supposes that there are no more than a small number of variables.

### CHAOS AND PROBABILITY

The disorderly behavior of chaotic systems can be called "random" in a loose and popular sense. Might the behavior of at least some such systems be random in a stronger sense? The suggestion that chaos might provide a foundation for probabilistic theories such as statistical mechanics has been one of the more fruitful contributions of chaos theory to philosophy.

The best scientific theories of certain deterministic or near deterministic systems are probabilistic. Perhaps the most prominent examples are the systems characterized by statistical mechanics and population genetics; the simplest examples are various gambling setups such as a roulette wheel or a thrown die. The probabilistic characterization of these systems is apt because the various events that make up their behavior (die throws or deaths, for example) are patterned in characteristically statistical ways, that is, in ways that are captured directly by one or other of the canonical probability distributions in statistical theory.

The mathematics of chaos offers an explanation of the probabilistic aspect of these patterns, and so offers an explanation of the success of probabilistic theories applied to certain sorts of deterministic systems.

The explanation, or rather the family of explanations, is quite complex, but it can be loosely characterized in the following way. A paradigmatically probabilistic pattern has two aspects: A short term disorder, or randomness, familiar to every gambler, and a long term order that is quantified by the statistics characterizing a probability distribution, such as the one-half frequency of "heads" in a long series of coin tosses.

Chaotic systems are capable of producing probabilistic patterns because they are capable of producing both this short term disorder and the requisite kinds of long-term order. The short-term disorder is due to the sensitive dependence on initial conditions; the long-term order to other aspects of the "geometry of chaos," principally chaotic dynamics' resemblance to a "stretch-and-fold" process.

Nowhere near all chaotic systems, it should be noted, generate probabilistic patterns. Indeed this area of investigation is not, in a certain sense, mainstream chaos theory: There are no strange attractors or period-doubling cascades, though there is a characteristically chaotic geometry to the relevant trajectory tangles. As well as explaining the success of probabilistic theorizing in science, chaos has been put forward—for much the same reasons—as a foundation for the metaphysics of probability, on the principle that what explains the probabilistic pattern is deserving to a considerable extent of the name probability.

### PHILOSOPHICAL SIGNIFICANCE

What is the philosophical significance of chaos? With respect to general philosophy of science, opinion is divided. Some philosophers, for example Stephen Kellert, have argued that chaos theory requires the abandoning of prediction as the touchstone of successful science, a new conception of the nature of scientific explanation, and the end of reductionism. Others, for example Peter Smith, have argued that these conclusions are too extreme, and that insofar as they are justified, chaos theory is not necessary for their justification, though it may well have brought to philosophy's attention problems previously wrongly ignored.

With respect to certain foundational questions about science, the significance of chaos is less controversial. The notion of determinism and (in the context of processes that are deterministic deep down) the notions of randomness and probability cannot be discussed without reference to work on dynamical systems since Poincaré that falls within the ambit—broadly conceived—of chaos theory.

## CHARDIN, PIERRE TEILHARD DE

See *Teilhard de Chardin, Pierre*

## CHARRON, PIERRE (1541–1603)

Pierre Charron, a skeptical philosopher and theologian, was born in Paris in a family of twenty-five children. He studied at the universities of Paris, Bourges, Orléans, and Montpellier and received a law degree from Montpellier in 1571. Sometime during his student years he became a priest. He was a successful preacher and theologian in southern France, serving as preacher in ordinary to Queen Margaret of Navarre and as a theological advisor and teacher in various dioceses in the Midi. In spite of his many worldly successes, he tried to retire to a monastic order in 1589 but was refused admittance because of his age.

During the 1580s Charron met Michel Eyquem de Montaigne in Bordeaux and became his close friend and disciple. Montaigne made Charron his intellectual heir, adopting Charron as his son. After Montaigne's death in 1592 Charron wrote his major works: *Les trois veritez* (Bordeaux, 1593), *Discours chrestiens* (Bordeaux, 1601; Paris, 1604), *De la sagesse* (Bordeaux, 1601), and *Petit traité de sagesse* (written in 1603, published posthumously in Paris, 1606). These works were popular and

were republished often in the seventeenth century, especially the skeptical *De la sagesse*, which was highly influential in disseminating skeptical views and arguments into philosophical and theological discussions and played an important role in the development of modern thought, libertinism, and fideism.

## OPPOSITION TO CHARRON

Serious efforts to suppress and reject Charron's skeptical views were made by such figures as the Jesuit Father François Garasse, who in 1623 accused Charron of having supplied *le brèviare des libertins* and of having been a secret atheist trying to destroy religion. His work, which was first condemned in 1605, was seen as more dangerous than Montaigne's, partly because Charron was a professional theologian, partly because he wrote more didactically. Pierre Chanut, a Protestant medical doctor, published *Considerations sur la sagesse de Charon* (1643), an attempted Aristotelian refutation of Charron's skepticism about the possibility of knowledge.

Although Charron, like Montaigne, was attacked on many sides, his views were also defended and advanced by the so-called *libertins érudits*—Gabriel Naudé, Guy Patin, François de La Mothe Le Vayer, and Pierre Gassendi—and were supported in varying degrees as theologically orthodox by various French Counter-Reformation leaders. Pierre Bayle considered Charron an excellent and prime representative of fideistic Christian thought. Interest in and concern with Charron's views diminished in the eighteenth century, and he came to be considered a second-rate and derivative Montaigne whose style lacked the freshness and literary quality of his mentor's. In the light of more recent criticism suggesting that Montaigne was or might have been a sincere believer and that his skepticism was part of a theological movement of the period, Charron, too, has begun to be reexamined and reevaluated.

## CHARRON'S VIEWS

The first statement of Charron's views was the *Trois veritez*, a tract against Calvinism and the views of its French leader, Philippe Duplessis-Mornay. The three truths Charron sought to establish were that God exists, that Christianity is the correct view of God, and that Catholicism is the true statement of Christianity. Most of this enormous work deals with the last claim. However, the work begins with a brief discourse on knowledge of God, developing skepticism about the possibility of human knowledge in this area, on the basis of both human rational limitations and the nature of God. One's

own capacities are so limited and unreliable that it is doubtful that one could really know anything in either the natural or the supernatural realm. God's nature is infinite and therefore surpasses all attempts to define or limit it. Hence, one cannot know, in rational terms, what God is. Thus, the greatest theologians and philosophers know as much or as little about God as do the humblest artisans. One's knowledge consists only of negative information, what God is not. In fact, Charron announced, "the true knowledge of God is a perfect ignorance about Him" (*Trois vritez*, 1595, p. 26).

Charron combined the skeptic's views about the inadequacy and unreliability of human knowledge with the mystic's and negative theologian's view that God is unknowable because he is infinite and then utilized this combination to attack atheism. The denial that God exists proceeds from some definition of God, from which absurd conclusions are then drawn. Such a definition can only be the result of human presumption, the attempt to measure divinity by human means, and, as such, is worthless, since atheists do not, and cannot, know what they are talking about.

Throughout the *Trois veritez* Charron argued principally in a negative way, trying to show that it is unreasonable not to believe in God, Christianity, and Catholicism and that the evidence adduced by opponents is unreliable or dubious. He often contended that opponents, usually Calvinists, had to base their case on the results obtained by the weak and miserable human capacities, employing these defective results as measures of divine truth.

## DE LA SAGESSE

Charron's skeptical defense of the faith was made more explicit in *De la sagesse* and in his defense of that work, *Petit traicté de sagesse*. His major thesis was that since man cannot discover any truth except by revelation, morality should be based on following nature, except when guided by divine light. To support this thesis, Charron first put forth most of Montaigne's skeptical views in an organized fashion. One must first know oneself ("The true science and the true study of man is man," *De la sagesse*, book 1, chapter 1), and this involves knowing the limitations on what one can know. Charron presented the traditional skeptical critique of sense knowledge, questioning whether one possesses the requisite senses for gaining knowledge, whether one can distinguish illusions and dreams from veridical experience, and whether one can, in view of the enormous variability of sense experiences, determine which ones correspond to objective states of affairs. Next, he raised skeptical questions about one's

rational abilities, contending that one possesses no adequate or certain criteria that enable one to distinguish truth from falsehood. He pointed out that in fact one believes things mainly as a result of passions and social pressures, not reasons and evidence. One actually functions as a beast and not as a rational being. Hence, one should accept Montaigne's contention that men possess no genuine principles unless God reveals them. Everything else is only dreams and smoke.

The second book of *De la sagesse* presents a discourse on the method for avoiding error and finding truth, in view of the human predicament. Charron's method closely resembles the one René Descartes set forth later: examine all questions freely and dispassionately, keep prejudice and emotions out of all decisions, develop a universality of mind, and reject any decisions that are in the slightest degree dubious. This skeptical method, Charron claimed, is of greater service to religion than any other there may be. It leads one to reject all dubious opinions until one's mind is "blank, naked and ready" to receive the divine revelation on faith alone. The complete skeptic will never be a heretic, since if he or she has no opinions, he or she cannot have the wrong ones. If God pleases to give him or her information, then the skeptic will have true knowledge. Until the skeptic receives the revelation, he or she should live by a *morale provisoire*, following nature. The last book of *De la sagesse* presents this theory of natural morality, showing how one ought to live as a skeptic and noble savage if one has no divine guidance.

*De la sagesse* was one of the first important philosophical works to be written in a modern language and to present a moral theory apart from religious considerations. Some considered the work a basic didactic statement of Pyrrhonian skepticism, challenging both traditional philosophical claims to knowledge and religious ones and thus preparing the ground for a thoroughly naturalistic view of human nature and conduct. Charron claimed that the argument in *De la sagesse* only represented part of his view, dealing with the human situation apart from divine guidance.

The overall theory stated in his various works, his ecclesiastical career, and the piety expressed in his *Discours chrestiens* suggest that he was a sincere fideist, who saw skepticism as a means of destroying the enemies of the true faith while preparing the soul for salvation.

The problem of interpreting Charron's views involves a larger issue, that of assessing the purport of the revival of skepticism in the Renaissance and the relation of this revival to Reformation and Counter-Reformation

thought. Skeptical thought, perhaps, played several different and possibly incompatible roles in the period. Both then and now, skeptics like Charron could provide the “rationale” both for antirational fideism and for irreligious naturalism.

## CHARTRES, SCHOOL OF

A cathedral school existed at Chartres as early as the sixth century but did not become famous until the eleventh and twelfth centuries. Under Bishop Fulbert (d. 1028), a pupil of Gerbert of Aurillac, students, among them Berengar of Tours, flocked to Chartres to study the *trivium* and *quadrivium*, medicine and theology. Later, Bishop Ivo brought renown in canon law. The high point was reached in the early twelfth century under Bernard of Chartres and his brother Theodoric (Thierry) and their pupils Gilbert of Poitiers (de la Porrée), William of Conches, and Clarembald of Arras. Also associated with the school in various ways were Bernard of Tours, Adalard of Bath, Alan of Lille, and John of Salisbury. The Chartrains of this period were humanists who loved the literature and philosophy of classical antiquity. The richness of their program of studies is evident in Theodoric’s *Heptateuch*, a handbook of the seven liberal arts and a collection of the authors who were read. In the early twelfth century Chartres was the center of Latin Platonism. Plato himself was known only indirectly through a fragment of the *Timaeus* in the translation and commentary of Chalcidius and through Macrobius, Apuleius, Seneca, and Boethius, whose *Opuscula Sacra* and *Consolatio Philosophiae* were much commented on. Devotion to Platonism produced realist interpretations of the problem of universals, speculations about the Ideas, matter and form, cosmological thought, and discussions about the world soul. Aristotle was generally less highly esteemed. The Chartrains knew only his logical writings (the *Organon*), including the *logica nova* (the rediscovered *Prior Analytics*, *Topics*, and *Sophistic Refutations*), which makes an early appearance in Theodoric’s *Heptateuch*. Under the inspiration of Boethius, attempts were

made to reconcile Aristotelianism and Platonism. Theology was presented largely in philosophical clothing. Confident of the harmony of faith and learning, the Chartreans attempted to establish the existence of God by numerical speculations, to synthesize Platonic cosmology and biblical revelation, and to compare the Platonic world soul with the Holy Spirit, as in William of Conches. God was considered to be the form of all being, a view that has been called pantheistic by some historians. Greek and Arabian writings on medicine, astronomy, and mathematics, including works by Hippocrates, Galen, Ptolemy, Euclid, al-Khwarizmi, Johannitius, and others were circulated and read in translation. In the early twelfth century Chartres was without a peer as a school of classical and humane learning and of Platonism, and it was rivaled in philosophy only by Paris. The bloom was fading fast by midcentury, but the influence of the school continued to be marked among the disciples of Gilbert of Poitiers, in thirteenth-century writings on natural philosophy, and still later in the works of Nicholas of Cusa.

## CHATEAUBRIAND, FRANÇOIS RENÉ DE (1768–1848)

François René de Chateaubriand, the French author, was born at Saint-Malo in Brittany and educated at Dol-de-

Bretagne and Rennes in preparation for studying for the priesthood at the Collège de Dinan. Finding that he had no vocation, he followed the tradition of his social class and became an army officer instead. In 1788 he joined the order of the Knights of Malta, went to Paris, and began to associate with men of letters. From then on literature was his chief interest in life, though his literary career was paralleled by a career in diplomacy and politics. In 1803 he was appointed an attaché at the French embassy in Rome, and upon the return of Louis XVIII to power he played a role in politics in the Ministry of the Interior. His main diplomatic post was that of French plenipotentiary at the Congress of Verona, an account of which he published in 1838.

Chateaubriand's political as well as his religious views were in a state of constant flux. As a young man he had been favorable to the revolution, but he was soon disillusioned and in 1792 went into voluntary exile in London. There he published his *Essai historique, politique et moral sur les révolutions*, which he later retracted. This work was clearly influenced by the Philosophes, especially Jean-Jacques Rousseau, and, though far from atheistic, was definitely favorable to deism and opposed to Christianity. As Charles-Augustin Sainte-Beuve showed a half-century later in his *Causeries du Lundi*, the printed version of Chateaubriand's views was much less extreme than what he really thought. Having undergone a personal crisis when he learned of the death of his mother, he returned from exile in 1800 and began the preparation of one of his most famous works, *Le génie du Christianisme*. The aim of the volume was to persuade the public that Christianity had as many themes worthy of artistic expression as paganism. It produced, said Sainte-Beuve, "a whole army of parlor Christians." This was precisely the goal of its author, to make Christianity fashionable.

In September 1816, Chateaubriand published his pamphlet *De la monarchie selon la charte*, which preached political liberalism in a constitutional monarchy. This brought on his temporary political ruin, but he soon recovered and was utilized by the government in various diplomatic posts. Toward the close of his life he developed an intimacy with Mme. Récamier and her circle but withdrew from politics and devoted himself to the preparation of his memoirs, the *Mémoires d'outretombe* (published posthumously in 1849).

Chateaubriand's contributions to French philosophy were indirect. The early *Essai sur les révolutions* made it clear that he considered any type of philosophy to be antireligious and religion to be a substitute for philosophy. In it he attempted to show that no philosophy could

ever hope to reach the truth, for truth was discovered not by reasoning but by some inner light, a kind of feeling (*sentiment*), perhaps what Blaise Pascal called the heart. It was this belief that appeared in such works as *Atala*, where the theme of the Noble Savage is developed. Though *Atala* is herself a Christian, she is a Christian by sentiment, not by reason, and her form of Christianity was believed by her inventor to be higher and nobler than that deduced by argument.

Similarly, Chateaubriand anticipated William Wordsworth in maintaining even as a young man that in the contemplation of nature, in the sense of the landscape, there is a spontaneous revelation of the truths of morality and religion. The famous passage "Night among the American Savages," which terminates the *Essai* and was reprinted in part in the *Génie du Christianisme*, is not only a description of a moonlight scene near Niagara Falls but also an evocation of the nobility of soul that belongs only to men who have lived in a state of cultural primitivism far from the contamination of society. Like Rousseau, Chateaubriand pitted nature and society against each other, and it is significant that in this passage the Indians are only two women, two small children at the breast, and two warriors. There is no mention of a tribe or village. The sole contact these people have with anything outside themselves is with the "ocean of trees." But it is to be noted that far from reinforcing the sense of individuality, this contact, on the contrary, induces an absence of all distinct thoughts and feelings, a kind of mystical union with that God who is nature itself.

This type of anti-intellectualism reappeared in the *Génie du Christianisme*. Chateaubriand said in the preface to this work that he turned away from eighteenth-century liberalism when he learned of his mother's death. He was in exile in London at the time. "I wept," he wrote, "and I believed." The evidence of tears was proof of the truths of Catholicism, as in the *Essai* the feelings aroused by natural scenery were proofs of the truth of deism. But Catholicism is hardly a religion spontaneously kindled in the hearts of all people. It is a religion initiated and developed in society. Hence, Chateaubriand found himself aligned with the Traditionalists, a group as far from Rousseauistic sentimentalism as can be imagined. For whereas Joseph Marie de Maistre and the Vicomte de Bonald believed reason was the faculty that united human beings, the sentimentalists believed it was what divided them into conflicting sects.

It was perhaps for this reason that Chateaubriand emphasized the gifts Christianity had made to European culture. He wrote at the height of the Neoclassical move-

ment, when the masters were Jacques Delille in poetry, Antonio Canova in sculpture, and Jacques Louis David in painting. They, of course, found their inspiration in classical mythology and history. Chateaubriand tried to prove that there was more to be found in the Catholic tradition. However true this may have been, the point he was making was that to the extent that any set of beliefs increases the amount of beauty and goodness in the world, that set of beliefs is true. There is a concealed pragmatic test here that is of interest historically and would probably not be able to resist criticism. But at a time when men had lived through a period of horror brought on by the suppression of religion, it was understandable that they should attribute the horrors to the philosophy they believed had generated the antireligious practices. To Chateaubriand at this time the one alternative to philosophy was Catholicism, not that natural religion which he had lauded in the *Essai*. And this belief he never abandoned. He was not the type of writer to set down a body of premises from which he would deduce certain inferences. On the contrary, his hatred of philosophy was such that he simply stated his conclusions as his heart dictated; it remained for others to disentangle the form of his argument. He established a cultural atmosphere rather than a set of doctrines, and his works are more properly viewed as long poems of a purely lyrical nature than as doctrinal treatises.

## CHATTON, WALTER

(c. 1285–1343)

Walter Chatton was born in the village of Chatton in Northumbria. He entered the Order of Friars Minor at a young age and pursued the normal course of theological studies. His first lectures on the Sentences of Peter Lombard, called *Reportatio*, were held between 1321 and 1323. At the time Chatton, with William of Ockham and Adam Wodeham, was located in one of the Franciscan studia, probably London or Oxford, where Wodeham was the scribe or *reportator* of Chatton's lectures. A second commentary on the Sentences (incomplete), called *Lectura*, dates from 1328 to 1330. Besides these two Sentence commentaries, a single set of *Quodlibetal Questions* (incomplete) survives. Chatton became the fifty-third regent master for the Franciscans at Oxford in 1330. He went to Avignon in 1333 and was appointed by Popes Benedict XII (d. 1342) and Clement VI (c. 1291–1352) as one of the examiners of the writings of Thomas Waleys (d. 1349) and Durandus of Saint-Pourcain. He was appointed as bishop designate of the diocese of St. Asaph in Wales but died before the see had become vacant.

In virtually every distinction, question, and article of his lectures, Chatton attacks the views of Ockham, who in turn was appraised of these criticisms by Ockham's most noteworthy disciple, Wodeham. Chatton's other favored opponent was Peter Aureol, who had frequently criticized Chatton's favorite philosopher-theologian, John Duns Scotus. It is practically impossible to follow Chatton's train of thought without knowledge of the views of Ockham and Aureol.

One of Chatton's frequently invoked hermeneutical principles was designated as "my proposition" and can be called the antirazor as the foil of Ockham's principle of parsimony. If a situation cannot be adequately described by two propositions, then a third must be invoked, and if this is not adequate a fourth is required and so on.

In the domain of natural philosophy, Chatton was an indivisibilist, who viewed the continua, both permanent and successive, quantitative and temporal, as composed

of indivisibles or instants. The argument being that whatever God by his absolute power can do successively, he could do instantaneously, and thus there would be, according to the divisibilists' view, an infinite multitude capable of accretion ad infinitum. Chatton is conscious that he is in the minority and is counter to the views of Aristotle and most philosopher-theologians.

Concerning the ten Categories of Aristotle, Ockham held that only substance and quality enjoyed extramental existence. In contrast, Chatton claimed that all the categories in one way or another were distinct realities and he took every opportunity to attack Ockham's claim that quantity was simply extended substance and not extramentally real.

According to Ockham relations as such are not some *tertia quid*. A white thing A and a white thing B both regarding their fundament whiteness and their distinct termini as things enjoy extramental reality, but this does not mean that their relation of similarity requires extramental status. Naturally, Chatton posits *res respectivae* and counters Ockham's views whenever possible.

Initially, Ockham held that concepts were nothing more than *esse obiectiva* (their being known) and not accidents or qualities of the mind. Because of Chatton's critique, Ockham modified his view and admitted that concepts were qualities of the mind. However, this did not mean that universals qua universals were things outside the mind, such that Ockham is best qualified as a conceptualist (nominalist in the medieval sense), where as Chatton and Scotus are best classified as moderate realists.

Chatton's other principal adversary was Aureol. The latter had criticized Scotus's opinion that a univocal concept of being was absolutely essential in any attempt to prove the existence of God. Aureol noted that the modes "finite" and "infinite" did not come under the purview of "being" as univocal. Chatton admits the objection while claiming that there is a concept of being that includes all its modes, including the ultimate individual difference or individual property (the word *haecitas* occurs rarely and perhaps only once in Scotus's writings) and is a purely logical concept and not a metaphysical one.

Scotus's view of the principle of individuation as not being a double-negation (Henry of Ghent), a determinate quantity (St. Thomas Aquinas), or a collection of accidents (Porphyry and Anicius Manlius Severinus Boethius), but something positive that Scotus called the ultimate or individual difference or property, came under considerable attack from his successors. Ockham would

claim that no such principle was required because God created individuals and not species, genera, or universals. Chatton, however, strove to defend Scotus's view even while cognizant of its difficulties.

Just as Chatton regularly attacked Ockham, so Wodeham frequently criticized Chatton's views, particularly if Chatton was seen as misinterpreting or misunderstanding Ockham's positions.

In the realm of theology Chatton may be read as favoring positive theology, namely, as concerned with what the scriptures and the church fathers had to say. He is less concerned about what God might do or what he might have done by his absolute power (hypothetical theology).

Chatton is thus one of the earliest Scotists and his views attest to the intellectual ferment of his age. He is an interpreter of Scotus and offers alternative approaches in philosophical-theological discourse to his fellow Franciscans, Aureol, Ockham, and Wodeham.

## CHEMISTRY, PHILOSOPHY OF

Ideas about the diversity of matter in terms of elements and compound substances and their transformations have been pivotal to any scientific or prescientific approach to nature. From ancient natural philosophy and alchemy to modern nineteenth-century chemistry, these ideas were made the basis of philosophical systems and became the target of critical reflection. After a temporary interruption when modern philosophy of science focused on mathematical physics, philosophy of chemistry emerged anew in the 1980s and has become a flourishing field in which philosophers, chemists, and historians of chemistry are engaged. While many of the old philosophical issues have been rediscovered and discussed, new issues have also appeared as a result of shifts of general philosophical focus, alliances with historians and sociologists of science, the development of chemistry, and changes in its role in society.

### ONTOLOGICAL ISSUES

The objects of chemistry are subject to many ontological debates beyond simple issues of definition, and these debates also have an impact on epistemological and methodological issues. Following the example of microphysics, many philosophers and chemists take atoms and molecules as the basic objects of chemistry. Yet despite the numerous techniques available to visualize molecules, the notion of a molecule is a theoretical concept with many model assumptions that do not apply to nonmolecular substances, such as water, metals, and salts. It is not so much the lack of optional microstructural descriptions for these substances, but the variety of models, which are continuously refined and adapted to certain contexts and

problems, that makes such models a weak basis for defining the basic objects of chemistry. Another option is to take material substances, either elementary or compound, as the basic objects. Yet, far from being phenomenologically given entities, pure substances are the final results of infinite purification operations; that is, they are ideal laboratory artifacts. This fact has in turn inspired operational definitions. Whether one takes microstructures or pure substances as basic is not an arbitrary decision, but rather has direct impact on chemical classification and all derived concepts, because there is no simple one-to-one relationship between the two kinds of entities. There are microstructures without corresponding pure substances, and there are substances with many different microstructures.

A second but related ontological issue is about natural kinds in chemistry. Microstructuralists, following Hilary Putnam, have claimed that water is a natural kind because it is determined by a microstructural essence. This claim faces the problems mentioned above. Yet the substance-based approach to natural kinds is confronted not only with a potentially infinite number of possibly essential properties (see below) but also with the artificiality of pure substances. Even if pure substances were stable kinds independent of our conceptualization, they are not independent of laboratory purification. Nonetheless, the experimental reproducibility of sufficiently pure substances provides, within limits, a successful operation to ensure relatively stable kinds.

A third ontological issue is about whether substances (or microstructures) or transformations are the basic objects of chemistry. This issue refers to the general debate between substance and process philosophy. If not closed in bottles, substances continuously undergo chemical reactions and are only intermediate states in an ongoing process. Quantum chemistry describes even these states as processes. Furthermore, traditional chemical characterization of substances goes by chemical properties, that is, by all the dispositions of substances to transform into other substances under certain conditions, including the presence of still other substances as reactants. Substance philosophers define a chemical reaction as the change of certain substances, whereas process philosophers define a substance by its characteristic chemical reactions. A third option, proposed by Joachim Schummer, combines substances and processes in a network of dynamic relations, as the proper object of chemical research. On this view, substances and reactivities mutually define each other. Answering the ontological question has direct consequences on whether chemists

can best organize their knowledge in the form of substance databases, reaction databases, or combined substance-reaction databases.

Although all substances and transformations are usually considered objects of chemistry, the metaphysical distinction between natural and synthetic pervades both commonsense and chemical reasoning. Yet the notion of natural substances—substances that can be isolated from natural resources by purification—is questionable. Not only is purification a technical operation; also, most elements would have to count as synthetic when natural resources are lacking. On the other side of the ledger, all substances that can be isolated from natural resources can also be synthesized in the early twenty-first century, which undermines the distinction. Furthermore, we have little evidence to claim that a synthetic substance will never be isolable from natural resources in the entire universe.

## EPISTEMOLOGICAL AND METHODOLOGICAL ISSUES

A central epistemological issue is whether chemical knowledge can be complete or not. Microstructural essentialists claim that a perfect microstructural description of any substance yields complete chemical knowledge. However, chemical properties are not manifest properties but dispositional relations (that is, relations of the form “*A* under certain conditions is disposed to react with *B* to form *C* and *D*”). This means that the structure of experimental chemical knowledge is relational, dispositional, and open-ended. Because new properties are defined by new conditions and new potential reactants (currently produced at 15.5 million new chemicals per year), experimental chemical knowledge can increase indefinitely without reaching a state of being complete. It is an open question to what extent theoretical approaches can compensate for the incompleteness on the experimental level.

Chemistry differs from other sciences in that its theoretical concepts need to serve different methodological goals. Besides the traditional goals of accurately describing, explaining, and predicting phenomena, theoretical concepts in chemistry also fulfill purposes of classification and synthesis. By 2004 the chemical classification system had distinguished 78.3 million different substances and ordered them by classes and subclasses. And beyond mere prediction of phenomena, theoretical concepts provide experimental guidelines for producing millions of new substances and reactions per year. For all three methodological goals, the main theoretical

approach has been chemical-structure theory, which emerged in mid-nineteenth century and has been influenced and diversified by many different developments since, including quantum chemistry and spectroscopic instrumentation. Apart from this theory, a multitude of other theoretical concepts and models have been developed for particular substance classes and phenomena and for various purposes.

The main methodological issue in current philosophy of chemistry is to bring order to this complex picture without imposing upon chemistry methodologies tailored to other disciplines. Several case studies have shown that received approaches, for instance, Karl Popper's view that science makes progress by falsifying theories, are rather useless in chemistry. There is some agreement that chemists favor methodological pluralism and pragmatic application of models, rather than methodological universalism and the ideal of a single axiomatic theory. A study on scientific realism has suggested that entity realism, rather than theory realism, is a more appropriate methodological ideal in chemistry. The received methodological focus on methods of justification has been widened to include methods for research, that is, for developing new knowledge. Many detailed studies on the different kinds and uses of models in chemistry, from theoretical chemistry to chemical engineering, have been undertaken. Besides the impact of quantum mechanics (see the next section), the impact of spectroscopic instrumentation on theoretical concepts since the mid-twentieth century has received considerable attention, in fact, so much attention that interest in the "instrumental revolution" has replaced the older focus on the eighteenth-century "chemical revolution" by Antoine-Laurent Lavoisier and others. The methodological integration of both chemical analysis and synthesis, which form the major experimental activity of chemists, has overcome received distinctions between science and technology. Studies on the formal sign-language system of chemistry, consisting of structural formulas and reaction mechanisms, have illuminated its multipurpose theoretical capacity, but further studies are required to understand changes stemming from various theoretical and experimental developments.

## REDUCIBILITY TO PHYSICS

Whether chemistry is reducible to physics is a question that could come up only in the mid-nineteenth century, when modern physics emerged as its own discipline, because the former meaning of "physics" (natural science or natural philosophy) included chemistry as a branch.

Before then, mechanical (physical) approaches were among several competing approaches within theoretical chemistry, though not very successful. The question became meaningful only with the development of quantum mechanics and its application to chemistry since the late 1920s. Following a speech by Paul Dirac in 1929, many quantum physicists and philosophers of physics have taken for granted that the whole of chemistry would be reducible to quantum mechanics, and so would be part of physics.

Wary of making such bold claims, philosophers have carefully distinguished between different meanings of "reduction." An ontological reduction claims that the supposed objects of chemistry are actually nothing other than the objects of quantum mechanics and that quantum-mechanical laws govern their relations. In its strong, eliminative version, an ontological reduction states that there are no chemical objects proper. Antireductionists argue that theoretical entities are determined by their corresponding theories, and that theoretical entities of different theories cannot be identified. For instance, from the different meanings of the term "electron" in quantum electrodynamics and in chemical-reaction mechanisms, they conclude that the term "electron" has different references, which rules out an ontological reduction. An epistemological or theoretical reduction claims that all theories, laws, and fundamental concepts of chemistry can be derived from first-principle quantum mechanics as a more basic and more comprehensive theory. This claim has prompted many detailed studies (see below). Methodological reductionism, while acknowledging the current failure of epistemological reduction, recommends applying quantum-mechanical methods to all chemical problems, because that would be the most successful approach in the long run (approximate reductionism). But the mere promise of future success is not convincing unless accompanied by a comparative assessment of different methods. By modifying the popular notion that the whole is nothing but the sum of its parts, philosophers have developed two further versions of reductionism. Emergentism acknowledges that new properties of wholes (say of water) emerge when the parts (say oxygen and hydrogen) are combined, but it does not deny that the properties of the whole can be explained or derived from the relations between the parts (epistemological reductionism). Supervenience, in a simple version, means that, although epistemological reductionism might be wrong, the properties of a whole asymmetrically depend on the properties of the parts, so that every change of the properties of the whole is based on changes of the properties of the parts or the relations between the parts, but not the other way round.

When these terms are applied to the reduction of chemistry to quantum mechanics, that is, to chemical entities as wholes and quantum-mechanical entities as parts, emergentism and supervenience presuppose elements of epistemological or ontological reductionism. Thus, criticism of these positions applies accordingly. For instance, if one denies that chemical electrons are the same as quantum-electrodynamic electrons or, more generally, that quantum-mechanical entities are proper parts of chemical wholes, one ends up rejecting supervenience altogether.

Recent criticism has focused on epistemological reductionism by pointing out the technical limits of quantum mechanics with regard to particular chemical concepts, laws, and problems. Two quantum chemists, Guy Woolley and Hans Primas, have shown that the concept of molecular structure, which is central to most chemical theories, cannot be derived from first-principle quantum mechanics, because molecular structures cannot be represented by quantum-mechanical observables. Eric Scerri has argued that current quantum-mechanical approaches cannot calculate the exact electronic configuration of atoms, which was formerly considered a successful reduction of the chemical law that underlies the periodic system of elements. Jaap van Brakel has pointed out that successful applications of quantum mechanics to chemical problems frequently include model assumptions and concepts taken from chemistry. Joachim Schummer has argued that quantum-mechanical approaches are nearly absent and useless in areas that chemists are mainly concerned with: chemical reactions, synthesis, and classification.

Criticism of the reduction of chemistry to quantum mechanics, as the lowest level in the standard hierarchy of reductions, also challenges microreductionism as a general position and thus contributes to general philosophy. In the most detailed philosophical study on various forms of reductionism, Jaap van Brakel has used the case of chemistry to argue for a kind of pragmatism in which the “manifest image” of common sense and the empirical sciences is epistemologically primary over the “scientific image” of microphysics. Nikos Psarros presupposes a rejection of reductionism in his extensive project of seeking the cultural foundation of chemical concepts, laws, and theories in prescientific cultural practices, norms, and values. For many others, including Joachim Schummer, rejecting reductionism supports a pragmatist and pluralist position that clearly distinguishes between fields of research where quantum-mechanical approaches are strong and even indispensable and those where they are poor or even useless compared to other approaches. Once

reductionism has lost its function of securing the unity of the sciences, new relationships between chemistry and other disciplines could become subject to philosophical and historical investigations, including studies of such multidisciplinary fields as atmospheric science, biomedical science, materials science, and nanotechnology.

## FURTHER TOPICS

Current philosophy of chemistry reaches far beyond ontological, epistemological, and methodological issues. On the one hand, there are strong trends in historical research. Pertinent classical works on chemistry by such philosophers as Aristotle, Immanuel Kant, Georg Wilhelm Friedrich Hegel, Pierre Duhem, Ernst Cassirer, and Gaston Bachelard have been rediscovered, and these have allowed reinterpretations of the history of philosophy of science. Philosophical works by chemists of the past, such as Benjamin C. Brodie, Wilhelm Ostwald, Frantisek Wald, Edward F. Caldin, Fritz Paneth, and Michael Polanyi, have also been rediscovered. Historians and philosophers of chemistry have explored the development of many fundamental concepts in chemistry, such as chemical substance, element, atom, the periodic system of elements, molecular structure, chemical bond, chemical reaction, affinity, and aromaticity. In addition, important historical developments in chemistry have been philosophically scrutinized, such as the transitions from alchemy to modern chemistry and from phlogistic to antiphlogistic chemistry; the emergence of physical chemistry, quantum chemistry, and biochemistry; and the development of molecular-model building and instrumentalization.

On the other hand, philosophers of chemistry have also applied theoretical insights to practical problems, discovered a wider spectrum of philosophical perspectives on chemistry, and engaged in contemporary issues. Epistemological and ontological studies have found useful applications in chemistry education and information management. Beyond the traditional scope of philosophy of science, perspectives on chemistry from philosophy of technology, language, culture, and literature, and from metaphysics, aesthetics, ethics, sociology, and public understanding of science have all been exploited. For instance, studies on the role of visualization and aesthetics in chemical research have been undertaken to understand the heuristics and dynamics of research in a broader cultural context beyond traditional epistemic and technological goals. Philosophers and historians have investigated the historical roots and the cultural value conflicts underlying the widespread chemophobic attitude of society and the peculiar opposition of natural

versus chemical. In addition to taking up general professional ethics, philosophers have challenged the legitimacy of chemical-weapon research, questioned the alleged moral neutrality of synthesizing new substances for scientific purposes, discussed the scope of moral responsibility of chemists for their synthetic products, and developed moral frameworks for assessing chemical-research practice. Finally, with the rise of nanotechnology, in which chemistry is particularly involved, philosophers of chemistry have taken a leading role in discussing the societal and ethical implications of this nanotechnology of the ultra-small.

## CHENG HAO

(1032–1085)

Cheng Hao, also called Cheng Mingdao, was cofounder, with his brother Cheng Yi, of the neo-Confucian school of Nature and Principle (*li*). He held some minor official posts but devoted most of his life to teaching.

By making principle the foundation of his philosophy and identifying it with the nature of man and things, Cheng Hao and his brother set the pattern for the neo-Confucian philosophical movement known since the eleventh century as the school of Nature and Principle. To Cheng Hao principle was the principle of nature (*tian li*), a concept that he evolved himself; it was the natural law. It had all the characteristics of principle as conceived by Cheng Yi, but as the principle of nature it was self-existent and unalterable. Whereas Cheng Yi stressed the doctrine that principle is one but its manifestations are many, Cheng Hao emphasized more strongly the principle of production and reproduction as the chief characteristic of nature. To him the spirit of life was in all things. This creative quality was *ren*, the highest good. In man, *ren* becomes humanity, or love, which makes him the moral being he is. It enables him to embrace all things and heaven and earth as one body.

Whatever is produced in man, that is, whatever is inborn in him, is his nature. In its original, tranquil state, human nature is neither good nor evil. The distinction arises when human nature is aroused and manifested in feelings and actions and when these feelings and actions abide by or deviate from the mean. The chief task of moral and spiritual cultivation is to calm one's nature through absolute impartiality and the identification of

internal and external life. To achieve this end Cheng Hao advocated sincerity and seriousness.

There can be no denying that Cheng Hao was the more idealistic and his brother the more rationalistic. Cheng Hao more or less concentrated on self-cultivation, whereas his brother advocated both seriousness and learning. Under the influence of Buddhism Cheng Hao also advocated quietism. The two brothers had vastly different temperaments and therefore showed divergent tendencies, but it is not true, as some scholars claim, that one was monistic and the other dualistic.

## CHENG YI

(1033-1107)

Cheng Yi, or Cheng Yi-chuan, was the most outstanding Chinese teacher of his time, a lecturer to the emperor on Confucian classics, and cofounder, with his brother

Cheng Hao, of the neo-Confucian school of principle (*li*) that dominated Chinese thought for many centuries.

The central concept of the school is principle. The concept, negligible in ancient Confucianism, had been developed by the neo-Daoists and Buddhists, but the Cheng brothers were the first to build their philosophy primarily on it. To them, principle is self-evident and self-sufficient, extending everywhere and governing all things. It is laid before our very eyes. It cannot be augmented or diminished. It is many, but it is essentially one, for "definite principles" are but principle. "Principle is one but its manifestations are many." It is universal truth, universal order, universal law. Most important of all, it is the universal principle of creation. It is dynamic and vital. Man and all things form one body because all of them share this principle. It is identical with the mind and with the nature of man and things. Since principle is principle of creation and since life-giving is good, principle is the source of goodness. To be good is to obey principle. Thus, principle is both natural and moral and both general and specific. It has meaning as an abstract reality, but more so as the moral law of man.

The relation between principle and material force, which actualizes things, is not a dualistic one. Although Cheng Yi said that "material force exists after physical form and is therefore with it whereas the Way [principle] exists before form and is therefore without it," he also said that "what makes yin and yang [material force] is the Way." Material force is the physical aspect of principle. In the process of creation each operation is new, for material force is perpetually generated by Origination. (Origination is comparable to creation, except that it is natural and self-caused and is not an act of any being.)

To understand principle one can study one thing intensively or many things extensively. One can also read books, study history, or handle human affairs, for all things and affairs, including blades of grass, possess principle. This intellectual approach makes Cheng's system strongly rationalistic. The approach, however, is balanced by the moral, for whereas "the pursuit of learning depends on the extension of knowledge," "self-cultivation requires seriousness." This dual emphasis reminds one of the Buddhist twofold formula of meditation (*dhyana*) and wisdom (*prajna*).

CHERNYSHEVSKI, NIKOLAI  
GAVRILOVICH

See *Chernyshevskii, Nikolai Gavrilovich*

CHERNYSHEVSKII,  
NIKOLAI GAVRILOVICH  
(1828–1889)

Nikolai Gavrilovich Chernyshevskii, the Russian literary and social critic, was the guiding spirit of Russian nihilism and a major representative of positivistic materialism in nineteenth-century Russian philosophy.

Chernyshevskii was born in Saratov, Russia. The son of an Orthodox priest, he attended a theological seminary before entering the University of St. Petersburg in 1846. After his graduation in 1850, he taught secondary school in Saratov until 1853, when he returned to St. Petersburg, secured a master's degree in Russian literature, and began writing for leading reviews. He soon became a principal editor of *Sovremennik* (The contemporary), and by the early 1860s was the foremost spokesman of radical socialist thought in Russia. Arrested in 1862, he was banished to Siberia in 1864 and passed the remaining twenty-five years of his life in forced exile. He was permitted to return

to Saratov, in failing health, a few months before his death.

In his student days Chernyshevskii was attracted to the writings of the French socialists and of G. W. F. Hegel and the left-wing Hegelians. In 1849 he read Ludwig Feuerbach's *Essence of Christianity* and by 1850 had formed an allegiance to Feuerbach that was decisive in his philosophical development. He was also influenced by the English utilitarians, notably John Stuart Mill, whose *Principles of Political Economy* he translated into Russian in 1860.

Chernyshevskii's master's dissertation and first philosophical work, *Esteticheskie otnosheniia iskusstva k deistvitel'nosti* (The aesthetic relation of art to reality; St. Petersburg, 1855), is a critique of Hegelian aesthetics "deduced" (as Chernyshevskii later expressed it) from Feuerbach's naturalistic principles. Chernyshevskii argued that art is an aesthetically inferior substitute for concrete reality. The essential purpose of art is to reproduce the phenomena of real life that are of interest to man, compensating for his lack of opportunity to experience the reality itself. The derivative purposes of art, which give it a moral dimension, are to explain this reality for the benefit of man and to pass judgment upon it. Chernyshevskii developed his aesthetic views further, emphasizing the social context of art, in his *Ohcerki gogolevskogo perioda russkoi literatury* (St. Petersburg, 1855–1856; translated as *Essays on the Gogol Period of Russian Literature*).

In his chief philosophical work, a long essay titled *Antropologicheskii printsip v filosofii* (The anthropological principle in philosophy; 1860), Chernyshevskii exhibited his acceptance of Feuerbach's anthropologism and adopted the materialistic position he retained throughout his life. By "the anthropological principle" Chernyshevskii meant the conception of man as a unitary organism whose nature is not bifurcated into "spiritual" and "material" elements. He argued that philosophical questions can be resolved only from this point of view and by the methods of the natural sciences. Indeed, in all their essentials such questions had already been resolved by the sciences, according to Chernyshevskii: Man is a complex chemical compound whose behavior is strictly subject to the law of causality, who in every action seeks his own pleasure, and whose character is determined by the features of the environment within which he is obliged to act.

On this basis Chernyshevskii advocated "rational egoism"—an ethical theory of enlightened egoistic utilitarianism—and maintained that radical reconstruction

of the social environment is needed to create happy and productive individuals. He portrayed these “new people” and the socialist order of the future in a novel, *Chto delat’?* (*What Is to Be Done?*, St. Petersburg, 1863), which was the principal literary tract of Russian nihilism and was for decades enormously influential in the radical movement. In his socioeconomic thought in general Chernyshevskii emphasized the peasant commune and the *artel* and is considered an important forerunner of Russian Populism.

Chernyshevskii was a severe critic of neo-Kantian phenomenalism. In a number of letters and in the essay *Kharakter Chelovecheskovo Znaniya* (*The character of human knowledge*; Moscow, 1885), written in exile, he espoused epistemological realism and condemned the skepticism and “illusionism” (as he called it) of such scientists as Rudolf Virchow and Emil Heinrich Du Bois-Reymond.

## CHICHERIN, BORIS NIKOLAEVICH (1828–1904)

Boris Nikolaevich Chicherin, a Russian philosopher, was educated at Moscow University, where he studied under both K. D. Kavelin and T. N. Granovskii. Until 1868 he

was a professor at Moscow University; he also served briefly as tutor to the royal family and as mayor of Moscow (1881–1883). He was cautiously liberal in politics and, after an early period of agnosticism, devoutly Russian Orthodox in religion.

Chicherin wrote substantial critical studies of Vladimir Solov’ev (1880) and Auguste Comte (1892), as well as several works on philosophy of law and on the state. His ethical individualism, like that of N. I. Kareev, was close to Immanuel Kant’s, but, unlike Kareev, Chicherin was an orthodox Hegelian in logic, ontology, and philosophy of history. This eclecticism generated an unresolved tension in his thought. On the one hand Chicherin asserted that great men are merely “organs and instruments of a universal spirit” and that, under certain conditions, a nationality (*narodnost’*) “may become an individual person.” On the other hand he insisted that man as a rational creature and “bearer of the Absolute” is an end in himself and must not be “treated as a mere instrument.”

Chicherin asserted, with N. K. Mikhailovskii, that “not society, but individuals, think, feel, and desire”; he opposed the “monstrous notion” that society is a higher organism, an all-devouring Moloch, whose function is “to make mankind happy by putting it in chains.” Chicherin was alert to encroachments by the social and political spheres on the private and personal realm; he saw the individual—the “foundation-stone of the entire social edifice”—as a single spiritual substance, possessed of reason and free will, and hence of a moral worth and dignity that demand respect.

Chicherin saw the dialectical movement of both thought and being as a passage from initial unity to final multiplicity, through the two intermediary stages of relation and combination. Thus, more explicitly than G. W. F. Hegel, he converted the dialectical triad into a tetrad.

### Bibliography

Two of Chicherin’s works, *Polozhitel’ naia filosofiiia i edinstvo nauki* (Positive philosophy and the unity of science; Moscow: n.p., 1892) and *Osnovaniia logiki i metafiziki* (Foundations of logic and metaphysics; Moscow: n.p., 1894), have been translated as *Philosophische Forschungen* (Heidelberg, 1899). Chicherin’s *Filosofiya prava* (Philosophy of law) was published in Moscow in 1900.

For discussion of Chicherin, see V. V. Zenkovsky, *Istoriia russkoi filosofii*, 2 vols. (Paris, 1948 and 1950), translated by G. L. Kline as *A History of Russian Philosophy*, 2 vols. (New York: Columbia University Press, 1953), pp. 606–620.

George L. Kline (1967)

## CHICHERIN, BORIS NIKOLAEVICH [ADDENDUM]

In the last quarter of the twentieth century the reputation of Boris Nikolaevich Chicherin underwent a remarkable revival, both in Russia and the West. Already before the collapse of the Soviet Union Chicherin fascinated those Soviet philosophers of law who sought stealthily to combine civil liberties with state power. That fascination, masked by an accompanying critique of Chicherin's bourgeois liberalism, was expressed in an important 1975 book by Valerii Dimitrievich Zor'kin. The collapse of the Soviet regime in 1991, the unexpected elevation of Zor'kin to the post of chief justice of the Russian Constitutional Court, the broad search by intellectuals for new ways to combine freedom and authority in the post-Soviet era, and a general scholarly reconsideration of the Russian national tradition in philosophy—all these factors contributed indirectly to the new interest in Chicherin's political thinking.

At the beginning of the new millennium Chicherin has found new admirers not among Russian liberals but among moderate conservatives who approve of his doctrine of the state as absolute or undivided sovereign, who applaud his pragmatic recognition that individual liberty must be balanced against the general needs of society, who share his support for capitalism constrained only by the needs of the economically defenseless, and who find his Realpolitik in statecraft wiser than dogmatic nationalism or naive internationalism. In addition to studying his political philosophy, post-Soviet Russian scholars have examined anew Chicherin's philosophy of history, making a much more positive assessment than before of his advocacy of a modified Hegelian approach to understanding the laws or regularities of historical development. The tendency has been to regard him as an important innovator, one of the originators of the influential state school of historical writing.

In the West Chicherin has been interpreted as the most important theoretician of liberalism in Russia, the figure who between 1855 and 1866 systematized hostility

toward serfdom and defense of civil rights into a coherent liberal political program favoring the gradual introduction into Russia of the rule of law. Chicherin's program sharply distinguished between civil rights (freedom of conscience and speech) and political rights (freedom of suffrage, constitutional guarantees, and representative government). He argued that Russian political culture at midcentury was not yet mature enough for political rights but that it could responsibly uphold civil rights. This view, based on Baron de Montesquieu's notion that liberty rests on a complex relationship among the geographical, cultural, social, political, and historical institutions prevailing in a given country, made Chicherin unpopular with the radical left and recalcitrant right.

In 1882–1883 Chicherin warned in his two-volume book *Sobstvennost' i gosudarstvo* (Property and the state) that individual liberty in Europe and Russia was being endangered by “a new monster rising above the state: it is called ‘society’” (Chicherin 1882, p. xix). His apprehension that social pressure for equality would soon destroy liberty bears strong resemblance to Alexis Tocqueville's (1805–1859) fear of the “tyranny of the majority.” Consequently, during the last two decades of his life Chicherin stood as Russia's strongest advocate of individual liberty against society and the state. His program came to approximate what Friedrich Augustus von Hayek would later call “classical liberalism” or what other scholars would name “the old liberalism” in distinction to the new, social liberalism that came to prevail in the West after John Stuart Mill. The philosophical foundations of that program, both Hegelian and Kantian, were elucidated in his remarkable *Filosofia prava* (Philosophy of law; 1900). In it Chicherin made plain his antipathy to the collectivist idealism of Plato, Johann Gottlieb Fichte, and Karl Christian Friedrich Krause; to Benthamite utilitarianism; to Rudolf von Jhering's (1818–1892) command theory of law; to Russian socialism in all its variants; to Marxism; and to Vladimir Sergeevich Solov'ev's (Solovyov) mystical fusion of law and morality.

That Chicherin's name has been appropriated both by Russian *étatist* conservatives and Western individualists may point back to the “unresolved tension in his thought” (George Louis Kline's phrase) between Hegelian determinism and Kantian individualism, but may also be an indication of Chicherin's life-long effort to find an appropriate balance between authority and liberty, duty and right, the needs of society and the requirements of the individual. His conviction that it is impossible in politics to realize simultaneously all values in their fullness and that some values (e.g., liberty and equality) are irrec-

oncilable in principle anticipated the value pluralism of Isaiah Berlin.

## CHINESE PHILOSOPHY

*This composite entry is comprised of the following sub-entries:*

OVERVIEW  
 BUDDHISM  
 CONFUCIANISM  
 CONTEMPORARY  
 DAOISM  
 ETHICS  
 LANGUAGE AND LOGIC  
 METAPHYSICS AND EPISTEMOLOGY  
 RELIGION  
 SOCIAL AND POLITICAL THOUGHT

### OVERVIEW

In its twenty-five hundred years of evolution Chinese philosophy has passed through four periods: the ancient period (until 221 BCE), when the so-called Hundred Schools contended; the middle period (221 BCE–960 CE), when Confucianism emerged supreme in the social and political spheres, only to be overshadowed in philosophy first by Neo-Daoism and then by Buddhism; the modern period (960–1900), when Neo-Confucianism was the uncontested philosophy, although by no means without variety or conflicts of its own; and the contemporary period (from 1912), when Neo-Confucianism,

having become decadent and being challenged by Western philosophy, first succumbed to it, then was revived and reconstructed, but at mid century was overwhelmed by Marxism.

### ANCIENT PERIOD: HUNDRED SCHOOLS (UNTIL 221 BCE)

The Hundred Schools, which included individual agriculturalists, diplomatists, military strategists, and other independent thinkers, had one thing in common, their primary concern with man both as an individual and as a member of society. This humanistic note was dominant from the earliest times and characterized all schools. The most prominent of the schools were the Confucianists, the Daoists, the Mohists, the Logicians, the Yin Yang school, and the Legalists.

Chinese thought at the dawn of civilization was dominated by the fear of spiritual beings. During the Shang dynasty (1751–1112 BCE) the Chinese would do nothing important without first finding out, through divination, the pleasure of the spirits. But when the Zhou overthrew the Shang, in 1112 BCE, human talent was needed to consolidate the newly established kingdom and to fight the surrounding barbarians. Human skill in irrigation proved to be more effective than praying to the spirits for rain. And the tribal anthropomorphic Lord (*Di*), who controlled human destiny at his whim, was now replaced by impartial and universal Heaven (*Tian*). The Mandate of Heaven (divine election) for the House of Zhou to rule rested on the moral ground that rule belongs to the man of virtue. In the final analysis, it was man's ability and virtue that counted. Humanism had reached a high pitch.

**CONFUCIAN SCHOOL.** The person who elevated humanism to the highest degree was Confucius (551–479 BCE). His central concerns were the "superior man" and a well-ordered society. Up to his time the ideal man was the aristocrat, the *junzi* (literally, "son of a ruler") a perfectly natural concept in a feudal society. In a radical departure from the past, Confucius formulated an entirely new ideal, the superior man, one who is wise, humane, and courageous, who is motivated by righteousness instead of profit, and who "studies the Way [Dao] and loves men." This conception of the superior man has never changed in the Confucian tradition.

*Nature of the individual.* Confucius never explained how it is possible for one to become a superior man. He seemed to imply that man is good by nature, but he said only that "by nature men are alike but through practice

they have become far apart.” It was necessary to explain how we know that man can be good. Mencius (c. 372–c. 298 BCE), one of his two major followers, supplied that explanation. From the facts that all children know how to love their parents and that a man seeing a child about to fall into a well will instinctively try to save him, Mencius concluded that man’s nature is originally good, possessing the “Four Beginnings”—humanity (*ren*), righteousness (*yi*), propriety (*li*), and wisdom—and the innate knowledge of the good and the innate ability to do good. Evil is due not to one’s nature but to bad environment, lack of education, and “casting oneself away.” The superior man is one who “develops his mind to the utmost” and “nourishes his nature.”

Xunzi (c. 295–c. 238 BCE), although holding essentially the same idea of the superior man, contended that the original nature of man is evil. He argued that by nature man seeks for gain and is envious. Because conflict and strife inevitably follow, rules of propriety and righteousness have been formulated to control evil and to train men to be good. Propriety and righteousness are not native moral characteristics of man but the artificial efforts of sages. Thus, Xunzi was directly opposed to Mencius. Nevertheless, both were truly Confucian because their central objective was the good man.

*Nature of society.* Confucius wanted a society governed by men of virtue who, through personal examples and moral persuasion rather than law or punishment, would bring about the people’s welfare and social order. Mencius, applying his theory of original goodness, reasoned that if a ruler applies his originally humane mind to the administration of his government, he will have a humane government, and what Confucius desired will naturally ensue. Xunzi, on the other hand, felt that since man’s nature is evil, he needs rulers to regulate him by law and teachers to guide him by rules of propriety and righteousness. Once more he and Mencius were opposed, but again they aimed at the same thing—namely, a well-ordered society.

*Relation of the individual and society.* The Confucian school, then, is devoted to the harmonious development of the individual and society. This theme is systematically presented in the little classic *The Great Learning*, traditionally ascribed to the Confucian pupil Zengzi (505–c. 436 BCE). It consists of eight successive steps: the investigation of things, the extension of knowledge, the sincerity of the will, the rectification of the mind, the cultivation of the personal life, the regulation of the family, national order, and world peace. The goal is

a harmonious world in which man and society are well developed and adjusted.

The harmony of the individual and society rests on several basic ideas. Foremost of these is humanity (*ren*). Confucius discussed humanity more than any other subject, and throughout history it has remained one of the key concepts in Confucianism. Previously the term connoted particular virtues, such as kindness, benevolence, and affection. Confucius interpreted it to mean the general virtue, the foundation of all particular virtues. Humanity is the moral character, which enables man to attain true manhood. The moral character is developed in oneself and in one’s relations with others. A man of *ren*, “wishing to establish his own character, also establishes the character of others.” Thus, *ren* has two aspects, conscientiousness (*zhong*) and altruism (*shu*).

Following Confucius, Mencius stressed humanity. But he almost always mentioned humanity and righteousness (*yi*) together, the first in the Confucian school to do so. By this time a clear distinction between what is good, correct, or proper and what is evil, incorrect, or improper had to be made. He wanted the innate sense of correctness fully exercised. Xunzi felt the same necessity to define correctness, but he sought to achieve this end through the precision of and distinctions made in law, rules of propriety, and music.

Another idea behind the harmony of the individual and society is the rectification of names. For Confucius it meant verifying or implementing an exact correspondence between titles of rank and actual fulfillment of responsibilities. Mencius, however, took “rectification” to mean correcting errors in one’s heart (moral errors). Xunzi gave it a logical interpretation. To him rectification was distinguishing the concepts of names and actualities, similarities and differences, and particularity and generality. In doing this he developed the only logical aspect, in the formal sense, of ancient Confucianism. Confucius, Mencius, and Xunzi all believed that when names are rectified the positions of the individual and society will be well adjusted.

The third concept basic to social harmony is the mean (*zhongyong*). By this Confucius chiefly meant moderation as a guide to human action, but he implicitly referred to the ideals of centrality and harmony as well. The reference to centrality and harmony was greatly elaborated in the classic *The Doctrine of the Mean*, traditionally ascribed to Confucius’s grandson Tzu-ssu (492–431 BCE). Centrality (*zhong*) consists in not deviating from the mean, and harmony (*yong*) exists in the common, the ordinary, and the universal. Centrality in the individual is

the state of equilibrium in one's mind before the feelings are aroused, and harmony is the state after they are aroused. In society centrality and harmony together mean complete concord in human relations. Ultimately, through the moral principle, heaven and earth will attain their proper order and all things will flourish in a harmonious universal operation. At this point the doctrine of the mean assumed metaphysical significance, which made it a profound influence on Neo-Confucianism.

When the individual behaves correctly and society operates in the right manner, the Way is said to prevail. The Way (Dao) is the moral law, or moral order. It is the Way of Heaven. Heaven was no longer conceived of as the anthropomorphic Lord (*Di*), the greatest of all spiritual beings. To Confucius, Heaven was the origin of all things the Supreme Reality, whose purposive character is manifested in the Way. The Supreme Being only reigns, leaving the Way to operate by itself. But no one can be separated from this Way, and for the Way to be meaningful it must be demonstrated by man. "It is man that can make the Way great," Confucius said. The note of humanism was sounded again.

**DAOIST SCHOOL.** To the Confucian school Dao was a system of moral truth, the expression of Heaven. To the Daoist school, however, it was Nature itself. Laozi (c. sixth century BCE), the founder of the school, equated Dao with Heaven, the "self-so" (*ziran*), and the One. It is eternal, spontaneous, nameless, and indescribable, at once the beginning of all things and the way in which they pursue their course. It is nonbeing, not in the sense of nothingness but in the sense of not being any particular thing. It is absolute and mystical. When it is possessed by an individual thing, it becomes that thing's character or virtue (*de*). The ideal life of the individual, the ideal order of society, and the ideal type of government are all based on it and guided by it. As the way of life it denotes simplicity, spontaneity, tranquility, weakness, and, most important of all, nonaction (*wuwei*), or, rather, letting Nature take its own course. Laozi's concept of Dao was so radically different from those of other schools that his school alone eventually came to be known as the Daoist school (Daojia).

Zhuangzi (born c. 369 BCE), Laozi's chief follower, took a step forward and interpreted Dao as the Way of unceasing transformation. In so doing he gave Dao a dynamic character. In the universal process of constant flux all things are equalized from the point of view of Dao. At the same time, since everything transforms in its own way, its individual nature is to be respected. Thus, in

the ideas of Zhuangzi there is a curious combination of universality and particularity, a point that had far-reaching effect on later Daoist developments.

Although the Daoist school was definitely more transcendental than the Confucian, its chief concern, like that of the Confucian school, was man. Laozi discoursed mainly on government, and Zhuangzi discussed at great length the way to find spiritual freedom and peace. There is no desertion of society or the individual in Daoism.

The dominant notes in the Daoist school were, however, oneness and naturalness. It is not surprising that the Daoists strongly attacked other schools, particularly the Confucian, for making distinctions of all kinds. But so far as interest in man and society was concerned, the school agreed with the Confucian and other schools.

**MOHIST SCHOOL.** The Daoist school in time became strong enough to compete with Confucianism, but in the ancient period it was the Mohist school, founded by Mozi (c. 470–c. 391 BCE), that rivaled Confucianism in prominence. In practically all its major doctrines it stood opposed to Confucianism. The most serious and irreconcilable issue was that between the Mohist doctrine of universal love and the Confucian doctrine of love with distinctions. Mozi wanted people to love other people's parents as they love their own, whereas the Confucianists, especially Mencius, insisted that although one should show love to all, one should show special affection to his own parents. Otherwise there would be no difference between other people's parents and one's own, and family relationships would collapse.

In further opposition Mozi condemned religious rites and musical festivals as economically wasteful; the Confucianists held that ceremonies and music are necessary to provide proper expression and restraint in social behavior. This conflict on the practical level stemmed from the fundamental opposition of utilitarianism and moralism. In this issue, as in the issue of universal versus graded love, Mozi justified his doctrines on the basis of "benefits to Heaven, to spiritual beings, and to all men."

Mozi also attacked the Confucianists' teaching of humanity (*ren*) and righteousness (*yi*), for advocating them but for failing to recognize that humanity and righteousness originated with Heaven. As he repeatedly said, it is the will of Heaven that man should practice humanity and righteousness, be economical, and practice universal love, and it is man's duty to obey the will of Heaven. Of all the ancient schools only the Mohist placed ethics on a religious basis.

**LOGICIANS.** The Mohist doctrine of universal love was subscribed to by the Logicians. Their main interest, however, lay in a discussion of names and actualities. The school was small and has left little imprint, if any, on subsequent Chinese intellectual history. But it was the only school devoted to such metaphysical problems as existence, relativity, space, time, quality, actuality, and causes. Its most outstanding scholars were Hui Shi (c. 380–c. 305 BCE) and Gongsun Long (born 380 BCE). To Hui Shi things were relative, but to Gongsun Long they were absolute. The former emphasized change, whereas the latter stressed universality and permanence. The Logicians employed metaphysical and epistemological concepts that were primitive and crude, but they were the only group in ancient China interested in these concepts for their own sake.

**YIN YANG SCHOOL.** While the schools mentioned above were thriving, the Yin Yang school prevailed and influenced all of them. We know nothing about its origin or early representatives, but its ideas are simple and clear. Basically, it conceived of two cosmic forces, one yin, which is negative, passive, weak, and disintegrative, and the other yang, which is positive, active, strong, and integrative. All things are produced through the interaction of the two. Associated with the theory of yin and yang is that of the five agents, or elements (*wuzing*)—metal, wood, water, fire, and earth. According to this theory things succeed one another as the five agents take their turns. Originally the two doctrines were separate. It is generally believed that Zou Yan (305–240 BCE), the representative thinker of the Yin Yang school, was the one who combined the interaction of yin and yang with the rotation of the five agents.

Yin and yang were at first conceived as opposed to each other, succeeding each other, or complementary to each other. The five agents, too, were conceived as overcoming one another or producing one another. Eventually all alternatives were synthesized so that harmony reigns over conflict and unity exists in multiplicity. Yin, yang, and the five agents are forces, powers, and agents rather than material elements. The whole focus is on process, order, and laws of operation. Existence is viewed as a dynamic process of change obeying definite laws, following definite patterns, and based on a preestablished harmony.

One implication of this doctrine is the correspondence and at the same time the unity of man and Nature, for both are governed by the same process. Another is that the universe is a systematic, structural one, determi-

nate, describable, and even predictable. Still another implication is that the universe is a perpetual process of rotation. Just as the five agents rotate, so history proceeds in cycles, and just as yin and yang increase and decrease, so things rise and fall. The Yin Yang school, more than any other, put Chinese ethical and social teachings on a cosmological basis. Generally speaking, its ideas have affected every aspect of Chinese life, be it metaphysics, art, marriage, or even cooking. Wherever harmony is sought or change takes place, the forces of yin and yang are at work.

**LEGALIST SCHOOL.** Philosophically the Legalist school is the least important because it had no new concept to offer. In fact, it did not concern itself with ethical, metaphysical, or logical concepts, as other schools do. Its chief objective was the concentration of power in the ruler. Within the Legalist school there were three tendencies—the enforcement of law with heavy reward and punishment, the manipulation of statecraft, and the exercise of power. The school, called Fajia (meaning school of law) in Chinese, had many representatives, some of them prime ministers, but the most outstanding was Han Feizi (died 233 BCE), who combined the three tendencies of his school.

The Legalist school assumed the evil nature of man and rejected moral values in favor of concrete results. In insisting that laws be applicable to all, it unwittingly subscribed to the doctrine of the equality of all men, and in insisting that assignments be fulfilled with concrete results, it strengthened the doctrine of the correspondence of names and actualities. There is no doubt that compared to other schools, it looked to circumstances rather than principles and to the present rather than the past. It agreed with them in one respect, that life is in a process of constant change.

The Legalists helped the Qin to liquidate the feudal states and establish a new dynasty in 221 BCE. The Qin enforced the Legalists' totalitarian philosophy, suppressed other schools, and burned their books in 213 BCE. The contest of the Hundred Schools now came to an end.

#### MIDDLE PERIOD (221 BCE–960 CE)

The Legalists ruled the Qin with absolute power and tolerated no other schools, but other schools were by no means totally absent from the scene. When the dynasty was overthrown by the Han in 206 BCE, some of these schools reemerged, carrying with them a crosscurrent of thought. The result was a syncretic movement.

**SYNCRETIC CONFUCIANISM.** Confucianism became the state ideology in 136 BCE. It was supreme in government, society, education, and literature and remained so until the twentieth century. But philosophically it was almost overwhelmed by the doctrine of yin and yang. This can readily be seen in the philosophies of the *Book of Changes* and Dong Zhongshu.

The *Book of Changes* (*Yijing*) is a Confucian classic, but the Daoists also made much use of it. (Tradition ascribes part of the work to Confucius, but it was most probably composed several centuries later, although portions may have been in existence in Confucius's lifetime.) It shows the strong impact of the Yin Yang school. According to the *Book of Changes* creation of the world begins with the Great Ultimate (*taiji*), which engenders yin and yang. Yin and yang, in their turn, give rise to the four forms of major and minor yin and yang. The four forms produce the eight elements (*bagua*), which, through interaction and multiplication, produce the universe. The cosmogony is naive and elementary, but it introduced into Confucianism the strong features of Daoist naturalism and the interaction of yin and yang. Since then the Confucianists have viewed the universe as a natural and well-coordinated system in which the process of change never ceases.

The syncretic spirit was also strong in Dong Zhongshu (179–104 BCE), the most outstanding Confucian philosopher of the period. He combined the Confucian doctrines of ethics and history with the ideas of yin and yang. Greed and humanity, the two foremost moral qualities, he correlated with yin and yang, respectively. Likewise, he equated human nature and feelings with yang and yin and thereby with good and evil. All things are grouped into pairs or into sets of five to correspond to yin and yang and the five agents. Ultimately they are reduced to numbers. In this arrangement historical periods parallel the succession of the five agents, and man, the microcosm, corresponds to Nature, the macrocosm. But Dong went beyond the idea of mere correspondence. To him, things of the same kind activate each other. There is the universal phenomenon of mutual activation and influence that makes the universe a dynamic, organic whole.

Unfortunately, this doctrine soon degenerated into superstition. Early in the Han dynasty (206 BCE–220 CE) there was a wide belief in prodigies, which were taken to be influences of Nature on man or vice versa. Wang Chong (27 CE–c. 100 CE), an independent thinker, revolted against this. He declared that Heaven (Nature) takes no action and that natural events, including prodigies, occur spontaneously. Man is an insignificant being

in the vast universe, and he does not influence Nature or become a ghost at death to influence people. In addition, Wang Chong insisted that any theory must be tested by concrete evidence, and he supported his own theories with numerous facts. Thus, he raised rationalistic naturalism to a height never before reached in Chinese history and prepared for the advent of rationalistic and naturalistic Neo-Daoism, which was to replace Confucian philosophy.

**NEO-DAOISM.** Under the influence of the doctrine of the correspondence of man and Nature and the belief in prodigies, Han dynasty thinkers were chiefly concerned with phenomena. Thinkers of the Wei-Jin period (220–420), however, went beyond phenomena to find reality behind space and time. They were interested in what is profound and abstruse (*xuan*), and consequently their school is called Xuan Xuanxue (“profound studies”) or the Metaphysical school. They developed their doctrines in their commentaries on the *Laozi*, the *Zhuangzi*, and the *Book of Changes*, the “three profound studies.” To Wang Bi (226–249), the most brilliant Neo-Daoist, ultimate reality is original nonbeing (*benwu*). It is not nothingness but the pure being, original substance, which transcends all distinctions and descriptions. It is whole and strong. And it is always correct because it is in accord with principle (*li*), the universal rational principle that unites all particular concepts and events. The note of principle was a new one. It anticipated Neo-Confucianism, which is based entirely on it.

Guo Xiang (died 312), another famous Neo-Daoist, developed his theory in his comments on Zhuangzi's doctrine of self-transformation. To Guo Xiang, things transform themselves according to principle, but each and every thing has its own principle. Everything is therefore self-sufficient, and there is no need for an overall original reality to combine or govern them, as Wang Bi believed. Whereas Wang Bi emphasized nonbeing, the one, and transcendence, Guo Xiang emphasized being, the many, and immanence.

As a movement Neo-Daoism did not last long, but its effect on later philosophy was great. It raised the Daoist concepts of being and nonbeing to a higher level and thereby formed the bridge between Chinese and Buddhist philosophies.

**BUDDHISM.** In the first several centuries Buddhism existed in China as a popular religion rather than as a philosophy. When Buddhists came into contact with the Chinese literati, especially the Neo-Daoists, in the third

century, they matched Buddhist concepts with those of Daoism, identifying *Tathatā* (Thusness, *Nirvāṇa*) with the Daoist “original nonbeing,” for example. Under Neo-Daoist influence, early Buddhist schools in China all engaged in discussions on being and nonbeing.

**Middle Doctrine and Dharma Character.** The problems of being and nonbeing largely characterize the two major Buddhist schools that developed in China in the sixth century, the Middle Doctrine (Zhonglun), or Three Treatise (San-lun), school and the Dharma Character (Faxiang), or Consciousness Only (Weishi), school. The Middle Doctrine school, systematized by Jizang (549–623), was based on three Indian scriptures—the *Mādhyamika Śāstra* (Treatise on the Middle Doctrine), by Nāgārjuna (c. 100–200), the *Dvādaśamīkāya Śāstra* (Twelve gates treatise), also by Nāgārjuna, and the *Śata Śāstra* (One-hundred verses treatise), by Ārya-deva (exact dates unknown), a pupil of Nāgārjuna. This school regarded both being and nonbeing as extremes whose opposition must be resolved in a synthesis. The synthesis, itself a new extreme with its own antithesis, needs to be synthesized also. In the end all oppositions are dissolved in the True Middle or emptiness. The school was essentially nihilistic and is often called the school of Nonbeing.

In contrast, the Consciousness Only school, which was founded by Zuangzang (596–664), regarded all dharmas (elements of existence) and their characters—that is, the phenomenal world—as real, although only to a certain degree because they are illusory, apparent, and dependent. The school divides the mind into eight consciousnesses, the last of which contains “seeds” or effects of previous deeds and thoughts that affect future deeds and thoughts. Future deeds and thoughts are “transformations” of present ones, and present ones are “transformations” of past ones. When an individual attains perfect wisdom all transformations are transcended. In these transformations dharmas are produced. Some, the products of imagination, have only illusory existence. Others have dependent existence because they depend on causes for their production. But those of the “nature of perfect reality” have true existence. Since the school accepts dharmas and their character as real, it is often called the school of Being.

In spite of the fact that their basic problems of being and nonbeing are Chinese, the two schools were essentially no more than Indian schools transplanted to Chinese soil. They lacked the spirit of synthesis and were too extreme for the Chinese, and they declined after a few centuries, a relatively short time compared to other schools. In the meantime the Chinese spirit of synthesis

asserted itself, notably in the Tiantai (Heavenly Terrace) and Huayan (Flower Splendor) schools.

**Tiantai.** According to the Tiantai school, which was founded by Zhiyi (538–597) in the Tiantai Mountains, dharmas are empty because they have no self-nature and depend on causes for production. This is the Truth of Emptiness. But since they are produced, they do possess temporary and dependent existence. This is the Truth of Temporary Truth. Thus, dharmas are both empty and temporary. This is the Truth of the Mean. Each truth involves the other two so that three are one and one is three. This mutual identification is the true state of all dharmas. In the realm of temporary truth—that is, the phenomenal world—all realms of existence, whether of Buddhas, men, or beasts, and all characters of being, such as cause, effect, and substance, involve one another, so that each element, even an instant of thought, involves the entire universe. This all-is-one-and-one-is-all philosophy is expressed in the famous saying “Every color or fragrance is none other than the Middle Path.”

**Huayan.** In the same spirit of synthesis, the Huayan school, established by Fazang (596–664), propagated the doctrine of the universal causation of the realm of dharmas. This realm is fourfold. It contains the realm of facts, the realm of principle, the realm of principle and facts harmonized, and the realm of all facts interwoven and mutually identified. Principle is emptiness, static, the noumenon, whereas facts are specific characters, dynamic, constituting the phenomenal world. They interact and interpenetrate and in this way form a perfect harmony. This doctrine rests on the theory of the six characters, which states that each dharma possess the six characteristics of universality, speciality, similarity, difference, integration, and disintegration. Thus, each dharma is both one and all. The world is in reality a perfect harmony in all its flowery splendor.

**Chan.** Whereas Buddhist philosophy in the sixth and seventh centuries came to be more and more Chinese with the Tiantai and Huayan schools, Confucian philosophy remained dormant. In the eighth and ninth centuries its very life was threatened by the growth of Chan, or the Meditation school (Zen in Japan).

The Meditation doctrine, introduced from India by Bodhidharma (fl. 460–534), aimed at the realization of the Ultimate Reality through sitting in meditation. Its emphasis was on concentration to the point of absence of thought in order to get rid of attachments. As the Meditation school developed it conceived of the mind as split into the true mind, which does not have thought or attachments to the characters of dharmas, and the false

mind, which has them. Sitting in meditation was the effort to get rid of them.

Hui Neng (638–713), an aboriginal from the south, rose in revolt against the tradition. He and his followers refused to divide the mind but maintained that it is one and originally pure. Erroneous thoughts and erroneous attachments are similar to clouds hiding the sun. When they are removed the original nature will be revealed and great wisdom obtained. The way to discover the original nature is calmness and wisdom. Calmness does not mean not thinking or having nothing to do with the characters of dharmas. Rather, it means not being carried away by thought in the process of thought and being free from characters while in the midst of them. Sitting in meditation is useless, and external effort, such as reciting scriptures or worshipping Buddhas, is futile. When the mind is unperturbed by selfishness or deliberate effort and is left to take its own course, it will reveal its pure nature, and enlightenment will come suddenly. Instead of assuming a dualistic nature of the mind, ignoring the external world, and aiming at uniting with the Infinite, as Indian meditation did, Chinese meditation assumed the original goodness of nature, took place in the midst of daily affairs, and aimed at self-realization.

Chinese influences on Chan are obvious. Buddhism had become characteristically Chinese, with its interest in the here and now. It swept all over China. The Confucian Way was in imminent danger of disappearance. Han Yu (768–824), the greatest Confucianist of the Tang dynasty (618–907), had to defend the Confucian Way and demanded that Buddhist and Daoist books be burned. His contribution to Confucian philosophy is negligible, but he paved the way for Confucian awakening.

#### MODERN PERIOD: NEO-CONFUCIANISM (960–1912)

The combination of the wide spread of Chan and the attractiveness of the Huayan and Tiantai metaphysics, as well as the Chan psychology, woke the Confucianists from a long slumber. For centuries, within the Confucian school itself, efforts had been confined to textual studies and flowery compositions. Reaction, long overdue, now set in. Consequently in the early years of the Song dynasty (960–1279) Confucianists raised new problems and attempted to find solutions.

Since the *Book of Changes* had exerted tremendous influence throughout the ages, the Confucianists naturally turned to it for inspiration and support. But instead of using it for divination, as the Daoists did, they used it for a study of human nature and destiny on the basis of

principle. This new movement eventually came to be known as the school of Nature and Principle (Xingli Xue or, in English, Neo-Confucianism).

The man who opened the vista and determined the direction of Neo-Confucianism was Zhou Dunyi (also called Zhou Lianxi, 1017–1073). Elaborating on the cosmogony of the *Book of Changes*, he held that in the evolution of the universe from the Great Ultimate through the two material forces of yin and yang and the five agents to the myriad things, the five agents are the basis of the differentiation of things, whereas yin and yang constitute their actuality. The two forces are fundamentally one. Consequently the many are ultimately one and the one is actually differentiated in the many. Both the one and the many have their own correct states of being. The nature and destiny of man and things will be correct in their differentiated state if they all follow the same universal principle. This was the central thesis of Neo-Confucianism for the next several centuries. The influence of the Buddhist one-in-all-and-all-in-one philosophy is unmistakable.

**RATIONALISTIC NEO-CONFUCIANISM.** Neo-Confucianism developed in two different directions, the rationalistic school of Principle and the idealistic school of Mind.

*Cheng–Zhu philosophy.* The central figures in the rationalistic movement were Cheng Yi (Cheng Yichuan, 1033–1107), who formulated the major concepts and provided the basic arguments, and Zhu Xi (1130–1200), who supplemented and refined them and brought Neo-Confucianism into a systemic, rationalistic whole. At the center of the school is its concept of principle (*li*); its other major concepts are the Great Ultimate, material force, the nature of man and things, the investigation of things, and the moral quality of humanity, or *ren*.

The idea of principle, virtually absent in ancient Confucianism, probably came from Neo-Daoism and Buddhism. If so, it was employed to oppose them. In the view of the Neo-Confucianists of the Song dynasty both Daoist nonbeing and Buddhist emptiness are too abstract, but their principle is concrete. Cheng Yi repeatedly said that for a thing to exist there must first be its principle, the law according to which it will exist. Principle is definite, correct, self-evident, and self-sufficient. It is in each and every thing. Put differently, the principle for each particular thing is a definite one.

Since the possible number of things in the world is infinite, the number of actual and potential principles is infinite. As new things appear, new principles are realized.

In the production and reproduction in the universe the process of daily renewal never ceases. This is a principle in itself, and there is always a new principle to make a new thing possible. But all principles are at bottom one, called the Great Ultimate. As substance the Great Ultimate is one, but as it functions it is manifested in the many, or the innumerable concrete things. The Great Ultimate is both the sum total of all principles and principle in its oneness.

The manifestations of the Great Ultimate depend on material force, which actualizes things. Operating as yin and yang, material force provides the stuff that makes a thing concrete. Things differ from one another because of their material endowments, and they resemble one another because of principle. Principle as the Great Ultimate exists before physical form (*xing er shang*), whereas material force exists after physical form (*xing er xia*). Logically speaking, principle is prior to material force, but as Zhu Xi emphasized, they are never separate. Without material force principle would be neither concrete nor definite, and without principle there would be no law by which material force could operate. In the universe there has never been any material force without principle or principle without material force.

When principle is endowed in man it becomes his nature. Man's nature is originally good because principle is good, and principle is good because it is the source of all goodness. Evil arises when feelings are aroused and deviate from principle. In this respect Neo-Confucianism retains the traditional Confucian doctrine that Nature is good whereas feelings are sources of evil. The Song Neo-Confucianists made a sharp distinction between the principle of Nature and selfish human desires.

Through moral cultivation selfish desires can be eliminated and the principle of Nature realized. To the rationalistic Neo-Confucianists the first step toward cultivation was the investigation of things (*gewu*). According to Cheng Yi every blade of grass and every tree possesses principle. Therefore, all things should be investigated. One can investigate by studying inductively or deductively, by reading books, or by handling human affairs. When things are investigated, as *The Great Learning* taught, one's knowledge will be extended, one's will sincere, one's feelings correct, and one's personal life cultivated. When this is done one will have fully developed one's nature and fulfilled one's destiny.

The development of human nature, according to the Cheng Yi–Zhu philosophy, does not stop with personal perfection but involves all things. This is where the concept of *ren* comes in. To Cheng Yi and Zhu Xi, as to previous Confucianists, *ren* is humanity, the moral quality

that makes man a true man. But under the influence of the century-old Confucian doctrine of the unity of man and Nature and also the cosmological scale of Buddhist ethics, the Neo-Confucianists applied the concept of *ren* to all things and said that through it man can “form one body with heaven, earth, and all things.” Furthermore, they added a new note to *ren* by interpreting the word in its other sense, that of seed or growth. *ren* was then understood to be the chief characteristic of heaven and earth, the production and reproduction of things. This life-giving character is the highest good. It is inherent in man's nature. Man's duty is to develop it and put it into practice. Neo-Confucianism returned to the chief topic and fundamental ethical concern of Confucius and gave it new meaning.

As has been indicated, Zhu Xi and Cheng Yi were the chief figures of rationalistic Neo-Confucianism. However, Cheng Yi's older brother Cheng Hao, their uncle Zhang Zai, and Shao Yong, who with Cheng Yi and Zhou Dunyi are called the Five Masters of early Song Neo-Confucianism, also contributed substantially to it.

**Cheng Hao.** Cheng Hao (Cheng Mingdao, 1032–1085) shared many ideas with his brother. The two were really the twin leaders of the school in its formative stage. Whereas Cheng Yi stressed the idea of principle as one and its manifestations many, Cheng Hao stressed principle as production and reproduction. He saw the spirit of life in everything, which impressed him much more than the rational character of things. Furthermore, to Cheng Hao the highest principle was the principle of Nature, a concept he evolved himself. He believed that principle is more than the rational basis of being. It is the principle of Nature, the self-evident universal truth that carries with it the dictate to distinguish right from wrong and the imperative to do good. Instead of focusing his attention on the investigation of things, he directed it to the calmness of mind. Only when the mind is calm—that is, free from selfishness, cunning, and deliberate effort—can it be peaceful. One can then respond to things as they come and naturally maintain a balance between the internal and the external. Cheng Hao considered understanding the nature of *ren* to be of the greatest importance. The man who has such an understanding will be free from all opposition between the self and the other and will be able to form one body with all things. It can easily be seen that although he differed from his brother on many points, Cheng Hao strengthened Neo-Confucianism by providing it with warmth and spirituality.

**Zhang Zai.** Unlike the Cheng brothers, Zhang Zai (Zhang Hengqu, 1020–1077) regarded principle not as

above or different from material force but as the law according to which material force operates. He identified material force with the Great Ultimate and considered yin and yang as merely the two aspects of material force. As substance, before consolidation takes place, material force is the Great Vacuity (*taixu*). As function, in its activity and tranquility, integration and disintegration, and so forth, it is the Great Harmony. But the two are the same as the Way (Dao). In its ultimate state material force is one, but in its contraction and expansion and the like it is manifested in the many. Similarly, in ethics *ren* is one, but in its application in the various human relations, as filial piety toward parents, brotherly respect toward brothers, and so on, it is many. Zhang Zai's advocacy of the concept of vacuity was too Daoistic to be attractive to his fellow Neo-Confucianists, but in making the doctrine of the one and the many the metaphysical foundation of Confucian ethics, he made "a great contribution to the Confucian school," in Zhu Xi's description.

**Shao Yong.** Shao Yong (1011–1077) agreed with his contemporaries that there are supreme principles governing the universe, but he added that they can be discerned in terms of numbers. In his cosmology change is due to spirit; spirit gives rise to number, number to form, and form to concrete things. Since the Great Ultimate engenders the four forms of major and minor yin and yang, Shao Yong used the number 4 to classify all phenomena. In his scheme there are the four seasons, the four heavenly bodies, the four kinds of rulers, the four periods of history, and so on. Since the structure of the universe is mathematical, elements of the universe can be calculated and objectively known. The best way to know is to "view things as things." All these are new notes in Neo-Confucianism that set Shao Yong apart from the rest. He was as much interested in the basic problems of principle, nature, and destiny as were other Neo-Confucianists. However, he hardly discussed social and moral problems, and his whole metaphysical outlook was too near Daoist occultism to be considered part of the main current of rationalistic Neo-Confucianism.

**IDEALISTIC NEO-CONFUCIANISM.** In spite of the fact that the rationalistic Neo-Confucianists tried to maintain a balance between principle and material force in metaphysics and between the investigation of things and moral cultivation in the way of life, they tended to be one-sided in their emphasis on principle and the investigation of things.

**Lu Xiangshan.** Opposition to these trends arose in Zhu Xi's own time, notably from his friend and chief

opponent, Lu Xiangshan (Lu Jiuyuan, 1139–1193). Cheng Yi and Zhu Xi had regarded mind as the function of man's nature, which is identical with principle. To Lu mind *was* principle. It is originally good and endowed with the innate knowledge of the good and the innate ability to do good, as Mencius had taught long before. It is one and indissoluble. There is no such distinction as that between the moral mind, which is good, and the human mind, which is liable to evil, a distinction made by Zhu Xi. Both the principle of Nature and human desires are good, and they should not be contrasted, as they were by Zhu Xi. The mind fills the whole universe. Throughout all ages and in all directions there is the same mind. It is identical with all things, for there is nothing outside the Way and there is no Way outside things. In short, the mind is the universe. To investigate things, then, is to investigate the mind. Since all principles are inherent and complete in the mind, there is no need to look outside, as did Cheng Yi and Zhu Xi.

This thoroughgoing idealism shows not only the influence of Mencius but also the impact of Buddhism. However, Lu was no less a critic of Buddhism than were other Neo-Confucianists. Actually, he criticized Zhu Xi not to promote Buddhism but to uphold Confucianism. In his opinion the way of Zhu Xi led to a divided mind, aimless drifting, and devotion to isolated details that meant little to life. Lu advocated instead a simple, easy, and direct method of recovering one's originally good nature. It consisted in having a firm purpose, "establishing the nobler part of one's nature," and coming to grips with fundamentals. In short, Zhu's way was "following the path of study and inquiry," whereas Lu's way was "honoring the moral nature."

Lu's opposition did not have any immediate effect, for rationalistic Neo-Confucianism was too strong to be checked. It dominated the Chinese intellectual world for several hundred years. By the fifteenth century, however, it had degenerated into concern only with isolated details and had lost touch with the fundamentals of life. There was no longer any intellectual creativity or moral vigor in it.

**Wang Yangming.** Opposition rose again, this time from Wang Yangming (Wang Shouren, 1472–1529), who pushed the idealistic movement to its highest point in Chinese history. Wang reiterated most of Xiangshan's ideas but carried some of them to new heights. Like Lu, he said that the mind is principle and that things are in the mind, but he emphasized the direction of the mind—that is, the will. To him a thing (or affair) was nothing but the mind determined to realize it. There is no such thing

as filial piety, for example, unless one is determined to put it into practice and actually does so. Like Lu, Wang said that the investigation of things is the investigation of the mind; however, he added that since the most important aspect of the mind is the will, the sincerity of the will must precede the investigation of things, an idea diametrically opposed to Zhu Xi's contention that as things are investigated, one's will becomes sincere. Going beyond Mencius's doctrine of the innate knowledge of good, Wang held that because of one's innate ability to do good, one necessarily extends the innate knowledge into action. Knowledge and action are really identical; one is the beginning and the other the completion. Here are two original doctrines, the extension of the innate knowledge and the unity of knowledge and action, both of which represent new steps in Chinese thought.

**Wang Fuzhi.** For 150 years the idealistic philosophy of Wang Yangming dominated China, putting Zhu Xi's rationalism on the defensive. A number of philosophers attempted compromise, without much success. In the seventeenth century Wang's idealism declined, and Zhu Xi's rationalism reasserted itself. But rationalism enjoyed neither monopoly nor prominence, for revolts arose one after another. From the seventeenth century on, Confucianists regarded both Zhu and Wang as too speculative. The spirit of the time demanded the evident, the concrete, and the practical.

One of the first to rebel was Wang Fuzhi (Wang Chuanshan, 1619–1692). He rejected the central Neo-Confucian thesis that principle is a universal, transcending and prior to material force. Instead, he contended that principle is identical with material force. It is not a separate entity that can be grasped but the order and arrangement of things. The Great Ultimate and the principle of Nature are no transcendent abstractions. They, along with the mind and the nature of things, are all within material force. Wang Fuzhi boldly declared, "The world consists only of concrete things." He also refused to accept either the distinction between the principle of Nature and human desires or the subordination of human desires.

**Dai Zhen.** In the same spirit, Dai Zhen (Dai Dongyuan, 1723–1777) attacked the Neo-Confucianists, particularly those of the Song dynasty, for their conception of principle. He said that they looked upon principle "as if it were a thing." To him principle was nothing but the order of things, and by things he meant daily affairs, such as drinking and eating. The way to investigate principle, he thought, is not by intellectual speculation or by introspection of the mind but by critical, analytical, minutely detailed, and objective study of things based on

concrete evidence. Dai Zhen's conception of principle led him to oppose vigorously the Neo-Confucianists' view of human feelings and desires, which he thought they had undermined. In his belief principle can never prevail when feelings are not satisfied, for principles are merely "feelings that do not err." Dai Zhen perpetuated the Neo-Confucian doctrine that the universe is an unceasing process of production and reproduction, except that to him Nature, like principle, was but an order.

**Kang Youwei.** By the end of the nineteenth century there was a swing back to the philosophy of Wang Yangming. The sad situation in China called for dynamic and purposive action that only an idealism like Wang's could provide. All of these factors conditioned the thought of Kang Youwei (1858–1927), the greatest Confucianist of the time. In an attempt to translate Confucian philosophy into action he enunciated the extraordinary theory that Confucius was first and last a reformer. Kang himself engineered the abortive political reform of 1898. Obviously influenced by the Christian concepts of utopia and progress, he envisaged the Age of Great Unity. In his theory of historical progress history proceeds from the Age of Chaos to the Small Peace and finally to the Great Unity, when nations, families, classes, and all kinds of distinctions will be totally abolished. The philosophical basis for this utopia is his interpretation of *ren*. He equates it with what Mencius called "the mind that cannot bear" to see the suffering of others. It is compassion. It is also the power of attraction that pulls all peoples together. As such it is ether and electricity, which permeate all things everywhere.

Kang was philosophically superficial but historically important. He showed that at the turn of the twentieth century China was at a philosophical crossroad.

## CONTEMPORARY PERIOD (FROM 1912)

Philosophy in twentieth-century China was indeed confusing and chaotic, but certain tendencies could clearly be seen. There was first of all importation from the West. In the first three decades Charles Darwin, Ernst Heinrich Haeckel, Friedrich Nietzsche, Arthur Schopenhauer, Henri Bergson, Immanuel Kant, René Descartes, William James, John Dewey, Karl Marx, and others were introduced, each with his champion. Of these, James and Dewey were the most influential, since pragmatism was advocated by Hu Shih, leader of the intellectual revolution. Only Marxism, however, has remained strong, and it has become the established state philosophy.

Under the stimulation of Western philosophy both Confucianism and Buddhism resurged from a long

period of decadence. In the 1920s and early 1930s, Ouyang Jingwu (1871–1943), strongly impressed by Western idealism, sought to revive Buddhist idealism as it was centuries ago, and his opponent, Abbot Taixu (1889–1947), attempted to transform Buddhist idealism in the light of Western philosophy. Since neither knew Western philosophy or was really a philosopher, their movements, though extensive and vigorous, resulted more in religious reform than in intellectual advancement, and in the late 1930s their work quickly disappeared from the philosophical scene.

The renewal of Confucian philosophy, however, was different. Feng Youlan (1895–1990) developed his philosophy on the basis of rationalistic Neo-Confucianism, and Xiong Shili (1885–1968) built his on the foundation of idealistic Neo-Confucianism. Since the 1930s they became the two most prominent philosophical thinkers in China. While importation from the West and reconstruction of traditional philosophy were going on, certain philosophers tried to evolve their own systems out of Western thought. The most successful of these was Zhang Dongsun (1886–1962), who alone produced a comprehensive and mature philosophy.

**Feng Youlan.** Trained in philosophy at Columbia University, Feng Youlan derived his rationalism from the Neo-Confucianism of Cheng Yi and Zhu Xi and converted Neo-Confucian concepts into formal logical concepts. According to him, his “new rationalistic Confucianism” is based on four main metaphysical concepts—principle, material force, the substance of Dao, and the Great Whole. The concept of principle is derived from the Cheng-Zhu proposition “As there are things, there must be their specific principles.” A thing must follow principle, but principle does not have to be actualized in a thing. It belongs to the realm of reality but not actuality and is purely a formal concept. The concept of material force is derived from the Cheng-Zhu proposition “If there is principle, there must be material force” by which a thing can exist. Material force is basic to the concept of existence but does not itself exist in the actual world. It is only a formal logical concept. The concept of Dao means a “universal operation,” the universe of “daily renewal” and incessant change. Finally, the Great Whole, in which one is all and all is one, is also a formal concept, being the general name for all, not an assertion about the actual world. It corresponds to the Absolute in Western philosophy.

Basically, Feng’s philosophy is a combination of Neo-Confucianism and Western realism and logic. Feng called his own system a “new tradition.” It is new not only

because it has interpreted Neo-Confucian ideas as formal concepts. In addition, Feng’s system has replaced Neo-Confucianism, which is essentially a philosophy of immanence, with a philosophy of transcendence. To Feng the world of actuality is secondary.

In 1950, Feng repudiated his philosophy because it “neglects the concrete and the particular,” but in 1957 he still maintained that Confucius was an idealist rather than a materialist. This suggests that he was not entirely Marxian in his interpretation of Chinese thought. He remained the most important Chinese philosopher of the last thirty years—the most original, the most productive, and the most criticized.

**Xiong Shili.** Xiong Shili called his philosophy the “new doctrine of consciousness-only.” According to his main thesis reality is endless transformation of closing and opening, which constitute a process of unceasing production and reproduction. The original substance is in perpetual transition at every instant, continually arising anew and thus resulting in many manifestations. But reality and manifestations, or substance and function, are one. In its closing aspect original substance has the tendency to integrate, resulting in what may temporarily be called matter, whereas in its opening aspect it has the tendency to maintain its own nature and be its own master, resulting in what may temporarily be called mind. This mind itself is one part of the original mind, which in its various aspects is mind, will, and consciousness.

Xiong’s terminology comes from the *Book of Changes* and the Buddhist Consciousness Only school, but his basic ideas—the unity of substance and function and the primacy of the original mind—come from Neo-Confucianism, especially that of Wang Yangming. He avoided Zhu Xi’s bifurcation of principle and material force and Wang’s subordination of material force to the mind and has provided the dynamic idea of change in Neo-Confucianism with a metaphysical foundation.

**Zhang Dongsun.** The theory of Zhang Dongsun (born 1886) has been variously called revised Kantianism, epistemological pluralism, and panstructuralism. Chiefly formulated between 1929 and 1947, it is derived from Kant but rejects Kant’s bifurcation of reality into phenomena and noumena and Kant’s division of the nature of knowledge into the a posteriori and the a priori. To Zhang knowledge is a synthesis of sense data, form, and methodological assumptions. Perception, conception, mind, and consciousness are all syntheses, or “constructs,” and constructs are products of society and culture. He maintained that although he combined Western logic with modern psychology and sociology, his sys-

tem was his own. During World War II he shifted more and more from metaphysics to the sociology of knowledge and thus was drawn closer and closer to Marxism.

During the years since World War II neither Xiong's, Feng's nor Zhang's philosophy has become a movement, although Xiong has exercised considerable influence on a number of young philosophers. While Zhang is keeping silent, Xiong maintaining his position, and Feng still reconsidering his philosophy, Marxism has become the triumphant and official system of thought. It demands that philosophy be practical, scientific, democratic, and for the masses. Traditional philosophy is being studied and will survive, but it is being interpreted in a new light.

## BUDDHISM

In India, Buddhism was a heterodox religious movement against the authority of the Vedas, the Bible of orthodox Hinduism. Gautama Buddha (c. 563–c. 483 BCE) dismissed the extreme ascetic way of life often adopted by Indian religious believers and taught the middle way. While Hindu philosophers asserted the existence of atman (I, self, ego, or soul) as the innermost essence of a human being and ontologically identified this essence with Brahma, the absolute reality of the universe, the Buddha repudiated the ideas of atman and Brahma, and proclaimed that everything is causally conditioned and nothing is absolute, permanent, and eternal.

All Buddhists have accepted the Buddha's teaching of anatman (nonself), but have apprehended his philosophical message differently. For the early, conservative Hinayana Buddhists, the Buddha's denial of atman implies and even entails the existence of dharmas (divine laws), changing realities of the universe, and impermanent constituents of human beings. But later, progressive Mahayana Buddhists contended that the concept of dharma is as unintelligible as that of atman. Both monistic absolutism and pluralistic realism are extreme views and should be eradicated. The true teaching of the Buddha is that all things are empty (*sunya*).

Both conservative and progressive Buddhist teachings had been introduced to China by the first century

CE. The Chinese preferred Mahayana and revered Nāgārjuna (c. 163–263) as the father of Mahayana Buddhism. The first Mahayana school founded by Nāgārjuna in India was named Mādhyamika, a name derived from the Sanskrit noun *madhyamā*, meaning middle or neutral. The Mahayana philosophy of emptiness as the middle way had laid a fine foundation for the development of Buddhism in China. The creation of new Chinese Buddhist schools—such as Tiantai, Huayan, Chan, and Pure Land—was directly or indirectly related to Nāgārjuna’s philosophy.

### THE SANLUN PHILOSOPHY OF EMPTINESS

In China, Indian Mādhyamika Buddhism is called the Sanlun (three-treatises) School. Nāgārjuna’s *Madhyamakārikā* (Middle way treatise), *Dvādaśanikāyaśāstra* (*Twelve Gate Treatise*), and *Śataśāstra* (Hundred verse treatise), with the main verses by Āryadeva (third cent.), are devoted to the philosophy of emptiness and have been emphasized by Chinese Sanlun Buddhists. For Chinese Sanlun Buddhists, the notions of anatman, the middle way, and emptiness are synonymous in the Buddha’s philosophy. Thus, the Sanlun school is also known as the middle-way school (*Zhongdao Zong*) and the emptiness school (*Kong Zong*).

More than any other Chinese philosophers, the Sanlun masters had a great interest in logical analysis and logical argument. They analyzed the dynamic and static worldviews, and they critically examined the nature and function of language and basic linguistic units such as subject, predicate, and predication. They questioned the essence and use of truth, knowledge, and logic, and they investigated various logical concepts and constructs such as right and wrong, negation and affirmation, and the meaning of thesis, antithesis, and synthesis in rational reasoning and conceptual disputes.

Usually people accept motion or change as an undeniable fact of experience. Even the Buddha, as well as the *Yijing* (Book of changes), seems to teach that all things are in a constant state of flux. Laozi’s *Daodejing* (Way and power classic) also proclaims that “reversing” is the Dao (Way) of heaven. But under the influence of Indian Mahayana philosophy, Sengzhao (373–414), a brilliant Sanlun philosopher, wrote the famous essay *Wu buqian lun* (Things do not shift), arguing that motion is empty. He analyzed motion and pointed out that so-called motion consists of a part that has already passed (*yiqu*), a part that has yet to pass (*weiqu*), and a part that is passing (*qushi*). Change cannot be found in the part already

passed, since it is already gone. Nor can it be found in the part yet to pass, since it is not yet. Nor can it be apprehended in the part that is passing, since passing makes sense if and only if there is an act of passing. But in examining whether there is an act of passing, we cannot use the act of passing to establish an act of passing without begging the question. So motion is impossible.

Zeno, a Greek philosopher, was well known for his argument that motion is impossible. Unlike Zeno, the Chinese Sanlun denial of motion does not entail the affirmation of rest. For Sanlun Mādhyamika, the concept of rest cannot be established either. Rest is the cessation of motion. If it is real, it must happen at some place and time. Does rest occur where something has already past, or where something has yet to pass, or where something is passing? None of these can be established. Therefore there can be no rest, or cessation of motion. For Sanlun masters, motion and rest are both empty, devoid of definite nature or essence, and hence not real. So one cannot maintain that reality is either permanent or impermanent. Therefore, any substantive or dynamic metaphysics must be repudiated.

According to Chinese Sanlun Mādhyamikas, philosophers appear to be very intelligent, but actually have often been fooled by language. Both Hindu and traditional Buddhist metaphysicians have failed to see the emptiness of words and names. Laozi understood the inadequacy of human language, as can be seen in the opening to his *Daodejing*, where he wrote, “The way that can be stated is not the real Way; Names that can be named are not real names.” However, Laozi and later Daoists did not logically analyze language and did not present discursive arguments to substantiate their philosophy. Following Nāgārjuna’s philosophy, Chinese Sanlun masters did logically analyze language, arguing that language is a conceptual game (*xilun*).

Sanlun masters critically examined the nature and the structure of conceptual and verbal statements, and argued that the relationship between two basic linguistic units, the subject (*kexiang*) and the predicate (*xiang*), cannot be rationally well formed, and that predication in our ordinary use of language is really not intelligible. They studied the precise relationship between the subject and the predicate, examining whether they are identical or different from one another. On the one hand, if two are identical, they are one, and it makes no sense to call one a subject and the other a predicate. Logically, the sentence is then a tautology and does not say anything about the world. Hence, in this case, predication is doing no real work. On the other hand, if the subject and the predicate

differ, predication is again unintelligible, since being (the similarity of subject and predicate) and not being (the difference between subject and predicate) cannot be at the same place at the same time. Hence it is absurd to unite what is different to form one sentence describing the same thing. Since every logical or conceptual statement consists of a subject and predicate, reality cannot be intelligently described. Therefore, so-called logic is in essence illogical.

In the view of the Sanlun masters, language and logic are empty. They are conventional and do not have a priori or absolute validity. Words have no definite meaning in themselves. The meaning of a term is not the object for which it stands, but depends on conditions and circumstances. If conditions change, the meaning of the word changes and might even be lost.

For the Sanlun masters, conceptualization, like a fish trap, has no intrinsic value and reality by itself, though it does have a practical use and can be employed to attract unenlightened persons to Buddhism. Yet the true message of the Buddha's teachings can be properly apprehended only if people comprehend the emptiness of words and discard conceptualization. Jizang (549–623), the most eminent Sanlun master, stated, "It is not that language is given in order to have Dharma [the Buddha's truth or teachings], but rather that Dharma is presented in order to eliminate language (Jizang 1854, p. 94c; Cheng 1984, p. 119).

According to Jizang, without practical benefits, truth and logic would lose their meaning. In ordinary life, humans have all sorts of emotional and intellectual attachments; they are attached to some view and stick to some law or principle. To free them from attachment, the Buddha preached a certain truth and followed a certain logic. To avoid the substantive or static view of the universe, he taught that everything is in flux, and to repudiate the dynamic view of the universe, he claimed that existence is real. Actually, terms such as "being" and "non-being," "permanent" and "impermanent," "to be" and "not to be," "real" and "unreal" are all empty. The Buddha's message can be regarded as the truth insofar as it helps dispel ignorance and illusion.

Ultimately, all conceptualizations should be discarded, and one should be silent. Such silence is not a form of absolutism or nihilism, but the manifestation of *prajñā* (wisdom). For ordinary people, to know is to know something; epistemology assumes objects to be known, acts of knowing, and a knower. In the ordinary way of thinking, an assertion of knowledge implies an ontological commitment. *Prajñā* is not to know some-

thing, but rather to apprehend that reality is empty, and so to be freed from attachments. In his essay *Boruo wuzhi* (*Prajñā* as nonknowing), Sengzhao (384–414) stated, "Real *prajñā* is as pure as empty space, without knowing, without seeing, without acting, and without objects. Thus knowledge is in itself without knowing, and does not depend on anything in order to be without knowing (Sengzhao 1858, p. 153; Cheng 1984a, p. 105).

To apprehend the empty logic of *prajñā*, one should understand, according to Jizang's *Sanlun xuanyi* (Profound meaning of the three treatises), that the refutation of erroneous views is the illumination of the right view (*poxie xianzheng*). In ordinary or even Aristotelian logic, negation and affirmation differ. Negation is usually asserted with the aim of affirming, establishing a thesis: Not *P* implies something other than *P*; the denial of a thesis entails the affirmation of an antithesis. For Chinese Sanlun masters, enlightened persons are empty-minded, free from affirmation and negation. Negation is used merely to repudiate erroneous views or to affirm negation itself. Not *P* means only the absence of *P*. *Prajñā* is the absence of any view, and is not a view in itself. The refutation of erroneous views and the affirmation of right views are not separate acts but the same. If a right view is held in place of an erroneous view, it becomes a new erroneous view and requires refutation. For Jizang, "Originally there was nothing to affirm and now there is nothing to negate (Jizang 1852, p. 6; Cheng 1984a, p. 47). An attachment to some view is a sickness (*bing*), and the logic of emptiness is the medicine (*yao*) to cure this intellectual sickness.

The Buddhist doctrine of emptiness, according to Chinese Sanlun masters, is not a metaphysical view. Rather, it is the doctrine that one should repudiate all metaphysical views, and to do so requires not the presentation of another metaphysical view, but simply the abolition of all metaphysics.

Emptiness (*śūnyatā*) is essentially a soteriological device. It is merely an instrument for eliminating extreme views. If there is no extreme to be removed, there need be no affirmation or negation. The so-called right view is really just as empty as the wrong view, and it is cited as right "only when there is neither affirmation nor negation." If possible, one should not use such terms as "right" and "wrong." For Jizang, "we are forced to use the word 'right' in order to put an end to wrong. Once wrong has been ended, then right no longer remains. Then the mind is attached to nothing." Even emptiness is empty. Jizang contended, "If one still clings to emptiness, then there is

no medicine that can eliminate the disease (Jizang 1852, p. 7).

The Sanlun philosophy was brilliant and authentically derived from Indian Mādhyamika thought. But the philosophy was too abstract and too Indian for the Chinese. Consequently, the Sanlun School declined in China after the death of Jizang in 623. However, its teachings inspired various Chinese Buddhists to develop new Buddhist movements in China.

### THE ROUND TEACHING OF Tiantai

Tiantai Buddhism, a sect of Mahayana Buddhism, had no Indian counterpart and was founded in China in the sixth century. It was initiated by Huiwen (550–577) and was well established by Zhiyi, also known as Zhikai (538–597), the greatest Tiantai master. Zhiyi lived and taught in the area of Mt. Tiantai in Zhejiang province, and hence the school came to be called the Tiantai School (Tendai in Japanese). Tiantai masters examined the Buddhist scriptures and held that the text *Saddharma-puṇḍarīka* (Lotus of the wonderful law) contains the best and most perfect doctrinal teaching of the Buddha, and consequently this school is also known as the Lotus (*huafang*) School.

Since ancient times Chinese have tended to think holistically or inclusively. Confucians and Daoists tended to observe things as they are and, with increasing ontological penetration, to see differences. The wonder of the universe, for Confucianism and Daoism, is a harmony among diversities and even opposites. According to the Yin-Yang School, the *Yijing* (Book of changes), and the *Daodejing* (Way and power classic), the universe is a united whole. It is composed of pairs of opposites: yin and yang, positive and negative, male and female, right and wrong. The interaction of yin and yang produces all things and all kinds of movement. Following this vein of thinking, Tiantai masters adopted the *yuanjiao* (round approach, doctrine, or teaching) and developed a philosophy of all in one and one in all.

Tiantai Buddhism disliked the analytic approach. For Tiantai masters, the analytic approach is a deductive and exclusive way of thinking that may reduce a complex world to one single reality, as seen in Hinduism, or a few simple fixed entities, as seen in Theravada Buddhism. Such thinking is one-sided and extreme, and hence should be eradicated. To avoid extremes, Tiantai Buddhists maintained that the Buddha's dharma is the direct observation, and pure and total description, of what is immediately given. Buddhism, for Tiantai masters, seeks to describe or to see things as they present themselves.

“What the Buddha has accomplished is the teaching foremost, rare and inconceivable. Only the Buddhas can realize the true nature of all things; that is to say, all things are thus-formed, thus-natured, thus-substantiated, thus-caused, thus-forced, thus-activated, thus-circumstanced, thus-effected, thus-enumerated and thus-beginning-ending-completing (*Saddharma-puṇḍarīka* [The wonderful law of lotus], chapter 2).

Tiantai Buddhists held that Hindu and other Buddhist philosophers had distorted the original or true state of the things and polluted our comprehension of the universe. Tiantai philosophy sought to return to things themselves, that is, to penetrate to original, pure phenomena as they present themselves before any conceptualization or analytic judgment. “Thus-formed, thus-natured,” in Tiantai teaching, indicates things as they present themselves. The Buddha's dharma, for Tiantai masters, seeks to penetrate to the fundamental or original data, to return to reality (*rushi*), as they appear to us in immediate experience. One should return to things themselves by means of direct awareness. For Tiantai masters, whoever sees things in this way sees what they called the original or true state of things (*zhufa shixiang*).

According to Tiantai masters, secular and even Buddhist philosophers have often ignored the richness of the universe and chopped complex, concrete, living facts into one absolute reality or a few simple elements. Tiantai Buddhists dismissed such philosophies as discriminative doctrines (*biejiao*). They did not divide the harmonious world into noumenon (*li*) and phenomena (*shi*). Nor did they reduce one concrete thing to another or give up any assertion; instead, they attempted to describe each fact in its fullness. They called their attitude and approach to the world the *yuanjiao* (round teaching, doctrine, or approach).

According to the round approach, all things, absolute and relative, are a united whole; noumenon is phenomena, and phenomena are noumenon. The relationship between the one and the many is like that of the ocean and waves. One ocean cannot be an ocean without many waves, and many waves cannot occur outside the one ocean. Thus, all is one, and one is all.

The Tiantai round approach is also used to apprehend Buddhist truth. Nāgārjuna is said to have taught, “Emptiness is called the middle way. For it is a provisional name for causality (Nāgārjuna, “Zhong Lun” [The middle treatise], 18). For Huiwen and his followers, Nāgārjuna's statement taught that causality (*yinyuan*, dependent co-arising) indicates lack of permanence and hence emptiness (*kong*), and thus it can serve as a substi-

tute name (*jiaming*) for the middle way (*zhongdao*). This awakened Huiwen to perceive the triple truth of emptiness, of temporariness, and of the mean. For Tiantai Buddhists, all things are empty because they are causally conditioned and hence are devoid of self-nature, but they do have temporary existence. Things by nature are empty and temporary; this principle constitutes the mean. These three—emptiness, temporariness, and the mean—penetrate one another and are found perfectly harmonized and united. A thing is empty but exists temporarily. It is temporary because it is empty. The fact that everything is empty and at the same time temporary constitutes the middle truth. One should consider the three truths not as separate but as a perfectly harmonious threefold truth.

In reality, the three truths, according to Tiantai Buddhism, are three in one and one in three. The principle is one, but its explanation is threefold, and each of the three truths has the value of all. From the perspective of emptiness, we may deny the existence of the temporary and the middle, for we consider emptiness as transcending all. The three principles would be empty. The same is the case from the perspective of temporariness or the mean. So when one principle is empty, all will be empty; when one is temporary, all will be temporary; when one is middle, all will be middle. These three principles are otherwise called identical emptiness, identical temporariness, and identical mean, and also the absolute threefold truth.

## HUAYAN BUDDHISM AND THE MYRIAD MANIFESTATIONS

Huayan Buddhism, another sect of Mahayana Buddhism, was founded in China in the seventh century. It is named after the title of its chief scripture *Huayan jing* (*Avatamsaka sutra*, Flower-wreath sutra). According to this school, the Buddhist dharma is like the seed of a fine plant. It was planted by the Buddha in India; it grew and produced branches and leaves; eventually it blossomed, bearing beautiful flowers. Early Buddhism, various Hinayana and Mahayana schools, are the branches and leaves of the dharma. Huayan Buddhism is the flower of the dharma, the highest and the most splendid outcome of the Buddha's dharma.

The Huayan School was initiated by Dushun, also known as Fashun (557–640), but Fazang (643–712) is usually considered the real founder of the school because he was responsible for the final systematization of its teachings. Like Tiantai Buddhists, Huayan Buddhists developed a philosophy of one in all and all in one, and they also called their way of conceptualizing things *yuanyao* (round approach, teaching, or doctrine). They

wanted to observe and describe all things, phenomenal and noumenal, as purely and as fully as possible. They first rejected ordinary empiricism, which cuts up things into simple sense data, and they questioned Indian scholastic Buddhism, which reduced complex phenomena to simple dharmas. For Huayan masters, genuine phenomena are not the same as sensory phenomena. Alleged empirical facts or sensory appearances are really constituted phenomena and do not represent the true state of things.

The denial that sensory appearances represent the true state of the things does not, however, imply that Huayan masters denied sensory appearance in the world. In his famous *Jin shizi zhang* (Essay on the gold lion), Fazang used a gold lion to illustrate the case. We do perceive sensory phenomena such as a gold lion, but the appearance of the gold lion is not of a real lion. The proper understanding of things is that the true essence of such things is something other than physical form.

Sensory phenomena are empty; they do appear to exist, but their state of existence is not genuine. In the strict sense, sense experience is the manifestation of illusion (*huan*). To understand genuine being or genuine phenomena, one must contemplate things without qualities (*wuxiang*) by suspending one's natural belief in the existence of sense qualities or sense data. For Fazang, "To contemplate the qualityless is [to contemplate] the fact that the qualities of the tiniest part of matter arise out of the evolution of mind ... , lacking any inherent nature of their own. This fact is called that of the qualityless" (Fazang, *Huayanjing yihai baimen* [The hundred gates on the meaning of the flower splendor scripture] 1875, p. 627).

The contemplation of things without qualities, according to Huayan Buddhism, leads one to apprehend *li* (principle, noumenon) and to know the essence of the world. Such contemplation is a kind of empty-minded, disinterested observation of things, both objective and subjective, in their fullest breadth and depth. Thus seeing things as they are and as they are not is a round approach. For Huayan masters, it would empty or open up one's mind to see that being and nonbeing produce each other, to see that qualities and the qualityless complement each other, and thus to be aware of the essential relationship between phenomena and noumenon. Fazang wrote, "Noumenon does not interfere with phenomenon, what is pure is ever mixed. [Likewise] phenomena ever comprise noumenon in its totality, for what is mixed is ever so.... There is no barrier between what is pure and what is mixed" (Fazang, *Huayanjing yihai baimen* [The hun-

dred gates on the meaning of the flower splendor scripture] 1875, p. 627).

Every event or fact is rich and complex. In describing the complex world, Huayan Buddhists claimed that a tiny particular thing involves and embraces all things in totality. Fazang wrote, “All things of the senses are revealed in their true essence and become merged into one great mass. Great functions arise, every one of which represents the Absolute. The myriad manifestations, despite their variety, harmonize and are not disparate. The all is the one, for all things equally have the nature of non-being. The one is the all, for cause and effect follow in an unbroken sequence. In their power and function, each implies the other and freely rolls up or spreads out. This is called the perfect teaching of the One Vehicle [the highest Buddhist truth]” (Fazang, *Jinshizi Zhang* [Essay on the gold lion], chapter 7).

In Huayan Buddhism, the universe is composed of an infinite number of possible differentiated worlds (*dharmadhātu*). As a whole, the universe is to be regarded as fourfold: the world of phenomena (*shifajie*, the realm of facts), the world of noumenon (*lifajie*, the realm of principle), the world of phenomena and noumenon united (*shiliwuaifajie*), and the world of phenomena united or interwoven with other phenomena (*shishiwuaifajie*). For Huayan masters, the Tiantai round approach is not inclusive or comprehensive enough. It merely touches on the first three realms of the universe but fails to see the world of phenomena united with other phenomena. According to the Huayan School, Huayan Buddhism better and more fully investigates and describes things themselves than other teachings. From its preeminent doctrine of *yuanjiao*, one can see that all things form a harmonious whole by mutually penetrating (*xiangru*) and mutually identifying (*xiangji*), and that phenomena are “the fact and the world of fact perfectly harmonized” (*shishiwuaifajie*) (Cheng 1984b, p. 222).

The distinct feature of Tiantai and Huayan Buddhism is their propagation of *yuanjiao* (round teaching, doctrine, or approach). In many ways, the Chinese round teaching in both Tiantai and Huayan philosophies is similar to Western phenomenology. Phenomenology can be seen as a purely descriptive study of any subject matter in which phenomena are described by means of direct awareness (*Anschauung*). In phenomenology, phenomena are not identified with sense experience or sense data, and the truth and falsity of phenomenological statements do not depend on sensory observation. For phenomenologists, sensory observation is instituted and categorized under certain general concepts, and hence in the strict

sense, sensory experience is already constituted or polluted. The ideal of phenomenology is to return “to the things themselves” (*zu den Sachen selbst*). Actually, this is also the ideal of the round teaching that Tiantai and Huayan masters had tried to practice.

The object of phenomenological research includes whatever can conceivably be experienced, even what occurs in wild dreams. Phenomenologists do not neglect any aspect of our experience and seek to describe all things in their full possible concreteness. Tiantai and Huayan Buddhists had a similar objective in their round approach. Like phenomenologists, they aimed to investigate things, both subject and object, in their fullest breadth and depth. This is why Huayan masters taught the fourfold *dharmadhātu* as a way of exploring the infinite number of possible differentiated worlds, and claimed that their philosophy was “more round,” “more complete,” better, and higher than Tiantai and other Buddhist teachings. This is also why Huayan Buddhism is said to be the most splendid flower of the Buddha’s dharma.

The phenomenological approach has negative and positive aspects, involving, as it does, turning away from something and turning toward something else. Negatively, it avoids preconceptions and brackets constituted phenomena. Positively, it turns to the things themselves and describes them as purely and as fully as possible. The negative aspect has a positive function: to facilitate genuine intuition of the given. In a similar way, the Buddhist round approach has a double character: *zhi* (cessation, stoppage, or stillness) and *guan* (observation, contemplation, awareness, or examination). *Zhi* is like Husserl’s *epochē*, the suspension of all natural belief in the objects of experience. This is not to deny the world, but to become a disinterested spectator who can rediscover what has previously been lost. By means of *guan*, one can penetrate to the essence of things and obtain the unattached insight of true reality.

The phenomenological method is said to involve a change of attitude. One must look at the world with new eyes. The result is said to be a change in one’s experience. The method of *zhiguan* in the Buddhist round approach also involves a change of attitude. One transforms from an attached way of life to an enlightened one, experiencing a sense of peace and transcendence: “How calm, still and pure! How deep, stable, and quiet! How pure and clear the inner silence! It functions without the character of functioning, and acts without the character of acting” (Fazang, *Dasheng Zhiguan Famen* [The Mahayana method of zhiquan], chapter 4.) Through this transformation, the true state of all things is apprehended, and

the universe is seen as the manifestation of an absolute mind, known as *zhenru* (true reality) or *rulaizang* (*tathā-gatagarbha*).

It is interesting to see that the final outcome of the method of *zhiguan* is similar to that of Husserl's transcendental deduction, namely, the discovery of transcendental consciousness or mind. This is not subjective idealism, because subject and object, as well as the absolute and the relative, are seen to be interdependent, mutually penetrating, and even mutually identifying.

## CHAN (ZEN)

Unlike Tiantai and Huayan Buddhism, the Chan School (Zen in Japanese), founded in China in the sixth century, does not aim to establish a round doctrine or to fully describe the universe. Chan Buddhism was claimed not to be a doctrine at all but a way of avoiding systematic views. Chan stories repeatedly teach that Chan Buddhism is not a body of fixed truths; instead, it is the abandonment of all views.

Although Chan masters did not develop theories, Chan Buddhism has some philosophical foundations found in Western philosophy: critical inquiry, autonomy, intellectual freedom, and creativity. Socrates is well known for saying that the unexamined life is not worth living. For him and many others, the philosophical enterprise consisted of inquiry rather than an accumulation of final truths. In the West, philosophy has often been regarded as the highest form of inquiry because, unlike other sciences, it alone does not involve presuppositions. True philosophers take nothing for granted. Similarly, Chan masters took nothing for granted.

Chan Buddhism has been critical of Buddhism viewed as a religion. Often a religion presupposes the authority or divinity of its founder and the infallibility of his words, but Chan Buddhism invoked no such presuppositions. Chan masters often rejected any special status for Gautama Buddha and repudiated the certainty of Buddhist scriptures. When the Buddha was born, he is alleged to have proclaimed, "Above the earth and below the heavens, I alone am the Honored One!" Chan master Yunmen (864–949) commented on this saying, "If I had been with him at the moment of his uttering this, I would surely have struck him dead with one blow and thrown the corpse into the maw of a hungry dog" (Suzuki 1964, p. 40). Chan masters would not subscribe to the views of a religious leader. One must enlighten oneself. Enlightenment (*wu*) must occur within and be done personally. In fact, according to Chan masters, any person who obtains enlightenment is a Buddha.

For Socrates, the autonomous activity of philosophy was integral to being genuinely human. For Chan Buddhism, to live genuinely is to live the life of enlightenment, and to live the life of enlightenment is to live autonomously. Simply following the Buddha faithfully and practicing the dharma diligently does not engender an enlightened outlook. Rather, one must be autonomous (*zizhu*). In the Chan lifestyle, a true Buddhist conducts his life freely and leisurely (*ziyou zizai*).

The main message of Chan Buddhism, believed to have been composed by Bodhidharma (470–543), is succinctly stated thus:

A special transmission outside scriptures;

No dependence upon words and letters;

Direct pointing at human mind;

Seeing into one's own nature to attain Buddhahood (Dumoulin 1988, p. 85).

Chan masters repudiate any blind acceptance of scriptures, for "the entire scriptures from beginning to end are nothing but deceitful words" (Chung-yuan 1971, p.143). The so-called holy scriptures of Buddhism have often been set aside, thrown away, and even burned by Chan masters.

The radical approach of Chan Buddhism created a refreshing Buddhist epistemology that emphasized opening up the mind to the serious issue of what truth is. For some Buddhists, truth is objective and can be spoken and written about. In this view, the Buddha and the patriarchs transmitted truth, and the scriptures contain their messages, often identified with the dharma. But for Chan Buddhism, truth is not something objective, nor can it be spoken and written about. The Buddhist dharma is not conveyed by ink marks on the pages of scripture. Huineng (638–713), the sixth patriarch, was said to be illiterate, and yet was a Chan master. When Fada, a devout monk, studied the *Lotus Sutra* three thousand times and still could not understand it, he came to ask Huineng for instruction. The master said, "The Dharma is quite clear; it is only your mind that is not clear. Whether Sutra-reciting can enlighten you or not all depends on yourself. ... If the mind is deluded, the *Lotus [Sutra]* turns you around, if the mind is enlightened, you turn around the *Lotus [Sutra]*" (Huineng 1952, p. 24).

Truth, for Chan Buddhism, is something living and personal. To equate truth with a proposition is to objectify and conceptualize it, to make it static and dead. For Chan masters, "The real truth is nothing else but one's own mind. Thus ... the real teaching must be transmitted

directly from one mind to another” (Chung-yuan 1971, p. 86). Genuine spiritual education occurs in personal communication between Chan master and disciple. This mind-to-mind transmission resembles what Martin Buber, the great twentieth-century thinker, described as an I-thou relationship, rather than an I-it relationship. To see the truth as an object and to conceptualize it is to shift from a personal I-thou point of view to an impersonal I-it understanding.

True meditation, a central Chan practice, does not refer to sitting in a certain posture with legs crossed, but to “the brightening up of the mind-works” (Suzuki 1956, p. 85). Mazu (709–788) used to sit diligently and frequently in meditation. Master Huairang (677–744) asked him, “Virtuous one, why are you sitting in meditation?” Mazu replied, “I want to become a Buddha.” Thereupon the master picked up a tile and rubbed it repeatedly in front of the hermitage. Mazu asked, “What is the master doing?” Huairang answered, “I am polishing the tile to make a mirror.” Mazu exclaimed, “How can you make a mirror by polishing a tile?” The master responded, “How can you make a Buddha by practicing sitting meditation?” (*Jingde Chuandeng Lu*, Vol. 5). The monk was said to be enlightened immediately, and later became a great Chan master.

The personal experience of the dharma, according to Chan masters, is not remote, abstract, or transcendent. It occurs in one’s present daily life. Zhaozhou (778–897) asked Master Nanquan (748–834), “What is the Dao [the Way]?” The master replied, “Everyday-mindedness is Dao.” In another instance, after attaining great enlightenment under Mazu, Pangyun stated, “I am an ordinary man who fulfills his daily tasks. How plain are the Buddhist teachings!” According to the Chan School, “In the carrying of water and the chopping of wood—therein lies Dao” (Chung-yuan 1971, p. 145).

An enlightened person does not live outside samsara, or this world of rebirth, and he should not ignore karma, or cause and effect. He should treasure this life and value the virtues of labor in daily affairs. Baizhang (720–814), who founded the Chan monastic order, was said to live by the principle “A day without work—a day without eating” (Dumoulin 1988, p. 103). When he was old and his disciples hid his tools, he refused to eat until he could work again. Chan practitioners do not adhere to rigid moral precepts, but practice a work ethic in daily life.

Chan philosophy has similarities with contemporary ordinary-language philosophy in that both favor the ordinary use of language. For Chan Buddhism, however, any concrete fact or lived experience is rich and complex.

Things may appear to be simple and ordinary, yet are really quite complicated and extraordinary. Chan Buddhists have sometimes used metaphysical statements to convey their understanding, and have also expressed themselves through strange words and strange acts (*qiyān qixing*). Consequently, the Chan literature abounds with irrational statements and absurd actions.

The use of strange words and strange acts in Chan Buddhism actually accords with the Mādhyamika practice of revealing the truth of emptiness and the middle way. According to Nāgārjuna, the Buddha’s dharma was given, and hence should be understood, by means of twofold truth, a convenient term for the perspectives of conventional and ultimate truth. The former sees things from a viewpoint deluded by attachment, while the latter sees things without attachment.

Following Nāgārjuna’s philosophy, Chan masters often expressed themselves through twofold truth, and hence their teachings and practices may be apprehended from two standpoints. Ordinary sentient beings do not see the emptiness of all things. So, to comply with conventional usage, Chan masters may say, “I see” or “you should see” the objects of right knowledge. But from a higher, unattached standpoint, all things are empty, and so the same master may also state, “I do not see” or “one should not see” any right object; on the contrary, one should see the emptiness of all things. For instance, once Shenhui asked Huineng, “Do you see or not?” The master replied, “I both see and also do not see.” The puzzled disciple asked, “How can you see and also not see?” The master instructed, “If your mind is attached, you do not see; if your mind is without attachment, you see.” The seemingly inconsistent expressions of Chan Buddhism were delivered with twofold truth in mind. Understood in this light, they are not as illogical as they might appear.

Although Chan Buddhism is a Mahayana practice, in many ways it strongly reflects Chinese thinking and feeling. Such Chan ideas as *xing* (nature, essence, own nature), *xin* (mind, human mind), *foxing* (Buddha nature), *foxin* (Buddha mind), and the key message that everyone has a Buddha nature are more like Chinese Confucian thought than Indian Mahayana Buddhism.

The central message that Bodhidharma brought from India to China in the sixth century also differs from the Indian Mahayana philosophy of emptiness. For Nāgārjuna, all things are causally conditioned and hence empty of any nature (*xing*) of their own. So, whereas the Chan masters instruct one to see the nature of things (*jianxing*), the Indian Mahayana scriptures teach the believer to reject this idea. Chan practice has to be

regarded as a special transmission outside the scriptures. For Chan masters, one cannot and should not follow the ancient Indian scriptures literally; otherwise one will never be enlightened. Therefore, Chan Buddhism advises, “No dependence on words and letters.”

The notion of the nature of things (*xing*) was important in the minds of Chinese thinkers long before Buddhism was introduced to China. Both orthodox and less orthodox Confucianists accepted the view that things had natures. Confucius and Mencius are well known as saying that human nature is good. In their teachings, the mind (*xin*) is the nature of a human. This human nature or mind is more important for its axiological value rather than for its ontological substance, in contrast with such notions as Hindu Brahma and atman, Theravada Buddhist *svabhava* (inborn nature), and Greek substratum. This notion of value makes humans valuable and endows them with a spiritual quality. Without this nature, a person would be merely a beast. With this nature, a person can become a sage. According to Mencius, Confucianism teaches that one should exhaust one’s mind and know one’s nature (*jinxin zhixing*). One who practices this will be a gentleman and a sage.

Chan masters skillfully assimilated the Confucian sense of nature, mind, and sagehood into Buddhist thought. The result of this skillful measure (*fangbian*, *upaya* in Sanskrit) was the doctrine of “direct pointing at the human mind; seeing into nature to attain Buddhahood” (Dumoulin 1988, p. 85). Huineng opened his famous *Platform Sutra* with the same message: “Virtuous ones! The Bodhi-nature is originally pure. Making use of this mind alone, one can directly become a Buddha” (Huineng 1952, opening statement).

Inspired by Confucian thought, Chan masters transformed the traditional Buddhist doctrine of gradual enlightenment into the teaching and practice of abrupt or sudden enlightenment (*dunwu*). In Indian Buddhist teachings, not everyone has a Buddha nature and can become a Buddha. But according to Confucius and Mencius, all human beings are alike in nature and become different owing to different external environments. In the original state, humans have innocent, fine minds that cannot bear to see the suffering of others. But this mind was lost. The aim of education is to recover what has been lost. Can we find the original mind? Mencius’s answer was positive and optimistic. He wrote that the original mind is “all already complete in oneself,” and that the truth “is not far to seek, but right by oneself.” Following this positive, optimistic philosophy, Chan masters proclaimed that everyone has a Buddha nature, is able to

become a Buddha, and can suddenly attain enlightenment.

#### PURE LAND’S MESSAGE OF HOPE

While most Buddhists took a positive view of human nature, Pure Land Buddhism (Jingtu, Jōdo in Japanese), also founded in China in the sixth century, acknowledged human weakness and was pessimistic about individual efforts to achieve nirvana. Reading scriptures, sitting in meditation, keeping moral precepts, understanding the dharma, and training for enlightenment are all fine, but really too much and too extreme for most. Pure Land Buddhism is a protest against, as well as a step away from, intellectual, scriptural, and disciplinary forms of Buddhism. The main message of Pure Land Buddhism is that one cannot and need not attain nirvana by effort, but may obtain it with the help and compassion of Amitabha Buddha.

The Pure Land message, according to this school, was the Buddha’s original teaching, which was rediscovered by Nāgārjuna, later revered as the first patriarch of the Pure Land School. According to Pure Land masters, Nāgārjuna taught, “Although there are innumerable ways in the teachings of the Buddha, they can be classified roughly: the difficult way and the easy way.” The difficult way is to approach *Avāivartike* (a state of no return to the world of delusion) by diligently following the eightfold path and practicing the six virtues of perfection (*pāramitās*); the easy way teaches faith in Amitabha Buddha. The Mahayana doctrine of emptiness is the teaching of the easy way, for it teaches the emptiness of all our views and efforts.

Although Indian Mahayana teachings appear to differ from Pure Land Buddhism, Tanluan (476–524), the real founder of Pure Land Buddhism in China, is said to have been inspired by Nāgārjuna’s philosophy of emptiness. He drew on Nāgārjuna’s *Dasabhumi-vibhāstra* (A commentary by Nagarjuna on the ten stages in bodhisattva wisdom) to advocate that, because humans have little spiritual capacity, they should not pursue the difficult path. Traditional religious life represents the difficult way, which, more properly speaking, according to Tanluan, is the teaching of enlightenment through one’s own power (*zili*). But the Mahayana way teaches salvation by relying on an external power (*tali*). By relying on the Buddha’s help and compassion, one can empty oneself and be awakened and saved by the Buddha’s help and compassion.

Pure Land Buddhism shifted the focus of the Buddha’s dharma from the discipline of observing moral pre-

cepts (*vinaya*) and an emphasis on wisdom (*prajñā*) to the spread of compassion (*karuṇā*). Pure Land Buddhism is a religion of repentance, mercy, forgiveness, and grace. One obtains salvation by faith and devotion rather than by work or learning. Life, according to the Buddha's first noble truth, involves suffering. Yet formal religion has not made our lives more comfortable; on the contrary, it has frustrated and confused the minds of many clerics and laypeople because few can sustain the rigors of mastering Buddhist doctrine, either by practicing monastic discipline or by studying scriptures. An enlightened Buddha would see this state of suffering, have compassion, and be willing to help humans rise from the ocean of sufferings.

Amitabha, a compassionate bodhisattva according to Pure Land Buddhism, saw the miserable condition of sentient beings and determined to extend his great mercy to them, making forty-eight vows to save them. Failing his vows, he would not become a Buddha. Thus, while people may not be smart enough to digest Buddhist scriptures and may not have time to sit in meditation, they may yet hope for salvation by calling on the name of Amitabha Buddha (*Amituofo* in Chinese). The recitation or invocation of Amitabha's name became the trademark of Pure Land Buddhism. This simple act was said to help people enter into the western paradise, or the Pure Land. In fact, it became the most common Buddhist practice in China, Korea, and Japan, and the most popular means for salvation by which millions have sought release from suffering. So Pure Land Buddhism transformed Buddhism into a popular religion by preaching the simple gospel of hope.

Pure Land masters equated chanting "Amituofo" with Buddhism. Daochuo (562–645), the second patriarch of Pure Land Buddhism, was said to repeat the name of Amitabha Buddha seventy thousand times per day. Chanting "Amituofo" was believed to enable a person to be reborn in the Pure Land. Here, religious language does not describe the universe nor analyze truth. Rather, it is a calling for help, a therapy to relieve anxiety, frustration, despair, and other sufferings in life. The sound of "Amituofo" seems to have a power to comfort people and pacify the mind. The ultimate cause of the effectiveness of the invocation, according to Pure Land masters, is Amitabha Buddha himself, who aspired to save all beings. It is really through the power of Amitabha Buddha's vows that mortals, by reciting his name, can be released from the hell fires that a life of sin and evil bring on.

The power of chanting "Amituofo" is good news, because even persons who have committed the most egregious sins can be saved if they recite the name of

Amitabha Buddha. According to Shandao (613–681), an eminent Pure Land master, Pure Land Buddhism not only offers salvation to known sinners, but also leads good people to repent and confess their sins. Those who sincerely acknowledge and believe that they are sinful, lowly persons continually involved in error and shut off from salvation are enlightened Buddhists. If one can repent of sin, no matter how small the sin, one will gain a deep sense of release from suffering and can aspire to birth in the Pure Land through Amitabha Buddha's vows. Confession, repentance, humility, and forgiveness, rather than punishment and condemnation, are the virtues promoted and practiced by the Pure Land community.

## BUDDHISM IN CHINESE CULTURE

From the sixth century, Indian Buddhism became sinicized. Divergent Chinese Buddhist philosophies and practices were assimilated and fitted into the Chinese tradition, and exercised a lasting influence on almost every aspect of Chinese life. By the eighth century, Chinese Buddhism became firmly established and triumphantly spread throughout China. Chinese culture became an aggregation and synthesis of Confucianism, Daoism, and Buddhism. However, this syncretism did not go easily and smoothly. There were three major persecutions of Buddhists in Chinese history. The most devastating one occurred in 845. After this, most Buddhist schools declined in China. Then the Chan and Pure Land schools became predominant over other Buddhist schools and practices.

From the Song dynasty (960–1279) onward, chanting "Amituofo" has been the major religious practice among devout Buddhists. Chan philosophy was attractive to and popular among Chinese intellectuals, and was a vital cultural force, especially in literature and the arts. In fact, it led Confucian scholars to reexamine classical Confucian philosophy and develop neo-Confucianism, even though neo-Confucian scholars frequently attacked Buddhism when defending their orthodox teachings. Like Chan Buddhists, neo-Confucian scholars cultivated the mind, and even used Buddhist terms, some equating *li* (principle, reason) with the Dao, and others with the mind. Like Tiantai and Huayan Buddhists, many Confucianists adopted the round approach to develop an all-in-one and one-in-all worldview. In many ways what was new in neo-Confucianism was quite Buddhist in spirit.

The influence of Buddhism can also be seen in twentieth-century new Confucianism, as in Feng Youlan's (1895–1988) famous book *Xin lixue* (A new study of principle). Like metaphysically minded Buddhists, Feng

investigated the principles in and behind things with the aim of reaching the highest sphere of life, namely “forming one body with all things.” Xiong Shili (1885–1968), the founder of twentieth-century new Confucianism, was obviously a Buddhist Confucian. He promoted the Mahayana philosophy of consciousness only (*weishi*) and reinterpreted the Confucian metaphysics found in the *Yijing* (Book of changes) in the light of this doctrine. His eminent disciples, among them Tang Junyi (1909–1978) and Mou Zongsan (1909–1995), examined the round approach (*yuanyao*), and they debated whether Tiantai or Huayan philosophy represented the highest teaching. Mou Zongsan found the Tiantai School to be the best. To develop his moral metaphysics, he adopted Tiantai philosophy, especially the idea that phenomena are noumenon and noumenon is phenomena. Tang Junyi, Fang Dongmei (1899–1977), and many other twentieth-century Confucian scholars have contended that Huayan philosophy, rather than Tiantai philosophy, represented a fuller development of Buddhist thought.

Fang Dongmei, just before his death, made the following statement:

From emptiness I came.

To emptiness I return.

Emptying the emptiness without possessing any being

It is in nowhere that my heart will dwell (Shen 2003).

Thus, the latest approaches to Confucianism have been profoundly influenced by Buddhist thought. One cannot properly understand Chinese philosophy or the history of Chinese thought without knowing Buddhist philosophy.

## CONFUCIANISM

### CONFUCIANISM AS AN ETHICAL TRADITION

After the Zhou people conquered the Shang people in the middle of the eleventh century BCE, the early Zhou kings ruled by letting feudal lords govern vassal states. As their powers grew, feudal lords fought one another and resisted the Zhou king until the state of Qin conquered all other states in 221 BCE. A number of ethical and political thinkers lived in the period from the sixth to third century BCE, proposing different ways of restoring order as well as ideal ways of life for human beings. Among them, several thinkers, including Confucius (sixth century BCE), Mencius (fourth century BCE) and Xunzi (third century BCE), as well as their followers, were regarded as belonging to the same movement of thought. This move-

ment of thought was referred to retrospectively in the Han dynasty (206 BCE to 220 CE) as *rujia*, or the school of *ru*. The English term *Confucianism* is now often used as a translation of *rujia* to refer to this school of thought.

Unlike what the term *Confucianism* suggests, the expression *rujia*, or “the school of *ru*,” does not bear any special relation to the name of the individual known as Confucius. Instead, *ru* referred to a social group that already existed before the time of Confucius. The group consisted of professional ritualists who performed rituals in such ceremonial contexts as funeral rites, sacrifices to ancestors, and marriage ceremonies. In addition, these ritualists were often professional teachers, not just of rituals but also of other disciplines such as music. Certain individuals who were members of this group in virtue of being professional ritualists and teachers (including Confucius, Mencius, and Xunzi) came to develop concerns that were no longer restricted to rituals or to their own economic sustenance. Instead, they directed their attention to finding a remedy for the chaotic social and political situation of the times and to establishing the ideal way of life for human beings. They believed that the remedy lay with the maintenance and restoration of certain traditional norms and values, including but going beyond rituals, and proposed that, ideally, people should follow a way of life that embodies such norms and values. Unlike what the term *Confucianism* might suggest, these norms and values did not originate with Confucius but date back to a much earlier time.

Still, in referring to this movement of thought as *rujia* or “the school of *ru*,” the Chinese did regard Confucius as the first and most important thinker of the movement. Both Mencius and Xunzi, the two other major Confucian thinkers from that period, also regarded themselves as defending Confucius’s teachings, and their different developments of Confucius’s teachings competed for influence in the Han dynasty. In the Tang dynasty (618–907), the Confucian thinker Han Yu (768–824) regarded Mencius as the true transmitter of Confucius’s teachings, and this view was endorsed by Zhu Xi (1130–1200) of the Song dynasty (960–1279). Zhu Xi included the *Analects* (*Lunyu*) of Confucius and the *Mencius* (*Mengzi*), along with the *Great Learning* (*Daxue*) and *Centrality and Commonality* (*Zhongyong*), the latter two texts dating probably to early Han, among the Four Books. These texts eventually became the canons of the Confucian school, and Mencius came to be regarded as second only to Confucius in importance. Different kinds of Confucian teachings continued to evolve after Zhu Xi’s times, represented by major figures such as Wang Yang-

ming (1472–1529) of the Ming dynasty (1368–1644) and Dai Zhen (1724–1777) of the Qing dynasty (1644–1912).

Suppose we characterize ethics in terms of a concern with the question how one should live, where the scope of “one” is supposed to extend considerably beyond the person raising the question. Confucian thinkers do share a concern of this kind. Furthermore, they are reflective not just in having a conception of how one should live, but also in being concerned with the proper spirit behind the observance of rituals and other traditional norms, and with the grounds for observing these traditional norms and values. This warrants describing them as ethical thinkers. Also, although there are substantive differences in the views of different Confucian thinkers, these thinkers also share a broad similarity, both in defending certain traditional norms and values and in the use of certain common key terms in elaborating on their thinking. They share the same allegiance to Confucius’s teachings and, after the time of Zhu Xi, also share a conception of certain canonical texts that define the Confucian school. These similarities warrant regarding them as belonging to the same tradition of thought and describing Confucianism as an ethical tradition. The rest of the article will elaborate on some of the main characteristics of this ethical tradition.

## CONCEPTION OF THE SELF

To start with, let us consider how the Confucians view the self and the human constitution. They use the term *ti*, often translated as “body,” to talk about a person’s body, and they also have ways of referring to parts of the body, such as the four limbs and the senses. These parts of the body are not regarded as inert; not only do they have certain capacities, such as the eye’s capacity of sight, but they also exhibit certain characteristic tendencies. For example, the four limbs are drawn toward rest, while the senses are drawn toward such ideal objects as beautiful colors or pleasurable objects of taste. Such tendencies are referred to as *yu*, a term often translated as “desires” and paired with an opposite term often translated as “aversion.” These terms have, respectively, the connotations of being drawn toward and being repelled by certain things. The terms can be used not just for parts of the body but also for the person as a whole to describe how the person is drawn toward things like life and honor and repelled by things like death and disgrace.

That human beings have such tendencies as part of their basic constitution is regarded as a fact about them that is pervasive and difficult to alter. Facts of this kind are referred to as the *qing* of human beings, where *qing*

means “facts” and, in this context, the connotation of certain facts about human beings that reveal what they are genuinely like. Later, *qing* comes to refer to what we would describe as emotions, including such things as joy, sorrow, and anger, these also being regarded as parts of the basic constitution of a person.

There is another feature of the Chinese view of the person for which it is difficult to find a Western equivalent. The body of a person is supposed to be filled with *qi*, a kind of energy or force that flows freely in and gives life to the person. *Qi* is responsible for the operation of the senses; for example, it is supposed to make possible speech in the mouth and sight in the eyes. Conversely, it can be affected by what happens to the senses; for example, *qi* can grow when the mouth takes in tastes and the ear takes in sounds. Also, *qi* is linked to the emotions, and what we would describe as a person’s physical and psychological well-being is regarded as dependent on a proper balance of *qi*. For example, both illness and such emotional responses as fear are explained in terms of the condition of *qi*.

Among the different parts of the person, special significance is attached to *xin*, the organ of the heart that is viewed as the site of what we would describe as cognitive and affective activities. *Xin*, a term often translated as “heart” or “mind,” can have desires (*yu*) and emotions (*qing*) and can take pleasure in or feel displeasure at certain things. It can also deliberate about a situation, direct attention to and ponder about certain things, and keep certain things in mind. One capacity of the heart/mind (*xin*) that is particularly important for Confucian thinkers is its ability to set directions that guide one’s life and shape one’s person as a whole. Such directions of the heart/mind are referred to as *zhi*, a term sometimes translated as “will.”

*Zhi* can refer to specific intentions such as the intention to stay in or leave a certain place, or to general goals in life such as the goal of learning to be a sage. It is something that can be set up, nourished, and attained; it can also be altered by oneself or swayed under others’ influence, and lost through insufficient persistence or preoccupation with other things. Early texts sometimes compare setting one’s *zhi* in certain directions to aiming at a target in archery, and *zhi* is sometimes used interchangeably with another character that means “recording something” or “bearing something in mind.” Probably, *zhi* has to do with the heart/mind’s focusing itself on and constantly bearing in mind certain courses of action or goals in life, in such a way that *zhi* will guide one’s action or one’s life unless it is changed by oneself or under oth-

ers’ influence or unless one is led to deviate from it by other distractions. *Zhi* (directions of the heart/mind) differs from *yu* (desires) in this respect: although *zhi* pertains to the heart/mind, *yu* can pertain to the heart/mind or to parts of the body such as the senses or the four limbs. Furthermore, whereas *zhi* involves focusing the heart/mind in a way that guides one’s actions or one’s life in general, *yu* involves tendencies that one may choose to resist rather than act on.

With this survey of the different aspects of the person as background, let us consider the notion of self as it applies to Confucian thought. Now, besides the use of first-person pronouns, the Chinese language has two characters with the meaning of “oneself.” *Zi* is used in reflexive binomials referring to one’s doing something connected with oneself, such as one’s examining oneself or bringing disgrace upon oneself. *Ji* is used to talk about not just one’s doing something connected with oneself but also others doing something connected with oneself (such as others appreciating oneself), oneself doing something connected with others (such as oneself causing harm to others), or one’s desiring or having something (such as a certain character) in oneself. The two characters differ in that the former emphasizes one’s relation to oneself, whereas the latter emphasizes oneself as contrasted with others. In addition, the character *shen*, which is used to refer sometimes to the body and sometimes to the person as a whole, can also be used to refer to oneself or to one’s own person when prefixed with the appropriate possessive pronoun.

These linguistic observations show that the Chinese have a conception of the way one relates to oneself. Furthermore, in connection with Confucian thought, the characters just mentioned are often used to talk about one’s examining oneself and cultivating oneself on the basis of such self-examination. This further observation shows that Confucian thinkers also work with a conception of one’s being related to oneself in a self-reflective manner, with the capacity to reflect on, examine, and bring about changes in oneself. So they have a conception of the self in the sense of a conception of how one relates to oneself in this self-reflective manner.

Confucian thinkers ascribe the capacity of self-reflection just described to the heart/mind, to which they also ascribe a guiding role. They emphasize the importance of self-cultivation—that is, the process of constantly reflecting on and examining oneself, setting one’s heart/mind in the proper direction, and bringing about ethical improvements in oneself under the guidance of the heart/mind. There has been extensive disagree-

ment within the Confucian tradition about how the heart/mind can set itself in the proper direction. For example, Mencius and Xunzi disagree about whether a certain ethical direction is already built into the heart/mind and whether one should derive the proper direction by reflecting on the heart/mind or by learning from the outside. Later, Zhu Xi and Wang Yangming disagree in the different emphases they place on learning and on attending to the heart/mind in the process of self-cultivation. Despite such disagreements, they all regard the heart/mind as that which guides the process of self-cultivation.

Furthermore, they also agree on another distinctive feature of the heart/mind—not only can it set directions that guide the person's life and shape the person as a whole, but it is also independent of external control in having the capacity to hold on to the directions it sets without being swayed by external forces. For example, both the *Analects* and the *Mencius* emphasize its guiding role, comparing the directions (*zhi*) of the heart/mind to the commander of an army. In addition, the *Analects* notes one point of dissimilarity—although an army can be deprived of its commander, even a common person cannot be deprived of the directions set by the heart/mind. Such directions can, of course, be influenced by outside factors, but the point is that the heart/mind has the capacity to resist such influences and, for the Confucian thinkers, one should ideally cultivate oneself to attain such a steadfastness of purpose after having set the heart/mind in the proper directions. This independence of the heart/mind from external control is also emphasized by Xunzi, who compares the heart/mind to the position of the ruler and the senses to the offices of government; like the ruler, the heart/mind issues order but does not take order from anything.

Not only is the heart/mind independent of external control, but it also has the capacity to constantly step back to reflect on and improve its own operations. Three early Confucian texts—the *Xunzi*, *Great Learning*, and *Centrality and Commonality*—emphasize the idea that the heart/mind should cautiously watch over its own activities to ensure that all of them, however minute or subtle, are completely oriented in an ethical direction. This idea is presented in terms of watching over *du*, where *du* refers to the minute and subtle workings of the heart/mind that are not yet manifested outwardly and to which one alone has access. The idea is taken up by later Confucian thinkers, who in addition emphasize the importance of watching out for and eliminating what they call “selfish desires,” that is, the distortive influences in the

heart/mind that might lead one to deviate from the ethical direction. This aspect of Confucian thought shows that the Confucians ascribe to the heart/mind a self-reflexiveness; for any of its own activities, however minute and subtle, it has the capacity to reflect on and reshape such activities to ensure their orientation in an ethical direction. This self-reflexiveness is related to the independence of the heart/mind from external control—even though its activities can be influenced by external circumstances, the heart/mind has the capacity to constantly step back and reshape its own activities under the conception of what is proper, which it forms on the basis of its own reflections.

Given their emphasis on the distinctive role of the heart/mind, did Confucian thinkers believe in some kind of mind-body distinction? In a sense, they do emphasize a distinction between the heart/mind and other aspects of the person. The heart/mind has the distinctive capacity to reflect on these other aspects and on its own activities, to form a conception of what is proper, and to regulate and shape other aspects of the person and its own activities under such a conception. On the other hand, the distinction that the Confucian thinkers emphasize pertains to the distinctive capacities and modes of operation of the heart/mind rather than to the heart/mind as a distinctive kind of entity that occupies a “mental” as opposed to a “physical” realm. The character *xin*, translated here as “heart/mind,” refers to the organ of the heart that is a part of the body just as the senses are. And just as the heart/mind can operate in the manner described earlier, the senses also have their own modes of operation, such as distinguishing between and being drawn toward certain sensory objects. What distinguishes the heart/mind from other parts of the body is not that it pertains to a “mental” as opposed to a “physical” realm but that its modes of operation are different from, and enable it to perform a guiding function in relation to, other parts of the body.

Furthermore, there is also a sense in which Confucian thinkers deemphasize the distinction between the heart/mind and other aspects of the person. Earlier, we considered the Confucian emphasis on one's cautiously watching over the minute and subtle activities of the heart/mind, activities that are not yet outwardly manifested. In elaborating on this idea, the relevant texts also emphasize the point that, though initially not discernible from the outside, these activities of the heart/mind will inevitably be manifested outwardly, and so one cannot conceal from others the way one truly is. Indeed, the different aspects of the person described earlier are all inter-

active. For example, the life forces (*qi*) that fill the body can be affected by what happens to the body, such as the tastes that the mouth takes in and the sounds that the ear hears; conversely, the life forces can generate speech in the mouth and sight in the eyes. Also, the directions (*zhi*) of the heart/mind can guide and shape the life forces while depending on the life forces for their execution; conversely, the directions of the heart/mind can be swayed if the life forces are not adequately nourished.

It follows from the intimate link between the heart/mind and the life forces, and between the life forces and the body, that the heart/mind is also intimately linked to the body. Various Confucian texts observe how the condition of the heart/mind makes a difference to one's bodily appearance. For example, Mencius observes how one's ethical qualities, while being rooted in one's heart/mind, are reflected in one's face, back, and the four limbs, while the *Great Learning* observes how virtue adorns the whole person just as riches adorn a house. Thus, while the heart/mind is distinguished from other aspects of the person by its modes of operation and its guiding role, it is at the same time intimately linked to other aspects of the person. It is not a kind of "private" or "inner" entity that eludes observation by others, but its condition is inevitably reflected in other parts of the person. In their emphasis on self-cultivation, the Confucians have in mind a transformation not just of the heart/mind but of the person as a whole. Accordingly, if the self is viewed as the object as well as the subject of self-reflection and self-cultivation, it would be more appropriate to describe the Confucian conception of the self as comprising not just the heart/mind but the whole person, including various parts of the body.

Indeed, not only does self-cultivation affect one's whole person, but it also has an attractive and transformative power on others, a power that many Confucians regard as the ideal basis for government. For them, the ideal goal of government is to transform people's character, and the way to accomplish this is to first cultivate oneself and to let the transformative power of one's cultivated character take effect. This does not mean that governmental policies are not important. However, proper policies are themselves a manifestation of the cultivated character of those in power, and properly carrying out policies transmitted from the past also requires a cultivated character. So the ultimate basis for order in society lies with cultivating oneself, and there is an intimate link between self-cultivation and transformation of others' character.

## ETHICAL IDEAL

Having considered the Confucian conception of the self, let us consider the nature of the ethical ideal that the Confucians espouse. This ideal is presented through several key terms, three of the most important being *li*, *yi*, and *ren*.

*Li* originally referred to rites of sacrifice and subsequently broadened in scope to include rules governing ceremonial behavior in various social contexts, such as marriages and burials, as well as ways of presenting gifts, receiving guests, asking after the health of parents, or having audience with a prince. Subsequently, its scope broadened further to include rules governing behavior appropriate to one's social position, such as supporting one's parents in their old age. Though the term can be used to include social norms in general, *li* often retains the connotation of ceremonial behaviour. The *Xunzi*, for example, although sometimes using *li* interchangeably with *li yi* ("rites and propriety") to refer to various social norms, more often uses *li* in connection with ceremonial practices and their minute details. Whether it is the ceremonial or nonceremonial that is emphasized, *li* includes only rules that are part of a continuing cultural tradition and that pertain to the relations between people in different social positions or in recurring social contexts; behavior such as saving a drowning person, though proper, is not a matter of *li*. Also, Confucian thinkers emphasize the importance of the proper spirit behind the observance of *li*, which include attitudes such as respectfulness, attentiveness, and seriousness.

From a contemporary perspective, it may appear puzzling how rules as diverse as those ranging from details of rituals to rules governing conduct between people in different social positions could be placed together under one single concept. However, the rules of *li* do exhibit a unity both in the attitude that they are supposed to reflect and in the social functions they perform. A serious and reverential attitude toward others underlies both the observance of the responsibilities one has in virtue of one's social position and the observance of rules governing ceremonial behavior; a breach of *li*, even in ceremonial contexts—such as being dressed improperly when receiving a guest—demonstrates a lack of the proper attitude and constitutes a serious offense. And, just as the rules governing interaction between individuals in different social positions promote order and minimize conflict, the rules governing ceremonial behavior promote harmony and the proper channeling and beautification of one's feelings in those areas of life associated with strong emotions, such as funerals and mourning or marriage

ceremonies, during which individuals from different families become united as one family. The common spirit underlying the various rules of *li* and their common social functions show that their being grouped together is not based on a failure to distinguish between categorically different areas of life.

Another point worth noting is that the Confucian attitude toward *li* is not entirely conservative. Although the *Analects* contain only one passage that apparently endorses, on economic grounds, a deviation from an existing *li* practice, the *Mencius* is more explicit in asserting that *li* can be overridden by other considerations in exigencies. The *Xunzi* discusses the importance of adapting *li* to the changing circumstances of life, and later Confucian thinkers such as Wang Yang-ming also observe that what is of importance is to preserve the spirit behind *li* rather than to adhere to its minute details.

The Confucian readiness to deviate from or adopt *li* relates to another key term in Confucian thought, *yi*. *Yi* has the earlier meaning of a proper regard for oneself or a sense of honor, involving one's not brooking an insult, and lack of *yi* is often linked to disgrace in early texts. It is subsequently used to refer to what is proper or fitting to a situation, and is linked to *chi*, a character often translated as "shame."

*Chi* is a reaction to an occurrence or situation that one regards as beneath oneself and potentially lowering one's standing, and it is like shame in presupposing standards to which one is seriously committed. However, it is unlike shame in that it can be directed not just to past occurrences that fall below such standards but also to future prospects of such occurrences. Although *chi* can be directed to the manner in which one is treated in public, it is not typically associated with the thought of being seen or heard, and the typical reaction associated with it is not hiding or disappearing. Rather, it is associated with the thought of one's being tainted by a certain occurrence, and the typical reaction associated with it is to "wash off" what is tainting by distancing oneself from or remedying the situation. Even when directed to the past, it does not carry the connotation of dwelling on the past occurrence, but instead emphasizes a firm resolution to remedy the situation. It is more like the attitude of regarding something as contemptible or beneath oneself, and is linked to ideas such as disdain or a refusal to do certain things.

*Yi*, for Confucian thinkers, has to do with a firm commitment to certain ethical standards, involving one's disdaining and regarding as beneath oneself anything that falls below such standards. These standards include

not being treated in a disgraceful manner as measured by certain public norms, and so one common example of *yi* behavior is a refusal to accept treatment in violation of *li*. However, they also include other measures that go beyond what is honourable or disgraceful by public standards; the *Xunzi* emphasizes a distinction between social honor and disgrace, as opposed to "propriety" (*yi*) honor, and disgrace. Accordingly, *yi* can also provide a basis for departing from a rule of *li*.

The firm commitment that *yi* involves is also related to a certain attitude toward external goods not within one's control. The Confucians advocate one's not being swayed in one's purpose by such external considerations and one's willingly accepting the consequences. In face of adversities to oneself or the prospect of great profits, one is supposed not just to conform to what is proper in one's behavior but also to be free from any distortive influences that might lead to a deviation from what is proper. One should not be subject to fear or uncertainty in face of adversities, and one should willingly accept such adversities, an attitude conveyed in the use of the the character *ming*.

Though often translated as "fate" or "destiny," *ming* does not refer to some opaque force operative in human events that cannot be thwarted. Instead, it serves primarily to express a certain attitude toward occurrences that go against one's wishes and to which one attaches importance, an attitude that follows upon one's recognition of certain constraints on one's activities. The constraints may be causal in that the occurrences are actually not within one's control, such as the failure of one's political endeavors or unexpected illness or death. The constraints may be normative such that the occurrences are something one could alter even though such alteration would involve improper conduct. Whichever is the case, having done what one could within the limits of what is proper, one should willingly accept the undesirable outcome by not engaging in improper conduct to alter things and not worrying about that outcome. Instead, one should resolve to redirect attention to other pursuits, such as Confucius's turning his attention to teaching after having accepted the failure of his political mission.

Finally, let us turn to the Confucian notion of *ren*. In its earlier use, *ren* refers either to kindness, especially from a ruler to his subjects, or to the qualities distinctive of members of certain aristocratic clans. It is used by Confucian thinkers sometimes in a broader sense to encompass all the ideal ethical attributes for human beings and sometimes to refer to a specific ethical attribute that emphasizes affective concern for others. Even for

early Confucians such as Mencius, such affective concern should extend not just to human beings, but also to certain kinds of animals. For later Confucians of the Sung-Ming period, it involves a concern for everything, including plants and what we would describe as inanimate objects. For both early and later Confucians, *ren* involves a gradation. One should have a special concern for parents and family members that one does not have for other people, not just in the sense of a more intense affection but also in the sense of observing certain special obligations to them as defined by *li*. One's relation to other human beings also differs from one's relation to other animals and objects; for example, in the case of animals bred for food, *ren* toward them is primarily a matter of one's being sparing in their use, not using them in excess, and not treating them in an abusive manner.

In later Confucian thought, *ren* is understood in terms of two ideas associated with Heaven (*tian*), which has the connotations of both a supreme deity and the underlying purpose or design of the natural order. In early texts, Heaven, the ideal ruler, and even oneself are often described as forming one body with other people and things. Later Confucian thinkers continue to advocate similar ideas and characterize *ren* in these terms. Heaven and Earth and the ten thousand things originally forming one body with myself, and *ren* involves attaining this state of unity with all things. Though one may have deviated from this state of existence, the task of self-cultivation is to enlarge one's heart/mind until one sees everything as connected to oneself. This idea is sometimes put in terms of a medical analogy. Just as medical texts refer to as a lack of *ren* numbness in one's limbs, an inability to feel for other people is also a lack of *ren*.

In early texts, Heaven is also regarded as what gives birth to things, and its operation is described in terms of a ceaseless life-giving force, an idea highlighted in the early text *Book of Change (Yijing)*. In later Confucian thought, Heaven's giving birth to and nourishing the ten thousand things is described as its *ren*. The heart/mind of humans should be identical with the heart/mind of Heaven and Earth, which is to give life to things. This is *ren* in the human context, a quality compared to the life-giving power of a seed. This idea of a ceaseless life-giving force is related to the idea of forming one body with the ten thousand things—in giving life to all things, it is as if all things are part of one's own body.

With the above explication of the ethical ideal as background, let us consider the Confucian view of the relation between the self and the social order. As in the case of the relation between the heart/mind and other

aspects of the person, there is a sense in which Confucian thinkers emphasize the independence of the self from the social order, and a sense in which they emphasize their intimate relation.

As we have seen, Confucian thinkers emphasize the capacity of the heart/mind to reflect on one's own life, including the activities of the heart/mind itself, as well as its capacity to reshape one's life and its own activities on the basis of such reflection. In virtue of such a capacity, one also has the capacity to step back from one's place in the social order and assess one's relation to it. In the *Analects*, for example, we find passages describing hermitlike individuals who shun the social and political order, at times ridiculing Confucius and his disciples for their persistent and (to these individuals) futile attempts to bring about social and political reform. The Confucian emphasis on the preparedness to deviate from or adapt traditional norms, less explicit in the *Analects* but more conspicuous in the *Mencius* and the *Xunzi*, also presupposes a capacity to step back and reflect on the existing social order.

At the same time, Confucian thinkers also view the self as intimately related to the social roles one occupies. In viewing human beings as a species distinct from other animals, they see the distinction as residing in the capacity of human beings to draw social distinctions and to abide by social norms associated with such distinctions. The point is found explicitly in the *Xunzi*, which states that what makes human beings human beings is not their biological or physiological constitution but their capability of social differentiation and distinction. It also accounts for Mencius's observation that someone who denies social distinctions or fails to make use of this social capacity is, or has become close to, a lower animal. Later Confucians such as Zhu Xi, although acknowledging that certain other animals exhibit something like social relations, also emphasize that human beings are different from other animals in their unique ability to bring to fruition such relations.

Also, as we have seen, Confucian thinkers advocate an ethical ideal that is informed by the traditional social setup that they advocate. The ideal involves a general observance of traditional norms that govern people's behavior either in virtue of the social positions they occupy (such as being a son or an official) or within other kinds of recurring social contexts (such as a host receiving a guest or sacrificial ceremonies); it also involves the embodiment of certain attitudes (such as reverence) appropriate to such behavior. In addition, it involves the cultivation of desirable qualities within various social

contexts, such as filial piety within the family or devotion when serving in government. Confucian thinkers do acknowledge the importance of a preparedness to deviate from or adapt traditional norms, and later Confucians such as Zhu Xi and Wang Yangming explicitly mention that the fine details of the *li* of ancient times are not all applicable to their times. Nevertheless, they see such deviation and adaptation as themselves based on a certain rationale underlying the social order that, although calling for changes in details in response to changing circumstances, is at the same time something that can be realized only in the evolving social order. It is through participating in this social order and letting oneself be shaped by it that one becomes fully human.

### SELF-CULTIVATION

Let us now turn to self-cultivation, the process of, shaping one's own character out of a reflexive concern with the kind of person one is. Confucius stressed learning and reflection as part of the process. The former involves drawing moral lessons from the cultural heritage, which includes such elements as poetry, history, rites (*li*), music, and archery, and embodying such lessons in one's life. The latter involves reflecting on what one has learned so as to adapt it to one's present circumstances. Confucian thinkers after Confucius's times developed different views of human nature, different views of what the basic human constitution is like prior to learning and social influence. These different views have led to different conceptions of self-cultivation.

Some Confucian thinkers, such as Xunzi and Dai Zhen, emphasize the basic biological desires of human beings in elaborating on the basic human constitution. For them, living up to the Confucian ideal is instrumental in satisfying these basic human desires. According to Xunzi, when human beings act out of these desires without regulation, strife and disorder follow. The Confucian Way regulates and transforms such basic desires so that people can satisfy them in an orderly fashion. On this view, self-cultivation involves reshaping and transforming basic human desires, something that Xunzi at times compares to straightening a crooked piece of wood. Dai Zhen also emphasizes the basic biological desires and feelings. He sees the Confucian Way as a matter of one's using one's desires and feelings as a way of gauging others' desires and feelings, and one's satisfying others' desires as one would one's own.

Certain Confucian thinkers, such as Mencius, view human nature primarily in terms of ethical predispositions that human beings share. Mencius opposes

the biological conceptions of human nature of his contemporaries and argues that the human heart/mind has a sense of propriety (*yi*) and that human beings do give precedence to propriety over biological desires. He believes that human beings already share certain ethical predispositions, such as the sense of commiseration upon suddenly seeing a child on the verge of falling into a well or the sense of shame when a beggar is given food in an abusive manner. For him, self-cultivation is a process of fully developing these ethical predispositions, a process that he compares to the development of a sprout into a full-grown plant. By directing attention to and nourishing these ethical predispositions, everyone is able to attain the ethical ideal.

Sung-Ming Confucians such as Zhu Xi and Wang Yangming, being self-professed Mencians, draw on the Mencian view but develop it in a different direction. Unlike Mencius, who regards human beings as having ethical predispositions that require nourishment to develop into the ideal ethical attributes, they regard these attributes as already present in the heart/mind in a full-blown form. Certain distortive influences, which they call selfish desires and sometimes selfish thoughts, can prevent the ethical attributes from fully manifesting themselves. *Si*, the character translated here as "selfish," has to do with focusing on oneself, or on people and things with which one forms close associations, in a way that inappropriately neglects other people and things. It involves a separation of the self from other people and things, preventing the life-giving force of *ren* from reaching all things and detracting from one's original unity with them. So, for both Zhu Xi and Wang Yangming, self-cultivation involves restoring the original state of the heart/mind, thereby allowing full manifestation of the ethical attributes. This process is illustrated with analogies such as the clear mirror obscured by dust or still water disturbed by sediments; the ethical task is to remove the dust or sediments to restore the original clarity of the mirror and of water. Zhu Xi and Wang Yangming differ on how to implement this task, the former emphasizing learning and the latter recommending focusing on the operations of the heart/mind.

The Confucian emphasis on self-cultivation, the process of one's doing something to shape one's own character out of a reflective concern with the kind of person one is, is arguably one of the more distinctive features of Confucian ethical thought. This emphasis, however, can lead to the worry that it involves a misdirection of one's ethical attention. This worry can take two different

forms—that this concern with one’s own character is either too other-directed or too self-directed.

First, some may be concerned that this emphasis on self-cultivation may involve an excessive concern for others’ opinion of oneself, especially if it involves one’s thinking in terms of cultivating such attributes as *ren* and *yi*. The thought is that the terms that refer to ethical attributes are typically used in third-person descriptions rather than in the content of the ethical person’s deliberations. So it appears that the first-person exercise of cultivating these attributes in oneself involves being concerned primarily with the way others would describe oneself. It seems that, in aiming at *ren* and *yi* or at becoming like the ancient sages, one’s primary concern is with one’s being describable by others in a certain way or with acquiring the kind of stature that the ancient sages have in others’ eyes. If so, this kind of concern does seem other-directed in a disturbing way.

Part of the response to this worry is that, even if we grant that *ren* and *yi* are more often used by others as a third-person description of the ethical person, a concern with these attributes need not be a concern with one’s being describable by others in a certain way. Instead, it can be a concern with one’s becoming like the kind of person that one would oneself describe in this way. That is, the third-person description in terms of *ren* and *yi* can be a description of others by oneself rather than of oneself by others. Furthermore, in being concerned with becoming like the kind of person that one would oneself describe in this way, one’s primary object of concern is not with the description but with having a certain character that can be described in this way. Likewise, a concern to be like the ancient sages can be a concern with one’s character being like theirs, rather than with one’s having the kind of stature that they have in others’ eyes.

Still, even if a concern with *ren* and *yi* need not be a concern with how others view oneself, it is a concern with one’s own character, and this can lead to the second worry that such a concern may be too self-directed. This concern can be too self-directed in two ways: One may be concerned with preserving or promoting one’s own self-image as a certain kind of person, or one may be making one’s own character the most important ethical consideration, more important than other-regarding considerations. These two forms of the worry are different. The first focuses on the way in which one is concerned with one’s character, how it can take on a distortive form so that one’s object of concern is one’s image of oneself rather than one’s character as such. The second focuses on the importance one attaches to one’s own character,

how one puts undue weight on one’s character in comparison to other-regarding considerations.

In connection with the first form of the worry, we have seen that a concern with *ren* and *yi* is a concern with improving one’s character. Just as such a concern need not be a concern with the way others’ view oneself, it need not be a concern with preserving or promoting one’s own self-image. However, the worry about a concern with self-image may arise with regard to the particular actions that one performs, in relation to both acts of *ren* and acts of *yi*. Let us therefore consider the two kinds of action in turn.

In the case of *ren*, let us take a helping action as example. Suppose one’s thought in helping is that one should be doing what is *ren*. If so, it seems that what one is concerned with is that one gives expression to one’s *ren* character, that one does what is *ren*, or that one preserves one’s image of oneself as a *ren* person. In any case, it seems that there is indeed a misdirection of one’s attention in acting.

It is unclear, though, that the Confucians would advocate performing such acts with thoughts about one’s own *ren*. For example, in the case of the child on the verge of falling into a well, one’s compassionate response is described as a direct response to the imminent death of the child, unmediated by thoughts about one’s own character. It is true that, in cases in which one acts not out a sufficient concern for others but out of a concern that one should become the kind of person who would be so moved, one might act with the thought of doing what is *ren*. Even so, one’s acting with such a thought is itself a way of transforming oneself so that one will act out of a more direct concern for others. Although, ideally, one should not need to act with such a thought, one’s doing so is instrumental in the attainment of this ideal and so should not itself be problematic.

*Yi* involves a firm commitment to distancing oneself from certain things that one regards as below oneself. In acting out of such a commitment, it seems, one’s primary concern is with avoiding smears on one’s own character, which is a self-directed kind of concern. Now, even if this is correct, it seems that this kind of self-directed concern need not be problematic for actions that do not—at least directly—affect the well-being of others. For example, in the case of the beggar’s rejecting food given with abuse, there does not seem to be anything problematic with the thought that to submit to such treatment to avoid starvation is beneath one’s dignity. If there is something problematic about acting out of this kind of concern, it will

have to do with acts that also affect the well-being of others.

Let us therefore consider an act of this kind, such as King Wu's overthrowing the corrupt last king of the Shang dynasty. In the description of this occurrence in the *Mencius*, there is a reference to *chi*, or regarding something as below oneself. Now, although King Wu's attitude was that he regarded it as below him that he, who was in a position to remedy the situation, should allow the people's suffering to continue, there are two ways in which he was also acting out of a concern that is not self-directed. First, what he regarded as below him is also something he would view with aversion if done by someone else in a comparable position. That is, although he reacted with *chi* because of his special relation to the situation, underlying this reaction is the more general attitude of aversion directed to the act, whether by himself or by others, of allowing avoidable suffering to continue. So, in acting out of *chi*, he was in part also acting out of a more general concern that an act of this kind did not take place. Second, his acting out of *chi* is not exclusive of his acting out of a genuine concern for the people. Presumably, it was because he had such concern that he regarded it as below him that the situation be allowed to continue. As long as this other-regarding concern also played a role in his action, his action did not seem to suffer from a misdirection of attention.

This last point assumes that a concern to avoid what is below oneself and a concern for others converge; but what if the two should come into conflict? This takes us to the second form of the worry about an excessive concern with oneself: the worry that one may attach too much weight to one's own character by comparison to other-regarding considerations. Indeed, Mencius himself had been accused of precisely this kind of self-centeredness. The *Mencius* contains several examples of his refusing to see a ruler because he had not been summoned or treated in accordance with certain rules of *li* appropriate to his position. His critics made the point that, if only he had been willing to "bend" himself a little and have audience with the ruler, he might have been able to effect desirable political changes and thereby help the people. By insisting on an adherence to *li*, he was apparently putting more weight on preserving his own sense of honor than on the well-being of the people.

This is a serious charge, and Mencius's response was to draw on the early Confucian view about the transformative power of a cultivated character. The basis of order in society is the cultivated character of those in power, and what Mencius sought to accomplish in the political realm

was to "straighten out" those in power. And straightening out others depends on one's being straight oneself; there has never been a case of one's bending oneself while succeeding in straightening others. So, according to Mencius, it is not possible to achieve the desired political changes by bending oneself. And, to the extent that the well-being of the people depends on a reform of the political order, which in turn depends on the transformative effect of a cultivated person, there cannot be a conflict between a concern for one's character and a concern for others. The same point applies to the relation between one's character and the character of others. Given the belief that the transformative effect on others' character is a natural outgrowth of one's cultivating one's own character, there cannot be a conflict between a concern for one's character and a concern for others' character.

## CONTEMPORARY

The People's Republic of China (PRC) was established in 1949 under the leadership of Chairman Mao Zedong (1893–1976). This date marks an important watershed in the development of Chinese philosophy. Since 1949 the official ideology of the communist regime on mainland China has without question been Marxism-Leninism-Maoism, while other thoughts were ruthlessly suppressed—especially during the period of Cultural Revolution from 1966 to 1977. The nationalist regime had been driven to the island of Taiwan, which in the early twenty-first century still carries the banner of the Republic of China (ROC, 1912–). The official ideology of the Republic of China was the Three People's Principles, formulated by Sun Yat-sen (1866–1925).

Yet apart from anticommunist and political struggles, other thoughts were more or less tolerated. In Hong Kong—a British colony not taken back by China until 1997—freedom of speech was protected. Furthermore, refugee scholars were allowed to develop and express their thoughts in borrowed space and time. Additionally, there was the Chinese diaspora overseas. Among the various elements in the development of Chinese philosophy, there are several mainstreams of thought that can be discerned. This entry will examine Maoism, Western liberalism, and contemporary neo-Confucianism.

### MAOISM

The success of Maoism has been credited to Mao Zedong's talent to adapt Marxism-Leninism to the Chinese soil. Mao contributed two articles—"On Contradic-

tion" and "On Practice"—to expound the philosophy of dialectical materialism. He believed he had succeeded the orthodox line of Marxism-Leninism after the death of Stalin, and as such battled against Western imperialism on the one hand and soviet revisionism on the other. According to Feng Youlan (Fung Yu-lan), Mao's thought went through three stages (Feng 1992).

In the first stage Mao advocated new democracy; in the second, he promoted socialism; and in the last stage he was obsessed with extreme leftist thought. The first stage was represented by Mao's essay "On New Democracy," published in 1940 (Mao 1967). According to his diagnosis at that time, China was not ready for a socialist revolution and had to go through a transitory stage of new democracy. This new democracy was led by the proletariat, the workers and farmers, in conjunction with the petite bourgeoisie. Together they formed a united front, and even the national capitalists were allowed to play a part. This united front joined forces to deal with the problems of a semicolonial, semifeudal society.

When the PRC was established in 1949, the government policy followed such a guideline. But the stage abruptly ended in 1954 when the constitution was drafted. Mao's thought entered the second stage, composed of big change: The goal for the next five years was to accomplish a socialist revolution. Thus the nature of the revolution determined what should be done at any particular stage in the revolution, regardless of actual societal conditions. The telos was a kind of utopian socialism, which surfaced after Mao took control to become the great helmsman of the new China.

In the final stage of his thought, Mao went against the bureaucracy and his own party organization and initiated the disastrous Cultural Revolution, putting his authority behind the Gang of Four. His intention was to do away with private property and to establish communes, which he believed would allow poor people to eat without pay. The release of the destructive powers of the Red Guards caused damages unprecedented in Chinese history.

Mao died in 1976, and in 1977 the Gang of Four was removed by Deng Xiaoping (1904–1997), who adopted an open policy to bring about the revival of China. Since then, capitalism has been seen as a necessary stage for China to go through before the socialist revolution can be implemented. As the doors of China opened to the outside world, many intellectuals were attracted by thought other than Marxism. One editorial in the *People's Daily News* in the 1980s said that Marx's ideas were the product of the nineteenth century, that they did not provide all

the answers, and hence it was desirable to further develop Marxism. Revisionism, therefore, seems to no longer be a crime, and a prevalent view shared by both mainland China and overseas scholars in the late-twentieth and early twenty-first centuries is that a healthy interaction between Marxism, Western liberalism, and Confucianism may find a direction for the future of China.

### WESTERN LIBERALISM

Western liberalism was imported to China near the end of Qing dynasty (1644–1912), but somehow it failed to adapt well to the Chinese soil. The most famous liberal in the early Republic of China era was Hu Shih (1891–1962), a disciple of John Dewey, who during the New Culture Movement (c. 1919) promoted the ideals of democracy and science vigorously, urging for wholesale westernization or modernization without reservation (Chow 1960). Yet his approach by gradual reform quickly lost its appeal and radicalism became the vogue. After the communists took over mainland China in 1949, Hu left for the United States, then in 1958 went to Taiwan to serve as the head of Academia Sinica, where he remained until his untimely death in 1962. In his later years he disengaged from political activities and avoided making severe criticisms of the nationalist government under the leadership of Generalissimo Chiang Kai-shek (1887–1975). Instead, he put an emphasis on tolerance.

Among the liberals in Taiwan, one individual who stood out was Yin Haiguang (Yin Hai-kwong, 1919–1969), honored as a spokesman for the democratic movement in Taiwan under the authoritarian rule by the nationalist regime. In 1966 the government (the ministry of education) prevented Yin from teaching his classes at Taiwan University. He would be diagnosed with cancer in 1967 and die two years later.

A follower of logical positivism, Yin was not a deep thinker. His mentors included Bertrand Russell, A. N. Whitehead, Karl Popper, and F. A. Hayek. For Yin, only formal and empirical sciences are cognitively meaningful, yet he was willing to risk his life to fight for the implementation of democratic ideals. In his later years he returned to tradition and lauded Mencius's affirmation of moral courage to defend what is right under adverse environment (Yin 1966). Because he dared to stand up against the mighty powers of an authoritarian regime, eventually Yin was viewed as a martyr and gained respect because he was able to fulfill the duties of an intellectual as he saw it. At the turn of the twenty-first century certain aspects of Western liberalism have held a great attraction for some

liberal-minded intellectuals on mainland China since it opened its doors to the outside world.

Both in Hong Kong and Taiwan, the influx of various trends of Western thought has not ceased. In recent years, these trends poured into mainland China with great speed. Although a majority of Chinese intellectuals in the twentieth century criticized Confucianism, that tradition never died. In fact, the most creative talents were found in the contemporary New Confucian movement, which sought to bring about a synthesis between East and West (Bresciani 2001). Despite the prediction of Joseph Levenson in the late 1960s that Confucianism would become something dead that could only be found in museums (Levenson 1968), it appears to be thriving at the present time like a phoenix reborn from the ashes.

### CONTEMPORARY NEO-CONFUCIANISM

Confucianism may mean different things to different people, but it is possible to adopt the following threefold division (Liu 1998): (1) spiritual Confucianism, the tradition of the great Confucian thinkers; (2) politicized Confucianism, the tradition of Han Confucianism that served as the official ideology of the dynasties; and (3) popular (or vulgar) Confucianism, belief at the grassroots level that emphasizes family values, diligence, and education—and note that Confucianism in this last stage cannot be separated from beliefs in popular Daoism and Buddhism or various kinds of superstitions. The three forms of Confucianism must be kept distinct on the conceptual level, however, although in reality they are intricately related. Indeed, institutional Confucianism died when the last dynasty was overthrown in 1912, but the other forms of Confucianism survive. For example, some sociologists, such as Peter Berger, believe that vulgar Confucianism has contributed a great deal to the economic miracles accomplished since the 1970s by Japan and the so-called Four Mini-dragons: Taiwan, Hong Kong, Singapore, and Korea (Berger and Hsiao 1988). Politicized Confucianism has also attracted a large number of admirers. The cover of the June 14, 1993, issue of *Time* magazine was a portrait of Confucius; the issue reported that Francis Fukuyama, author of *The End of History*, was of the opinion that the kind of soft authoritarianism practiced in Singapore posed a greater challenge to Western liberalism than did Islam.

Spiritual Confucianism is a vigorous movement of thought. In 1986, mainland China designated Contemporary New Confucianism as a national research program for a period of ten years (Fang 1997). At first its scope was

not clearly defined; it included scholars with various backgrounds, such as scholar-thinker Liang Shuming (Liang Sou-ming, 1893–1988), scholar-statesman Zhang Junmai (Carsun Chang, 1887–1969), historian Qian Mu (Ch'ien Mu, 1895–1990), and intellectual historian and political commentator Xu Fuguan (Hsü Fu-kuan, 1903–1982). After broad consultations and extensive discussions under the guidance of Fang Ke-li and Li Jingquan, the directors of the program, ten case studies were completed.

In addition to the above-named scholars, the program also included six philosophers: Xiong Shili (Hsiung Shih-li, 1885–1968), Feng Youlan (1895–1990), He Lin (Ho Lin, 1902–1992), Fang Dongmei (Thomé H. Fang, 1899–1977), Tang Junyi (T'ang Chün-i, 1909–1978), and Mou Zongsan (Mou Tsung-san, 1909–1995). Later, four younger scholars were included: Yu Yingshi (Yü Ying-shih, 1930–), Liu Shuxian (Liu Shu-hsien, 1934–), Cheng Zhongying (Cheng Chung-ying, 1935–), and Du Weiming (Tu Wei-ming, 1940). The addition of Ma Yifu (1883–1967), a noted scholar in classics studies from the older generation, was also added. Eventually, fifteen names were chosen, and these fifteen may be assigned to four groups in three generations (Liu 2003):

The First Generation:

Group I: Liang, Xiong, Ma, and Zhang

Group II: Feng, He, Qian, and Fang

The Second Generation:

Group III: Tang, Mou, and Xu

The Third Generation:

Group IV: Yu, Liu, Cheng, and Du

Liang, Xiong, and Ma have been recognized as the three elders in the first generation, all of whom chose to remain in mainland China. Only Zhang, as the leader of a third force political party, fled overseas. Liang is seen as the person who initiated the movement, but it was Xiong, known only in a small scholarly circle, who became the spiritual leader of contemporary neo-Confucianism in the narrower sense. The three important representatives of the movement, Tang, Mou, and Xu, were disciples of Xiong.

The scholars in Group II were somewhat younger. Feng and He chose to remain in mainland China. Qian Mu fled to Hong Kong, where he and Tang became the cofounders of New Asia College, an undisputed center for contemporary neo-Confucianism. Fang, once a teacher of Tang, fled to Taiwan, where he taught at Taiwan University and had Liu and Cheng among his disciples. Xu and

Mou also went to Taiwan, and from 1963 to 1969 made Tunghai University in Taichung a second center for contemporary neo-Confucianism.

#### THE IMPORTANCE OF THE THREE GENERATIONS.

Without question, the mainstay of contemporary neo-Confucianism is represented by the second generation of scholars: Tang, Mou, and Xu. They signed the famous “Manifesto for a Reappraisal of Sinology and Reconstruction of Chinese Culture,” drafted by Tang and issued on New Year’s Day in 1958. The other signatory was Zhang, of the first generation (Liu 1996). The third generation scholars, disciples of Hong Kong and Taiwan New Confucians, received advanced academic training and had teaching careers in the United States, thereby acquiring an international dimension in their thought (Liu 2003).

For obvious reasons only refugee scholars outside of mainland China were able to make significant contributions to the further development of Confucian thought. Fang, of the older generation, received his academic training in the United States. He had a grand scheme of philosophy of culture with a comparative perspective of a fourfold division: ancient Greek, modern European, Chinese, and Indian. He also strongly criticized the dualism of modern European thought, which was believed to have a hidden nihilistic tendency (Fang 1957). Fang opted for messages of creative creativity and comprehensive harmony of primordial Confucianism (Fang 1981), as well as urging others to overcome the limitations of different cultures in order to bring about a synthesis of East and West.

Tang and Mou were also well versed in Western philosophy. While Tang had a Hegelian bent, Mou showed an unmistakable Kantian temperament. The famous manifesto drafted by Tang urged the sinologists in the West to study the Chinese culture not just through the eyes of the missionaries, the archaeologists, or the political strategists, but with a sense of reverence and sympathetic understanding of that culture. According to the manifesto, the wisdom of Chinese philosophy is crystallized in its philosophy of mind and human nature (*xin* and *xing*), an unmistakable reference to Sung-Ming neo-Confucianism. Although recognizing the need for the Chinese culture to learn from the West by absorbing its achievements in science and democracy, the manifesto claims that there is something invaluable in the Chinese tradition and suggests that the West may learn from Chinese thought in the following five items:

- (1) The spirit to assert what is here and now and to let everything go (in order for nature to take its own course);
- (2) All-round and all-embracing understanding or wisdom;
- (3) A feeling of warmth and compassion;
- (4) The wisdom of how to perpetuate the culture;
- (5) The attitude that the whole world is like a family.

THE THREE TRADITIONS' DOCTRINE. In his later years Tang devoted himself to tracing the origins of insights in traditional Chinese philosophy. The last work he published was a comprehensive system of philosophy conceived in his lifetime. The book deals with the whole existence of humans and tries to understand the different activities of the mind, distinguishing the following nine worlds:

- (1) the world of discrete things;
- (2) the world of species and genus in terms of empirical generalization;
- (3) the world of functional operation;
- (4) the world of perceptions interpenetrating with one another;
- (5) the world of contemplation of what is transcendent and vacuous;
- (6) the world of moral practice;
- (7) the world of aspiration toward God;
- (8) the world of emptiness (*śūnyatā*) of both the self (*ātman*) and elements (*dharma*);
- (9) the world of the embodiment of heavenly virtues.

Mou, however, was perhaps the most original thinker in his generation. Going further than the manifesto, he formulated the doctrine of three traditions:

- (1) The assertion of *Daotong* (the tradition of the Way): We must assert the value of morality and religion, jealously guarding the fountainhead of the universe and human life as realized by Confucius and Mencius through a revitalization of the learning of the mind and the human nature.
- (2) The development of *Xuetong* (the tradition of learning): We must expand our cultural life and further develop the learning subject as to absorb the Western tradition of formal sciences such as logic

and mathematics on the one hand and empirical sciences on the other.

- (3) The continuation and expansion of *Zhengtong* (the tradition of politics): We must recognize the necessity of adopting the democratic system of government as developed in the West in order to fulfill truly the political ideal of a government of humanity of the sages and worthies in the past.

After Mou dug deeply in the Chinese tradition and devoted himself to scholarly studies of Daoism, Confucianism, and Buddhism, in the latest stage of his thought he brought into focus a comparative perspective. In *Intellectual Intuition and Chinese Philosophy* he pointed out that the major difference between Chinese and Western philosophies lies in the fact that the three major Chinese traditions all believed in the possibility of intellectual intuition, whereas major Western traditions deny that there is such a possibility. Mou used Kant as his point of departure because Kant believed that all human knowledge must depend on sensible intuition, and only God has intellectual intuition. For Kant, freedom of the will, immortality of the soul, and the existence of God can only be postulates of the practical reason, hence Mou was of the opinion that Kant could only develop a metaphysics of morals, not a moral metaphysics. In *Phenomenon and the Thing-in-itself* Mou made a distinction between what he called "ontology with adherence" and "ontology without adherence." The former has been highly developed in the Western traditions, and the latter has been elaborately formulated in the Oriental traditions. When the infinite mind puts restrictions on itself, the knowing subject is formed; this is the result of a dialectical process. The adherence of the knowing mind and the realization of the infinite mind actually share the same origin. It is here that a foundation for the unity of the two perspectives can be found (Liu 1989).

Because the second generation neo-Confucians developed their ideas within a most adverse environment, they tended to stress what is positive in the Confucian tradition. But the third generation neo-Confucians face a very different context—they presuppose the pluralistic framework of the West. For example, Du Weiming feels that there is no need to prove that the Confucian tradition is better than other spiritual traditions, so long as it can be shown that it is one of the worthy spiritual traditions in the world; from modern to postmodern era, the flexible understanding of reason and the emphasis on harmony in the Confucian tradition are to its advantage. Liu Shuxian offers a new interpretation of *liyi fenshu* (one principle, many manifestations) which he inherited from

Sung-Ming neo-Confucian philosophy. He fully realizes that the Confucian tradition certainly does not have a monopoly of one principle, which would find different manifestations in different spiritual traditions. For example, the Golden Rule, credited to Confucius by Hans Küng, has been formulated in different ways in the East and in the West as well as in the ancient and modern times (1993). Thus, Liu vigorously supported the formulation of a global ethic in the awakening of a global consciousness. Because the world has turned into a global village with only limited resources, and because people need to live peacefully together, certainly the Confucians will have something significant to say in the future.

## DAOISM

Philosophical Daoism (also spelled Taoism) dates from the classical period (fifth through third century BC) and conventionally refers to the contents of the *Zhuangzi* (*Chuang Tzu*) and the *Laozi* (*Lao Tzu* or *Daode Jing/Tao-Te Ching*). Some extend the term to cover less philosophical transitional texts of popularized Daoism of the Han (second century BC)—for example, the *Liezi* and the *Huainanzi*. Another movement, called Neo-Daoism, dates from the end of the Han (200-plus). The term "Daoism" is fundamentally misleading since no group, no leader, and no association linked those thinkers. The Han historians who coined the term centuries later viewed the philosophers as founders of their credulous religion, Huang-Lao, which flourished after classical philosophy was extinguished by Qin despotism (220 BCE). The main basis for the classification was thus: (1) their philosophical interest in the concept of *dao* (way or normative guide); and (2) relatively skeptical, anarchic, antisocial attitudes which contrasted with Confucianism.

### PHILOSOPHICAL DAOISM: A QUICK TOUR

The concept of *dao* (tao) was central to ancient Chinese philosophizing. It is essentially a normative, practical concept—a way or guide to action. Almost all ancient Chinese thinkers philosophized about *dao*, about choosing, reforming, following *daos* as well as understanding

their relation to “constant” nature (*tian*<sup>nature:sky</sup>), to human nature (*xing*<sup>nature</sup>), and to society.

Those subsequently classed as daoist thinkers are distinguished by their more metaethical interest in *dao* in contrast to Confucians and Mohists who mainly advocated a variety of normative *daos*. Daoists discussed mainly three kinds of *dao*: human (or social) *dao*; *tian*<sup>natural</sup> *dao*; and “Great” *dao*. When I instruct you to cross the road on the green light, I am delivering a bit of human *dao*. Natural *dao* (often translated heavenly *dao*) is akin to what we would consider the constancies of science. Natural *dao* is the way things reliably (constantly) happen. The salient contrast is that Chinese thinkers do not elaborate this idea with the idea of law—universal, modally necessary propositions. Great *Dao* refers to the entire actual history of space and time—whatever has happened, is happening or will eventually happen in the universe is part of Great *Dao*. *Dao* is simply the counterpart of Ludwig Wittgenstein’s “All that is the case.” What amounts to determinism in Chinese thought is treating *tian dao* and Great *Dao* as identical—the constancies in nature make only one world history possible.

Daoist philosophers typically distance themselves from various human *dao* (paradigmatically Confucian or Mohist *dao*) by contrasting them to natural *dao* and/or Great *Dao* (the actual *dao*). Ancient Chinese moralists had tended to treat *tian*<sup>nature:sky</sup> as the authority for their account of the correct human *dao*. “Primitivist” daoism, usually regarded as an earlier form associated with Yang Zhu (sometimes called “Yangism”) and the *Laozi* advocates being natural and rejects the social (historical or conventional *daos*). “Mature” Daoist analysis, typified by the inner chapters of the *Zhuangzi* centers on the insight that while human *daos* are normative, neither the natural nor the actual *dao* are, and that the guidance of any human *dao* depends on and presupposes natural *dao*.

Mature Daoism avers that nature does not authorize or endorse any *particular* social *dao*. This claim has two versions: pluralist and primitivist. Denying *one* is compatible with their being either *many* or *none*. The pluralist (relativist) reading of the claim takes it to entail that de facto rival practices are natural *daos* in virtue of their being actual practices. Thus, they are continuous with natural constancies. Great *Dao* versions suggest that all *actual* rival *daos* are part of Great *Dao* simply in virtue of actually being followed—*daos* are made by “walking” them. Pluralist Daoists end up vaguely associated with anarchism because they reject the Confucian-Mohist assumption that political authority exists to bring about a harmony of *daos*—making everyone follow a single *dao*.

The social world survives as well (or better) when people follow different ways of life. Focus on either *tian*<sup>nature:sky</sup> *dao* or Great *Dao* thus undermines the sense that it is imperative to impose any particular first-order *dao* on all of society.

Primitivist versions of Daoism, however, typically take the form that nature does endorse a particular normative *dao*, though not a human one. That a single, constant, correct way of life cannot be expressed or presented in practices, rules, narratives, maps, examples, songs or any other human or social form of communication and advocacy. Though we usually think in terms of one natural *dao*, there could, in principle, be multiple, equally “primitive” *daos*.

The ambiguity between these two versions is neatly expressed in the opening stanza of the *Daode Jing*: “Any *dao* that can *dao* (guide) is not constant *dao*.” Both primitive and mature versions underwrite a shared theme of harmony with nature—the pluralist seeing the point of such harmony as permissive and tolerant and the primitivist seeing it as more intolerant, as rejecting or prohibiting any conventional *dao*.

Metaphysically, Daoism is naturalistic though religious versions of Daoist primitivism evoke mystical and supernaturalist themes that remind interpreters of European, Middle Eastern, and South Asian mystical supernaturalism. The various mystical analyses, following the Indo-European model, are buttressed by an intuitive epistemology. Detaching from social *daos* means eschewing language, words, and norms of use that underwrite public discourse (reasoning) about what to do. The essential form language norms take is learned inclinations to distinguish or discriminate what is “this” from “not this.” Intuitionism advocates “recovering” the simple, primitive, pre-social dispositions by forgetting names and the attitudes that linked them to action.

Translated to the language of Indo-European rationalism, this line of reasoning treats the pluralist insight as entailing an irrationalist absolutist conclusion. It endorses the tempting illicit inference from relativism (our distinctions are “socially constructed”) to dogmatic, absolutist monism (there are no distinctions in [moral] reality). Religious and other nonphilosophical interpreters view this non-sequitur as the essence of Daoism.

## HISTORICAL OUTLINE: THE RANGE OF DAOISM(S)

Moralizing schools proposed rival *dao* (social guiding discourse) for general order. The term “Daoism” was

applied to the general reflection on what it was to propose, accept, reject, a *dao*—the epistemology, semantics and metaphysics of *dao*. This meta-focus on *dao* inclined these thinkers to a variety of metaethical positions: skeptical, relativist, and mystical. Their doubt about the goal of unifying society's *dao* and their philosophical “distancing” from direct advocacy of a normative *dao* made them seem ethically amoral and politically liberal, libertarian and even anarchistic. Zhuangzi in particular emphasized his differences with the moralists—the Confucians and Mohists.

Religious Daoism, by contrast, is an extremely broad classification of popular and/or local religions that took many different forms at different times in China are distinguished mainly negatively—by their not identifying primarily with Confucianism or Buddhism. The earliest known example was the “Huang-Lao” sect that flourished at the beginning of China's philosophical dark age induced by Qin repression and Han Confucian orthodoxy. Religious Daoism's relation to philosophical Daoism is both controversial and obscure. Daoism acquired organizational religious trappings from its interactions with Buddhism after the latter arrived in China around the second century AD. Characterizing aspects of Daoism as “religious” prior to that time is simply to draw a distinction between relatively credulous, superstitious, popular readings and more reflective, skeptical, philosophical readings of the same texts.

It is common to trace a Daoist political “ethos” to hermits who lectured Confucius against social involvement. Another way to trace Daoism's origins runs through the shadowy figure of Yang Zhu. He seems to have drawn on something like the romantic conflict between what Yang Zhu thought of as our nature (our natural mode of development) and social-political structures. We know of him mainly through the Mencius's attack on him as an egoist. Mencius reports that Yang Zhu refused to risk a single body hair to “save the empire.” The Yangist theme survives in Daoism—where it is also known as “primitivism.”

In more orthodox Chinese moralizing, Confucian and Mohist, human nature is “shaped” via our being socialized through following some *dao*—a shared guiding discourse. Primitivists resist this social shaping and seek to “restore” natural and spontaneous patterns of action. Mencius's attack probably distorts primitivism, therefore, since it arguably rejects only social or conventional *daos*, not all guidance.

The picture is further blurred by subsequent history of Daoism. These interpretive tensions became part of

the Chinese conception of Daoism in later periods. A philosophical “dark age” prior to the Han followed by the credulous Confucian orthodoxy that emerged as the “spirit” of the Han dynasty, effectively extinguished critical philosophical thought.

The autocratic rulers of the Qin and Han were highly superstitious and the courts tended toward the more authoritarian, dogmatic readings. Such readings sustain their claims of special or esoteric access to knowledge (for example, trance states induced by breathing exercises) that imperiously ignores any demand for deeper justification (for example, intuitionism or mysticism).

The Han eventually enshrined Confucianism as an official orthodoxy and the basis of the examinations that qualify one for political office. This inclined Confucian theorists to view their tradition as embracing and subsuming all other learning and treating Daoism as compatible with Confucianism. This task was made easier by emphasis on the more “religious” texts identified as Daoist. These Han texts borrowed stories, attitudes, and phrases from the two original daoist writings. Hence, the *Liezi*, the *Huainanzi*, and the *Baopuzi* were often included among the classics of Daoism.

The fall of the Han saw the emergence of a “mixed teaching”—Neo-Daoism. Its most influential writers were avowed Confucians motivated by the urge to “harmonize” the two traditions. The first, Wang Bi (c. 300) probably was familiar mainly with the Han religious echoes of Daoist thinking. He interpreted the *Laozi* alongside a cosmological divination manual, *The Book of Changes* (*I Ching* or *Yijing*). He treated *dao* as a term of creationist cosmology. *The Book of Changes* with its *yinyang* account of change and its generational cosmology thus entered the list of Daoist texts.

Neo-Daoism, in turn, eventually facilitated and informed the assimilation of the newly imported Indian Buddhism which in turn inspired the development of a uniquely Chinese form of Buddhism—Chan (Zen). This blended outlook is one major vehicle by which Daoism survived in Chinese thinking.

One could say that Daoist philosophy, per se, was successfully extinguished by imperial suppression of thought that initiated China's philosophical dark age and the institution of the Han “official Confucian orthodoxy” which cemented it firmly in place. The result is that so many religious forms are regarded as Daoist, the term may have no meaningful value in identifying a unified philosophical trend or movement.

## AN “INTERNAL” HISTORY OF PHILOSOPHICAL DAOISM

The *Zhuangzi* contains its own history of thought (Chapter 33) tracing the development of ideas leading up to Zhuangzi’s doctrine, which we *could* call “mature” Daoism. The word “Daoism” however, had still not been coined and the *Zhuangzi* history takes itself as simply tracing a movement of thought motivated by progressive attempts to remove bias and replace narrow perspectives with more impartial ones.

This “internal” account of a “Daoist” dialectic starts from a traditional baseline and takes its first step with thinkers like the Mohists (90/33/17). They question the assumption that tradition is right and seek for a neutral standard for deciding which social *dao* to use in the public moral education project. They legitimized their chosen *dao* by appealing to a standard—the intentions of *tian*<sup>nature:sky</sup>. That was equivalent to a *natural* distinction between benefit and harm (the *natural* urge to benefit and aversion to harm). This standard motivates their utilitarianism, which formed such a demanding morality that they “wore out their heels” running from state to state stopping wars, opposing despots, relieving starvation and so forth.

The next phase of the urge to impartiality leads to a version of primitivism—attempting to identify and remove the biases that socialization has instilled in the *xin*<sup>heart:mind</sup>. It is these, they argue that divide men, induce competition, fuel disagreement, and make life miserable by creating desires which can be satisfied for only a few. They targeted the obviously social desires such as status, “cultivated” tastes, honor and so on (other texts attribute related slogans to them; for example, “to be insulted is no disgrace” and “farewell to narrowness.”) The natural desires, they argued, are few and more easily satisfied. They are also universal in contrast to the cultivated desires which differ depending on tradition.

The first clear focus on the meta-nature of *daos* is then attributed to Shen Dao, Tian Ping, and Peng Meng. Shen Dao is also famous as a contributor to legalism. They started from the shared early classical assumption that we should follow a natural *dao*<sup>guide</sup>. And, like Mencius, thought of language as the paradigm of what is “unnatural.” So impartiality comes from avoiding all language—all judgment about what is *shi-fei*<sup>this-not this</sup>. They motivate this by developing a concept of “Great *Dao*”—Great *Dao* is collection of all things and all events in a kind of everything concept. It is *dao*-like because it is a process, not an object. It is the history of all objects

through all time, including the future. It “leaves nothing out.”

The various competing normative *dao*<sup>guides</sup> imply that some possible future course of events (a *way* things might go) is the one we should “walk.” To *dao*<sup>guide</sup> that *dao*<sup>guide</sup> is to recommend the future histories that result from the selected “walking.” To learn one of those *dao*<sup>guides</sup> is to learn how to contribute to bringing about some future history. While there are many such possible future histories, there is only one actual history—one actual past and one actual future. He calls that actual history of the world, that actual course of events that all things will follow, Great *Dao*. The actual is natural so the Great *Dao*, the natural pattern of behaviors, events, and processes, requires no learning, no knowledge, no language or *shi-fei*<sup>this-not this</sup> distinctions.

This conception of the actual *dao* of the past and future has a deterministic flavor. Nothing we do can “miss” the Great *Dao*. Even a clod of earth cannot miss it (HY/92/33/50). From this conception of the world as all that is or will be, Shen Dao draws fatalistic sounding conclusions—“abandon knowledge and discard self” (HY/92/33/45). Flow with the inevitable and be indifferent, make not *shi-fei*<sup>this-not this</sup> judgments. He rejects all moral (and other) teaching and just ... lives ...

The account is critical of Shen Dao’s theory: “Shen Dao’s guide does not lead to the conduct of a living man but the tendency of a dead man. It is really very strange. ... They made reversing what is human a constant value; didn’t take the common view and couldn’t avoid inconsistency. That which they called a guide was a non-guide and what they approved could not but be wrong. [They] did not know how to guide. ...” (HY 92/33/51-4). Laozi, traditionally regarded as the founder of Daoism slots into the “internal history” at this point. He, like Shen Dao, is attracted to the conception of impartiality that underlies a recommendation that we “abandon knowledge.” However, the *Laozi* does not seem to appeal to a Great *Dao* conception to justify it. Its appeal is more to “freedom” than to “determinism.” The freedom, however, is relative to society, conventions and language.

The *Daode Jing* contains a classic expression of the ancient Chinese contrast theory of names. Words come in opposites and are learned together. In learning them, we learn to divide things in one of a range of possible ways and become “blind” to alternate ways of doing it. Along with the socially sanctioned distinctions, we learn to desire in socially prescribed ways thus acquiring the society’s *dao*. Behavior motivated by this system of names, divisions and desires is called *wei*<sup>deem:do</sup> and the Laozi

advocates that we should avoid *wei-ing* (*Wu-wei* = lack deeming-actions).

Thus if we can “forget” what we learn from conventional society, we can return to natural spontaneous action—symbolized by the newborn child. The child does move, but the motions are not motivated by any conception of how to divide the world into socially sanctioned categories or conditioned, socialized desires. We recover a natural freedom that is also a much reduced level of simpler desires that will enable people to live in peace—not necessarily together because the “natural” structure of primitive desires may only support society at the level of Neolithic villages. This idyllic return is sometimes called primitivism and the *Daode Jing* contains a classic depiction of this peaceful world of agrarian villages whose peaceful, contented inhabitants lack any incentive even to visit the next door village—though they can “hear the cocks crow and the dogs bark” (Ch. 81).

This primitivism still countenances a “natural” *dao*—a prescriptive course of action that originates from *tian*<sup>nature:sky</sup> and contrasts with the artificial *daos* of moralizing society—the Confucians and the Mohists. The moralists like Mozi would also maintain that their conception of the moral *dao* was the *dao* of *tian*<sup>nature</sup>. Mencius, similarly, appeals to the normative authority of *tian*<sup>nature</sup> to justify action according to the “innate” (Confucian) moral tendencies that grow in the *xin*<sup>heart-mind</sup>. Mencius is critical of Yang Zhu, a figure often treated as a proto-Daoist who, thought he seems to have no meta-theory of Dao, is reputed to espouse a version of primitivism (which some call Yangism). Implicitly that his argument also seems to appeal to the notion of *tian*<sup>nature:sky</sup> as an authority—where the command of *tian*<sup>nature:sky</sup> is a “simpler” dictate to care for the essentials of life and abandon the dangers of political and social involvement.

In fact, despite leaving behind the deterministic tone of Shen Dao’s “Great *Dao*,” the *Laozi* is caught in a similar paradox. Shen Dao’s reasoning illustrates what is wrong with any *dao* that has blanket anti-language interpretations. His advice to “abandon knowledge” is self-refuting advice since that falls within the range of what it advocates abandoning—prescriptive doctrines. It is a prescriptive paradox—if we obey it, we disobey it. So we can continue to learn *daos* and still be natural. The deep point is that natural *daos* are irrelevant to the issues being debated by the moralists. In being natural they lose their capacity to guide. The could not warrant any particular *shi-fei*<sup>this-not this</sup> that was relevant to judging or choosing some human action. Everything that happens must be the same—either all *shi*<sup>this:right</sup>, all *fei*<sup>not-this:wrong</sup>, all both or all

neither. The crucial implication of his approach is that an injunction like “be natural” has no normative force.

So the trend of thought first recognized as forming the pattern we have come to call Daoism is one that reacts to Confucian conventionalism by trying to find a more universal, impartial point of view. It may include movements such as primitivism that seek to remove all social-conventional influence and those that analyze how conventions shape and induce our attitudes, desires and actions, and to a general interest in natural or transcendent standards or “ways” that undermine dogmatic conventionalism. The hint of paradox in the latter positions may be recognized and embraced or accepted as inescapable. The paradox, particularly of the anti-language implications of these developments led to the mature phase of philosophical daoism.

#### MATURE PHILOSOPHICAL DAOISM: THE ZHUANGZI

Classical thinkers found names and language relevant to not only Daoism. The *Analects* community of Confucianism became committed to “rectifying” names to make role-based behavior guides prescriptively reliable. Gongsun Long presented himself as defending Confucian practice with his one-name-one-thing rule. Confucians may not have wanted to claim him since he derived from this his notorious commitment to the assertability of “white horse not horse.” Mohism produced the most sophisticated of these theories—an early version of semantic realism that may have derived from reflections on Mozi’s three *fa*<sup>standards</sup> (standards) of *yan*<sup>language</sup> (language).

Mohists argued that name boundaries are determined by objective similarities and differences in things. So, against the name “rectifiers,” they maintained that a “reality” can properly be called by several names—at times general or particular. But this position, they discovered, still left many puzzles. One was this: Which similarities count in correct naming or types? The others puzzles concern how to deal with compounding of names and strings. Mohists developed no syntactical theory of word-roles such as adjective and verb. All descriptive terms that picked out parts of reality were called “names.” The way the parts combine when the words combine, however, struck them as irregular. Beyond noting and classifying some of the variation, however, Mohists did not seem to propose a systematic solution.

Zhuangzi, traditionally cited as the second daoist philosopher, engaged frequently in discussion with Hui Shi, cited as among the members of the “school of

names.” Hui Shi however, seems to represent a third posture within the school of names—name relativism. His implicit criticism of the realists emerges when he draws attention to terms that are implicitly comparative; for example, ‘large’, before, and ‘high’, and indexicals, for example, ‘today’ and ‘south.’ These do not apply in virtue of objective similarity. More theoretically, he averred that any two things, no matter how different, are similar in *some* respect, and no matter how similar, are different in *some* respect. So any two things can be included in the scope of a term in virtue of some similarity or could be placed included in a different range and named by different terms in virtue of *some* difference. Thus placement of things in a named range, even if based on similarity and difference, is not a *constant* or *reliable dao*.

Despite the relativist ground of his linguistic reasoning, Hui Shi seems to have drawn an absolutist conclusion. Since all linguistic divisions are relative, the absolute or language-independent world must be devoid of any distinctions—a mystical, unnamable, one. In effect, distinctions and differences among things are socially constructed. Since naming is based on distinctions and since language is constructed of names, Hui Shi’s ending position resembles that of Shen Dao and Laozi—the familiar, anti-language, Daoist, mystical, monism—all is an inexpressible one. From this, Hui Shi then drew a hybrid Mohist-Daoist prescriptive conclusion, “Love all things equally, the cosmos is one body.”

The Later Mohists, however, diagnosed the problem in these defeatist, negative conclusions about language and distinction-based judgment. The problem may take different forms and the Mohist diagnosis is repeated in three forms. First, distinctions are manifest in language in *shi-fei*<sup>this-not this</sup> indexicals. With a name in view, it does or does not apply to some indexically accessed item—“this” or “not this.” To have a distinction is for something to be “not-this.” So, to oppose all distinctions is to oppose *fei*-ing. However to oppose *fei*-ing is to *fei fei*-ing. Anyone who does so confronts a pragmatic contradiction. To *fei fei*-ing is to *fei*. Similarly, to deem all language as *bei*<sup>not-acceptable</sup> (not-acceptable) is *bei*<sup>not-acceptable</sup>. And since, in the context of primitivism, such views amount to rejecting learning or education in language the third form is to teach that teaching is wrong is wrong. This explains the paradox that plagued Shen Dao and Laozi and any doctrine (for example, some interpretations of Mencius) that denigrate principles or linguistic guides in general in favor of following only “natural” *daos*.

Zhuangzi takes the paradox seriously and responds first by abandoning all such anti-language claims and

appeals to *tian*<sup>nature</sup> as an authority for *dao* while, second, still sustaining his skeptical, relativist distance from Confucian convention. The trick is to note that all (actually existing) language is natural—as natural as such nonhuman sounds as the whistling of wind or twittering of birds. Humans, their societies, and their languages are products of nature as much as are ground squirrels and their high-pitched chirps.

The disagreeing human thinkers—the 10,000 distinctions and differences marked in language—are among the “pipes of *tian*<sup>nature</sup>.” Thus he avoids taking an anti-language stance while still standing as an ironic “Daoist” distance from convention. From that stance he can continue to “poke fun” at the moralists—not for pretending to express “natural” *dao* (they do) but insisting that others, their opponents, *do not*. The sense in which theirs are natural (as indeed they are) is the sense in which their opponents *daos* are natural too.

All the warring discourse *daos* are, by hypothesis, natural. How, Zhuangzi asks, can a language exist without its being acceptable (in that community) to speak it? All *dao* that are actually walked (that generate behavior) are (in virtue of having emerged naturally in a natural world) *natural*. All the *daos* that anyone may *actually* appeal to in condemning rival *daos* must exist—and hence be natural. This does not entail that all *possible daos* are natural, but all existing and, no doubt, *many* that don’t exist, are natural in the sense they have or might emerge in nature—for example, without any supernatural intervention.

This allows Zhuangzi to continue Daoism’s trend of detachment and ironic neutrality in the fervent debates among the moralists. He also generalizes earlier themes (noted above) of how different *daos* shape our attitudes, our desires, and our descriptive language. This generalization emerges with a hint of mild skepticism. The anti-language position is an error position—all doctrines of morality/reality are false. The Mohist paradox undermines that. We cannot consistently conclude that no claims in language are correct. Neither can we claim that all linguistic utterance is correct since judgments according the standards of one natural language conflict with those of another. Each treats its own use as acceptable and others an unacceptable.

Each position in debate about *dao* depends on presuppositions—a presupposed *dao*. The *dao* is the *way* of speaking that language. An argument for one *dao* over another, also presupposes an implicit *dao*—a *way* of choosing which *dao* to follow in a situation. And even when we have selected which *dao* to follow, we may disagree about how to interpret our agreed *dao*. A way of

interpreting *this dao* is still another presupposed *dao*. When we perform any *dao*, we perform an entire hierarchy of *daos*.

Thus, winning an argument doesn't give one assurance of being right *simpliciter*—it presupposes some way of picking a winner. There is no completely *neutral* way of assigning a right and wrong. Zhuangzi's skepticism is not based on contrasting human cognitive weakness with some ideal perspective, but draws on the infinite regress of standards involved in guidance by a way, a *dao*. It is skepticism because it doesn't deny we might have acted rightly, only that we cannot know in ways that we could, correctly show others is correct (that is move as judged from their *daos*). Skepticism in the *Zhuangzi* rests on the observation that we cannot be sure we are using the right standard of "knowing."

Zhuangzi expresses another aspect of the same point. Consider the standard objection to "Ideal Observer" theories of morality (eg. Right = if what some God-like judge would judge to be right). The objection goes that what the Ideal Observer should do is irrelevant to my decision about what I, an ordinary observer, should do. The *Zhuangzi* frequently reflects on the theme of how a perfect perspective is neither useful nor comprehensible to us. What God should do is wildly irrelevant to the real practical questions that confront us. We could neither understand nor use the answer to "What would a perfect person do?"

This leads in two ways back to the naturalism characteristic of Daoism. Not only are *actual* conventions natural, but there is a natural *dao* that both guides the selection (evolution) of conventional *dao* and guides the interpretation of them. Thus, the *Zhuangzi* argues that there is no way to disentangle the realm of *tian*<sup>nature:sky</sup> and the realm of *ren*<sup>human</sup>—no way to ground the claims of moralists or mystics to have found *the* single naturally correct way.

## THE FATE OF DAOISM UNDER THE EMPIRE

Philosophy in China suffered a dark age initiated in the third century BC by the emergence of the imperial structure under a totalitarian ideology. Authoritarian misgivings about the tendency of philosophers to cast doubt on conventional ways of making distinctions and the assumed political goal of unifying the social world under one *dao* motivated this political authoritarianism. Paradoxically, most would say the Qin favored Daoism since the superstitious rulers sought in it the "secret of long life." This, of course, served rather to replace Daoism's philo-

sophical reflections with credulous religious dogma and the interpretation dominant in "legalist" commentary. The Qin dynastic family and its so-called "legalist" *dao* of governance lasted only one generation. However, the institutional structure survived in the Han which anointed Confucianism as the unifying *dao*.

This totalizing position led Confucianism to an eclecticism which sought to embrace everything from royal superstitions to naturalistic cosmic forces (yin and yang) and ground them in a Confucian *dao* that they could use to manipulate the ruler. Confucians assured us that this moralized cosmology "incorporated Daoism" harmoniously with Confucianism, implying that Daoism entailed the superstitious yin-yang cosmology they had worked out. Several new "Daoist" texts emerged which mixed quotations from the *Zhuangzi* and this moralized yin-yang cosmology. These further tended to shape the accepted interpretation of Daoism to better suit the bureaucracy's purpose.

The stasis of a naturalized Confucianism and a cosmologized Daoism survived with slight variation until the modern period. The main interruption was the importation of Buddhism, which continued the stable institutional model and the tendency to eclectic blending into a single harmonious officially recognized *dao*. Imperial rule tended always to patronize some "approved" eclectic ideology. In such contexts, the critical and skeptical quality of thought of the classical period never re-emerged.

The fall of the Han brought with it a crisis in confidence in this cosmic Confucianism. This did little to disrupt the assumption of fundamental compatibility of Daoism and Confucianism, but did lead to greater focus on the classical Daoist philosophical texts. The result has been called Neo-Daoism, though the main thinkers identified themselves as Confucians. They inflated the cosmic interpretation of Daoism into something closer to pure metaphysics (via its explicit interest in the contrast of *being and non-being*). The result was a holistic "round" metaphysics with *non-being* at the core (basic *non-being*) and "being" as the periphery (functionally oscillating fluctuations in the field of "*non-being*").

The main point of controversy within Neo-Daoism was whether the *non-being* was really nothing or really "something." From there the philosophical level of Daoist discourse declines more than advances. Wang Bi interpreted the *Laozi* in tandem with a cosmological divination manual, the *Yi-Jing*, into what he assumed was a single system. *Non-being* was the basis of everything, the great-ultimate that was also the non-ultimate. Wang Bi

explained the dynamic between *non-being* and *being* not as causation, but as the relation of “substance and function.”

Guo Xiang interpreted the *Zhuangzi* giving us the received version and conforming to the outlines of Wang Bi’s system except for his Parmenidean insistence that *non-being* simply was not. This he coupled with a radically un-Parmenidean view that *being* constantly changed “of itself.” The Neo-Daoist systems were the originating models of the puzzling substance-function dualism that re-appeared regularly in most later philosophical systems, both Buddhist and Neo-Confucian, right up through modern times.

Neo-Daoist speculations on *being and non-being* helped facilitate early discussions of Buddhist philosophy—particularly the puzzle of the nature of Nirvana (and thus of the Buddha-Nature). Buddhism, however, brought with it the apparatus of monastic ecclesiastical authority that bequeathed more familiar religious structures to the existing fragments of “Daoist” superstition. The resulting religious movements are what survived the Buddhist period into modern times as what the West came to know as “Daoism.”

## KEY DAOIST CONCEPTS

This section explores two concepts that play a central role in Daoist philosophy—*dao*<sup>guide</sup> and *de*<sup>virtuosity</sup> (virtuosity). Together the terms have come to mean something like “ethics.” We, however, take them to be the basic concepts of a broader notion of normativity. The normativity is broader because there can be a *dao* (and *de*) of language (correct way of use) of knowledge (ways to know) as well as to act.

DAO (WAY, GUIDE, ROAD). The main characteristic that justified Chinese historians in identifying a school to call Daoism is philosophical interest in the concept of *dao*. The almost universally accepted translation is a primitive of English—“way.” So it subsumes “manner,” “course,” “technique,” “system,” “fashion,” “custom,” “style,” “practice,” “tradition,” “discipline,” “road,” “direction,” “path,” and so forth.

A way is an answer to a “how” or “what-to-do” question. We typically use talk of ways in advising someone. Ways are thus *practical* (prescriptive or normative) concepts. A road, as a concrete (or asphalt!) example guides us and facilitates our arrival somewhere. Ways are prescriptive structures that have physical realizations. We can refer to the physical forms as ways or *daos* without thereby recommending them. The *Zhuangzi* reminds us

that thievery has a *dao*. We can use both *dao* and “way” simply to describe—as when a Confucian undertakes to pursue his father’s *dao* for three years after his death or we say, “I saw the way you did that.”

There are interesting differences between *dao* and “way.” Classical Chinese language lacks pluralization; for example, not simply has no plurals, but has no grammatical role for plurals. Most common nouns function like collective nouns, roughly analogous to plurals or mass nouns of English. So *dao* is more like “ways” or “way-stuff” or “the way-part or aspect of things” than it is like “a way.” Like other common nouns, *dao* has a part-whole structure, that is additive—two parts simply yield a larger part of the same thing. What we describe as one way would function like one part or component of what in Chinese we call *dao*. Multiplicity in common nouns in ancient Chinese emerges via modification. So they might discuss, for example, *my-dao*, *Sage-King’s-dao*, *natural-dao*, *past-time’s-dao* and so forth. This feature explains why *dao* might appear more *metaphysical* than “way” and helps appreciate familiar Daoist spatial metaphors like “humans encounter each other in *dao* as fish do in water” (*Zhuangzi* Ch. 6). *Dao* is a little like the water—a feature of the realm in which humans live, work, and play. To be human is to be in a framework of ways to act, go, and speak. So-called Daoists are more likely to play with these metaphysical metaphors than Confucians or Mohists—who mainly point to (their favored part of) *dao*.

A second difference is that unlike “way,” *dao* may be used as a verb. The best-known example is the famous first line of the *Daode Jing*. Literally “*dao* can be *dao* not constant *dao*.” For the middle *dao*, roughly one out of three translators uses “speak,” another third use “tell” and the rest use near synonyms such as “expressed,” “defined in words,” or “stated.” In a famous Confucian example of this use, Confucius criticizes *dao*-ing the people with laws rather than *dao*-ing them with ritual. (This verbal sense is often marked by a graphic variation *dao*<sup>to direct</sup>.)

“Speak” is in some ways too narrow and in others too broad as a way translating this verbal use. It is too broad because in Western tradition, speaking is conventionally linked to describing, representing, picturing, expressing, defining, or “capturing” some reality. The Chinese verbal use resembles more what a European would express by “advocate” “acknowledge” or “recommend,” for example, to “guide-speak.” To *dao* is to put guidance into language. *Dao*-ing is giving advice.

“Speak” is, in other ways, too narrow. One can *dao* in written form or even by example—as when we *dao* with law or with ritual (texts or exemplars). Consider, again,

the concrete translation for *dao*: “road” or “path.” A woodsman with an ax *daos* when he chops bark from the trees as he enters the forest; He is *dao*-ing when he is “blazing” the trail. As the *Zhuangzi* notes, “A *dao* is made by walking it.”

What a road shares with a pattern of blazes in a forest is that both, like maps and verbal instructions, can serve as normative guides. What they also share, is that they require *reading* and *interpretation*. In following any kind of *dao*, we “interpret” it. This might be hard, as when we interpret blazes in bark, or piles of stones left by boy scouts or a Hansel’s string of bread crumbs or the two-days-old tracks left by a deer. Or it may be relatively easy, as when I follow the asphalt ribbon between my house and the store. These examples should illustrate the symbolic guiding nature of all “roads.” To interpret a road/path/*dao* is to extract guidance in the form of an actual “walking,” not to develop a theory or belief. This use of “interpretation” is more familiar in artistic contexts—in music, dance, or drama. The interpretation of a score, line or character in a play consists in a performance of it.

The metaphysics of *dao* should mark this distinction between normative way *types* (treated as guides) and interpretive tokens (the result of practically interpreting a guide). The token is an actual history, a string of actions. The token may itself be *taken as a guide* (that is as an exemplary model), but in that case, it in turn requires interpretation. There are various *ways* to follow the example. We have to extrapolate from the exemplar’s situation to our own. So the distinction between type and token ways can be relative; it is actually a distinction between normative and descriptive senses. When we treat a token as subject to evaluation relative to some normative *dao*-type, it is descriptive. When we treat it as a *model* guiding our own performance, it is normative.

This should help us understand the notion of natural *daos*. Roads and ways need not be human constructions. Nature’s “engineers,” deer or mountain goats, also make paths. Famously animals from ants to pack rats, swallows to dogs make or mark and read their own ways. Other species may read and use these as humans do when lost in the mountains. Other “ways” are pure natural possibilities of sequences that will result in attaining a goal; for example, their being a way through a forest or across a river. That way consists of their being a fallen log or several large stones in a fortuitous configuration—fortuitous, that is, from the point of view of human actors. We discover these structures in nature as we “feel our way”

along. We may learn to read natural signs and exact guidance from natural clues better over time.

However, the concept of a naturally constant *dao* threatens to follow the Great *Dao* into losing its normative role. The *Zhuangzi* recognized this danger most clearly in pointing out that all recommendations (all prescribed *dao*) are *natural* in virtue of actually being advanced and promoted. Nature—the structure of natural constancy—does not select any of these. Any selection requires a *dao* interpreter and interpreters select using different standards—higher-level *daos* of selection and interpretation. Thus, while some *daos* are impossible, the appeal to nature does not adjudicate among any actual rival formulations, such as those of Confucians versus Mohists. Nature does not evaluate or prescribe its possibilities. Like the Great *dao*, they just are.

DE (VIRTUOSITY, VIRTUE, POWER). A Daoist formula for *de* is “*dao* within.” Translators most commonly use “virtue” as a translation but hurry to remind us that it is “virtue” in the ancient Greek sense of an excellence. “Power” can work as an alternative translation because it reflects the link between *de* and successful action or achievement for its possessor. This author prefers “virtuosity” to capture both the sensitivity to context and *fit* and to remind us of the aesthetic features of these normative concepts. Virtuosity is the capacity of a performer to “interpret” a score-like *dao* into a *superb* performance (in that theater, for that audience, and so forth). Thus *de* is the capacity to perform *dao* correctly—successfully, beautifully, and well.

Daoist reflections on *de* sometimes point to “natural” or prelearned capacities to learn or perform some *dao* with skill. Think of Wittgenstein’s talk of the unexplained human ability to catch on and continue the correct grammar of a human language. This stress sometimes suggests the hardwiring or the machine language translation required to implement or interpret other programming. While many Daoist comments may be taken to refer to such “natural” skills, the concept of *de* itself seems to include *de* that is acquired in the process of learning, internalizing, practicing, and fine-tuning our performance of some *dao*.

Natural *dao* is presupposed in learning social *daos* in a number of ways. There is a natural way humans learn to acquire and perform normative *dao* and there are different ways to perform in different natural contexts. There are both natural and social-practice ways to select which *dao*-type to execute and multiple ways to evaluate the performance-generated *dao*-tokens. So, as *Zhuangzi*

observes, we live so pervasively in such a “sea” of *dao* that, like fish in water, we forget that we forget *dao* as we swim around it.

## ETHICS

The first recorded dynasty in Chinese history is the Shang (1766–1050 BCE). It came to an end when the Zhou family overthrew the Shang and justified its act on the grounds that the Shang kings had become corrupt and forfeited the right to rule conferred by the ruling force of the world, *tian* (which literally means "sky" and is usually translated as "Heaven"). Although the Zhou kings claimed validation by Heaven, their rule declined in the time of Kongzi (551–479 BCE; better known in the West by his Latinized name Confucius), entailing a breakdown

of the social, political, and moral order. The dao, the way or path, that the Zhou claimed to possess was lost. As Angus C. Graham (1989) puts it, the primary question of the age was: Where is the dao? Whoever could rediscover it could regain the *de*, the human power and excellence, that enabled the early Zhou kings to create the golden age of harmony and flourishing that was lost. Each philosophy of the ancient period provides its version of the dao.

## CONFUCIAN ETHICS

Benjamin Isadore Schwartz (1985) characterizes the Confucian dao as emphasizing respect for rightful authority, where the rightfulness of authority is based on the achievement of ethical excellence. Confucianism is a virtue ethic because of its central focus on three interrelated subjects: character traits identified as the virtues; the good and worthwhile life; and contextualist modes of ethical deliberation. The virtues are traits of character that are necessary for living a good life and that typically involve judging in the context at hand what must be done. The virtues belong to the *junzi* (the noble person, most often translated as "gentleman"), who is living in accord with the dao. Such a person can be said to have realized in a high degree the overall ethical excellence that befits human beings.

Consider the virtue of *ren*. In 12.22 Kongzi identifies *ren* with loving or caring for people. Understood in this way, *ren* is one particular virtue among a number possessed by the *junzi* such as wisdom and courage. Translators such as D. C. Lau (1979) focus on this meaning of *ren* and translate it as "benevolence." However, *ren* has a much broader meaning in the *Analects* (but perhaps not in the *Mengzi*, where it seems restricted to the meaning of a particular virtue). At a number of places, *ren* is associated with an array of different virtues: for example, the observance of ritual in 3.3, and sympathetic understanding of others in 6.30. In fact, *ren* seems so closely associated with the ideal of the *junzi*, or morally noble person, that it seems to stand for complete human excellence.

A virtue distinctive of the Confucian ethic is that of ritual observance or ritual propriety. In the *Analects* the rituals (*li*) include ceremonies of ancestor worship, the burial of parents, and the rules governing respectful and appropriate behavior between parents and children. In general, the *li* in the *Analects* are ceremonies or customary practices that express one or more of several ethically significant attitudes: reverence, respect, care, gratitude, and a feeling of indebtedness. Later, the word came to cover a broad range of customs and practices that spelled out courteous and respectful behavior between people occu-

pying specific social stations. Herbert Fingarette (1972) argues that this emphasis on ritual propriety conveys the profound insight that ceremonies, customs, and conventions constitute much of what is distinctive about human activity. A handshake means nothing unless understood against a background of conventions that establish the relevant physical movements as a way of greeting another person. So too, many of the ways of respecting and expressing care or gratitude toward others are possible only because they have been conventionally established as ways to express those attitudes. This implies that *ren* as complete human excellence cannot be understood as something separate and independent from *li*.

As Kwong-loi Shun (1993) points out, however, this does not mean that *ren* reduces to any given set of practices adopted by a community, since alternative practices in a different community might be devised to express the same ethical attitude or there might be nonconventional means of expressing that attitude. *Li* also are portrayed in the *Analects* as crucial for the project of ethical self-cultivation: dedicated observance of the rites, along with a sincere commitment to have the appropriate attitudes they are conventionally established to express, are crucial for developing and strengthening the dispositions to have those attitudes. Sincerely engaging in a ritual that is conventionally established to express reverence for parents or ancestors makes stronger the disposition to revere. Finally, there is an aesthetic dimension to the ethical importance of *li*. One is more or less graceful and elegant in the performance of *li*. One has made such observance more or less a second nature, from which it flows effortlessly and spontaneously. One who is so accomplished lives a life of beauty, and this is part of the *junzi* ideal.

The concept of *yi* refers both to that which is right or appropriate for the given situation and to the trait of character that consists in reliably identifying and acting on what is right. The *Analects* 4:10 says that the *junzi* is not predisposed to be for or against anything, but goes with what is *yi*. As Antonio Cua (1998) points out, traditional rules of ritual propriety provide one with a sense of what is courteous and respectful action given standard contexts, while the virtue of *yi* allows one to identify when those rules need to be set aside in exigent circumstances. In 4A17 Mengzi (371–289 BCE; better known in the West as Mencius) observes that to save the life of one's drowning sister-in-law one must suspend the customary rule of propriety prohibiting the touching of man and woman when they are giving and receiving. When his interlocutor wants to apply this idea of suspending the usual rules of propriety to save the entire country from

drowning, Mengzi replies that one saves one's sister-in-law with one's hand but cannot save the country from drowning in chaos and corruption with one's hand. The country can only be pulled out by the *dao*.

This passage not only illustrates that one may have to set aside customary rules of propriety in exigent circumstances but also that analogy is a way to judge what is *yi* for the situation at hand. One starts with a case where the judgment seems right (touching the sister-in-law when she is drowning) and attempts to transfer a like judgment to a like situation. One can also criticize an analogy by pointing out a relevant unlikeness between the two cases. One cannot save the country through violations of ritual propriety, but only through setting it back on the *dao*, which itself may require one to observe propriety on many occasions.

The term *de* is used to refer to the power or excellence that a thing can achieve when it acts according to the *dao* for things of its kind. One who gets or attains the *dao* and achieves virtues such as *yi* achieves a power or excellence appropriate to things of one's kind. In the *Analects* the human *de* that is *ren* brings with it a power to influence and attract other people and even the surrounding environment. Human *de* is a kind of moral charisma that comes with the achievement of the virtues just discussed and can be possessed by any good human being, but when it appears in rulers, it allows them to command others without appealing to physical threats (as Edward Slingerland [2003] points out, such an ideal may manifest the theme of *wu-wei*, or effortless action, which is traditionally associated with the daoists). The Confucian prescription for bringing China back to the *dao* is partly based on this belief in *de* as possessed by rulers and in the strategy of Confucian scholars offering their moral advice to rulers.

Western interest in Confucianism rests on reasons that are similar to those underlying the enduring interest in Western virtue ethics. Those who are skeptical of the modernist ambition to construct ethical theories around general principles of action, seeing them as too vague and abstract to provide much guidance on the one hand, and too reductivist to capture the rich array of ethical considerations on the other hand, turn to the ancient ideals of good character and judgment that are sensitive to context. Virtue ethics also tend to embody the theme that the ethical life of right (and in the case of Chinese and contemporary Western virtue ethics) caring relationship to others is necessary for human flourishing. In the *Mengzi* this theme emerges in identification of the distinctively

human potentials with the incipient tendencies to develop the moral virtues.

At the same time, Confucian ethics is distinctive for the centrality it gives to family life in its conception of the good life. Part of the reason for this centrality lies in the Confucian appreciation for the family as the first arena in which care, respect, and deference to legitimate authority is learned (*Analects* 1.2). The way in which particularist reasoning is illustrated in historical stories such as those about Shun is also a distinctive feature of Confucian ethics. These stories present paradigms of good judgment and of good individuals, from which persons engaged in ethical self-cultivation should learn through analogy with relevantly similar situations in their own lives. Those who hold that much moral learning and reflection is accomplished through the telling of and listening to stories and other narratives have reason to study Confucianism. Another distinctive feature of Confucian ethics, as mentioned earlier, is the emphasis it gives to rituals as providing much of the distinctive substance of human life, as a necessary dimension of moral self-cultivation, and as contributing to the aesthetic dimension of the good life.

Mengzi and Xunzi (313–238 BCE) engaged in a vigorous, provocative debate over human nature and whether there are natural tendencies that form the basis for development of a good person. Mengzi holds that there are innate moral concepts that infuse intuitive judgments and feelings (people spontaneously feel compassion for a child about to fall into a well; a beggar knows intuitively to reject food that has been thrown on the ground and trampled on). Xunzi holds that human nature is dominated by the desire for gain and sensual gratification and that rather than having a natural basis, morality is invented to prevent the destructive conflict caused by people acting from their natures.

The contrasting ways in which Mengzi and Xunzi portray moral development raise important issues about the relation between reasoning, feeling, and moral judgment. Mengzi tends to portray moral perception, reasoning, and feeling as working in concert in ways that call into question any strict separation between perception and reasoning on the one hand and feelings such as shame and compassion on the other (Wong 1991, 2002). By contrast, Xunzi holds that the mind has the power to shape and retrain its desires and feelings, but his portrait of moral development seems to presuppose appropriate cognitive and affective elements that form the base for such reshaping (Van Norden 1992, Wong 1996). Taking all these distinctive features together, it is fair to say that Confucianism offers an especially rich moral psychology

that Antonio Cua (1998, 2005), Philip J. Ivanhoe (2000), David S. Nivison (1996), and Shun (1997) illuminate.

Another respect in which Confucianism differs from modern Western moral theories bears especially on the cross-cultural comparison of values. Confucian morality lacks a focus comparable to that found in modern Western moralities on individual rights to liberty and to other goods, where the basis for attributing such rights to persons lies in a moral worth attributed to each individual independently of what conduces to individual's responsibilities to self and others. Confucianism rather assumes that the ethical life of responsibility to others and individual flourishing are inextricably intertwined, and in such a way, Craig Ihara (2004) argues, that the individual's dignity is honored without resort to the concept of rights. A frequent Western interpretation of Confucian ethics is that it subordinates the individual to the group. David L. Hall and Roger T. Ames (1998) respond that this interpretation erroneously presupposes that the individual and community are potentially at odds in ways the Chinese tradition does not conceive them to be. The nature of the individual is conceived relationally, they argue, so that it is just plain wrong to have the Chinese separating the individual from the group in the first place, much less subordinating the individual to the group.

Another frequent criticism from the Western side is that Confucianism fails to provide adequate protection to those legitimate interests an individual has that may conflict with community interests. On the other side, Henry Rosemont (1991) criticizes rights-focused moralities for ignoring the social nature of human beings and of portraying human life in an excessively atomistic fashion. Against those who argue that Confucianism does not sufficiently protect the individual, Rosemont (2004) replies that the Confucian framework of responsibilities to others can afford significant economic and social protections to the individual and arguably addresses the human need for community and belonging better than rights frameworks.

Moreover, it is arguable that rights in some sense can play a role in the Confucian tradition, even if such rights are not grounded in the idea of the independent moral worth of the autonomous individual. Within that tradition, Joseph Chan (1999) argues, rights might function to protect individuals' interests when the right relationships of care irretrievably break down. Furthermore, rights to be protected in one's speech can receive a Confucian justification as conducive to the health of the community. Mengzi advised kings to attach more weight to the opin-

ions of their people than to those of their ministers and officers in making certain crucial decisions. Xunzi recognized the need for subordinates to speak their views freely to their superiors. If one carries the reasoning in Mencius and Xunzi one step further, one sees the need to protect a space in which they may speak freely without fear of suppression, and hence derive a right in the “thin” sense of what one has whenever one has justifiable claims on others to assure one’s possession of things or one’s exercise of certain capacities (Wong 2004).

That there are developments of each tradition that bring each closer to the other may suggest that each could learn from the other. One might worry about the kind of individualism that prompts citizens in affluent nations such as the United States to tolerate gross inequality of opportunity. One therefore might look to a tradition that appreciates the way people thrive or falter within specific communities that nurture or shut them out. On the other side, a tradition that has tended to value the idea of social harmony at the cost of sufficiently protecting dissenters pointing out abuses of power or just plain bad judgment by authorities would do well to look at enduring traditions that do not value social harmony as highly.

### MOHIST ETHICS

Mozi (470–391 BCE) is said to have begun as a student of Confucianism and eventually came to reject it in favor of a consequentialism that in important respects anticipates Western utilitarianism by two millennia. While Confucians saw the problem with China as loss of respect for authority and a related loss of moral basis for authority, Mozi saw the problem as partiality. Heads of families knew only to love their own families and mobilized their families to usurp others. Lords knew only to love their own states and consequently mobilize their own to attack others. Such partiality causes destructive conflict that harms everyone, so the proper conclusion is to override one’s own tendencies to partiality and to practice *jianai*, sometimes translated as “universal love” but arguably better translated as “impartial concern.”

Schwartz (1985) points out that *ai* in the *Mozi* means neither *Eros* nor *agape* but something closer to a concern for all that is justified on the basis that its practice advances one’s own welfare and the welfare of those to whom one is partial. The doctrine of impartial concern, when combined with Mozi’s emphasis on evaluating beliefs according to the benefits and harms that result from them, qualifies him as a kind of utilitarian. His is not, however, a hedonistic or welfare utilitarianism of the kind most commonly represented in the Western tradi-

tion. His conception of benefit and harm refers to no psychological goods and harms such as pleasure and pain but exclusively to material goods and harms such as enriching the poor, increasing the population, and bringing about order.

Because he advocated impartial concern, Mozi had no use for the Confucian doctrine of graded concern: that the degree of one’s concern should depend on the nature of one’s relationship to the person in question (one’s family being owed the most concern). Because he relied on pragmatic appeals to people’s existing interests to justify his moral position and because he took the rationalist position that people should have no trouble doing what they see to be in their interests, he saw no use for Confucian ritual as a mode of moral self-cultivation.

The traditional attitude toward Mozi is that he was a relatively minor philosopher, but that is changing. His criticism of Confucian-graded concern and his advocacy of impartial concern is of broad interest and raises the question of how to fit within a coherent moral framework the special concern parents and children ought to have toward one another with the universal and equal concern one ought to have toward all persons as persons (Wong 1989). Moreover, Chad Hansen (1992) argues persuasively that Mozi’s vigorous argumentation against the Confucians constituted a pivotal point, after which subsequent Confucian thinkers such as Mengzi and Xunzi had to defend Confucianism with argument. Mozi was unique in developing explicit standards for argumentation, and his school developed a distinctive focus on questions of logic, argumentation, and philosophy of language.

### DAOIST ETHICS

The two great daoist texts of the ancient period are the *Daodejing* (Book of the way and its power; traditionally but dubiously attributed to the historical figure Laozi, c. sixth century BCE), and the *Zhuangzi* (a good part of the first seven chapters, the so-called inner chapters, was probably written by the historical figure Zhuangzi, c. 360 BCE). It may seem paradoxical to write of daoist ethics, but daoism thrives on (apparent?) paradox. On the one hand daoism expresses strong skepticism about distinctions between good and bad, right and wrong. On the other hand it also makes recommendations that add up to putting forward a way of life. Joel J. Kupperman (1999) observes that the *Zhuangzi* commends a way of life that does not take oneself and one’s ideas so seriously.

The way of life commended in the *Zhuangzi* also includes openness to what might escape one’s current

conceptualizations and preconceptions. One is invited to see that one's conceptualizations of the world are inevitably incomplete and distorting. One attempts to order the world by sorting its features under pairs of opposites, but opposites in the real world never match neatly with one's conceptual opposites. Real "opposites" escape one's attempts to cleanly separate them. Despite one's best efforts, they switch places in one's conceptual maps, blur, and merge into one another. That is why chapter 2 of the *Zhuangzi* says that the sage recognizes a *this*, but a *this* that is also *that*, a *that* that is also *this*. In chapter 5, men who have had their feet amputated as criminal punishment are scorned by society, but not by their daoist masters, who see what is of worth in them. In fact, both the *Zhuangzi* and *Daodejing* express an underlying suspicion of the needs that evaluative judgments serve; it is precisely to dominate or to undermine others that one subsumes them under the disfavored halves of one's value dichotomies.

The *Zhuangzi* further emphasizes the need to accept the inevitable in human life, the need to manage one's desires to achieve tranquility in the face of the inevitable, and to identify with the world that makes acceptance and management of desires possible. Both the *Zhuangzi* and *Daodejing* commend *wu-wei*, literally translated as "non-action," but meaning something like unforced acting with the grain of things. It is a style of action that consists in being receptive rather than aggressive, following from behind rather than leading in front, accommodating rather than confrontational, and being flexible and ready to change with the situation rather than rigid and operating from general predetermined principles. Seeing what is of worth in people and getting attuned to the grain of things are themes that stand in tension with the skepticism expressed by both the *Zhuangzi* and *Daodejing*, and one of the central interpretative problems is how to reconcile them (Hansen 1992, Kjellberg and Ivanhoe 1996, Wong 2005).

The *Zhuangzi* addresses such recommendations largely to the private individual who has become disaffected with the popular striving after conventional success and with the earnest moral idealism of the Confucians. By contrast, the *Daodejing* often addresses its recommendations to rulers, and even when it does not it expresses a primitivist social philosophy that holds that humanity was at its best when its desires were the fewest and when it did not guide itself through self-conscious valuing. Chapter 19, for example, says, "Exterminate the sage, discard the wise, and the people will benefit a hundredfold; exterminate benevolence, discard rectitude, and

the people again will be filial; exterminate ingenuity, discard profit, and there will be no more thieves and bandits" (Lau 1985, p. 23). The rejection of conventional success and earnest idealism is here paired with the promise that if one stops trying to impose one's will on others (along with the usual value dichotomies) one may actually result in the ends one originally hoped to achieve.

What is interesting about *wu-wei* as applied to political leadership, as Michael Lafargue (1992) points out, is that it implies an organic notion of social harmony that contrasts with the conception of harmony as imposed by a dominating person who stands out from the rest of the group. A leader in an organic social group models the kind of self-effacement and sparseness of desire that all members should have. One suspects that such a leader must do more than model to be effective, but the *Daodejing* does not dispense specific advice or strategies. It rather provides metaphors from nature about the strength to be found in water and in valleys, associated with the female, that can overmatch the strength to be found in rock and in mountains, associated with the male.

In the *Daodejing* both the skepticism about the adequacy of conceptual structures and the confidence in *wu-wei* have traditionally been thought to be rooted in a monistic vision of the universe that is centered on the notion of the dao. Consider chapter 4 of that text where the dao is described as being empty, as seeming something like the ancestor of the myriad of things, as appearing to precede the Lord (*di*). In chapter 1, the constant dao is characterized as nameless, and the nameless is the origin of Heaven and Earth. Insofar as it is named, one could call it the mother of all things. The dao of the *Daodejing* might be the indeterminate ground in which determinate things are incipient, as suggested by Robert Neville (1989). Chung-ying Cheng (1989) suggests that the embrace of an indeterminate ground of the determinate may reflect the decision to give the phenomenon of change a fundamental place in ontology, rather than an absolutely stable being as in Parmenidean ontology and as later reflected in Aristotelian and Cartesian notions of substance. One reason for a continuing Western interest in Chinese metaphysics has partly been fueled by the perception that contemporary physics has undermined the strategy of giving determinate being ontological primacy.

## BUDDHIST ETHICS

In Chinese strains of Buddhism, especially Chan Buddhist texts such as the *Liuzu tanjing* (Platform sutra of the

sixth patriarch) by Huineng (638–713), there is also a sense that evaluative categories cannot reliably order the world and the confidence that one can become attuned to the world so as to move with its grain. This is not surprising since daoism profoundly influenced Buddhism on its importation into China. However, Buddhist ethics is distinguished by its special emphasis on the elimination of suffering and on the way it explains suffering by referring to the human attachment to the self as a fixed ego entity. The Buddhist scripture, *The Questions of King Milinda* (Conze 1959), articulates a view of the self as based on nothing more than a floating collection of various psychophysical reactions and responses. Contrary to the folk belief, there is no fixed center or relatively unchanging ego entity. One's bodily attributes, various feelings, perceptions, ideas, wishes, dreams, and in general a consciousness of the world display a constant interplay and interconnection that leads one to believe that there is some definite *I* that underlies and is independent of the ever-shifting series, but there is only the interacting and interconnected series.

In Buddhism, this view of the self has deep practical implications. It points toward the answer to human suffering, which ultimately stems from a concern for the existence and pleasures and pains of the kind of self that never existed in the first place. The recognition that none of the "things" of ordinary life are fixed and separate entities, anymore than the self is, leads to recognizing all of life as an interdependent whole and to the practical attitude of compassion for all of life. One can only be struck by the similarity between the Buddhist view of the self and David Hume's doubts in *The Treatise of Human Nature* about the existence of a unitary and stable self. Such a conception of the self may lay claim to one's renewed attention because it fits better with a naturalized conception of human beings as part of this world and not as Cartesian-thinking substances that somehow operate apart from the rest of nature. Consider also Derek Parfit's (1984) argument that acceptance of a Humean or a Buddhist view of the self can lead to sense that one is less separate from other selves and to a wider concern when one's projects seem not so absolutely different from other people's projects. Some might see Buddhist impersonal concern as unreasonably demanding of human beings who are so strongly partial to themselves and their own (a criticism made of utilitarianism also), but as Owen Flanagan (1991) argues, that Buddhism is a vibrant and long-lived tradition with many committed practitioners provides some support for the viability of impersonal concern as an ideal that is capable of claiming allegiance and influencing how people try to live their lives.

Another concern some have about Buddhist ethics is that it appears to advocate a dampening of desire and attachment to things and people. Attachment and clinging to the impermanent is deemed the root of suffering. There is a similar vein of thought in daoism, but combined with a more complex attitude that allows attachments to remain in a transformed state, allowing one to accept the death of a loved one as part of the process of change that one embraces and even celebrates. Chapter 18 of the *Zhuangzi* portrays its namesake as sobbing on the death of his wife, but stopping and even turning to drumming on a pot and singing after he realizes that his wife has gone to become a companion to spring, summer, autumn, and winter. This more complex attitude also surfaces in Buddhism, and not surprisingly in Chinese versions of it such as Chan (later becoming Zen in Japan), where it is stressed that enlightenment is to be found in the ordinary, in one's life here and now, not in a rejection of or escape from this life.

#### NEO-CONFUCIAN ETHICS

The neo-Confucian Zhuxi (1130–1200) reinterpreted ethical themes inherited from the classical thinkers and grounded them in a cosmology and metaphysics, partly as a response to the growing influence of daoism and Buddhism in his time. The dao or way of Heaven is expressed in principle (*li*, not to be confused with the *li* that means ritual propriety). It is embedded in something like the indeterminate ground of the daoists, but results in the myriad of determinate things when it is sheathed in *qi*, the material energy stuff of the universe. This sheathing, however, also results in base emotions and conflict. The task of human beings is to return to their own original goodness through purification of *qi* so that *li* can be expressed, an idea that is similar to the Buddhist theme that the Buddha nature is present in all things and that enlightenment is attained through purification of that nature. Another great neo-Confucian, Wang Yangming (1472–1529), seems more pragmatic than metaphysical. He taught of the sage who formed one body with Heaven and Earth and the myriad things, but he showed little of Zhu's interest in the *li* or principle of existent things, focusing rather on the rectification of the base thoughts of the mind.

#### THE LEGALIST CRITIQUE OF AN ETHICS-BASED APPROACH TO GOVERNMENT

Confucian, daoist, and Buddhist ethics recommend in one way or another the project of self-cultivation result-

ing in significant self-transformation, even if the basis of such transformation is present in human nature. In Confucian ethics and in some versions of daoist and Buddhist ethics, this transformation can result in the ethical transformation of a whole society. The legalist Hanfeizi (281–233 BCE) expresses skepticism about the ambitions of such projects, and in particular the Confucian project of bringing a society back to the dao through the ethical self-cultivation of the ruling elite. Hanfeizi argues that widespread good behavior, never mind the right motivations, is an achievement requiring fortuitous circumstances. He does not dispute the Confucian belief that the sage-kings of ancient times were virtuous and ruled over a harmonious and prosperous society. He does dispute that their virtue was the primary cause. What about, he asks, those kings in more recent times who were *ren* and *yi*, benevolent and righteous, and who got wiped out for their trouble? Virtue is not the explanation of success or failure. The explanation, argues Hanfeizi, has much more to do with the scarcity of goods in relation to the number of people.

Hanfeizi's subsequent emphasis on authority, on clear and consistent law, backed by severe punishment for its violation, is designed not to provide an alternative method of making the people follow the dao, but first and foremost to prevent the worst things from happening, the worst forms of chaos, bloodshed, and human misery. Legalism is commonly regarded as a philosophy of pure Realpolitik, but is perhaps better conceived as an ethic and political philosophy that is shaped by a severe pessimism about human nature and about the practicality of moral idealism.

### SOME METHODOLOGICAL ISSUES

A common Western perception of Chinese ethical teaching is that it is "wisdom" literature, composed primarily of stories and sayings designed to move the audience to adopt a way of life or to confirm its adoption of that way of life. By contrast, Western ethical philosophy is systematic argumentation and theory. One reason to think there is such a difference is the fairly widespread wariness in Chinese philosophy of a discursive rationality that operates by deduction of conclusions about the particular from high-level generalizations. Confucians seem more willing than daoists to articulate their teachings in the form of principles, but in accordance with the conception of *yi* as action that is right for the circumstances at hand, such principles seem to function as designators of values or general considerations that ought to be given weight in judgments about what to do. Never lost is recognition of

the necessity for the exercise of discretion in judgment according to the particular circumstances at hand. However, such contextualist themes appear in Western philosophical traditions, beginning with Aristotle. Perhaps it is fairest to say that the Chinese and Western traditions have differed over the emphasis and relative dominance accorded to particularism versus top-down normative theorizing.

Arne Naes and Alastair Hanay (1972) characterize Chinese philosophy as invitational in its method of persuasion, meaning that it portrays a way of life in a vivid fashion so as to invite the audience to consider its adoption. The *Analects*, for example, portrays the ideal of the *junzi* as realized by persons of genuine substance who are undisturbed by the failure of others to recognize their merits (1.1: "To be unrecognized by others yet not complain, is this not the mark of the junzi?"). In the *Mengzi* 2A2, such a person possesses a kind of equanimity or heart that is unperturbed by the prospects of fame and success. This unperturbed heart corresponds to the cultivation of one's *qi* (vital energies) by uprightness.

One might be able to see such passages as appealing to experiences the audience might have in its encounters with persons who do seem to possess special strength, substance, and tranquility through identification with and commitment to a cause they perceive to be far greater than themselves. One need not interpret such sayings as attempting to persuade by the pure emotive effect of certain words, as in propaganda. Rather, they may correspond to a way of doing philosophy that attempts to say something about values in life that can be supported by experience, even if not all testimony will agree (Kupperman 1999). The daoists recommend a way of life that they explicitly characterize as one that cannot be argued for, but their recommendation receives some support through commonly shared experience.

Consider again the notion of *wu-wei* and its illustrations in the *Zhuangzi* through stories of exemplary craft. Most famously, Zhungzi's Cook Ding cuts up an ox so smoothly and effortlessly that his knife never dulls, as if he is doing a dance with his knife as it zips through the spaces between the joints. He does this not through "perception and understanding" but through *qi*, the vital energies of the body. Suggested here is a portrait of acting in the world that consists of complete and full attention to present circumstances so that the agent can act with the grain of things (the Cook Ding passage refers to *tianli* or heavenly patterns). Such a portrait does resonate with the actual experience of craftspeople, artists, athletes, musicians, and dancers who have advanced beyond self-

conscious technique and rule-following, who become fully absorbed in the experience of working with the material, the instruments, or in the movement of their bodies and who experience their actions as an effortless flow and in fact perform at high levels. In such ways, Chinese thinkers draw a picture of the world that must in the end be evaluated by explanatory power in some broad sense. One must ask whether the picture helps make sense of one's experience of the world (again in a broad sense of experience not limited to quantifiable observations in replicable experiments) and whether it preserves features of that experience that one thinks are *prima facie* genuine.

The contrast between Chinese philosophy as invitational and Western philosophy as argumentative has some truth in it, but the difference is more a matter of degree than an absolute contrast. It was Aristotle in the *Nicomachean Ethics*, after all, who said that discussions about the good in human life cannot be properly assimilated by the young because they do not have enough experience of life. And Plato, despite his insistence on the centrality of argumentation to philosophy, dispatches the short analytical arguments presented in book 1 of the *Republic* in favor of long expository portraits of the ideal city-state and the harmonious soul for the rest of that work, often presenting little or no argument for some of his most crucial claims. Other of his claims, about the divisive effects of family loyalties and the ill effects of democracy, obviously appeal to experience, even if not all testimony will agree. Furthermore, as noted earlier, Mozi's criticism of Confucians required response in kind. Shun (1997) reveals the extensive argumentative context behind Mengzi's response to the Mohists. Methods of argumentation reach their most sophisticated state of development in Xunzi (see Cua 1985), who vigorously criticizes Mozi's, Zhuangzi's, and Mengzi's theory of human nature.

Differences in the way philosophy is done may reflect differences in the interests philosophy is meant to satisfy. Hansen (1992) argues that the classical Chinese thinkers did not conceive of the primary function of language to be descriptive and as attempting to match propositions with states of affairs, but as a pragmatic instrument for guiding behavior. Western interpreters have been unable to see this, argues Hansen, because they have imposed their own concerns with correspondence truth and metaphysics on the Chinese tradition. One result, in his view, is the wrong-headed interpretation of daoism as founded on the mystical doctrine of attunement to a metaphysically absolute dao. Hall and Ames (1987) criticize Fingarette's (1972) influential interpretation of Confucius's

dao as an ideal normative order transcending the contingencies of time, place, history, and culture. Hall and Ames argue Confucius's dao was not conceived as a tradition and language-independent reality against which linguistically formulated beliefs were to be measured as reliable or unreliable, but in fact a cumulative creation of individuals working from within a context provided by a society's tradition, consisting of customs, conventions, conceptions of proper behavior and good manners, and conceptions of right conduct and of what is of ultimate value and of what lives are worth living. Such controversies indicate the continuing vibrancy of the Chinese philosophical tradition as it interacts with the West.

David B. Wong (2005)

## LANGUAGE AND LOGIC

This entry focuses on concepts, issues, and themes of Chinese philosophy that involve language in view of its relation to reality, thought, and logic; the discussion is thus arranged on three central concerns in this regard: the issue of the relation between language and reality; the issue of the relation between language and thought; and the issue of the relation between language and logic. This entry is neither a historical study nor a comprehensive survey of the relevant ideas of thinkers from different historical periods, although there will inevitably be references to them. It is known that the term "logic" has been ambiguously and vaguely used; in this entry on language and logic in Chinese philosophy, first, by "logic" is meant primarily two things: (1) logical *reasoning* as embedded or expressed in natural (Chinese) language; and (2) the syntactic-semantic structure of Chinese language that underlies the surface grammar of Chinese language. The author neither pretend nor plan to discuss them exhaustively but to the extent that the issues to be addressed bear on Chinese philosophy and/or that the issues to be addressed are philosophically interesting. In this sense, this entry is not a discussion of logic or logical thought on their own in the history of Chinese thought, no matter how the term "logic" is understood.

## LANGUAGE AND REALITY

The issue of the relation between language and reality has been one classical concern in philosophical study of language concerning what language is about, in Chinese tradition as well as in Western tradition. The classical issue emerged in Chinese tradition in terms of the issue of *ming-shi* (*ming* means "name" while *shi* means "reality") in its broad sense. In this part is discussed how some representative approaches in Chinese tradition explore four aspects of the issue: first, the issue of the issue of *zheng-*

*ming* (name rectification), the issue of reference, the issue of whether language can capture reality, and the issue of the relation between truth concern and *dao* concern.

**NAME AND ACTUALITY: NAME-RECTIFICATION APPROACH.** In the pre-*Qin* period three figures put forward their doctrines of name rectification: Confucius (551–479 BCE), Gongsun Long (320–250 BCE), and Xun Zi (298–238 BCE). The points of Confucius' and Gongsun Long's accounts are here rendered more philosophically interesting, though Xun Zi suggested a much more systematic account of names. The focus is on the first two due to space.

It is known that Confucius' major concern is with moral and social issues. His doctrine of name rectification serves his major concern. Nevertheless, the focus here is on those interesting points suggested in this doctrine from the point of view of philosophy of language. The passages in the *Analects* that are directly related to the issue of name rectification are three: 13.3, 12.11, 12.17, of which I make full citation to give a complete account (my translations).

13.3: Zi-lu asked, "If the ruler of the *Wei* State has you in charge of the state administration to governing the state and the people, what would be the priority of your administration?" Confucius replied, "It would surely be the rectification of names." Zi-lu wondered, "Is it so? What a pedantic way! Why is there need to bring in the rectification of names?" Confucius said, "You, how unenlightened you are! When a *junzi* (an enlightened gentleman) is ignorant of something, he is not expected to offer any opinion on it. If names are not rectified, then what is said in speech would not be in accord with things as they are (supposed to be); if what is said in speech would not be in accord with things as they are (supposed to be), then what is [supposed] to be done by using words would not be accomplished; if what is [supposed] to be done by using words is not be accomplished, then the [adequate] socially established ritual rules as manifested via ceremonies and music will not implemented; if these [adequate] socially established ritual rules will not implemented, then punishment will not be just; if punishment would not be just, then the people will not know where to move forward. Therefore, a *junzi* should give names only to those that surely can be adequately delivered in speech and deliver in

speech only what surely can be adequately carried out in practice."

12.17: Jikangzi asked Confucius about governing. Confucius replied, "To govern is to rectify. If you lead the people by rectifying yourself, who would dare not to be rectified?"

12.11: Duke Jing of the Qi State asked Confucius about governing. Confucius replied, "Let the ruler [those that bear the title 'ruler' in the society] be the ruler [become what is prescriptively symbolized by the name 'ruler'], the minister be the minister, the father be the father, and the son be the son." The Duke said, "Excellent! Surely, if a ruler is not the ruler, a minister not the minister, a father not the father, and a son not the son, then, even if there are all the grain, how could I get to eat it?"

Confucius' doctrine of name rectification might as well be another way of presenting his teachings on moral cultivation and adequate governing: the teaching delivered in 12.17 is to rectify yourself to fit what those terms that signify your ranks, duties, functions and moral attributes mean (12:17), which amounts to sageliness within, while the teaching delivered in 12.11 is to participate in rectifying others to fit what those terms that signify their ranks, duties, functions, and moral attributes mean (12:11), which amounts to kingliness without. However, what really interests us here is some, explicitly or implicitly, suggested general point concerning the relation between language and reality. Let us start with an apparent puzzle: There appears to be a tension between the suggested two kinds of rectification approaches. On the one hand, the trademark title of this doctrine is "name rectification," and, as highlighted in 13.3, Confucius emphasizes the significance of name rectification. Nevertheless, on the other hand, 12.17 and 12.11 indicate that what is rectified is actually the persons who bear the (social-title) name. Which one is the primary goal while which serves as means? What is the due relation between the two kinds of rectification? Why doesn't Confucius directly emphasize rectifying the moral agent?

The reason seems to be this. To rectify the person (self and others) for the sake of self cultivation and of social reform, there needs a standard or norm that per se needs language as means or even as medium for the sake of its being carried out, communicated and passed on. Actually this is a two-level rectification process with the goal of rectifying the agent into a certain prescriptively specified person. The first step is to take a semantic accent strategy: instead of directly talking about how to rectify

the agent, it is to first rectify her (social-title) name under examination through assigning it a certain due prescriptive content which specifies the standard or norm to be met by any eligible referents of the name and thus gives the primary identity condition of such referents. The second step is to rectify the agent based on the primary identity condition of the expected referents of the name that has been established in the preceding semantic accent strategy.

An interesting point concern the relation between name and actuality, which is implicitly suggested by Confucius' account of name rectification is this. The due identity condition of actuality of a thing (say, a ruler) is not simply its status-quo happening or current appearance (say, the ruler-title-bearing person); rather, it consists in realization of its due place without transgressing its due scope (say, the person who really possesses the moral character that is expected for the ruler); name rectification will play its important or even indispensable role through the name carrying out and delivering the norm which specifies such a due place of the thing that is normatively denoted by the name (say, through rectifying the name "ruler").

If Confucius' account only implicitly suggests the foregoing point concerning social-title names and their due referents, one of Gongsun Long's contributions in this regard lies in his explicitly making the point in more general terms concerning any name and its related actuality and in a more sophisticated way. In this essay "*Ming-Shi-Lun*" (On name and actuality), Gongsun Long explains, "What the heaven and earth produce are things. When a thing goes its own way without transgressing its limit, it achieves its actuality (*shi*); when its actuality goes its own way without being out of its track, it achieves its due place (*wei*). If a thing goes beyond its due place, it is in wrong place; if a thing is in its due place, it is in right place. One is expected to rectify a thing in wrong place into right place; one is not expected to challenge a thing in due place by virtue of it being in wrong place. The rectification of a thing is the rectification of its actuality; the rectification of its actuality is implemented through the rectification of its name. Once its name is rectified, the standards for 'that' and 'this' will be formed up and stabilized" (my translation). Gongsun Long here emphasizes that a thing needs to go its own way without transgressing its limit to achieve its actuality; he further stresses that, once a thing achieves its actuality, there remains an issue of how to keep its actuality in due place; he explicitly points out that the so-called name rectification lies in rectifying the actuality of a thing in its due place through

rectifying the due content of its name which identifies such due place and thus gives due identity condition for the thing and its actuality.

THE ISSUE OF REFERENCE: PURPOSE-PERSPECTIVE-SENSITIVITY APPROACH. But the above Confucius' and Gongsun Long's views on the relation of name and actuality via their accounts of name rectification would raise one general question concerning the issue of reference: whether, and in which way, the subject would contribute to the identity of a thing when she refers to the thing. Though with their distinctive backgrounds and concerns, Gongsun Long, the Mohist, and Zhuang Zi are kindred in spirit on this issue, taking essentially the same approach to the effect that an referring agent's referring action, which involves her purpose and focus, assigns a certain identity to the thing referred to, or specifies some aspect(s) of the referent as its identity (or multiple identities) and that, sensitive to one's purpose and focus, one is entitled to make her perspective shift in one's referring practice to focus on some other aspect of the referent as its identity. This approach might as well be called the "purpose-perspective-sensitivity approach." This section will focus on Gongsun Long's account and then briefly present Zhuang Zi's view; the Mohist relevant point will be addressed when the Mohist view on reasoning is discussed in the "Language and Logic" part of this essay.

In his essay "*Zhi-Wu-Lun*" (On referring to things), Gongsun Long emphasizes "No things [that are identified or named as things] are not what are referred to [by linguistic names] ... if there is no referring in the world, nothing can be called a 'thing.' If without referring [names], can anything in the world be called 'what is referring to?'" (my translation). Gongsun Long's point here is that the relevant contributing elements involved in the subject's act of referring via a name (such as what is the subject's purpose, which aspect of the referent the subject intends to seek or focus on) make their intrinsic contributions to identity of the referent of the name. This point is also explicitly and emphatically addressed in his essay, "*Bai-Ma-Lun*" (On the white horse), as indicated in the passage "What makes a white horse a horse is their same [common] aspect given that it is what is sought. If what is sought is the common aspect, a white horse would be not distinct from (*bu-yi*) a horse [in regard to the common aspect]. If what is sought is not some distinct but the same aspect, then why is it that yellow and black horses meet what is sought in one case but not in the other? It is evident that the two cases are distinct" (my translation).

This crucial passage gives the fundamental rationale behind a number of Gongsun Long's arguments for the thesis "[the] white horse [is] not [the] horse." The statement "The white horse is not the horse" is just another way to say in our ordinary discourse "The white horse has its distinct aspect which the horse does not [necessarily] have," while the statement "The white horse is the horse" is just another way to say in our ordinary discourse "The white horse has its common aspect which the horse [necessarily] does have." Each of the two can be right, depending on which aspect of the white horse the referring subject is seeking or focusing on and thus refers to concerning the identity of the white horse. In so doing, she alerts us to avoiding the danger of over-assimilating distinctions, especially when the distinctive aspects need to be emphatically focused on.

Zhuang Zi proceeds essentially in the same direction on the issue (*The Zhuang-Zi*, Inner Chapter 3 "Yong-Sheng-Zhu"). Given an ox as whole already there, now what is its identity? How should one refer to it in terms of language? How should one identify it? As something exclusively determined by its "essence" or as a pack of flesh and bones? It seems to Zhuang Zi that, based on one's specific purpose, one can legitimately refer an ox as a pack of flesh and bones. One can say that, from the Zhuang Zi style view of the philosophy of language, the relation between language and an object in the world is not one-to-one relation but many-to-one relation: There are multiple referring expressions that refer to various genuine aspects of the same object. Depending on one's purpose, one is entitled to take a certain perspective to focus on one aspect of the object and thus identify the object as what the referring expression capturing that aspect would tell. What is important is that these distinctive referring expressions refer to different aspects of the same object, the ox as a whole, which are metaphysically complementary to each other.

THE DAO CONCERN IN CHINESE PHILOSOPHY AND ITS LANGUAGE ENGAGEMENT. A classical issue in Chinese tradition is whether, through language engagement, we can capture and deliver the ultimate reality, which the Chinese term "dao" primarily means (that is, the so-called metaphysical dao). The term "language engagement (with an ultimate concern)" means any reflective endeavor to capture (reach or characterize) what is ultimately concerned through language. Let us have a case examination of the opening statement, *Dao-ke-dao-fei-chang-Dao*, of Chapter 1, of the daoist classic the *Dao-De-Jing* whose legendary author is Lao Zi. For one thing, this passage has been considered to give a rep-

resentative or classical presentation of the daoist attitude toward the relation between language and the world; for another thing, many subsequent interpreters in Chinese tradition resorts to this passage to make their points in this regard.

One standard, and also most prevalent, interpretative translation (Creel 1983) of this passage is this: "The *dao* that can be told of [in language] is not the eternal *dao*" (Chan 1963, p.139). According to this interpretation, what the first statement reveals is a fundamental daoist insight that is strikingly similar to that of Wittgenstein's well-known idea about the spoken and the unspoken: Language expressions or formulations cannot really capture what those expressions or formulations aim to say; any language engagement is doomed to fail to capture the genuine *dao*; the genuine *dao* has to be captured in a way that is beyond language; contemplation of the *dao* in silence requires sharply distinguishing the eternal *dao* from what can be formulated or captured in (or by) language, for the two are simply opposed to each other. This standard interpretation is partially correct: The *dao* that has been characterized in terms of language does not exhaust, and is not identical to, the genuine *dao*.

Although this interpretative translation has been circulated for a long time and does deliver part of the daoist message, it has been challenged whether it completely captures and delivers Lao Zi's genuine point as a whole in the context of the *Dao-De-Jing*. It is not merely because this standard interpretative translation neither syntactically nor semantically captures the Chinese original but also because it seems to miss some important point of Daoism in this regard. Another interpretation (Mou 2000) gives the following interpretative translation of the opening statement: "The *Dao* can be reached in language [*Dao-ke-dao*], but the *Dao* that has been characterized in language is not identical with, or does not exhaust, the eternal *Dao* [*fei-chang-Dao*]." Though partially agreeing to the first interpretation, this interpretation differs from the first one in this significant aspect: The *dao* that have been captured in language is not bogus *dao* but still parts of the genuine *dao*; and this understanding of the partial *dao* in terms of language engagement would significantly contribute to our capturing the *dao* as a whole. This is based on one crucial characteristic of the metaphysical *dao*: The metaphysical *dao* as unifying force that runs through the whole universe is not something separate or beyond and above all those finite things in the world that are particular and concrete; particular things in the universe, *wan-wu* (ten-thousand things), which obtain the power from the *dao*, are considered as manifestations of

the metaphysical *dao* and individualized-particularized *daos*; the relation between the metaphysical *dao* and its manifestations in *wan-wu* is essentially *yin-yang* complementary; *dao* and *wan-wu* are interdependent, interpenetrating, interactive and correlative.

Epistemologically speaking, and from the point of view of language engagement, the metaphysical *dao* thus can be somehow captured through our language and our understanding of *wan-wu*. In this way, the point of the second interpretation is this: Instead of indiscriminately giving a negative claim against any language engagement with the ultimate concern, in the opening statement, Lao Zi reveals a two-sided transcendental insight which, on the one hand, positively affirms the role of the language-engaged finite point of view in capturing the ultimate concern and, on the other hand, alerts us to the limitation of the finite point of view and emphasizes the transcendental dimension of the *dao*.

It is noted that, in this regard, A. C. Graham's view seems to be much more moderate than the foregoing standard interpretation when he explains why there is the trouble with words: "The trouble with words is not that they do not fit at all but they always fit imperfectly; they can help us towards the Way, but only if each formulation in its inadequacy is balanced by the opposite which diverges in the other direction" (Graham 1989, p. 219). Nevertheless, the above second interpretation is more moderate than Graham's to this extent: It is not the case that the language engagement *always* fits *imperfectly*. That really depends on which part, dimension, or layer of the *dao* is set out to be captured in language engagement and on what kind of language function is at issue.

First, if a language engagement does not pretend to be exhaustive or conclusive regarding the *dao* but rather takes a finite point of view, it is reasonable to say that what has been captured in language in that case does fit adequately. When a language engagement takes a finite point of view, what is needed is not to reject such a finite point of view *per se*, but to hold the transcendental insight simultaneously, which would alert us to the limitation of the finite point of view and its due scope. Second, capturing something in language does not necessarily mean imposing a definition or formulation with a certain fixed format, meaning or usage. For instance, in contrast to *mere* description and descriptive designation, rigid designation via direct reference is one way to reach the genuine *dao* as a whole, as Lao Zi's own language-engagement practice illustrates (for example, Lao Zi did somehow successfully use the term *dao* to designate the *dao* as a whole).

TRUTH CONCERN AND DAO CONCERN. It seems that the truth concern is a dominant concern in Western tradition while the *dao* concern is a dominant concern in Chinese tradition. What is the relation between the truth concern and the *dao* concern? Are they dramatically and totally different reflective concerns in philosophy? (Given that the term "dao" primarily means the metaphysical *dao* concerning the way of the world as it is, especially in Daoism, and that any reflective concern, including the *dao* concern, that is open to criticism and self-criticism needs to be characterized in terms of language, and also given that one important aspect of the truth concern is about the relation between language and reality, this is a significant topic concerning the relation between language and reality at the meta-philosophical level.)

Although, as this author sees it, a silent majority of philosophers who are familiar with Chinese philosophy have considered both concerns essentially in accordance with each other, some scholars argue otherwise. There are two representative views. One takes it that, in contrast to what is called "Western sentential philosophy," the dominant portion of the classical Chinese philosophy is a non-sentential philosophy that is not essentially related to those concepts that are intrinsically connected with sentential philosophy like proposition (or semantic content), truth and belief (Hansen 1985/2003). This argument might as well be called the "no-sentential-concern argument." Another view takes it that the significant part and the primary concern of the classical Chinese philosophy have been considered be its moral concern and its ethical accounts; and the moral concern is not with how to understand impersonal material world but with the ethical constitution in the human society. In this way, it is not the by-default account of truth (the correspondence account) but a pragmatic account of truth that plays the role (Hall 1997, 2001). This argument might as well be called the "pragmatic truth argument."

In contrast to the silent majority's presupposed position, these views have been voiced prominently and loudly especially in West and thus have left on many who are not familiar with Chinese philosophy the impression to the effect that there is no truth concern in Chinese philosophy and that the truth concern in Western tradition and the *dao* concern in Chinese tradition are dramatically different from each other. This impression is incorrect at least to the following extent: First, it is highly controversial; second, to many experts, it is not so. But their views deserve careful examination, and the involved issue deserves a systematic discussion, instead of being silently dismissed. Though it is not a place to give such a detailed

discussion here, I intend to use the following strategy to assist the interested reader in examining the issue: this entry briefly addresses a number of basic things, to which one needs to pay due attention when one intends to explore the issue and give adequate evaluation of the competing views, but which might be ignored by some advocates of the above mentioned challenges.

Let us start with our pre-theoretic, or “folk,” understanding of truth: A true (linguistic) sentence or statement (or the thought/belief it delivers) describes or characterizes (extra-linguistic) things as they are. When the term “our” is used here, its reference by no means includes only people in West but surely also includes people in Chinese speaking regions, now and in the past, no matter how such a pre-theoretic understanding has been indicated in their natural languages—whether it is expressed by a unified single term in a phonetic language (like “truth” in English), or it is expressed via various multiple-character phrases in the Chinese ideographic language (such as *shi-shi-qiu-shi*, meaning “seeking what things actually are,” or *qiu-dao*, meaning “pursuing the *dao*/way of the world”). For convenience, this pre-theoretic understanding of truth is sometimes called our pre-theoretical “correspondence” understanding to highlight the accordance relation of our thought or our language with (the *dao*/way of) the world (including the human society) in which truth under such an understanding consists. Now the reader can think about this: Given that those approaches in Chinese philosophy as discussed in the preceding sections of this part are all distinctive illustrations of the *dao*-concern on several significant fronts and thus that all of them are thus intended to capture and deliver extra-linguistic things as they are, are those approaches dramatically separate and different from the reflective truth concern that is based on the foregoing pre-theoretic understanding of truth?

At this point three notes are due. First, the metaphysical commitment of our pre-theoretic understanding of truth per se as presented above is minimal: It does not commit to any ad hoc metaphysical criterion for what counts as reality, and it is compatible with a variety of ontological accounts of extra-linguistic things (say, snow’s being white). For example, a *realist* pre-theoretic “correspondence” understanding of truth is actually a *combination* of our pre-theoretic understanding of truth and a *realist* ontological understanding or explanation of what counts as, say, snow’s being white. (In this way, any argument that resorts either to the fact that some specific version of the truth concern in West is combined with some unfavorable metaphysical explanation or to the fact

that a certain metaphysical account of the *dao* is so different from some representative metaphysical understanding of what counts as reality cannot automatically imply that the *dao* concern in Chinese tradition and the truth concern in Western tradition are dramatically different.)

Second, it is arguably right that our pre-theoretical “correspondence” understanding of truth plays its important and enormous explanatory role both in our daily lives and in our reflective lives (including philosophical inquiries). In most cases, whether for the sake of psychological satisfaction, intellectual enjoyment, scientific honesty, legal obligation or success of our actions or even for its own sake, we intend to understand what really happen(ed) around us rather than illusions, we hope that others tell us truths instead of lies or mere wishful thinking, we want to know those beliefs, thoughts or statements that are true. Moreover, in almost all of cases, we (even for those who advocate some understandings of truth that clearly revise or go against our pre-theoretic understanding of truth) seriously intend that the genuine contents of our own thoughts and claims to be delivered (or represented) to, and understood by, others “correspondently”—or without distorting or losing their original contents; we intend to behave in a way that does not go against the laws or *dao*/way of the world. In this sense and to this extent, it is not merely the case that, in many situations, with such a pre-theoretic understanding of truth, we consciously pursue truths; rather, it is a stronger case: whether consciously or unconsciously, we unavoidably presuppose our pre-theoretic “correspondence” understanding of truth both in our ordinary folk talks and in our reflective talks including philosophical discourses, either as one central explanatory norm to regulate and explain the purpose of our thoughts and actions or as one important explanatory basis to explain some other significant things in our folk and reflective lives.

Third, there is the distinction between truth nature and truth criterion: The former is examined by asking what truth is, what truth consist in or what it is for a statement (or belief) to be true, while the latter is examined by asking what is the criterion by which one can identify, judge and distinguish true statements from false ones. Our pre-theoretic understanding of truth is about the truth nature instead of truth criterion. Actually, the foregoing three notes indicate three significant respects, among others, in which one can critically examine the relation between the truth concern and the *dao* concern in Chinese tradition as well as the nature and due functions of major competing theoretic accounts of truth in

the Western tradition. (For further discussion of the issue, see Mou 2006.)

## LANGUAGE AND THOUGHT

Besides the issue of the relation between language and reality, another important concern of philosophical reflection on language is the issue of the relation between language and thought. This entry will discuss this issue as explored in Chinese tradition in two fronts: (1) the issue of the relation between speech and ideas in mind in regard to whether and to what extent the former can capture and deliver the latter; (2) a reflective concern with how the structure of Chinese language bear on the orientation of philosophical thought in Chinese tradition.

**SPEECH AND IDEAS: FOUR APPROACHES.** The relation between speech and ideas in mind is one central concern in the so-called *yan-yi-zhi-bian*, that is, the debate on the relation between speech (*yan*) and meaning (*yi*, in the sense to be explained), which originated in the *Wei-Jin* period; but the following discussion will not be limited to a number of representative approaches in this debate during that time but incorporates some other representative approach in Chinese tradition. (Note that, though using the ready-made translation “speech and meaning” of *yan-yi* here for the sake of convenience, and though *yi* in this debate also means *dao*-like principles in its metaphysical sense and the human understanding of them, by *yan-yi* is meant “speech and ideas in mind” in this context.) In the following, four representative approaches are focused on: (1) the “meaning-delivery-beyond-speech-capacity” approach; (2) “forgetting-speech-once-achieving-meaning” approach; (3) the “meaning-delivery-within-speech-capacity” approach; (4) the context-sensitivity approach. The first three approaches are three representative approaches in the *yan-yi-zhi-bian* during the *Wei-Jin* period, though the first two are actually kindred in spirit (see Chen 2004 for a recent discussion; my interpretation of the third approach is somewhat different than his), while the fourth one is my interpretative elaboration of the relevant points of Ji Zang’s Buddhist Middle-Way doctrine of double truth.

The “meaning-delivery-beyond-speech-capacity” approach was advocated by Ji Kan (223–262). This approach’s main arguments are these. First, some of our ideas in mind are so delicate and sophisticated that speech simply cannot capture them. Second, our ideas in mind are dynamic while speech is static, and therefore speech cannot fully capture ideas in mind. The “forgetting-speech-once-achieving-meaning” approach was

advocated by Wang Bi (226–249). This approach acknowledges a certain important role played by speech as a means to achieve meaning. For example, when one intends to understand some other’s ideas or when one intends to have one’s own ideas to be understood by some other, one has to rely on speech to understand them or express them.

But this approach still takes it that eventually speech would hinder one’s understanding ideas per se and so that one should forget speech once achieving the ideas. This line of thought sounds like a Wittgenstein’s well-known metaphor to the effect that, once one climbs up on the building by means of a ladder, one needs to discard the ladder to keep oneself in the high position. It is noted that, though the first and second approaches have their differences in emphasis and focus, they share the basic positions concerning the relation between speech and ideas. Both think that ideas are primary while speech is only secondary, that ideas and speech can, and should, be separate and that at most speech serves merely as a means and makes no contribution to the constitution of thought and ideas.

The “meaning-delivery-within-speech-capacity” approach is suggested by Ouyang Jian (?–300). This view has been ignored for a long time and not a strong voice in the traditional Chinese philosophy in contrast to the mainstream approach on this issue; but some of the points of this approach deserve a close examination. Ouyang argues that:

Surely one can achieve a principle in the form of ideas in one’s mind; however, without language [as media and as means], those ideas cannot exist in a smooth and coherent way. Given that a thing has been stabilized in a certain definite aspect, without language [in terms of name], one cannot identify and thus distinguish the thing [in view of the stabilized definite aspect] from the others. If one’s ideas cannot exist in a smooth and coherent way through the role of language, they cannot hold tight in connection with each other; if the thing cannot be identified and distinguished in terms of name, the distinctive ideas and insights cannot be shown evidently. But, as a matter of fact, the distinctive ideas can be shown evidently in terms of distinctive names, and speech holds ideas tight in connection and in a smooth and coherent way. Let us see why it is so. It is not because a thing has its ready-made fixed name; it is not because a principle has its fixed unchangeable language

expression. The reason is this. When people intend to capture things as they are in a distinguishing way, they give them distinctive names. When people intend to declare their distinctive ideas, they employ distinctive language expressions that fit distinctive ideas. Names [and/or their meanings] change in accordance with the transformation of their named things; while speeches [and/or their meanings] change in accordance with the change of the contents of ideas. It is just like echo responds to sound, shadows attaches to body; they do not exist as two separate things. If they are not separate things, then speech can fully capture ideas; this is why I hold on my position.

(*YI-WEN-LEI-JU*, VOL. 19)  
(MY TRANSLATION)

There are two interesting points that seem to really engage with the two preceding views. First, speech is not merely a means but also a medium of ideas at least in regard to its contribution to their internal coherent construction. Second, as far as speech as means is concerned, though speech is relatively static and stable, that certainly does not mean that language is just as static as a dead thing; language itself also keep changing responding to the change of what it is to express. This is true as evidenced by the history of the development of natural languages. Although Ouyang's first point is still quite vaguely made and expressed, his position makes distinct contribution on the issue.

The fourth approach, the context-sensitivity approach, suggested by Ji Zang (540–623), a significant figure of Chinese Buddhism who elaborated and systematized *Mahayana* doctrine of Buddhism. Ji Zang's doctrine of double truth has interesting implications from the point of view of philosophy of language. First, a brief outline of the major ideas of his double-truth account. It seems to Ji Zang that there are two kinds of truth, truth in the common sense and truth in the higher sense, on each of three varying levels; what is the truth in the higher sense at a lower level becomes merely truth in the common sense at the higher level. At the first level, the common people take all things as really being and know nothing about their non-being, while the Buddhas have told them that actually all things are non-being and empty. At the second level, to say that all things are being is one-sided, but to say that all things are non-being is also one-sided; at this level, the Buddhas would say that what is being is simultaneously what is non-being. At the third level, saying that the middle truth consists in what

is not one-sided means to make distinctions, and so this is merely a common sense truth; the higher truth consists in saying that all distinctions are themselves one-sided, and the middle path is neither one-sided nor not-one-sided. That amounts to denying the adequacy of any speech to capture the truth in the higher sense at this highest level, that is, the highest truth, which needs to be contemplated in silence.

Although Ji Zang as a Buddhist thinker still maintains that the highest truth cannot be captured and delivered via language but has to be contemplated in silence, but he emphasizes that all those truths, both in the common sense and in the higher sense and both at the first level and at the second level, can be captured and delivered in terms of language that involves relatively stabilized and fixed conceptual distinctions. With his explicitly distinguishing truths in distinct senses and at distinctive levels and acknowledging important role played by language at the first and second levels, Ji Zang's general point is philosophically interesting: we need to have it sensitive to the context whether speech can effectively capture and deliver the truths, that is, our understandings and comprehensions of the world.

There are two notes concerning evaluation of the foregoing views. First, to evaluate the ancient thinkers' views here, we indeed need to pay attention to those still valuable thoughts; on the other hand, we also need to note that one of the reasons why those ancient thinkers held that speech is not able to fully capture meaning is this: some conceptual and explanatory resources in contemporary philosophy that are available to us to capture and deliver some sophisticated ideas and thoughts were simply unavailable to those ancient thinkers; so there is no wonder why they felt the linguistic means then available to them were not sufficient to capture some complicated thoughts and ideas. Second, as emphasized at the outset, the term *yi* in the *yan-yi-zhi-bian* (the debate on the relation between speech and meaning) has its much wider coverage than what the term "thought" in the contemporary debate on the relation between language and thought is to cover: the latter primarily mean propositional thoughts while the former's coverage includes non-propositional ideas, emotions and some characteristic existential experience; a claim putting into doubt or denying the capacity of speech to capture such non-propositional mental things could be compatible with the positions by those whose primary concern is with the relation between language and propositional thoughts.

THE ISSUE OF THE STRUCTURE OF CHINESE LANGUAGE AND REFLECTIVE WAY OF THINKING IN CHINESE PHILOSOPHY. It seems that certain characteristic features of Chinese language influence or encourage some orientations in the Chinese (folk and reflective) way of thinking. Due to the topic, the focus will be on such influence on reflective inquiry in Chinese philosophy. Nevertheless, the reflective way of thinking is not separate from, but largely in accordance with the folk way of thinking via some reasonable pre-theoretic intuitive understanding on those issues that deserve further reflection.

We start with some known facts about certain characteristic features of Chinese ideographic language and Western phonetic language (say, English) in comparison that might, to some extent and in a certain scope, reflect some distinctive orientations or tendencies in the ways of thinking of the two linguistic communities. We know how we as English speakers give our names and addresses: We first give our given names (thus being called “first name”) and last give our family names (thus being called “last name”). However, in Chinese, the family name goes first (thus the family name is really the first name in Chinese way) and then the given name (for example, the real order of my whole name in Chinese is “Mou Bo” instead of “Bo Mou”). For, in philosophical terms, the family (name) is both metaphysically and logically prior to the individual (name), and the former provides a necessary holistic background for understanding the latter. By the same token, in contrast to its way in English, a mailing address (taking mine as an example) should go this way when delivered in Chinese: “USA, California, San Jose, San Jose State University, Department of Philosophy, Mou Bo”; that is, the larger thing goes first while the smaller thing next. It is arguably right that the structure of Chinese language in this respect to some extent bears on the orientation of the way of thinking of the Chinese people as a whole.

(There are two notes. First, when the word “bear on” is used instead of “influence” alone, what is meant is that the relation between the former and the latter is bi-directional instead of one-directional. The actual situation might be this: When the way of the Chinese language originally formed up, it was influenced by the way of thinking of the people around that time; on the other hand, when such a way has become relatively stable and been followed and passed on generation by generation, it has conversely influences the way of thinking of the future Chinese language speakers to some extent. Second, the foregoing influence certainly implies neither that the

people speaking in Chinese tend to put the family/the collective interest first nor that, say, English speakers tend to do otherwise. Even if such a distinctive order of which one is mentioned first, next, and last indeed influence which one would first go in mind at some level, surely one can say that, though saying things in a certain order, I actually think about all the involved things once for all simultaneously. Exactly how it would happen if any has yet to be carefully examined.)

Now, through a representative case analysis, we examine how the structure of Chinese language bears on the orientation of reflective inquiries in Chinese philosophy through one case analysis. The Platonic one-many problem has been a long-term issue in the Western philosophical tradition. The problem begins with the following observation: objects around us share features with other objects; and many particular individuals, say, horses bear the same name “horse.” The Platonic one-many problem presupposes that there is one single universal entity which is common or strictly identical across all those particular concrete horses and by virtue of which many individual horses bear the same name “horse”; the single universal entity is labeled “horseness.” The Platonic one-many problem is how to characterize the status of universals and the ways by which particulars share universals. However, there seems to be one puzzle: why the classical Platonic one-many problem in the Western philosophical tradition has not been consciously posed in the Chinese philosophical tradition and why, generally speaking, classical Chinese philosophers seem less interested in debating the relevant ontological issues. One suspects that the structures (the surface and deep ones together) and uses of different languages might play their roles in pushing philosophical theorization in different directions; the ways of speaking and writing of the Chinese language might somehow reveal and reflect Chinese folk ideology and then influence the ways in which certain philosophical questions are posed and certain ontological insights are formed.

The problem of relating Chinese thought to the structure and functions of the Chinese language has for generations tantalized sinologists and those philosophers who are concerned with the problem. Nevertheless, in the last two decade, some significant progress has been made in this regard. Chad Hansen (1983) advances a novel and provocative theory about the nature of the classical Chinese language. The central thesis of Hansen’s theory is his mass-noun hypothesis. Its main ideas are these: (1) the (folk) semantics of Chinese nouns are like those of mass-nouns (i.e., those nouns referring to the so-called inter-

penetrating stuffs, like the nouns “water” and “snow”), and naming in Chinese is not grounded on the existence of, or roles for, abstract entities (either on the ontic level or on the conceptual level) but rather on finding “boundaries” between things; (2) influenced by the mass-noun semantics, the classical Chinese semantic theorists and ontological theorists use words in ways that are natural to view mass nouns rather than count nouns, and Chinese theorists tend to organize the objects in the world in a mereological stuff-whole model of reality (the term “mereology,” in its technical sense, means the (mathematical) theory of the relation of parts to whole).

In this way, according to Hansen, the language theory of classical Chinese philosophers differs fundamentally from the language theory of Western philosophy. This hypothesis has been challenged mainly in three ways. One way is to challenge the mass-stuff model from the perspective of a holographic process ontology (Cheng 1987, Hall and Ames, 1987).

Although some scholars also emphasize the implicit ontology of Chinese language, they focus on the case analysis of the typical philosophical nouns or terms, such as *tai-ji*, *wu*, *yin-yang*, *wu-xing*, which constitute the basic lexico (vocabulary) of Chinese metaphysical systems as found in the writings of the early Confucianists, the early daoist, and Neo-Confucianists. They argue that those nouns stand for interpenetrating wholes and parts in a quite different sense from Hansen’s: the individual things behave in the on-going patterns and in the events or processes of interaction among them, and the universe behaves as an organic whole with parts exemplifying the structure of the whole; they claim that Chinese words in general share this ontological feature of combining universality and particularity, abstractness and concreteness, activity and the result of activity. In this way, some writers (Hall and Ames, 1987) prefer to consider the relations of “parts” and “wholes” in terms of the model of “focus” and “field” and take Chinese ontological views as holographic rather than mereological.

Another way is to directly challenge Hansen’s mass noun hypothesis, arguing that there is a clear grammatical distinction in classical Chinese between count nouns and other nouns (Harbsmeier 1989, 1991). Claiming that there is a clear grammatical distinction in classical Chinese between count nouns and other nouns (generic nouns and mass nouns), Harbsmeier (1991) insists that the mass-noun hypothesis is “historically implausible and grammatically quite wrong-headed.” However, as Hansen himself emphasizes (1992), his mass-noun hypothesis is not a syntactic claim that classical Chinese nouns have

mass-noun grammar but a semantic interpretive hypothesis that the semantics of Chinese nouns may be like those of mass nouns, and classical Chinese theorists view words in ways that are natural to view mass nouns. So it seems to Hansen that Harbsmeier systematically confuses syntax and semantics and misinterprets his semantic hypothesis. Although one can agree with Hansen at this point, Harbsmeier’s criticism is not irrelevant in the following sense. It seems that Harbsmeier insists that his alleged distinction between count nouns and other nouns is not merely grammatical but also semantic (or takes the grammatical difference in question to have semantic implications); Hansen thus needs to deal with the linguistic (semantic) evidence against his hypothesis that the semantics of classical Chinese nouns may be like those of mass-nouns.

The foregoing first challenge from the point of view of a holographic process ontology could be compatible with Hansen’s approach; for the process ontology is essentially compatible with the ontological position, a kind of nominalism, presupposed or implied by Hansen’s mereological mass-stuff hypothesis. Hansen’s view is given in a semantic perspective that can be compatible with a pragmatic perspective with its focus-field orientation. I have responded to Hansen’s view in a similar semantic perspective and within the same mereological-analysis track. But, disagreeing with Hansen’s mass-noun hypothesis, I suggest and argue for a collective-noun hypothesis (Mou 1999). Its main ideas are these: (1) Chinese common nouns typically function, semantically and syntactically, in the way collective-nouns (that is, those nouns that denote collections of individual things, like the English nouns “people” or “cattle”) function, and the folk semantics of Chinese nouns are like those of collective-nouns; (2) their implicit ontology is a mereological ontology of collection-of-individuals both with the part-whole structure and with the member-class structure, which does justice to the role of abstraction at the conceptual level; and (3) encouraged and shaped by the folk semantics of Chinese nouns, the classical Chinese theorists of language take this kind of mereological nominalism for granted; as a result, the classical Platonic one-many problem in the Western philosophical tradition has not been consciously posed in the Chinese philosophical tradition, and classical Chinese philosophers seem less interested in debating the relevant ontological issues. This mereological collection-of-individuals model of reality would provide a more reasonable interpretation of the semantics of classical Chinese nouns and the classical Chinese ontological theory. The collective-noun hypothesis makes a stronger claim that Chinese nouns do

not function as count nouns but typically function, both syntactically and semantically, as collective-nouns.

## LANGUAGE AND LOGIC

As indicated at the outset, the term “logic” in this essay on language and logic in Chinese philosophy means two related things: first, logical reasoning as embedded or expressed in natural (Chinese) language; second, the syntactic-semantic structure of Chinese language that underlies the surface grammar of Chinese language. The two are related in this way: The reasoning as embedded in a language is intrinsically connected with the syntactic structure of such a language and makes sense in view of its semantic structure which per se is related to its syntactic structure; thus, to understand the reasoning as embedded in natural (Chinese) language, one needs to understand its syntactic-semantic structure. Actually, in the discussions of the previous two parts, the second issue has already been addressed in view of its relations with the central concerns there. In this part, we focus on the first issue. With space limitation, the strategy is this: we will start with an examination of some reasoning patterns in the Mohist discourse and then raise a general issue about the due relation between two modes of reasoning; that is, deductive reasoning versus evocative reasoning, in view of Chinese philosophical practice.

**REASONING PATTERNS IN THE MOHIST DISCOURSE.** The two trademark basic principles for deductive reasoning are the principle of non-contradiction and the law of identity, both of which are expected to be observed for the sake of good deductive reasoning. The principle of noncontradiction states that it is not the case that both that  $p$  and not  $p$  (where  $p$  is any proposition). The law of identity states that everything is identical with itself (for everything  $x$ ,  $x = x$ ). We begin with an example of reasoning via Aristotelian deductive logic:

Pr.1 If  $x$  is  $y$ , then to do something to  $x$  is to do it to  $y$ .

Pr.2 Robbers are people.

Therefore, killing robbers is killing people.

Pr.3 It is wrong to kill people.

Therefore, it is wrong to kill robbers.

However, the Mohist disagrees to this reasoning, arguing that killing robbers is not killing people. Their reason is this. In our ordinary language use, we often shift our attention from what is shared between them to what is distinct between them, depending on the nature of context and concrete situation. The Mohist distinguishes

three sorts of contexts and considered the case of “killing robbers/killing people” as one case of the second kind (Graham 1989).

(1) The involved context would typically call our attention to what is shared between involved parties: In such a kind of contexts, for example, we say “Black horses are horses” or “Riding black horses is riding horses.” (Typically, for the purpose of riding a horse, the color of the horse does not matter.) One example given in the Mohist text is this: “Huo is a person; to be concerned for Huo is to be concerned for persons.” In the context of the Mohist text, Huo is a slave who is too humble for one to be concerned for anything about them except that he is a person; someone concerned for him is concerned for anyone as a person. Also note that the Mohist held the view of universal concern for anyone.

(2) The involved context would typically call our attention to what is distinct between involved parties. Consider three sentences in such a kind of contexts. First, “A carriage is wood; but riding a carriage is not riding wood”: Typically, what is concerned with in the context of talking on riding something is whether or not the thing has the riding-function. Second, “Her younger brother is a handsome man; but loving her younger brother is not loving a handsome man”: Typically, in this context, loving him is not for his looks. Third, “Robbers are people; abounding in robbers is not abounding in people, being without robbers is not being without people: Typically, in this context, what is called attention to is something distinct with robbers.

(3) The involved context would typically call our attention to both what is common and what is distinct between involved parties. One might say both “The white horse is not the horse” (in so saying, as analyzed before in view of Gongsun Long’s approach, one pays attention to the distinct aspect of the white horse from the horse) and “Riding the white horse is riding the horse” (for the sake of riding a horse, the color of the horse does not matter).

What the Mohist calls our attention to is a variety of reasoning patterns embedded in our linguistic practice and the context in which reasoning utterances are made. In contrast, deductive reasoning focuses on logical necessity and logical entailment that seems to be concerned about only in the context (1) among the foregoing three kinds of contexts as the Mohist identifies. It is noted that such a focus-shift is not supposed to make at random but has its due metaphysical foundation: an object of study really possesses its multiple aspects/layers/dimensions. When saying “robbers are people,” one focuses on the aspect of robbers, A, that makes them being people; nev-

ertheless, when saying “killing robbers is not killing people,” one’s focus shifts to some other aspect of robbers, A\*, which is possessed by robbers rather than by the other people and which makes robbers deserve being killed (from the Mohist point of view): killing robbers for the sake of A\*; that does not amount to killing people for the sake of A\* because people generally speaking do not possess A\*. Note that this challenge is rather to the indiscriminate applicability of deductive reasoning at the surface level than to its applicability to various extents in different linguistic contexts. That constitutes a deep reason why the Mohist view, as A. C. Graham points out, has its “Wittgensteinian look,” which emphasizes the language use and claims that meaning consists in use.

**LOGICAL VERSUS EVOCATIVE ARGUMENTATIONS IN CHINESE PHILOSOPHY.** It is known that any philosophical inquiry needs to base its conclusion on justification or argumentation rather than simply dogmatically taking something for granted. There are two basic modes of argumentations in philosophy, one is logical (in its narrow sense) and the other evocative, though sometimes only the former is highlighted and celebrated. The two modes of argumentations are sometimes contrasted as “logical versus rhetoric,” “inferential versus preferential” or “probative versus prohairetic.” A logical argument is a set of statements in which one or more of the statements, the premises, purports to provide a reason or evidence for the truth of another statement, the conclusion, either in deductive way or in inductive way. When it does, we say that the premises entail or support the conclusion, or that the conclusion “follows from” the premises. We traditionally divide logical arguments into deductive and inductive arguments. The term “evocative” is used in contrast to the term “logical” used in the narrow sense; it means producing or suggesting or triggering (generally speaking, evoking) some subsequent thought or conclusion primarily in some non-“logical” way, neither deductively nor inductively as specified above. Among a variety of evocative argumentations, what have been often addresses especially in humanities are argument by (relevant) analogy [drawing its conclusion by evoking a similarity between some particular aspect of two things from, or on the basis of, their similarity in some other particular aspect(s) or in some other general aspect], argument by appealing to value [drawing its conclusion by appealing to one’s value which is appreciated through one’s life-experience and understanding of the world (and/or the human society)], and argument by appealing to (credible) authority [draws its conclusion by appealing to trust-

worthy and knowledgeable authority on the issue under examination].

Both modes of argumentations are widely used in the classical Chinese philosophy. Let us consider some examples in Confucius’ *Analects* to illustrate the point. Contrary to some unjustified impression, this classical text is not lack of deductive reasoning; though some of the deductive-reasoning cases need one to be careful enough to identify between lines, some other are quite evident—for example, the reasoning given in the previous citation where Confucius’ doctrine of name rectification is discussed. On the other hand, the argumentation implicit in Confucius’ version of the Golden Rule as delivered in 6.28 of the *Analects* illustrate both argument by analogy and argument by appealing to value. Its conclusion is that one should treat others in a certain moral way; which way? One is expected to identify the way partially based on how one would like to be treated: Due to the common human-being identity among human beings that result in similarities in many relevant aspects between human moral beings, [Confucius’ version of] the Golden Rule guides the moral agent to “draw the analogy from oneself [the way one would desire to be treated]” to how to treat others in a moral way (that is, to evoke the similarity in regard to what would be desired and what would be rendered moral, by both the moral agent and the moral recipient). Furthermore, the moral agent is not expected to start from nowhere but to be a moral agent with (a certain degree of) moral sensibility; that is, the virtue of *ren*; this initial moral sensibility serves as the internal starting point of how the moral agent is to adequately draw the analogy. This moral value, according to Confucius, is commonly, more or less, shared by all human moral agents; this moral value would thus contribute to what would be rendered moral by both the moral agent and the moral recipient (the similarity in this regard). In this way, Confucius’ version of the Golden Rule appeals to the moral value to justify a reasonable version of the Golden Rule. Through this example, one can see how argument by analogy and argument by appealing to value interplay in the argumentation in Confucius’ version of the Golden rule.

Indeed, when appealing to value and appealing to authority, one should be careful; otherwise, one might fall into fallacies. But, what is at issue is not whether people and philosophers have ever made adequate argument by appealing to value or to authority in their reflective practice. Philosophers do it, more or less, directly or indirectly, and explicitly or implicitly, in their argumentations and explanations, and both in the Chinese tradition and

in the Western tradition. What is really philosophically interesting is how to do it in some adequate way to avoid fallacies. In this connection, unlike deductive reasoning, there is no formal rule manual available but some general guidelines. Those general guidelines, largely, present themselves as explanations of what constitute fallacies in reasoning or argumentation. One case is the fallacy of dubious authority regarding current situation: An argument commits this fallacy when it mistakes some person as a trustworthy and knowledgeable authority about the current situation. Another case is the fallacy of relevance: mistaking relevant dissimilarities as irrelevant: An argument (typically, an argument by analogy) commits this fallacy when it mistakes relevant differences between two (kinds of) things as irrelevant to the issue under examination. For example, to illustrate the fallacy of relevance, let us consider how Mencius criticizes an argument by analogy made by Gao Zi, his contemporary in regard to the original human (moral) nature:

Gao Zi said, “[Original] Human [moral] nature is like the willow tree, and righteousness is like making a drinking cup. To turn human nature into humanity and righteousness is like turning the willow tree into cups.” Mencius responded, “Could you make the cups out of the willow tree without violating its nature, or do you have to violate the nature of the willow tree before you can make the cups? If you have to violate the nature of the willow tree in order to make cups, then [based on your analogy] do you have to also violate human nature in order to make it into humanity and righteousness? Your analogy would lead all people in the world to consider humanity and righteousness as the source of disaster [because they required the violation of human nature]!” (*Mencius* 6A:1. My modification of the translation in Chan 1963, p. 51)

Mencius here criticizes Gao Zi for his inadequately paying attention only to some superficial similarity between making a cup and building character but ignoring a crucial difference between making a cup out of the willow tree (injuring the willow) and building human moral character from the human original moral nature (without involving violence and injury); in this way, in our terminology here, Mencius actually criticizes Gao Zi for his mistaking one significantly relevant dissimilarity between both as irrelevant in his argument by analogy.

The relation of the two modes of argumentations together with their respective nature and status in philosophical inquiry has been under reflective examination.

We can think about a number of questions in view of the cited cases above in the traditional Chinese philosophy and through examining our own reflective practice in argumentation: When carrying out deductive (or evocative) argumentation, could one’s argumentation be totally immune from evocative (or deductive) argumentation? (Think about where premises in many deductive arguments come from; also think about whether one still needs to rely on a certain standard and resort to the two basic principles of deductive reasoning mentioned above in some way when carrying out evocative argumentation.) One strategic methodological point in regard to the relation between the two modes of argumentation is that they come into “mutually supportive overall harmonization” (Rescher 1994, p. 58). That is especially true in view of Chinese philosophical practice. For this orientation is kindred in spirit with the *yin-yang* way of thinking which emphasizes the complementary nature between seemingly competing approaches. Indeed, the *yin-yang* way of thinking has fundamentally influenced the orientation of mentality, and the way of carrying out reflective argumentation, of subsequent Chinese thinkers in various schools or movements.

## METAPHYSICS AND EPISTEMOLOGY

In traditional Chinese philosophy, epistemology was not an explicitly developed discipline, even if Chinese philosophers since ancient times were interested in problems related to human knowledge and developed some implicit theories of knowledge. Traditionally, there was no technical Chinese term equivalent to “epistemology” in Western philosophy, for which Chinese now use the terms “zhishilun” and “renshilun” as modern translations. In contrast, metaphysics has been a central interest of Chinese philosophy, traceable back to its origin in the *Yijing* or *Zhouyi* (The [Zhou] book of changes, c. 6th–5th century BCE). The discourse on the Way (*daolun*), in various forms, has always been an essential constituent of traditional Chinese philosophy. The term “xinger-shangxue,” or simply “xingshangxue,” now serving as the Chinese translation of the term “metaphysics” in Western philosophy, comes from the great appendix of the *Zhouyi*, where we read, “What is above forms [*xing er shang*] is the Way [*dao*]; what is under forms [*xing er xia*] is concrete things [*qi*]” (Kong, juan, p. 158). Knowledge of metaphysical reality, essential to Chinese philosophy, is also a fundamental concern of Chinese theory of knowledge.

The following discussion will first deal with Chinese theories of knowledge, ascending from ordinary knowledge to science to wisdom. All three moments have their metaphysical presuppositions, especially wisdom, which is in essence the knowledge of ultimate reality and thus leads to metaphysics properly speaking.

### KNOWLEDGE

It is easy to identify some texts in which traditional Chinese philosophers discussed the subject-object structure of knowledge or the knower-known relation in the process of knowing. For example, Xunzi (298–238 BCE) said, “That by which one can know is human nature; that which can be known are the principles of things” (p. 523). Mo Di (fl. 400 BCE) said, “Wisdom (*zhi*) is the capacity

... by which, when one knows, one necessarily knows (as with eyesight)" (p. 212), and "Wisdom, by means of the capacity to know when in contact with things, enables one to describe it, like the seen" (p. 212). Unlike in Western epistemology, where the relation between subject and object or knower and known plays an essential role, in Chinese philosophy, this is only instrumental to a deeper dynamic process in which the individual attains knowledge of external things and cognitively appropriates objects in the world for building a meaningful life.

Chinese philosophers distinguished different types of knowledge, such as the Mohists' distinction between knowledge by hearsay, knowledge by explanation, and knowledge by personal experience, and Mencius's distinction between knowledge by the senses and knowledge by thinking. But more important is the Chinese concern with how to prepare the mind to know external things as they are, without bias. This can be seen in the Huanglao Daoist ideas of emptying (*xu*), unifying (*yi*), and quieting (*jing*) the mind. These notions were later developed by Xunzi as a way to attain the great clear enlightened state of mind (*da qingming*). Xunzi can be seen as the greatest theorist of knowledge in Chinese philosophy. The last master thinker in the Jixia Academy (374–221 BCE), Xunzi developed his epistemological thinking as theoretical support for scholarly argumentation in the academy, which consisted of different competing schools.

In the manner of an intellectualist, Xunzi emphasized humans' cognitive ability to discern right and wrong, which he termed "discernment" (*bian*). When expressed in discourse, this ability is displayed in what he called "discerning discourse" or "argumentation" (*bian-shuo*). Xunzi conceived of the Way as the ultimate standard for discerning right and wrong, which included classes (*lei*), coherence (*tong*), and distinctions (*fen*) as subcriteria. Since things exist in different classes or categories (*lei*), their corresponding names should also be divided similarly or differently, as the case may be. The function of discourse is to make proper distinctions and classifications (*fen*) among things and names. Finally, all classifications and distinctions in discourse should be composed into a coherent system (*tong*).

To judge right from wrong well, one has to keep one's mind in a great clear enlightened state, attained by making one's mind empty, one, and still (*xu, yi er jing*), ideas that Xunzi received and developed from the Daoists, especially (370–290 BCE). Xunzi understood that when the mind is empty, "what has already been stored [in the mind] does not hinder the reception of new knowledge," that when the mind is one, "the knowledge of particular

things does not hinder their unity," and that when the mind is still, "dreams and noisy fancies do not disorder one's knowing mind" (Xunzi, p. 510).

According to Xunzi, in the process of knowing and arguing for one's knowledge, one must, negatively, discard all obscuring factors and, positively, be alert to other, easily neglected aspects of an issue in dispute. Human knowledge is expressed by concepts, which, for Xunzi, are names (*ming*). Names can be analyzed according to the concepts of intentions and extensions of Western formal logic. With respect to intentions, Xunzi distinguished between names discerning superiority/inferiority and names discerning identity/difference, representing concepts respectively indicating values and facts, for him the former being higher than the latter. With respect to extensions, Xunzi made the distinction between generic names (*gongming*) and specific names (*bieming*), analyzable by reference to the relations of "inclusion" and "belonging to" between classes and subclasses. Classes can be seen as the basis of all deductive and inductive reasoning. Since the Way, as the ultimate standard for judging right from wrong, can be classified into different classes (*lei*), *lei* is imbued with both logical and ontological meanings.

## SCIENCE

Before modern European science emerged in the sixteenth century, Chinese science was much more advanced than European science, as shown by Joseph Needham in *Science and Civilization in China*. Chinese philosophers were often enthusiastic about and full of scientific knowledge. For example, Zhu Xi (1130–1200), though living in the twelfth century, was well acquainted with different kinds of scientific knowledge, and is therefore a good example to showcase the philosophical import of Chinese science. Zhu Xi can be seen as the great synthesizer of medieval Chinese scientific knowledge and its philosophical foundation, even if he lived earlier than such Western medieval thinkers as Robert Grosseteste (1175–1253), Roger Bacon (1210–1292), Albert the Great (1200–1280), St. Bonaventura (1217–1274), and St. Thomas Aquinas (1225–1274). Zhu Xi's *Wenji* (Collected writings) and *Yulei* (Classified conversations) display his rich knowledge in the domains of calendrical astronomy, botany, music and harmonics, geomancy, medicine, etc. Also, he frequently discussed matters of science with his disciples, sometimes for the sake of scientific knowledge, sometimes to illustrate Chinese classical texts.

Some of Zhu Xi's observations on natural phenomena are quite interesting and true. For example, he said, "Mountains were formed by the elevation of sea bottom."

He then proceeded to prove it by pointing to the presence of seashells on top of mountains, saying, “On high mountains there are often seen shells of oyster and shellfish in the rocks. These rocks must have been earth in ancient times, and those shells from oysters and shellfish in the water. The lower becomes the higher, the soft becomes hard. This phenomenon is worthy of pondering upon, for these facts can be verified” (1999, bk. 5, p. 19). In this particular case, Joseph Needham admires Zhu Xi, writing, “Zhu Xi recognized the fact that the mountains had been elevated since the day when the shells of the living animals had been buried in the silt mud of the sea-bottom” (1959, p. 598). Note that Zhu Xi’s remarks here concern mountain formation as well as fossils of sea animals. In other areas of science, Zhu Xi also correctly observed that the source of moonlight was the sun, and he correctly explained such phenomena as tides and eclipses of sun and moon.

Even if Zhu Xi was full of natural knowledge and was rational in attitude, he was not satisfied with the technical dimension of scientific knowledge and sought deeper understanding by exhausting the principles of all things and developing a holistic vision of reality. In fact, his interest in knowledge of nature should be understood in his philosophical concepts of *gewu zhizhi* (investigating things to extend knowledge). For Zhu Xi, *li*, meaning principle, reason, or order, could be found in everything and was worthy of investigation. He said, “As high as the Ultimate Infinite, the Great Ultimate, and as low as one herb, one tree, as tiny as one insect, each has its principle. ... If we leave one thing uninvestigated, then we lack one principle” (1999, bk. 1, p. 295). The object of Zhu Xi’s investigation was the order existing in other things, which presupposed that things and their principles possessed a certain otherness. The attainment of knowledge would include knowledge of other things and knowledge of self, or better said, a detour through the other that leads to a return to oneself, as when one finally achieves sudden penetration into the nature of things and attains transparent self-knowledge. Thus, the investigation of things is a detour in which one first goes outside one’s self to the other and by knowing the other, one can finally come back to knowing one’s own self.

So much for the Zhu Xi example. What is to be said about the epistemological specificity of Chinese science in comparison with European modern science? Generally speaking, Western modern science was historically grounded in the Greek heritage of *theōria*, the disinterested pursuit of truth and sheer intellectual curiosity. Aristotle said in his *Metaphysics* that science began in a

way of life that included leisure (*rhaistōnē*) and recreation (*diagōgē*), such as the Egyptian priests enjoyed who discovered geometry. They did not need to care about daily necessities of life and could wonder about the causes of things and seek knowledge for its own sake. The result of their wonder was theories, whose meaning, according to Aristotle, was determined, in one sense, by practice, “not in virtue of being able to act, but of having the theory for themselves and knowing the causes” (*Metaphysics* 981b 6–7), and, in another sense, with respect to universal objects, seen by Aristotle as the first characteristic of science (*Metaphysics*, 982a 3–10, 20–23).

In contrast, Chinese science in general began as a concern leading not to universal theorization but to universal praxis. It was because of his concern with the destiny of the individual and society that Chinese began to philosophize. The great appendix of the *Zhouyi* asserts that the study of changes began with concern and anxiety over natural calamity, not in leisure and recreation. It also suggests that the practical intention of Chinese science was to serve as guidance for a universal praxis. Nevertheless, both modern European science and traditional Chinese science are concerned with the universal, or better, the universalizable, character of science, the one more with universal theories, the other more with universal praxis, yet both of them criticize and seek to transcend particular interests, with a view to attaining universality.

Because of its pragmatic concern, Chinese traditional science, in thinking about the secrets of nature, tends to use concrete images and construct concrete models for understanding natural phenomena. These images or models came directly from an intuitive or speculative vision of reality. Models in traditional Chinese science were based on analogies, that is, they were concrete models of images or small-scale models that combined the functions of explanation and pragmatic operation. For example, the construction of astronomic clepsydras (water clocks), very important in Chinese astronomy and hydraulics, expressed the genius of traditional Chinese science. Here were models that linked the movements of the heavens with the more visible movement of water or other fluid to create a visible image. In modern terms, the Chinese way of thinking in science is more analogous in form, giving birth to images and icons, which provide a more intuitive grasp of a situation in action. By contrast, the construction of models in modern European science is guided by theories presentable in mathematic form. Such models serve to mediate between mathematical theories and concrete empirical data. Modern European science, as exemplified by Newton’s physics and Leibniz’s

*mathesis universalis* (a universal science modeled on mathematics), is akin to the digital way of thinking and provides a more structured and lucidly conceptualizable understanding.

The special features of traditional Chinese science in comparison with modern European science concerning the epistemic structures involved in the process of constructing scientific knowledge are these: First, on the rational side, modern European science, in constructing theories, uses logically and mathematically structured languages to formulate theories of local validity, that is, with explanatory and predictive power in a particular domain of phenomena. In comparison, Chinese traditional science did not utilize logico-mathematical structures in its theory formation. Chinese never pondered about the structure of language to the point of elaborating a logic system for the formulation and control of scientific discourse. Mathematics, although highly developed, was used only for describing and organizing data, not for formulating theories. Chinese quasi-scientific theories, lacking logical and mathematical structure, were principally presented through intuition and speculative imagination. They might have the advantage of offering insight into the totality of life and environment and giving a reasonable interpretation of them, but these “theories” somehow lacked the rigor of structural organization and logical formulation.

Second, on the empirical side, modern European science is characterized by well-controlled systematic experimentation, which, by elaborating on the sensible data and our perception of them, keeps in touch with the real world, but in an artificial, technically controlled way. In contrast, the empirical data in traditional Chinese sciences were gathered through detailed but passive observations, with or without the assistance of instruments. Traditional Chinese science seldom tried any systematically organized experimentation to exercise active artificial control over human perception of natural objects.

Third, in modern European science, there is conscious checking of the correspondence between the rational side and the empirical side to combine them into a coherent whole so as to serve the objective of explaining and controlling the world. The rational side of science builds up a theoretical vision of the world, while the empirical side relates this vision to the scientist’s sensible construction and controlled experience of the world. Philosophical reflection, in checking the correspondence between these two aspects, assures us of their coherence and unity. In contrast, traditional Chinese science did not conceive of any interactive relation such as deduction/fal-

sification or induction/verification or tests/confirmation to relate empirical knowledge and its intelligible ground of unity. Although Chinese traditional science did have its visions of proper science and knowledge in general, it did not have modern European science’s epistemological reflection and philosophy of science—disciplines that check the nature of and correspondence between empirical and rational constructs.

Still, there is unity in traditional Chinese science. Confucius (551–479 BCE) said that there is a unity binding, or a guiding thread penetrating, all his knowledge. Confucius thus seemed to affirm the complementary interaction between empirical data and thinking. He said, “He who learns without thought is confused. He who thinks without learning is in danger” (*Analects* 2.15). These words remind one of Kant’s proposition that sensibility without concepts is blind, whereas concepts without sensibility are void. But we should be clear that the mode of unity in traditional Chinese science was a kind of mental integration with ultimate reality through ethical praxis. Here praxis or practical action was not the technical application of theories to control concrete natural or social phenomena. Rather, it was an active process of realizing what is proper in the life of the individual and society. Science and technology are not to be ignored, but must be reconsidered in the context of this ethical praxis.

From the analysis above, it becomes clear that traditional Chinese science should be characterized as reasonable, and not rational in the sense of modern Western science. To be rational, one has to control the gathering of empirical data through systematic experimentation, to formulate theories in logico-mathematical language, and to check the relation of empirical data and theories through philosophical reflection. By contrast, to be reasonable, one has to find meaning for human life with reference to the totality of existence. Chinese philosophy, in its quest for what is reasonable, was caught in the tension between reference to the totality of human existence and reference to the totality of all existence. Confucianism insists on referring to the totality of human existence, whereas Daoism seeks to escape from the all too human tendencies of humanist philosophy and to refer rather to the totality of all existence, as expressed by the concept of the Way (*dao*). Daoist philosophy, as a philosophy anchored in the Way and the totality of all existence, and Confucianism, as a philosophy anchored in the totality of human existence, exemplify two complementary aspects of Chinese reasonableness.

## WISDOM

Wisdom is the common concern of Chinese epistemology and metaphysics. Ultimately speaking, in all Chinese philosophical traditions, wisdom is what one's knowledge should finally achieve, and wisdom in some sense always refers to what is really real, to ultimate reality. In ancient China, the same ideogram (*zhi*) was used for both knowledge and wisdom, but later a radical was added to the character to differentiate wisdom (*zhi*) from knowledge (also *zhi*). The modern term for wisdom is *zhìhuì*. Chinese Mahayana Buddhism, while using *zhìhuì*, prefers the term *banruo*, a Chinese phonetic translation of the Sanskrit *prajñā*. When Xuanzang (596–664) set up a system of regulations for his translation project, he showed a particular respect for the term *banruo* in his “five categories of terms not to be translated” (*wu bu fan*), while the Chinese term *zhìhuì* appeared for him to be superficial. Nevertheless, the term *zhìhuì* was also often used in Chinese Buddhism to express the idea of wisdom.

In Confucianism, wisdom means three things. First, wisdom means accumulating knowledge under a unifying thread or penetrating unity, as Confucius said. In this sense, knowledge comes from investigating the natures or principles of things so as to be able to unfold them according to their natures, instead of imposing theories upon them or exploiting their energy for human short-term interests. Second, wisdom means achieving total self-understanding. For Wang Yangming (1472–1529), this entails achieving one's inborn knowledge, completely developing one's true nature, and arriving at one's full potential of the moral knowledge proper to humans. Finally, wisdom means awareness of one's own destiny or heavenly mandate. Confucius took his understanding of his heavenly mandate, at age fifty, as a crucial point of his life. Also, the *Doctrine of the Mean* (c. 5th century BCE) says, “Wishing to know man, he must not fail to know Heaven” (Chan, p. 105).

In Daoism, *Laozi*, despite its critical and negative attitude toward instrumental knowledge and calculation, as shown in its negative use of the term “knowledge,” nevertheless uses the term *ming*, defined as enlightened knowledge of the constant law of nature: “To know harmony is to accord with the constant; to know the constant is wisdom” (chap. 55). According to Daoism, to be wise, which is more than possessing mere intellectual knowledge, is to know the constant laws of nature, and from there, to be one with the Way and thereby to live a life of freedom, understood not as merely making free choices or arriving at autonomous decisions, but rather as complying with the spontaneous rhythms of nature.

In Chinese Mahayana Buddhism, the Chinese term *banruo* is taken to mean only perfect wisdom. This is a development of the Indian tradition, where the term *prajñā* means knowledge as well as wisdom, perfect wisdom as well as imperfect wisdom. In Chinese Buddhism, wisdom means attaining enlightenment, a state in which one understands that all is empty and thus seeks to rid oneself of original ignorance. The term *zhìhuì* (wisdom) was used to translate *prajñā*, especially in Weishi's (for example, in Xuanzang's Cheng Weishi Lun, 659 CE) concept of transforming consciousness into wisdom (*zhuan shi de zhi* or *zhuan shi cheng zhi*). For the Weishi School, more Indian than Chinese, wisdom arises from Alaya consciousness (Alya vijñāna). But for the Sanlun School, wisdom means realizing the ultimate emptiness of the world. In Chan (Zen) Buddhism, wisdom is the immediate self-realization of Buddhahood in the details of everyday life.

In his *Banruo wuzhi lun* (Wisdom as nonknowing), Sengzhao (383–414) distinguished wisdom from common knowledge. For him, knowledge is epistemologically structured by the relation of the knowing subject and known object, and therefore is relative and limited to a particular object. The content of knowledge is expressed in logical propositions that should be free of logical contradiction. In contrast, wisdom is all-knowing and comprehends all things, including itself. Therefore, it lacks subject-object structure and is not limited and relative to any particular object. Its self-awareness results from its own crystal-clear mirroring and not from any self-reflection or intuition. For Sengzhao, wisdom was a mysterious function of a mind characterized by emptiness, and emptiness he identified with ultimate reality, which belongs to the ontology and therefore is beyond all logical considerations, including the principle of noncontradiction. For Sengzhao, wisdom was absolutely pure and was beyond all sorts of delusions arising from relative knowledge.

Jizang (549–623) developed a typology of three types of wisdom. First was ultimate wisdom (*shixiang banruo*), which penetrates into ultimate reality, or the emptiness of all things. This is the ultimate ground of the other types of wisdom. Second was illumining wisdom (*zhengguan banruo*), which throws light upon the ultimate reality in all its different facets and manifestations. In this application of ultimate wisdom in meditating on the essence of each and every thing, one comes to see that each of them is empty. Third was linguistic wisdom (*wenzi banruo*), which enables one to give powerful linguistic expression to the perfect congruence between ultimate reality and its manifestations.

## METAPHYSICS AS KNOWLEDGE OF ULTIMATE REALITY

Metaphysics concerns knowledge of ultimate reality. Even if all the schools of Chinese philosophy used “dao” (the Way) as a common term to refer to ultimate reality, there were other terms used in different schools, even different terms used by different philosophers within one school. For example, in Confucianism, different Confucians took the concepts of heaven, humanness, sincerity, and principle or reason as ultimate reality. In the following sections, we will see what different schools took as ultimate reality: heaven, humanness, sincerity, and principle in Confucianism, the Way in Daoism, and emptiness in Buddhism.

**ULTIMATE REALITY IN CONFUCIANISM.** Generally, the concept of ultimate reality in Confucianism moves from heaven (*tian*), a residue from ancient Chinese religious beliefs; to humanness (*ren*) in Confucius himself; then to sincerity (*cheng*) in Zisi, Confucius’s grandson; and to mind (*xin*) or principle (*li*) in neo-Confucianism. In the prephilosophical tradition, the *Shijing* (Book of odes) and the *Shangshu* (Book of documents) used the concept of heaven, imbued with a religious sense, to represent God on High. A residue of this notion could still be found in Confucius when he said, “If heaven wished to destroy this legacy, we latecomers would not have access to it. Since heaven is not going to destroy this culture of ours, what can the people of Kuang do to me?” (*Analects* 9.7). Confucius also said that he prayed to heaven, yet heaven, though manifesting itself through regular cosmic movement, remained silent, thus maintaining a certain unfathomability. Confucius said, “Does heaven speak? And yet the four seasons turn, and the myriad things are born and grow within it” (*Analects* 17.19).

Confucius’s proper contribution consisted in proposing the concept of humanness (*ren*) as a transcendental foundation for ritual (*li*). Humanness, a transcendental capacity in each person, had an ontological dimension in that it presupposed that all beings are interconnected, and this allows humans to be affected and respond to other people and things. Confucius considered this transcendental capacity of each person to affect and respond to others as the transcendental foundation of ritual. Sometimes humanness was combined with the Way to specify the way of humanness. With this metaphysical move, the concept of *ren* achieved metaphysical status in neo-Confucians such as Zhou Dunyi (1017–1073) and Zhang Zai (1020–1077), who extended humanness to the whole cosmos (a cosmic humanness), surely a metaphysical concept. Also, Zisi (493–406 BEC),

Confucius’s grandson, developed Confucius’s idea of ultimate reality in *Zhongyong* (*Doctrine of the Mean*) with the concept of sincerity (*cheng*), which had two levels of meaning: On the psychological level, *cheng* meant being true to one’s own self; on the metaphysical level, *cheng* meant the really real, truth, or reality itself.

Under the influence of Tiantai Buddhism and Chan Buddhism, idealist neo-Confucians such as Lu Xiangsan (1139–1193) and Wang Yangming took mind imbued with moral values to be ultimate reality. Such a mind was attainable through moral practice and moral effort. They thereby laid the foundation for a kind of moral metaphysics. In affirming that the Great Ultimate is principle or reason (*li*), the realist neo-Confucian Zhu Xi took principle or reason to be ultimate reality. For Zhu Xi, even if everything has its own principle, by way of metaphysical participation they share their reality with the cosmic principle that ultimately governs the whole world.

**ULTIMATE REALITY IN DAOISM.** Daoism coherently used “Way” (*dao*) as a metaphysical concept to denote various levels of metaphysical reality and ultimate reality itself. Etymologically, the ideogram for *dao* is composed of two elements, the head and the act of walking on a way. Together they mean a way on which one could find direction and a way to some point. Though *dao* was never limited to the idea of a physical way, this image of a way suggests the meaning of *dao*: The *dao* puts everything on its way. In common use, *dao* also means “to say,” “to speak,” or “to discourse,” such as the second “dao” in the opening of *Laozi*, which says, “The way that can be spoken of is not the constant Way” (chap. 1). In Daoism, the function of discourse is always negative. Discourse, once said, must be hushed; words, once written, must be erased. One can never discourse about ultimate reality in any human language. This is quite different from Western philosophy, from the beginning of which emphasis has been on the function of language, of logos, to express reality. Apart from these two levels of meaning, *dao* in Daoism has three other uses that are more philosophical:

First, it refers to laws of becoming or laws of nature, especially in the term *tiandao* (the Way of heaven) or *tiandi zhi dao* (the Way of heaven and earth). In Daoism, the laws of nature have two aspects: (1) The structural law says that all things are structurally constituted of different yet complementary elements, such as being and nonbeing, yin and yang, movement and rest, weak and strong, and so on. (2) The dynamic law says that once a state of affairs has developed to the extreme in a process of

change, it will naturally move to its opposite state of affairs.

Second, it refers to the origin giving birth to all things. If all things are regulated by laws of nature, there must be an origin that gave birth to all things, there must be a cosmic law. Normally, the origin gives birth to all things in a process of differentiation and complexification, as indicated by these words in *Laozi*: “The Way gave birth to one. One gave birth to two. Two gave birth to three. Three gave birth to all things” (chap. 42).

Finally, it refers to ultimate reality. The Way ultimately represents the ever self-manifesting act of existence. If there is an origin giving birth to all things, then before the origin, there must be a self-manifesting act of existence, defined in relation to all things. The self-manifesting act of existence is reality itself, whereas everything we say about the Way is but a constructed reality, which can never be reality itself. One can mention the Way to express something about it, but what is said becomes a constructed reality and not reality itself. To keep one’s mind open to reality itself, all human constructions stand in need of further deconstruction.

Most of the time in traditional Daoism, these three levels of the Way were closely related one another, so closely that they were often mixed up and seldom clearly distinguished in the texts. It is with philosophical effort that they can be analyzed into clearly distinguished aspects of a well-connected whole. This is to say, in traditional Daoism, ultimate reality and its multifaceted manifestations can be logically distinguished but are not ontologically distinct.

**ULTIMATE REALITY IN BUDDHISM.** Chinese Mahayana Buddhism, like Indian Buddhism, takes emptiness as ultimate reality. Although the Sanskrit term *śūnyatā* has many meanings in the Indian tradition, its Chinese equivalent *kong* has three major philosophical meanings, each with its own focus: First, on the ontological level, emptiness means that all things come and go through interdependent causation and therefore lack any self-nature or substance of their own. Second, on the spiritual level, it means that the spiritual achievement of the sage consists in total freedom, attaching himself neither to being nor to nonbeing, neither to dualism nor to non-dualism, not even to any form of spiritual achievement, no matter how high or deep it is. To keep one’s spirit totally free, one must even empty the emptiness. Third, on the linguistic level, emptiness means that all the words we use are artificially constructed, without any fixed correspondence or reference to reality.

Although Indian Buddhism put more emphasis on the ontological and the linguistic senses of emptiness, Chinese Mahayana Buddhism, generally speaking, emphasized mostly the spiritual sense of emptiness. For example, in the *Buzhen kong lun* (On the emptiness of the unreal), Sengzhao, appropriating Daoist philosophy, interpreted emptiness as the spiritual achievement of a sage (though he also gave other meanings to the term “emptiness”). For example, we read, “The sage moves within the thousand transformations but does not change, and travels on ten thousand paths of delusion but always goes through. This is so because he leaves the empty self-nature of things as it is and does not employ the term ‘emptiness’ to make things empty” (Chan 1963, p. 356, with corrections).

The spiritual achievement of a sage, who has no attachment to the realm of either being or nonbeing, not even any attachment to his own spiritual achievement, results from a mysterious function of his mind, which on the one hand is nonsubstantial and empty, yet on the other hand is mysterious in function and self-transcending. Because of this, the Way (emptiness as the ultimate reality) and sagehood are not far away from us and can be realized at the moment of enlightenment. “Things when touched become real. ... Man when enlightened becomes mysterious” (Sengzhao, vol. 45, pp. 152–153). The idea of a mysteriously enlightened mind rendering real all things touched by it significantly influenced other Chinese Mahayana schools, especially Tiantai and Chan. In Tiantai and Chan Buddhism, the mind was taken to be ultimate reality.

## INBORN KNOWLEDGE AND MORAL METAPHYSICS

Idealist neo-Confucianists, such as Lu Xiangsan and Wang Yangming, considered moral knowledge as inborn and the realization of moral knowledge to be the only access to the really real. They were idealists in the sense that they took mind as the ultimate reality, identifying the human mind and the cosmic mind, which they saw as the ontological source of all values and moral knowledge. For them, knowledge meant mainly moral knowledge and was therefore value-laden. Since moral knowledge comes from the mind, humans must be capable of knowing it before all empirical knowledge. As a kind of innate knowledge, it is to be realized through human moral effort and moral practice, called “realization of innate knowledge” by Wang Yangming. Innate moral knowledge is like a permanent light within everyone, arising before the emotions. The individual realizes it by overcoming

selfish tendencies, and thereby arrives at ultimate reality. Morality was thus considered a pragmatic way to access ultimate reality, and thus had metaphysical import.

Inheriting this line of thought, Mou Zongsan (1909–1995), a well-known figure in modern Confucianism, proposed the idea of moral metaphysics (*daode de xingshangxue*). He distinguished between moral metaphysics and the metaphysics of morals, the latter being a metaphysical study of morality and therefore moral philosophy rather than metaphysics. His idea of moral metaphysics represented an effort to emphasize the role of Confucianism and moral actions in Chinese metaphysical thinking. He also distinguished between the moral metaphysics of Confucianism and the liberation metaphysics (*jietuo de xingshangxue*) of Daoism and Buddhism. Even for Mou, these three traditions of Chinese philosophy saw the human mind as capable of intellectual intuition (*zhi de zhijue*), yet he preferred the Confucian way of attaining ultimate reality through moral practice and moral self-awareness. He thought that humans could achieve intellectual intuition through moral action and realize the noumenon of humanness (*ren*), which represented for him the ultimate reality or the thing in itself. Sometimes Mou named it “the free infinite mind/heart,” or “the true self,” that, as noumenon, possessed universality, infinity, and creativity, and through a process of self-negation similar to Johann Gottlieb Fichte’s “I” positing a “non-I,” it could unfold itself into a world of phenomena. In Mou’s philosophy, intellectual intuition is an act of self-awareness of the free infinite mind, which replaced the concept of a personal God in Christianity, Islam, and Judaism.

Mou’s moral metaphysics, by making Confucianism a kind of metaphysics, and thus making Confucian moral praxis an instrument for attaining ultimate reality, neglected the proper value and practical methods of Confucian moral praxis. Also, he considered morality a matter of finding one’s true self, without relation to others, and thus without a proper ethical dimension. In this way, Confucianism lends its own weak points to a grand metaphysical system modeled after European philosophy. Also, by positing such an exclusively moral metaphysics, Mou neglected other metaphysical experiences, such as those in encounters with nature, in artistic creativity, in religious piety, and in historical encounters—all so rich in metaphysical implications in traditional Chinese culture. In his absolute idealism, Mou blurred and even confused the distinction between reality itself and constructed reality.

## METAPHORICAL METAPHYSICS

Chinese philosophical traditions such as Confucianism, Daoism, and Buddhism all hold that ultimate reality, whatever its name, always has an unfathomable dimension and therefore is hidden from all human constructions and human languages. For this reason, the terms Chinese philosophers use to indicate ultimate reality—terms such as *tian* (heaven), *ren* (humanness), *cheng* (sincerity), *dao* (the Way), the mind, principles, emptiness, etc.—are used metaphorically rather than descriptively or ostensively. They express ideas about ultimate reality with a certain tangible image of it, which is to say that they are in some sense image-ideas, instead of pure ideas. Chinese philosophers, when grasping ultimate reality with enlightening insight, tend to form original image-ideas, something between a pure idea and an iconic image, thereby retaining the holistic character of the manifestation and the intuitive nature of the perception. This idea-image evokes the richness of ultimate reality without exhausting it, and therefore has the status of a metaphor.

This basic characteristic of Chinese metaphysics provides foundations for Chinese artistic, moral, and scientific practices and historical actions. Artistic creativity, by imagination and poetic transformation, renders this idea-image into a concrete iconic image and thereby materializes it. In moral and ethical reasoning, practical reason brings the idea-image to bear on an ethical situation, leading one to intervene and thereby take moral responsibility. In science, natural philosophers built models with reference to image-ideas, creating analogical images of reality so as to grasp natural processes in an organic and holistic way. In the historical arena, one can discern, by referring to idea-images, traces of notions of ultimate reality in the historical events and actions taken by historical agents. In this sense, Chinese art, ethics, science, and history are imbued with metaphysical significance.

Generally speaking, metaphor allows us to see one thing as something else. In other words, metaphor has an “as-structure,” a term first used by Martin Heidegger to characterize interpretation. In the Chinese tradition, metaphysics or discourse on the Way is already a metaphorical interpretation of ultimate reality. Compared with the original manifestation of ultimate reality, various ways of realizing idea-images also possess an as-structure, in the sense that they allow us to see ultimate reality as idea-images, the later thereby serving a certain metaphorical function. In this sense, Chinese metaphysics can be characterized as a kind of metaphorical metaphysics. Viewing it in this way, one can achieve a true understanding of the spirit of Chinese philosophy.

## RELIGION

The subject of the religious dimensions of Chinese philosophy covers both a vast time period—at least two and a half millennia—and a vast array of religious traditions, including theistic religions like Islam and Christianity. This entry, however, will focus on only a few topics and on two indigenous traditions—Confucianism and Daoism—and those streams of Buddhism often, if controversially, said to be most characteristically Chinese, such as the Chan (Japanese Zen) tradition. These traditions not only share features but adherents of each, even fierce adherents, often adopted ideas and practices from the other traditions in ways that can seem disconcerting to people familiar with only Western religions. (Thus, the truth in the clichés that a person can be a Confucian at work and a Daoist at home or that Chinese Buddhists often employ Confucian ethical ideas.) This phenomenon raises interesting philosophical questions about the meaning, in China, of a religious tradition as well as about the character of an adherent’s structure of beliefs, but this entry will treat them only obliquely in what follows.

Another, perhaps more vexing concern is the nature of the relationship between religion and philosophy in China. This subject has often been examined, in both China and the West, in a way that basically reflects the desire to guarantee that Chinese philosophy has none of the baleful qualities that characterize religion (religion in this context usually means folk religion, or put more baldly, superstition and magic). The relationship is, however, complicated, and one can best approach it by discussing the notion of religion as it affects this subject.

### THE NOTIONS OF RELIGION AND RELIGIOUS THOUGHT

The attempt to define the phenomenon of religion and religious thought (and thereby also specify the forms of various religions and their processes of thinking) is a modern Western project—and one with many critics. It often combines attempts to map out a sphere of human life in a reasonably objective fashion with a desire to improve human life, which usually means to make human affairs more rational. The treatment of Chinese religion, a notoriously messy phenomenon or set of phenomena, exemplifies most that is bad and good in the project.

One is, however, interested in only one facet of that treatment, and one can begin this investigation by turning to Clifford Geertz’s (1973) sophisticated and

immensely influential account (or definition) of religion. For him a religion is: “(1) a system of symbols which acts to (2) establish powerful, pervasive, and long-lasting moods and motivations in men [an ethos] by (3) formulating conceptions of a general order of existence [a worldview] and (4) clothing these conceptions with such an aura of factuality that (5) the moods and motivations seem uniquely realistic.” Geertz comments at length on this definition, but of special importance is his claim that “a group’s ethos is rendered intellectually reasonable by being ... adapted to the ... world view ... while the world view is rendered emotionally convincing by being presented as an image of [the ethos]” (pp. 89–90).

This account seems to fit much Chinese religious thought, even to pinpoint crucial features of it. This is especially true if one focuses both on how Geertz exhibits the porous boundaries between elite and popular attitudes and, especially, on how he develops the ways his five elements interact with each other to create a closed perspective, a seamless web of reflection and reinforcement, in which ethos and worldview interact. Daoism is replete with stunning examples of these processes, but they also appear prominently in other traditions.

Moreover, and of special significance for this entry, the religious thought that results is detailed and can even count as rigorous, given its premises and notions of entailment. Furthermore, it often involves cosmological or cosmogonic subjects, many of which include science-like accounts of both natural and human phenomenon. (Correlative thinking, which finds homologies between the natural and human to control the latter through aligning it with the former, is only one of the most prominent and famous instances.) Finally, much of this thinking depicts a universe that is well, even fabulously, endowed with a great variety of beings (e.g., see Wang Bi 1994; Ko Hung 1966; Robinet, 1997, pp. 115–148, 195–256.).

Such thinking shares, however, few of the assumptions and notions that would make it credible to one’s common contemporary experience, much less to one’s understanding of philosophy. That is, this thinking cannot be formulated in a way that meets the conditions of plausibility found in an experience informed by, for instance, modern scientific explanation, historical consciousness, and ideas about the rights of all humans. Moreover, it makes difficult any understanding both of changes within a tradition, even if such changes were not always clearly recognized by participants, and of reasoned conversations among adherents of different traditions.

A focus on these kinds of Chinese religious thought, a common focus among scholars today, surely can be justified as a valuable and integral kind of historical inquiry. Nevertheless, this kind of focus also underlies the common perception that almost all Chinese philosophy lacks real analytical rigor, sophisticated modes of inquiry, and evident ways in which to attend to significant alternative views and therefore to reflect critically on given social forms.

The aim here, in contrast to the kind of historical inquiry just noted, is to show the ways in which many religious dimensions in Chinese thought are imperfectly captured by such criticisms and therefore have a claim on one’s philosophical attention. Indeed, by examining three topics at length, and mentioning several others, this entry will illustrate how one can enrich an understanding of both philosophy and religion that, understandably, arises mainly from Western examples. One can, that is, be involved in the distinctive sort of intellectual exercise in which one tries to place oneself within a world that is much larger than the world one normally inhabits, a world the modern situation has, thankfully, forced on one. Before beginning that, however, one needs briefly to examine a different approach to the idea of religion.

The word *religious* refers of course to many phenomena, but most important in this case is the reference to an orientation that differs from and judges many features of the ordinary world, even if it also underlies other features of that world. (It is the latter feature that Geertz’s [1973] examination usually emphasizes.) The religious, in this sense, rejects commonplace approaches to human fulfillment because normal life contains too many apparently insurmountable difficulties and because a marvelous spiritual actualization is possible.

The dialectic of great need and grand fulfillment means this orientation fits within what can be called a discontinuous or nonameliorative type of religion. This type of religion is, in many ways, fundamentally discontinuous with the activities and expectations of normal life; it seeks far more than just to ameliorate the problems ordinary life produces, and therefore it makes a substantial break with normal life rejecting attempts to build on what is already present. In contrast, in a continuous or ameliorative religion people work within the framework normal life provides. Their aim is to deepen and extend the best ideas and practices people have. The latter applies bandages to what are perceived as minor wounds, while the former calls for major surgery. The latter, of course, labels that kind of major surgery mutilation, while the

former labels the mere application of bandages malpractice.

The distinction between discontinuous and continuous religion is not a simple binary one. Rather, the two types define the ends of a continuum and specific features of a religious tradition will fit at places within the continuum. Significant features of Confucianism, for example, fit on the continuous end and significant features of early Daoism and Chan Buddhism on the discontinuous end. (Moreover, many of the most substantial debates among and within these traditions are illuminated by understanding where on the continuum a disputed feature, such as meditational activity, fits.) Nevertheless, all of them have pronounced discontinuous elements, and they appear prominently in their most able philosophical thinkers (e.g., see Mencius 1970, Book 2A; Chuang-Tzu 2001, pp. 76–93; Hui-neng 1967, #28–#47, #149–#174; Graham 1958, pp. 67–91).

These traditions may lack many of the discontinuous qualities that characterize theistic religious, but they also share other features, if often manifesting them in a distinctive way. Put schematically, three discontinuous religious elements are especially important in these traditions. One is a focus on a sacred realm that is related to but differs dramatically from the human realm. This realm provides thinkers with a perspective from which they can evaluate ordinary activities in ways that most people find perplexing at best and insulting at worst. Another is a belief that kinds of empowerment occur that exceed what appears in ordinary life, are crucial to people attaining any true flourishing, and can produce people who transcend the limits of ordinary understanding. Specifying exactly how this empowerment operates and how sacred and human realms interact, even how independent they are, is difficult enough, however, to demand special uses of language. (As it will be seen, despite its theoretical imprecision the needed language aids rather than impedes the fundamental spiritual discipline of self-cultivation.)

A final discontinuous element is the distinctive quality of members' adherence to the traditions of which they are a part. These thinkers recognize that traditions contain regenerative powers individuals alone could not produce and yet also can be a source of debilitating false fixities. This recognition leads them both to treasure their traditions and to be extremely sensitive to the dangers present in false teachings, misleading authorities, and the communities that gather around them.

## TOPICS IN CHINESE RELIGIOUS THOUGHT

One can now turn to three subjects that illustrate the distinctive contribution to philosophy that religious elements in Chinese philosophy can provide. One is the subject of ritual, a second the differences and similarities between normal and religious excellences, and a third the need to employ various genres to present religious realities persuasively, a topic that helps one understand some distinctive, formal features of Chinese philosophy. Before beginning that examination, however, one should briefly note six other topics that illustrate the range of pertinent material that could be examined. This entry will, if telegraphically, describe each of the six; provide one paradigmatic, and accessible, instance from early Chinese thought; and then note resemblances to Western materials, thereby risking the embarrassment brief generalizations can produce.

- (1) In each tradition one finds the belief that skillful people, and thus the idea of skillfulness, manifests a religious excellence that tells one much about the character of perfected action, thought, and selfhood. Little that resembles this focus, and the understanding that results from it, has ever appeared in Western philosophical discussions (Chuang-Tzu 2001, pp. 62–65, 135–142).
- (2) Each tradition treats, if often with different results, the question of participation in or retreat from social or political involvement, seeing it as a choice that can be understood philosophically only if one grasps the religious dimensions of each alternative. A version of the question has, of course, been central in the West, but its religious dimensions—and what arises from considering them—has been far less central (Mencius 1970, Books 4A, 5B).
- (3) Each tradition sees the purported religious excellence of aimless wandering (*you*), powerfully presented in early Daoism, as an ideal that raises the deepest philosophical questions about ordinary ideas of intention and responsibility. The absence of a similar ideal, and thus of the resulting questions, means certain religious challenges to basic ideas about human purposes and obligations are never fully engaged in the West (Chuang-Tzu 2001, pp. 43–47, 66–75).
- (4) An agnostic posture toward many central religious notions is understood by many thinkers in these traditions to be a mark of true spiritual achievement. Neither the implications nor the gen-

eral importance of this posture are probed in the West as they are in China, although the attitude surely is not absent (Xunzi 1994, pp. 3–32, 88–112).

(5) Humor is a crucial religious excellence in early Daoism (as well as in the Chan tradition) and the philosophical import of the perspective humor generates is illustrated constantly and occasionally even analyzed at length. With some notable exceptions, humor is rarely a central subject in especially Western theistic traditions (Chuang-Tzu 2001, pp. 122–125, 207–210).

(6) All these traditions provide myriad illustrations of the ways in which commentaries on texts thought to be religiously authoritative constitute a, perhaps the, major way in which philosophical thinking is both motivated and constrained. The resemblance to traditional practices in the West is close here, but both the elusive character of the Chinese texts commented on and the character of the constraints on inquiry provide illuminating insights (Confucius 2003, Books 4–7).

Any of these six topics could productively be examined at length, but now the focus of this entry will shift to three topics that are especially illuminating for one's inquiry: ritual, the relationship between normal and religious virtues, and the genres needed to present religious realities persuasively.

## RITUAL

Ritual, probably the most adequate of the multitudinous translations of the character *li*, is surely among the most distinctive and complex of all Chinese notions. Put simply, the single notion covers two activities that most contemporary Westerners think are quite different. One activity is solemn, explicit religious activities such as marriage or internment services. The other activity, however, is what can be called etiquette or, more accurately, those reasonable and humane learned conventions that make up the ethos of a culture (e.g., see Xunzi 1994, pp. 49–73; Chuang-Tzu 2001, pp. 87–93; Robinet 1997, pp. 166–183; Gregory 1991, pp. 41–43, 274–285; Ching 2000, pp. 72–90).

Ritual covers, then, everything from the solemn performance of an elaborate ceremony to the “excuse me” after a sneeze. Explicit religious activities and social activities are, that is, part of one continuum, although there are, of course, notable differences. In specifically religious rituals, for example, the focus is on humans facing

thresholds, situations where people move to a new state or respond to what lies beyond their ordinary routines.

The combining of these two senses of ritual is open to the criticism that it displays an unsophisticated kind of thinking that fails to differentiate what can and should be separated. The defense of the combination, one most evident in Confucianism but present in the other two traditions, rests on the notion that social rituals are more than just pedestrian social facts. Social and religious rituals resemble each other, that is, because both are sacred ceremonies that express and foster a spontaneous coordination that is rooted in reverence. Moreover, both exemplify learned, conventional behavior that manifests distinctly human rather than simply animal-like actions. Both therefore promote crucial human qualities and respond to central human needs.

Ritual is, then, a notion of overarching significance in Chinese religious thought and contests about its character and value are frequent. In fact, debates about ritual often served to focus debates among competing visions of life. Seeing, therefore, the various views of ritual (social and religious) that continually appear, if in somewhat different forms in different times and traditions, can help one understand the philosophical import of the idea.

Especially prominent in these debates are three kinds of attacks on ritual and three defenses of it. Put telegraphically, the different positions are as follows. One group attacks rituals as a wasteful, even unjust, use of scarce natural and human resources. Another group attacks them as a social artifice that distorts significant human capacities and reinforces destructive social organizations. A third group sees them as an inadequate form of social control that is best replaced by clear rewards and punishments.

One defense of ritual sees in it a process that activates transhuman forces and uses those forces to help humans. Another justifies ritual in terms of the innate human capacities for it or even inertial tendencies toward it; human beings, that is, need ritual if they are to be actualized. A last defense believes rituals are sanctified by tradition; they therefore need no real justification and must always be meticulously followed no matter what the apparent price.

Many, although surely not all, of the most sophisticated thinkers from these traditions think each of these approaches is flawed, and they therefore reinterpret religious rituals both to win outsiders' assent and to deepen their own and other adherents' assent. They usually proceed, to focus just on religious rituals, by distinguishing

among three different kinds. First are rituals that are useless or even harmful; sacrificing a pig to cure an illness falls in this class. Second are rituals that adorn life in important but not critical ways; rituals to produce rain fall in this class. Third are rituals that provide a crucial service to human life; death or internment rituals fall in this class.

Such reformulations manifest a set of common characteristics, and they are worth noting because of what they tell one about attitudes to religion. Most generally, the overarching goal of all these reformulations is the protection and encouragement of fully flourishing human activity. That goal provides the criterion both for dividing necessary from unnecessary religious ideas and actions and for reforming the meaning of the necessary ones. Second, these reformulations critically examine all simple anthropomorphic descriptions of the transhuman realm and replace them with designations that are symbolic or stress the mysterious. Third, if closely related to the second, they criticize depictions of activities that describe a manipulative relationship between the human and the transhuman. In fact, they often redescribe those activities in terms of how feelings are rearranged and spiritual attitudes are generated.

The grounds these thinkers use to defend ritual tell one much about the role of religion in Chinese philosophy. They usually, that is, presume that one is frail in ways that often are difficult for one to accept. Not only does one live between origins and terminations one cannot control but one also constantly faces the numinous. Moreover, one is prone to primordial reactions, and one must treat them in a fashion that both controls their destructive side and nurtures their constructive side. Stringent limits, then, define what people can do; they cannot immediately form themselves into what simple rational judgment might commend them to be. Ritual roles present, for instance, roles that people have no real choice but to assume, with the role of the mourner, however defined, being perhaps the clearest instance.

Underlying this perspective is a negative judgment about a philosophical approach that rejects ritual because it desires to produce a rigorous and coherent picture of the world that will provide simple, reasonable grounds for ideas and actions. Proponents of this approach reject internment rituals, for example, because to them the principle of noncontradiction is crucial; a person is either dead or not dead. They want to face life and death directly and they put everything into clear-cut categories.

Against such an approach, it is argued that when life is seen clearly, and in the death of others one sees it espe-

cially clearly, one can neither make it into a coherent understandable whole, nor respond adequately to it by focusing on simple practical expedients. Human life is too fragile and delicate, too complex and contradictory to capture in simple rational systems. One touches life as it actually is, then, only through the complex pathos, the human contradictions, the struggle to find peace, and the openness to the numinous that rituals exemplify. A related but different kind of judgment on some kinds of ordinary philosophical attitudes underlies the second subject, and to that one may now turn.

## RELIGIOUS AND ORDINARY VIRTUES

To distinguish between religious and ordinary virtues (or excellences) in Chinese thought might seem to be problematic or even just wrong-headed, but investigating the subject can illustrate, among other things, the usefulness of examining apparently inapplicable Western ideas in the Chinese context. The relevant Chinese thinkers never, of course, make any formal distinction between normal and religious virtues, except when discussing those virtues that bind only those adepts who adopt monastic rules. Moreover, their general conceptual framework does not lead them (and probably literally could not allow them) to distinguish between what, say, Catholic Christianity calls natural and supernatural virtues. They surely would, that is, reject any distinction that rests on a clear-cut differentiation between what humans cause and what a deity, distinguished by the quality of aseity or being unmoved, causes.

Nevertheless, a crucial feature of much Chinese philosophy is the conviction that some virtues (or unnamed features of some virtues) have a special character. They produce actions and attitudes that both differ from normal virtues and change a range of normal actions in profoundly important ways. In fact, a number of traditional Western ways of theoretically distinguishing religious and normal virtues seem to be implied. Examples include sharp distinctions made among the kinds of objects pursued, among the goals of the intentions manifested, among the precise forms of behavior produced, and among the kinds of empowerment displayed. Moreover, and perhaps even more striking, many think humans are susceptible to transformations so total as to make some individuals fundamentally different from the rest, to make them, for example, the possessors of truly extraordinary abilities to affect the natural and human world (e.g., see Chuang-Tzu 2001, pp. 96–99, 143–150; Yearley 1990, pp. 144–168; Gregory 1991, pp. 255–274; Graham 1958, pp. 96–118).

A simpler example of such transformations concerns the role of distinctive kinds of belief in adherents' lives, a role that both resembles and differs from the role of faith in some theistic traditions. These beliefs go considerably beyond the evidence that would, and should, compel assent in normal affairs, and they often play a prominent role in guiding action. They include beliefs about the significance of certain books and historical figures, but most revealing may be beliefs about the role of some virtues and perspectives.

Two straightforward but illuminating examples of these latter beliefs come from what is probably the earliest part of the earliest (and arguably most important) book in Chinese thought, Confucius's *Analects* (Lunyu): "Virtue (*de*) never dwells in solitude; it will always bring neighbors" (4, 25), and "The Master said 'In the morning hear the Way (*Dao*); in the evening, die content'" (4, 8). Each passage represents a dramatic enough claim to be considered religious, as well as, of course, a claim that can be, and was, probed philosophically.

Indeed, beliefs like these are often at the center of debates with those people who lack them because they find them either unintelligible or unjustified. The religious perspectives that define each of these traditions, that is, are far from self evident to everyone. They include attitudes and confident judgments about many matters that seem problematic or even bizarre to many people outside the tradition. Moreover, adherents within a tradition also entertain questions about their own beliefs; they are not inoculated against the queries and doubts that other people manifest. One crucial spiritual dynamic in all these traditions, then, is to see obvious problems in their own position, if one uses either ordinary standards or another tradition's standards, and yet continually to reaffirm specific, central beliefs.

These Chinese ideas on religious beliefs, as well as on other virtues, reflect an ontological perspective in which the sacred realm and the ordinary realm are closely intertwined, in which an organismic, an interrelated and interdependent, cosmology operates. Indeed, Chinese religious thought manifests in its own fashion the ontological principle that guides the analysis of this topic in, say, Aristotelian Christianity: The sacred does not destroy but presupposes and perfects the normal. Unlike many traditions the ordinary is not, that is, eradicated by the religious and replaced by something fundamentally different. (This feature probably most clearly distinguishes discontinuous Chinese religious traditions from most other discontinuous traditions.) Rather, the ordinary provides the basis that is developed into a more

actualized form. In fact, one can even argue that Chinese thinkers are able to develop this principle more fully than could Aristotelian Christians because they lack those theological ideas that impede a full development, notably the notion of a natural order created by a God distinguished from it by aseity.

These ideas lead Chinese philosophers to understand (perhaps even more clearly than do their counterparts in other traditions) that treating religious virtue well involves a kind of balancing of opposing demands. On the one hand, religious virtues are virtues where one cannot draw on too many normal presumptions and arguments to defend, or even to make plausible, the virtue else it ceases to be a religious virtue. On the other hand, however, one cannot simply disregard normal presumptions and arguments else the virtue ceases to be a plausible option for most people. This activity involves balancing on a tightrope, a posture that recalls Ludwig Wittgenstein's comment that an "honest religious thinker is like a tightrope walker ... [who] almost looks as though he were walking on nothing but air ... [because his] support is the slenderest imaginable ... [and] yet it really is possible to walk on it" (1984, p. 73e).

The balancing act involves not falling into either of two dangerous alternatives. On the one hand, the religious virtue must not rely on notions that no reasonable person can really entertain seriously. The claim that only through sacrificial rituals is one able to appease a spirit's anger or a dead person's perturbation is an example of such a notion. The virtues cannot rest, then, on what seems to sensible people to be implausible ideas. On the other hand, if the virtue is truly a religious one, it must not rely on such common and sensible notions that most people would, with little thought, accept it. The idea that one should help others if the help causes neither pain nor dislocation would be an example. The virtue cannot, then, simply repeat the conventional wisdom of the day. The need for this kind of distinctive balancing when presenting religious materials leads one to the genres such an approach demands.

#### GENRE AND THE PERSUASIVE PRESENTATION OF RELIGIOUS REALITIES

The delicate kind of balancing we see in the presentation of religious virtues leads directly to the subject of the ways in which religious features affect the genres, the modes of presentation, manifest in much Chinese philosophy. (These choices about genre are, moreover, especially significant because a number of these philosophers

were capable of, and well trained in, more rigorous forms of theoretical analysis.) Indeed, the rationale for presenting religious features in different genres provides an excellent way to examine the widespread perception that Chinese philosophy often does not seem to operate as philosophy ought to operate (e.g., see Mencius 1970, Book 6A; Chuang-Tzu 2001, pp. 48–61, 106–107; Hui-neng 1967, #1–#10; Wang Yang-Ming 1963, # 139, #168–#171, #226–231).

It is said, that is, that Chinese thought (as noted earlier) lacks sustained formal argumentation, sophisticated forms of analytic inquiry, and evident ways in which to reflect critically on presuppositions. These criticisms can witness to the kind of disabling parochialism (and circularity) that allows for little discussion, but their more powerful forms focus well the subject of how presentation and persuasion operate in Chinese religious philosophy.

The best way to approach this subject is to look at responses to a simple, deceptively simple, question: How can one persuasively represent a world, a world the understanding of which is crucial to any true human fulfillment, that far exceeds one's normal understanding? Representing that world persuasively is critical because only through such representation can one keep before people realities central to any religious vision but discontinuous with ordinary understandings. Representing that world is exceedingly difficult because it involves presenting realities that differ from, and even challenge, people's ordinary perspectives. The needed kinds of language must therefore persuade people in ways that differ from the kinds of persuasion either logical argument or even ordinary language utilize.

One illuminating instance of such a mode, and one much favored in China, is the use of concise, compelling, and often elusive locutions, such as the two from Confucius noted earlier about virtue always bringing neighbors and about the Way and death. These expressions provide one with a great deal of textured material in a terse, striking form. Indeed, they both arrest and often stay with one because they give one something intriguing and rewarding to which one can return. These statements can, then, embed themselves in one's mind and lead one to mull them over, searching out their various implications and applications to one's own life. Such statements become meditational objects that work on one, as do all meditational objects, in both evident and mysterious ways. A specific literary device like this aims, then, to produce in the reader fascination, sympathetic identification, attentive perplexity, and other even more complex emotional

states, such as pretending. All are states that can produce significant personal changes.

Put another way, two features of religious perspectives make necessary forms like these: First, simple rational arguments about such perspectives will only rarely affect those people who most need help, a group that includes most of everyone at different points in their lives. Second, those arguments, or even the appropriate principles they produce, will often not fundamentally affect most people in those situations where they most need help.

Especially important, therefore, is persuading people that ideas, actions, and perspectives they find odd, perplexing, or simply wrong are worth considering, even worth adopting. And that task's difficulty is heightened by the relative absence, in comparison to theistic traditions, either of limpid theological propositions about the sacred's character or of graphic accounts in authoritative texts of the actions of the highest sacred beings.

The problem, then, is how to employ language that is odd, often very odd, and yet still have it be persuasive. (It resembles, therefore, the balancing needed in presenting ordinary and religious virtues, but the scope of operations is much wider.) To attain the needed representation one must stretch language beyond its evident limits and recognizable shapes while one also understands that such stretching seems to violate those forms and expectations that allow language to convey meaning. How can one, that is, represent a world that transcends one's ordinary categories and even reference points in a way that is both realistic and persuasive? The Chinese responses to these interrelated questions, evident more in their practices than in their theories, rest on three ideas, or more accurately claims, that are implicit in their practice.

The first and most obvious involves distinguishing the persuasively presented from the well argued and emphasizing the former. Presentations may, then, fail to fit well the criteria for good argument, indeed may even be instances of reasoned attempts to doubt the value, when the subject is religious, of many kinds of reasoned arguments. (*Persuasively presented* is, of course, a considerably wider category than is *well argued*, and utilizing it necessarily involves one, as it will be seen, in the treatment of issues about the character of rhetorical presentation and those subjects that follow in its wake.)

Second is a general characteristic of much Chinese religious thought: the judgment that considerations about the deepest religious matters best manifest their distinctive subject matter when understood as treating

irresolvable but illuminating and productive tensions. These tensions arise from the presence of apparently conflicting ideas and experiences each of which is irreducible; any resolution, therefore, that even diminishes the tensions must be rejected. Indeed, a resolution need not even be sought because keeping the tension's irresolvability in mind both enables people to understand better the character of religious reflection and presentation and clarifies their relationship to religious realities.

The third notion or claim is a direct corollary of the preceding two: the idea that literalism is the most dangerous of all human deformations at least when religion is the subject, and probably even when life itself is the subject. Literalism can take different forms but at one end of the spectrum is an unwillingness (or perhaps inability) to read beyond a surface meaning—literalism in its most evident sense. At the other end, however, is an unwillingness (or perhaps inability) to do anything but read beyond the most evident sense; the wooden pursuit of allegorical readings displays another, more abstract kind of literalism. The first fails to grasp the import of the representation; the second's easy movement beyond the surface overlooks all the surface's rich texture.

Chinese religious thinkers, then, usually focus less on straightforward conceptual analysis or argument and more on persuasive presentations that work with irresolvable but revelatory and productive tensions, aim to change people's understanding and action, and nurture the avoidance of literalism. That focus helps to explain their use of genres that are, to employ Western categories, more often literary than theoretical.

The use of these genres, genres that aim to present realities that can be made evident or compelling in no other way, means rhetoric is crucial. And that means that one does not simply face passages that are the shadow-graphs of ideas, passages that can be put into propositional forms that leave no remainder. The language used is not the mere adornment of an idea; it is constitutive of the idea. The language used is not just a device to persuade the recalcitrant or intellectually inept. Rather, it is what makes possible any appropriation of the proper perspective.

Processes of persuasion like these can be thought to be problematic for many reasons. For example, the process seems to disregard too many significant, if ordinary, kinds of thinking; the process will often fail to provide warrants for adjudicating differences; and the process is not attentive enough to the need for the theoretical analysis and justification of at least many rhetorical statements.

Chinese thinkers are aware of these problems. They understand they must evaluate rhetoric and that such an evaluation involves both a detailed understanding of how rhetoric works and a grasp of the character and appropriate roles of logical argument. (In fact, they often display a remarkable grasp of different rhetorical modes and therefore also of the ways in which such modes may obfuscate.) Probably most important, however, is a recognition that rhetorical presentations are part of a more general process of self-cultivation that involves teachers, various spiritual disciplines, and participation in a tradition. This remains true despite the difficulties they often see in the ordinary understandings of self-cultivation and of traditions that dominate most communities.

Nevertheless, it remains true that they often gravitate to distinctive genres when presenting religious perspectives because only those genres can produce what must be produced. They accept, that is, a version of the "good person criterion," a criterion also evident in the Aristotelian tradition (Yearley 1990, pp. 62–72). They believe that a person's character determines what can be perceived and understood, and therefore that the ultimate measure of a person or an action's excellence, or even meaning, is the excellence of the person who makes the judgment. Most important here, they recognize that this criterion has dramatic implications for both presentation and persuasion, and they are more than willing to live with the consequences.

## SOCIAL AND POLITICAL THOUGHT

Chinese philosophy began in the sixth century BCE with social and political philosophy as a response to the collapse of traditional bronze-age feudal society (Shang and Zhou dynasties). As the loyalty of the nobility to the Zhou kings began to give way to the realpolitik of sheer military might, dozens of small kingdoms vied with one another for imperial domination in what became known appropriately as the Warring States period (475–221 BCE). This strife ended when the kingdom of Qin finally conquered the last of its competitors to unite, for the first time, the many warring states into a single military, imperial empire.

The problem was how to unify and rule such a heterogeneous collection of different ethnic groups. Into this breach came China's first philosophers. In the feudal period, social custom was maintained by etiquette as practiced and maintained by the aristocrats and by punishments applied to ordinary people. People did the morally right thing not out of an inner sense of obligation but simply because this was the prescribed behavior for anyone born into a particular class. As the feudal order broke up, Confucians attempted to convert the customary etiquette of the hereditary nobility into an internally felt and inwardly directed moral imperative for everyone. The Daoists advocated a back-to-nature simplification in which government does little and simply lets the people pursue their own affairs, as they traditionally did for centuries. The Mohists tried to break down ethnic and tribal boundaries through the practice of

impartial universal love. And the legalists tried to extend the role of punishment more broadly to everyone: aristocrats and educated elite, as well as peasants. There were thus four recommended replacements for the dying feudal social order: develop a universal personal morality (Confucians); return to a nearly anarchic state of nature (Daoists); embrace a policy of universal impartial love (Mohists); establish and universally enforce applicable law (legalists).

## CONFUCIUS

Confucius (551–479 BCE) was the first thinker to offer new methods for the postfeudal period. Philosophers in the early Warring States period tended to be either conservatives who wanted to preserve the old values of the dying feudal system or revolutionaries who wanted to start afresh with new ideas and a new set of values. Confucius was one of the conservatives. He sought to revive on a new foundation the values of the Zhou dynasty, the last of the feudal regimes. Confucius claimed not to be an original thinker; he always said he was just preserving the past. But since the feudal order had virtually disappeared by the time Confucius was born, he realized that these values could only be preserved by restructuring them so as to meet the new conditions. In this effort he was certainly original. In the past, aristocratic feudal values were informally handed down from parents to children in elite noble families. Confucius was the first Chinese thinker to advocate that these values be systematized, logically defended, universalized, and formally taught to everyone. If everyone would learn and practice the ancient virtues of loyalty to elders and rulers (*cheng*), moral righteousness (*yi*), and compassion for others (*ren*), the country would be well run, contented, and prosperous. Indeed, Confucius insisted that if people would simply fulfill the roles assigned to them, all would behave virtuously. For example, if the ruler would act like a ruler (that is, protect and care for his people), the country would be well taken care of. The ruler who takes advantage of his subjects to enrich himself is not a true ruler and should not be called a ruler (*wang*). This is what Confucius called the "rectification of names": Things should be called by their right names, and people should live up to the roles assigned them by their designated titles.

Beyond assuming a universal basis for such an extension of the old feudal values, Confucius did not develop a theory of universal human nature. This he left to his followers. When the Daoists and other competing schools of philosophy criticized Confucius for foolishly trying to revive the old values of the nobility of a then defunct feu-

dal era, Confucius's followers responded by arguing that all people have the same basic nature, that to be happy and successful, people must fulfill this nature, and that this required developing and following the traditional Chinese virtues of the ancient feudal nobility.

Soon after Confucius's death there arose many competing schools of philosophy in China and many competing varieties of Confucianism itself, reflecting serious disagreements among the followers of Confucius, especially Mencius and Xunzi. When the small warring states were finally united for the first time under the military dictatorship of Ying Zheng (259–210 BCE), China's first imperial emperor, the legalist philosophers (*fajia*) convinced the emperor that the only way to truly unite the country was to eliminate all the argumentative and therefore divisive schools of philosophy (except legalism). In 213 BCE all the philosophy books the government could find were burned, and some Confucians and other philosophers who refused to abandon their philosophical practice were buried alive. Shortly afterwards, during the Han dynasty (206 BCE–220 CE), the legalist position was reversed, an attempt was made to revive the ancient schools of philosophy, and after a prolonged debate, Confucianism was adopted over Daoism and Mohism as the official philosophy of the state. The only other philosophical school besides Confucianism to survive was Daoism, which then became a private philosophy of the educated elite, whose public lives were primarily Confucian. Confucianism thereby became China's official legitimizing discourse justifying imperial rule, although quietly and behind the scenes legalism continued to provide the practical basis for actual rule.

Confucius did not develop the systematic ethical theory we know today as Confucianism. This was left to his followers: Mencius, Xunzi, and Dong Zhongshu. Confucius himself sought to return to traditional feudal values (such as filial piety) of the Zhou dynasty. Confucius's critics, especially the Daoists, attacked this attempt to rehabilitate the traditional virtues. Just because such virtues may have worked in the past, what reason was there to suppose that these rules were applicable to the new circumstances? A theory of ethics should be based on something more permanent in nature and reality, not the historical conventions of a particular society at a particular time and place. In response to this criticism, the followers of Confucius developed the idea that the traditional Chinese virtues could be defended as based on an unchanging and eternal human nature shared by people of all classes, at all times, and at all places.

But *is* there a common human nature, and if so, what is that nature? Here the followers of Confucius could not reach agreement. Mencius held that human nature is essentially good, while Xunzi argued that it is essentially evil, to which Dong Zhongshu argued that it is both, that human nature comprised two opposing elements, one good and the other evil.

## MENCIUS

In many ways Mencius (c. 376–c. 292 BCE) followed the example of Confucius. Like Confucius, he divided his time between offering (mostly unwanted) advice to the rulers of his day and teaching students in a private capacity. Also like Confucius, Mencius sought to rectify names. Things should be called by their correct names, and things (people) that did not live up to their names (titles) should not be called by those names. For example, when Mencius was asked whether it was morally permissible to kill a king, Mencius replied in effect that if this so-called king is a true king, then of course it is wrong to kill him, but if this so-called king is not a true king but only a tyrant, then killing him is not killing a king but only a tyrant, and so is morally permissible.

But in other ways Mencius deviated from the path followed by Confucius and most other Confucians before and after him. More than any other Confucian, including Confucius himself, Mencius emphasized the morality of following nature, human nature, as opposed to social convention. In this respect Mencius comes close to the Daoists. In one episode recorded in his book, Mencius tells the story of the man from Song who helped his rice plants grow taller by pulling on them, which of course caused them to wither and die. Mencius's point is that the farmer should have let nature take its course. Of course, the rice has to be planted and then transplanted and weeded and watered and protected from birds and other animals, but beyond that the rice plants should be left to grow and develop all by themselves without further human interference. By analogy, we should not impose alien social practices on children but should help them cultivate their innate human nature.

By the time of Mencius there were many competing schools of philosophy. Mencius often bemoaned the enormous popularity of what he regarded as two extremist schools of thought, the followers of Mozi (c. 468–c. 376 BCE) and Yang Zhu (440–360 BCE), Mozi arguing that we should love all people equally and Yang Zhu that we should not lift a finger to help anyone but ourselves. Like Confucius, Mencius followed a middle path between these two extremes, emphasizing the traditional Chinese

virtue of filial piety, that is, loyalty to members of one's own family and obligation to those immediately above and below in the social hierarchy of one's particular community.

According to Mencius, all people are born with the potential and tendency to be kind-hearted and virtuous, though this potential can either be nourished and developed, so that the individual becomes good, or else neglected, thwarted, and perverted, so that the individual becomes bad. Mencius was not saying that children are moral from birth. He realized that they must be trained and taught, and that they learn by practice and experience. He also realized that neglected or mistreated children will usually become bad. Nonetheless, his theory is that in either case there is an innate tendency or disposition to be good.

In his most famous example, Mencius asked what is the immediate and spontaneous response of any person upon seeing a child about to fall into a well. Mencius said that everyone naturally and spontaneously wants to rush to help the child. This does not mean that everyone is a morally good person. It only means that everyone is born with the germ of the Confucian virtue of compassion (*ren*), along with the germ of the other traditional Chinese virtues of righteousness (*yi*), propriety (*li*), and wisdom (*zhi*).

Mencius valued this distinctively human capacity for virtue above all other parts of a person and urged readers to honor, preserve, and develop that part of themselves above all else. "To know one's nature is to know heaven [*tian*]" (*The Mencius*). That is, humans alone have the capacity to realize what their nature is and to choose to follow it and in this way to consciously align themselves with heaven. Mencius saw this human capacity as a bodily part (the benevolent mind that cannot bear to see others suffer), though the highest part, coming from heaven, in contrast with the rest of the human body, which people share with the lower animals and which comes from earth.

Although Mencius did not stress rationality as what is distinctively human, as Western philosophers do, he did stress the capacity of the mind (*xin*) to think. In *Mencius* (the book), Mencius argued that some people become better than others (even though they all have the same human nature) because they realize the value of this small but superior part of themselves.

Finally, Mencius is often called the most democratic of Chinese philosophers. Although Mencius, like Confucius before him, defended the ancient feudal traditions,

especially of the Zhou dynasty, he radically reinterpreted them to conform to his own political ideas of equality. For example, in feudal times, society was arranged for the benefit of the aristocracy and defended as being mandated by Heaven (*tian ming*). Of course, it is hard to tell who has the mandate of heaven, except in a circular way by who actually rules. The ruler in power can claim to enjoy the mandate of heaven, and the only argument against this claim by those who oppose him is their ability to oust him from power and take over themselves. Mencius offers an independent, noncircular criterion for who has and does not have the mandate of heaven: that the ordinary people support and are happy with the government. The only justification for government and economic policy is that it serve the people. To give another example, in feudal times the division of political and economic duties was hereditary, whereas for Mencius this division of labor can only be justified on grounds of merit. Let each person serve according to his innate ability, whether as farmers, teachers, or government officials.

## XUNZI

In the third century BCE the most prominent Confucian and one of the most important philosophers in China was Xunzi (340–245 BCE). Xunzi argued, against Mencius, that human nature is essentially evil, that is, selfish and aggressively antisocial. It is only through education, training, discipline, and the threat of punishment, Xunzi argued, that people become socially cooperative. Xunzi speculated that originally men were free to follow their own selfish bent without fear of recrimination or punishment. But when they realized that they were as often the victims of aggressive abuse as its perpetrators, that they were getting robbed as often as they were robbing from others, they willingly accepted the authority of a ruler capable of maintaining order and punishing transgressions. Like the social-contract philosopher Thomas Hobbes, Xunzi argued from people's evil nature to the need for a strong central government to control human behavior by education and a system of rewards and punishments. If strong governmental authority were removed, Xunzi speculated, chaos would result as the strong rode rough shod over the weak, with no law enforcement to prevent or punish them.

One major difference between Mencius's and Xunzi's theories of human nature is that Mencius defined human nature as what is uniquely and distinctively human, whereas Xunzi defined human nature as what all people are born with, even if this allotment is also shared with lower animals. Relating his theory to ancient, prephilo-

sophical Chinese traditions, Xunzi said that human nature is the product of two factors. One, the contribution of heaven (*tian*), gives human beings the rational and intelligent capacity to be civilized, cultured, and virtuous, and the other, the contribution of earth (*di*), is our animal nature, which we are conscious of as feeling and emotion. Whereas Mencius said that we receive from heaven the germ of moral virtue, Xunzi maintained that we receive from heaven only the capacity or potential for virtue and civilized life.

Thus, for Xunzi, a person at birth is just like one of the lower animals except for possessing the capacity of becoming civilized and virtuous. If we define human nature as Xunzi did (as what all people are born with), then we will point to the tendencies people actually have to be greedy, selfish, and aggressive, but if we define human nature as Mencius did (as what is unique to people), then we will tend to discount greedy behavior, since it is shared with lower animals, and to emphasize instead the capacity of humans to develop virtuous behavior, to become moral creatures. As Mencius says, "Slight is the difference between man and the brutes. The ordinary person loses this distinguishing feature, while the true human being retains it" (*The Mencius*).

In a sense, the difference between Mencius and Xunzi is very small. Both acknowledged that we have natural desires for food and sex, and both acknowledged that we have the capacity to resist such desires when it is dangerous or inappropriate to indulge them. The difference is largely a matter of the relative weight placed on nature and nurture. Xunzi thought that because human beings are intelligent, when they realize the difficulties that uncontrolled indulgence in the desire for food and sex can lead to, they seek to set limits on those desires. Like Mencius, Xunzi acknowledged that the ordinary person can become a sage.

According to Xunzi, human goodness comes from development of human culture. Culture is uniquely human. "Heaven has its seasons, Earth has its resources, man has his culture" (*The Xunzi*). Humans should properly take what comes from heaven and earth and create a distinctly human culture. Just as Mencius held there were the four germs of human goodness, so Xunzi held there are the four germs of evil, all of which spring from the innate desire for profit and sensual pleasure. How, then, do humans become good? And what motivates them to become good if they are inherently evil? Xunzi developed two lines of argument.

First, humans need (and know they need) some kind of social organization, cooperation, and mutual support.

To secure the required social organization, they need rules of conduct, ceremonial rites (*li*). (Ceremonial rites were of greater importance to Xunzi than to Confucius, who stressed compassion for others, *ren*.) We need rules of conduct to set limits on the satisfaction of desires.

Second, we need morality (*li*), culture, civilization to complete our humanity. The rules of conduct cultivate and refine our humanity. Unlike the Daoists, who rejected what comes from humans to return to nature, Xunzi advocated the way of humanity.

Xunzi further developed Confucius's sophisticated view of the utility of elaborate ceremonies, without the need for belief in conscious humanlike deities. For Xunzi, this involved a kind of aesthetic distance. We have both intellect and emotion. We intellectually know that death is the end of everything (and that gods cannot help improve the weather through prayers), but we emotionally need to hold on to some hope of something better to follow death (and the possibility of some help from a benevolent heaven). So we create in our rituals a kind of poetic imagination in which we believe and disbelieve all at the same time. Ordinary people can believe literally, while educated people can appreciate the same ceremonies aesthetically and symbolically. For civility, human emotions must have a physical embodiment, which distances the emotion from its natural expression. Thus, art and music become a way of inculcating proper social attitudes in the educational process and avoiding natural, animalistic expressions of such attitudes as aggression, for example.

Xunzi regarded dispute and argumentation as a sign of political disorder, and so encouraged the idea that a return of political order (at the end of the feudal period) would lead to the end of philosophical disputes and argumentation among the many different contending schools of philosophy. Unfortunately, through Xunzi's influence on the legalists Li Si and Han Fei, this contributed to the famous book burning of 213 BCE.

In some ways Xunzi resembled the Daoists, especially in his rationalist, scientific attitude toward nature or heaven (*tian*). In other ways, however, Xunzi followed Confucius in arguing that we ought nonetheless to keep up all the state ceremonies, even sacrifices to ancestors and gods, though they have no real causal effect. Why? Because these practices were socially beneficial; the emperor publicly praying for a good harvest did not make the crops grow any better, but it did help unify the people and organize their efforts toward a common goal.

## DONG ZHONGSHU

Is there a human nature shared by all people, and if so what is it like? As discussed above, the followers of Confucius could not agree. Mencius held that it was essentially good, while Xunzi argued that it was essentially evil, to which Dong Zhongshu (179–104 BCE) argued that it was both, that human nature was composed of two opposing elements, one good and the other evil. Dong, in other words, found a middle ground between the views of Mencius and Xunzi (though probably closer to Xunzi). He agreed with Mencius that in a sense human nature contains the germ of goodness, but he disagreed with Mencius that this is enough to say that humans are by nature good. The germ of goodness is not actually good any more than a tomato seed is a tomato or an egg is a chicken. To become good, that germ must be nurtured and cultivated. He thus agreed more with Xunzi's emphasis on the need for government to educate and train people to become good citizens. Whereas Mencius said that goodness is a natural "tendency" of people, Dong claimed it is a mere "potential."

Dong also developed the theory that human nature must compete with people's innate tendencies toward greed and selfishness. In Dong's human psychology, the opposing forces of yin (emotion and feeling) and yang (our distinctively human nature) are in constant conflict with one another. If both these tendencies are innate, one may ask, are they both not parts of human nature? The answer here can be related to the idea that human nature is a normative concept. Like Mencius, Dong would like to say that human nature is the higher, better part of humans, the morally good part (derived from the positive yang aspect of heaven), which humans alone are capable of. The instinctive, emotional part (derived from the negative yin aspect of heaven), which all humans possess but also share with lower animals, is just as innate, but lacks the normative quality of the morally good potential of human nature.

The main difference between Mencius and Dong lies in their views of the role of government in fostering moral goodness. Mencius would have government take a far less intrusive role, merely encouraging and cultivating the germ of moral goodness already there. In contrast, Dong, like Xunzi, thinking of the enormous challenge of the Qin and Han dynasties in unifying the many previously warring states, held that government must mold and shape humans, who have the capacity for goodness but cannot become good without the intervention of the state. Lurking in the background of this Confucian debate lay the worry that moral cultivation, however noble an

ideal, would not politically unify the vast military empire without strong state coercion.

## MOZI

Mozi, or Mo Di as he is also known (c. 468–c. 376 BCE), was China's second philosopher, after Confucius. In his own lifetime and for two hundred years following his death, Mohism was at least as influential as Confucianism or any other early Chinese school of philosophy. But by the time of the Han dynasty (206 BCE–220 CE), Confucianism and Daoism had absorbed all the other schools of philosophy, and from then on, Mozi exercised little influence.

Philosophy arose in China at the end of the feudal period, and many scholars believe that the Confucians emerged from the ritual advisors (the *ru*) to the early feudal lords, while the Mohists emerged from the feudal warrior class. Certainly, Mozi's philosophy is much more down to earth, practical, and less elitist than Confucianism. Mozi opposed Confucius on several grounds, but four stand out as most important: that right action is determined by its practical results and consequences and not, as Confucius had urged, because duty required it, regardless of the consequences; that one should not privilege members of one's own family, especially one's parents, siblings, and children, but should love everyone equally; that morality should be based not on an unchanging human nature, which may or may not exist, but on our ability to transform people into morally better individuals through education and law; and that we should honor and obey a personal God, who rules heaven and earth, rewarding the faithful and punishing all others.

Mozi argued that the cause of the world's ills was the fact that people loved each other partially, that you love your mother and your clansmen more than you love my mother and my clansmen, for example, and that the cure for the world's ills is therefore to embrace universal, impartial love, in which everyone loves everyone else equally. Where there is competition, partial love leads "us" to hate and want to destroy "them." And so we have discrimination, ethnic cleansing, genocide, and warfare. How does one overcome these tendencies? According to Mozi, "Partial love should be replaced by universal, impartial love" (*The Mozi*).

Mozi realized (with the help of his Confucian critics) that impartial love is contrary to our ordinary feelings; you will tend to favor your relatives over mine. The Confucians were naturally appalled at Mozi's rejection of the traditional Chinese virtue of filial piety, that one's pri-

mary responsibility in life is to one's own parents and children. The Confucians therefore vigorously argued against Mozi's views on impartial love, arguing that since this is contrary to nature, no one could or would follow Mozi's advice (even if he were right). Nonetheless, Mozi argued that a system of rewards and punishments can induce and socially condition people to practice universal love (if not actually to *feel* love equally toward everyone).

Specifically, he argued that if the ruler urges people to love one another impartially, they would strive to do so; that since God created humans and loves them all impartially, God wants us to love each other impartially and rewards us when we do and punishes us when we do not; and that this too encourages people to embrace impartial love. Mozi did not think or argue that we are born with a sense of universal love of humanity in our hearts, only that we can be trained to adopt such an attitude. In this regard, Mozi argued that humans are infinitely pliable and can be molded into any form desired by the government (either to love partially or to love impartially).

Contrary to Confucius, Mozi argued that we should do the right thing to receive the rewards (*li*) we will receive by doing the right thing and to avoid the punishment we will suffer in this life and the next if we do the wrong thing. Sometimes Mozi argued that we should do what will produce the best results for everyone, not just for ourselves, and here he sounds like the nineteenth-century British utilitarians (Jeremy Bentham, James Mill, and John Stuart Mill), who argued that we should always do what will produce the greatest happiness for the greatest number of people.

Like Confucius, Mozi took his political theories to government leaders, offering his advice on how to improve government performance and social conditions, and like Confucius, his advice was largely ignored. Mozi was utilitarian in the sense that his standard for judging a philosophical position was whether it will benefit the people. Like John Stuart Mill, Mozi produced a theory that is more social and political than moral. That is, he was less interested in describing why individuals should love their neighbors as much as themselves than in telling government leaders how ordinary people can be motivated to practice universal, impartial love and how this will benefit the country as a whole.

Mozi explicitly criticized Confucius and the Confucians for preaching atheism (since this makes the gods angry, and the gods will then take it out on the people, making their lives miserable). He also criticized the Confucians for extravagance in spending on lavish state cere-

monies (including musical ceremonies) and funerals (including three years of mourning), for proposing a complex educational system (it is simply too much to master all the old Zhou-dynasty ritual and history classics), and finally for relying too much on fate (*ming*). Like Xunzi, Mozi argued that without government there would be chaos and hardship, with constant disagreements over what should be done, and that the people thus decided that it is better to have an absolute dictator to decide disputes for all.

## DAOISM

Like Confucians and Mohists, Daoists also tried to influence government, and very nearly succeeded in convincing the Han emperor Wu Di (r. 141–87 BCE) to choose Daoism over Confucianism as the official philosophy of the state. Only the extraordinary influence of Dong Zhongshu led the emperor to give the nod in the end to Confucianism.

The Daoists favored the natural over the artificial and mercilessly criticized the Confucians for their emphasis on the humanly created civilized culture of art and literature, ritual and custom, which children must learn through an elaborate process of socialization and acculturation. The Daoists were especially critical of the Confucians' attempts actively to foster and promote morality. Sometimes the Daoists expressed themselves by saying that one should practice "nonaction" (*wu wei*), which, the context makes clear, does not mean doing nothing, which is impossible, but rather not acting too deliberately, purposefully, or self-consciously, that is, not trying so hard, just letting events take their natural course.

Trying too hard to do anything, the Daoists thought, only proves how lacking one is in that regard. Also, generally speaking, the harder we try, the less we succeed, the Daoists argued. Morality, like humor and lightheartedness, cannot be learned by rote, by mechanically following some set of rules, the Daoists insisted, but must spring from the heart spontaneously. Since morality is generally pitted against natural impulses, the Daoists were firmly opposed to morality as it is generally understood, that is, as a set of socially approved guidelines or rules to which all are expected to conform.

The Daoists also found themselves at the opposite extreme from the Confucian moral theory of government. The Daoists advocated just letting events take their natural course, leaving well enough alone. According to the Daoists, events happen naturally, spontaneously (*ziran*), of their own accord. The principle that directs the

growth and development of creatures and other things in the world is not some cause from outside, but a guiding force stemming from within those creatures. This is the natural and therefore preferred order of things. The worst thing one can do, especially rulers, is to try to improve on this natural order by enacting and enforcing laws.

It seems perfectly natural for rulers to feel that affairs are not going as well as they might and therefore to try to figure out what would make them better and to enact laws to bring about those changes. But for the Daoists, it is better for governments to let the people alone. Ordinary people have been managing their affairs from time immemorial, not by following formally enacted laws, but simply by following time-honored traditions and customs, which generally work just fine. By trying to improve the situation, the ruler may upset these established customs, confuse people, and make the situation worse.

Before governments found it necessary to introduce harsh laws to regulate behavior and punishments to enforce those laws, people lived simply without the need for laws. The ruler should keep government at this simple, primitive level. It is better not to give the ordinary people fancy ideas or encourage them to improve their lot. Keep them ignorant and simple. The Confucians were wrong to encourage knowledge and virtue. By insisting on learning and moral training, they made people feel ignorant and immoral, sense a need to study and learn what they did not know, and want to reform their ordinary ways of behaving.

Thus, even moral education is bad, according to the Daoists, because it tries to force on people overly sophisticated and difficult culture that goes against their nature. In direct opposition to the Confucians, the Daoists therefore rejected indoctrination in the traditional virtues: compassion, righteousness, propriety, and wisdom. If you have to teach morality, that is a sure sign that the situation has been allowed seriously to deteriorate. When affairs are running smoothly, the people naturally and spontaneously know what to do and how to behave—without thinking about it and without the need of books and formal instruction. Just like children, people are happier this way, not feeling inadequate and unhappy because they are constantly told how ignorant or sinful or uneducated or uncultivated they are.

It is also a mistake, the Daoists argued, to encourage the acquisition of expensive goods and higher standards of living. This just makes people envious of their richer neighbors and leads them to lie and steal and even kill to enrich themselves. The wise ruler will keep the people

ignorant of fancy, expensive goods. If they never see such goods, they will never want them and never be tempted to stray from their simple everyday lives to get goods they cannot afford. Once the ruler allows inflated desires and competition among the people, the ruler must promulgate and enforce laws to prevent people from stealing and taking advantage of one another. But the more laws are passed and enforced, the more people see the laws and the government as their enemy, and therefore the more they will try to break the laws and overthrow the government. And this requires still more laws and severer punishments, in a vicious upward spiral.

## LEGALISM

The legalist theory was best expressed by Han Fei, also known as Han Feizi (c. 280–233 BCE), at the end of the Warring States period. The legalists thought that it was not enough just to leave the people to their traditional customs, as the Daoists recommended, but that it was too much to transform everyone into a moral agent, as the Confucians and Mohists proposed. Neither sort of advice really takes into account what rulers themselves want. Rulers are generally not interested in being morally good, nor are they satisfied in just keeping the people quiet and docile. They usually have their own agendas: to gain fame by conquering neighboring kingdoms, to enrich themselves and their families, or perhaps both. Since most of the early Chinese philosophers were trying to persuade rulers of the time how best to govern, the legalists thought it better to advise rulers on how to achieve what rulers themselves wanted than to try to get them to accept the moralistic goals of the philosophers (who had no experience in ruling). The problem that Confucius faced in training kings to be philosophers was that the kings did not want to be philosophers—they wanted lives of action, wealth, and power. The legalists (ever political realists) accordingly dropped the more ambitious normative project of formulating the ends that governments should strive for and opted instead for a more instrumental approach to how to achieve the goals rulers already had.

To accomplish these political goals, the legalists advised the rulers to adopt a law-and-order administration supported by a strict system of rewards and punishments. Like their Western counterparts, the legalists were realists, arguing that it is not necessary for the king to be morally virtuous or for the bulk of the population to practice moral behavior. All the king needs to do, the legalists maintained, is to decide what he wants and then to insure compliance by formulating clear laws with absolutely certain rewards (for obeying these laws) and

punishments (for disobeying them), and the people will do whatever the king wants. After all, he is the king. He does not have to follow the moral principles of someone else—certainly not those of a philosopher! The king can propose whatever he wants and call this “justice” and make others call it “justice” as well, however inherently unjust his proposals may in fact be. And since he has the army to back him up, he cannot be seriously challenged.

Most Chinese philosophers were conservatives, revering and urging a return to a halcyon past, as Confucius thought the Zhou dynasty had been. Han Fei, on the other hand, as a legal and historical realist, argued that different historical eras face different problems requiring different solutions, and that the solutions of the past are not necessarily appropriate for the present. The story he offered is of a farmer who, seeing a hare kill itself by running into a tree stump, abandons farming to sit and wait by the tree stump for another hare. In the new expansionist military dictatorships following the end of the feudal period, a strict system of rewards and punishments for clearly formulated and promulgated laws is a much surer way of ensuring compliance than moral education, the legalists felt. Even if the ruler enacts a system of universal moral education, how many people are actually going to become moral agents, always doing the right thing simply because it is the morally right thing to do?

The ruler also needs statecraft (*shu*). He need not do the work himself; he need simply hold people to their job descriptions (the rectification of names). As a pragmatist, the ruler is concerned not with the methods needed to achieve results but only with the results. If the minister lives up to his job description, he is rewarded; otherwise, punished. After a while, incompetents do not apply.

In a sense, the legalist ruler follows the Daoist injunction of nonaction: “doing nothing, yet there is nothing that is not done” (*Daodejing*). And all this rests securely on the simple but basic foundation of human self-interest. Like his teacher Xunzi, Han Fei thought that human nature was evil, but unlike Xunzi, he sought not change human nature through education and training but only to establish a workable system of government built on this self-interested human nature. The legalists were strangely like the Daoists: Do not fight human nature; work with it. Even the Daoist Zhuangzi (c. 369–c. 286 BCE), seems to agree with the legalist principles of management: “The superior must have no activity, so as thus to have control of events; but the subordinates must have activity, so as thus to be controlled by events. This is the invariable way” (*The Zhuangzi*). The tax collector, for example, knows that he must collect taxes. If at the end of

the year he has collected his allotted quota, the ruler rewards him; if not, the ruler punishes (and replaces) him. He may fail because of drought and famine, in which case, but, whether fair or unfair, he will lose his job—if not his head. In this way, the job gets done. The subordinates are controlled by events, and yet the ruler has done nothing except employ the right statecraft.

In another way, however, the legalists advocated the complete opposite of what the Daoists advocated. The Daoists held that human beings were completely innocent; the legalists that they were completely self-interested. The Daoists upheld individual freedom; the legalists, absolute social control. The Daoists regarded the legalists as shallow pragmatists—they knew that certain methods worked, but they had no idea *why* they worked.

## CONCLUSION

In a way, the Daoists agreed with Confucius and Mencius that the ruler needs to have fundamental knowledge of human nature. Like the Confucians but unlike the Daoists, the legalists developed a social and moral philosophy in tune with the breakdown of feudal class distinctions. The Confucians and Mohists were revolutionary and idealistic—they sought to transform human nature (or, in the case of the Mohists, at least human behavior) by developing an inner sense of right and wrong through education. In contrast, the more realistic and pragmatic legalists developed methods for controlling people with their self-interested natures.

For two millennia China’s political philosophy has been a combination of openly espousing legitimizing Confucian discourse while silently employing the more pragmatic legalist methods to achieve the ruler’s objectives, along with Daoist principles of not interfering in the day-to-day affairs of the vast majority of the peasant population where their affairs did not conflict with the ruler’s personal objectives.

## CHINESE ROOM ARGUMENT

In 1980 the philosopher John R. Searle published in the journal *Behavioral and Brain Sciences* a simple thought experiment that he called the “Chinese Room Argument” against “Strong Artificial Intelligence (AI).” The thesis of Strong AI has since come to be called “computationalism,” according to which cognition is just computation, hence mental states are just computational states:

### COMPUTATIONALISM

According to computationalism, to explain how the mind works, cognitive science needs to find out what the right computations are—the ones that the brain performs to generate the mind and its capacities. Once we know that, then every system that performs those computations will have those mental states: Every computer that runs the mind’s program will have a mind, because computation is hardware-independent: Any hardware that is running the right program has the right computational states.

### THE TURING TEST

How do we know which program is the right program? Although it is not strictly a tenet of computationalism, an answer that many computationalists will agree to is that the right program will be the one that can pass the Tur-

ing Test (TT), which is to be a system that is able to interact by e-mail with real people exactly the way real people do—so exactly that no person can ever tell that the computer program is not another real person. Alan M. Turing (1950) had suggested that once a computer can do everything a real person can do so well that we cannot even tell them apart, it would be arbitrary to deny that that computer has a mind, that it is intelligent, that it can understand just as a real person can.

This, then, is the thesis that Searle set out to show was wrong: (1) mental states are just computational states, (2) the right computational states are the ones that can pass the TT, and (3) any and every hardware on which you run those computational states will have those mental states too.

### HARDWARE-INDEPENDENCE

Searle’s thought experiment was extremely simple. Normally, there is no way I can tell whether anyone or anything other than myself has mental states. The only mental states we can be sure about are our own. We cannot be someone else, to check whether they have mental states too. But computationalism has an important vulnerability in this regard: hardware-independence. Because any and every dynamical system (i.e., any physical hardware) that is executing the right computer program would have to have the right mental states, Searle himself can execute the computer program, thereby himself becoming the hardware, and then check whether he has the right mental states. In particular, Searle asks whether the computer that passes the TT really understands the e-mails it is receiving and sending.

### THE CHINESE ROOM

To test this, Searle obviously cannot conduct the TT in English, for he already understands English. So in his thought-experiment the TT is conducted in Chinese: The (hypothetical) computer program he is testing in his thought-experiment is able to pass the TT in Chinese. That means it is able to receive and send e-mail in Chinese in such a way that none of its (real) Chinese pen-pals would ever suspect that they were not communicating with a real Chinese-speaking and Chinese-understanding person. (We are to imagine the e-mail exchanges going on as frequently we like, with as many people as we like, as long as we like, even for an entire lifetime. The TT is not just a short-term trick.)

## SYMBOL MANIPULATION

In the original version of Searle's Chinese Room Argument he imagined himself in the Chinese Room, receiving the Chinese e-mails (a long string of Chinese symbols, completely unintelligible to Searle). He would then consult the TT-passing computer program, in the form of rules written (in English) on the wall of the room, explaining to Searle exactly how he should manipulate the symbols, based on the incoming e-mail, to generate the outgoing e-mail. It is important to understand that computation is just rule-based symbol manipulation and that the manipulation and matching is done purely on the basis of the shape of the symbols, not on the basis of their meaning.

Now the gist of Searle's argument is very simple: In doing all that, he would be doing exactly the same thing any other piece of hardware executing that TT-passing program was doing: rule-fully manipulating the input symbols on the basis of their shapes and generating output symbols that make sense to a Chinese pen-pal—the kind of e-mail reply a real pen-pal would send, a pen-pal that had understood the e-mail received, as well as the e-mail sent.

## UNDERSTANDING

But Searle goes on to point out that in executing the program he himself would not be understanding the e-mails at all! He would just be manipulating meaningless symbols, on the basis of their shapes, according to the rules on the wall. Therefore, because of the hardware-independence of computation, if Searle would not be understanding Chinese under those conditions, neither would any other piece of hardware executing that Chinese TT-passing program. So much for computationalism and the theory that cognition is just computation.

## THE SYSTEM REPLY

Searle correctly anticipated that his computationalist critics would not be happy with the handwriting on the wall: Their "System Reply" would be that Searle was only *part* of the TT-passing system. That whereas Searle would not be understanding Chinese under those conditions, the *system as a whole* would be!

Searle rightly replied that he found it hard to believe that he plus the walls together could constitute a mental state, but, playing the game, he added: Then forget about the walls and the room. Imagine that I have memorized all the symbol manipulation rules and can conduct them

from memory. Then the whole system is me: Where's the understanding?

Desperate computationalists were still ready to argue that somewhere in there, inside Searle, under those conditions, there would lurk a Chinese understanding of which Searle himself was unaware, as in multiple personality disorder—but this seems even more far-fetched than the idea that a person plus walls has a joint mental state of which the person is unaware.

## BRAIN POWER

So the Chinese Room Argument is right, such as it is, and computationalism is wrong. But if cognition is not just computation, what is it then? Here, Searle is not much help, for he first overstates what his argument has shown, concluding that it has shown (1) that cognition is not computation at all—whereas all it has shown is that cognition is not all computation. Searle also concludes that his argument has shown (2) that the Turing Test is invalid, whereas all it has shown is that the TT would be invalid if it could be passed by a purely computational system. His only positive recommendation is to turn brain-ward, trying to understand the causal powers of the brain instead of the computational powers of computers.

But it is not yet apparent what the relevant causal powers of the brain are, nor how to discover them. The TT itself is a potential guide: Surely the relevant causal power of the brain is its power to pass the TT! We know now (thanks to the Chinese Room Argument) that if a system could pass the TT via computation alone, that would not be enough. What would be missing?

## THE ROBOT REPLY

One of the attempted refutations of the Chinese Room Argument—the "Robot Reply"—contained the seeds of an answer, but they were sown in the wrong soil. A robot's sensors and effectors were invoked to strengthen the System Reply: It is not Searle plus the walls of the Chinese Room that constitutes the Chinese-understanding system, it is Searle plus a robot's sensors and effectors. Searle rightly points out that it would still be him doing all the computations, and it was the computations that were on trial in the Chinese Room. But perhaps the TT itself needs to be looked at more closely here:

## BEHAVIORAL CAPACITY

Turing's original Test was indeed the e-mail version of the TT. But there is nothing in Turing's paper or his arguments on behalf of the TT to suggest that it should be

restricted to candidates that are just computers, or even that it should be restricted to e-mail! The power of the TT is the argument that if the candidate can do everything a real person can do—and do it indistinguishably from the way real people do it, as judged by real people—then it would be mere prejudice to conclude that it lacked mental states when we were told it was a machine. We don't even really know what a machine is, or isn't!

But we do know that real people can do a lot more than just send e-mail to one another. They can see, touch, name, manipulate, and describe most of the things they talk about in their e-mail. Indeed, it is hard to imagine how either a real pen-pal or any designer of a TT-passing computer program could deal intelligibly with all the symbols in an e-mail message without also being able to do at least some of the things we can all do with the objects and events in the world that those symbols stand for.

### SENSORIMOTOR GROUNDING OF SYMBOLS

Computation, as noted, is symbol manipulation, by rules based on the symbols' shapes, not their meanings. Computation, like language itself, is universal, and perhaps all-powerful (in that it can encode just about anything). But surely if we want the ability to understand the symbols' meanings to be among the mental states of the TT-passing system, this calls for more than just the symbols and the ability to manipulate them. Some, at least, of those symbols must be grounded in something other than just more meaningless symbols and symbol manipulations—otherwise the system is in the same situation as someone trying to look up the meaning of a word in a language—let us say, Chinese—that he does not understand ... in a Chinese-Chinese dictionary! E-mailing the definitions of the words would be intelligible enough to a pen-pal who already understood Chinese, but they would be of no use to anyone or anything that did not understand Chinese. Some of the symbols must be grounded in the capacity to recognize and manipulate the things in the world that the symbols refer to.

### MIND READING

So the TT candidate must be a robot, able to interact with the world that the symbols are about—including us—directly, not just via e-mail. And it must be able to do so indistinguishably from the way any of the rest of us interact with the world or with one another. That is the gist of the TT. The reason Turing originally formulated his test in its pen-pal form was so that we would not be biased by

the candidate's appearance. But in today's cinematic sci-fi world we have, if anything, been primed to be overcredulous about robots, so much more capable are our familiar fictional on-screen cyborgs than any TT candidate yet designed in a cog-sci lab. In real life our subtle and biologically based “mind reading” skills (Frith and Frith 1999) will be all we need once cognitive science starts to catch up with science fiction and we can begin T-Testing in earnest.

### THE OTHER-MINDS PROBLEM

Could the Chinese Room Argument be resurrected to debunk a TT-passing robot? Certainly not. For Searle's argument depended crucially on the hardware-independence of computation. That was what allowed Searle to “become” the candidate and then report back to us (truthfully) that we were mistaken if we thought he understood Chinese. But we cannot become the TT-passing robot, to check whether it really understands, any more than we can become another person. It is this parity (between other people and other robots) that is at the heart of the TT. And anyone who thinks this is not an exacting enough test of having a mind need only remind himself that the Blind Watchmaker (Darwinian evolution), our “natural designer,” is no more capable of mind reading than any of the rest of us is. That leaves only the robot to know for sure whether or not it really understands.

## CHISHOLM, RODERICK (1916–1999)

Roderick Chisholm was a twentieth-century American philosopher who made major contributions in almost every area of philosophy, but most notably in epistemol-

ogy and metaphysics. Chisolm was an undergraduate at Brown University from 1934 to 1938 and a graduate student at Harvard from 1938 to 1942. He served in the military from 1942 to 1946, and then, after briefly holding a teaching post with the Barnes Foundation and the University of Pennsylvania, he returned in 1947 to Brown University, where he remained until his death.

### EPISTEMOLOGY

In epistemology Chisholm was a defender of foundationalism. He asserted that any proposition that it is justified for a person to believe gets at least part of its justification from basic propositions, which are themselves justified but not by anything else. Contingent propositions are basic insofar as they correspond to self-presenting states of the person, which for Chisholm are states such that whenever one is in the state and believes that one is in it, one's belief is maximally justified. There are two types of self-presenting states: intentional states (ways of thinking, hoping, fearing, desiring, wondering, intending, etc.) and sensory states (ways of being appeared to by the various senses). A noncontingent proposition is basic if understanding it is sufficient for understanding that it is true and also sufficient for making it justified. "2 + 3 = 5" and "If Jones is ill and Smith is away, then Jones is ill" are examples of such propositions, says Chisholm.

Self-presentation and understanding are among the basic sources of epistemic justification, but according to Chisholm there are other sources as well. The most important of these other sources are perception, memory, belief coupled with a lack of negative coherence (e.g., no inconsistencies among the propositions believed), and belief coupled with positive coherence (i.e., mutual support among the proposition believed). For each of these sources, Chisholm forwards an epistemic principle that describes the conditions under which the source generates justification.

Despite his thinking that there are many sources of epistemic justification, Chisholm is rightly regarded as a foundationalist because all the sources are such that they can produce justified beliefs only because some propositions are justified basically. For example, Chisholm's principles concerning perception and memory make reference to propositions that are justified because they correspond to self-presenting states. In the case of perception, the relevant states are sensings, and for memory the relevant states are beliefs, in particular, beliefs to the effect that one remembers something. In a similar spirit, Chisholm says that coherence relations among propositions are not capable of generating justification for

propositions that have nothing else to recommend them; their role instead is to increase the degree of justification that propositions have by virtue of being supported by basic propositions.

Chisholm is also a proponent of internalism in epistemology, in two senses of the term. First, he thinks that epistemic justification supervenes on human conscious states; thus, whether one's beliefs are justified is determined by one's own internal states rather than by conditions obtaining in one's external environment. Second, he thinks that the conditions, if any, that justify one's beliefs are accessible to one; thus, one is always able to determine if one reflects carefully enough, whether one's beliefs are justified.

Chisholm's epistemology is resolutely antiskeptical. Indeed, he says that the proper way to begin doing epistemology is by presupposing that some human beliefs are justified and that indeed some constitute knowledge. Epistemology, so conceived, becomes primarily a search for the conditions that account for these beliefs being justified. A second task is to define the conditions that turn a true belief into knowledge. Chisholm's approach to this latter task is to defend a nondefeasibility account of knowledge. One knows a proposition  $p$ , he says, whenever one believes  $p$ ,  $p$  is true, and  $p$  is nondefectively evident for that person, where  $p$  is nondefectively evident that person (some details aside) just in case there is a set of basic propositions that justify  $p$  and that justify nothing false.

## METAPHYSICS

Chisholm also had well-worked-out views on almost every major issue in metaphysics, but his most influential views were concerned with thought and language, ontology, action, and material bodies.

With respect to thought and language, Chisholm was a defender of the primacy of thought; the intentionality of language is to be understood in terms of the intentionality of thought, he says, rather than conversely. He develops this idea in his direct attribution theory of reference. At the heart of the theory is a proposal that people are able to refer to things other than themselves by directly attributing properties to them and that people indirectly attribute properties to things by directly attributing properties to themselves. For example, if John is the only person in a room with Sally and John is wearing a blue sweater, then by directly attributing to herself the property of being a person  $x$  such that the only other person in the room with  $x$  is wearing a blue sweater, Sally indirectly attributes to John the property of wearing a blue

sweater and thereby refers to John. Using these notions of direct and indirect attribution, Chisholm provides an account of various semantic notions including sense and reference.

In ontology, Chisholm's view is that there are only two kinds of entities: attributes and the individual things that have these attributes. Everything else, including propositions, states of affairs, possible worlds, and sets, can be understood in terms of these two categories. Attributes are possible objects of thought—more specifically, what people are able to attribute, either directly (to themselves) or indirectly (both to themselves and other things). Thus in ontology, Chisholm once again is a defender of the primacy of thought in that he uses the phenomenon of intentionality to identify and understand what kinds of entities there are.

His theory of action is an indeterministic one. The fundamental notions are those of undertaking and causing, and with respect to the latter notion he carefully distinguishes among necessary causal conditions for an event, sufficient causal conditions, and causal contributions. With these notions in hand, he opposes compatibilist attempts to understand what it is for a person to be free to undertake something, insisting that one has undertaken to do something freely only if there was no sufficient causal condition for one to undertake it (although there may have been extensive causal contributions to the undertaking).

Much of Chisholm's work on bodies is concerned with puzzles about the persistence of physical bodies through time, and most of these puzzles, in turn, are concerned with apparent violations of Leibniz's principle of the indiscernibility of identicals. According to this principle, if  $X$  and  $Y$  are identical, then whatever is true of  $X$  is also true of  $Y$ . One famous puzzle, for example, is the ship of Theseus. Even if one plank of the ship is replaced at a time  $t$ , it is the same ship—namely Theseus's—that exists before  $t$  and after  $t$ , and yet the ship might appear to have different properties before  $t$  and after  $t$ . Chisholm attempts to solve this and other puzzles about the identity of physical bodies through time by using his fundamental ontological categories, attributes, and individual things, to make precise the seventeenth-century distinction between substances and their modes.

## CHOMSKY, NOAM

(1928–)

Noam Chomsky is the foremost linguistic theorist of the post–World War II era, an important contributor to philosophical debates, and a notable radical activist. His influence is felt in many other fields, however, most notably, perhaps, in the area of cognitive studies.

Chomsky's main achievement was to distinguish linguistic competence from its manifestations in performance and to characterize competence as a system of explicit rules for the construction and interpretation of sentences. Indeed, this achievement provided a model for investigations, in this and other cognitive domains, that replaced then-dominant models based on the notion of analogy and oriented to the causal explanation of behavior.

The competence of individuals to use their language is constituted, on Chomsky's account, by their (tacit) knowledge of a formal grammar (or system of rules); their linguistic performance, involving the deployment of

such knowledge, may be influenced by a host of extraneous factors that need not be accounted for by the grammar itself but, instead and if possible, by subsidiary theories (e.g., of perceptual processing, etc.). Furthermore, knowledge of such a system of rules permits a kind of creativity in performance that exhibits itself in the novelty, in relation to speakers' prior linguistic experiences, of (many of) the sentences they actually produce. (Crudely put, they can understand and produce sentences they have never before encountered.)

The competence/performance distinction reflects Chomsky's preference for "Galilean" theorizing (i.e., for a "modular" approach), and its introduction was tremendously liberating. A direct attack on performance, under broadly behavioristic auspices, had proved barren, for reasons Chomsky identified with devastating clarity in his review of B. F. Skinner's *Verbal Behavior*. Also pertinent was Chomsky's analysis of linguistic creativity in a second, distinct sense: the appropriateness and yet stimulus-independence (and therefore causal inexplicability) of much of what a speaker says in concrete circumstances. Shifting the linguist's problematic from behavior to the system underlying behavior was probably Chomsky's most important contribution to the development of "scientific" studies of social phenomena. (Of course, the competence/performance distinction owes much to Ferdinand de Saussure's earlier distinction between *langue* and *parole*. But Saussure did not think of the system underlying behavior as primarily rule-based, and so his distinction proved less fertile than Chomsky's.)

In a series of works beginning with *Cartesian Linguistics*, Chomsky took up what he came to call "Plato's problem"—that of explaining how the gap is bridged between individuals' limited opportunities, as children, for acquiring knowledge of their (native) language(s) and the competence to make many subtle and complex discriminations that, as mature speakers, they do indeed possess. He solved this problem, siding with classical rationalists such as Gottfried Wilhelm Leibniz, by assuming the existence, as an innate species-wide attribute, of a "universal grammar." During the course of language acquisition, limited data fixes the values of free "parameters" associated with this grammar, thus providing a basis for full-blown knowledge of the language that far exceeds the ordinary "inductive" implications of these data.

Chomsky has also been a notable advocate, very significantly in a discipline previously marked by instrumentalist assumptions about theorizing, of a realist perspective on theoretical entities and processes. In early work deep structures were postulated as sources, via

transformations, of familiar superficial structures of sentences. So, for instance, a superficially passive sentence was said to be derived from the same deep structure as its active counterpart. And while it might have been more in line with then-contemporary practice to treat these so-called deep structures as pure postulates, useful in simplifying the description and taxonomization of the superficial sentences of our “experience,” Chomsky advocated, instead, that they be treated as having psychological reality and thereby fostered many profound psycholinguistic studies intended to bear out or refute this contention. A topic of continuing importance is whether it is only structures or, instead, derivational processes as well that are to be treated as “real.”

Less noticed by commentators is Chomsky’s profoundly individualistic approach to linguistic phenomena. For him, language itself is a secondary phenomena; primacy is accorded to an individual’s competence, a purely psychological phenomenon. Indeed, Chomsky explains the coordination of linguistic interaction, not by reference to any transpersonal system of conventions (as might be thought appropriate in relation to other social phenomena), but, instead, to a harmony—between the competence of the speaker and the marginally different competence of the hearer—that depends largely on the innate constraints on their (typically) quite separate episodes of language acquisition. Even if each learns in isolation from the other, and has quite (though not “too”) different experiential bases for learning, each will acquire an “idiolect” that is accessible to the other: Otherwise rather different data-sets fix the free parameters of the universal grammar in sufficiently similar ways to permit mutual intelligibility.

Other philosophically important themes in Chomsky’s work include: (1) his identification of the ideological interests that are served by certain allegedly “scientific” approaches to the study of human behavior; (2) his argument for treating the capacity for language as species-specific and thus as an aspect of the human “essence”; (3) his speculations about the possibility that there are innate limitations on the human capacity for knowledge of the world; and (4) his continued defense, in the face of broadly “postmodernist” opposition, of the role of reason in understanding and improving the human condition and of the viability of the notion of “progress” in relation to these projects.

## CHRISTIANITY

The present entry is restricted to Christian belief and scarcely touches on the origins of “Christianity” or its history and institutional forms. Among Christian beliefs only a few can be treated; certain others, such as the existence and attributes of God, are discussed in other entries.

### CHRISTIAN BELIEF

Perhaps the first thing that should be said about Christian belief is that it does not constitute a philosophy. That is to say, it is not a metaphysical system comparable, for example, to Platonism or the systems of Aristotle and Benedict de Spinoza. Although the body of Christian doctrine does consist largely of metaphysical beliefs, in the sense that they are beliefs whose scope transcends the empirical world, it differs from what are usually identified as philosophical systems by its essential relation to and dependence on particular historical events and experiences. Such systems as Platonism begin with philosophical concepts and principles and seek by means of these to construct a comprehensive mental picture of the universe. Christianity, on the other hand, begins with particular, nonrecurrent historical events that are regarded as revelatory and on the basis of which Christian faith makes certain limited statements about the ultimate nature and structure of reality.

The relationship between experience and discursive reflection in Christianity can be brought out by distinguishing two orders of Christian belief. There is a primary level, consisting of direct reports of experience, secular and religious, and a secondary level, consisting of theological theories constructed on the basis of these reports.

At the primary level Christian literature affirms a number of both publicly verifiable historical facts and “religious facts,” or “facts of faith.” The latter consist of incidents in the history of Israel as understood and participated in by the prophets and in the life of Jesus as he was responded to by the apostles, these events being seen by faith as revelatory of God. The resulting testimonies of the prophets and apostles are not formulations of theological doctrine but direct expressions of moments of intense religious experience. The four New Testament gospels are writings on this primary level, recording events that occurred either within the purview of secular history or within the religious experience of the early Christian community.

Within this primary stratum of Christian belief certain facts of faith have always stood out as being preeminently important. By means of these Christianity has defined itself in distinction to other religions. Among the total body of those who have called themselves Christians there is no universally agreed-on list of these defining facts of faith, except insofar as such lists have been adopted, locally or more widely, by particular Christian communions, sects, or movements. However, it is safe to say that the main streams of contemporary Christianity, claiming continuity of faith with the first Christian generation, affirm at least the following: the reality of God and the propriety of speaking of him in a threefold manner, as Father, Son, and Spirit; the divine creation of the universe; human sinfulness; divine incarnation in the person of Jesus, the Christ; his reconciliation of man to God; his founding of the Christian church and the continuing operation of his Spirit within it; and an eventual end to human history and the fulfillment of God’s purpose for his creation. Stated in this general form these are facts of faith that cumulatively define Christianity. Many further tenets are regarded as essential by different subgroups within Christianity, but the above probably constitute the permanent core that is acknowledged by virtually the whole of Christendom, past and present.

The second order of Christian belief consists in theological theories or doctrines that seek to explain these facts of faith and to relate them to one another and/or to human knowledge in general. The formulation of doc-

trines is essentially a discursive and speculative activity, differing from theory construction in secular philosophy only in that the theologian includes in his data, and indeed accords a central and determinative importance to, the special facts of Christian faith.

This distinction can now be illustrated by reference to some of the central Christian themes, noting both the relevant facts of faith and the theological theories that have been developed about them.

**CREATION.** The doctrine of creation (which Christianity holds in common with Judaism) stands somewhat apart from the other doctrines to be described below. The others have arisen out of reflection on specific historical phenomena, but belief in the divine creation of the universe, although connected with the religious experience of absolute dependence on God, has presumably been arrived at primarily as an implicate of the monotheistic understanding of God as the sole ultimate reality.

The doctrine of the divine creation of the universe out of nothing stands in contrast to other conceptions of its origin. This doctrine denies that the universe is eternal, although the denial does not entail the belief that it was created at some moment in time—Augustine, for example, taught that time is itself an aspect of the created world. The doctrine also excludes the Platonic notion of a Demiurge fashioning the world out of a formless matter and the Neoplatonic notion of the physical universe’s coming to be by emanation from the Absolute. In distinction to these ideas the doctrine of *creatio ex nihilo* asserts that the universe has been summoned into existence out of nothing (that is, not out of anything) by the creative will and purpose of God.

**INCARNATION.** Jesus was born about 5 BCE in Palestine and was executed by crucifixion at Jerusalem probably in 29 or 30 CE. There immediately arose a conviction among his disciples, reflected in all the New Testament documents, that he had been raised by God from the dead, and under the compulsion of this conviction the Christian church came into existence, witnessing to both the divine status and the saving power of Jesus, now proclaimed as the Christ.

The beliefs of Jesus’ disciples about him are reflected in the four memoirs, or gospels, which were produced in different centers of the apostolic church during the second half of the first century. On the one hand, these depict him as fully and authentically human, subject, like other men, to temptation, hunger, pain, fatigue, ignorance, and sorrow. But at the same time they affirm that

he is Lord, Messiah (*Christos*), the Son of God. This extremely exalted view reaches its highest expression in the Fourth Gospel, which claims in its prologue to Jesus' life that the Word (*Logos*), which was in the beginning with God, and was God, and through which all things were made, "became flesh, and dwelt among us, full of grace and truth; and we have beheld his glory, glory as of the only Son from the Father" (John 1:14; the conception of the *Logos* in the Fourth Gospel derives both from the Word and the wisdom of God in the Old Testament and from the *Logos* as the universal principle of reason in Greek philosophy). The faith that Jesus was the Christ apparently arose out of a practical acceptance of his status as one who had authority to forgive sins, to declare God's mind toward man, to reveal the true meaning of the divine Law, to heal diseases, and to assume that men's eternal destiny and welfare was bound up with their responses to him. This practical acknowledgment of his unique authority probably crystallized into conscious conviction as to his deity under the impact of the resurrection events.

In the gospels these two beliefs, identifying Jesus both as a son of man and as the Son of God, occur together without any attempt to theorize about the relationship between them. Thus, this primary stratum of Christian literature contains, as data for theological reflection, reports of (a) the publicly observable fact that Jesus was a man, and (b) the fact of faith that he was divine, in that "in him all the fullness of God was pleased to dwell" (Colossians 1:19).

During its first four centuries of life these data provided the church with its chief intellectual task. The eventual outcome of the Christological debates, formalized by the Council of Chalcedon (451), was not to propound any definitive theory concerning the relationship between Jesus' humanity and his divinity but simply to reaffirm, in the philosophical language of that day, the original facts of faith. The various views that were from time to time branded as heretical came under this condemnation because directly or by implication they denied one or the other of the two fixed points of Christian thought in this field, the human and divine natures of Christ.

The first of the Christological heresies, the Docetism of some of the Gnostics in the first and second centuries, denied the real humanity of Christ, suggesting that he was a human being in appearance only. The motive behind this theory was to exalt his divine status, but the effect was to deny one of the foundation facts of Christianity as historically based faith. The next great heresy, Arianism, in the fourth century, went to the opposite

extreme, denying continuity of being or nature between the Godhead and Christ and regarding him as a created being, so that "there was a time when he was not" (*ἦν ὅτε οὐκ ἦν*). It was in the controversy with Arianism that the notion of substance (*οὐσία*, *substantia*) became a key category in the Christological debates. Arius declared that the Son was *ὁμοιούσιον τῷ πατρὶ* (of like substance with the Father), whereas the Council of Nicaea (325), excluding Arianism as a heresy, insisted that the Son was *ὁμοούσιον τῷ πατρὶ* (of the same substance as the Father). It was made clear by Athanasius, the champion of orthodoxy, that the iota's difference between these formulations involved an immense religious difference, for only a savior who came from the Godward side of creation could offer man an ultimate salvation. This Homousian Christology was reaffirmed by the Council of Chalcedon and has ever since been the position of the main streams of historic Christianity.

Since the mid-nineteenth century a number of theologians (for example, the Ritschlian school and H. R. Mackintosh) who accept the Nicene and Chalcedonian affirmations of the full humanity and real deity of Christ have questioned the adequacy of the category of substance in terms of which that affirmation was made. They have pointed out that it belongs to the thought-worlds of Plato and Aristotle and that it is a static notion, contrasting in this respect with such characteristically dynamic biblical categories as purpose and action. Accordingly there is now a fairly widespread tendency to describe the incarnation as a complex event constituting God's self-revealing action in man's history. In the New Testament records we see God at work in and through a human life, dealing with human beings in a way that makes plain the divine nature in its relation to man. The acts and attitudes of Jesus toward the men and women with whom he had to do were God's acts and attitudes in relation to those particular individuals, expressed in the finitude of a human life. Along these and other lines Christological discussion continues.

**THE TRINITY.** The Trinitarian doctrine is a second-order Christian belief. It was gradually developed within the church both to take account of certain data at the experiential level and to aid the development of the general system of Christian doctrine, some of the key points of which are related by the Trinitarian framework.

The New Testament basis for this doctrine was the Christian community's threefold awareness of God, first as the transcendent moral creator witnessed to in the prophetic tradition received from Judaism; second, as

having been at work among them on earth in the person of Christ; and third, as the Holy Spirit, which was referred to apparently indiscriminately as the Spirit of God and the Spirit of Christ, inspiring and guiding both individuals and the Christian community.

The doctrine of the Trinity developed in close conjunction with Christology and made possible the completion of the church's thought concerning the person of Christ. For it had never been the accepted Christian conception that God, simply as such and in his totality, became man in the incarnation. The belief that "God was in Christ" (2 Corinthians 5:19) was held in conjunction with the belief that God was also and at the same time sustaining and governing the universe. The God who was incarnate in Christ was the God who had created heaven and earth. This was expressed by the affirmation that God is both Father and Son; and the reality of the Spirit, operating in the world both before and after the thirty or so years of the incarnation, required the further expansion into a Trinitarian formulation. Thus, the doctrine of the Trinity (*a*) asserts the full deity of Christ as the second person of the Trinity; (*b*) prohibits a too simple conception of incarnation (as one branch of the theological tradition has put it, Christ is *totus deus*, wholly God, but not *totum dei*, the whole of God); and (*c*) recognizes the universal presence and activity of God in the world as the divine Spirit. This latter point is of great practical importance because it entails a Christian message not only about God's actions in the past but also about a divine activity in the present that can directly affect the individual today.

In the Trinitarian discussions that accompanied the Christological debates one of the main questions concerned the issue of equality versus subordination within the Trinity. Is the Son subordinate to the Father, or the Spirit to both? The answer that was eventually embodied in the *Quicumque vult*, or "Athanasian" Creed, of the sixth century was that the members of the Trinity are coeternal and have an equal divine status; the Son is eternally begotten by the Father, and the Spirit eternally proceeds from the Father and the Son. (The latter point was the occasion of the rift in the sixth century between the Eastern church, with its center at Constantinople, and the Western church, with its center at Rome. In its original form the Nicene Creed described the Spirit as proceeding (only) from the Father. Later the Western church added the famous *filioque*—"and the Son"—an insertion that Eastern Christianity rejected as an unwarrantable tampering with the creed.)

In the accepted Trinitarian language the Father, the Son, and the Holy Spirit are spoken of as three "Persons," the Latin *persona* having been used to translate the Greek *ὑπόστασις* (which had displaced *πρόσωπον*—literally, "face"—in this context). *Persona* is not, of course, the equivalent of "person" in the modern sense of an individual center of consciousness and purpose. Originally a *persona* was the mask worn by an actor, then his part in the play, and then by further extension any part a person might play in life. Thus, whereas *τρεῖς ὑπόστασεις* suggests three divine entities, *tres personae* suggests three roles or functions of the deity. These two different conceptions have each been developed in Christian thought, leading to what have been called respectively "immanent," or "ontological," and "economic" theories of the Trinity.

According to the ontological theories the doctrine of the Trinity is an affirmation about the transcendent metaphysical structure of the Godhead. It asserts that God in his inner being consists of three divine realities that are individually distinct and yet bound together in a mysterious unity—"three in one and one in three." The extreme form of this view is the "social" conception of the Trinity as comprising three consciousnesses. According to the economic theories, on the other hand, the doctrine is about God specifically in his relation to the world. It asserts that the one God has acted toward humankind in three distinguishable ways—in creation and providence, in redemption, and in inner guidance and sanctification. God must indeed, in his inner being, be such as to become related in these ways to his creation, but this does not necessarily require the postulation of three distinct and yet intimately related divine realities.

REDEMPTION. That human beings are sinful is a theological statement of the observable fact that men and women are persistently self-centered and that even their highest moral achievements are quickly corrupted by selfishness. Yet although we thus fail, exhibiting a chronic moral weakness and poverty, our failure is not inevitable; we are ourselves, at least in part, responsible for it. The biblical story of the fall of man depicts this situation by means of the myth that man was originally created perfect but fell by his own fault into his present state, in which he is divided both in himself and from his fellows and God.

At its primary level of belief Christianity claims that by responding to God's free forgiveness, offered by Christ, men are released from the guilt of their moral failure (justification) and are drawn into a realm of grace in which

they are gradually re-created in character (sanctification). The basis of this claim is the Christian experience of reconciliation with God and, as a consequence, with other human beings, with life's circumstances and demands, and with oneself. The "justification by faith" of which Paul spoke, and which represented the main religious emphasis of the Reformation of the sixteenth century, means that men are freely accepted by God's gracious love, which they have only to receive in faith. In Paul Tillich's contemporary restatement, a man has only to accept the fact that although unacceptable even to himself, he is accepted by God.

In this case, work at the secondary level of theological reflection did not begin seriously until the church had been preaching the fact of divine reconciliation and atonement for about a thousand years. Anselm, in the eleventh century, taught that the death of Christ constituted a satisfaction to the divine honor for the stain cast upon it by man's disobedience, and this remains the core of Catholic atonement doctrine. Martin Luther and John Calvin, in the sixteenth century, spoke of Christ's death as a substitutionary sacrifice by which Christ suffered in his own person the punishment that was justly due humankind, and this remains the core of official Protestant atonement doctrine. In the nineteenth century, however, the thought was developed (going back to Anselm's contemporary Peter Abelard) that God's forgiveness does not need to be purchased by Christ's death, but that this brings home to the human heart both man's need for divine forgiveness and the reality of that forgiveness. There were in the twentieth century and on into the twenty-first century continuing efforts to understand Christ's redeeming work in a way that would bring together the valid insights in these and other traditional views, each of which by itself has seemed one-sided.

**HEAVEN, HELL, AND JUDGMENT.** Jesus impressed upon his hearers in the strongest possible terms the absolute importance of decisions made and deeds performed in this present life. He regarded men and women as free and responsible persons on whose daily choices depended their own final good and happiness or irretrievable loss and failure. In doing this he used the traditional language of heaven and hell, which were understood until comparatively recently in terms of a prescientific cosmology, with heaven located in the sky above our heads and hell in the ground beneath our feet. Heaven is now generally conceived of as the enjoyment of the full consciousness of God's presence and participation in the divine "kingdom," which represents the final

fulfillment of God's purpose for his creation; and hell is viewed as self-exclusion from this.

There are many perennially debated questions in this area. Are men divinely predestined, some to eternal salvation and others to eternal damnation ("double predestination"), as Augustine and Calvin taught? Does "hell" signify an eternal state, or is it a temporally bounded purgatorial experience that might lead to eventual salvation? (The adjective *αιώνιος*, which is used in the New Testament, can mean either "eternal" or "for the aeon, or age"). Or does "hell" perhaps signify sheer annihilation? Can the final frustration of God's purpose by the loss of part of his human creation be reconciled with his ultimate sovereignty, and does the idea of never-ending torment, as a form of suffering out of which no good is finally brought, rule out the possibility of a Christian theodicy? Are all men to be finally saved ("universalism"), or only some?

In relation to such questions it is perhaps useful to distinguish between two standpoints from which eschatological statements may be made. There is the existential standpoint of "real life," in which we exercise a fateful responsibility in our moral choices and are confronted with the tremendous alternatives of spiritual life and death, symbolized by heaven and hell. There is also the detached standpoint of theological reflection, in which it seems possible to deduce from the two premises of the sovereignty and the love of God that although damnation is abstractly conceivable and is known in existential experience as a dread possibility, God's saving purpose in relation to his creatures will nevertheless in the end be triumphant, and eternal loss will remain an unrealized possibility.

**THE CHURCH.** Although Christianity as historically institutionalized lies outside the narrow scope of this entry, it must be added that Christian faith has always drawn people together into a community of faith, or church. The largest Christian institution, the Roman Catholic Church, holds that the authentic Christian community is defined by its visible continuity, manifested in a succession of bishops and popes, with the earliest church. Protestantism holds that the Christian community is defined by a different continuity, that of faith, and affirms that the external institutions associated with Christian faith are continually in need of reformation in the light of the original Christian data embodied in the scriptures.

## CHRYSIPPUS

(c. 279–206 BCE)

Chrysippus, the Stoic philosopher born at Soli, in Cilicia, became the third leader of the Stoa at Athens upon the death of Cleanthes, in 232 BCE. This post he held until his own death. Because of his defense of the Stoa against the attacks of Arcesilaus and the skeptical Academy, and undoubtedly also on the basis of his voluminous writings, it was said in antiquity "if there had been no Chrysippus, there would be no Stoa." He wrote 705 books, about half of which, judging from the catalog preserved by Diogenes Laertius, dealt with logic and language. None of his works is extant, though quotations from his books and assessments of some of his views have survived in the works of other ancient authors.

Chrysippus's epistemology is empirical. Presentations of objects are produced in the ruling part of the soul by movements engendered in the sense organs of the perceiver. Illusory presentations can be distinguished from those that are veridical by deliberation, which consists in checking any given presentation against a fund of common notions, that is, families of remembered similar presentations; if the presentation is found to be sufficiently like some common notion, one may assent to it, thus acknowledging its veridical character.

Propositions are either simple or nonsimple. The truth condition of a simple proposition is the occurrence of the fact it conveys. The truth conditions of nonsimple propositions are functions of the truth-values of their ingredient propositions.

Chrysippus formulated five undemonstrated argument forms whose variables are to be specified by propositions. Among them are forms of the *modus ponens* and the *modus tollens* arguments. Arguments of varying complexity can be constructed by combining two or more of these basic forms. Chrysippus enjoyed a particular renown for his competence as a dialectician.

The moral philosophy of Chrysippus is concerned primarily with a statement of the final end of life and the relation of other things to it and with a consideration of the emotions and therapy for those enslaved by them. The final good is “to live in accordance with one’s experience of the things which come about by nature.” This is equivalent to living in accordance with reason, which in man supervenes upon instinct as a guide in life. The excellence of reason is wisdom, or knowledge of what is really good and what is really bad. Chrysippus’s view in regard to the source of this knowledge is ambivalent. On the one hand—and this is obviously the doctrine that coheres best with his epistemology—it derives from generalizations made upon particular experiences. On the other hand, there are fragments implying that his knowledge is innate.

Emotions are great obstacles to happiness and are to be totally eradicated. In keeping with his monistic psychology, which rejects the Platonic doctrine of a tripartite soul, Chrysippus conceived of an emotion as a recently formed false judgment about the goodness or badness of something; such a judgment causes “a forceful and excessive impulse.” Therapy for the emotions consists in persuading their victims that the judgments constituting the emotions are false.

The dominant motifs of the natural philosophy of Chrysippus are monism and determinism. The one substance that converts periodically into an elaborately structured universe has two constant aspects, a passive one and an active one. The passive is matter; the active is identified variously as reason, pneuma (spirit or breath), and God. Chrysippus regards so-called individual substances not as discrete units of matter but rather as “parts” of one primary substance. Everything that occurs is controlled unexceptionably by fate, which is “the continuous causal chain of the things that exist.” Nothing comes about except in accordance with antecedent causes. Even in the case of states of affairs that might seem to be of a spontaneous or uncaused nature, “obscure causes are working under the surface.” Chrysippus believed that humans were responsible for their conduct, and he sought in several ways to show that such a belief was not undermined by the rigorously deterministic view he espoused.

## CHUBB, THOMAS

(1679–1747)

Thomas Chubb, the English Arian and deist, was born at East Harnham, near Salisbury, the son of a maltster. Receiving little formal education, he read widely in geography, mathematics, and theology while working as apprentice to a glovemaking and, later, as a tallow chandler. At one time he lived in the house of Sir Joseph Jekyll, master of the rolls, in the capacity, it is alleged, of a sort of superior servant. Through the kindness of friends (one of whom was the celebrated surgeon William Cheselden) and the sales of his candles, his last years, spent at Salisbury, were largely devoted to study and to the presidency of a debating society. Chubb’s importance, frequently overlooked, lies in the fact that a self-educated and humble artisan developed a good style of writing and mastered the prevalent rationalistic thinking sufficiently well to compete on equal terms with highly educated upper-class scholars and divines. He was the first, and one of the few, leading English deists of poor circumstances (only Peter Annet and Thomas Morgan shared this humble background). With Chubb it was apparent that deism had filtered down to the level of the common people and had become widespread.

Chubb’s first publication was an Arian tract, *The Supremacy of the Father Asserted*, inspired by William Whiston’s *Primitive Christianity Revived* of 1711 and published in 1715 upon the recommendation of Whiston.

Although Chubb went through an early phase of Arminianism and was always hard pressed to reconcile Jehovah with the rationalistic concept of a Supreme Being, he nevertheless became and remained a “Christian deist.” Skeptical of the Jewish revelation, he was less so of

the Islamic and openly accepted the Christian, at least as he understood it. In *The True Gospel of Jesus Christ asserted* (1732) and *The True Gospel of Jesus Christ Vindicated* (1739) he identified the essence of Christianity with the few simple principles of natural religion as found, for example, in Lord Herbert of Cherbury. He openly compared the propagation of primitive Christianity with the then current spread of Methodism and thereby rejected the claims of supernatural power associated with the early church. He defended his sort of rationalistic Christianity against some of the aspersions of that formidable deist Matthew Tindal. Although Voltaire had some kind words to say about Chubb, it is unlikely that he had read many of Chubb's tracts and certainly did not accept the concept of "Christian deism."

Chubb, like the general run of deists, found reason sufficient to guide humankind to God's favor and the happiness of another world; he was suspicious of mystery and of miracles and critical of some passages in the Scriptures; he regarded revelation not as divine but as the work of honest men who gave a fair and faithful account of matters of fact; he was dubious about a particular providence and, therefore, of prayer; he argued against prophecy and miracle and believed in the dignity of human nature and in free will. Among the multitudinous answers to Chubb from the more orthodox, the foremost came in 1754 from Jonathan Edwards of Massachusetts. *A Careful and Strict Enquiry into The modern prevailing Notions of the Freedom of Will, Which is supposed to be essential To Moral Agency, Vertue and Vice, Reward and Punishment, Praise and Blame*, Edwards's chief claim to philosophical fame, devotes no fewer than nineteen pages to the refutation of Chubb on free will. Chubb, it may reasonably be inferred, was widely read in America.

In fine, though adding little constructive thought to the deistic movement, this humble and least formally educated of the English deists was definitely one of its most valuable and popular spokesmen. In the nonpejorative sense of the term he was a candid freethinker.

**See also** Deism.

### **Bibliography**

Chubb was prolific in publication, and his ardent deism was expressed in the titles of a few of his chief works: *The Comparative Excellence and Obligation of Moral and Positive Duties* (1730); *A Discourse concerning Reason, With regard to Religion and Divine Revelation* (1731); *The Sufficiency of Reason in Matters of Religion Farther Considered* (1732); *The Equity and Reasonableness of the Divine Conduct, In Pardoning Sinners upon Their Repentance Exemplified* (1737), which was directed against Bishop Butler's famous *Analogy*

*of Religion* of the previous year; *An Enquiry into the Ground and Foundation of Religion. Wherein Is shewn, that Religion Is founded in Nature* (1740); and *A Discourse on Miracles, Considered as Evidence to Prove the Divine Original of a Revelation* (1741).

Other works by Chubb include *Four Tracts* (1734) and *Some Observations Offered to Publick Consideration... In which the Credit of the History of the Old Testament Is Particularly Considered* (1735). The posthumous *Works of Mr. Thomas Chubb*, 2 vols. (London, 1748) contains the valuable "Author's Farewell to his readers."

## CHURCH, ALONZO (1903–1995)

Alonzo Church, an American logician and philosopher, was born in Washington, D.C. He received his PhD from Princeton in 1927, having written his dissertation under Oswald Veblen on alternatives to the axiom of choice. He spent a year at Harvard and then a year in Europe, studying first at Göttingen and then at Amsterdam with L.E.J. Brouwer. He returned to Princeton where he was professor of mathematics from 1929 to 1967, after which he moved to UCLA to become professor of mathematics and philosophy. He retired from teaching at UCLA in 1990. Church's most important contributions to logic were his analysis of the concept of effective computability and his proof of the undecidability of first-order logic (Church's theorem).

A function of natural number is effectively computable if there is an algorithm—a surefire method requiring no ingenuity to follow—that will yield the value of the function for any given natural number as input. Church devised a formal system, the lambda calculus (which subsequently became an important tool in computer science), and proposed that a function of natural numbers be taken to be computable if it is *lambda definable*—definable by way of a

formula in the calculus. The analysis has little to recommend it initially, but experience with intuitively computable functions led Church to conjecture that every such function is lambda definable—a conjecture now known as *Church's thesis*. Alan Turing gave a more compelling analysis of computability in terms of abstract computing machines (Turing machines) and it was subsequently shown that lambda definability is equivalent to this notion of *Turing computability*. Various other analyses have been proposed and all have turned out to be equivalent to Church's definition. This is often regarded by logicians as evidence for the correctness of the conjecture. Church's thesis is now almost universally accepted.

Say, for instance, that a property of an expression is (effectively) decidable if there is an algorithm for deciding whether or not any given expression has the property. This notion can be identified with a certain sort of effective computability by supposing that all expressions have been assigned numbers (in some effectively determinate way) and then saying that a property of an expression is *effectively decidable* if there is an algorithm that will yield 0 (*no*) when applied to the number for the expression if the expression does not have the property and will yield 1 (*yes*) if the expression does have the property. If one then identifies the existence of such an algorithm with the lambda definability (or Turing computability) of that function, as Church's (or the Church-Turing) thesis proposes, one has a precise definition of effective decidability. Church's theorem shows that the property of being a valid formula of first-order predicate logic is not decidable in this sense. Thus, unlike the propositional calculus for which truth tables yield an effective procedure for deciding tautologousness, the validity of a first-order formula can not be decided, yea or nay, by any uniform algorithmic procedure.

Church's most important philosophical contributions involve the realism-nominalism controversy in the philosophy of mathematics and logic and problems and theories about meaning. He was a realist or Platonist about abstract entities and provided powerful arguments against various attempts to explain away such entities.

Rudolf Carnap and others associated with logical positivism displayed a general animosity toward such abstracta as numbers, functions, properties, and propositions. Carnap attempted to analyze sentences ostensibly ascribing belief in a proposition to someone in terms of sentences and a relation of "intensional isomorphism" between sentences. Roughly, the relation holds when the sentences in question are made up of necessarily equivalent parts, arranged in the same order. Church objected

that a sentence ascribing a belief to someone does not mention a sentence of a particular language. He goes on to give a detailed and compelling refutation of Carnap's specific proposal. The method used, what is now called the "translation argument," appears to be of general applicability and makes it seem implausible that any replacement of propositions by more concrete things such as sentences will be successful. Church also raised powerful objections to nominalist maneuvers by A. J. Ayer and Israel Scheffler. Problems about the notion of synonymy were raised by Nelson Goodman and Benson Mates. Church answered these decisively.

Church's work on the logic of sense and denotation, a formal intensional logic incorporating some of Gottlob Frege's ideas about meaning, was one of his most important projects for philosophy, but it remains unfinished. The basic new idea is the "delta-relation"—the relation that holds between the sense of an expression and the denotation of that expression in some possible (N.B.) language. This is taken to be a logical relation and it is said that the sense is a *concept* of the denotation. It is postulated that a concept (the sense of some expression in some possible language) is a concept of at most one thing. And if  $F$  is a concept of a function  $f$  and  $X$  is a concept of an object  $x$ , then  $F[X]$  is a concept of  $f(x)$ . Church assumes that one can construe concepts of functions as certain functions on concepts, so that  $F[X]$ , plausibly taken to be a certain complex entity, is just construed as application of the function  $F$  to an argument  $X$ .

Various difficulties were encountered in working out this last idea, as well as in developing an axiomatic treatment of a *criterion of identity* for concepts that would render them suitable for the analysis and logic of the propositional attitudes—belief, knowledge, and the like. Modifying Carnap's notion of intensional isomorphism, Church proposed that two sentences (or other complex expressions) express the same proposition (or concept) if they are *synonymously isomorphic*—roughly, that they consist of synonymous expressions arranged in the same order. The development of axioms for the logic of sense and denotation that this idea suggests Church calls "Alternative (0)." Church was unable to complete an adequate formalization of this important conception.

## CHWISTEK, LEON

(1884–1944)

Leon Chwistek, a Polish mathematical logician, philosopher, aesthetician, essayist, and painter, was a lecturer at the University of Kraków and from 1930 a professor of mathematical logic at the University of Lvov.

### THEORY OF REALITIES

The central problem of Chwistek’s philosophy was a criticism of the idea of a uniform reality. It had been shown by Bertrand Russell that in logic admission of the totality of all functions of  $x$  produces contradictions; Chwistek claimed that in philosophy, likewise, many obscure and misleading thoughts result from the assumption of a single all-inclusive reality.

The results of this criticism led Chwistek to the thesis of a plurality of realities. Out of many possible realities

four are particularly important to philosophy. The first, the reality of natural objects, is assumed by common sense; natural objects are of a given form regardless of our perception. Chwistek’s defense of natural reality and our knowledge of it is reminiscent of the British common-sense philosophy of the nineteenth century. The objects studied in physics are not natural; the telescopic and microscopic worlds, matter, and the particles upon which the forces are supposed to act form a second reality. They are constructions, not something naturally given. The third reality, that of impressions, the elements of sensation, as studied by David Hume or Ernst Mach, forms the world of appearances. The fourth reality is that of images, produced by us and dependent on our will, fantasy, and creative processes.

All four of these realities are necessary to account for our knowledge. In addition, when we reflect that we speak about a reality, we cannot include ourselves or our reflection in this reality. Such a reflection must be a part of a higher reality. Otherwise confusions and contradictions arise. The act of discourse cannot be a part of the universe of discourse.

### AESTHETICS

Chwistek applied the doctrine of plurality of realities to investigations in many areas—aesthetics, for example. Natural reality is dealt with by primitive art. In primitive art each object is given one color only, and perspective is not obeyed. The primitivist paints not as he sees but as things are supposed to be by themselves. He uses his vision, but mainly he uses his knowledge about the world. Realism in art depicts the physical reality as it is conceived at a given time. Impressionism is the art of the reality of impressions; it flourished in a society that had developed psychological research and made psychologism its fundamental scientific method. Futurism is the art of free images, of an actively created reality of fantasy and mental constructions.

In each style of art the artist tries to give a perfect form to his creation independent of the kind of reality he is working with. The form is the common feature of all works of art. Thus, Chwistek justified all styles by relating them to different realities, and he advocated formism: evaluation of form, not of reality, is the proper aesthetic evaluation.

### MATHEMATICS AND SEMANTICS

Chwistek extended his pluralism to mathematics. There is no one system of mathematics, but there are many mutually exclusive systems. Various geometries coincide only

in part. When we build analysis based on logic, we can accept, reject, or accept the negations of some extralogical existence axioms, such as the axiom of choice, the axiom of infinity, and the assumption of the existence of transfinite cardinal numbers. Logic itself should not decide any existence problem.

This restrained program for logic was paired with the requirement that logic be understandable in a nominalistic manner and deal with expressions in a constructive, mechanically computable way. Among principles often accepted as logical are some propositions questionable from the constructivist point of view—for example, the axiom of reducibility and the axiom of extensionality. The axiom of reducibility has to do with the distinction between predicative and impredicative concepts. An impredicative concept is a concept definable only by a definiens containing a quantifier that accepts as one of its values the very concept being defined. Russell and Chwistek ruled out such definitions as involving a vicious circle.

As was incisively pointed out by Kurt Gödel (in *The Philosophy of Bertrand Russell*, P. A. Schilpp, ed. [Evanston, IL, 1946], pp. 135–138), impredicative definitions involve a vicious circle only if one takes, as Chwistek did and Russell did not, a nominalistic attitude toward logic. Only if the quantifier is understood as a summary reference (infinite conjunction) to all of its values that are expressions and if one of the values of a quantifier that occurs in the definiens is the expression that is the definiendum do we presuppose what we want to define. Russell was not a nominalist. His exclusion of impredicative definitions was a way of avoiding antinomies. By differentiating between ranges of values of variables according to the way the quantifier binding a variable occurs, Russell constructed the ramified theory of logical types. This is a somewhat awkward theory. In analysis we want to speak about, for example, the real number that is the least upper bound of a set of real numbers that has a bound. To introduce this concept we must quantify over real numbers greater than all real numbers of a class that includes the least of them. Russell's theory avoids this impredicateness by setting the least upper bound in a different logical type from the starting real numbers. But then the least upper bound and the real numbers involved cannot be values of the same variables, and several statements about particular sets of real numbers (for example, that a given function is continuous) are impossible.

To overcome this difficulty Russell accepted the axiom of reducibility, which says that every propositional function is coextensive with a predicative one. In many

cases we cannot construct such a predicative function, and therefore constructivists, such as Chwistek, cannot accept this axiom. Moreover, for a nominalist, that two propositional functions are coextensive is not a sufficient guarantee of their identity. Thus, Chwistek attempted the task, which Russell called “heroic,” of forming a purely constructivist system of the foundations of mathematics without impredicative definitions, the axiom of reducibility, or the axiom of extensionality. He observed, as F. P. Ramsey did, that results similar to Russell's can be obtained by the simple theory of types (where one distinguishes only between variables ranging over individuals, properties of individuals, properties of such properties, etc.) instead of the more complicated ramified theory. But simple type theory is inconsistent with the axiom of intensionality, which Chwistek wanted to be free to accept and which asserts the nonidentity of the concepts defined by two different propositional functions (even if they are coextensive).

The systems Chwistek constructed for the foundations of mathematics were such that they answered the philosophical needs of their author. They were admittedly more complicated than Russell's. “But it may be erroneous to think that clear ideas are never complicated; while we must agree that many simple ideas are, as a matter of fact, very obscure.” Chwistek presented several formulations of his attempts at a constructivist theory, all of them too sketchy to be judged definitive. The relation to other constructivist systems is hard to establish. The last few versions were called “rational metamathematics.” This theory deals with expressions, some of which are theorems.

A principal part of rational metamathematics, the fundamental system of semantics, uses two specific primitive signs,  $c$  and  $*$ , about which we stipulate that  $c$  is an expression and that if  $E$  and  $F$  are expressions, then  $*EF$  is an expression. These formation rules assign a definite tree (or grouping) structure to each finite expression as well as to any two expressions written one after the other. Some of the allowed combinations of  $c$  and  $*$  may have no meaning—in this Chwistek was a formalist. To some other expressions we assign meaning, and in accordance with this assignment we accept proper axioms. We take  $0$  to be an abbreviation of  $*cc$ . The fundamental substitution pattern ( $EFGH$ )—which is read “ $H$  is the result of substituting  $G$  for every occurrence of  $F$  in  $E$ ”—is taken to be an abbreviation of  $***EE*FF*GG*HH$ . The Sheffer stroke function,  $|EF$ , is regarded as an abbreviation of  $***EE**EE*EE***FF**FE*FF$ . Identity =  $EF$  stands for ( $EOOF$ ).

## CICERO, MARCUS TULLIUS

(106–43 BCE)

The Roman orator and statesman Marcus Tullius Cicero, of Arpinum, had a lifelong interest in philosophy and wrote a number of philosophical works during periods of forced retirement from public life. He was well acquainted with the four main Greek schools of his time and counted among his friends and teachers the Epicureans Phaedrus and Zeno, the Stoic Posidonius, the Peripatetic Staseas, the Academics Philo and Antiochus, and many others. He identified himself primarily with the Academy, though he found much to admire also in the Stoa and Lyceum. He rejected Epicureanism.

In a famous passage in a letter to Atticus (xii, 52, May 21, 45 BCE), with reference to some of his books on philosophy, Cicero calls them copies (“apographa”), written

with little effort; he supplied only the words (“Verba tantum adfero, quibus abundo”). A week earlier he had written: “It is incredible how much I write, even at night; for I cannot sleep” (*Ad Atticum* xiii, 26). Modern scholars have found in such passages support for the view that these writings are chiefly valuable for the reconstruction of lost Greek originals, which Cicero in his haste sometimes misunderstood or jumbled together. The search for sources has been a major preoccupation of Ciceronian scholars for almost a century.

A more generous view is that in spite of his own statements Cicero’s philosophical writings are more than hasty copies of Greek originals; they present a fairly coherent and modestly original system of thought. At a minimum Cicero took from the Academy a framework for his views. The Platonism of the New Academy had abandoned the search for truth and was occupied, rather, with the confrontation of conflicting opinions. Carneades, its leading spokesman, had even devised criteria for preferring one opinion to another. Within such a framework Cicero examines alternative views and makes his selection (though not necessarily in terms of Carneades’ criteria). The views examined extend to all three commonly accepted branches of philosophy—logic, physics, ethics—and the presentation follows an orderly plan. Within this broad coverage, however, are many unresolved conflicts; clearly, Cicero’s primary purpose was to offer to his Roman readers a wide range of philosophical opinions rather than to construct a well-integrated system.

## PHILOSOPHY AND RHETORIC

Whatever originality Cicero’s views possess is not in their components (he believed that the Greeks had already exhausted the varieties of possible opinions) but in their combination. The most conspicuous feature of his thought is the union of philosophy with rhetoric. This union carries with it some criticism of Socrates, who was blamed for their separation (see *De Oratore* iii, 61), and appears to align Cicero with Isocrates rather than Plato; yet he does not consider the union incompatible with Platonism. Carneades had prepared the way for a reconciliation between rhetoric and the Academy when he made philosophy a contest between opinions, and Greek theoretical rhetoricians had long since sought to implement Plato’s prescription in the *Phaedrus* for a scientific rhetoric. Cicero could also point to the literary excellence of the dialogues as evidence that Plato was a master of the rhetorical art (*ibid.* i, 47).

The union of rhetoric and philosophy gave Cicero the materials for construction of his humanistic ideal.

The highest human achievement lies in the effective use of knowledge for the guidance of human affairs. Philosophy and the specialized disciplines supply the knowledge, and rhetorical persuasion makes it effective. Each is useless without the other, and the great man is master of both. Cicero associates this ideal with a free society—that is, a constitutional republic in which persuasion rather than violence is the instrument of political power. He believes that Rome has the essential features of such a state but that unless a great man is found to guide it, its freedom is in jeopardy.

Commitment to the union of eloquence and knowledge led Cicero to the view that if the statesman-philosopher is to speak persuasively on all subjects, he must have knowledge of all subjects. But recognizing the impossibility of such a requirement, Cicero advocated liberal education as the best approximation. An important part of liberal education is the study of philosophy, and Cicero's philosophical works provided materials for this study. Thus, in his philosophical writings no less than in his great public orations, he was combining wisdom and eloquence in the service of the Roman people.

## PHILOSOPHICAL WORKS

The literary form that Cicero used emphasizes his didactic intent. Most of the philosophical works are dialogues, preceded by an introduction in defense of philosophical studies. The speakers are distinguished Romans, including Cicero himself, and frequently the listeners are young men just beginning their political careers. Conflicting views are presented in long speeches, with few interruptions. Sometimes the clash of opinions leads to insult and denunciation, especially when Epicureans are involved, but personal abuse of one speaker by another is avoided. There is hardly a vestige of dramatic conflict in such dialogues as *Tusculanae Disputationes*, where the conversation is between a young man and his preceptor. In two late works, *De Officiis* (*On Duties*, addressed to Cicero's son) and *Topica* (addressed to a young lawyer, Trebatius), the dialogue form is discarded.

In logic Cicero wrote *Academica*, in two versions (45 BCE), on the dispute between dogmatists and Academic skeptics about the criterion of truth; only portions of these are extant. *Topica* (44 BCE), though usually grouped with the rhetorical works, is also on logic. The title is from Aristotle, but the treatment is not. Cicero compiles a single exhaustive list of kinds of argument without distinction between the philosophical and the rhetorical.

There are three works, planned as a unit, on physics: (1) *De Natura Deorum*, (2) *De Divinatione*, and (3) *De Fato* (45–44 BCE). They present Epicurean, Stoic, and Academic arguments and counterarguments about religion and cosmology. Cicero himself was inclined to accept the Stoic arguments for a divine providence, but he rejected the Stoic doctrine of fate.

The major ethical writings are *De Finibus Bonorum et Malorum* (45 BCE), in which Epicurean, Stoic, and Peripatetic ethical views are examined; *Tusculanae Disputationes* (45 BCE), on fear of death, on pain, on distress of mind, and on other matters; and *De Officiis* (44 BCE), a practical ethics based on Stoic principles.

On political theory Cicero wrote two dialogues with titles taken from Plato. There is *De Re Publica* (51 BCE), from which the famous "Dream of Scipio" is an excerpt. The subject matter of the "Dream" ensured its preservation; it portrays the virtuous soul enjoying a more perfect existence after death in the region above the moon. The rest of the work is fragmentary. The other political dialogue, *De Legibus* (date uncertain), depicts Roman law as a very nearly perfect realization of Greek (chiefly Stoic) theory.

Some of the rhetorical works, especially the first book of *De Oratore* (55 BCE), discuss the relation of philosophy to rhetoric and present the ideal of the great man in whom both are united.

Minor works on philosophical themes include *Paradoxa Stoicorum*, *De Senectute*, *De Amicitia*, and the lost *Consolatio* and *Hortensius*. Cicero also translated two Platonic dialogues, *Protagoras* (lost) and *Timaeus* (W. Ax, ed., Leipzig, 1938).

## Bibliography

### TEXTS AND TRANSLATIONS

The standard Latin editions for most of Cicero's works are published by Teubner (various editors). New critical editions of the philosophical works are being published by Oxford University Press; two have appeared (more are imminent): *De Finibus*, edited by L. D. Reynolds (1998), and *De Officiis*, edited by Michael Winterbottom (1994). Texts and facing translations of the entire corpus, including all philosophical works except a partial Latin translation of Plato's *Timaeus*, are published by the *Loeb Classical Library*, various editor-translators (Cambridge, MA: Harvard University Press, 1914–1949). Superior translations of philosophical works include:

- Academica*: Brittain, Charles. *Cicero: On Academic Scepticism*. Indianapolis, IN: Hackett, 2005.
- De Amicitia*: Powell, Jonathan G. F. *Cicero: On Friendship and The Dream of Scipio*. Warminster: Aris and Phillips, 1990.
- De Fato*: Sharples, Robert W. *Cicero: On Fate, and Boethius: The Consolation of Philosophy IV.5–7, V*. Warminster: Aris and Phillips, 1991.
- De Finibus Bonorum et Malorum*: Annas, Julia, and Raphael Woolf. *Cicero: On Moral Ends*. Cambridge, U.K.: Cambridge University Press, 2001.
- De Legibus*: Zetzel, James E. G. *Cicero: On the Commonwealth and On the Laws*. Cambridge, U.K.: Cambridge University Press, 1999.
- De Natura Deorum*: Walsh, Patrick G. *Cicero: The Nature of the Gods*. Oxford: Oxford University Press, 1997.
- De Officiis*: Atkins, E. Margaret, and Miriam T. Griffin. *Cicero: On Duties*. Cambridge, U.K.: Cambridge University Press, 1991.
- De Oratore*: May, James M., and Jakob Wisse. *Cicero: On the Ideal Orator*. New York: Oxford University Press, 2001.

## CIVIL DISOBEDIENCE

The idea of civil disobedience comes out of the tradition of social and political protest whose best known advocates are the nineteenth-century American transcendentalist Henry David Thoreau, the Indian reformer Mohandas Gandhi, and the American civil rights leader, Martin Luther King, Jr. While the idea of civil disobedience has diverse roots, the views of these activist/thinkers set the stage for academic and popular discussion.

Philosophical discussions of civil disobedience generally focus on two questions. First, what is civil disobedience? Second, can acts of civil disobedience be morally justified?

### DEFINING "CIVIL DISOBEDIENCE"

The definition of civil disobedience that best accords with the tradition of Thoreau, Gandhi, and King categorizes acts as civil disobedience if they have four features. They must be: (1) illegal; (2) nonviolent; (3) public; and (4) done to protest a governmental law or policy.

Thoreau's refusal to pay his taxes has all these features. It was illegal, nonviolent, and public. (Unlike a tax evader, Thoreau did not hide his not paying.) And, it was done to protest policies of the United States government that Thoreau thought were seriously unjust—support of slavery and an aggressive war against Mexico.

Actions such as Thoreau's are sometimes described as "conscientious refusal," refusing to obey a law that requires one to act immorally. While conscientious refusal is not identical with publicly protesting a policy, the two usually go together. Generally, people who refuse to obey unjust laws hope that their act will stimulate others to see that the law is wrong and to work for change. Thoreau spoke publicly about the reasons for his act, and his lecture became the classic essay "Civil Disobedience."

Gandhi and King went beyond individual conscientious refusal and organized large numbers of people to disobey the law as a means of protest. These illegal acts were intended to publicize serious injustices and to rally support for change. If enough people were to disobey an unjust law, it might be impossible for a government to enforce it.

Acts of civil disobedience cover a spectrum ranging from: (a) conscientious refusal by individuals; to (b) symbolic disobedience that is meant to convey a message about the wrongness of government policy; to (c) large-scale acts of disobedience that aim to render a government unable to carry out its policies.

Not everyone would accept the definition given above. Some argue that civil disobedients must accept the punishment, but this does not seem necessary. For example, someone who publicly burns a draft card might flee the country if the punishment were extremely severe; yet the original act would still be civil disobedience, even if the act of fleeing is not. John Rawls (1999) has argued that civil disobedience addresses a community's sense of justice, but this overlooks the fact that a community can have mistaken or conflicting conceptions of justice. Finally, some argue that civil disobedience can be violent, but this overlooks the connotations of the word "civil" and violates the tradition of Gandhi and King, who were explicitly committed to nonviolent strategies of resistance. Moreover, because violent acts require stronger types of justification, including them in the definition complicates the evaluation of civil disobedience. Violent acts will have to be distinguished from nonviolent ones when people try to see if civil disobedience can be morally justified. In the end, the test of definitions is that they help to clarify matters, and lumping together violent and nonviolent acts in this case does not seem helpful.

Using the definition above, the question "Is civil disobedience ever morally justified?" can be understood to mean "Is it ever morally permissible to engage in nonviolent, public violations of the law in order to protest a governmental law or policy?"

### THE DUTY TO OBEY THE LAW

Asking whether civil disobedience can be morally justified presupposes that there is a moral duty to obey the law. If there were no such moral duty, then breaking the law would not need a special justification. In addition, people who think that civil disobedience can never be justified must believe that the moral duty to obey the law is absolute and can never be overridden by other moral concerns.

Socrates' arguments in the *Crito* are often taken as a source of the view that people must always obey the law. Socrates appears to argue that people must always obey the law because the state is like a parent and one must obey one's parents, that the state has benefited him and therefore should be obeyed, and that he has made a tacit agreement to obey the laws by living in Athens all his life.

In the *Apology*, however, Socrates states that he will disobey the law if it requires him to violate the commands of the gods. Socrates, then, is a source of both the individualist tradition that approves civil disobedience and the authoritarian, statist tradition that condemns it.

In his *Leviathan*, Thomas Hobbes provides a famous argument for the duty of obedience to law. He argued that recognition of government's authority is justified because it is the only way for people to avoid a state of nature in which everyone is a threat to everyone else. If all people followed their own judgment and recognized no legal authority, this would lead to a situation of unlimited conflict in which life is "nasty, brutish, and short" (*Leviathan*, Ch. XIII). Hobbes thought that peace could be achieved only if people agree to obey a sovereign who enforces the laws. If everyone claims a right to act according to their own judgment and to disregard the law, then government would be undermined, and there would be a return to anarchy and a state of war by "every man, against every man" (*Leviathan*, Ch. XIII). In short, individuals must trade away their personal autonomy if peace and security are to be possible.

In a much discussed argument from the 1960s, Robert Paul Wolff turned Hobbes's argument on its head in order to defend a version of philosophical anarchism. Wolff agrees with Hobbes that governments claim authority over what citizens should do and thus take away personal autonomy. But, Wolff claimed, personal autonomy—deciding what is right and wrong for oneself and acting on those decisions—can never legitimately be traded away (Wolff 1976). Therefore, governmental authority can never be morally legitimate. From Wolff's anarchist perspective, it is obedience to law rather than disobedience that is morally questionable.

There is also a cynical tradition that sees laws as devices for protecting the interests of the rich and powerful. Thrasymachus, a character in Plato's *Republic*, defined justice as whatever is in the interests of the stronger. This idea is echoed in the Marxist view that the legal system is a device whose real purpose is to protect the property and power of the wealthy. This cynical perspective suggests that it is foolish to believe in a moral obligation to obey the law.

### JUSTIFYING CIVIL DISOBEDIENCE

Debates about civil disobedience are often conducted in all-or-nothing terms. They presuppose either (a) that there is an absolute obligation to obey the law no matter what, or (b) that there is no obligation to obey the law at all. From this perspective, support for civil disobedience

leads to anarchism, whereas opposition to it requires mindless conformity to governmental authority.

A different tradition emerges from John Locke's *Second Treatise on Civil Government*. While Locke argued that governments and laws could be legitimate and should be taken seriously, he also defended a right of revolution in cases where the government violates the rights that it is supposed to defend. According to Locke, the duty to obey is conditional on the nature of the government. There is no duty to obey a tyrannical government. This Lockean view acknowledges a general moral duty to obey the law while recognizing that there are circumstances in which disobedience—and even revolution—might be justified. Locke's view is echoed in the American *Declaration of Independence*, which affirms a right to “alter or abolish” a government that violates its people's rights.

Defenders of civil disobedience, then, need not be anarchists. They can recognize the moral force of the law while at the same time believe that the moral force of the law is conditional. When the right conditions do not exist, various forms of disobedience—including civil disobedience—may be justified. If the conditions that warrant obedience to law do exist, then people who violate the law are acting wrongly. Just as obedience to law can be morally required in some cases and morally forbidden in others, so likewise civil disobedience can be justified in some cases and not in others.

The argument for civil disobedience is strongest when a specific law requires people to act immorally. A broader justification for disobedience arises when a government lacks legitimacy. Gandhi's campaign for Indian independence, for example, challenged the legitimacy of British colonial rule. If British rule was illegitimate, then there was no moral duty to obey British laws. Still, for both moral and tactical reasons, Gandhi used civil disobedience selectively.

### KING'S DEFENSE OF SELECTIVE OBEDIENCE

While there are plausible justifications for disobedience to some laws and some governments, a serious problem faces people who engage in civil disobedience but nonetheless appeal to others to obey the law. Martin Luther King Jr.'s classic “Letter from a Birmingham Jail” discusses just this problem. Critics charged that King was inconsistent because he urged segregationists to obey laws that enforced racial equality at the same time that King and his followers stated their willingness to violate other laws. If selective obedience was permissible for King, why was it not permissible for his opponents?

King defended himself by providing criteria for justified disobedience. He argued that it is morally permissible to disobey the law: (a) when the law itself is unjust because it “degrades human personality” rather than respecting people; (b) when the laws are binding on a minority group but do not bind the majority that imposes it; (c) when those who are mistreated are deprived of rights of democratic participation in the process of enacting the law; or (d) when a proper law is unjustly applied so as to deprive people of their rights of protest. These conditions, he argued, were met by those campaigning for racial equality but not by those who supported segregation.

King's argument shows how one can consistently defend the right to disobey the law and also take obedience to law seriously. He recognizes a strong presumption in favor of obedience but argues that the presumption is overridden in the kinds of circumstances he describes.

### UNJUSTIFIED CIVIL DISOBEDIENCE

Acts of civil disobedience are not as difficult to justify as forms of protest that use violence. Nonetheless, acts of civil disobedience can be morally wrong. For example, they can be committed on behalf of an unjust cause. Thoreau, Gandhi, and King all protested serious evils, but if a person mistakenly believes that a law or policy is unjust, then an act of disobedience against it will not be morally justified. Moreover, even if a law or policy is bad, its defects may not be serious enough to justify violating the law. If obedience to law is something people expect of others when they disagree with a law, then those same people are not justified if they disobey laws simply because they disagree with them. Disobedience must be reserved for serious cases, and even then, it may not be justified if legal means are available for effectively promoting change. It is only when effective, legal means are unavailable that civil disobedience is permissible. Finally, such acts can be wrong if they undermine just and valuable institutions.

A strong case, then, can be made for the view that civil disobedience can be morally justified under certain conditions. Whether specific acts of civil disobedience are justified, however, is often controversial. This is because people often disagree about the seriousness of the evils being opposed, the availability of other effective means of protest, and the long-term effects on valuable institutions and practices. People who agree that civil disobedience can be justified in theory can still disagree about whether it is justified in practice.

## CIXOUS, HÉLÈNE

(1937–)

Hélène Cixous was born in Oran, Algeria, on June 5, 1937. Her father was of French-colonial and Jewish descent and her mother was Austro-German. Cixous grew up in Algeria, although she studied in France and began her academic career there. Her first text, *Le prénom de Dieu* (God's first name), was published in 1967. Since 1968, she has been a professor of English literature at Université de Paris VIII–Vincennes, a university considered "revolutionary" for its opposition to traditional institutional structures, which she helped found. Cixous also established the first women's studies center in Europe at Université de Paris VIII.

Cixous has been consistently concerned with the repressive and exclusionary consequences of institutional and systemic forms of power. She has been interested in both individual and collective liberation struggles, such as the liberation of the self from the impact of psychoanalysis, the liberation of women, and Third World struggles. She has published approximately fifty novels, plays, and theoretical essays. Within the United States, the best

known of her writings have been "The Laugh of the Medusa" (1976) and *The Newly Born Woman* (1986). Much of her work has been originally published in French and has not been translated into English.

Cixous is well known for her notion of *écriture féminine*. In "The Laugh of the Medusa," Cixous maintains that to define a feminine practice of writing, or *écriture féminine*, is not possible since "it will always surpass the discourse that regulates the phallogocentric system" that aims to theorize or enclose it (1976, p. 883). Cixous discusses her wariness of reductive language that would simplify or capture her practice of *écriture féminine*. Nonetheless, her basic attempt is to free language and to offer new ways of writing and speaking. To do so, she emphasizes the fictional and poetic elements in her writing. In questioning structures of power, Cixous advocates the freeing of self through writing. In turn, freeing the self (or the subject) means rethinking traditionally repressed categories; for example, woman, the body, and writing. Cixous argues against the association of the phallic subject with narcissism and death, which simultaneously equates women with death. In contrast to an emphasis on narcissism and death, Cixous suggests an economy of the gift—an economy that is based on giving and receiving. The exchange represented by an economy of the gift would mark a new mode of exchange, for Cixous, and would arise through linguistic changes. In turn, in Cixous's view, it is only through linguistic changes that social changes are possible. Thus, Cixous encourages women to "write themselves"; that is, women should write their bodies and their desires, which have always and only been written and discussed by men.

The transformation of the relationship between self and other is central to Cixous's writing and constitutes its political dimension. While Cixous wrote her dissertation on Irish author James Joyce, her emphasis on life over death separated her from him. Although Cixous recognized Joyce for his emphasis on transforming linguistic structures as a means of changing mental structures, Joyce ultimately maintained that one must lose (kill the other) in order to have (live). Despite Cixous's recognition of loss and death as inevitable for life, her aim is to emphasize life over death (thereby reversing the emphasis of many male authors). One way in which Cixous highlights life, and the economy of the gift, is through a focus on the mother and child relationship; specifically, the mother and daughter relationship. Cixous suggests that the woman/mother gives insofar as she nourishes the child. Woman is both the container and the contained. Woman's relationship to the Other, or to otherness, thus

differs from the relationship between man and the Other since things happen to him from the outside. Cixous uses the metaphor of “white ink,” or of writing in breast milk, to convey the idea of reuniting with the maternal body. She also argues for a bisexuality that would extend subjectivity beyond dualisms to configure a multiple, rather than a fixed and static, subject.

In addition to Joyce, Cixous’s work has been informed by several German and French philosophers, including Martin Heidegger and Jacques Derrida. In *La Venue à l’écriture* (1977), a strongly Derridean work, Cixous advances the position that *écriture féminine* is not necessarily writing by a woman; instead, it is writing likewise practiced by certain male authors (such as Joyce and Jean Genet). Cixous has furthered the work of psychoanalyst Jacques Lacan, though amidst controversy, by pointing out that women and men enter into the symbolic order (the structure of language) differently. She critiques Lacan’s naming of the phallus as the center of the symbolic and suggests that this view marks language as “phallogocentric” (the idea that the structure of language is centered by the phallus). In this regard, she both echoes and presses Derrida’s insight that the Western privileging of spoken words over written words renders the structure of language as “logocentric.” Like Derrida, she interrogates the binary structure of language in the West and exposes its role in maintaining oppressive structures of thought.

Often Cixous is placed alongside Luce Irigaray, Julia Kristeva, and Catherine Clément as being one of the French or continental feminists. However, the use of the phrase, “the French feminists,” is problematic here in that it tends to conceal from consideration other feminists who are French. Moreover, the phrase overlooks the more complicated backgrounds of the so-called “French” feminists themselves. Not unlike these other thinkers however, and most notably Irigaray, Cixous has been charged with essentialism. That is, she has been criticized for engaging with an essential, identifiable, and named femininity within the texts she examines. Cixous’s response to such accusations, not unlike Irigaray’s, would be to claim that she does not intend to engage with a biological category “woman”; rather, she aims to interrogate the cultural position held by such categories within discourse and systems of language.

## CLANDESTINE PHILOSOPHICAL LITERATURE IN FRANCE

The body of clandestine literature in France that deals with philosophy, religion, ethics, and social problems is impressive. It can be traced back to the sixteenth century, and the diffusion, particularly wide between 1714 and 1740, of the allegedly atheistic treatise *La béatitude des Chrétiens ou le fléau de la foy*, published by Geoffroy Vallée in 1572, and of other tracts of early date bears witness to the continuity and vitality of the tradition of free thought in France. The term “Clandestine philosophical literature” usually refers to works known to have circulated in manuscript form during the first half of the eighteenth century and the importance of the subject lies in the fact that the circulation of these works provided one of the sources of the French encyclopedic movement and a solid foundation for liberalism. For the period between 1700 and 1750, I. O. Wade has listed 392 extant manuscripts of 102 different treatises, including 15 translations from other languages. Many more are known to have been in circulation.

The technique of the clandestine manuscript essay was used to circumvent the severe censorship and was most common between 1710 and 1740, when the activities of copyists, colporteurs, and the police were particularly vigorous. Works that found their way into print were often impounded, but they were copied and distributed until the French Revolution. Occasionally authors whose identities could be established were incarcerated. This happened to de Bonaventure de Fourcroy in 1698 for his

*Doutes sur la religion proposées à Mss. les Docteurs de Sorbonne*, but he soon secured his release from the Bastille. Most often the police found it futile to make arrests and concentrated on preventing the diffusion of the tracts. Public burning, usually in effigy, of works condemned by the Parlement of Paris did not prevent reprints and manuscript copies from being made in the Low Countries, one of the centers of the clandestine trade. After 1750, however, covert circulation became increasingly unnecessary, owing to the breakdown of the censorship, and a number of the more important treatises were printed, many with the indication of a false place of publication.

Voltaire, Henri-Joseph Dulaurens, Baron d'Holbach, and Jacques-André Naigeon, in their desire to foster deism or atheism, prolonged the life of the anonymous tracts by including them in collective volumes, such as *Nouvelles Libertés de penser* (Amsterdam, 1743, 1770), *Recueil nécessaire* (by Voltaire; Geneva, 1765, 1766, 1768, 1776), *L'évangile de la raison* (by Voltaire; Geneva, 1764, 1765, 1767, 1768), *Recueil philosophique* (by Naigeon; "Londres," 1770), and *Bibliothèque du bon sens portatif* (by Holbach; "Londres," 1773). The treatises constituted one of the main sources from which the *philosophes* drew their polemics.

Through the records preserved in the Archives de la Bastille and from statements appearing in manuscripts and letters by Dubuisson, Nicolas Fréret, G. de Bure, and Charles-Marie de la Condamine, we know something of the organization and diffusion of these manuscripts. Le Coulteux, Charles Bonnet, Lépinié, and a certain Mathieu or Morléon (who was incarcerated in 1729) are known to have specialized in the works of Henri de Boulainvilliers and his friends. These works were distributed often in the vicinity of the Procope and other cafés to listed patrons and initiates, including members of the clergy and the Parlement. Copies such as those of Jean Meslier's *Testament* were made by professionals, occasionally the personal secretaries of men like the Comte de Boulainvilliers, the Comte d'Argenson, and Chrétien-Guillaume de Lamignon de Malesherbes, and the practice of employing copyists was continued throughout the century. The price of such copies varied greatly. A sum as prohibitively high as twenty pistoles is known to have been asked for Jean-Baptiste de Mirabaud's *Examen critique du Nouveau Testament*.

The clandestine movement, fed by new discoveries in science, reflected the climate of world opinion, an attitude to life and society, man and his welfare, God and the universe which, although not new, was reinforced by new arguments and gained an ever-increasing audience.

Although the tracts appeared sporadically and were mostly anonymous, they share a few common characteristics and must be judged as a stage in the history of free thought, which goes back to the Renaissance in France and has its deepest roots in the works of Epicurus and Lucretius.

### THEOPHRASTUS REDIVIVUS

The *Theophrastus Redivivus* (1659) is significant in that it establishes a link between the atheism of men of the Renaissance and that of men of the seventeenth century (it refers, for example, to Lucilio Vanini and Cyrano de Bergerac) and also of the eighteenth century, when it was secretly circulated. The author, possibly a regent in one of the Parisian colleges, wrote in Latin a 2,000-folio-page compendium of historical references. He developed the arguments that if God exists he is the Sun and that the world is eternal. For the author all religions are false, and miracles, oracles, prophecies, and revelations are man-made. The resurrection of the dead and the immortality of the soul are absurdities; happiness is to be found only in living according to nature, which is revealed to us through experience; there is no absolute good or evil, as we may deduce from the multiplicity of customs and laws; man is a species of animal endowed with speech and reason. Animals, however, are not totally devoid of these faculties. The author referred neither to Pierre Gassendi nor to René Descartes, but he did mention the treatise *De Tribus Impostoribus*, attributing to Frederick II the proposition that Moses, Christ, and Muḥammad were three remarkable impostors.

### BACKGROUND

Throughout the seventeenth century the *libertins* in the wake of François Rabelais and Michel Eyquem de Montaigne became erudite skeptics, radical naturalists, associating freedom of morals and freedom of belief. As freethinkers they were prompted more by a feeling of revolt against asceticism and scholasticism than by any convincing argument. Gassendi contributed to the rehabilitation of Epicurus and Lucretius. Emmanuel Maignan, too, in his *Cursus*, evolved a philosophy that bridged Aristotle and Epicurus, linking matter and thought, sensationism and the spiritual world, and developing the idea of a scale of being. But it was from Descartes that the movement of free thought gained its greatest impetus. Cartesian rationalism and mechanism provided freethinkers with a new certainty and their systems with a new coherence. Long after his philosophy had been adopted by the Jesuits and had consequently grown

unpopular, Descartes continued to exercise a determining influence on free thought through the method he advocated. His philosophy, however, was commonly misunderstood by freethinkers and with Julien Offray de La Mettrie it culminated in an extreme mechanistic materialism that Descartes would have decried.

Benedict de Spinoza's influence on the clandestine literature was considerable but rather indirect. His work was largely known through the writings of other thinkers, like Pierre Bayle and Boulainvilliers, and his philosophy was commonly distorted by Cartesian misrepresentation. The *Ethics* was little known, and frequently its views were reconstituted through refutations. The *Tractatus Theologico-Politicus* was of interest on account of its biblical criticism, and in Holland, Jean Le Clerc, professor of philosophy and Hebrew at the University of Amsterdam, was allowed to carry on this critical work. In France, however, the uncompromising attitude of Jacques Bénigne Bossuet stifled biblical criticism. Richard Simon, a well-known teacher at the Oratorian school at Juilly who had admitted in his *Histoire critique du Vieux Testament* (1678) the truth of much of Spinoza's exegesis while recognizing the authority of the Bible, succeeded in offending both Catholics and Protestants and was expelled from the Oratorian congregation in 1678. He retired to continue his rational critique in two *instructions pastorales* (1702, 1703), *Histoire critique du texte du Nouveau Testament* (1683), *Histoire critique des versions du Nouveau Testament* (1690), and *Histoire critique des principaux commentateurs du Nouveau Testament* (1692).

Disputes that reached the general public—such as those over the authorship of the Pentateuch, in which Isaac La Peyrère, Thomas Hobbes, Spinoza, Simon, Le Clerc, and others held different views—led to much perplexity. The body of anonymous treatises that continued such discussions and in many cases rejected revelation is naturally large. These include the *Examen de la religion*, the *Analyse de la religion* (written after 1739), and the *Militaire philosophe* (composed between 1706 and 1711).

Hobbes's *Leviathan* (1651) seems to have been little known in France. Bayle's *Dictionnaire*, however, enjoyed great authority, and his *Lettre sur la comète de 1680* popularized the ideas that the conception of Providence did not rest on rational premises and that atheists could be good men. Bayle's views were those of a protestant, but his argument was such that his articles could easily be used to develop anti-Christian ideas. The anonymous writers also read Bernard Le Bovier de Fontenelle and knew something of the English deists whose thought developed along parallel lines. There were translations of

works by Bernard Mandeville, Lord Bolingbroke, John Toland, Anthony Collins, and Thomas Woolston, but it was only after the publication of Voltaire's *Lettres anglaises* (1734), which discussed Newtonian physics and philosophy and the ideas of John Locke, that the English influence became significant. Gottfried Wilhelm Leibniz's influence, too, was felt only at a late stage, partly because he was known primarily through Bayle and also through Pierre-Louis Moreau de Maupertuis, whose ideas served to link the *Monadology* with Denis Diderot and materialism.

## THE COTERIE OF BOULAINVILLIERS

The only group of writers known to have been involved in concerted action was that centered in the Comte de Boulainvilliers and closely linked with d'Argenson, the duc de Noailles, and the Académie des Inscriptions. This coterie included Nicolas Fréret, Mirabaud, César Dumasais, and J.-B. Le Mascrier. Voltaire, in his *Dîner du comte de Boulainvilliers* (1767), attested to the important influence of this group, which was especially responsible for the diffusion of Boulainvilliers's *Esprit de Spinoza* (known to have existed by 1706 and first published in 1719 in Holland).

FRÉRET. Nicolas Fréret (1688–1761), a student of law, joined the coterie of Boulainvilliers at the age of nineteen. Fréret appended to copies of the *Histoire ancienne* an account of Boulainvilliers's life and works. In 1714 he was admitted to the Académie des Inscriptions; in 1715 he was imprisoned for some months in the Bastille, where he read Bayle's *Dictionnaire* and wrote a Chinese grammar. From 1720 to 1721 he was preceptor of the duc de Noailles.

The *Lettre de Thrasibule à Leucippe* (written c. 1722 and published in London, probably in 1768; also published in *Oeuvres de Fréret*, Vol. IV, London, 1775) is generally attributed to him. Systematic and Cartesian in its presentation, this treatise combines sensationist psychology and naturalist ethics. Thrasibule, a Roman, describes the early Christians as combining Jewish beliefs with Stoicism and as influenced by both monotheist and polytheist currents. He argues that knowledge is acquired through our senses and has only relative validity. Only the truths of mathematics and reason are universal. Religious beliefs however, do not spring from reason; it is reason alone that should guide man in regulating his life, establishing society and laws, and achieving happiness. This work can be seen as an early essay in comparative religion, and it sharply reflects the growing interest in the sci-

ence of law and social philosophy. It perhaps influenced Baron de Montesquieu, and Jean-Jacques Rousseau annotated it while engaged in writing the *Discours sur l'inégalité*.

Fréret is also reputed to be the author of an *Examen critique des apologistes de la religion chrétienne* (composed after 1733), which introduces the historical method adopted by Voltaire in, for example, the *Essai sur les mœurs* and the *Dictionnaire philosophique*, in which Voltaire acknowledged his debt. Fréret was held in high esteem as a savant. He was a chronologist, a geographer, an orientalist, and a philologist as well as a philosopher, and he delivered papers on a wide variety of subjects to the Académie des Inscriptions, becoming its permanent secretary in 1743. These *Mémoires de l'Académie* outline new methods for the study of prehistory and geography as well as history. Fréret specialized in mythology, opposing the *évhéméristes*, who believed that all myths had a basis in historical fact. A pioneer in comparative philology, he made known the Chinese linguistic system. His *Oeuvres complètes* were published by Leclerc de Septchènes in Paris, 1796–1799, but about half his works were omitted (many of his manuscripts bequeathed to the Académie des Inscriptions have never been published), and a few of the treatises included cannot be attributed to him.

MIRABAUD. Jean-Baptiste de Mirabaud (1675–1760) was educated by the Oratorian congregation and entered a military career. He then became secretary to the duchess of Orléans and preceptor of her two youngest daughters. In 1724 he translated *Gerusalemme liberata* by Torquato Tasso. He was elected to the Académie Française in 1726, becoming its secretary in 1742. Mirabaud read his manuscripts to select groups of friends. He was probably the author of four essays (described below), often to be found together, that threw new doubts on biblical chronology and promoted Fontenelle's method of oblique attack on miracles. Many of Mirabaud's notes recall ideas expressed in *La religion chrétienne analysée* (a popular post-1742 tract attributed by Voltaire and Claude François Nonnotte to Dumarsais). The *Opinion des anciens sur le monde* (c. 1706–1722) challenges the story of Genesis. In the *Opinions des anciens sur la nature de l'âme* (composed before 1728, published in *Nouvelles Libertés de penser*) Mirabaud pointed out that the Jews, the Greeks, and the Romans envisaged the soul as material and that the Egyptians introduced the belief in the immortality of the soul as a restraining influence on public morals. The *Opinion des anciens sur les Juifs* (c. 1706–1722), based on Jacques Basnage's *Histoire des Juifs* (1706), tries to prove that the

Jews had no right to claim to be a "chosen" people. The *Examen critique du Nouveau Testament* (c. 1706–1722), which deals with the canonical and the noncanonical gospels, stresses that neither Philo nor Josephus mentioned Christ and that Christian morality conflicts with natural morality. Much of our information on Mirabaud is derived from the *Notice sur Jean-Baptiste de Mirabaud* (Paris, 1895), by Paul Mirabaud.

DUMARSAIS. César Chesneau Dumarsais (1676–1756), a grammarian, was personally known to Fontenelle and Voltaire and was associated with the *Encyclopédie* until his death. For a time he was preceptor in the family of John Law. Dumarsais edited, with Le Mascrier, some of the deistic works of Mirabaud and wrote a defense of Fontenelle's *Histoire des oracles* and probably the deterministic essay *Le philosophe* (written before 1728); edited by Herbert Dieckmann in 1948). He was probably responsible for *La religion chrétienne analysée* (also known as *Examen de la religion* and *Doutes*, in which inconsistencies in the Bible are shown up, the doctrine of original sin is attacked, and the doctrine of the Trinity is stated to be contrary to reason. It is argued that God should be worshiped without ceremony and that man must follow his reason, which is his *lumière naturelle*, and adopt a social morality incompatible with Christian dogma.

MESLIER. The most interesting of the clandestine authors was no doubt Jean Meslier (1664–1729), a priest who was directly or indirectly influenced by Spinoza. (Reading François de Salignad de La Mothe Fénelon's *Démonstration de l'existence de Dieu* and R.-J. de Tournemine's *Réflexions sur l'athéisme* helped Meslier clarify his ideas.) He identified nature with matter, which he saw as eternal and as endowed with movement. He favored a mechanical interpretation of nature, rejecting the arguments of those who believed in chance and in a divine design. In his 1,200-page *Testament*, Meslier listed the errors, illusions, and impostures of Christianity. His attack on Christianity is one of the most detailed and comprehensive ever written, and his materialistic system is particularly interesting in that it foreshadows many aspects of Diderot's thought.

Voltaire is known to have acquired a copy of the *Testament* and to have made extracts, which he dated 1742 and published in 1761 or 1762 under the title *Extrait*. The first edition sold out immediately and was followed in the same year by an edition of 5,000 copies. In 1772 Holbach published extracts under the title *Le bon sens du curé*

Meslier, and in 1789 Sylvain Maréchal published *Le Cathéchisme du curé Meslier*.

Meslier's social ideas were remarkable for the time. He claimed in very general terms that all men are equal and have the right to live, to be free, and to share in the fruits of the earth. He divided humankind into workers and parasites and saw in revolt the best hope of better conditions. He dreamed of a class struggle, not reconciliation.

## OTHER WORKS

Among other anonymous works that cast doubts on the proofs of the truth of Christianity and allege contradictions in the Bible are five manuscript volumes of the *Examen de la Genèse* and the *Examen du Nouveau Testament* (probably written in the late 1730s or early 1740s), which are attributed to Mme. du Châtelet, Voltaire's mistress. She purports to have proved that the stories of the Bible relate barbarous and cruel events and cannot have been inspired by God. No doubt she received some help from Voltaire, but she relied chiefly on the work of Meslier and Woolston and especially on the *Commentaire littéral sur tous les livres de l'Ancien et du Nouveau Testament* (23 vols., Paris, 1707–1716) by Augustin Dom Calmet.

Among other manuscripts whose authorship is now known is *Le ciel ouvert à tous les hommes* (also titled *Le paradis ouvert* and *Nouveau Système de la religion chrétienne*), by the priest Pierre Cuppé, which must have been in draft in 1716. The tract never assails orthodoxy, but Cuppé submitted the Scriptures to scrutiny and preached toleration and brotherly love, concluding that all men are saved by God's love. Cuppé's stress on his respect for reason, as well as his deistic beliefs, led to his being considered a forerunner of French deism.

The author of *Le militaire philosophe* (1706–1711; published in London by Naigeon in 1768) is unknown. It is first a commentary of Nicolas Malebranche's views on religion. It gives a frank exposition of deism, which won Voltaire's commendation. After a strongly worded criticism of the Old and the New Testaments, the work rejects Christianity and develops the doctrine of natural religion, stressing the roles of reason and instinct. Man, who is both body and soul, is free and immortal, and his behavior should be governed by reason and by conscience. Man must worship God and abide by the golden rule. The author foreshadowed Montesquieu in his insistence on the absolute character of justice and the relative nature of civil laws and in his treatment of chance, which he rejected as an explanation of events. He anticipated Voltaire in his use of the figure of a watchmaker to

explain the function of God. His idea that truth is to be found in the individual soul was later developed by Rousseau.

A widely disseminated treatise was *Israël vengé*, by Isaac Orobio, a Spanish Jew who escaped from the Inquisition to France and then to Holland and died in 1687 or 1688. His originally unpublished critical attack on the Christian religion was translated by A. Henriquez and published in London in 1770. It was circulated by Jean Lévesque de Burigny.

The *Jordanus Brunus Redivivus* is a materialistic compilation. The author believed in the Copernican system (and the existence of other solar systems with living beings) and in the eternity of matter. There are no innate ideas, no objective good or evil. Man is motivated by pain and by pleasure. Experience can deceive us. Reason alone is valid but must not be thought infallible. The laws of nature are eternal, but everything is in a state of flux. Certain passages of this work bring to mind Diderot's *Rêve de d'Alembert*. Other manuscripts whose authorship is uncertain include *Lettre d'Hypocrate à Damagette* (1700 at latest), *Recherches curieuses de philosophie* (1713), *Suite des Purrhoniens: qu'on peut douter si les religions viennent immédiatement de Dieu ou de l'invention des politiques pour faire craindre et garder les préceptes de l'homme* (c. 1723), *Traité de la liberté* (a determinist and materialist tract, probably by Fontenelle, c. 1700), *Essai sur la recherche de la vérité*, and *Dissertation sur la formation du monde* (1738), which was inspired by Lucretius and formulates transformist theories while upholding the conception of fixed species.

## INFLUENCE

It will be seen that the clandestine tracts fall into two main categories, those written from the standpoint of critical deism and those that are atheistic, deterministic and materialistic. The outstanding eighteenth-century literary works based on this movement can be similarly characterized. Montesquieu's adoption of the letter form for *Les lettres persanes* (1731) may owe something to the *Lettre à Damagette*, and the views expressed in *Lettre persane* 46 reflect those expressed in *La religion chrétienne analysée*. Voltaire, who adopted the form for his *Lettres philosophiques*, published anonymously in 1734, wrote in the same year a *Traité de métaphysique* (which Mme. du Châtelet kept under lock and key), which embodied his own deism as well as many of the ideas expressed in the clandestine literature.

Toward the middle of the century atheism gained ground, no doubt encouraged by such treatises as *Lettre*

sur la religion, sur l'âme et sur l'existence de Dieu. Diderot's *Pensées philosophiques*, published anonymously in 1746, allegedly at the Hague but actually in Paris, and condemned to be burned by the Parlement of Paris, is characteristic of this tendency. Although based on a translation of the Earl of Shaftesbury, the work succeeds in presenting an original and vividly expressed atheism side by side with more commonplace arguments in favor of natural religion. In particular it challenges Christian belief in miracles, outlining the principles of the new biblical criticism. In the eighteenth century alone the *Pensées philosophiques* ran to twenty editions (some with crude interpolations) and reprints. It was translated into German, Italian, and English and was the subject of long and heated controversy. Twelve signed or anonymous refutations by Protestants, Catholics, parliamentarians, and others were published, some of them, together with Diderot's text, being circulated in manuscript form.

As government policy wavered and censorship grew slack, an increasing number of the manuscripts of earlier date were published, and anonymity became a thin veil, if not a mere convention. The main current of what has become known as clandestine literature, which many have identified with the tradition of free thought, came to an end with the advent of Montesquieu, Voltaire, Rousseau, and Diderot. In their works it found its finest literary expression, and thanks to them it became integrated into coherent patterns that have won it a place in the history of ideas.

## CLARKE, SAMUEL (1675–1729)

Samuel Clarke, the most important British philosopher and theologian of his generation, was born in Norwich, England, on October 11, 1675. He took his BA degree at Cambridge in 1695, defending Isaac Newton's views. In 1697 he provided a new annotated Latin translation of Jacques Rohault's *Treatise of Physics*, and in his notes criticized René Descartes's physics in favor of Newton's. In that same year he was introduced into the Newtonian circle, probably by William Whiston (1667–1752), whom he had befriended. In 1704 he delivered his first set of Boyle Lectures, *A Demonstration of the Being and Attributes of God: More Particularly in Answer to Mr. Hobbes, Spinoza, and Their Followers*. They were so successful that he was asked to deliver the 1705 lectures as well under the title *A Discourse concerning the Unchangeable Obligations of Natural Religion and the Truth and Certainty of Christian Revelation*. His connection with Newton became official in 1706, when he translated the *Opticks* into Latin. In the same year Anthony Collins, a materialist follower of John

Locke's, engaged Clarke in a long and famous exchange on whether matter can think.

After becoming one of Queen Anne's (1665–1714) chaplains, Clarke was elevated in 1709 to the rectory of St. James's, Westminster. In 1712 Clarke published *The Scripture Doctrine of the Trinity*, which was accused of Arianism, the view that Christ is divine but created. The ensuing theological controversy culminated two years later in his humiliating promise to the Upper House of Convocation not to preach or write on the trinity any longer. However, suspicions of crypto-Arianism remained. François-Marie Arouet de Voltaire reports that Bishop Edmund Gibson (1669–1748) effectively prevented Clarke's elevation to the see of Canterbury by pointing out that Clarke was indeed the most learned and honest man in the kingdom, but had one defect: He was not a Christian.

After the Hanoverian accession Clarke developed a close relationship with Caroline of Anspach (1683–1737), the Princess of Wales, and through her mediation he engaged Gottfried Wilhelm Leibniz in the most famous philosophical correspondence of the eighteenth century. The exchange dealt with many of the issues that had occupied Clarke in his Boyle Lectures, such as divine immensity and eternity, the relation of God to the world, the soul and its relation to the body, free will, space and time, and the nature of miracles. It also discussed more strictly scientific topics, such as the nature of matter, the existence of atoms and the void, the size of the universe, and the nature of motive force, which were then often given both a philosophical and a scientific treatment. In 1717 Clarke published his translation of the correspondence with Leibniz together with an attack on a work by Collins denying the existence of free will. This was his last significant philosophical work, although in 1728 he wrote a short essay for the *Philosophical Transactions* trying to show, against the Leibnizians, that the proper measure of force is not  $mv^2$  but  $mv$ . He died in 1729 after a short illness and was survived by his wife, Katherine, and five of his seven children.

Clarke was a polite and courtly man who, however, was vivacious with his friends and seems to have been fond of playing cards. He was also a classicist of repute, and seems to have held Marcus Tullius Cicero's views in high esteem. Voltaire, who met him, was impressed by his piety and admired his logical skills so much that he called him "a veritable thinking machine." Indeed, his reputation was such that in 1710 George Berkeley sent him the first edition of his *A Treatise concerning the Principles of Human Knowledge* (Clarke declined to comment on it).

## THE ATTACK AGAINST NATURALISM AND THE DEFENSE OF NATURAL RELIGION

Clarke's primary philosophical interests lay in theology, metaphysics, and, to a lesser degree, ethics. His philosophical vocabulary and some of his metaphysical ideas were influenced by Descartes, whom he followed in holding that the world contains two types of substance, mind and matter, the combination of which constitutes humans. However, he sided with Nicolas Malebranche and Locke in denying that introspection lets one reach the substance of the soul. Indeed, like Locke and Newton, he held that one just does not know the substance of things. Furthermore, Clarke's overall judgment of Descartes was critical. He shared the view expressed by Henry More, Blaise Pascal, Pierre Bayle, and Leibniz that Descartes's system could be, and had been, used to further irreligion and had naturally developed into Spinozism. In particular, he believed that Descartes's identification of matter with extension, and therefore space, entails making it eternal and infinite. He defended natural religion from naturalism (the view that nature constitutes a self-sufficient system of which humans are but a part) and revealed religion from deism.

Clarke's attack against naturalism revolved around five connected points. First, God is a necessarily existent omnipotent, omniscient, eternal, omnipresent, and supremely benevolent person. Second, nature and its laws are radically contingent. God, endowed with a libertarian will, chose to create the world and to operate in it by a reasonable but uncaused fiat. Third, although space and time are infinite, matter is spatiotemporally finite, and being endowed only with *vis inertiae* it has no power of self-motion. Fourth, God is substantially present in nature (or better, nature is literally in God, since space and time are divine attributes) and constantly exercises his power by applying attractive and repulsive forces to bodies. Except for the law of inertia, which describes the essentially passive nature of matter, strictly speaking, the laws of nature do not describe the behavior of matter, which is just dead mass constantly pushed around, but the modalities of the ordinary operation of the divine power. As for occasionalism, natural laws prescribe the actions of the divine will rather than describe those of bodies.

Fifth, although the soul is extended and interacts with the body, it is necessarily immaterial because matter, being constituted of merely juxtaposed parts, cannot possibly think even by divine intervention; moreover, the soul has been endowed by God with a libertarian will.

The first four points guarantee that nature is not a self-sufficient system, so much so that without direct and constant divine physical intervention planets would fly away from their orbits, atoms would break into their components, and the machinery of the world would literally grind to a halt; the fifth guarantees that the soul is not a part of nature. In the remainder of this entry, it will be seen that these points emerge from a consideration of Clarke's views on God, free will, matter and the laws of nature, space and time, and the soul.

## GOD

The proof of the necessary existence and attributes of God occupies most of *A Demonstration of the Being and Attributes of God*. The main lines of Clarke's argument are as follows. Since something exists now, something has always existed because nothing comes from nothing. What has existed from eternity is either an independent being (one having in itself the reason of its existence), or an infinite series of dependent beings. However, such a series cannot be the being that has existed from eternity because by hypothesis it can have no external cause, and no internal cause (no dependent being in it) can cause the whole series. Hence, an independent being exists. As a separate argument, Clarke also reasoned that since space and time cannot be thought of as nonexistent and they are obviously not self-subsistent, the substance on which they depend, God, must exist necessarily as well. Finally, teleological considerations show that God is necessarily endowed with intelligence and wisdom. In addition, God has, though not with metaphysical necessity, all the moral perfections, whose nature is the same in the divine being as in humans.

Clarke rejected the view of God as substantially removed from space and time. Divine eternity involves both necessary existence and infinite duration. Rather traditionally, the former consists in the fact that God contains the reason (but not the cause) of his own existence. The latter, however, cannot be identified with the traditional view that God exists in an unchanging permanent present without any succession since, like Newton, he considered such a position unintelligible. Consequently, Clarke attributed distinct and successive thoughts to God, as he perceived these as preconditions of the will. Hence, God is immutable with respect to his will and his general and particular decrees only in the sense that the divine being does not change his mind. However, as Clarke also made clear in his exchanges with Joseph Butler, God is not in space and time.

Clarke's criticism of the Scholastic view of divine immensity or omnipresence was analogous to that concerning eternity: the claim that the immensity of God is a point, as his eternity is an instant is, he held, unintelligible. However, while for Clarke God's temporal presence is analogous to humans' at least in involving temporal succession, his views about God's spatial presence were somewhat less clear because he did not explicitly state whether he adopted holism (the view that the divine substance is whole in the whole of space and whole in each and every part) or the view that God is dimensionally extended. Nevertheless, there is evidence that he held the latter view. For Clarke vigorously denied Leibniz's charge that extension is incompatible with divine simplicity, because it introduces parts in God, without making any reference to holism, and in addition he did not defend holism from More's famous critique. Finally, Collins mentions him with Thomas Turner (1645–1714) and More as supporters of the dimensional extension of God.

For Clarke, divine eternity and immensity are to be identified with space and time. Usually, he held that space and time are just divine properties. However, in his fourth letter he also told Leibniz that, in addition, they are necessary effects of God's existence and necessary requirements for divine eternity and ubiquity, without supplying any argument to show that these different accounts are equivalent or even compatible. At other times, as in the letter to Daniel Waterland (1683–1740) and in the *Avertissement* to Pierre Des Maizeaux (1673–1745), in the latter of which Newton had more than a hand, he held that they are not, strictly speaking, properties.

As Leibniz and an anonymous correspondent (almost certainly Waterland) readily noted, echoing Bayle's critique of Newton and Malebranche, the identification of divine immensity with space endangers the simplicity of the divine being because space has parts, albeit not separable ones. Clarke's solution was to claim parity between spatial and temporal extendedness: Since the former is compatible with the simplicity of what "stretches" temporally, the latter is compatible with the simplicity of what stretches spatially. In addition, from the fact that the divine consciousness is extended, one should not infer that it is proper to talk about it in terms of spatial parts any more than it is to talk of the spatial parts of an instant of time although, as Newton had noted in the General Scholium to book 3 of *Principia*, an instant is the same everywhere.

## FREE WILL

Clarke attached great importance to the issue of free will. He held that the highest form of freedom involves willing as one should, namely, having one's will in step with one's right values. He also believed that freedom of the will, or liberty, entails a libertarian power of self-determination (a point he emphasized against Leibniz's compatibilist views) and that it is a necessary condition both for that higher form of freedom and for religion. Thomas Hobbes's and Benedict (Baruch) de Spinoza's views—which in Clarke's mind Leibniz had *de facto* adopted—that everything happens deterministically or necessarily destroys liberty. Against them he held that the causal version of the principle of sufficient reason in the cosmological argument shows that the necessary being on which the contingent world depends must have a libertarian will. For the notion of a necessary agent is contradictory, as agency involves the libertarian capacity of suspending action. Moreover, if God operated necessarily, things could not be different from how they are. But the number of planets, their orbits, indeed, the law of gravitation itself could have been different, as any reasonable person (but not Spinoza) could plainly see. Furthermore, the obvious presence of final causes indicates that divine activity follows not necessary but architectonic patterns.

Besides attacking necessitarianism and determinism with arguments drawn from general metaphysical considerations, Clarke criticized the Hobbesian view that volition is caused by one's last evaluative judgment and the Spinozistic position that the two are identical. He was ready to grant that the understanding is fully determined to assent to a proposition perceived as true in the same way in which an open eye is fully determined to see objects. In this sense the assent is necessary. However, he held, the necessity of the last evaluative judgment is totally immaterial to the issue of freedom. In his judgment, his opponents were guilty of basic philosophical errors. On the one hand, if they maintained that the content of the evaluation, the evaluative proposition, is identical with the volition or causes it, they were confusing reasons with causes. As he explained to Collins, the proposition "doing X is better than doing Y" can provide a reason for action but cannot cause anything because it is an abstract entity. On the other hand, if Clarke's opponents maintained that not the evaluative proposition but one's perceiving or believing it is identical with, or a partial cause of, volition, then they were falling foul of a basic causal principle. Against Descartes, Clarke insisted that judging (assenting to what appears true and dissenting from what appears false) is not an action but a passion.

But what is passive cannot cause anything active. So, there is no causal link between evaluation and volition. What causes the volition is the principle of action itself, which Clarke identified with the agent, that is, the spiritual substance.

Having shown that God is endowed with liberty, Clarke argued that humans are as well. Not involving qualities such as complete causal independence and self-existence, liberty is a power God can transfer to one. Furthermore, experience assures one that one has been granted liberty, since one's actions seem to one to be free, exactly as they would do on the supposition that one is really a free agent. Of course, he conceded, this does not amount to a strict demonstration; but denying that one has free will is on a par with denying the existence of the external world, a coherent but unreasonable option. The burden of proof, he felt, is not on the supporter of liberty, but on its denier.

## MATTER AND THE LAWS OF NATURE

Clarke's views on matter are best seen in connection with his ideas about miracles. Like Joseph Glanville (1636–1680), Thomas Sprat (1635–1713), Robert Boyle, and Locke, he belonged to that group of English intellectuals associated with the Royal Society, who thought that miracles could be used as evidence for the claim that Christianity is the true religion. According to Clarke a miracle is a work effected in an unusual manner (by which he seems to have meant in a way not subsumable under the laws of nature) by God himself or some intelligent agent superior to man for the proof or evidence of some doctrine, or the attestation of the authority of some person. However, he claimed, "modern deists," noticing that nature is regular, have concluded that there are in matter certain absolutely inalterable laws or powers that render the course of nature unchangeable and therefore miracles impossible.

The deistic view, Clarke argued, is completely wrong. Everything that is done in the world is done either immediately by God himself or by sentient beings; matter is not capable of any laws or powers whatsoever, except for the negative power of inertia. Consequently, the apparent effects of the natural powers of matter—the laws of motion, gravitation, or attraction—are but the effects of God's acting on matter continually, either directly or through intelligent creatures. The course of nature, then, is just the divine will operating continuously and uniformly. This mode of operation is perfectly free and as easily altered as preserved at any time. Of course, Clarke admitted, the divine will infallibly follows necessarily cor-

rect judgments, and consequently God always acts on the basis of rules of “uniformity and proportion.” However, given that the will, in God as in humans, is not causally determined by the understanding, the rules governing the ordinary power of God, a subset of which are the laws of nature, are freely self-imposed, and not the unavoidable result of the necessarily correct divine understanding. They are a manifestation of God’s moral, and therefore free, attributes, not God’s metaphysical, and therefore necessary, ones.

Clarke steadfastly maintained that matter has neither an essential nor an accidental power of self-motion. The first claim was common among early modern philosophers and held not only by the occasionalists but also by thinkers of different persuasions like Descartes, Locke, and Boyle. In fact, even Pierre Gassendi, who had upheld the notion of an active matter by claiming that atoms have an internal corporeal principle of action, had fallen short of claiming that they possess it essentially. Clarke’s second claim, however, was more controversial. For although mechanists programmatically tried to substitute a nature made of inert particles for the living nature of Renaissance philosophy, the attempt soon ran into great difficulties. Strict mechanism proved inadequate to explain phenomena like exothermic reactions or the spring of the air, which causes a deflated closed balloon in a vacuum tube to expand. Consequently, mechanism was altered to include particles variously endowed with powers of motion, attraction, and repulsion.

Clarke’s position on the activity of matter was radical: The various nonmechanical powers of particles are the result of direct divine or spiritual activity. He could not bring himself to accept active matter because he thought it a prelude to atheism. For, as noted earlier, he believed that denying divine continuous, direct intervention in nature in effect amounts to eliminating God, as John Toland had by endowing matter with essential self-motive powers. Clarke’s views, however, had serious drawbacks. A God who is actually extended and constantly operates physically on matter looks suspiciously like the soul of the world, as Leibniz charged using Newton’s identification in the *Opticks* of space as the *sensorium* of God. Similarly, the placement of gravitational forces within the purview of ordinary divine activity drew from Leibniz the accusation of obscurantism, a throwback to the quaint idea of angels causing the rotation of the spheres.

## SPACE AND TIME

According to Clarke the ideas of space and time are the two first and most obvious simple ideas that exist. Like many of the philosophers who investigated the nature of space and time, he tended to produce arguments with regard to space, presumably leaving the reader to infer that parallel arguments could be drawn with respect to time. With Newton, he argued that while matter can be thought of as nonexistent, space exists necessarily because to suppose any part or the whole of space removed is to suppose it removed from and out of itself, namely taken away while it still remains, which is contradictory. Although space is not sensible, it is not nothingness, mere absence of matter, as it has properties such as quantity and dimensions. One might add other properties Clarke attributed to it, such as homogeneity, immutability, continuity, and, probably, impenetrability since bodies do not penetrate space but space penetrates them. For Clarke, space is also not an aggregate of its parts but presumably an essential whole preceding all its parts, a position motivated at least in part by the view that space is a divine property. As for Newton, space is necessarily infinite because limiting it is supposing it is bounded by something that itself takes up space or supposing it is bounded by other space, and both suppositions are contradictory.

Since absolute space has an essential and invariable structure independent of the bodies in it and is not altered by their presence, any possible world must conform to it, as creatures must be in space and God, whose power is limited to the metaphysically possible, cannot alter the essence of things. The same is true of time, which flows equably independently of anything in it. In short, in contrast to God all creatures occupy an absolute position in space and time that one may or may not be able to determine.

The introduction of absolute space, allegedly demanded by Newtonian physics, offered Clarke an immediate philosophical advantage in the fight against Spinoza. For it showed that the Cartesian identification of extension with matter, which had made possible Spinoza’s excesses, was wrong—a consequence that was not lost on Bayle and was insisted on by Colin Maclaurin (1698–1746). Of course, the existence of absolute space introduced a new difficulty, that of its relation to God, but Clarke thought he had solved it by claiming that space and time are attributes of God or the result of divine existence.

## THE SOUL

In 1706 Henry Dodwell (1641–1711) published a book in which he defended conditional immortality: One's soul is naturally mortal and following the death of the body can be kept in existence only by divine supernatural intervention. Clarke wrote an open letter to Dodwell complaining that he had opened the floodgates to libertinism by providing an excuse for the wicked not to fear eternal punishment. He then argued that the soul, being immaterial, is naturally immortal and gave his own version of the traditional argument for the immateriality of the soul from the alleged unity of consciousness, insisting that not even God could make matter conscious. Clarke's argument failed to convince Collins, who made no bones about his materialist leanings and intervened in defense of Dodwell. Clarke told Collins that if thinking in humans were a mode of matter, it would be natural to conceive that it may be the same in other beings. Then, Clarke continued, every thinking being, including God, would be ruled by the same absolute necessity governing the motion of a clock. The result would be the destruction of every possibility of self-determination and the undermining of the very foundations of religion.

Clarke's argument for the immateriality of the soul revolved around three basic claims. First, necessarily consciousness is an individual power, that is, each consciousness is one undivided entity, not a multitude of distinct consciousnesses added together. Second, an individual power cannot result from, or inhere in, a divisible substance; or, alternatively, an individual power can only be produced by, or inhere in, an individual being. Third, matter is not, and cannot possibly be, an individual being. The conclusion is that consciousness cannot possibly be the product of, or inhere in, matter.

For Clarke, although the soul is necessarily immaterial, it can causally affect the body because material qualities such as figure and mobility are deficiencies or imperfections that can be brought about by consciousness, which is a positive quality; moreover, one experiences the causal power by which one moves one's body. However, his position on whether the body causally affects the soul was less than clear. At times he leaned toward the view that it does, and at other times that it does not.

According to Clarke the soul is in space and is extended. As he eventually told Leibniz, the soul is in a particular place, the *sensorium*, which a part of the brain occupies. Clarke inferred the presence of the soul in the *sensorium* through an argument employing two independent premises: first, that something can act only

where it is substantially, and second, that the soul interacts with the body. The conclusion is that the soul is substantially present where (at least) a part of the body is.

Saying that the soul must be substantially present where a part of the brain is does not fully determine how the soul is present. It rules out mere Cartesian operational presence, but it fails to determine whether the soul's presence is to be understood in terms of holism or in terms of dimensional extension. However, there is cumulative evidence that for Clarke the soul is merely coextended with a part of the brain. Clarke used an analogy with space, which he took to be both extended and indivisible, to explain how the soul could be extended and indivisible; but holism does not apply to space. He did not address Leibniz's accusation that the extension of the soul destroys its unity by appealing to holism; rather, he defended the claim that the soul "fills" the *sensorium*. In sum, Clarke's views on freedom, with their ties to morality and religion, together with his views on causality, pushed him toward the thesis that the soul is extended.

## ETHICS AND REVEALED RELIGION

Although some of his sermons contain interesting analyses of individual Christian virtues, the most sustained exposition of Clarke's ethics is contained in *A Discourse concerning the Unalterable Obligations of Natural Religion and the Truth and Certainty of the Christian Revelation*, his second set of Boyle Lectures. Clarke started by stating that clearly there are different relations among persons and that from these relations there arises a "fitness" or "unfitness" of behavior among persons. So, for example, given the relation of infinite disproportion between humans and God, it is fit that one honors, worships, and imitates the Lord. In other words, from certain eternal and immutable factual relations among persons there arise certain eternal and immutable obligations, which in their broad features can be rationally apprehended by anyone with a sound mind, although in some particularly complex cases one may be at a loss in clearly demarcating right from wrong. For Clarke, being grounded in necessary relations, morality, like geometry, is universal and necessary. As such, it is independent of any will, be it divine or human, and of any consideration of punishment or reward as anyone, but not Hobbes, can plainly see. So, Clarke's view thus far can be characterized as a variety of rationalist deontology.

For Clarke, morality has three main branches: dealing with duties toward God, other humans, and oneself—all grounded in the notion of fitness. Duties toward

others are governed by equity, which demands that one deals with other persons as one can reasonably expect others to deal with oneself, and by love, which demands that one furthers the happiness of all persons. Duties toward oneself demand that one preserves one's life and spiritual well-being so as to be able to perform one's duties. Suicide, then, is wrong.

Since God's will is uncorrupted by self-interest or passion, divine volitions and moral commands are extensionally equivalent. Hence, God wants one to follow morality, and such a desire is manifested in laws God has set up. But since laws require sanctions, and since such sanctions are not uniformly present in this life, moral laws are associated with reward and punishment in the next life. Moreover, human depravity makes the prospect of future sanctions a necessary incentive for proper behavior.

However, Clarke seemed prepared to go further, claiming against the Stoics and his beloved Cicero that in one's present state virtue is not the highest good (this being happiness) and that consequently it would be unreasonable, not just psychologically difficult, to lay down one's life for the sake of duty. Virtue, Clarke claimed, is not happiness but only a means to it, as in a race running is not itself the prize but the way to obtain it. The present sorry state of humankind, beset by ignorance, prejudice, and corrupt passions, renders divine revelation necessary, contrary to what deists think, and therefore the remaining lectures are mainly devoted to establishing the reliability of the Gospels.

Clarke's theory was criticized on several grounds. He never quite explained the nature of the relations among persons that ground morality, leaving both his followers and detractors to argue inconclusively about it. Hume famously charged Clarke's theory with motivational impotence because the intellectual perception of fitness cannot, alone, move the will. Matthew Tindal, who devoted chapter fourteen of his *Christianity as Old as the Creation* to an analysis of Clarke's ethics, noted that Clarke's rationalist strand hardly fits with his insistence on the need for Christian revelation, since his arguments establishing the reliability of scripture seem to require much more intellectual effort than the apprehension of one's moral duties. Even more pointedly, Tindal, who approved Leibniz's claim that the Chinese should send missionaries in natural theology and its subsequent morality to Europe, noted that revelation is neither necessary nor sufficient for proper moral behavior even for common people.

## CLASSICAL FOUNDATIONALISM

Classical foundationalism maintains that all knowledge and justified belief rest ultimately on a *foundation* of knowledge and justified belief that has not been inferred from other knowledge or belief. Because the classical foundationalist typically assumes an account of knowledge in terms of justified or rational true belief, it might be best to focus on the distinction invoked between inferentially and noninferentially justified beliefs. What is written in this entry will apply *mutatis mutandis* to the distinction between inferential and noninferential knowledge.

### THE PRINCIPLE OF INFERENTIAL JUSTIFICATION

If one thinks about most of the beliefs one takes to be justified and asks what justifies them, it seems natural to answer in terms of other justified beliefs. A person's justification for believing that it will rain, for example, may consist in part of that person's justifiably believing that the barometer is dropping rapidly. But under what conditions can one justifiably infer the truth of one proposition *P* from another *E*? The classic foundationalist typically insists that to be justified in believing *P* on the basis of *E* one must be justified in believing *E*. So, for example, one cannot be justified in believing that the world will end tomorrow by basing that belief on an unsupported hunch that the earth will be hit by a giant meteor. More controversially, many classic foundationalists—at least implicitly—also seemed to presuppose that to be justified in believing *P* by inferring it from *E* one must also be justified in believing that *E* confirms (makes probable) *P* (where *E*'s entailing *P* is the upper limit of *E*'s making probable *P*). Thus, one cannot justifiably infer the arrival of Armageddon from a fortune-teller's prediction that the world will end tomorrow unless one has some good reason to believe that the fortune-teller's predictions make probable the occurrence of the events predicted. Call the principle stating both of the above requirements for justification the principle of inferential justification (PIJ):

To be justified in believing *P* on the basis of *E* one must be: (1) justified in believing *E*; and (2) justified in believing that *E* makes probable *P*.

The principle of inferential justification is a crucial premise in the famous regress argument for foundationalism. If the principle is correct, then to be justified in believing some proposition *P* on the basis of some other evidence, *E1*, one would need to be justified in believing *E1*. But if all justification were inferential, then to be justified in believing *E1* one would need to infer it from something else *E2*, which one justifiably believes, and so on *ad infinitum*. This first regress is generated invoking only clause (1) of the principle of inferential justification. If the second clause is correct, the potential regresses proliferate endlessly. To be justified in inferring *P* from *E1* one must justifiably believe not only *E1* but also that *E1* makes likely *P*, and one must infer this from something else *F1*, which one must justifiably infer from some other proposition *E2*, which one justifiably infers .... And so on.

But one must also justifiably believe that *F1* makes likely that *E1* makes likely *P*, so one must justifiably infer *that* from some other proposition *G1*, which one justifiably infers .... And so on. If all justification were inferential then to justifiably believe any proposition *P* a person would need to complete not just one but an infinite number of infinitely long chains of reasoning. However, the human mind is finite and cannot complete infinitely long chains of reasoning. To avoid the absurd conclusion that people cannot ever be justified in believing anything whatsoever, we must suppose that some beliefs are justified without inference and that these noninferentially justified beliefs ground the justification of all other justified beliefs.

The principle of inferential justification is also often a critical assumption of classic skeptical arguments, most of which presuppose a strong form of foundationalism. So, for example, Hume seemed to conclude that we have no reason for believing any description of an external world when ultimately all we have to rely on as evidence is our knowledge of fleeting and subjective experience. The problem, Hume argued, is that we have no way of establishing sensations as reliable indicators of the existence of external objects that they take to be their cause. Indeed, the difficulty of avoiding a fairly radical skepticism within the constraints of classical foundationalism is one reason so many philosophers became disillusioned with the view.

## NONINFERENCEAL JUSTIFICATION

Classical foundationalists refer to the foundations of knowledge and justified belief in a variety of ways—for example: noninferentially justified beliefs, self-evident truths, directly evident truths, incorrigible beliefs, infallible beliefs, and so on—but there is no consensus on what confers foundational status on a belief. Some, following Descartes, seek foundations in beliefs that do not admit of the possibility of error. As will be seen, the possibility in question may be interpreted in a number of different ways, but classical foundationalists usually invoked a very strong concept of possibility: If a belief is foundational it must be inconceivable that the belief be false. The having of the belief must somehow entail its truth. Thus Descartes famously purported to find an ideal foundation for knowledge in one's belief that one existed. It seems trivially true that if someone *S* really does believe that he or she exists, that belief couldn't possibly be false. *S* has to exist in order to believe that *S* exists (or to be in any other conscious state).

Still other foundationalists sought to identify noninferential justification with whatever fact is the truth-maker for the alleged noninferentially justified belief. So, for example, some foundationalists would claim that my justification for believing I am in pain—when I am—is the pain itself. Of course, such a view hardly qualifies as a philosophical theory until its proponent gives a principled account of how some truth-makers justify us in believing the claims they make true, whereas others do not.

Although it was not always spelled out, many other classical foundationalists sought the source of foundational knowledge in some relation (other than belief) obtaining between a believer and the truth conditions of what is believed. One metaphor often invoked is the concept of acquaintance. When one believes that one is in pain when one is in pain, for example, one is directly acquainted or confronted with the pain itself (the very state that makes true the proposition believed). It is the knower's direct confrontation with the relevant aspect of reality to which the truth in question corresponds that obviates the need for any inference. Another variation on the view might insist that noninferential justification consists not just in acquaintance with the fact that is the truth-maker for one's belief but also acquaintance with the correspondence between the truth bearer (sometimes taken to be a thought or "picture" of reality) and the truth-maker.

In addition to direct acquaintance with contingent facts that can yield noninferentially justified beliefs in

empirical propositions, there may also be direct acquaintance with logical relations holding between propositions, states of affairs, or properties that yields direct knowledge of necessary truths. So, for example, one might claim that one's noninferential justification for believing that squares have four sides is constituted in part by one's acquaintance with the properties of being a square and having four sides and the way in which the former contains the latter. Or one might hold that one's noninferential justification for believing that nothing can be both red all over and blue all over at the same time is constituted in part by one's acquaintance with the way in which being red excludes being blue.

On the above view, one might locate the source of both a priori and a posteriori foundational knowledge in the same relation of acquaintance. Traditionally, philosophers have made a great deal of the distinction between a priori knowledge (knowledge of necessary truths that is in some sense independent of sense experience) and a posteriori knowledge (knowledge of contingent truth that somehow relies on sense experience). But it is hard to see in what sense knowledge of one's own beliefs, for example, fits neatly into this traditional way of making the distinction. That one believes that it will rain tomorrow is a contingent truth that one knows, but it doesn't seem that one's knowledge of that truth depends on sense experience. On the acquaintance theory, the difference between a priori and a posteriori knowledge might better be thought of as lying more on the side of the relation of the acquaintance relation than on the source of the knowledge.

## CRITICISMS

Classical foundationalism has come under considerable attack from many different directions. The second clause of the principle of inferential justification is particularly controversial. A worry exists that it is far too strong a requirement for inferential justification and may simply invite a vicious regress. In assessing the claim that inferential justification requires access to a probability connection between one's premises and one's conclusion, it is important to make sure that the arguments one considers are not enthymematic. As we ordinarily talk, it is natural to describe the dark clouds overhead as evidence of an approaching storm. But it is doubtful that the presence of the clouds by itself constitutes the entire body of evidence from which people predict the storm; it is the dark clouds together with one's knowledge of a past association between dark clouds and storms. One might argue that when one considers genuinely non-

enthymematic reasoning it is less plausible to suppose that one needs knowledge of connections between premises and conclusion in order to legitimately infer one's conclusion.

Still, even in the case of deductively valid arguments there is a great deal of plausibility to the claim that one cannot get justification for believing the conclusion of the argument unless one not only has reason to believe the premises but also sees the connection between premises and conclusion. To avoid regress, people need noninferential knowledge of connections between premises and conclusions; and whereas it may not be that hard to convince oneself that one can discover without inference that one proposition entails another, it is much harder to convince oneself that one can just "see" probability connections (connections that are lower than entailment).

Without noninferential awareness of probability, however, skepticism looms on the horizon. Of course, in deciding what one can or cannot be noninferentially justified in believing, the question of just what might constitute noninferential justification needs to be addressed.

**WHAT CONSTITUTES NONINFERENTIAL JUSTIFICATION?** Some would argue that the search for infallible beliefs as the foundations of knowledge is both fruitless and misguided—at least if infallibility is understood in terms of a belief's entailing the truth of what is believed. As has been shown, there are trivial examples of beliefs that do entail the truth of what is believed. My beliefs that "I exist; that I am conscious; that I have beliefs" are all trivially infallible in the sense defined. Critics have pointed out, however, that if one believes a necessary truth, one's belief will also trivially entail the truth of what is believed. If one says that *P* entails *Q* when it is impossible for *P* to be true while *Q* is false, then every proposition will entail a necessary truth—necessary truths cannot be false.

But surely belief in a necessary truth does not constitute knowledge if the person holds the belief as a matter of pure whimsy. If one becomes irrationally convinced that every third sentence of a book expresses a truth, and by employing this decision procedure for belief ends up, by a remarkable coincidence, believing an extraordinarily complex necessary truth (far too complex for one to even recognize as a necessary truth) it hardly seems right to suppose that one would have any justification whatsoever for believing that truth. Once one sees that the entailment relation between belief and the truth of what one believes is not sufficient for knowledge or justified belief, one

might begin to wonder whether it is ever getting at the heart of any interesting *epistemic* concept.

Still other philosophers have pointed out that beliefs that entail their truth are few and far between, and that if knowledge rests on a foundation of these, then that foundation is precarious indeed. Consider a favorite example of a foundational belief offered by classical foundationalists: the belief one has that one is in pain. Believing that one is in pain seems to be a state logically distinct from the pain. As such it seems always at least conceivable that the belief could occur—perhaps produced by some evil demon—without the pain. For all we know, the brain state causally responsible for one's believing that one is in pain is a distinct brain state from the one causally responsible for the pain. If so, then one could presumably induce belief in pain without producing the pain. Yet if one cannot get foundational justification or knowledge for accepting descriptions of one's own psychological states, then an impoverished foundation indeed exists upon which to attempt to build an edifice of knowledge.

**EXTERNALIST APPROACHES TO INFALLIBILITY.** Some contemporary philosophers are sympathetic to the idea of direct knowledge understood in terms of beliefs that cannot be false, but have understood the relevant possibility in causal or nomological terms. Thus the circumstances that produce the belief that *P* may be *causally* sufficient for the truth of *P*. It is not easy to spell out in an interesting way how one might specify the relevant circumstances causally responsible for a belief, but this approach does succeed in raising an alternative to the classical foundationalists' emphasis on conceivability or logical possibility as the relevant concept to employ in defining epistemically interesting concepts of infallibility. It also raises the prospects of a much richer array of propositions being contained in the foundations. Such externalist approaches to understanding infallibility, however, are probably anathema to classical foundationalists, who typically wanted the conditions that constitute foundational knowledge or justification to be conditions to which people have a kind of unproblematic direct access (a desire that might itself raise again the specter of vicious regress).

It was pointed out earlier that one cannot very well identify truth-makers as the source of noninferential justification without giving a plausible account of just what gives some truth-makers a critical epistemic role that most others fail to have. But reliance on the concept of acquaintance to define the concept of foundational knowledge has not fared much better when it comes to

contemporary philosophical fashion. The standard line most often taken is that there is no such relation and, even if there were, it would be of no epistemic interest. Foundational knowledge must be knowledge of *propositions* if it is to yield the premises from which people can infer the rest of what they justifiably believe. But acquaintance with a fact seems to be a relation that has nothing to do with anything that has a truth value. Facts are not the kinds of things that can be true or false. How does acquaintance with a fact yield access to truth? Indeed, can one even make sense of reference to facts independently of truth? Some philosophers would argue that to refer to a fact is just another way of referring to a proposition's being true. If facts are reducible to truths, it would clearly be uninformative to locate the source of noninferential knowledge of truths in terms of acquaintance with facts to which truths correspond.

The claim that acquaintance with facts is not by itself constitutive of noninferential knowledge of truths is one that an acquaintance theorist might grant, however. As was noted earlier, one might introduce a critical role for truth-bearers to play in one's acquaintance theory. To be noninferentially justified in believing some proposition *P*, one might argue, one must be acquainted not only with the fact that *P* but the truth-making relation of correspondence between the thought that *P* and the fact that *P*. When one has acquaintance with the truth-bearer, the truth-maker, and the truth-making relation that holds between them, one is in a complex state that does just constitute the most fundamental kind of propositional knowledge.

**NONINFERENTIAL JUSTIFICATION.** To attack various versions of foundationalism is not, of course, to respond to the regress argument for foundationalism. It has already been noted that some contemporary foundationalists accept the fundamental idea that there are foundations to knowledge but reject classical accounts of what those foundations consist in. As was seen in considering alternative conceptions of infallibility, many externalists identify justificatory conditions for belief with the circumstances producing the belief. Reliabilists, for example, count a belief as justified if it is reliably produced and they allow that a belief might be reliably produced even if the input producing the belief involves no other beliefs. Such reliable "belief-independent" processes can end a regress of beliefs justified by reference to other beliefs. Reliabilist conceptions of noninferential justification also divorce noninferential justification from infallible justification. According to some reliabilists, a justified belief

might result from nondoxastic input and be just barely more likely to be true than not.

As was true of those who seek foundations in the causal impossibility of mistake, reliabilists offer the prospect of a greatly expanded class of propositions that might be noninferentially justified. Like other versions of externalism, however, it is not clear that reliabilism succeeds in capturing a concept of justification that would interest the classical foundationalist. The classical foundationalist sought justification that would provide a kind of assurance of truth, and it is not clear how the causal origin of a belief by itself (when one has no access to that origin) could satisfy one's intellectual curiosity.

### THE COHERENCE THEORY OF JUSTIFICATION

Historically, the other main alternative to classical foundationalism was the coherence theory of justification. The coherentist rejects the classical foundationalist's assumption that justification is linear in structure. According to the coherentist, there is no escape from the circle of one's beliefs—nothing can justify a belief but other beliefs. But one doesn't justify a belief by reference to other prior justified beliefs. Rather, each belief is justified by reference to its fit in an entire system of beliefs. When each belief does its part in contributing to a clear, coherent picture of the world, each belief is justified. The coherentist, however, faces a serious dilemma. The coherentist must choose between the view that coherence by itself confers positive epistemic status on the beliefs that cohere, and the view that it is one's awareness of the coherence between one's beliefs that confers such status. If the coherentists embrace the first horn of the dilemma, they are left with a view that seems vulnerable to counterexample. Does one really want to allow that if one consults one's astrologer and comes to believe a set of complex propositions that coincidentally cohere beautifully—even though due to their complexity one could never discover that coherence—the beliefs in question are all justified?

However, if one requires that one must be aware of the coherence among one's beliefs in order to acquire justification for those beliefs, one faces once again the regress that drove so many to foundationalism. To be aware of coherence one must be aware of the fact—that is, have a justified belief—that one has the beliefs one has and that they stand in various logical and probabilistic connections. But how does one come to know what one believes? If one answers in terms of coherence to which one has access the problem just arises again. If one gives

oneself unproblematic direct access to one's beliefs and the connections that hold between them, one has simply returned to classical foundationalism.

## CLASSICAL MECHANICS, PHILOSOPHY OF

Classical physics is the research tradition beginning with Isaac Newton's *Mathematical Principles of Natural Philosophy* (often called simply the *Principia*) of 1687, which was overtaken by relativity theory and quantum mechanics in the early twentieth century and is still undergoing lively development in such areas as chaos and catastrophe theory. The "Newtonian" physics canonized in textbooks includes many elements added long after Newton, such as vector notation, the analytical mechanics that Joseph-Louis Lagrange and William Hamilton developed in the late eighteenth and early nineteenth centuries, and the laws of energy conservation and of electromagnetic phenomena formulated in the mid-nineteenth century. Indeed, Leonhard Euler in 1749 was the first to express Newton's second law as the familiar relation between a body's instantaneous acceleration and the momentary force that the body experiences; Newton's own version of the law set the body's change in momentum during a finite period of time equal to the impulse on the body (the force times the period's length, for constant force over the period). However, the subject of this entry is the anachronistic classical mechanics found in textbooks.

Though classical mechanics is false, as relativity and quantum mechanics reveal, there are many reasons for philosophers to continue investigating its proper interpretation (i.e., what the world would be like if classical mechanics were true). Many of the difficulties encountered in trying to interpret modern physics also arise in connection with classical physics, but in a simpler context. Moreover, many of the venerable metaphysical and epistemological ideas vigorously developed by modern philosophers such as George Berkeley, David Hume, and Immanuel Kant are best understood in connection with the classical physics that originally prompted them. Furthermore, one should not wait to deploy one's interpretive faculties only after physics has secured the final theory of everything; if one did, progress in both physics and philosophy would suffer. Finally, although classical physics lacks some of the provocative features exhibited by relativity and quantum mechanics, it has long served philosophers as the exemplar of what genuine scientific understanding would be. By studying it, one can learn about the concepts, logic, and limits of science. This entry touches on only a few of the metaphysical and epistemological questions that classical physics provokes.

## BASIC ONTOLOGY: MASS AND MATTER

Philosophers have worked to identify the ontologically fundamental objects, properties, and relations that classical mechanics posits. Among the candidates proposed have been distance, time interval, velocity, force, matter, mass, electric charge, and inertial reference frame. All raise difficult questions.

Mass is the single parameter relating a body's motion to the force on the body. Remarkably, that relation in classical mechanics is the same for macroscopic bodies as for their constituents; classical mechanics "scales up." Newton defined mass as measuring the amount of matter composing a body, though he did not define *matter* itself. In contrast, the nineteenth-century Scots physicist James Clerk Maxwell (1952), who formulated the laws of electromagnetism, defined mass in terms of momentum and energy, which he believed more fundamental. An alternative approach later pursued by Ernst Mach (1960), the Moravian physicist and philosopher, characterizes mass operationally: The masses of two bodies are related as the inverse ratio of their mutually induced accelerations when isolated from other bodies. If mass is not defined operationally, but instead is an intrinsic property responsible for resistance to force, then according to many philosophers, one knows the effects for which mass is responsible, but one cannot know what mass is in itself. Similar considerations apply to electric charge.

Classical mechanics is sometimes interpreted as deeming a macroscopic body to be a swarm of point bodies in a void. In an alternative interpretation classical mechanics takes bulk matter to be continuous space-filling stuff, or instead to be composed of many bodies of a small but finite dimension made of continuous media, having no internal structure, and separated by empty space. Newton's laws and Charles-Augustin de Coulomb's electrostatic force law are often codified in terms of pointlike bodies, whereas the basic equations of hydrodynamics and the theory of elastic solids are typically expressed in terms of continua. Mass points present obvious difficulties; when two collide, they must be inside each other and the gravitational force between them becomes infinite. Continuous media avoid the latter problem, since at a point, there is no finite quantity of mass; there is only mass density, defined as the limit of mass per volume as the volume becomes arbitrarily small. But collisions still present a problem: When two bodies collide, do they occupy a common point? Or is there simply no finite volume between them? (If a point separates them, then how are they in contact?)

## BASIC ONTOLOGY: MOTION AND FORCE

A body's velocity is its position's instantaneous rate of change, and its acceleration is its velocity's instantaneous rate of change. As ordinarily defined, a quantity's rate of change at an instant is its average rate of change during a finite interval around that instant, in the limit of an arbitrarily short interval. Hence, a body's velocity at time  $t$  is just a mathematical property of the body's trajectory in a neighborhood of  $t$ , which includes some of the body's trajectory after  $t$ . But its velocity at  $t$  is supposed to be an initial condition in the causal explanation of its subsequent trajectory. That would apparently require points in that subsequent trajectory to help causally explain themselves. This is puzzling. Furthermore, consider a body moving uniformly across the surface of a smooth horizontal table and then falling off the edge. At the final moment that the body is on the table (assuming that the table includes its edge), its trajectory's second derivative is undefined; taken from the left it is zero, but taken from the right it is equal to the gravitational acceleration. Presumably, though, a body has a well-defined acceleration at all times.

Force is characterized by William Thomson and Peter Guthrie Tait in their canonical mid-nineteenth-century physics text as "a direct object of sense" (1895–1896, p. 220). However, other natural philosophers regarded forces as redundant in classical mechanics once fields are admitted as local causes or remote charges and masses are acknowledged as acting at a distance. The late nineteenth-century German physicist Heinrich Hertz regarded forces as mere calculational devices between cause and effect, "simply sleeping partners, which keep out of the business altogether when actual facts have to be represented" (1956, p. 11).

## FUNDAMENTAL LAWS

Newton's three laws of motion, with his inverse-square law of gravity, are commonly regarded as the fundamental laws of classical physics. In the nineteenth century the laws of electromagnetism were added to them. The status of the conservation laws and the variational principles of classical physics remains more controversial, as will be seen.

Newton's second law is sometimes taken to be "The net force on a body, divided by its mass, equals its acceleration in any inertial frame of reference." But how is *inertial frame* defined? Mach suggested that inertial frames are frames where the universe's average matter is not accelerating. But this definition leads to predictions

that depart from those made by Newtonian mechanics regarding, say, a body in otherwise empty space or in a universe where (according to Newton) all other matter is accelerating. Sometimes *inertial frame* is taken to be defined by Newton's first law: a frame is inertial exactly when a body feeling no forces remains at rest or in uniform rectilinear motion in that frame. But then Newton's first law is true by definition.

The chief alternative is to presuppose points of absolute space, as Newton did, and to define an *inertial frame* as a rigid Euclidean frame at rest or in uniform rectilinear motion with respect to those points. However, even disregarding objections to absolute space as either empirically inaccessible or in contravention of metaphysical scruples, Newton's approach contains surplus ontological structure. A particular frame need not be privileged as at rest. Rectilinear uniform motion need only be distinguished from other paths; the frames pursuing such trajectories are inertial. *Inertial frame* is thereby defined independent of Newton's first law, which is not tautologous but just a consequence of Newton's second law. (Newton's first law is never instantiated, since every body feels some component gravitational forces.)

In this "neo-Newtonian" space-time, there is no fact of the matter regarding a body's velocity. (But there is a fact regarding its acceleration and its velocity relative to another body.) There is also no fact regarding the distance between two nonsimultaneous events, unlike in Newton's absolute space and time. All inertial frames are equal in neo-Newtonian space-time.

However, absolute velocity figures in the classical laws of electromagnetism. Absolute space is then no longer superfluous. This fact opened one of Albert Einstein's paths to relativity theory.

### HOW MUCH DOES CLASSICAL PHYSICS SAY?

Thomson and Tait interpret Newton's second law as requiring every acceleration to be caused by some force (1895–1896, p. 223). But simply as an equation, Newton's laws make no explicit mention of causes and effects; they merely relate a perpetually isolated system's past and future states to its current state. Accordingly, Bertrand Arthur William Russell concludes that the notion of a causal relation (insofar as it goes beyond a correlation demanded by the laws) has no place in physics, but is "a relic of a bygone age" (1929, p. 247). David Lewis (1983–1986) draws a different moral, arguing instead that since classical physics reveals causal relations, those rela-

tions must supervene on the laws and the actual course of events.

There are many similar questions about how richly or austere classical physics describes the world. For instance, the law of energy conservation might be interpreted as specifying that the universe's total quantity of energy is fixed. But it might instead be taken as saying more: That for any volume over any temporal interval, the change in energy within must equal the energy that has flowed across its boundary. Alternatively, the conservation laws (of mass, energy, linear momentum, and angular momentum) might not be understood as laws of classical physics at all. They do not follow immediately from Newton's laws of motion and gravity.

### TIME-REVERSAL INVARIANCE

Newton's laws are time-reversal invariant. Roughly speaking, if a sequence of events is permitted by the laws, then the laws also permit those events to occur in reverse order. The laws recognize no difference between past and future just as they fail to discriminate among spatial directions. However, certain macroscopic processes are never observed to occur in reverse. For example, when two bodies of unequal temperature touch, heat flows from the warmer to the cooler body. Although there are configurations of the bodies' molecules that would lead by Newton's laws to the warmer body's becoming still warmer, many more configurations would produce the result one sees. So irreversibility can be reconciled with Newton's laws if, roughly speaking, all the possible micro-realizations of a system's macrostate are equally likely.

But this equiprobability is not required by Newton's laws. Its origin remains puzzling. Furthermore, even if a closed system far from equilibrium (e.g., with an unequal distribution of heat) were much more likely to head toward equilibrium (i.e., to increase its entropy) than away from equilibrium, entropy's increase in the space-time region one observes would remain unexplained. It would still be mysterious why one's space-time region is so far from equilibrium in the first place.

### MECHANISM AND DETERMINISM

Classical mechanics suggests that the universe is like a majestic clockwork, the laws fully determining the universe's past and future states given its present state, and a body changing its motion only because another body touches it. But gravity and electromagnetism apparently operate by action at a distance. Newton famously offered no hypotheses (*hypotheses non fingo*) regarding the means by which gravity operates. Accordingly, some natural

philosophers ceased to seek local causes for all effects. In contrast, Michael Faraday and Maxwell regarded fields of force as existing on a par with bodies. The field at a given location would cause a body there to feel a force. The field picture avoids positing action at a distance but departs significantly from the picture of material particles in the void: Fields occupy all locations, even where there is no ordinary matter.

In 1814 Pierre Simon de Laplace invoked his famous “demon” to explain the determinism of the clockwork universe:

Given for one instant an intelligence which could comprehend all the forces by which nature is animated and the respective situation of the beings who compose it—an intelligence sufficiently vast to submit these data to analysis—it would embrace in the same formula the movements of the greatest bodies of the universe and those of the lightest atom; for it, nothing would be uncertain and the future, as the past, would be present to its eyes. (1951, p. 4)

Twentieth-century research revealed that Laplace may have overstated the determinism of a universe governed by classical physics (although there is no obvious way in which the indeterminism of classical physics supports the freedom of the will). When two point bodies collide, their mutual gravitational interaction becomes infinite, yet the laws of energy and momentum conservation nevertheless allow an analytic solution to the classical equations of motion to be extended uniquely through the collision singularity. However, this extension is generally impossible when three bodies collide. Furthermore, Newton’s laws enable a closed system of point bodies to undergo an infinite number of triple near collisions in a finite time (as the sequence of encounter times converges to some particular moment). By the slingshot effect resulting from these close approaches, certain bodies attain infinite acceleration in finite time and so afterward are absent from any finite region of the universe. They are literally nowhere to be found. Since Newton’s laws are time-reversal invariant, they permit this sequence of events to proceed in reverse, so that “space invaders” suddenly appear in the system from nowhere. Determinism is thereby violated without a collision occurring. Of course, the invaders’ unanticipated appearance violates mass, energy, and momentum conservation, illustrating that these principles fail to follow from Newton’s laws alone.

## ANALYTICAL MECHANICS

In 1661 Pierre de Fermat derived the law of refraction from the postulate that in traveling from one location to another, a ray of light takes the path that minimizes the travel time. To some (such as the eighteenth-century French mathematician Pierre-Louis Moreau de Maupertuis), Fermat’s principle suggested that nature produces effects with the greatest economy, efficiency, or ease—demonstrating God’s wisdom. However, this metaphysical moral was undermined somewhat by the discovery that light may also take the path of greatest travel time. For example, consider a point light source at the center of an ellipsoidal mirror. The points around the mirror’s margin that can reflect light back to the center are exactly the two points along the mirror’s minor axis (i.e., where the edge is closest to the center) and the two points along the mirror’s major axis (i.e., where the edge is farthest from the center).

Fermat’s principle was generalized by Euler, Lagrange, and Hamilton into the variational principles of analytical mechanics. Given the system’s initial configuration (the initial positions and velocities of its particles) and final configuration, there are various paths (through configuration space) by which the system may get from one to the other. These paths may differ, for instance, in the time it takes the system to arrive at its final configuration and in the configurations through which the system passes along the way. Roughly speaking, the Euler-Lagrange “principle of least action” states that the time integral of the system’s total kinetic energy is “stationary” along the actual path as compared to all sufficiently close possible paths. That is, roughly speaking, the sum of the kinetic energies at all the points along the path actually taken is a minimum, maximum, or saddle point as compared to the sums for similar paths that are not taken. (So “the principle of least action” does not demand that the action be “least.”)

Similarly, Hamilton’s principle states roughly that of all the possible paths by which the system may proceed from one specified configuration to another in a specified time, the actual path as compared to other possible, slightly different paths makes stationary the time integral of the system’s Lagrangian (i.e., the difference between the system’s total kinetic and potential energies). A possible path may violate energy conservation and other laws; Hamilton’s principle picks out the path demanded by the laws. So to apply Hamilton’s principle, scientists must contemplate counterlegals: what would have been the case, had the system violated natural laws in certain ways. But a possible path must respect the constraints on the

system, which may include a body's having to remain rigid or in contact with a certain surface.

These constraints may be plugged into the variational principles without the forces that constrain the system having to be specified. This gives variational principles a practical advantage over Newton's laws, since the forces of constraint may be unknown, and emphasizes the style of explanation that variational principles supply. Newton's laws are differential equations; they determine the instantaneous rates of change of the system's properties from the system's conditions at that moment, such as the forces on it. The system's trajectory over a finite time interval is then built up, point by point, and the forces are efficient causes of the system's acceleration. In contrast, variational principles make no mention of forces; instead, they invoke the system's energy. The explanations they supply specify no efficient causes. Variational principles involve integral equations; they determine the system's trajectory as a whole, rather than point by point.

## TELEOLOGY

Explanations that use variational principles sound teleological; the system appears to aim at making a certain integral stationary. But then the system's final configuration apparently helps to explain the path that the system takes to that destination; later events help to explain earlier ones. That is puzzling. How does a light ray "know," at the start of its journey, which path will take less time? How can the light adjust the earlier part of its route to minimize its later path through optically dense regions (where it cannot travel as fast) unless it knows about those distant regions before it sets off?

Some natural philosophers (such as Max Planck) suggested that variational principles are more basic laws than Newtonian differential equations, especially considering that unlike Newton's laws, variational equations of the same form apply to any set of variables sufficient to specify the system's configuration. Other natural philosophers (notably Gottfried Wilhelm Leibniz) embraced both mechanical and teleological explanations as equally fundamental. Leibniz declared that there are

two kingdoms even in corporeal nature, which interpenetrate without confusing or interfering with each other—the realm of power, according to which everything can be explained mechanically by efficient causes when we have sufficiently penetrated into its interior, and the realm of wisdom, according to which everything can be explained architectonically, so to speak, or by

final causes when we understand its ways sufficiently. (1969, pp. 478–479)

Other natural philosophers (such as Mach) denied final causes but also denied efficient causes as well (allowing only the relations specified by natural laws). The most common view, however, has been to reject teleological explanations as a relic of anthropomorphic characterizations of nature and to regard variational principles as logical consequences of more fundamental, mechanical laws. The variational principles follow from the Newtonian differential equations roughly because the entire path can minimize the integral only if each infinitesimal part does (since otherwise, by replacing that part with another, one would create a new path with a smaller integral), and the minimum for each infinitesimal part reflects the gradient of the potential there, which is the force. The variational principle thus arises as a byproduct of the relation between the force and an infinitesimal section of the path.

## CLASSIFICATION

See *Definition; Logical Terms, Glossary of*

## CLAUBERG, JOHANNES (1622–1665)

Johannes Clauberg, a German Cartesian philosopher, was born in Soligen, February 24, 1622, and died in Duisburg, January 31, 1665. Though he lived a short life, his philosophical output was considerable; his name became almost synonymous with that of René Descartes in Germany. Clauberg studied in Cologne and Bremen, where he came under the influence of reformed scholasticism and the pedagogical and methodological ideals of Jan Amos Comenius. At Bremen he also met Tobias Andreae, whom he later joined in Groningen in 1644 after Andreae was appointed professor of History and Greek. He disputed some theses in 1646 and published his first independent treatise, *Ontosophia*, in 1647. Clauberg's initial works, including *Ontosophia*, do not display the influence of Descartes's philosophy, though Clauberg rewrote the book along Cartesian lines in later editions. After travels to France, to the Protestant Academy in Saumur and Paris (where he seems to have met some early Cartesians), and to England, Clauberg attended the lectures of the Cartesian Johannes de Raey in Leiden in 1648. It is clear that by

1648 Clauberg had become interested in Descartes's philosophy. Clauberg made his official entrance into the Cartesian world as a result of his participation in what is sometimes called the "Conversation with Burman." The latter is a manuscript of the University of Göttingen reporting a lengthy discussion between Descartes and (presumably) Frans Burman, a young theology student at Leiden. The discussion, conducted in Latin, apparently occurred on April 16, 1648, at Descartes's retreat in Egmont. According to the manuscript, Burman dictated his impressions of the meeting to Clauberg on April 20. Clauberg evidently kept a copy and had a second one made by some unknown scribe some months later; this is the surviving copy.

In that period Clauberg was approached about becoming a professor of theology in Herborn; he began his duties the following year, in 1649, as professor of philosophy instead, with occasional teaching in theology. However, he was not happy with his position; his teaching load was heavy and he probably resented the combination of theology and philosophy, protesting as well that the professor of theology had some teaching duties in philosophy. A conflict with his more conservative colleagues developed. On November 1, 1651, Clauberg's employer, the Count of Nassau, officially decreed that the only philosophy allowed in Herborn was Aristotelico-Ramist philosophy, either separately or jointly. As a result, Clauberg and his friend and fellow Cartesian Christoph Wittich, who had been appointed professor of mathematics, left Herborn in December 1651 and accepted posts in Duisburg, a town that fell under the jurisdiction of the Elector of Brandenburg. In Duisburg, Clauberg's position was initially Rector of the town's Gymnasium; when the Academy of Duisburg was opened in 1655 he and Wittich became doctors of theology. Clauberg married Catharina Mercator in 1652; they had one son and five daughters. For the rest of his life, the now-settled Clauberg lived the life of a professor in a small German town; he was even rector of the Academy in 1655 and 1659. He attracted many students to Duisburg, several of whom became professors themselves.

## WORKS

Clauberg must have already started on his second book, *Defensio cartesiana*, when still in Leiden, though it was published only in 1652. It is primarily a reply to *Consideratio theologica* (1648), a detailed commentary on Descartes's *Discourse on Method* from an orthodox theological point of view, by the Leiden Professor Jacobus Revius. Clauberg also added materials attacking his erst-

while colleague Cyrianus Lentulus (or Lentz), Professor of Practical Philosophy at Hernborn. The *Defensio Cartesianiana* provoked a reply from Revius, which Clauberg answered with *Initiatio Philosophi sive dubitatio cartesianiana* (1655). The conflict also involved Andreae, who published a two-volume response to Revius in 1653–1654, triggering yet another treatise from Revius in 1654. In his defense of Cartesianism, Clauberg distinguished between Descartes's popular and his esoteric works; according to Clauberg, the *Discourse on Method* belongs to the first category, whereas the *Meditations* and *Principles of Philosophy* belong to the second.

The promulgation of Cartesianism required Clauberg to write a number of other works explaining Descartes's physics and metaphysics, such as *Paraphrasis in Renati Descartes Meditationes*, *Differentia inter Cartesianam et alias*, and *Physica*. Clauberg also published some volumes of disputations. But doubtless his most influential books were *Logica vetus et nova*, first published by Elzevier in 1654, and the smaller *Logica contracta*. After Clauberg's death, the Amsterdam professor of philosophy Johann Theodor Schallbruch provided an edition of his works, *Opera omnia philosophica*, partly based on unpublished material in the possession of Clauberg's son, Johann Christopher; the added material included Clauberg's notes on Descartes's *Principles of Philosophy*, his correspondence with Andreae, a biography of Clauberg, and a general index to all of Clauberg's treatises.

## CARTESIANISM

Clauberg's work is a paradigm of what first-generation Cartesian scholastics needed to accomplish. Clauberg made progress elaborating Cartesian themes, such as espousing occasionalism for the relation between mind and body, and created texts to fill the gaps in the collegiate curriculum as it would be taught by a Cartesian. With the *Principles of Philosophy*, Descartes began the process of producing textbooks from which to teach Cartesian philosophy. However, scholastic textbooks usually had quadripartite arrangements mirroring the structure of the collegiate curriculum: logic, ethics, physics, and metaphysics. And Descartes produced at best only a partial physics and what could be called a general metaphysics; he did not finish his physics—he did not produce the expected final two parts of the *Principles of Philosophy* on animals and on man—and did not write a particular metaphysics. He did not produce a logic or ethics for his followers to use or to teach from. These things must have been perceived as glaring deficiencies in the Cartesian

program and in the aspiration to replace Aristotelian philosophy in the schools.

So the Cartesians rushed in to fill the voids. One can understand Louis de la Forge's additions to the *Traité de l'homme*, for example, as an attempt to complete the physics, and Clauberg's later editions of *Ontosophia* or Baruch Spinoza's *Cogitata metaphysica*, for instance, as endeavors to produce a more conventional-looking metaphysics. Descartes, of course, saw himself as presenting Cartesian metaphysics as well as physics, both the roots and trunk of his tree of philosophy. But from the point of view of schools texts, the metaphysical elements of physics (general metaphysics) that needed to be discussed by Descartes—such as the principles of bodies: matter, form, and privation; causation; motion: generation and corruption, growth, and diminution; place, void, infinity, and time—were expected to be taught in a course on physics. The scholastic course on metaphysics (particular metaphysics) dealt with other topics, not discussed directly in the *Principles of Philosophy*, such as being, existence, and essence; unity, quantity, and individuation; truth and falsity; good and evil. Such courses usually also ended up with questions about knowledge of God, names or attributes of God, God's will and power, and God's goodness. The *Principles of Philosophy* by itself was not sufficient as a text for the standard course in metaphysics.

Clauberg's *Ontosophia*, however, discussed being in general, dividing it into its general and primary sense of “intelligible” being, a secondary and lesser sense of “something” to be distinguished from “nothing,” and a third, particular sense of “real” being, being outside the intellect, or substance, contrasting it with accident and mode. Clauberg went on to talk about essence, existence, and duration. His remaining chapters concerned pairs of concepts such as one and many; true and false; good and evil; perfect and imperfect; distinct and opposite; the same and another; exemplar and image.

## CARTESIAN LOGIC

Beyond completing Cartesian physics and metaphysics, there were even attempts at producing Cartesian ethics; a Latin-language manual called *Ethica*, printed in 1685, was said to have been authored by Descartes. Descartes never wrote such a work, but a translator was able to put together a tripartite treatise out of Descartes's own words: (1) on the greatest good, happiness, and free will; (2) on passions; and (3) on love. There were numerous stabs at creating Cartesian-style logic texts as well, Clauberg's *Logica vetus et nova* being first of its kind, together with the *Logique* of Jacques Du Roure. The attempt to publish

a Cartesian textbook that would mirror what was taught in the schools culminated in the famous multivolume works of Pierre-Sylvain Régis and of Antoine Le Grand, which included expanded versions of Cartesian physics and metaphysics, together with treatises on ethics and logic.

Scholastic logic, as taught in the seventeenth century, typically followed an order of topics dictated by the various books of Aristotle's *Organon: Categories, On Interpretation, Prior Analytics, Posterior Analytics, Topics, and Sophistical Refutations*. For example, after some preliminary questions on the usefulness of logic, whether logic can be called science or art, and the definition and divisions of logic, Scipion Dupleix wrote a six-part logic, corresponding to Aristotle's six logical works: (1) categories—that is, substance, quantity, quality, relations, and so forth; (2) nouns, verbs, and statements; (3) syllogism; (4) science and demonstration; (5) topics; and (6) paralogisms. One can say similar things about the logic textbooks of other early seventeenth-century scholastics, such as Eustachius a Sancto Paulo and Pierre du Moulin. Clauberg's *Logica contracta* followed a similar pattern, starting with the categories and continuing with attribute and accident, cause and effect, subject and adjunct, relation, whole and part, the same and other, universal and singular, definition, and division. His second part of logic began with the grades of judgment, qualitative statement, truth and falsity, opposition, conversion and equivalence, and composite statement, and continued with argument and syllogism, both perfect and imperfect, and true and false. Clauberg's third part of logic dealt with the grades of memory and his fourth part concerned teaching and dialectics, order, and fallacy. Very little of this was Cartesian.

A major problem to resolve in producing a Cartesian logic was that Descartes, in keeping with a standard Renaissance view, was extremely negative about the subject. According to Descartes in the *Discourse on Method* (repeating views he had previously elaborated in the unfinished *Rules*), syllogisms are useless: they serve to explain things one already knows, or even to speak without judgment on matters of which one is ignorant, rather than to learn them; although logic might contain true and good precepts, nevertheless there are so many other precepts mixed up with them, that are either harmful or superfluous, that it is practically impossible to separate them from one another. Descartes proposed instead his four rules of method—the rules of evidence, of the division of difficulties, of the order of inquiry, and of the

completeness of enumerations—as a method of discovery exempt from the faults of formal logic.

However, Descartes also called his rules of method the principal rules of logic. According to Descartes, before applying himself to true philosophy a person who has only common and imperfect knowledge should study “logic,” but not the logic of the Schools: Such logic corrupts good sense rather than increasing it. Descartes's logic instead teaches people to direct their reason with a view to discovering the truths of which they are ignorant. The more moderate late Cartesian views about logic were reinforced in a text familiar to Clauberg. Commenting to Burman on the *Discourse* passage about the harmful role of logic, Descartes supposedly asserted that his statements did not apply so much to logic, which provides demonstrative proof on all subjects, but to dialectic, which teaches how to hold forth on all subjects. Descartes's subtle shift in position allowed Clauberg to reinterpret Descartes's rules of method as part of logic, now integrated into a legitimate branch of learning that even included syllogisms.

Clauberg's *Logica vetus et nova* begins with a Prolegomena arguing, along Descartes's line from the end of *Principles of Philosophy*, Part 1, that the principal origin of error is to be found in the prejudices of childhood. Logic is the corrective for these mental imperfections; thus, in the first book of his logic, Clauberg devises a scheme that involves Descartes's rules of method and traditional logic, following the pattern of his *logica contracta*, as three “grades” or levels of logic. The first level has to do with accepting clear and distinct perceptions; it includes the rule of evidence and ends up with the rule about the division of difficulties, but it also discusses traditional topics such as: substance, attribute, and mode; essence and existence; universal and singular; definition; and division. The second level concerns right judgment and involves the rule about the order of inquiry, ending with the rule of the completeness of enumerations; it also discusses induction and syllogism. Clauberg's third level concerns memory.

Clauberg provided the initial pattern for Cartesian logic, though other Cartesians found it more expedient to follow more closely the scholastic order in logic, grafting on a section about method at the end of their treatises. Later Cartesian logics, such as the Port-Royal Logic and Le Grand's *Logick* are divided into four parts: (1) Ideas, including Aristotle's categories, universals, and names; (2) Propositions (or Judgments), truth and falsehood; (3) Reasoning (or Discourse), including syllogisms, topics, and sophisms; and (4) Method. By method, however,

these writers meant analysis and synthesis, which does not have to be anything particularly Cartesian, though we do find Descartes's rules of method enumerated in the chapters on analysis. The Port-Royal Logic supplanted Clauberg's logic and was ultimately adopted and abbreviated by Régis as his logic in his *General System of Cartesian Philosophy*. One can legitimately think, however, that Clauberg understood Descartes's views on logic better than subsequent Cartesians.

### WORKS BY CLAUBERG

*Tessarakas thesium philosophicarum, de logicae ab aliis disciplinis quibus cum vulgo confundi assolet distinctione ... moderatore Tobias Andreae.* Groningen, Netherlands: J. Nicolai, 1646.

*Disputatio theologico-practica de conscientia ... sub praesidio Matthiae Pasoris...* Groningen, Netherlands: Eissens, 1646.

*Elementa philosophiae sive Ontosophia. Scientia prima, de iis quae Deo creaturisque suo modo communiter attribuuntur.* Groningen, Netherlands: Nicolai, 1647. With editions in 1660 and 1664.

*Defensio cartesiana adversus Iacobum Revium Theologum Leidensem, et Cyriacum Lentulum, professorum Herborensem: pars prior exoterica, in qua Renati Cartesii Dissertatio de Methodo vindicatur, simul illustrata Cartesianae logicae et philosophiae specimina exhibentur.* Amsterdam: Elsevier, 1652.

*Logica vetus et nova, modum inveniendae ac tradendae veritatis, in Genesi simul et analysi facili methodo exhibens.* Amsterdam: Elsevier, 1654. With editions in 1656, 1658, 1683, 1685, and 1692.

*Initiatio philosophi, sive dubitatio Cartesiana, ad metaphysicam certitudinem viam aperiens.* Leiden, Netherlands: Wyngaerden, 1655.

*De Cognitione Dei et nostri, quatenus naturali rationis lumine, secundum veram philosophiam, potest comparari, exercitationes centum.* Duisburg, Germany: Wyngaerden, 1656, with another edition in 1685.

*Logica contracta.* 3rd ed. Duisburg, Germany: Cunradi, 1670. With editions in 1683, 1701, 1702, 1711, 1737, and 1721. There might have been a first edition plus a second edition in 1659. The *Logica contracta* is also printed with adaptations of Clauberg's works, such as *Ontosophia, quae vulgo metaphysica vocatur, notis perpetuis in philosophiae et theologiae studiosorum usum illustrata, a Joh. Henrico Suicero. In calce annexa est Claubergii logica contracta* (Zurich: Gessner, 1694).

*Unterschied zwischen der cartesianischen und der sonst in den Schulen gebräuchlichen Philosophie.* Duisburg, Germany: Wyngaerden, 1658. Dutch translation, Nijmegen: Van Hervelt, 1658. The work is best known in a Latin version, *Differentia inter Cartesianam et alias in Scholis usitatum Philosophiam conscripta...* (Groningen, Netherlands: Edzardi, 1680) with another edition in 1681.

*Paraphrasis in Renati Descartes meditationes de prima Philosophia. In quibus Dei existentia, et Animae humanae à Corpore distinctio demonstrantur.* Duisburg, Germany: Wyngaerden, 1658, with another edition in 1668. Dutch translation, 1683.

*Ars etymologica Teutonem e philosophiae fontibus derivata; id est, via Germanicarum vocum & origines & praestantiam detegendi, cum plurium, tum harum Vernunft, Suchen, Aufspruch exemplis.* Duisburg, Germany: Asendorf, 1663.

*Physica, quibus rerum corporearum vis & natura ... explicantur.* Amsterdam: Elsevier, 1664.

*Theologorum academiae Duisbergensis Johannis Claubergii et Martini Hundii disputationes selectae, quibus controversiae fidei adversus omnis generis adversarios.* Duisburg, Germany: Haius, 1665.

*Chilias thesium ad philosophiam naturalem pertinentium ... disputanda in Academia Duisburgensi.* Groningen, Netherlands: Cöllen, 1668.

*Dictata physica privata, id est physica contracta seu theses physicae, commentario perpetuo explicatae.* Frankfurt: Ilsner, 1681. With another edition in 1689.

*Opera omnia philosophica.* Edited by Johannes Theodor Schalbruch. 2 vols. Amsterdam: Blaeu, 1691. With another edition in 1710. Reprint, Hildesheim: Olms, 1968. (Contains *Physica Contracta*; *Disputationes Physicae*; *Theoria Corporum Viventium*; *Metaphysica de Ente, cum Notis*; *Paraphrasis in Meditationes Cartesii*; *Notae breves in Cartesii Principia Philosophiae: nunc primum editae*; *Exercitationes Centum de Cognitione Dei et Nostri*; *Logica vetus et nova*; *Logica contracta*; *Defensio Cartesiana*; *Dubitatio Cartesiana*; *Differentia Cartesianam inter & Vulgarem Philosophiam*; *Exercitationes & Epistolae Joh. Claubergii & Tob. Andreae varii argumentis, nunc primum editae*; plus an *Index locupletissimus* and a *Vita* of Clauberg by Henricus Christianus Henninus.)

## CLEANTHES

(c. 331–330 BCE–c. 230–229 BCE)

Cleanthes (sometimes referred to as Cleanthes of Assos) was the second head of the Stoic school. Ancient biographical information is found in Diogenes Laërtius's *Lives of the Philosophers* (7. 168–176) and in Philodemus's history of Stoicism (columns 18–19). Born in 331–330 BCE, in Asia Minor, he came to Athens in 281–280. He took over leadership of the school on the death of its founder, Zeno of Citium, in 262–261 and held that position until his own death in 230–229. The most important contemporary Stoic was Ariston of Chios, against whom Cleanthes defended the version of Zeno's legacy that became standard, insisting on the vital importance of logic and physics as well as ethics. His own student and successor, Chrysippus, maintained this integrated system. Cleanthes also defended Stoic epistemology against the skepticism of the academic Arcesilaus.

Cleanthes was a prolific author in every area of philosophy. He wrote four books of interpretation of Heraclitus, a defense of Zeno's natural philosophy, and works on the interpretation of poetry and myth, which probably aimed to show that ancient wisdom supported Stoicism. He is now better known for the surviving portions of his philosophical poetry, which includes thirty-nine lines of his *Hymn to Zeus* and four lines on the topic of fate. In physics he wrote on the basic principles (active and passive, God and matter), on cosmogony (a cyclical recreation of the cosmos punctuated by recurring conflagrations of all matter), and on cosmology (with a particular emphasis on the role of the sun as the organizing principle). In theology he is important for his theory about the origins of the conception of God reported in book two of Cicero's *On the Nature of the Gods* and other more dialectical arguments reported by Sextus Empiricus.

Cleanthes' response to the Master Argument of Diodorus Cronus was to hold (1) that there are possibilities which neither are nor will be true and (2) that the impossible does not follow from the possible; but (3) to deny that every past truth is necessary, thereby perhaps avoiding an excessively necessitarian version of his determin-

ism. He was a materialist, holding that anything that causes or is caused must be material, but followed Zeno in invoking incorporeal predicates as necessary features of a causal account of material interaction. He may have been the first to use the term *lekton* ("sayable") for such items. He wrote several works on dialectic, logic, and epistemology, but ultimately his contribution in this area was eclipsed by that of his brilliant successor Chrysippus.

Like all Stoics he held that the soul is a material stuff, a warm, breathy substance capable of perception and intelligence; he invoked the authority of Heraclitus particularly for his psychology. One argument for the physical nature of the soul was the heritability of psychological traits as well as corporeal characteristics. Cleanthes held that the soul survived the death of the person but only until the next conflagration; postmortem survival of personal traits seems not to have been envisaged.

In ethics he held that living according to nature is equivalent to living virtuously and took a particularly strong anti-hedonistic stance, using parables and images to dramatize the starkness of the choices one must make in planning one's life. He held the controversial view that in planning one's life one must look only to cosmic nature rather than to any more limited nature (such as that of the species or the individual), a position that coheres with his theological and cosmological views. He wrote extensively on practical ethics, but held that the norms applicable specifically to individuals in their social roles must be based on general philosophical principles. He held a strong version of the unity of virtues, maintaining that it is a single disposition (called "strength" and "power" rather than "health") manifested as different virtues (such as courage and justice) according to the circumstances where it is applied. Virtue is a cognitive state consisting of the secure and irreversible knowledge of doctrines and factors relevant to decision making. Hence it is a permanent trait once achieved.

His psychology is often thought to have had a dualistic character because Galen, perhaps following Posidonius, exploited Cleanthes' writings when arguing against the monistic views of Chrysippus. It would, however, be a mistake to infer dualistic psychology from the fact that Cleanthes dramatized a debate between reason and emotion in a poem, no doubt for protreptic purposes. In all areas of his philosophy Cleanthes was committed to the main lines of Stoic orthodoxy as set down by his master Zeno.

## CLEMENT OF ALEXANDRIA

(c. 150–c. 213)

Clement of Alexandria (full Latin name, Titus Flavius Clemens), the Christian theologian of the Alexandrian school, was born of pagan parents, probably in Athens. Clement learned from several teachers in the Mediterranean world before he came to Alexandria, where he studied under the Christian philosopher Pantaenus, a converted Stoic who was the head of the catechetical school. Clement remained in Alexandria from 175 to 202, writing and teaching, until he fled during the persecution of the emperor Septimius Severus. He died in Palestine.

Alexandria's heritage of learning, culture, syncretism, and religious mystery may be seen in his writing. His three major works form a trilogy that leads from paganism to mature Christianity. In the *Protrepticus* (Exhortation) he attacks the absurdities of pagan deities and exhorts his readers to turn to Christianity. In the *Paedagogus* (Tutor) he instructs Christians in the good life. In his chief work, the unfinished *Stromateis* (Patchwork), he sets down his philosophical opinions in unsystematic notes—"Gnostic notes concerning the true philosophy." This work, which represents the final stage of instruction, includes much material that he had learned from his teachers but hesitated to write about because of its difficult and sacred nature. He regards obscurity, compression of style, and haphazard arrangement as safeguards against the abuse of sophistry. Clement used the word *gnostic* because he wanted to show that there was a true Christian *gnosis*, or knowledge, which developed out of faith and which was better than the boasted knowledge of the heretical Gnostics. Gnosticism was especially strong in Alexandria. Clement put forward an attractive alternative to it and attacked what he considered to be its peculiar tenets of esoteric knowledge, dualism, and ethical determinism. Knowledge, he said, grows out of faith and is not distinct from it. There is one God who made all things. Men are free to choose the way they will go.

Clement wrote against the background of Middle Platonism, of Antiochus of Ascalon, Maximus of Tyre, Albinus, and Numenius, whose thought was governed by the problem of defining the relation between the one and the one-many, and of deriving the latter from the former. The difference between a one and a one-many, or between simple and complex unity, is like the difference between the unity of a pinpoint and the unity of a spider's web. In Middle Platonism these two unities were developed into divine entities. Simple unity is divine and transcendent, while complex unity is divine and immanent. Clement was influenced by the Alexandrian Jewish Platonist Philo, for whom God is a simple, bare unity and the Logos an all-embracing cosmic whole. Clement's thought is governed by the pattern of simple and complex unity; and his accounts of God, goodness, and truth are expressed in these terms.

God is the transcendent one, a simple unity, the ultimate first principle and cause of all things. The categories of logic cannot be applied to him. "Nor are any parts to be ascribed to him, for the one is indivisible." God cannot properly be named. The good names we give him are supports to our minds to stop us from erring. Taken separately, these names do not say what God is like, but together they show his power. While God cannot be known, the Son, or the Logos, is wisdom, knowledge, and truth. He unites in himself the world of Platonic forms, or "powers," as they are also called in later Platonism. "The Son is not simply one thing as one thing nor many things as parts, but one thing as all things. All things come from him. For he is the circle of all the powers rolled into one and united." Within this unity of the Son the individual believer is saved. Faith is union in him, while disbelief is separation, estrangement, and division. Paganism is wrong because it multiplies the nature of divinity, and Marcion, the Christian heretic, is wrong because he divides the supreme God from the Creator of the world, making two Gods instead of one.

God's goodness is perfect and unique. God does not prevent evil and suffering from taking place, but when they do, he turns them to good account. He may use suffering as a form of correction for sinners. After death, imperfect souls may be sanctified by an intelligent non-material fire. The complex goodness of men is always assimilation to God—growing like him by participation in his goodness. Clement constantly refers to Plato's statement in the *Theaetetus* concerning assimilation to God. All men, says Clement, receive the image of God at their birth and all may then, as they choose, become assimilated to him and receive his likeness. In the *Paedagogus*,

Clement gives detailed instruction for Christian behavior. From Plato came the emphasis on self-knowledge, and the conception of evil as ignorance and virtue as knowledge. Virtue comes through discipline and the pursuit of goodness, without thought of ulterior gain. The harmony of the soul is aided by the harmony of the body. From Aristotle, Clement draws the notion of virtue as the fulfillment of man's function and the achievement of his end. This fulfillment is found in pursuing the mean between extremes and in possessing right reason. Clement draws heavily on Stoic ethics, commending what is in accord with nature and in harmony with reason. There is a class of things intermediate between good and evil. One should recognize the things that are in one's power and the things which are not, and avoid being dominated by one's irrational passions.

Clement speaks of truth in two ways. The simple elements of Christianity are true, and heresy is to be rejected as false. Truth is one and unique, powerful and strong in delivering men from error. It comes from God and is preserved within the tradition of the church. Second, Clement speaks of truth as including all that is consistent with basic Christian truth. This truth is a whole composed of many parts. It is one body from which each of the philosophical sects has torn a limb, or part, falsely imagining it to be the whole of truth. The many parts must be brought together, so that the perfect Logos, the truth, may be known. The truth of philosophy was partial, but real. It was for the Greeks, as the Law was for the Jews, a schoolmaster to bring them to Christ. Clement shared with others the quaint notion that the Greeks stole their ideas from the Hebrews.

Faith is an act not a process. Faith is the acceptance from God of an indemonstrable first principle from which all other truth may be deduced. It is a judgment of the soul, an Epicurean preconception, and a Stoic assent. Knowledge (*gnosis*) is both logical and spiritual, joining things together either by logical reasoning or by spiritual vision. The eighth book of the *Stromateis* is a notebook of logic composed of materials from various sources. It deals with demonstration and definition in an Aristotelian way, gives a Stoic refutation of the skeptical suspension of judgment (that is, if one must suspend judgment, then one should suspend judgment concerning suspense of judgment), and treats of cause, using both Stoic and Aristotelian terms. Causes may be original, sufficient, cooperating, and necessary. Spiritual knowledge is growth in Christ, awareness of God's universal presence, and union with him in love. Symbolism reveals hidden connections

and points to unity. Knowledge is always a complex unity, while faith is a simple unity.

Clement achieved the first real synthesis of classical philosophy and Christianity. The Apologists had used particular ideas to bridge the gap between philosophy and Christianity. In Justin's writings, for example, God is described in terms of the Platonic ineffable being, and the divine reason implanted in men is expounded along Stoic lines; but there is no comprehensive conceptual framework that enables these and other ideas to modify one another. Clement's synthesis was developed by Origen, and the result was the theology of the fourth-century Greek Fathers and of Augustine.

## CLIFFORD, WILLIAM KINGDON (1845–1879)

A English mathematician and philosopher, William Kingdon Clifford was born in Exeter, the son of a justice of the peace. At the age of fifteen he went to Kings College, London. There he gained a minor scholarship to Trinity College, Cambridge, to which he went in 1863. He began to exhibit powers of originality in mathematics, publishing a number of mathematical papers during the year in which he first entered Cambridge.

At the university Clifford distinguished himself not only by his intellect but also by his singular character. As one of the most prominent undergraduates, he was soon invited to join the Apostles, an exclusive Cambridge club made up of the twelve most distinguished undergraduates of the time. Here he exhibited some of that breadth of learning and clarity of mind for which he was to be noted all his life. It appears that he was highly concerned about religious questions because he studied Thomas Aquinas and learnedly supported the Catholic position. Later, however, he became an agnostic and turned against religion; Herbert Spencer and Charles Darwin became the most important influences upon his thinking in many areas.

Clifford was elected a fellow of Trinity in 1868. In that year he began the practice of giving public lectures, a source from which most of his published work stems. He participated in a scientific expedition, which was wrecked off the coast of Catania, Sicily. In 1870 he was appointed professor of applied mathematics at University College, London. Soon after, he became a member of the most distinguished intellectual society of the day, the Metaphysical Society, as well as of the London Mathematical Society. Tragically, his life was drawing to a close, for he had contracted tuberculosis. His condition worsened, until by 1878 it was evident that the disease was far advanced. In 1879 he traveled south to try to counteract the disease, but he died on March 3 of that year.

During Clifford's lifetime he published only a textbook on dynamics and some scattered technical and non-technical papers based on his lectures. It remained for a number of his friends to gather together his work. H. J. S. Smith edited the mathematical papers, F. Pollock the philosophical ones. The young Karl Pearson edited and completed his popular work on science, *The Common Sense of the Exact Sciences*.

## SCIENTIFIC EPISTEMOLOGY

Clifford's philosophical views must be placed within the context of several major influences upon his thought: the Kantian frame in epistemology, the Riemannian frame in geometry, and the Darwinian frame in biology. On the basis of these and other influences, Clifford constructed a scientific epistemology and attempted to construct a scientific metaphysic. A discussion of his epistemology is first in order, since out of it grew his metaphysics. Clifford conceived of knowledge as a biological response to the world. Its structure, therefore, is determined by that adjustment. Nevertheless, any analysis of knowledge as such reveals that within it the form and the content of knowledge are distinguishable from each other. Immanuel Kant believed that he had determined a method to make this distinction in all cases. Clifford, taking his cue from Kant, believed that he too could make this distinction, but in a way that took into account the ultimately biological character of knowledge. He thought that an analysis of the foundations of science, and in particular of the axioms of geometry, would reveal that these axioms are forms of experience in the life of any particular individual. Thus, since the biological adaptation of the race has crystallized three-dimensional Euclidean space, this spatial framework has become the one in which individuals see spatially locatable objects. Clifford went even further in this direction by claiming that such a construction is ultimately a growth of experience which has been transformed into neural capacities. Thus, Clifford conceived of the form-content distinction of knowledge as one relative to the biological development of the race. What is at one time the content of experience is later, through a biological process, transformed into a form of experience.

The principles of geometry and arithmetic serve, for individuals, to structure their experience. They are or correspond to ways in which our sense data are "spatially" or "numerically" organized. Their logical status is therefore closely akin to the one that Kant assigned to them. They are a priori, for no experience is capable of verifying or falsifying them, whereas at the same time they are synthetic, since the predicate term is not contained in the subject term.

Within this framework of thought it is intelligible to discuss Clifford's concrete epistemological ideas. He offered analyses of what might be called (1) perceptual statements, (2) geometric, arithmetical, and even physical principles, and (3) belief statements in general.

**PERCEPTUAL STATEMENTS.** In various essays Clifford offered an analysis of perceptual statements concerning objects, persons, and the spatial aspects of objects and persons. In general, he refused to admit a phenomenalist analysis of such statements. In all cases some ideal conception, be it of “an ejet” (a technical term that will be explained later) or of “a form of experience”—in other words, a conception which is not itself definable in terms of a set of sense experiences—enters into the meaning of the statement, either explicitly or implicitly. This is true with the qualification that Clifford sometimes suggested that statements about physical objects are reducible to statements about sense experiences.

**GEOMETRIC, ARITHMETICAL, AND PHYSICAL PRINCIPLES.** The analysis that Clifford provided of the several kinds of statements differed somewhat from one another, and it would be wise to examine them in sequence. As has already been indicated, the statements of geometry and arithmetic state universal and therefore formal characteristics of experience. In the case of geometric statements, Clifford asserted that they are universally true about the objects of our perceptions, in the sense that all perceptions of spatial relationships must conform to them. Furthermore, they are necessary, since the perceptions compatible with the negations of such statements are impossible. Clifford contended that Kant had established the necessary properties of space by a subjective method, a method of introspection, whereas Clifford attempted to demonstrate such properties by a consideration of the neurological bases of perception. The limits of what is perceptible, given man’s neurological structure, were, for Clifford, what is known a priori to the individual, while those perceptions whose contradictions are not imperceivable, again given man’s neurological structure, are known a posteriori. Clifford proceeded to demonstrate, to his satisfaction, that at this level of analysis both Euclidean and non-Euclidean space are compatible with the neurological structure of perception, and that it is a matter of the general explicatory value of a geometric theory as to which of the various geometries is to be accepted. Of course, man’s neurological structure evolves over time, so that what is necessary at one time is not necessary at another—this indicates that Clifford used the term *necessary*, in this context, in a relative sense.

Clifford’s analysis of arithmetical statements differs somewhat from his analysis of geometric statements. He thought that their validity depended upon several factors: (1) the tautological character of certain parts of language, (2) the acceptance of a general principle of the unifor-

mity of nature of the kind that J. S. Mill suggested, and (3) the acceptance of an analysis of arithmetical operations in terms of the physical operation of counting. Numerals are assigned in a one-to-one correspondence with standard sets of objects, each set containing one member more than the preceding set. The operations of addition, multiplication, and, by implication, subtraction and division are next defined in terms of the physical operations of juxtaposition of sets of objects. Clifford then claimed that if the meaning of “distinct objects” were granted, along with the assumption that all objects maintain their identity through space and time (the uniformity of nature), then the laws of arithmetic can be seen to hold for all objects. On the basis of the natural numbers, he sketched the development of the more complex number systems.

Clifford did not have much to say about the status of physical laws and theories, except to suggest that there are some principles of physics that are, like the principles of geometry and arithmetic, rules for the ordering of sense impressions.

**BELIEF STATEMENTS.** Clifford’s examination of the basis of belief in the natural sciences led him to a more general analysis of belief. Indeed, it was this general analysis of belief and the agnostic and antireligious conclusion to which it led that occasioned great opposition on the part of William James and others. Clifford claimed that no statement is worthy of belief unless all the possible evidence points to the truth of the statement. He recognized that in practice it is impossible to have available all the possible evidence about the truth or falsity of a proposition. Failure of memory, the expenses of collecting information, and a host of other factors contribute to this impossibility. But he claimed that an acceptance of the principle that similar causes have similar effects (another version of the principle of the uniformity of nature) permits our acceptance of many beliefs in cases where the standard of all possible evidence is not met. Such a principle permits an inductive inference from known facts to unknown ones, and thus permits us to make up for evidence we do not possess. These ideas are contained in his essay “The Ethics of Belief,” to which James’s famous essay “The Will to Believe” is a reply. In that essay James claimed that a belief is worthy of acceptance in some cases where there is no empirical evidence either for or against the content of the belief. And this criterion permitted James to believe in the existence of God.

## SCIENTIFIC METAPHYSICS

Clifford's epistemological views were the occasion for his speculative metaphysical ideas. He had been wrestling with the problem of whether the existent world is wholly phenomenal in character or whether there are entities of a nonphenomenal character which go to make it up. In earlier essays—for example, "The Philosophy of Pure Sciences"—he inclined toward a purely phenomenalist view, but in his more mature and well-known essay "On the Nature of Things-in-Themselves" he reversed his former stand. Not all existence is phenomenal in character. He was clear, for example, that the ego cannot be analyzed in purely phenomenal terms. Clifford thus postulated the existence of what he termed "ejects" as well as of phenomenal "objects." An eject is distinguished from an object in the following way: An object can be an object of *my* consciousness, an eject is something *outside* my consciousness. Thus, another's ego (and this holds for all persons) is an eject; it is never in my consciousness. Clifford postulated that there are nonpersonal as well as personal entities that are ejects. The elements of ejects are themselves what Clifford called feelings. They are constituents of everything, he claimed, since the fact that there is a continuity of forms in nature gives assurance that, at least to some degree, any entity in nature possesses the same qualities that all others have. Since feelings are elements of consciousness, all entities therefore have this aspect of consciousness to a certain extent, although it is only to more complex entities that we ascribe consciousness. The elementary entities that are called "feelings" were considered by Clifford to be absolute existents and therefore things-in-themselves. Clifford then named these elementary entities mind-stuff, since they participate somehow in the character of the mental. Their necessarily incomplete representation in the mind of man is what is known as the material world. There exists a complex mirroring relation—indeed, Clifford used the image of two reflecting mirrors—between the external world and its representation in knowledge. Thus, Clifford's speculative metaphysic ultimately postulated a Spinozistic world in which the mental and physical are really two different ways of looking at the same world. Another possible interpretation of his thought is that all existence is ultimately infused with a psychic aspect, that is, that panpsychism is the most correct view of reality.

In conclusion, it is worthwhile mentioning several areas of thought in which Clifford was ahead of his time:

(1) Clifford recognized the fact that scientific laws are always "practically inexact." By this notion he wished to point out that a scientific law is never exactly con-

firmed by the evidence for it but rather is confirmed within the limits of experimental error. A law is accepted on the basis of experimental evidence even if that experimental evidence does not exactly coincide with what, on the basis of deductions from the law, one might expect to be confirming evidence. This is so simply because all measurement of evidence in modern scientific practice involves taking into account errors of measurement, and such errors of measurement must be "factored out" before a definite conclusion is reached as to the relevance of the evidence.

(2) Clifford, in the brief note "On the Space-Theory of Matter," declared himself to be in the geometric tradition that holds that the determination of the truth or falsity of geometrical axioms is empirical. Clifford saw that through a change in the basic assumptions of microgeometry (geometry of the infinitesimally small) he could work out a system of geometry and physics that would clear up the anomalies in physical theory that existed in his day. He saw that a reformulation of microgeometry in non-Euclidean terms could achieve this result, and in this respect he anticipated, at least in part, Albert Einstein's program. He never, however, carried through this program on his own; he merely suggested that such a program was feasible.

(3) Clifford showed the possibility, at least in principle, of constructing a wholly empirical geometry in the following special sense: Geometry is considered to be a set of statements about the relations between geometrical objects such as points, lines, planes, and volumes. These geometrical objects and relations, however, are themselves characterized in a completely empirical way, not as ideal objects, as they are usually characterized in most treatments of geometry. That is, they are identified with the physical objects or aspects of physical objects. The principles of geometry are then empirical statements whose truth or falsity is a matter of observation. This point of view is close to a geometric operationalism. Clifford's account of it is found in his book *The Common Sense of the Exact Sciences*.

## COCKBURN, CATHARINE TROTTER (1679?–1749)

Catharine Trotter, according to her editor and biographer, was born on August 16, 1679, the younger of two daughters of David Trotter, a captain in the Royal Navy and his wife, Sarah Ballenden, of a well-connected Scottish family. Trotter's father died of the plague while on a voyage that was to have made his fortune. Instead, his family was forced to survive on an irregularly disbursed pension from the reigning monarch. Trotter was educated at home, and perhaps largely self-educated, although she seems to have taught herself French and Latin. She was a precocious writer, publishing a novella at a young age, followed by poems, and ultimately five plays, four appearing between 1695 and 1701 and the last in 1706, all of which achieved a certain renown.

In 1701 Trotter began to live with her married sister in Salisbury, where she remained until her own marriage in 1708. In Salisbury Trotter joined the circle surrounding Gilbert Burnet (1643–1715), the bishop of Salisbury, which included his wife, the devotional writer Elizabeth Burnet (1661–1709), and his cousin, Thomas Burnet of Kemnay (1656–1729), a lively correspondent of Trotter's. It was during her time in Salisbury that Trotter's theological and philosophical interests began to manifest themselves. In 1702 she published *A Defense of Mr. Locke's Essay*, a reply to criticisms of John Locke by yet another Thomas Burnet (c. 1635–1715), and in 1707 *A Discourse concerning a Guide in Controversies*, the fruits of her struggles with Roman Catholicism, justifying her decision to return to the Church of England.

In 1708, she married the clergyman Patrick Cockburn (1678–1749), and her scholarly interests were for some time suspended while she struggled to raise a family of four in somewhat reduced circumstances, brought on when her husband lost his curacy, on finding himself unable to swear the oath of abjuration on the ascension

of George I (1660–1727) to the throne. In 1726 Cockburn was able to reconcile himself with this oath and became first the rector at Aberdeen and then the vicar of Long Worsley in Northumberland, where the family was still living at the time of Catherine's death in 1749.

With the restoration of the family fortunes, Cockburn's philosophical interests also revived, and in 1726 she published *A Letter to Dr. Holdsworth*. While she did not resume publishing until close to the end of her life, first bringing out *Remarks upon Some Writers in the Controversy concerning the Foundation of Moral Virtue and Moral Obligation* in 1743 and then *Remarks upon the Principles and Reasonings of Dr. Rutherford's Essay* in 1747, it is clear from letters written throughout this period, particularly those to a niece, Anne Arbuthnot, that Cockburn maintained a lively reading program and developed her intellectual interests in correspondence.

Cockburn's works were collected by Thomas Birch and published after her death, and include, in addition to her published philosophical work, several hitherto unpublished pieces, a play, and a fascinating collection of letters. Some doubts have been raised about the dates of Cockburn's life supplied by Birch, stimulated by a letter to G. Burnet written in 1707, in which she reports the marriage of a son and the birth of a grandchild. Since, according to Birch's reckoning, this would make Trotter a mere twenty-seven, it has been suggested that her birth date should be pushed back to accommodate the birth of a son and grandson. There are some limits, however, on the extent to which Trotter's age in 1706 can be adjusted, since according to Birch's account, she was seventy-one at the time of her death and was publishing close to that time. An alternative possibility is that Trotter was not in fact the birthmother of the son she mentions casually to Birch.

Each of Cockburn's works takes roughly the same form, that of a loosely organized commentary on some other work, often itself critical in nature. Her earlier work defends Locke against various attacks, and her later work is written in defense of Samuel Clarke.

Her presentation then can appear somewhat diffuse and disorganized. In her early defense of Locke against Thomas Burnet, for example, she considers three different criticisms: that Locke's rejection of innate moral principles leaves him with no resources on which to ground one's knowledge of moral principles, that Locke provides no way in which he can establish God's veracity, and, finally, that an account of personal identity based like Locke's on consciousness instead of substance does not provide grounds for personal immortality.

There are, however, some common threads that tend to reappear in much of her work. In particular, Cockburn is very much embroiled in eighteenth-century attempts to walk a middle ground between deism and voluntarism. Her concern is to argue that human beings can, by means of their intellectual resources, derive an understanding of moral concepts based on their nature as sensitive, rational, and social beings. It is through this complex understanding of ourselves that we are able to work out what is suitable or fit for us. Cockburn argues that the complexity of our nature does not limit our grasp of what is fit for us simply to what is pleasant or what is in our self-interest, but that we can derive a full sense of our moral obligation from our nature as rational, social beings. Therefore, there is no need to turn to an otherwise unmotivated appeal to God's decrees to account for the full range of our moral obligations. Cockburn also wants to maintain that, while our understanding of the nature of these obligations rests on our understanding of ourselves, it is nevertheless God's decrees that give these principles the force of law. But since we know that God is good, and we understand, from our own case, what it is to be good, we also know that God would not require of us actions that are, as we understand it, irrational. Her position is designed to guard against both the view that human morality is entirely independent of religion and against the view that our obligations have only a religious and no rational support.

## CODE, LORRAINE

(1937–)

Lorraine Code is a Canadian philosopher with interests in epistemology, feminist epistemology, and the politics of knowledge. She is Distinguished Research Professor of Philosophy at York University, where she is also appointed to the Graduate Programs in Women's Studies and Social and Political Thought. Code has authored five books and numerous articles, and has edited five collections. From 1999 to 2001, she served as a Canadian Council Research Fellow.

Code describes her work as an interrogation of local and global politics of knowledge that harm people and nature. She argues, for example, that traditional philosophical epistemologies foster the exploitation of people and nature by Western sciences and institutions because they include tenets that obscure the role of social and political relations in the formation of knowledge. Recently Code has undertaken the constructive project of developing an alternative, "ecologically modeled" epistemology that, she maintains, avoids the failings of traditional epistemologies.

Code's critical and constructive projects consistently focus on the ethical dimensions of knowledge making and epistemological accounts of it. In *Epistemic Responsibility* (1987) she argues that epistemic responsibility is not exhausted by "purely epistemological" standards. Code contends that an emphasis in epistemology on virtue and responsibility would result in attention to the social contexts of knowing, including the relevance of social relations and social roles to what is recognized as knowledge. Such analyses would, in turn lead, to more robust notions of epistemic responsibility.

A concern with the ethical implications of epistemology is also central in *What Can She Know?* (1991). Here Code focuses on the "alignments" in "mainstream epistemology": on one hand, characteristics its values (for example, objectivity and rationality) and, on the other hand, shifting conceptions of masculinity. Code argues that these alignments contribute to institutional knowledge (for example, in the sciences and law) and to social institutions that undermine women's abilities to act as

knowers while rendering invisible the politics of gender at work. She uses these alignments in a more general argument that subjective factors inform all knowledge claims and epistemic ideals. From this perspective, theories of knowledge that obscure the role of such factors are not just factually flawed, but they are also ethically flawed because they underwrite the continuation of a form of subjectivity that, although changing overtime, has consistently put women at a disadvantage. Not surprisingly, when Code poses the question in this work of whether a distinctly feminist epistemology is desirable, she is not enthusiastic. She holds that efforts to achieve universality, which she here attributes to epistemology in general, are at odds with the attention to particularity, context, and other aspects of subjectivity that her arguments call for.

In *Rhetorical Spaces: Essays on Gendered Locations* (1995), Code undertakes the kind of fine-grained studies she recommends. Her essays explore cases in which specific and rhetorically and socially constructed locations—including those of marginalization and power—have an impact on who is deemed credible and what counts as knowledge. In one, a victim of sexual harassment seeks to reconcile her memories with conflicting accounts and to understand how trusting herself relies in part on her credibility in the eyes of others. Other essays, focusing on institutionalized knowledge such as health care, explore ways in which everyday knowledge practices are sites of social interactions that contribute to or deny credibility to various subjects and groups.

In *Ecological Thinking* (2005) and elsewhere, Code builds from her earlier work to advance a sustained argument for what she calls “an ecologically modeled” theory of knowledge. Code maintains that explanatory models in ecology are promising for a theory of knowledge precisely because they assume a mutual dependency of organisms, an interrelatedness between their well-being and features of their environment, including features that are cruel. Code argues that such models contrast sharply with the individualism and instrumentalist conceptions of rationality that characterize traditional epistemology and obscure the ethics and politics of knowledge-making practices. Incorporating these noninstrumentalist ideas into epistemology, she maintains, would result in a model that could accommodate the insights of feminist, multi-cultural, and postcolonial studies into precisely those dimensions of knowledge making that have been obscured by traditional epistemology.

## COGNITIVE SCIENCE

Cognitive science is the interdisciplinary study of mind, in which the concepts and methods of artificial intelligence (AI) are central (Boden forthcoming). The most prominent disciplines within the field are AI, artificial life (A-life), psychology, linguistics, computational neuroscience, and philosophy—especially the philosophy of mind and language. Cognitive anthropology is included too, though often goes unseen under the label of evolutionary psychology.

The many relevant subfields include robotics, whether classical, situated, or evolutionary; studies of enactive vision, where the organism’s own movements (of eyes and/or body) provide crucial information for acting in the world; the psychology of human-computer interaction, including various aspects of virtual reality such as avatars; and computational theories of literature, art,

music, and scientific discovery. Nonhuman minds are studied by computational ethology and neuroethology, and by A-life.

### WHO IS A COGNITIVE SCIENTIST?

Not everyone working in the key disciplines is a cognitive scientist. Only those taking a computational approach to questions about mind are considered cognitive scientists.

Some AI workers, for example, are not cognitive scientists because they have no theoretical interest in human thought. Their aim is to challenge their ingenuity as computer engineers by getting a program or robot to do a task that people either cannot do or do not want to do. If hunches, or experimental evidence, about human psychology can help them achieve that goal, that is fine. But if nonhuman tricks are available, such as looking ahead in a chess game to consider all the legal possibilities for several moves, they will use them. These computer scientists are engaged in technological AI, not psychological AI. Only the latter is a proper part of cognitive science.

Even someone who does have a professional interest in human minds need not be a cognitive scientist. For instance, many social psychologists study patterns of interpersonal behavior without asking about the information processes that underlie them and make them possible. Even some cognitive psychologists insist that they are not cognitive scientists, because they follow James Gibson's (1979) affordance theory of perception—which allows for information pickup but not for information processing. (Their self-description is based on an overly narrow view of what cognitive science covers: Gibsonian insights have become prominent in various areas of cognitive science, such as enactive vision.)

Similarly, many linguists—sociolinguists and historical philologists, for instance—are not primarily concerned with just how language is generated and/or understood. But even those who do focus on these computational matters do not all agree. Chomskian linguistics, for example, was crucial in the rise of cognitive science and has deeply influenced the philosophy of mind; but non-Chomskian accounts of syntax have been developed since. In addition, theories of pragmatics have become at least as prominent as theories of syntax—and pragmatics is an aspect of situatedness, a concept of growing importance within cognitive science as a whole. As for anthropology, most anthropologists see their field as a hermeneutic enterprise, not a scientific one. They reject psychological explanations of culture in general, and computational accounts in particular.

### COGNITIVE SCIENCE IS ABOUT MORE THAN COGNITION

It includes cognitive psychology, of course: the study of language, memory, perception, problem solving, and creative thinking. What is more, most research has focused on individual human adult cognition. However, other aspects of mind are studied too: motivation, emotion, choice (Dennett 1984), development, psychopathology, interpersonal phenomena, motor control, and animal psychology.

Consider emotion, for example. The role of emotion in problem solving, attitude formation, and neurosis were topics of research in AI and computational psychology in the early 1960s. But the problems were too difficult, and were largely dropped. Interest revived later, partly because of neuroscientific work on emotional intelligence and partly because of advances in the computational theory of scheduling in multigoal systems (Slovan 1993). Interdisciplinary conferences on the psychology, neuroscience, computer modeling, and philosophy of emotion blossomed at the turn of the century, when the topic became a prominent aspect of research.

Whether the focus of attention is on development or psychopathology, emotion or motor control, the prime interest for cognitive science is in the abstractly defined computational functions that generate the behavior concerned. But the neural mechanisms that implement them are often studied too. Despite the functionalist doctrine of multiple realizability, many cognitive scientists want to know how psychological functions are actually implemented in the brain. When functionalism began in the 1960s, little attention was paid to the nervous system by philosophers or AI scientists. Since the 1980s, that has been less true.

Indeed, neuroscience as such has become increasingly concerned with computational questions. On the one hand, there are theories (and computer models) of specific neural circuits doing closely specified things. For instance, cells in the retina and/or visual cortex that compute particular visual features, such as light gradients or surface textures; or cells in the female cricket's brain that enable her to discriminate the song of male crickets of the same species, and to move accordingly. On the other hand, there are broad-brush theories about the computational functions carried out by large areas of the brain, where the focus is less on specific individual cells than on general neuroanatomy: the different cell types, locations, and connections of the neurons.

## DEVELOPMENTAL ISSUES

Most cognitive scientists study already established phenomena, although many include learning in their subject matter. Some, however, study—and model—mental development. And some do this because they believe that adult psychology cannot be properly understood without knowing how it developed. In short, they see the mind as an epigenetic system, deeply informed by its developmental history.

Epigenesis was stressed long ago by Conrad Waddington in biology and Jean Piaget in psychology. It is self-organized development, grounded in innate predispositions in continual dialectic interaction with the (internal and external) environment. For example, there are inborn dispositions to attend to broadly facelike stimuli, or to human speech-sounds. Once the attention is caught, learning can help develop the infant's pattern recognition and discriminatory powers. In some cases, such as face recognition, the neural mechanisms relevant at different stages have been largely identified.

An epigenetic view is not strictly environmentalist, nor strictly nativist either. Rather, it stresses the dialectical interplay between the two. Late twentieth-century work in developmental neuroscience and developmental psychology has therefore led to a radical reconceptualization of nativism (Elman et al. 1996). Some philosophers of biology have defined new accounts of self-organization and dynamical development accordingly (Oyama 1985).

## WHAT IT MEANS TO SAY THAT COGNITIVE SCIENCE IS COMPUTATIONAL

Cognitive science employs computational models of mind in two senses.

First, the substantive concepts in its theories are computational. The mind is seen as some sort of computational system (just what sort is hotly disputed), and mental structure and mental processes are described accordingly (Haugeland 1997). So whereas many psychologists (and other scientists) use computers to express/clarify their theories, and especially to manipulate their experimental data, only cognitive scientists import computational ideas into their theories.

Second, computer modeling is often used to clarify and test computational theories of mind. Often, but not always, some work in cognitive science (in AI and psychology, not just in philosophy) employs computational concepts and insights, but with insufficient detail to allow programs to be written. When programming is possible, it provides several advantages. Even program failures can

be scientifically illuminating, pointing out lacunae or mistakes in the theory, or fundamental limitations of the methodology being used. However, successes may be even more instructive. For if a program—or a robot—produces a given performance, one knows that it suffices to do so.

Whether real minds (or brains) use similar processes to produce equivalent performance is another matter: just because a program does something in a certain way, it does not follow that people do too. This question can be answered only by empirical evidence. Sometimes, a programmed theory models not only psychological phenomena at various levels, but also the details of their underlying neural base. In such cases, validation requires both psychological and neuroscientific evidence.

The references to computational ideas in the previous two paragraphs cover concepts rooted in two different intellectual traditions, namely, cybernetics and Turing computation. These were closely linked in the years when cognitive science began.

A seminal paper by Warren McCulloch and Walter Pitts (1943) prompted early work both in neural nets and in what is sometimes called GOFAI, or “Good Old-Fashioned AI.” (It also influenced the design of the von Neumann computer.) McCulloch and Pitts integrated three key ideas of the early twentieth century: propositional logic, neuron theory, and Turing computation. They proved that anything expressible in the propositional calculus is computable, and can be mapped onto some specifiable neural net. In addition, they suggested that a fourth key idea—feedback, the core concept of cybernetics—could be defined in terms of these networks, in which case purpose and learning could be embodied in them too.

A few years later they published another paper, in which they argued that probabilistic networks are more like brains and can do things naturally that logic-based systems cannot (Pitts and McCulloch 1947). They still insisted, nevertheless, that their original, logical, account was correct in principle.

In short, the concept of computational systems is normally used within the field to cover both GOFAI and connectionism. (Some philosophers, however, restrict it to the former.) Cognitive science includes both.

Sometimes, the reason why a computational theory is not actually modeled is that suitable computer technology does not yet exist. By the same token, many advances in cognitive science have depended partly upon advances in computing technology. These include both increases in

size (computing power) and new types of virtual machine, embodying forms of computation that were not possible previously.

In some cases, the core ideas had already been defined long before the technology was available to test/explore them. Parallel distributed processing, for instance, was envisaged over twenty years before computers became powerful enough for it to be implemented in interesting ways. Similarly form-generating interactive diffusion equations and cellular automata were both first defined in the 1950s, but not extensively studied until the advent of large machines and computer graphics in the late 1980s. And genetic algorithms, glimpsed in the 1950s and defined in the late 1960s, were first implemented in the 1980s. Once the technology was available, further questions arose that had not been posed before.

### SOME PHILOSOPHICAL PROBLEMS

Many philosophical disputes arise within cognitive science. One dispute concerns the relative merits of the two AI approaches mentioned above: classical (symbolic) AI and connectionism, or neural networks. The latter is broadly inspired by the basic structure of the brain. (Some recent work in artificial neural networks tries to take more account of the subtleties of real neurons; even so, these models are hugely oversimplified in comparison with the real thing.) There are several types of neural networks, but the one most widely used within cognitive science—and the one of greatest interest to philosophers—is parallel distributed processing, or PDP.

Some researchers champion only one of these AI approaches, whereas others admit both because of their complementary strengths and weaknesses. Symbolic AI, or GOFAI, is better for modeling behaviors that involve hierarchical structure, advance planning, deliberation, and/or strict sequential order. The conscious, deliberative aspects of the mind are best suited to this approach. Connectionism, by contrast, is better for modeling the tacit learning and knowledge involved in pattern recognition, including the fuzzy family resemblances between instances of one and the same concept.

It does not follow that all unconscious mental processes are best modeled by PDP systems. Some psychoneural theories of action errors, including various clinical syndromes, employ hybrid (mixed) models in which the hierarchical aspects represent both conscious and unconscious processing.

**INTERNAL REPRESENTATION.** Another debate concerns the nature and importance of various kinds of

internal representation. Connectionist representations are different from GOFAI ones, and several philosophers have argued that they are closer to the neural representations that embody concepts (Churchland 1989; Clark 1989, 1993; Cussins 1990). Computational neuroscience has described further types of representation. One example is emulator systems, which are neural mechanisms whose physical dynamics mimic the temporal changes being represented. Another, based on the anatomy of the cerebellum, is a way of representing motor behavior that is based neither on logic (GOFAI) nor on statistics (PDP), but on noneuclidean tensor geometry.

Some philosophers follow the AI community and/or the neuroscientists, in accepting that representations may take many different guises, depending on the role they have evolved to play. Others, however, argue that only formal-symbolic structures, expressed in a *language of thought*, are properly termed representations, and that only these can generate human conceptual/linguistic thought (Fodor 2000).

**NATURE OF COMPUTATION.** The nature of computation is a third topic of controversy (Scheutz 2002). Most philosophers define it as Alan Turing did in the 1930s—and his is still the only really clear definition. However, practicing AI scientists think of computation in a number of different ways, based on virtual machines whose properties are different from those of a Turing machine. Moreover, some people are trying to go beyond Turing computation by defining new forms of computers (hypercomputers), some—but not all—of which involve quantum computing. Some of these may turn out to be relevant to human brains, but others will not.

**MEANING IN THE REAL WORLD.** A fourth area of philosophical discussion focuses on whether—and if so, how—meaning (intentionality) can be grounded in the real world—and whether it can properly be attributed to programs and/or robots. Evolutionary theories of intentionality rule out GOFAI programs (as do many philosophers), but—arguably—allow meaning to be ascribed to some evolved robots. The grounding problem, on this view, is solved by the way in which the relevant mechanism has evolved in situated, embodied systems.

Empirical work that is closely related to the problem of intentionality includes research on *theory of mind*. Very young children are unable to grasp that each person is an agent with their own set of beliefs and interests, which may differ from those of the child. So although the child realizes that adults (and even other children) know many

things that they do not, the child does not appreciate that someone else may believe something to be true that the child knows to be false. (This is why infants do not lie: they cannot conceive of doing so.) Normally, theory of mind develops spontaneously at around ages four or five, although in autistic children it apparently does not. In other words, inbuilt predispositions have evolved that lead the young child first to engage with other humans (maintaining eye contact, pointing to direct attention, turn-taking in communication, etc.), and eventually to attribute intentional states to them. Philosophers have asked (for instance) whether they do this by theorizing about other people's minds or by simulating, or empathizing with, them (Davies and Stone 1995).

**CONSCIOUSNESS IN COMPUTATIONAL TERMS.** A fifth philosophical puzzle concerns whether consciousness could be explained in computational terms—or in any other scientific, naturalistic, manner (Heil 2004, Newell 1980, Searle 1993). Research in various disciplines within cognitive science has shown that there is no such thing as the problem of consciousness; rather, there are many problems of consciousness, because the term is used to make many different distinctions. Some of these are much better understood than they were twenty years ago, thanks to computational work in AI, psychology, and neuroscience. Reflective self-consciousness, for example, and the bizarre dissociations of consciousness typical of multiple personality, are intelligible in terms of recursive processing, guiding procedures, and access limitations within complex hierarchical structures for perception, memory, and action.

Considerable controversy, however, still attends the problem of qualia. Some cognitive scientists argue that *qualia* can be analyzed in terms of complex dispositions for making discriminatory computations (Dennett 1991). Others see them as aspects of an irreducible informational feature of the universe, applying not only to human brains but to atoms as well (Chalmers 1996). Still others make further suggestions, including several based on quantum physics. In short, there are many theories of *qualia*, and no agreement about what a successful theory might look like.

**OPPOSITION TO ORTHODOX COGNITIVE SCIENCE.** A sixth controversy—or rather, batch of controversies—arises from recent work that opposes orthodox (neo-Cartesian) cognitive science (Cliff, Harvey, and Husbands 1993; Port and van Gelder 1995; Wheeler 2005). This involves both empirical theory/modeling and philosophical discussion. In general, it draws on the traditions of

phenomenological philosophy and/or autopoietic biology, rather than Cartesianism. It rejects both symbolic and connectionist AI, and the concept of representation. It highlights embodied systems (not abstract simulations), embedded in their environment and responding directly to it. Examples include situated robotics in AI, dynamical systems theory, ecological psychology, and A-life studies of evolution and coevolution.

Philosophies inspired by these empirical researches include the theory of extended mind (Clark 1997). This starts from the position that minds must necessarily be embodied and that memory storage lies largely outside the skull (ideas familiar within phenomenology and GOFAI, respectively) and goes on to argue that an individual person's mind is extended over the surrounding cultural artifacts: language, customs, and material objects—from palaces to pencils. The claim is that mind is not merely deeply influenced by these things, but it is largely constituted by them.

Philosophical questions associated with A-life include whether evolution is a necessary characteristic of life, and whether the concept of autopoiesis captures the essence of life (Bedau 1996; Maturana and Varela 1987). If living things are defined as autopoietic systems—whose physical unity, boundaries, and self-maintenance are attained by self-organized metabolic processes—then questions about the origins of life take on a different color, as do questions about the possibility of strong A-life (life in computer memory)—so called by analogy to strong AI.

Philosophers of A-life consider not only the nature of life as such, but how and why it is related to mind. Must all minds be evolved, for example? Autopoietic theorists define all life as involving cognition, while insisting that only linguistic life (i.e., adult humans) involves representations. But questions remain about whether, and if so why, life really is essential for mind. By the same token, questions remain about whether the study of A-life is essentially unrelated to cognitive science or fundamental to it.

**CULTURE AND COGNITIVE SCIENCE.** Finally, culture-directed research in cognitive science raises philosophical questions too. One concerns the nature of group mind, or as it is more commonly called, distributed cognition (Hutchins 1995). Can one identify aspects of cognition that cannot be attributed to any single individual, but only to a team of enculturated persons acting in concert—and if so, can one model such phenomena in computers? Two more such questions concern the evolution

of information-processing mechanisms that underlie important cultural phenomena—religion or aesthetic appreciation, for example—and the evolution of culture as such.

### COHEN, HERMANN (1842–1918)

Hermann Cohen, a neo-Kantian philosopher, was born at Coswig, Anhalt, Germany. His father, Gerson Cohen, was a teacher and precentor at the synagogue; his mother was Friederike née Salomon. In 1878 Hermann married Martha Lewandowski, the daughter of Professor Louis Lewandowski, who was also a precentor at the synagogue and a composer of Jewish ritual songs. In 1853 Hermann went to the gymnasium of Dessau, which he attended for some years. He left there prematurely and went to the Jewish Theological Seminary at Breslau. Later, as a student at the University of Breslau, he wrote the essay "Über die Psychologie des Platon und Aristoteles," which won the prize of the philosophical faculty in August 1863. On August 5, 1864, he took the bachelor's examination as an extramural pupil at the Breslau Matthias Gymnasium. In the fall of the same year he went for further university studies to Berlin. He wrote an essay, "Philosophorum de Antinomia Necessitatis et Contingentiae Doctrinae" and

entered it for a university prize. Since the prize was not awarded to him, he submitted the work (somewhat altered) to the philosophical faculty at Halle. On the basis of this work he was awarded the doctorate of philosophy by this faculty on October 27, 1865.

On his return to Berlin he published several studies, some of them in *Zeitschrift für Völkerpsychologie und Sprachwissenschaft*. Heymann Steinthal, the coeditor of this periodical, who was warmly interested in the very gifted young man, had stimulated his interest in social psychology. It was not until 1870 that his publications disclosed a special interest of their author in Kantian philosophy. In that year Cohen intervened in the Homeric struggle that had broken out between Adolf Trendelenburg and Kuno Fischer over Trendelenburg's criticism of the Kantian transcendental aesthetic. Trendelenburg agreed with Immanuel Kant that the concepts of space and time are a priori, but he denied their exclusion from things-in-themselves, which was, in Kant's opinion, an unavoidable consequence of their intuitive apriority. According to Trendelenburg, a third possibility was left, namely the validity of space and time with regard to all existing objects *in spite of* the apriority of their *concepts*. Fischer, defending Kant against the charge of leaving this "gap," insisted that Kant's assignment of both space and time to human sensibility, in the transcendental aesthetic, was irrefutable. Cohen, a pupil of Trendelenburg, but not a favorite one, in an essay published in the above periodical (7 [3]: 239–296) gave the Solomonic judgment. Trendelenburg was right in criticizing Fischer, but wrong in criticizing Kant.

### PHILOSOPHICAL TEACHING

This judgment already contained in germ the whole of Cohen's future philosophical achievement. In the following year his first philosophical book, *Kants Theorie der Erfahrung* (Berlin, 1871) made it clear why, in his opinion, both Trendelenburg and Fischer were wrong. The teaching of the transcendental aesthetic, which showed space and time to be forms of our sensibility, had to be complemented by the teaching of the transcendental logic, where these forms are shown to be a priori conditions of possible experience. Possible experience, as Kant said throughout the *Critique*, is the only object of a priori knowledge. Therefore, the exclusive subjectivity of space and time, assumed by both parties to be Kant's complete view, disappears entirely if one takes into account the methodological difference between a psychological classification of space and time among native ideas and the

Kantian transcendental theory of their being the a priori conditions of the possibility of experience.

By thus extending the matter in question to the whole of Kant's theory of a priori knowledge, Cohen gave evidence of the philosophical turn of his gifts. In 1873 he presented to the philosophical faculty of Marburg a treatise titled *Die systematischen Begriffe in Kants vorkritischen Schriften* (Berlin, 1873) with an application for the *venia legendi* (lectureship). On the recommendation of F. A. Lange, Cohen's application was accepted. Lange died two years later, and in January 1876 Cohen, proposed by the faculty, was appointed to the vacant chair. He devoted his work to the fortification and extension of his new interpretation of Kant, which from the beginning had aroused admiration for the author's energy and devotion, though many doubted the compatibility of Cohen's interpretation with Kant's real opinion.

In any case, Cohen found himself confronted with a serious problem. If the objectivity of space and time consisted in their being a priori conditions of the possibility of experience, the question remained from what principle experience itself derived its validity. There was no identity between the conditions of experience and the conditions of things-in-themselves. This was unquestionably Kant's teaching. But, as Cohen observed, Kant had a new concept of experience. Actually, the innovation—if there was one—was David Hume's, not Kant's. Experience, according to Hume, is a statement on matters of fact presupposing some connection of these matters by general rules. The difference between Kant and Hume is not in the concept of experience but in the question of whether it is possible to justify the universality of that intellectual presupposition with regard to the objects of sense perception. Hume claimed it is not possible; those a priori assumptions are not a matter of intelligence at all. Man is driven to them by the laws of nature, which make him believe automatically in the possibility of experience.

This might not be a satisfactory answer. But Cohen's solution to the question—to derive the objectivity of those presuppositions (including space and time) from their being a priori conditions of experience—was not only not satisfactory—it was no answer at all. It was an answer that answered by what was the subject of the question. If, therefore, Cohen wished neither to accept the unconditioned subjectivity of Kant's possibility of experience nor to fall back on Hume's skepticism—which way was left to him?

It was the way of a cryptopositivism. The objectivity of doubtful a priori assumptions, such as space, time, and the categories, was demonstrable, according to Cohen, by

means of the “fact of science” (*das Faktum der Wissenschaft*). Surely it was a historical fact that Isaac Newton had used these assumptions as principles in establishing his mathematical theory of the phenomena of nature. It was also a fact that Newton was far from justifying the assumption of these principles by deriving them from experience. But this by no means made the fact of their use as nonempirical principles of natural science equivalent to the fact of an existing a priori knowledge of nature. It was, on the contrary, evident that none of Newton’s mathematical laws of natural phenomena, formulated in differential equations, could be called a knowledge of those phenomena if it was not verifiable by experience. How, then, could those principles presupposed by Newton’s physics assume the character of a priori requirements for the cognition of nature by the mere fact of being presupposed by Newton, if the cognitive character of these presuppositions with regard to natural phenomena was demonstrable only by experience?

Despite this unanswerable question, Cohen boldly proclaimed that Newtonian science demonstrated by its own historical facticity the possibility of an a priori knowledge of nature by means of the concepts of space, time, and the Kantian categories. He called the manner of this demonstration the “transcendental method.” It proved to be an enormous success. Cohen’s pupils vied with each other in showing that modern science would not have been possible if its promoters had not presupposed what they actually had—that is, space, time, and the principles assigned by Kant to pure understanding. This, if it was meant to be a legitimation of a priori knowledge of natural phenomena by means of those principles, was clearly a vicious circle.

The desire to escape this consequence determined Cohen’s philosophical development and the fate of neo-Kantianism in general. Cohen realized eventually that his transcendental method, if it were to prove effective with regard to a priori knowledge of nature, required the tearing down of the insurmountable barrier Kant had fixed between a priori and empirical knowledge by means of his distinction between sensibility as receptivity and understanding as spontaneity. Therefore Cohen posited a kind of thinking that originated by its own act the whole field of principles of our knowledge (“Denken des Ursprungs”). Thus, all human knowledge must be in principle a priori knowledge.

In *Die Logik der reinen Erkenntnis* (Berlin, 1902) Cohen elaborated this puzzling idea. He explained by abundant historical comments that the real task of metaphysics was the thinking of the origin. If this is to be

regarded as more than an utter triviality, it testifies that the author, in order to escape the deadly embrace of Hume, fled into the arms of Johann Gottlieb Fichte and G. W. F. Hegel. Once more he fell victim to the ancient illusion of being able to understand Kant better than Kant himself by dropping the conditions essential to the very problem of transcendental philosophy. Thus Cohen, however unintentionally, encouraged a new movement from Kant to Hegel in German neo-Kantianism. Even Heideggerian existentialism claimed some kinship with the critique of pure reason by proclaiming the search for the “common root” of sensibility and intelligibility, necessarily problematical with Kant, as a way of salvation from all possible transcendental problems.

### PRACTICAL PHILOSOPHY

Cohen similarly interpreted Kant’s moral philosophy according to the maxim that to interpret Kant one must go beyond him in his *Kants Begründung der Ethik* (Berlin, 1877). He inherited from Trendelenburg’s Aristotelianism the idea of virtue as the supreme problem of moral philosophy. Combined with the Kantian assumption of an a priori principle of morals, this idea generated the problem of ethics as the problem of an a priori science of virtue. Here again Aristotle intervened by his teaching that all other virtues are implied in justice. Thus, the problem of morals presented itself to Cohen as the problem of an a priori knowledge of justice. All a priori knowledge, according to Cohen’s transcendental method, required some factual science to justify it. Kant did not presuppose any such factual science in his *Critique of Practical Reason*. In this Cohen believed Kant to be mistaken. According to him, morals does have a basic science, jurisprudence, because the idea of justice is the constitutional law of this science. If there were no a priori law of justice, the sort of systematic knowledge of the laws that the Romans assigned to *iurisprudentia* would not be possible. In identifying *iurisprudentia* with *scientia iusti*, Cohen found that the a priori character of Kant’s categorical imperative was justified by the factual existence of jurisprudence.

### POLITICS

It is easy to observe that autonomy as conditioned by the categorical imperative is by no means the principle of a society that, like the state, is realizable under the conditions of experience. And it is no less easy to see that the positive laws of a given state, the objects of jurisprudence, in spite of the possibility of their being systematically treated by jurisprudence, do not necessarily agree with

some a priori idea of justice. Nevertheless, the idea of a human society constituted by the law of autonomy meant a quite personal engagement to Cohen, above and beyond all philosophical subtleties concerning its meaning or its justification. This engagement drove him from the field of transcendental deductions into politics. It made him a public champion of those whose personal dignity granted by the law of autonomy was infringed upon by society. He eventually found himself among them. Some years after he settled at Marburg, anti-Semitism appeared on the German political stage. The famous historian Heinrich von Treitschke published in his *Preussische Jahrbücher* (Vol. 1879, No. 11) an article in which he called attention to an attitude allegedly adopted by a good many Jewish writers, whom he accused of being antinational and anti-Christian. He held that they should respect the feelings of the majority. The weak point in Treitschke's pleas was the authority that he assigned to what in his romanticism he called Christian German culture.

Cohen in his *Eine Bekenntnis in der Judenfrage* (Berlin, 1880), without attacking Treitschke's romantic idea of a law given by Germano-Christian feeling, boldly announced that the Jews already belonged to the German nation—not *in spite of* their being Jews, but *because* they were Jews. This, of course, was too much for both parties. But to Cohen the philosopher and learned Jewish theologian it seemed quite simple to demonstrate. The Germans, he argued, are the nation of Kant. The Jews are a nation whose creed has been purified by the prophets. The teachings of the prophets, as Cohen's learnedness interpreted them, were identical with Kant's ethical idealism. Therefore, whoever tells a Jew that he can belong to the German nation only at the cost of his religion denounces him as having no true morality of his own. From that time on, Cohen continued as a collaborator in the interpretation of Jewish tradition by adapting it to his philosophy. His writings in this field were edited by Bruno Strauss and published with an introduction by Cohen's admirer Franz Rosenzweig as *Hermann Cohens jüdische Schriften* (3 vols., Berlin, 1924).

Besides the startling historical and ideological identifications of his Germano-Jewish patriotism, there was yet another reason for Cohen's reputation as a political outsider. It was not unusual to support the workingman's longing for a decent living according to the law of humanity. All the so-called *Katheders-Sozialisten*, among them some of the most influential professors of the German Empire, did it. But the mixture of philanthropy and justice that Cohen considered the supreme principle of his moral philosophy made him believe in a basic accor-

dance between the doctrine of Karl Marx and his own. Thus, he became responsible for the legend of a kinship between Kant and Marx. This was enough to color the politician Cohen with a red tinge—and if his true patriotic German feeling separated him from Jewish orthodoxy and Zionism, his rather innocent socialism did not make him a favorite with either his government or his faculty.

Hence, his retirement in 1912 brought a great disappointment with it. The faculty, not very fond of intricate transcendental deductions that were admired by students but doubted by philosophers, refused to give his chair to the man of his choice, Ernst Cassirer. The choice of his colleagues, Paul Natorp dissenting, was a young experimental psychologist.

### LATER RELIGIOUS VIEWS

Deeply hurt, Cohen left Marburg and retired to Berlin. There he devoted himself to a lectureship at the Lehranstalt für Wissenschaft des Judentums, of which he was already a member of the board of trustees. Thus, he was again a theologian. Meanwhile, his philosophy had dissolved theology into a transcendental deduction of the eternity of cultural progress governed by the "social ideal"; namely, the community of autonomous beings. But in actual fact there was no solid deduction even of this eternity. The question of whether religion had any meaning at all arose again. Cohen answered it in two books, *Der Begriff der Religion im System der Philosophie* (Giessen, 1915) and *Die Religion aus den Quellen des Judentums* (Leipzig, 1919). In both of these works the point of departure lies in the observation that the belief in the eternity of cultural progress is of little comfort to the individual in his personal sufferings. Therefore, an empty space has been left by philosophy. This space may be filled by God as a savior bringing personal consolation to all people. Cohen found this idea of the Divine Being splendidly expressed by the prophets and the Psalmist. But the mere idea of a powerful personal Helper does not cause that Helper to exist; and since this idea, according to Cohen himself, could not be justified by his philosophical system, the question of a savior's existence was left entirely to personal conviction. To the great satisfaction of his religious friends, Cohen, when he died, seemed to be in full possession of this conviction.

### AESTHETICS

The manner in which Cohen addressed religious problems in his last writings was prepared by his aesthetics. Aesthetics had been treated by Kant within the frame of

what he called the critique of judgment. Cohen's comment, published under the title *Kants Begründung der Ästhetik* (Berlin, 1889), once again disclosed the author's difficulty in harmonizing his own ideas in this field with the peculiar but at bottom simple Kantian theory of aesthetic pleasure.

In spite of the stock of questions left unanswered by Cohen's principles, he continues to live in the memory of philosophers as a Kantian who dominated to a great extent the philosophical discussions of his time. But if Cohen's own interpretation was attractive, it did not make Kant attractive; and his school of neo-Kantianism eventually expired. The unbearable viciousness of the famous gnosiological circle, wrongly imputed to Kant himself but inextricably woven into Cohen's own omnipresent transcendental method, drove the younger generation to the worship of new gods. But even so, Cohen has left a stimulus to study "that Kant" whom, as one of his pupils is reputed to have said, "nobody ever knew." The feeling expressed by these words was precisely Cohen's own feeling when he began his work.

## COHEN, HERMANN [ADDENDUM]

Philosophical research between 1960 and 2004 looked at Cohen's thought from both a historical and a theoretical viewpoint. In the age of the integration of German Jews

into German society, he was the foremost advocate of the need for a meeting between the Enlightenment and Judaism.

Cohen had an important influence on various philosophical fields. Ernst Cassirer's neo-Kantian approach to human culture (1943) and J. B. Soloveitchik's neo-Kantian attitude to religion, particularly Judaism (1986), owe their method to his work. Both Husserl's and Heidegger's interpretations of Kant's transcendental philosophy, and therefore the phenomenological or existentialist concept of the *self*, derive from Cohen's theory of knowledge (Dussort 1963, Vuillemin 1954). Hans Kelsen's juridical positivism was inspired by Cohen's idea of "natural right" (Winter 1980). Franz Rosenzweig's philosophy of divine revelation—as a bond between a human being and God through "religious love"—stems from Cohen (Altmann 1970). Lastly, Cohen's essays on the history of philosophy influenced Leo Strauss's interpretations of Spinoza, Maimonides, and the relation between "Jerusalem" and "Athens" (Kajon 2002).

Cohen's logic has inspired examinations into the fundamental principles of mathematics and physics (Holzhey 1986). Unlike Hegelianism on the one hand and postmodernism on the other, Cohen's ethics sought the relation between reason and the facts of law, state, and history (Gigliotti 1989). His aesthetics invites a criticism of *art for art's sake* (Poma 1997). His philosophy of religion expresses the need for a "religion of reason" which keeps the profundity of religious life (Zac 1984).

Cohen's thought stems from both Jewish tradition and European idealism, hence its fertile, albeit problematic, character.

## COHEN, MORRIS RAPHAEL (1880–1947)

Morris Raphael Cohen, the American naturalistic philosopher, was born in Minsk, Russia. When twelve years old, he was brought to New York City by his parents, who immigrated to America in search of greater opportunity and freedom. In his early youth he came under the influence of the Scottish freelance scholar Thomas Davidson. Cohen was graduated from the College of the City of New York (City College) in 1900 and received his PhD in philosophy from Harvard University in 1906. At Harvard he studied under Josiah Royce, William James, and Hugo Münsterberg.

From 1912 to 1938, Cohen taught philosophy at City College. He was an outstanding teacher, and some of his students became eminent teachers, philosophers, and lawyers. He was a visiting lecturer in philosophy at Johns Hopkins, Yale, Stanford, and Harvard and from 1938 through 1941 was a professor at the University of Chicago. For years he gave courses at the New School for Social Research. He was also a lecturer at the law schools of St. John's University, Columbia, Yale, Harvard, Cornell, the University of Buffalo, and New York University. Although an agnostic, he had been a dedicated Jew. His wit, his critical spirit, his erudition, and his interest in a

wide range of friends made him a colorful and animating person.

Cohen's philosophic interests included the philosophy of science, metaphysics, logic, social philosophy, legal philosophy, and the philosophy of history. His contribution to legal philosophy has been especially widely recognized.

### METAPHYSICAL AND LOGICAL PRINCIPLES

Cohen's general philosophic outlook is naturalistic. There is no place in his philosophy for the extranatural and no place for extrascientific methods to attain knowledge. His outlook is also rationalistic, for he assumed that rationality is inherent in nature. His philosophy is based on three principles: rationality, invariance, and polarity. These three principles, coherently interwoven, provide his view of reality.

**RATIONALITY.** In its long history the concept of rationality has acquired a variety of meanings. It has meant logical order, inductive generalization, and wisdom. Each of these meanings has been significant. Cohen did not offer an inclusive definition of rationality, but in his philosophy of nature the first meaning is dominant and in his ethical and legal philosophies the third meaning is central.

Rationality as logical order may be considered methodologically or ontologically. Methodologically, it is a procedure to order our objects of thought in a logical way. Most philosophers, except for mystics and irrationalists, feel the necessity of such a procedure. Yet Cohen went beyond the methodological use of rationality and insisted on its ontological status. The rules of logic and pure mathematics "may be viewed not only as the principle of inference applicable to all systems but also as descriptive of certain abstract invariant relations which constitute an objective order characteristic of any subject matter" (*Reason and Nature*, p. 142).

For Cohen, as a logical realist, the formal aspects of logic apply to everything. As against idealists, positivists, and pragmatists, he was firm in insisting that the rational order is independent of human or superhuman mind. Idealists, according to him, deny the objectivity of logical order by giving it only a psychological status, but the psychological description of reasoning as a mental event cannot determine, according to him, whether a given logical argument is valid. Positivists, his arch philosophic enemies, fall short in a similar way. As sensations are considered the only deliverance of the external world, for

positivists logical connections are mere fictions. Pragmatists, he argued, similarly depreciate the status of rational order. In their attempt to interpret the truth of judgment in terms of practical consequences, they consider logical relations as merely practical tools of thought without any ontological standing.

However, Cohen admitted an element of contingency in nature. “By no amount of reasoning,” he wrote, “can we altogether eliminate all contingency from our world” (ibid., p. 82). The universe is ultimately what it is, and contingency cannot be eliminated. And by contingency Cohen meant that the world contains an irrational element in the sense that “all form is the form of something which cannot be reduced to form alone” (*Studies in Philosophy and Science*, p. 11).

**INVARIANCE.** Science is not, as Cohen rightly pointed out, a mere observation of particular facts; it is never satisfied with stating only what has occurred. The aim of science is to determine the universal, invariant relations of particular events. To say that sulfur has melted at 125°C. is a mere statement of fact similar to the statement that Russians for generations have used the Cyrillic alphabet, but to say that sulfur always melts at 125°C. means that if ever anything conforms to the category of sulfur, it melts at this temperature. The second statement expresses not only a historical event but also an invariant relation that belongs to “the eternal present.”

Although the essence of particular things is their invariant relations, our knowledge of these is only probable. Only in logic or in mathematics can we attain certainty; in the world of facts our knowledge is only probable, for we cannot prove that the opposite of a given factual statement is absolutely impossible.

**POLARITY.** According to the principle of polarity, opposites involve each other. As Cohen expressed it in *Reason and Nature*, “Opposites such as immediacy and mediation, unity and plurality, the fixed and the flux, substance and function, ideal and real, actual and possible, and so on, like the north (positive) and the south (negative) poles of a magnet, all involve each other when applied to any significant entity” (p. 165).

In addition to its methodological value as a guide to the clarification of ideas, the principle of polarity, like the principle of rationality, has ontological status. Empirical facts, such as the existence of the north and south poles, are said to be resultants of opposing tendencies. Cohen generalized this alleged fact as the principle of “the neces-

sary copresence and mutual dependence of opposite determinations.”

## ETHICS

Historically, there have been two major opposing theories of morality—the absolutist and the relativist. Cohen examined both of these theories and found them unsatisfactory. The absolutist is too rigid and uncritical; the relativist is too chaotic, without guiding principles. Cohen thought the principle of polarity could reconcile the two opposing views. Actually, these two views provide a vantage point for arriving at the truth. Concretely, every issue of life involves choice. The absolutist is right “in insisting that every such choice logically involves a principle of decision,” and the relativist is right “in insisting on the primacy of the feeling or perception of the demands in the actual case before us” (ibid., p. 438). We may thus have an ethical system that is rigorously logical and at the same time richly empirical. Such an ethics must be grounded in what human beings desire and believe, and yet its primary condition must be the logical analysis of judgment as to what constitutes right and wrong, good and evil—an ethic that is the rational formulation of our ends.

## LAW

Cohen was a pioneer in introducing legal philosophy as a significant study to universities and law schools. As Leonora Cohen Rosenfield wrote, “His philosophical treatment of the law in relation to man and the social order may prove in time to be his foremost influence.”

For Cohen law is essentially a system for the orderly regulation of social action. Jurisprudence must avoid the extremes of positivism and formalism. “Law without concepts or rational ideas, law that is not logical is like pre-scientific medicine—a hodge-podge of sense and superstition,” yet law without reference to the actual facts of human conduct would be empty. A law is both stable and dynamic; it is a balance between prevailing customs and the emerging demands of society. Cohen was especially critical of what he called the “phonograph theory of law,” the theory that the judge arrives at his decision in a mechanical way, according to unchanging laws. Cohen effectively argued that the judge’s opinions on social and economic questions deeply influence his decisions. One of the chief merits of his analysis of law is his insistence on the interdependence of the factual and the normative. As he maintained, “Justice and the law, the ideal and the actual are inseparable, yet identifiable.”

## COHERENCE THEORY OF TRUTH

The coherence theory is one of the two traditional theories of truth, the other being the correspondence theory. The coherence theory is characteristic of the great rationalist system-building metaphysicians Gottfried Wilhelm Leibniz, Benedict (Baruch) de Spinoza, G. W. F. Hegel, and Francis Herbert Bradley; but it has also had a vogue with several members of the logical positivist school, notably Otto Neurath and Carl Gustav Hempel, who were much influenced by the systems of pure mathematics and theoretical physics. According to the coherence theory, to say that a statement (usually called a judgment) is true or

false is to say that it coheres or fails to cohere with a system of other statements; that it is a member of a system whose elements are related to each other by ties of logical implication as the elements in a system of pure mathematics are related. Many proponents of the theory hold, indeed, that each member of the system implies every other member. To test whether a statement is true is to test it for coherence with a system of statements. The system with which all true statements must cohere is said by its logical positivist supporters to be that accepted by the scientists of the contemporary culture. The metaphysical supporters of coherence, on the other hand, insist that a statement cannot properly be called true unless it fits into the one comprehensive account of the universe or reality, which itself forms a coherent system. In either case, no statement can be known to be true until it is known to cohere with every other statement of the system; where the system consists of all true statements, such knowledge is unattainable.

It is not altogether possible to give a plausible exposition of the theory independently of its close historical links with rationalist and idealist metaphysics, but the account might go something like this.

In practice, we sometimes reject as false an ordinary person's assertions—for instance, that he saw a ghost—or even a scientist's results—for instance, in experiments on extrasensory perception—on the ground that they do not cohere with the other commonsense or scientific views that we also hold as true.

### MEANING OF TRUTH

In the exact and reputable science of pure mathematics, the logical test for the truth or acceptability of any proposition is whether it coheres with some of the other propositions, and ultimately with the axioms, of its system. In this test, which is not merely a practical one, for a proposition to cohere with other propositions is for it to be logically deducible from them. Further, this coherence is what we mean by calling such a proposition true.

**INTERNAL RELATIONS.** It is characteristic of the parts of a logical system like that of pure mathematics that no part would be what it is if its relations to the other parts were different from what they are. Thus, 2 would not be the number we associate with the numeral 2 if it were the third of 4 instead of the half of 4 or the cube root of 27 instead of the cube root of 8. Hence, it is said, the meaning and the truth of, for instance, " $2 + 2 = 4$ " are bound up with the meaning and the truth of all the other statements in the arithmetical system; and our knowledge of

its meaning and its truth is bound up with our knowledge of their meaning and their truth. This principle that nothing would be what it is if its relations to other things were different—which is called the doctrine of internal relations—holds, say the metaphysical supporters of coherence, for every element, whether in thought or in reality. For example, they argue that we would not even understand, much less know the truth or falsity of, a statement about something blue if blue were “divorced in our thought from all the colours in the spectrum to which it is related by likeness and difference, all the shades within its own range, and all the definition it possesses in virtue of being thought as a quality rather than as a substance or a relation” (Brand Blanshard, *The Nature of Thought*, Vol. II, p. 316). Further, not only would we not know the meaning or truth of such a statement, but it also cannot properly be said to have its meaning or truth-value independently of its relations to other statements. The statement “Caesar crossed the Rubicon in 49 BCE” is said to be pregnant with a meaning “owing to the concrete political situation within which it took place” that it would not otherwise have.

**DEGREES OF TRUTH.** A corollary of the principle of internal relations and of the coherence theory in general is the doctrine of degrees of truth. If the truth of any given statement is bound up with, and can only be seen with, the truth of all the statements of the system and thus is bound up with the whole system, it is argued that individual statements as such are only partly true—and, therefore, partly false—while only the whole system is wholly true. “Truth,” said Bradley, “must exhibit the mark of expansion and all-inclusiveness.”

### CRITERION OF TRUTH

Coherence theorists might admit that their arguments hitherto have been drawn from the nature of the a priori reasoning typical of mathematics and metaphysics; but some have also claimed that an examination of the a posteriori reasoning of the empirical sciences and ordinary life also supports the theory, not only as giving the meaning of “truth” but also as giving the test of truth (ibid., pp. 226–237). In testing for truth it is obvious, runs the claim, that coherence is our only criterion when dealing with statements about the past. No one can now compare the statement that the battle of Hastings was fought in 1066 with anything else than other statements, such as those that occur in documents, history books, or works of art. However, we can contrast with this a statement about something present, such as “There is a cat on the mat.” If asked how you would test this, your reply might be “I

would look and see. If what I saw corresponded to what was asserted, I would call the judgment true.” However, you are assuming that “there is some solid chunk of fact, directly presented to sense and beyond all question, to which thought must adjust itself” (ibid., p. 228). What you take and use as a fact is really “another judgement or set of judgements, and what provides the verification is the coherence between the initial judgement and these” (ibid.). Consider how much of your previous experience and education, how great an exercise of your powers of conceptualization, has gone into your perception of the cat on the mat; how much, in a word, your supposed perception of fact is really a judgment, since, without a stock of judgments, what is seen could never be identified as a cat and a mat, respectively. Your test of the truth of the judgment that there is a cat on the mat or your comparison with what was there turns out to be a comparison of the original judgment with another judgment. This example, in addition, shows not only that coherence is the test or criterion of truth, but also that it gives the meaning of “truth,” for it shows that the truth of the tested judgment consists in its coherence with other judgments and not with something other than a judgment.

### ASSUMPTIONS OF THE THEORY

The arguments used by supporters of the coherence theory rest on various assumptions about meaning, fact, thought, and judgment that are linked partly with the impression made on them by the a priori reasoning of mathematics and logic and partly with their theory of knowledge.

**A PRIORI AS PARADIGM OF TRUTH.** Metaphysics is traditionally nonempirical; its conclusions are a priori deductions from certain tenets, such as George Berkeley’s “To be is to be perceived” or Zeno’s analysis of infinity. The conceptual statements typical of philosophy—such as that no one can know what is false, that no one can know what has not yet been proved, or that no one can know what is going to be—are true or false because of logical relations between such concepts as knowledge, truth, proof, and the future. Further, ever since Plato, mathematics has been the metaphysician’s ideal; Leibniz’s system was based on certain principles that he held to characterize logic and mathematics, and Spinoza’s famous book on ethics is subtitled “proved in geometrical order.” Some of the logical positivists, because of their training in mathematics and theoretical physics, sought to establish all knowledge as a vast system of logically interrelated statements expressed in the language of physics. In such systems, the criterion of truth is indeed

the coherence of the statement under consideration with at least some other members of the system.

*Criticism.* Coherence of a statement with other members of the system is not sufficient to prove the coherence theory of truth. First, the a priori statements typical of pure mathematics, unlike the empirical statements of science and everyday life, serve not to give information about characteristics of objects in the world but to show the various conclusions that can be derived from a given set of axioms and a given set of rules for operating on them. It is no objection to the truth of a given mathematical statement that there are or may be other systems with whose members it does not cohere or that it is a member of a system with no application to the world.

However, it is an objection to coherence as the meaning of “truth” or as the only criterion of truth that it is logically possible to have two different but equally comprehensive sets of coherent statements between which there would be, in the coherence theory, no way to decide which was the set of true statements. To reject a particular empirical statement like “He saw a ghost” because it conflicts with the body of our beliefs is not to assimilate the judgments of everyday life to those of mathematics, since this rejection, unlike the analogous one in mathematics, is made only because we think the body of our everyday beliefs has already been shown to be true of the world. Coherence of one judgment with another is accepted as a practical test of truth only because the second judgment is independently accepted as true.

Metaphysical supporters of the coherence theory distinguish their comprehensive system from particular systems such as those of mathematics by linking it to experience by means of their theory of knowledge, which assimilates what is thought, what is experienced, and what is. This appeal to experience and reality is indeed an inconsistency in the metaphysical version of the coherence theory, but it is more sensible than the position of the logical positivist supporters of the theory, who, in the name of consistency, allow that mutually incompatible but internally coherent systems of statements differ not in truth but only in the historical fact that our contemporaries have adopted one of the systems.

Second, there is in the a priori statements typical of mathematics and philosophy a close connection between meaning and truth. Such statements as “Twice two is half of eight” or “What is known cannot be false” are true in virtue of the meanings of the words that express them; it is because the meanings of the words are internally related as they are that these statements are true. It is not because of the relations between the meanings of “knowl-

edge” and “breakfast,” however, that it is true that no one knows what Pompey had for breakfast on the day he was murdered, nor is it because of the relations between the meanings of “two” and “four” that it is true that I made two mistakes on page four of my typescript.

Third, even within mathematics coherence gives the criterion, not the meaning, of truth. Mathematical statements are true in virtue of the criterion of coherence with each other, whereas it would seem that empirical statements are true in virtue of the criterion of correspondence with the nature of the world. However, to say that either kind of statement is true is to say that what it asserts is a fact. Whether “ $X$  is  $Y$ ” is a mathematical or an empirical statement, if “ $X$  is  $Y$ ” is true, then it is a fact that  $X$  is  $Y$ .

Fourth, even when confined to mathematics, the coherence doctrine of degrees of truth does not seem tenable. The fact that a given statement in mathematics is not true unless it coheres with some (or even all) other statements in the system does not imply that it is not itself wholly true; it could at most imply that it does not give the whole truth.

*Ambiguities in degrees of truth.* It is worth pointing out here how the theory of degrees of truth depends for its plausibility and its air of paradox on various ambiguities. There are at least three different ways in which we may qualify truth. First, we commonly ask how true something is, meaning how much truth is there in it, and commonly reply that it is partly, entirely, or perfectly true. For example, [in 1967] the report that African-Americans in the southern U.S. have been deprived of their right to vote might be said to be not quite true, either on the supposed grounds that they have been denied the opportunity to exercise their right rather than been deprived of it or that, although there has been a deprivation of the right, it is women who have been deprived.

Second, instead of asking how much truth there is in something, we may quite differently ask how much of *the* truth there is in it. To ask how much truth there is in something is to ask how much of what is not true is included; to ask how much of *the* truth there is in something is to ask how much of what is true is not included. A particular statement could be perfectly true without containing more than a minute proportion of the whole truth. Being wholly true is not the same as being the whole truth, nor is being partly true the same as being part of the truth. What is only partly true is necessarily partly false, but what is part of the truth may be entirely true.

Third, we can, in the case of general statements like “Water boils at 100° C,” ask how far or under what conditions it is true. It may, for example, be true of water at sea level but not at high altitudes.

When coherence theorists say that every statement is only partly true, they usually seem to mean that every statement is only part of the truth, since nothing but the whole system of statements can give the whole of the truth. What they mean, therefore, is quite correct but wrongly expressed, because they have confused the first and the second of the above qualifications of truth. A typically ambiguous assertion is Blanshard’s remark that “the trueness of a proposition is indistinguishable from the amount of truth it contains.” At other times, as in their discussion of mathematical statements, by “degrees of truth” they mean “true in certain conditions.” Thus, the statement “ $2 + 2 = 4$ ” is said to be only partly true, as it is true in pure mathematics but not necessarily in all applied fields. Here again, what is meant is correct enough—not that such statements are not perfectly true, but that they are not universally true. The main reason, however, for the coherence theorists’ belief in degrees of truth is based on a mistaken deduction from their doctrine of internal relations. Because each statement is, according to this doctrine, logically connected with other statements, it follows both that the truth of each statement is dependent on the truth of other statements and that our knowledge of its truth depends on our knowledge of the truth of these other statements. What appears to be true might turn out to be false when its further connections become known. Hence, it is said, “a given judgment is true in the degree to which its content could maintain itself in the light of a completed system of knowledge.” This conclusion, however, is mistaken. A statement can be perfectly true in itself even though it would not have been true unless it had been connected in certain ways with other true statements; and it can be perfectly true whether we know this or not.

**EPISTEMOLOGICAL ASSUMPTIONS.** The second main influence in the usual defense of the coherence theory—that of a particular theory of knowledge—can be seen most prominently in the argument for transforming the commonsense belief that a statement (or judgment) is true if and only if it corresponds to facts into the doctrine that the judgment is true if and only if it coheres with another judgment or set of judgments. The first move in this transformation is from (a) “‘There is a cat on the mat’ is true if and only if it corresponds to the fact that there is a cat on the mat” to (b) “‘There is a cat on the mat’ is true if and only if it corresponds to the situation

described as ‘There is a cat on the mat.’” This is an illegitimate move, however, since a fact is not a situation, an event, or an object; otherwise we would have to postulate negative and conditional situations, events, and objects, to be described by such statements as “It is a fact that no one has yet succeeded in doing this” and “It is a fact that anyone who did succeed would be munificently rewarded.” Hence, even if the moves designed to show that the situations, events, and objects we discover are not independent of our method of discovering them were valid, they would not show that facts are not independent of our methods of discovering them.

The second move in the transformation is from (b) “‘There is a cat on the mat’ is true if and only if it corresponds to the situation, event, or object describable as ‘There is a cat on the mat’” to (c) “‘There is a cat on the mat’ is true if and only if it corresponds to what is verified to be a cat on the mat.” This is illegitimate, however, since (b) is an explanation, although a false one, of the meaning of “true,” whereas (c) contains the reason why someone might hold that there is a cat on the mat. Something can be true without anyone’s knowing it to be true, although, of course, no one would sincerely say it was true unless he thought he knew it was. Idealist supporters of the coherence theory, like Bradley, move easily from (b) to (c) because they tend to identify reality with experience and knowledge, what is with what is experienced or with what is known. Further, they move distractingly to and fro between assertions about truth and assertions about *the* truth (the whole truth, the ultimate truth, a part of the truth), from assertions about the notion of truth to assertions about that which actually happens to be true. Thus, they speak of the identity of reality and truth when they mean the identity of reality and *the* truth, that is, what is true.

The third move in the transformation is from (c) “‘There is a cat on the mat’ is true if and only if it corresponds to what is verified to be a cat on the mat” to (d) “‘There is a cat on the mat’ is true if and only if it corresponds to a verification, or an experience, that would be expressed in the judgment (or, in logical positivist language, ‘the observation statement’) ‘I see (or there is) a cat on the mat.’” Because of this move they rule out the correspondence theory as a test of the truth of statements about the past, since there can be no verifying experience about what happened in the past. This move, too, is illegitimate because it assimilates what is verified, or experienced, to the verification, or experience, of it—the cat on the mat that I perceive to my perception of the cat on the mat. Such an assimilation is a standard part of the theory

of knowledge of the Idealist metaphysicians, but an analogous assimilation is made by some logical positivists who, in their talk about observation statements, do not carefully distinguish between the report of what is discovered and that of which it is a report. Having reached (*d*), the coherence theorist then emphasizes how much our previously acquired powers of judgment are exercised in this experience. He concludes that the second term with which our original judgment that there is a cat on the mat corresponds is not, as we thought, a fact; it is really another judgment or set of judgments.

Whether the whole argument is designed to show that correspondence is really coherence when the correspondence is put forward as giving the nature of truth or only when it is put forward as giving the criterion of truth, it seems equally invalid.

What the coherence theory really does is to give the criteria for the truth and falsity of a priori, or analytic, statements. Any attempt to change the meaning of “coherence” from coherence with other statements to coherence with fact (or reality of experience) is to abandon the theory. A merit of the theory is that it sees that the reasons for calling an analytic statement true or false are not those which some correspondence theorists, primarily thinking of empirical statements, try to fasten on all statements. When it sets itself up as the theory of truth, its mistake is twofold. First, it suggests that the criteria appropriate to a priori, or analytic, statements apply to every kind of statement; what the metaphysicians really did was to suppose all statements to be a priori.

Second, it confuses the reasons, or criteria, for calling a statement true or false with the meaning of “truth” or “falsity.” As far as the criteria of truth are concerned, we can say only of a priori, or analytic, statements that they are true because they cohere with each other, and only of empirical statements that they are true because of what the world is like; however, as far as the meaning of truth is concerned, we can say of any kind of statement that it is true if it corresponds to the facts. Thus, as well as saying that a true a priori statement coheres with other statements in the system, we can also say that it corresponds to the a priori facts. It may be a fact that the sum of the angles of a Lobachevskian triangle is less than two right angles and also that the field of Waterloo is a mile square. What we must remember is that although both sorts of statements, if true, state the facts—tell us how things are—this amounts to something different in the two cases; the size of the angles of a Lobachevskian triangle is not something in the world in the way that the size of the field of Waterloo is.

## COHERENTISM

One of the three major views of the nature of epistemic justification, the coherence theory (or "coherentism") experienced a revival during the 1970s and 1980s after its near total eclipse earlier in the twentieth century. Although its origins can be traced to idealists, including Francis Bradley, Bernard Bosanquet, and Brand Blanshard, the coherence theory has more recently been espoused by empiricist-minded contemporary philosophers such as Wilfrid Sellars, Nicholas Rescher, Keith Lehrer, Gilbert Harman, and Laurence Bonjour. The coherence theory of justification stands as an alternative to both the more traditional foundations theory and the view called reliabilism. It should not be confused with a coherence theory of truth. A coherence theorist about justification can acknowledge a fact that cripples the coherence theory of truth, namely, that there are instances of coherent, hence justified, beliefs in falsehoods.

Although the details of different versions of the coherence theory vary widely, all versions share a positive thesis and a resulting negative claim. The coherence theory's positive thesis is that a belief is justified or warranted for a person to the degree that that belief coheres with the rest of that person's belief system. As a fabric derives its strength from the reciprocal ties and interconnections among its constitutive threads, so, for the coherentist, beliefs derive their justification from their interconnectedness with one's other beliefs. The negative claim endorsed by all coherentists is that foundationalism is in error when it asserts that some of our justified beliefs are privileged or basic—that is, their justification is at least partly independent of their connectedness with other held beliefs.

The coherentist's picture of mutual support or fit among our beliefs departs (to varying degrees) from the strictly linear image of justification that classical foundationalism endorses. For the foundationalist epistemic jus-

tification is transmitted to nonbasic beliefs, from those that are basic or foundational, along lines of inference and explanation. Inferred beliefs are justified by those from which they are inferred. For the coherentist the belief's justificatory status has less to do with the grounds on which a belief is based and more to do with the whole cluster of relations (of consistency, implication, probability, explanation, and the like) that more or less strongly fix that belief within the network of other held beliefs.

The exact nature of epistemic coherence, however, is very difficult to clarify, and disagreements occur even among coherentists. Some have argued that coherence is always and ultimately explanatory coherence, a question of whether a belief is a member of the best overall explanatory account accessible to an individual. Others claim that there are justificatory relations of comparative reasonableness of competing beliefs that reflect concerns wider than explanation alone, including measures of subjective probability and the relative informativeness of the proposition believed. Logical consistency seems to be a minimal necessary condition for maximal coherence, but some have argued that at least certain inconsistencies are unavoidable but do not so undermine coherence as to prevent beliefs from being justified. Speaking generally, coherence is a property of a belief system that is determined by the (various) connections of intelligibility among the elements of the system. Most agree that these include deductive, inductive, and abductive relations, as well as other explanatory and probabilistic connections. Some writers, especially pragmatists, are prepared to add relations such as the relative simplicity or the power of the explanations contained in one's belief system as contributors to overall coherence.

Motivation for the coherence theory comes most directly from finding foundationalism unworkable and believing as a consequence that some version of coherence must be correct. Another motivation comes from the observation that it seems apt and possible to ask about any belief what a person's reasons are for holding it. The theory also appears particularly compatible with the realization that all instances of epistemic justification are defeasible—that is, the justification of a given belief is always liable to undermining by other held beliefs, no matter how strong the initial grounds or evidential basis of the belief might be. Since undermining can come from any element of one's system that might be negatively relevant to a specific belief, it appears that complete epistemic justification, the kind necessary to support claims of knowledge, is sensitive to all of the connections among our beliefs, precisely as the coherence theorist urges. This

argument for the coherence theory is not decisive, however, since foundationalists can freely admit that warrant is undermined by a lack of coherence while still rejecting the coherentist's positive claim that coherence is the source of all epistemic justification.

In addition to the unclarity surrounding measuring degrees of coherence, numerous objections have been offered to coherentism. Four have been particularly prominent.

### THE CIRCULARITY OBJECTION

If there are no foundational beliefs that act as the ultimate source of epistemic justification, and if the lines of justification transmission are not infinitely long (which appears absurd given the finitude of our mental capacities), then the coherence theory seems forced to claim that justification can be ultimately but not viciously circular. It is not immediately clear how circularity of this sort is anything but vicious, no matter how wide the circle may be, even though some have argued that wideness of a justificatory circle immunizes against viciousness. But if *A* is the source of justification for *B*, how can *B* be the source of justification for *A*? The coherentist can reply that the "source" of justification is the entire belief system. The linear model of justification on which the circularity objection is based may not be forceful against a more holistic construal of the relation. Taken as a holistic and higher-order relation constituted by lower-order reciprocal relations (at least some of which are asymmetric, such as "explaining" and "being explained by"), coherence might be able to avoid the problem of vicious circularity.

### THE PROBLEM OF PERCEPTUAL BELIEFS

Certain simple and apparently immediate perceptual beliefs seem to be justified for us on the basis of the perceptual experience we currently are having rather than on any considerations about how that belief coheres with the rest of our belief system. Experience often seems to warrant beliefs that are anomalous—that is, do not cohere with already-held beliefs. In such cases we do not think that we are justified in rejecting the new belief on grounds of incoherence but often concede that revision of some previously held beliefs is appropriate. Coherentists have replied to this objection by arguing that the justification of even the most immediate perceptual belief requires that that belief cohere with our metabeliefs regarding how reliable or trustworthy we take our perceptual processes to be in the particular conditions. It is

such metabeliefs that make it more reasonable to accept the anomalous perceptual experience than it is for us to conclude that we are hallucinating or have been deceived in some fashion. The introduction of metabeliefs into the explanation why immediate perceptual beliefs are often justified for us has struck many, however, as overintellectualizing our epistemic situation, as well as possibly reintroducing foundational principles into the theory of justification.

### THE ISOLATION OBJECTION

This objection, closely related to the problem of perceptual beliefs, begins with the observation that coherence is a cognitively internal relation, relating belief to belief. But might not a thoroughly coherent system of beliefs nonetheless fail to be justified because they are not properly linked to the external perceptual circumstances? Would acceptance of a coherent fiction be justified if it were entirely the product of wishful thinking? The continual perceptual input we receive from the world must be assimilated into our belief system or else the justification for those beliefs will often suffer from undermining. The coherence theory seems too internalist to be a complete theory of epistemic justification, the objection concludes. Since coherence does not necessarily serve the epistemic goals of pursuing truth and avoiding error in our belief system, further constraints seem necessary if our notion of justification is to relate appropriately to knowledge. Coherentists respond in a number of ways to the isolation objection.

One alternative is to admit the objection's force and add a requirement that all justified systems include the belief that certain kinds of spontaneously occurring beliefs such as perceptual and memory beliefs are reliable or likely to be true. Demonstrating that this constraint is not an ad hoc amendment to coherentism is a difficult matter. A similar requirement applied to acceptances based on spontaneous wishful thinking would be obviously ad hoc and unacceptable. Some have suggested that metabeliefs about the trustworthiness of our perceptual beliefs in certain circumstances are not ad hoc and are important and legitimate members of our belief system, justified, as all beliefs are, through their coherence with our other beliefs. Whether such beliefs can be noncircularly defended, whether they constitute a sort of foundational belief, and whether they are realistically necessary for epistemic justification are each open matters.

## THE INFERENTIAL-STRUCTURE OBJECTION

The foundationalist's traditional view—that whether one is epistemically justified in believing some proposition depends crucially upon the actual course of inference taken in arriving at a belief—is not easily relinquished. Coherence, however, is a relation determined only by the contents of beliefs and not by the order in which they have been inferred. Consequently, it appears possible that a series of beliefs inferred one from the other in a wholly fallacious manner might nevertheless cohere maximally with a background system of beliefs as long as there is another valid (but unused) course of inference that does connect them. This leads to the conclusion that, even if the coherence theory adequately captures the concept of epistemically justifiable beliefs relative to a system, it fails to explicate the notion of being justified in believing a proposition. Coherentists have responded to this challenge by relying once more on metabeliefs, claiming that when we infer *A* from *B* and *B* from *C* we also accept or believe that *A* follows from *B*, and not, for example, that *C* follows from *A*. Incorrect metabeliefs will, on some versions of coherentism, cause incoherence and loss of justification, keeping blatantly fallacious reasoning from ending in justified beliefs. This response, however, may generate an infinite regress of metabeliefs. Not all uses of inference schemes contain premises stating that the scheme is valid. One can infer *B* from *A* without first having to infer that *B* follows from *A*. Some coherentists answer this and other objections by admitting that their proposed conditions for coherence constitute ideals to which human knowers should aspire but seldom in actuality achieve. Debate over the merits of the coherence theory promises to continue unabated.

## COLERIDGE, SAMUEL TAYLOR (1772–1834)

Samuel Taylor Coleridge, the critic, romantic poet and philosopher, was born four years before the publication of Jeremy Bentham's *Fragment on Government*, and died only two years before the death of Bentham's most influential disciple, James Mill, at a time when the young John Stuart Mill was making a brilliant success in political journalism. The striking fact about Coleridge's place in English intellectual history, however, is that he developed a form of idealism in virtual isolation from the mainstream of empirical philosophy. In developing his own philosophical insights, Coleridge turned to Immanuel Kant. He had two reasons for doing this. First, he was deeply dissatisfied with the mechanistic theory of mind still flourishing in English philosophy, since he was unable to formulate within its terms certain views about poetic imagination; while Kant's *Critique of Judgment* (1790) had, however, set out with great rigor, and within a much more tractable conceptual framework, views essentially similar to Coleridge's own.

Second, Coleridge thought he saw in Kant's Transcendental Dialectic a way of combating the chronic latitudinarianism in English theology that had predominated throughout the eighteenth century and continued until the time of the Oxford Movement. But it must be remembered that although Coleridge was a serious student of Kant and one of Kant's earliest and ablest English interpreters, he was not a systematic or academic philosopher. His philosophical writings are always disorganized, eclectic, aphoristic. Philosophy became for him what poetry had always been: a necessary means for self-analysis, for the objectification of his personal engagement with life.

### PHILOSOPHICAL DEVELOPMENT

What can be very schematically called the first stage in Coleridge's philosophical development was a highly enthusiastic acceptance in 1794 of David Hartley's theory of association and the "necessitarianism" which that doctrine seemed to imply. Also at this time, after an intense

study of John Locke and of William Godwin's *Inquiry concerning Political Justice* (1793), Coleridge became strongly inspired by the Enlightenment ideal of social perfectibility. So inspired was he that in December of that year, having had these enthusiasms reciprocated by Robert Southey, he left Cambridge without taking his degree. In January 1795 he lectured at Bristol on religion and politics and became preoccupied with Southey on the project of a pantisocracy, an ideal socialist community consisting of twelve young men and their wives, which was to be established on the banks of the Susquehanna. This project never really got under way; but its rather serious practical outcome for Coleridge was his marriage on October 4, 1795, to the uncomplicated Sara Fricker, sister of Southey's pantisocratic fiancée. Coleridge's early marriage was unfortunate because it prevented his developing what would have been in every way a more compatible relationship with Sara Hutchinson, whom he met through the Wordsworths in 1799 and whose inaccessibility he spent the greater part of his life lamenting. (Thus the celebrated *Dejection: An Ode*, written in 1802, should be considered more as a crescendo in this lament than as a statement of any alleged conflict between imagination and metaphysics.)

Despite his temporary acquiescence in Hartley's psychology, it was in fact Hartley's theology that most of all appealed to Coleridge. In particular, Hartley's idea of an ascending scale of affections, from primary sensations of pleasure and pain through new complexes of association to self-interest and eventually to sympathy, moral sense, and theophany (*Religious Musing*, 1794–1796) made a lasting impression on him. To this idea, conceived of mechanistically by Hartley, Coleridge later found an organically conceived analogue in Friedrich von Schelling's *Naturphilosophie*. Possibly in 1795, and certainly in 1796, Coleridge read George Berkeley. The next important stage of his philosophical development consisted in the replacement of Hartley's passive concept of mind by Berkeley's never consistently expressed notion of finite mind being actually creative in perception and imagination when it is considered as participating in the infinite, all-productive mind of God. Once more it was the place of God in the philosophy of Berkeley that most concerned Coleridge; and Berkeley's view of nature as purposive, as divine language, found expression in a number of poems written between 1796 and 1800 (for instance, *Destiny of Nations*, ll. 18–20; *Frost at Midnight*, ll. 59–62; *Apologia pro Vita Sua*).

By 1797 the Godwin-Hartley-necessity phase was over. It is probably significant that Coleridge emanci-

pated himself from the mechanical theory of mind at the same time that he lost his once firmly held belief in the ideals of the French Revolution (*France: An Ode*, 1798). In September 1798, Coleridge accompanied the Wordsworths to Germany. After a short meeting in Hamburg with the poet F. G. Klopstock, Coleridge left the Wordsworths to see the countryside and settled himself at the University of Göttingen in order to improve his German and to collect material for a biography of Gotthold Ephraim Lessing. At Göttingen he attended the biological lectures of J. F. Blumenbach and had theological arguments with disciples of the rationalist J. G. Eichhorn. He returned to England in July 1799, transporting £30 worth of German philosophy books "with a view to the one work, to which I hope to dedicate in silence the prime of my life." This work was his never-completed *Opus Maximum*. Thus, the third period of Coleridge's philosophical development was a long assimilation of Kant and the German romantic philosophers, particularly Schelling, which he began in earnest in 1801 and continued well beyond 1816, when he was settled in the London house of James Gillman and able to write his most important philosophical works.

## PHILOSOPHY AND FAITH

That "seminal" quality of mind that J. S. Mill detected in Coleridge and praised so highly needs, as we shall see, slight reevaluation. Mill was perhaps right in claiming that the "Germano-Coleridgean" school had done more for the philosophy of human culture than any of their predecessors could have done. Yet, in stressing the great contributions made to social theory by a series of Continental thinkers from Johann Gottfried Herder to Jules Michelet and in attributing to Coleridge simply a share in those contributions, Mill tended to ignore the less philanthropic and more personalistic aspects of European romanticism. For Coleridge was a post-Kantian "philosopher of life" in the tradition of Heinrich Heine's *Die romantische Schule*. For example, the closeness in particular doctrines and virtual identity in general philosophical orientation between Coleridge and Friedrich von Schlegel is remarkable. Both thinkers are essentially religious critics of the Enlightenment's secular anthropology. That man is a "fallen creature ... diseased in his will" is a principle as axiomatic to Coleridge and Schlegel as it is self-dramatizing and even morally pernicious to the philosophical radicals.

Where Bentham and his followers write primarily as social reformers seeking, in the manner of David Hume and Claude-Adrien Helvétius, a means of harmonizing

individual egoism with the general good of society, the “Germano-Coleridgeans” take man’s tragic alienation from God to be the fundamental datum not only of religion but also of philosophy. For the Benthamites the area of moral significance is in socioeconomic relationships, the external actions of everyday public association. For Coleridge, on the other hand, almost as much as for Søren Kierkegaard, the locus of reality is in the individual’s experience of God. Thus, with thinkers like Coleridge philosophy inevitably becomes a form of theosophy. Religion is the highest exercise of the human spirit, and philosophy is a kind of rational prolegomenon that prepares the way for man’s fuller appreciation of his relationship with God. Philosophy does this by trying to ascertain “the origin and primary laws (or efficient causes) either of the world man included (which is Natural Philosophy)—or of Human Nature exclusively, and as far as it is human (which is Moral Philosophy).” The remaining branch of philosophy, according to Coleridge, is epistemology, which deals with “the question concerning the sufficiency of the human reason to arrive at the solution of both or either of the two former problems.

### REASON AND UNDERSTANDING

The core of Coleridge’s epistemology is contained in his distinction between Reason and Understanding and his insistence that these differ not in degree but in kind. Although the terminology Coleridge uses here is decidedly Kantian, Kant’s distinction between understanding (*Verstand*) and reason in the narrow sense (*Vernunft*) is only superficially similar to Coleridge’s. Like his parallel distinctions between Imagination and Fancy, Genius and Talent, Symbol and Allegory, Coleridge’s contrast between Reason and Understanding is more evaluative than descriptive and well illustrates his characteristic attempt to keep empiricist and associationist concepts in a subordinate position within a larger idealist framework. Understanding is “the faculty of judging according to sense ... the faculty by which we reflect and generalize,” which roughly corresponds to Locke’s definition of it as “the power of perception.” In other words, it is what Coleridge takes to be the pragmatic reasoning faculty of the empiricists.

The Coleridgean Reason, however, is a higher and more esoteric faculty that has at least three not very clearly differentiated functions. In its “speculative” aspect, Reason (1) provides us with basic logical rules of discourse, the so-called laws of thought; (2) is the origin of synthetic a priori truths in mathematics and science; and, in its most important “practical” aspect (3) is “the source

of ideas, which ... in their conversion to the responsible will, become ultimate ends.” Reason produces Ideas or ideals that, although not capable of demonstration, are nevertheless not self-contradictory and may have a clear and distinct form. But they can also, says Coleridge, be more like an instinct or longing: “a vague appetency towards something which the Mind incessantly hunts for ... or the impulse which fills the young Poet’s eye with tears, he knows not why.”

What Coleridge’s distinction amounts to is this: “Understanding” is a pejorative blanket term for the negative aspects of eighteenth-century logic and science, while “Reason” is an approbatory label for those personal ideals and religious beliefs that are psychologically foreign to, or at least not logically entailed by, scientific empiricism. “Reason” thus is clearly allied with Christian faith. Coleridge is not, then, doing a piece of straight conceptual analysis in making this distinction, even though he often writes as if he thinks he is. Instead, he is persuasively psychologizing in an attempt to reorient contemporary philosophical attitudes into unison with contemporary Christian ideals. The barely disguised function of Coleridge’s distinction is to give metaphysical respectability to those Ideas of God, freedom, and immortality that Kant had rightly regarded as merely regulative rather than constitutive elements of knowledge.

### MIND AND NATURE

Philosophy must begin, says Coleridge, with a primary intuition that can be neither merely speculative nor merely practical, but both in one. Here Coleridge significantly modifies the views of Schelling. If the existence of external nature is taken to be the primary intuition, as in natural philosophy, then it becomes necessary to explain how mind or consciousness can be related to it. If, conversely, mind is taken to be primary, as in the Cartesian *Cogito*, we must account for the existence and significance of nature. The only satisfactory way to do either of these things is to suppose that there is in fact no dualism between nature and mind. Nature appears as extrinsic, alien, and in antithesis to mind. The difference is not absolute, however, but merely one of degree of consciousness and, consequently, of freedom.

Nature is mind or spirit slumbering, unconscious of itself. It is representable under the forms of space and time, subject to the relations of cause and effect, and requires an antecedent explanation. Mind, however, originates in its own (that is, God’s) acts and exists in a realm of freedom. But if in its turn this qualitative difference between nature and mind is to be accounted for, a first

cause must be postulated that is itself neither exclusively mind nor exclusively nature, subject or object, but the identity of both. Such a first cause or unconditional principle could not be a natural thing or object because each thing is what it is in consequence of some other thing. Nor can this principle be mind as such, because mind exists only in antithesis to nature. (Rather than indulging in tautology here, Coleridge seems to be making the phenomenologist's point that consciousness is always intentional; i.e., is consciousness *of* something.) The unconditioned must be conceived, apparently, as a primeval synthesis of subject and object, consciousness and nature, in the self-consciousness of God. In God or Spirit lies the identity of the two, of being and knowing in the "absolute I AM."

Thus nature and mind seem to be conceived by Coleridge as two dialectical opposites resulting from God's free act of self-alienation in becoming self-conscious. On this last point, however, he is in his published works particularly (and perhaps necessarily) obscure. Unlike Johann Gottlieb Fichte and Schelling, Coleridge wishes to combine the dialectics of the Identity-Philosophy with the traditional Christian concept of dualism between creature and creator. In the unpublished *Opus Maximum* and other manuscripts, he elaborates this point of divergence from the Germans by distinguishing the "personicity" of God from the "personality" of man and goes to great lengths in accounting for the problem of evil. What is important and seminal in Coleridge's metaphysics, however, is not its details or conclusions, but the rich suggestiveness of its basic categories applied to certain problems in aesthetics and social theory.

### IMAGINATION AND FANCY

From the formal dialectics of his idealism Coleridge drew a living description of how the artist's mind works. Since conscious life exists only through contradiction, or doubleness, the whole of nature out of which conscious life develops must exhibit opposing forces in the reconciling and recurrence of which "consists the process and mystery of production." Art is produced through that same dialectical struggle for the reconciliation of opposites that takes place between mind and nature. Art is not, then, merely imitative, but symbolic of reality. Like all symbols (as Coleridge defines them), it is consequently an inherent part of the process it represents; and the artist as creator, his consciousness being the focus of nature and Idea, matter and form, becomes symbolic of God. So, like God, the artist or Genius must suffer alienation in order to cre-

ate. He needs to be in a special sense disinterested, emotionally aloof for a while from his subject matter and from himself. For in the joy of creation "individuality is lost." He must first "eloin himself from nature in order to return to her with full effect." Just as in the cosmic struggle for synthesis, so in the microcosm of art and the individual artist's mind, there is an attempted fusion of conscious and unconscious forces.

The artist (Coleridge usually considers the case of the poet) achieves such fusions in virtue of his special psychological makeup; that is, through his having the power of Imagination. Coleridge's theory of Imagination, however, does not neatly reflect any of the everyday uses of "imagination" distinguished by modern linguistic analysts. His poet does not create through merely imaginary (unreal) fantasy, nor does he imagine in the sense of making to himself or his reader a kind of supposal, veridical or false. And although it is of course true that the poet is imaginative in being creative or inventive, it is not the case, according to Coleridge, that it is in this fact alone that the poet's Imagination consists.

Nor is Imagination "invention" in the sense that it adds to the real, as common usage might suggest. Instead, as we have seen, Coleridge's view is that the poem and the poet are microcosmic analogues, indeed symbolic parts, of reality. His theory is not concerned, then, with an elucidation of ordinary senses of "in imagination" or even with ordinary senses of "with imagination." It is, typically, a piece of speculative (though not therefore unempirical) psychology that is the rather overweighted vehicle for a value judgment. In this and certain other respects, Coleridge's theory of Imagination has interesting affinities with Jean-Paul Sartre's theory in which imagination is related to the notion of nihilation of consciousness. Needless to say, Sartre is borrowing from a later development of the same German tradition to which Coleridge was indebted.

Coleridge considers three things: primary Imagination, secondary Imagination, and Fancy. The power of primary Imagination is not peculiar to poets, but is standard psychological equipment for all men. It is Coleridge's term for what he considers to be finite mind's repetition in perception of God's creative act. His view seems to be that by synthetically perceiving and categorizing things that are not me, I become conscious of myself, and that this state of human self-consciousness is analogous to God's own creative schizophrenia. Secondary Imagination is the specialized poetic faculty. Differing only in degree and in its mode of operation from primary Imagination, it is the poet's power of unifying

chaotic experience into the significant form of art. Thus, secondary or poetic Imagination “dissolves, diffuses, dissipates, in order to recreate ... it struggles to idealize and to unify. It is essentially *vital*, even as all objects (*as* objects) are essentially fixed and dead.”

Fancy, on the other hand, differs in kind from Imagination. While poetic Imagination is organic in its operation, producing true analogues of God’s creation, Fancy is merely mechanical, aggregative; it is at best imitative rather than symbolic and the instrument of Talent, as opposed to Genius. Fancy is in fact that lower-grade imagination that Locke and Hume set beside sense and memory as a third, nonreferential, source of ideas. Thus Fancy is allied to Understanding, while Imagination, in its ability to transcend and transform the phenomenal, is allied to Reason. It embodies in works of art that inner struggle between nature and mind within which art and Genius are temporary points of resolution.

Despite Coleridge’s unhelpful talk about Imagination and Fancy being mental faculties, there is no doubt that the concrete application of these essentially evaluative concepts leads to a highly practical literary criticism. To mention only one instance, Coleridge’s conception of the work of art as in some degree analogous to a biological organism and his distinction between mechanical regularity and organic form in poetry has had the greatest possible influence on modern criticism. Largely through the far-reaching implications of his distinction between Imagination and Fancy, Coleridge became the first English writer on poetry since the Renaissance to embody the highest powers of critical response within a framework of philosophical concepts that seemed to explain and reinforce that response rather than to inhibit or destroy it.

## MORALS AND POLITICS

Although Coleridge was in his ethical theory a follower and acute critic of Kant, he is interesting today not so much for his own positive views as for his attack upon utilitarianism. Coleridge launches this attack in two ways. First, he tries to demonstrate the logical absurdity of the greatest happiness principle by *reductio ad absurdum* techniques; second, he “postulates the Will,” which involves the claim that the utilitarian notion of personality is psychologically inadequate. On the logical side, Coleridge opens fire with the surprisingly modern assertion that the whole of moral philosophy is contained in one question: “Is *Good* a superfluous word ... for the pleasurable and its causes—at most a mere modification to express degree and comparative duration of pleasure?” His reply is that the meaning of *good* can be decided only

by an appeal to universal usage, for the distinction between *good* and *pleasurable*, which, he holds, is common to all languages of the civilized world, must “be the consequent of a common consciousness of man as man.”

Then, avoiding the error J. S. Mill was soon to make, Coleridge distinguishes between things that are good because they are desired, and things that are or ought to be desired because they are good. This leads him to conclude that *good* cannot be defined simply in terms of pleasure or happiness. Against the Benthamite view that the agent’s motive has nothing to do with the morality of his action, Coleridge makes two points, partly logical and partly psychological. The utilitarian position cannot generally hold, he says, because it follows from it that I could do a morally right act by sheer chance. But such complete lack of inward, conscious participation on my part could never be a sufficient criterion for my acting morally. The utilitarian principle therefore confounds morality with law. Moreover, it is no defense here to say that the principle was put forward as a criterion for judging the morality of the action and not that of the agent, because this last distinction is “merely logical, not real and vital.” Acts cannot be dissociated from an agent any more than ideas from a mind.

In his social philosophy, Coleridge writes in the tradition of Edmund Burke. His mature views are contained in *On the Constitution of the Church and State*, which was begun as an attempt to formulate objections to various bills for Catholic emancipation and finished as an idealist treatise containing the whole logomachy of organism and the reconciliation of opposites. In any society there are always two antithetical forces at work. Since, dialectically speaking, “opposite powers are always of the same kind, and tend to union,” Coleridge’s idea of a well-functioning society is the nonrevolutionary reconciliation of forces working for permanence with forces working for progression. These he identifies with, respectively, the aristocratic, landed interest and the bourgeois, commercial interest of early Victorian England; a monarch also being required to maintain cohesion.

Coleridge’s habit of generalizing from the history and the contemporary pattern of British political institutions rather than, as he alleges, drawing a description of the idea of a state, should at least make suspect his application of these largely a priori principles. This habit leaves Coleridge, like G. W. F. Hegel, wide open to the charge of surrounding the constitution of his own country with an aura of metaphysical sanctity to which it has no claim. Despite such ruinous methodology, however, what Coleridge has to say about the intelligentsia and the part

it has to play in the dissemination of culture has been influential.

Coleridge contrasts *cultivation* with *civilization*. Civilization he takes to denote external, material social progress, while cultivation is more inward and personal: the “harmonious development of these qualities and faculties that characterize our humanity.” So that cultivation can take place, Coleridge proposes the formation of a state-endowed class, the “clerisy” or “national church,” which would effectively consist of professors of liberal arts officially established throughout the country. The national church would, however, be in no sense identical with the Church of England or with any purely religious organization. Its purpose would be to preserve the results of learning, to “bind the present with the past” and to give every member of the community an understanding of his social rights and duties. The almost limitless possibilities for authoritarianism in such an arrangement are, again, obvious. Nevertheless, in Coleridge’s *Church and State* the idea of culture as something independent of material progress was first systematically introduced into English thinking, and was from then onward available in various forms, not merely to influence society but also to judge it.

## CONCLUSION

Though it is no doubt true that Coleridge was, with Bentham, one of the great seminal minds of England in his age, it is not true without qualification that the cultural powers wielded by Bentham and Coleridge were “opposite poles of one great force of progression.” Here Mill was surely indulging in public-spirited wish fulfillment rather than relating the facts. Coleridge and his German contemporaries undoubtedly brought to social consciousness those deeper insights into the nature of the individual and the organic complexities of human associations that were classically synthesized by Hegel in the *Philosophy of Right* (1821). Yet the inherent ambiguity of these insights has today become a disturbing commonplace. Mill inevitably overlooked the darker side of romanticism. For once the romantic artist or philosopher ceases to believe in God, he tends either to find a new object of veneration in history or hero worship or, more recently, to relinquish his very inwardness and imagination in solipsistic nausea. It was Coleridge’s curious fortune that he never lost his belief in God.

## Bibliography

*The Complete Works of S. T. Coleridge*, edited by W. G. T. Shedd, 7 vols. (New York: Harper, 1853 and 1884), was very far from complete. Fortunately, Professor Kathleen Coburn is now in the process of preparing the first scholarly and really comprehensive edition of practically everything Coleridge wrote, apart from the *Collected Letters*, edited by E. L. Griggs, 6 vols. (Oxford: Clarendon Press, 1956–1971). Coburn has already brought out two volumes of Coleridge’s *Notebooks* (London and New York, 1957 and 1962) and his *Philosophical Lectures* (London: Pilot Press, 1949). Coburn’s *Inquiring Spirit: A New Presentation of Coleridge from His Published and Unpublished Prose Writings* (New York: Pantheon, 1951) gives an exciting foretaste of what is to come.

Among the prose works essential for a study of Coleridge as a thinker, note particularly the following: *Biographia Literaria* (New York: Kirk and Merrein, 1817), edited by John Shawcross, 2 vols. (Oxford: Clarendon Press, 1907); *The Friend*, 3 vols. (London: Fenner, 1818); *Aids to Reflection* (London: Taylor and Hessey, 1825); *On the Constitution of the Church and State, According to the Idea of Each* (London, 1830); *Coleridge on Logic and Learning*, edited by A. D. Snyder (London, 1929); *S. T. Coleridge’s Treatise on Method*, edited by A. D. Snyder (London: Constable, 1934); *Coleridge’s Shakespearean Criticism*, edited by T. M. Raynor (London: Constable, 1930); *Specimens of the Table Talk of the late S. T. Coleridge*, edited by H. N. Coleridge, 2 vols. (London: Murray, 1835).

On Coleridge’s general philosophical position, see especially John H. Muirhead, *Coleridge as Philosopher* (London: Allen and Unwin, 1930) and Elizabeth Winkelmann, *Coleridge und die Kantische Philosophie* (Leipzig: Mayer and Müller, 1933). Both these works are reliable but philosophically very old-fashioned. Among the very large number of articles on Coleridge’s thought, A. O. Lovejoy, “Coleridge and Kant’s Two Worlds,” reprinted in *Essays in the History of Ideas* (Baltimore: Johns Hopkins Press, 1948) deserves special attention. James D. Boulger, *Coleridge as Religious Thinker* (New Haven, CT: Yale University Press, 1961) gives a good account of the later Coleridge.

On the theory of imagination, see especially James V. Baker, *The Sacred River* (Baton Rouge: Louisiana State University Press, 1957); I. A. Richards, *Coleridge on Imagination* (2nd ed., New York: Norton, 1950); René Wellek, *A History of Modern Criticism* (London, 1965), Vol. 2, Ch. 6; J. M. Cameron, “Poetic Imagination,” in *Proceedings of the Aristotelian Society*, n.s. 62 (1961–1962): 219–240. The best short work in this field is Gordon McKenzie, *Organic Unity in Coleridge*, University of California Publications in English, Vol. 7, No. 1 (Berkeley: University of California Press, 1939), 1–108. R. H. Fogle, *The Idea of Coleridge’s*

*Criticism* (Berkeley: University of California Press, 1962) is suggestive if not always epistemologically acute.

A reliable account of Coleridge's political thought is given in John Colmer, *Coleridge: Critic of Society* (Oxford: Clarendon Press, 1959). J. S. Mill, "Bentham" and "Coleridge," in *London and Westminster Review* (1838 and 1840) will always remain great classics. Also see F. R. Leavis, *Mill on Bentham and Coleridge* (London: Chatto and Windus, 1950) and Raymond Williams, *Culture and Society, 1780–1950* (New York: Columbia University Press, 1958), Part II, Ch. 3. Justus Buchler, *The Concept of Method* (New York: Columbia University Press, 1961) contains an interesting analysis of the *Treatise on Method* and compares Coleridge's views with those of other thinkers, including Bentham.

## COLET, JOHN

(1466–1519)

John Colet, the Christian humanist and English educator, was the founder of St. Paul's School for Boys, leader of the "Oxford Reformers" Sir Thomas More and Desiderius Erasmus, and chief transmitter of Florentine Platonism from Italy to such English Renaissance figures as Edmund Spenser, John Donne, and John Milton. The son of a London lord mayor, Colet took a master's degree from Oxford (1490) and then explored Plato, Plotinus, and Origen in Latin translation. From 1493 to 1496, he traveled in France and Italy. The appealing tradition that he studied in Florence under Marsilio Ficino was shattered in 1958 when Sears Jayne discovered correspondence between Colet and Ficino in a copy of Ficino's *Epistolae* (1495) at All Soul's College, Oxford. This correspondence shows that Colet never visited Florence or met Ficino.

Upon his return to Oxford in 1496, Colet delivered Latin lectures on St. Paul's Epistles to the Romans and Corinthians. The visiting Erasmus and others applauded as Colet, frequently quoting the Florentine Platonists, propounded a new "historical approach" to the study of Scripture. In 1504 Colet was appointed dean of St. Paul's Cathedral, where, contrary to custom he preached frequently and in English. His congregation included the young lawyer Thomas More.

Colet's penchant for controversy is illustrated by his *Convocation Sermon* (1512), in which he wrathfully condemned his own bishops for their moral laxness. Charges of heresy provoked by this sermon were dismissed by his friend Archbishop Warham, but Colet was soon again involved in controversy. He attacked the war policy of

Henry VIII and was summoned to court; but Henry, after hearing Colet's arguments, was so dazzled that he made the dean a royal chaplain.

Colet's chief contribution to philosophy was his remarkably successful attempt to blend pagan and Christian thought. In practice Colet followed the approach of St. Augustine, who argued that pagan philosophy, when properly controlled, is a useful handmaiden for Christianity. By pagan philosophy, Colet understood especially Florentine Platonism, a weird conglomeration of original Platonism, later Neoplatonism, and private Florentine speculation on man, love, beauty, and mystical union. Much of this speculation came to Colet through Ficino's *Theologia Platonica* (1482) and Giovanni Pico della Mirandola's *Heptaplus* (1489), both of which he admirably quoted or paraphrased in his scriptural treatises.

Despite his debt to the Florentines, Colet avoided the heretical Florentine approach which proclaimed that pagan philosophy and Christianity are equal and even identical. Instead, Colet was careful, as was his model Augustine, to purge pagan views of heretical "errors" before merging them with Christian doctrine. For example, Colet favored the Platonic soul-body terminology over Paul's spirit-flesh, but rejected Plato's dictum that the soul alone comprises the total personality. Again, Colet accepted the Neoplatonic view that Creation was a merging of form and matter, yet he was careful to emphasize that this form is not an emanationist overflow from God's essence, but rather an entity created by God outside himself. In the realm of redemption, Colet accepted Plato's position that only a harmonized soul can govern the body, but he deviated from Plato in insisting that such harmonization can come only from the Holy Spirit's infusion of sanctifying grace. Even in the delicate area of mysticism, Colet borrowed from the *Symposium* the view that love transforms the lover into the object loved.

Whether Colet was as successful in adhering to Catholic as to generally Christian doctrine is a controversial issue. A doctrinal cleavage between Colet and More would seem to be reflected in the *Dialogue on Tyndale* (1529), where More strongly rebuts a form of religion (described in words almost identical to Colet's *Exposition of Romans*), which condemns, as mere shadows, all types of external religion such as sacraments, vestments, and ritual. A comparative study of Colet and More suggests that Colet might have found himself in grave difficulty with Catholic authorities had he lived until the doctrinal reformation of 1534.

## Bibliography

During the period 1867–1876, Joseph Hirst Lupton issued five volumes in which he edited Colet's *Treatise on Sacraments* and translated the remainder of Colet's extant Latin works: two treatises on the Hierarchies of the pseudo-Dionysius (c. 490–550); the lectures on St. Paul's First Epistle to the Corinthians; a similar series on the Epistle to the Romans; a Genesis commentary in the form of *Letters to Radulphus*; an exposition (never given as lectures) on the first five chapters of Romans; and *On Christ's Mystical Body, the Church*. Lupton's translations have been out of print since 1893, but Bernard O'Kelly began modern translations with *John Colet's Enarratio Primum S. Pauli Epistolam ad Corinthios* (Oxford, 1963). Colet's only English works, the *Convocation Sermon* and the *Right Fruitful Monition* pamphlet, are printed in the appendix to Lupton's *A Life of John Colet* (London: Bell, 1887), still the indispensable biography. Another biographical classic is Frederic Seebohm's *The Oxford Reformers* (London: Longmans Green, 1867). Colet's influence as educator is detailed in M. F. McDonnell's *The History of St. Paul's School for Boys* (London, 1909).

Since World War II there has been a revival of interest in Colet's thought, as evidenced by Eugene Rice Jr., "John Colet and the Annihilation of the Natural," in *Harvard Theological Review* 45 (July 1952): 141–163; Albert Duhamel, "The Oxford Lectures of John Colet," in *Journal of the History of Ideas* 14 (October 1953): 493–510; Ernest William Hunt, *Dean Colet and His Theology* (London: Church Historical Society, 1956); Leland Miles, *John Colet and the Platonic Tradition* (La Salle, IL: Open Court, 1961; London, 1962), and Sears Jayne, *John Colet and Marsilio Ficino* (London: Oxford University Press, 1963).

## COLLIER, ARTHUR

(1680–1732)

Arthur Collier, an English idealist philosopher, was born at Langford Magna, Wiltshire, where his father was rector. In 1697 he entered Pembroke College, Oxford, but transferred in 1698 to Balliol. He took orders and in 1704 succeeded to the family living at Langford Magna. Such events as mark his life were of a private character. He was in constant financial difficulties, arising, it is said, from his own impracticality and the extravagance of his wife; his writings did nothing to bring him into contact with a

wider world since scarcely anybody read them. He was buried at Langford on September 9, 1732.

Collier makes no mention of John Locke. He read George Berkeley (with whose views his own partly coincide), but only after the publication of Collier's major work, *Clavis Universalis* (1713). René Descartes, Nicolas Malebranche, and Collier's neighbor John Norris were the philosophers who particularly interested Collier, although he was also considerably influenced by Francisco Suárez and other late scholastic philosophers.

Malebranche and John Norris had argued that perception provides us with no direct evidence for the existence of an external world. They did not deny, however, the existence of such a world, even though it is an embarrassment to their metaphysics. They retain it for theological reasons. Collier agreed with them in rejecting the view that perception reveals an external world to us but went on to argue that the very conception of an external world is self-contradictory.

## PHILOSOPHICAL VIEWS

In the Introduction to *Clavis Universalis* Collier begins by explaining just what he wishes to assert and what to deny. His starting point is that what we perceive is "in the mind"; the objects of perception, that is, depend upon the mind for their existence. In denying their externality Collier is denying their independence or self-subsistence; he is not at all denying that they exist. "It is with me a first principle," he writes, "that whatsoever is seen, is." Indeed, even what is imagined must exist, since it is an actual object of mind. Collier does not deny, either, that what we perceive seems to us to be independent of our minds. But, he suggests, this "quasi-externity" also characterizes what we imagine as much as what we see. The difference between types of objects of perception lies only in the degree of vividness with which they are perceived.

Collier is not, of course, alleging that our mind causes the ideas which it has. Ideas, he says, exist in the mind qua perceiver, not qua voluntary agent. Nor is he asserting that the ideas which other people perceive are internal to my mind. "The world which John sees is external to Peter, and the world which Peter sees is external to John." Peter's world and John's world may be similar, but they are numerically different. The crucial point for Collier is that every object must be "in-existent" to some mind; every object has existence, but no object has "extra-existence."

To establish his main conclusions, Collier makes use of two main lines of argument, to each of which a book

of the *Clavis Universalis* is devoted. In the first book he sets out to show that we have no good reason for believing that objects exist externally to mind. It is generally supposed that we directly perceive them to be external, but the "quasi-externity" of objects is no proof, he argues, that they are really external. Everybody admits that in hallucinations, for example, we can suppose objects to be external which are not in fact external. As for the Cartesian argument that there must be an external world because otherwise God would have deceived us when he implanted in us so strong an inclination to believe that there is, Collier points out that according to Descartes himself we are constantly mistaken about what is and what is not a property of the external world. If we can be mistaken about the externality of colors, for example, without God's veracity being impugned, why not about the existence of objects?

Thus far, Collier's argument has been in some measure an *argumentum ad hominem*; he has supposed it to be an intelligible hypothesis that there is an external world and has argued only that there is no good reason for accepting that hypothesis. In the second book he goes further. The concept of an external world is, he says, riddled with contradictions. To establish this point, he calls upon the commonplace skeptical arguments of his time, which had ordinarily been used, however, to demonstrate that the concept of the physical world is as full of mysteries and obscurities as are the concepts of theology rather than to show that it does not exist. Philosophers have demonstrated, Collier argues, that an external world must be finite and that it must be infinite, that it must be infinitely divisible and that it cannot be infinitely divisible, that it is capable of motion and that it cannot be capable of motion. Faced with this situation, we have no alternative but to declare that the very concept of an external world is self-contradictory. Finally, he argues, no intelligible account can be given of the relation between an external world and God. Stress its dependence on God's will, and its externality vanishes; stress its externality, and it takes on the attributes of God.

In a letter to the publisher Nathaniel Mist, Collier pushes his argument slightly further. The subtitle of *Clavis Universalis* was, he now says, misleading insofar as in it he professed to provide "a demonstration of the non-existence or impossibility of an external world." This suggests that the existence of an external world is a possibly true, even if in fact a false, hypothesis. The correct account of the matter is that the doctrine that an external world exists is "neither true nor false"; it is "all-over non-

sense and contradiction in terms,” the very concept of an external world being self-contradictory.

## RELIGIOUS VIEWS

Collier's other publications consist of *A Specimen of True Philosophy, in a Discourse on Genesis* (1730), which is designed as a preliminary essay to a complete commentary on the Bible, and a series of seven sermons published as *Logology* (1732). These works are primarily theological. Collier's metaphysical views are more clearly formulated in the brief "Confession" he wrote in 1709 but did not publish. There is, he says, one substance, God, which is "being itself, all being, universal being." The existence of everything else is dependent upon the existence of God not only causally but also in the sense that particular things have no substance of their own. However, although everything but God is ultimately dependent on him, everything except Christ is also relatively dependent on something else; qualities "in-exist" in objects, objects in the mind, and the mind in Christ, through whom God made the transition from universality to particularity. Not unnaturally, Collier was accused of Arianism. He thought of himself, however, as reconciling the Arians and the orthodox by admitting Christ's dependence on God but asserting his priority to all created things and even to time, Christ's begetting being "the first pulse of time."

In Great Britain attention was first drawn to Collier's work by Thomas Reid and Dugald Stewart, but he has never exerted any real influence, being overshadowed by Berkeley. In Germany he attracted some attention as a result of an abstract of the *Clavis Universalis* published in the *Acta Eruditorum* (1717) and a German translation by John Christopher Eschenbach in 1756. He is quoted by Christian Wolff, and it is sometimes supposed, without any real evidence, that the Kantian antinomies derive from his work.

J. de Vleeschauwer, "Les antinomies kantienne et la *Clavis Universalis* d'Arthur Collier," in *Mind* 47 (187) (1938): 303–320.

John Passmore (1967)

## COLLINGWOOD, ROBIN GEORGE (1889–1943)

Robin George Collingwood, the English philosopher and historian, was born in Coniston, Lancashire. His father, W. G. Collingwood, friend and biographer of John Ruskin, educated him at home until he was old enough to enter Rugby and imbued him with a Ruskinian devotion to craftsmanship and art and an adult attitude toward scholarship. Although Collingwood later wrote contemptuously of most of his teachers at Rugby and praised Oxford chiefly for leaving him to himself, his undergraduate work in Greek and Latin was excellent and in *literae humaniores* (philosophy and history from Greek and Latin texts), brilliant. He was elected to a fellowship at Pembroke College in 1912, and to the Waynflete professorship in 1934. Except for a period of service with the admiralty intelligence during World War I, he remained at Oxford throughout his career, until in 1941 illness compelled him to retire.

Although he always considered philosophy his chief vocation, Collingwood was a pupil of the great Romano-British archaeologist F. J. Haverfield. Since he alone of Haverfield's pupils both survived the war and remained at Oxford, Collingwood considered it his duty to transmit Haverfield's teachings to others. Although he was a competent excavator, most of Collingwood's work was theoretical. Both in suggesting questions that excavation might answer and in drawing together and interpreting the results of others' excavations, he was brilliant. The final monuments to his historical labors are his sections

on Roman Britain in the first volume of the *Oxford History of England* (1936; 2nd ed., 1937) and in Tenney Frank's *An Economic Survey of Ancient Rome* (5 vols., New York, 1933–1940). To these must be added his extensive contributions to the revised edition of the British section of Theodor Mommsen's *Corpus Inscriptionum Latinarum*, begun by Haverfield, for which Collingwood drew each inscription from his own accurate rubbings.

The consensus of present-day archaeologists appears to be that Collingwood's "imperishably accurate" work on inscriptions will prove more valuable than his works of synthesis and interpretation. Collingwood himself expected that his interpretations would be superseded, but he was convinced that first-rate thinking in history, as in natural science, remains valuable even if further evidence requires that its conclusions be revised. In most of his work his willingness to propose hypotheses was fruitful. He knew something that cautious historians often forget—that nothing is evidence except for or against some hypothesis.

Collingwood's philosophical work falls roughly into three periods: (1) 1912–1927, his acceptance of idealism; (2) 1927–1937, his mature philosophy of the special sciences, conceived as resting on an idealist foundation; and (3) 1937–1943, his rejection of idealism. His ethical and political views will be discussed separately.

### ACCEPTANCE OF IDEALISM

In his first book, *Religion and Philosophy* (London, 1916), Collingwood maintained three doctrines familiar to readers of his later work: (1) that creations of the human mind, no matter how primitive, must be studied historically, not psychologically; (2) that historical knowledge is attainable; and (3) that history and philosophy are identical. What he meant by this third doctrine depends on what he meant by "history" and by "philosophy"; in subsequent years he changed his mind about both.

In his *Autobiography* (London, 1939) Collingwood related that in 1917 a publisher rejected a manuscript, *Truth and Contradiction*, in which he had reached conclusions about truth and about the relation between history and philosophy that are characteristic of his thought at a much later period. Those conclusions are that truth or falsity does not belong to propositions but to complexes of questions and answers; that all such complexes rest on "absolute presuppositions" that are neither true nor false; and that since the business of philosophy is to elicit the absolute presuppositions held by different people at different times, philosophy is really a branch of history.

Since Collingwood destroyed the manuscript of *Truth and Contradiction* after writing his *Autobiography*, it is impossible to ascertain how closely the earlier work anticipated the later. However, in *Ruskin's Philosophy* (London, 1920), a lecture delivered in 1919, he asserted that a man's philosophy is "the [set of] principles which ... he assumes in all his thinking and acting"; and he went on to maintain that since most men do not know what their philosophy is, "it is the attempt to discover what people's philosophy is that marks the philosopher." At least until 1919, therefore, Collingwood conceived of philosophy as a historical investigation of humankind's ultimate and largely unacknowledged principles, but it may be doubted whether Collingwood at that time denied that ultimate principles are either true or false. In *Ruskin's Philosophy* he sympathized with G. W. F. Hegel's refusal to accept as ultimate any dualism, whether of reason and understanding or of theory and practice. And two years later, in an essay, "Croce's Philosophy of History" (*Hibbert Journal* 19 [1921]: 263–278), he attacked Benedetto Croce for holding that philosophy was being "absorbed" into history, so that it is "cancelled out entirely as already provided for" by history. Collingwood did not then think that either history or philosophy in the ordinary sense could absorb the other but rather that each, if seriously pursued, leads to the other. He agreed with the "idealistic" Giovanni Gentile that they are "poised in equilibrium."

**PUBLICATION OF SPECULUM MENTIS.** *Speculum Mentis* (Oxford, 1924) was Collingwood's first attempt to construct a philosophical system. In it he critically reviewed five "forms of experience," ordered according to the degree of truth each attains.

**Art.** Art, the lowest form of experience, Collingwood defined after Croce as pure imagination, which he distinguished from sensation, on the one hand, assertion, on the other. Unlike sensation, imagination is active and has its own guiding principle, Beauty. "Beauty," however, must be defined in terms of imagination and not vice versa. As a form of experience, the deficiency of art is that while in itself a work of art is neither true nor false, it inevitably suggests assertions: It is expressive. Despite Croce's definition, then, imagination in art is in conflict with expression in art, and their conflict shows that art alone cannot satisfy the human spirit.

**Religion.** Art gives rise to religion, in which something imagined is affirmed as real. Like art, religion has its own guiding principle, holiness. The artistic consciousness does not affirm that what it imagines is real; but religion, even Christianity, which Collingwood considered its

highest form, affirms something imagined—a Father in heaven, the Real Presence in the sacrament, the resurrection of the dead—as real. These affirmations, Collingwood held, symbolize something true; but religion requires that they be affirmed in their symbolic form: “A philosopher would not be regarded as a Christian for subscribing to a statement which he declared to be a mere paraphrase of the Apostles’ Creed in philosophic terms.”

Christianity, by affirming the incarnation and atoning death of God, symbolizes the overcoming of the opposition between man and God. This unity of man with God symbolizes man’s capacity to attain nonsymbolic, direct knowledge.

**Science.** Theoretical science is the first form of experience in which man tries by reason to grasp truth. But theoretical science, whether a priori as in mathematics or empirical as in natural science, is abstract. Natural science is the application of mathematics to the empirical world, conceived as subject to laws (mechanism) and composed of an ultimate undifferentiated stuff (materialism). But the world, as we experience it, is not merely mathematical, mechanical, and material. Theoretical science is therefore only supposition: Its truths are hypothetical. It can say truly, “If there were an *S*, there would be *P*,” where *S* and *P* are events in a material world specified in mechanistic terms; but mechanistic terms are not unconditionally applicable to the world of experience. They are abstract; and to abstract is to falsify.

**History.** History appears to offer a way of escape from the abstractness of theoretical science; for it treats of the world of experience as a concrete temporal process. In their highest development, all theoretical sciences—physics and biology no less than the social sciences—assume a historical form. But history, too, has its characteristic deficiency. At bottom it is an extension of the historian’s perception; and a perceived world is alien to its perceiver: a spectacle. Perception can never be knowledge because it can never grasp the whole historical process, and what is beyond the perceiver’s ken may have implications for what is within it. Every specialist in a period is ignorant of a large part of what came before it, and his ignorance “introduces a coefficient of error into his work of whose magnitude he can never be aware.” Even if this were not true, he could not escape the limitation of all attempts at knowledge in which subject and object are distinct. Since what is merely object is alien, it is falsified by the very process of appropriating it.

**Philosophy.** But one form of experience, philosophy, yields truth. Philosophy is self-knowledge. In it the distinction between knowing subject and known object van-

ishes. The self that is known is that which has attained all the subordinate forms of experience—art, religion, science, and history—and corrected their distortions. Philosophy has no positive content of its own: It is the awareness of what is true in those subordinate forms. In knowing their limitations it transcends them. Hence the absolute mind exists in the life of each individual mind to the extent that the individual mind raises and solves problems in any form of experience; as long as this process goes on, each mind is infinite. “The truth is not some perfect system of philosophy: It is simply the way in which all systems, however perfect, collapse into nothingness on the discovery that they are only systems.”

## MATURE PHILOSOPHY

**PHILOSOPHY OF RELIGION.** From 1924 to 1930, Collingwood further explored the positions of *Speculum Mentis*, especially those in aesthetics and religion. For the most part he remained content with his earlier theory of art, but in an essay, “Reason Is Faith Cultivating Itself” (*Hibbert Journal* 26 [1927]: 3–14), and a pamphlet, *Faith and Reason* (London, 1928), he abandoned the doctrine of *Speculum Mentis* that religion is essentially symbolic. Religion, he argued, can rid itself of superstition. Christianity correctly insists that there is a sphere of faith that transcends reason and is its basis. Neither the belief that the universe is rational nor that life is worth living can be established by scientific or ethical inquiry, yet they underlie natural science and rational ethics. Popular Christianity expresses those beliefs symbolically; but symbolizations are not essential to it. The ignorant believer who denounces philosophical or scientific paraphrases of Christian dogmas has no right to speak for Christianity.

**PHILOSOPHY OF HISTORY.** In his *Autobiography* Collingwood recorded that during the summer of 1928 he finally perceived the flaw that had vitiated his philosophy of history in *Speculum Mentis*. He presented his revised views in a pamphlet, *The Philosophy of History* (London, 1930). In 1936 he wrote the lectures that are the fullest statement of these views and that make up the greater part of his *Idea of History* (Oxford, 1946). The error he detected in *Speculum Mentis* was that the historical past is a spectacle, an object alien to the historian’s mind. It has two roots: the realist error that knowing is fundamentally like perceiving; and the idealist error that the same thought cannot exist in different contexts. Against the realists, Collingwood maintained that every thought is an act that may be performed at different times and by different minds. A historian can know that Caesar

enacted a certain thought if he can reconstruct that thought in his own mind (so reenacting it) and demonstrate by evidence that his reconstruction is true of Caesar. Against the idealists, he maintained that, while some contexts change the character of a thought, others do not. The fact that, with my knowledge of modern geometry, I rethink one of Euclid's thoughts, for instance, the forty-fifth proposition of his first book, does not entail that my thought is different from Euclid's.

The key to Collingwood's conception of historical verification is his repeated declaration that historical method is "Baconian," a matter of putting evidence to the question. Given any piece of evidence, more than one reconstruction can be made of the action of which it is a relic. But each reconstruction, taken together with other knowledge, will entail consequences different from those of its fellows. A given reconstruction is established if no consequence that can be drawn from it conflicts with the evidence and if every other reconstruction has some consequence that does conflict with it. If a historian cannot show that one reconstruction, and only one, can be reconciled with the evidence, he must suspend judgment.

Historians must not only show what happened but also explain it. Collingwood proved that the two tasks are accomplished together. The past happenings that historians are concerned to discover are acts; and an act is a physical event that expresses a thought. To discover that an act took place includes discovering the thought expressed in it; and discovering that thought explains the act.

**NATURAL SCIENCE.** Just as in *The Idea of History* and in the writings that preceded it Collingwood had demolished the historical skepticism of *Speculum Mentis*, so in a set of lectures written in 1933–1934, which became *The Idea of Nature* (Oxford, 1945), he renounced his earlier skepticism about natural science and confessed that since "the knowledge acquired for mankind by Galileo and Newton and their successors ... is genuine knowledge," philosophy must ask "not whether this quantitative material world can be known but why it can be known." His answer to that question, however, was equivocal. Collingwood named three constructive periods in European cosmological thought: the Greek, the Renaissance, and the modern, each with its characteristic view of nature. But he said curiously little about the question, "Why is one view of nature replaced by another?" In his introduction to *The Idea of Nature* he declared that "natural science must come first in order that philosophy may have something to reflect on," which suggests that views of nature

change only as scientific thought changes; but in his exposition of the change from the Renaissance to the modern view of nature and in his criticisms of modern views, he often wrote as though philosophy might decide what is or is not a tenable view of nature without referring to natural science at all.

**METAPHYSICS.** Abandoning his earlier view that philosophy is no more than awareness of the limitations of subordinate forms of experience, Collingwood, in his *Essay on Philosophical Method* (Oxford, 1933), assigned philosophy the task of "thinking out the idea of an object that shall completely satisfy the demands of reason." He no longer rejected natural science and history as offering false accounts of such an object. Instead, he described each as limited in its aims. Natural science attempts to find true universal hypothetical propositions; history seeks true categorical propositions, but only about individuals in the world. The propositions of philosophy must be both categorical (about something existent) and universal (about everything existent). Hence, its object can only be the *ens realissimum*, the being that comprehends all being, of which all finite beings are appearances.

Although distinct from history, philosophy is nevertheless closely allied to it. Just as the various definitions that have been proposed for any philosophical concept constitute a scale of forms, of which the lower are appearances of the higher, so do the various metaphysical systems that purport to give an account of the *ens realissimum*. The way to knowledge in metaphysics is through critical reflection on its history.

## REJECTION OF IDEALISM

**AESTHETICS AS THEORY OF LANGUAGE.** In 1937 Collingwood was invited to revise or to replace his *Outlines of Philosophy of Art* (London, 1925), in which he had largely followed the theory of art in *Speculum Mentis*. He chose to replace it; and his new book, *The Principles of Art* (Oxford, 1938), moved closer to Croce, whose article "Aesthetic" Collingwood had translated for the 1929 edition of the *Encyclopaedia Britannica*. Collingwood began by assuming that an aesthetic usage of the word *art* has been established in the modern European critical tradition and that it is the business of aesthetics to define what *art* so used means. The classical definition of art as representation (*mimesis*), in all its varieties, confounded art with craft (*techne, ars*), that is, with the production of something preconceived. Analysis shows that none of the classical definitions state either a necessary or a sufficient condition of art. Works of art may be, and commonly are,

also works of craft. But what makes something a work of art and determines whether it is a good or a bad one is not what makes it a work of craft.

A work of art is an imaginative creation; the function of imagination is to raise what is preconscious (for instance, mere feeling) to consciousness by giving it definite form. Since this activity is expression, Collingwood repudiated his earlier stand and accepted Croce's doctrine that imagination and expression are identical. He also accepted Croce's view that all expression, in any medium, is linguistic; for any form by which the preconscious is raised to consciousness is linguistic. Language thus begins in the cradle. Children speak before they learn their mother tongues.

The primitive language of the cradle is too narrow in range to serve the purposes of any but infants; it must be enriched by "intellectualizing" it so that it can express thoughts as well as feelings. An intellectualized language is one containing "conceptual" terms, and all conceptual thinking is abstract.

An intellectualized language does not cease to be expressive; rather its range of expressiveness is increased. Art is, therefore, not an activity cut off from, say, science. Every fresh linguistic utterance is imaginative and can be considered a work of art. Hence Croce was right when he said that there is poetry without prose, but no prose without poetry. And since it is the nature of art to be expressive, good art is successful expression. Bad art is the malperformance of the act of bringing preconscious thoughts and feelings to consciousness, a malperformance that misrepresents what is thought and felt. It can arise only in a corrupt consciousness. Critics can detect bad art, works of corrupt consciousness, by comparing them with successful works.

**PHILOSOPHY OF MIND.** In his last book, *The New Leviathan* (Oxford, 1942), Collingwood amplified and corrected the philosophy of mind he had outlined in *The Principles of Art*. Mind is consciousness, and while every act of consciousness has an object, no act of consciousness involves consciousness of itself. The various functions of consciousness are stratified into orders. The most primitive of them is consciousness of feeling. An act involving consciousness of a primitive act belongs to a higher order. Collingwood distinguished five such orders: primitive consciousness, appetite, desire, free choice, and reason. In principle, there is no upper limit to the orders of consciousness; for in reasoning about an act of reason a higher-order act is brought into being.

Holding that feeling (that is, sensation with its emotional charge) is not an act of consciousness, Collingwood denied that one can become conscious of an act of consciousness by introspection or inner sense. All acts of consciousness are linguistic; mind is the child of language. In analyzing the various forms of language, Collingwood reiterated his conclusion in *The Principles of Art* that conceptual thinking is abstract, and he expressly repudiated the idealist doctrine that to abstract is to falsify.

All theories of the relation between body and mind betray a philosophical misconception. Body and mind are not two related substances: They are man as investigated in two different ways, physiologically and historically. There is no conflict between physiology and history. To hold that Brutus's movement in stabbing Caesar can be investigated and explained physiologically does not imply that Brutus's act cannot be investigated historically nor does it detract from the value of a historical explanation of that act. Here Collingwood strikingly anticipated Gilbert Ryle's view as expressed in *The Concept of Mind* (New York, 1950).

**LATER METAPHYSICS.** In his *Autobiography* Collingwood reaffirmed his adherence to the conception of metaphysics as a historical science of absolute presuppositions which he claimed to have reached in *Truth and Contradiction*. In the *Essay on Metaphysics* (Oxford, 1940) he amplified this position. Every science, whether theoretical or practical, consists in asking and answering questions; and every sequence of questions rests ultimately on absolute presuppositions that are not answers to questions. Since truth or falsity belongs only to answers to questions, absolute presuppositions are neither true nor false. The task of metaphysics is to ascertain what is absolutely presupposed in a given society and how one set of absolute presuppositions has come to be replaced by another. Metaphysicians, however, must not criticize the absolute presuppositions they discover; for criticism presupposes that they are either true or false. A society does not consciously change its absolute presuppositions. Since most men are quite unconscious of their absolute presuppositions, any change in them is unconscious too and comes about because of internal strains.

Collingwood did not acknowledge what must have been obvious to his readers, that in the *Autobiography* and in the *Essay on Metaphysics* he had jettisoned the metaphysics of the *Essay on Philosophical Method*. His views in the *Essay on Metaphysics* are so incoherent that some sympathetic critics have ascribed his change of mind to

illness. (Both the *Autobiography* and the *Essay on Metaphysics* were written while he was recovering from a series of strokes.) However, his conception of metaphysics in the *Essay on Philosophical Method*, no less than his earlier conception in *Speculum Mentis*, rested on idealist doctrines from which he had been gradually freeing himself. He still believed that philosophical concepts are not abstract. The doctrine that philosophical propositions are both categorical and universal cannot be detached from the idealist theory of the concrete universal. But both in *The Principles of Art* (written before his illness) and in *The New Leviathan* Collingwood explicitly declared that all concepts are abstract.

Although in his *Autobiography* Collingwood repudiated his earlier idealist conception of philosophy, his views about religion, natural science, and history remained virtually intact. Nor were his views on art altered by his later historicism in metaphysics. This suggests that his change of mind in 1938 may be less fundamental than has been thought. After 1924 the main direction of Collingwood's thought was opposed to skepticism in the special sciences. His earlier skepticism had sprung from his idealistic rejection of abstract thinking and his conviction that philosophical thought is not abstract. By 1938 his work on the philosophy of art and the special sciences had overthrown both these errors, and it became clear that he could no longer hold the idealistic metaphysics of the *Essay on Philosophical Method*. It is natural that in seeking something to put in its place he reverted to his youthful historicism, and that it in turn proved inadequate. His inability to find a substitute for idealism does not show that he was mistaken in rejecting it; nor does it prejudice his achievements in aesthetics, philosophy of history, and philosophy of mind.

## ETHICS AND POLITICS

In *Speculum Mentis* Collingwood recognized three forms of ethics: utilitarian, in which action is conceived as a means to an end; duty or concrete ethics, in which action is conceived as determined by the will to act in accordance with the moral order of the objective world; and absolute ethics, in which the distinction between the individual and society, and with it the sense of abstract law, disappears. The first form was held to be characteristic of science, the second of history, and the third of philosophy. Both in *Speculum Mentis* and in the *Essay on Philosophical Method* he represented the forms of ethics on a scale in which the higher forms complete and correct the lower.

Collingwood never renounced this triadic scheme, although in *The New Leviathan* he proposed a new view of the connection between morality and theoretical science, namely, that theoretical science reflects moral practice. Teleological science reflects utilitarian morality; "regularian" science reflects a morality of law; and history reflects the concrete morality of "duty."

In *The New Leviathan* Collingwood set out to bring the "classical politics" of Thomas Hobbes and John Locke up to date. He accepted the classical conception of politics as bringing men out of a state of nature into a state of civil society. Essentially, political life is a process in which a nonsocial community (i.e., the state of nature) is transformed into a social one. This cannot happen unless the rulers understand that social life is a life in which people freely engage in joint enterprises. Civilization is "a process whereby a community undergoes a change from a condition of relative *barbarity* to one of *civility*." Barbarism is hostility to civilization; but although barbarous communities always strive to destroy civilized ones, in the long run the defeat of barbarism is certain.

## COLLINS, ANTHONY

(1676–1729)

Anthony Collins, the English deist, freethinker, theologian, and philosopher, was born at Hounslow, near London, the son of Henry Collins, a well-to-do gentleman. Anthony Collins was educated at Eton and at King's College, Cambridge, and for a while was a student in the Temple. This training in the law later enabled him to maintain an excellent reputation for many years as justice of the peace and deputy lieutenant in Middlesex and in Essex. He was married twice to daughters of the landed gentry. A devoted admirer of John Locke both as philosopher and as writer on religion, Collins, aged twenty-seven, made the pilgrimage to Oates early in 1703 to meet the master, then aged seventy. They were strongly attracted to one another. Later that year Locke wrote poignantly to Collins: "You complain of a great many defects [in yourself] and that complaint is the highest recommendation I could desire to make me love and esteem you and desire your friendship. And if I were now setting out in the world, I should think it my great happiness to have such a companion as you, who had a true relish of truth ... and, if I mistake not you have as much of it as I ever met with in anybody." In his will Locke left Collins a legacy of £110 and some books and maps, and named him one of three trustees of his estate. Collins arranged tributes to the master that appeared in 1708 as *Some Familiar Letters between Mr. Locke and several of his friends* and in 1720 as *A Collection of Several Pieces of Mr John Locke, published by M. Des Maizeaux under the direction of Mr Anthony Collins*.

By that time Collins had made a lasting, if at the time a notorious, name for himself through a series of outspoken yet restrained publications, all of which were anonymous (although most sophisticated readers were aware of the author's identity). The more important include *An Essay concerning the Use of Reason in Propositions, the Evidence wherof depends upon Human Testimony* (1707); *Priestcraft in Perfection: Or, A Detection of the Fraud of Inserting and Continuing this Clause (The Church hath Power to Decree Rites and Ceremonys, and Authority in Controversys in Faith) In the Twentieth Article of the Articles of the Church of England* (1710); *A Discourse of Free-Thinking, Occasion'd by the Rise and Growth of a Sect call'd Free-Thinkers* (1713; actually published late in 1712); *A Philosophical Inquiry concerning Human Liberty* (1715).

In 1711 Collins made the first of many visits to Holland, where he met numerous men of intellect. Soon after the appearance of the *Discourse of Free-Thinking*, with

accompanying public uproar, Collins visited Holland briefly, possibly for reasons of prudence. His later major works include *A Discourse of the Grounds and Reasons of the Christian Religion* (1724), which elicited thirty-five replies within two years and which Bishop Warburton later named one of the most plausible books ever written against Christianity, admitting that the replies might have been left to confute one another; *The Scheme of Literal Prophecy Considered* (The Hague, 1725; London, 1726), a sequel to the *Discourse*; *A Discourse concerning Ridicule and Irony in Writing* (1727); and the *Dissertation on Liberty and Necessity* (1729). This last, together with the earlier *Philosophical Inquiry concerning Human Liberty*, constitutes a powerful statement of the doctrine of necessitarianism. By and large, it is to be noted, the English deists upheld the freedom of the will.

During all this time Collins carried on vigorous, frequently witty, controversies with—to name but a few—Henry Dodwell the elder, famous nonjurist; and such clerical antagonists as Richard Bentley, the classical scholar; Samuel Clarke, the rationalist; and William Whiston, the biblical literalist. His health weakened by repeated attacks of the stone, Collins died late in 1729 and was buried in Oxford chapel. It is said that despite a lifetime of controversy, he was never attacked on the basis of his character. Collins represents the philosophical skeptic in the true sense of the word.

## FREETHINKING

The right and the necessity to inquire freely and fearlessly into all subjects, especially religion, was Collins's constant and fundamental thesis. Its master statement is the *Discourse of Free-Thinking*, but it was adumbrated in two earlier works. The *Essay concerning the Use of Reason* makes the point that reason is "that faculty of the Mind whereby it perceives the Truth, Falsehood, Probability or Improbability of Propositions." Truth and falsehood are known rationalistically and are certain. Probability may take the form of opinion when discovered by reason or of faith when perceived by testimony. Testimony is the foundation of much of our knowledge but can never impugn the natural (rationalistic) notions implanted in the mind of man. The Bible, consequently, is not to be taken seriously when it portrays God in human terms; certain parts of the Bible are to be accepted, while others are to be rejected. Thus, Collins combined Locke's arguments for the reasonableness of Christianity and morality and religious principles with the rationalistic Common Notions of Lord Herbert of Cherbury. *Priestcraft in Perfection* carried the attack, common to most deists of the eighteenth

century, against the dogmas of established churches. Such dogmas, Collins argued, must be viewed as fraudulent when contrary to reason. The appeal to mystery and to things above reason simply will not do.

The title page of the *Discourse of Free-Thinking* is embellished with several quotations: one from the Old Testament, one from the New Testament, one from Cicero, and one from the earl of Shaftesbury. The influence of Shaftesbury is apparent throughout, but Collins was less hesitant to employ the method of ridicule (as is fully attested in the *Discourse concerning Ridicule and Irony in Writing*). The general definition of the right to think freely was applied mainly to religion. Collins pointed out that the new science and the new philosophy had exposed many errors of the past; the Reformation was the result of fearless thinking on the part of a few leaders; the abundant literature of travel exposed the superstitions of peoples throughout the world and also the infinite numbers of pretenders to divine revelation. Freedom had exorcised the witches that so plagued James I and Charles I: “great numbers of witches have been almost annually executed in England, from the remotest antiquity to the late Revolution; when the liberty given and taken to think freely, the Devil’s power visibly declin’d, and England as well as the United Provinces ceas’d to be any part of his Christian territories.” (The “Witches Act” of 1603 was to be repealed in 1736.)

With tongue in cheek, Collins suggested that the Society for Propagating the Gospel in Foreign Parts was really a freethinking organization because infidels must be asked to examine and to reject their native traditional religions in order to accept true religion. He further suggested that such zealous divines as Francis Atterbury, George Smalridge, and Jonathan Swift be drafted annually for this enterprise in the same manner as “military missionaries.” The argument then turned against the priests of all ages who are responsible for quibbling about biblical interpretations and end up calling one another atheists. The Bible, Collins continued, is clearly replete with corrupted texts—30,000 in the New Testament alone, according to one authority. Its text, therefore, is to be examined in the same scholarly and critical manner as the texts of all ancient books. The *Discourse* concluded with a refutation of the standard objections to freethinking. Atheism is not, after all, the worst of all evils; enthusiasm and superstition hold that title, according to Francis Bacon. Cicero was quoted to confute the claim that some false ideas are necessary for the good of society (an early version of the Marxian notion of religion as the opiate of the people). A long list of freethinkers was given,

including Socrates, Plato, Aristotle, Epicurus, Plutarch, Cicero, and Seneca among the ancient pagans; Solomon and the prophets of the Old Testament; Josephus, the Pharisee; Origen, the Church Father; and, among the moderns, Bacon, Thomas Hobbes, and Archbishop Tillotson (“whom all English free-thinkers own as their head”). Collins then asserted that he might well have added other names, such as Michel Eyquem de Montaigne, René Descartes, Hugo Grotius, Richard Hooker, Lord Falkland, Lord Herbert of Cherbury, John Milton, Ralph Cudworth, Sir William Temple, and the master, Locke. All enemies of freethinking were branded crack-brained and enthusiastical, malicious, ambitious, inhumane, ignorant, or brutal—or courtiers of priests, women, and the mob.

### BIBLICAL CRITICISM

*The Discourse of the Grounds and Reasons of the Christian Religion and the Scheme of Literal Prophecy Considered* follow the rational, scholarly methods for biblical criticism described earlier, but concentrate on the question of the fulfillment of Old Testament prophecies in the New Testament. The most cogent attacks are on the virgin prophecy in the book of Isaiah and the unusually specific prophecies in the book of Daniel. In both works Collins pursued the theme of the necessity of thinking freely and went out of his way to defend the right of Whiston, one of his chief adversaries, to think freely—although wrongly, as he saw it—about prophecy. Whiston was a literalist, and Collins had no great difficulty and no little sport in pointing out the absurdities to which Whiston was driven. Collins himself had promised to investigate the miracles of the New Testament but was unable to do so before his final illness and death, and the task fell to Thomas Woolston.

Like John Toland before them, Collins and Woolston forced the issue of the scriptural canon upon the orthodox and opened the way in England for historical criticism.

## COLORS

The phenomena of “color” pose a special puzzle to philosophers characterizing the mind, the world, and the interaction of the two. In various ways, both subjective and objective, both appearance and reality, color has been the subject of wide disagreement. Besides the extreme view that colors are literally sensations—which would imply that they are not in the category of properties and that they last precisely as long as sensations—the main views are these.

### PHYSICALISM

D. M. Armstrong, J. J. C. Smart, and others have suggested that red (or being red), for example, is a physical property—perhaps a surface physical characteristic (like Robert Boyle’s “textures”)—or a propensity to reflect some kinds of light more than others. The threat that physical science might be unable to find a predicate coextensive with “red” seems small; but there are challenges to the idea that any such property can be identified with red. First, will a physical property have the same higher-level properties as red does? Red is a “unique” color—there is a “pure” shade of red with no hint of any other color

(unlike orange, every shade of which evidently contains red and yellow); however, it seems nonsense to say that some reflectance characteristic is “unique.” The physicalist may perhaps reply: A reflectance characteristic can indeed have the property of “uniqueness”—if that is understood as the property of *suggesting to a normal observer no hint of any other color*. (That higher-level property will no doubt be the subject of a later reduction.) A second challenge is this: Ordinary people surely know, for example, that red is more similar to orange than to blue, but if colors are properties whose true nature is revealed only in science, then (until they know more science) they should be in no position to know this. The physicalist may have a reply: This kind of knowledge is of phenomenal similarity, not physical similarity—and on that ordinary perceivers are authoritative. Both challenges suggest an important point, however—that physicalism can at best be a theory about properties that we think of initially without any thought of physical science.

### DISPOSITIONAL VIEWS

The view that colors are dispositions to produce experiences has long been nearly an orthodoxy in the field. Proposed by Boyle and John Locke it has seemed a perfect way to capture the connections between color concepts and color experience. You cannot, it seems, grasp the idea of red unless things sometimes look red to you. And you cannot have a full grasp of the idea unless you realize that your color judgments will be defeasible if it turns out that either you or the conditions are abnormal. The proposal may be strengthened by adding an actuality operator: To be red, an object needs to look red to such observers and in such conditions as *actually* count as normal. This last phrase shall be abbreviated as “to look red [etc.]”

A preliminary worry can perhaps be met. Are there any such things as “normal conditions” and “normal observers”? Normal conditions vary hugely with the nature of the object and with our interests; in some cases (e.g., bioluminescent fish) there may be no clear answer to the question what normal conditions are. “Normal observers” pose a further problem: Even when we rule out “color-blind” people, there is surprising disagreement among the remainder (e.g., over which shade of green is “unique”). These problems may not be fatal. If there is indeterminacy in the truth of “*x* is disposed to look red to normal observers under normal conditions,” there may be an exactly corresponding indeterminacy in the truth of “*x* is red”—the moral may be that some things have no determinate color, not that color is mischaracterized by the dispositional thesis.

Dispositional views vary according to whether they take the experience of a thing's looking red to be a sensation or a representation. The sensationalist version faces the suspicion that the required "sensations of red" (or the "red" regions of the visual field" in C. Peacocke's language) are mythical creatures of a modern-day sense-datum theory. The view also implies that when an object looks red, it looks disposed to produce red' regions in the visual field. And that seems excessively sophisticated.

The representational version has a related problem: if "red" literally means "disposed to look red [etc.]," then "looks red" will have to mean "looks disposed to look red [etc.]"—which is surely false. This—like related objections about circularity—shows that "red" cannot mean "disposed to look red [etc.]," but it may not rule out a nonobvious identity of redness and the disposition to look red [etc.], or an a priori necessary coextensiveness.

A final challenge—for both versions of the dispositional view—is more serious. Imagine a yellow object that also emits death rays, so that anyone who looks at it is killed before he can see its color. The object will be yellow but have no disposition to produce experiences as of yellow in normal observers. (The example is due to Saul Kripke.) One can indeed insist that the object would look yellow to normal observers if only we masked the death rays. But we need to mask the death rays without masking or changing the color. And there is no knowledge of what that amounts to, independent of a substantial conception of what color is. We may believe, for example, that the color of a surface is a matter of the way it reflects incident light; so we can change and mask anything that leaves intact the object's *way of changing incident light*. But if we have that belief, it is no thanks to the definition of yellow as simply "the disposition to look yellow [etc.]" Our prime conception of color must have a different source.

#### VIEWS AVAILABLE

If the physicalist and dispositional views can at best be true with respect to properties first identified by some other route, then we need a new account of our thought about color and of the object of that thought. If color thinking contains an error, the options are projectivism and eliminativism; more easily overlooked is the possibility that color thinking may contain no error and a nonreductive simple realism be the appropriate view.

#### PROJECTIVISM

Galileo Galilei and (at times) René Descartes and Locke are the first of many to treat colors as properties of expe-

riences, which we wrongly "project" onto external objects. Attractive though the view is, it faces two tasks. It must establish its right to a sensational conception of color vision; and it must clarify what exactly is meant by "projecting" a sensation. The difficulty is to find a precise account of projection that does not make the process so absurd that humans could not commit it or so innocent that it is not actually a mistake.

#### REPRESENTATIONAL ERROR THEORY AND ELIMINATIVISM

Some have suggested that color vision is representational—color vision involves the apparent representation of properties of external objects, but there is in fact no suitable external referent. C. L. Hardin has a related view: colors are properties neither of external objects nor of experiences. Colors are to be "eliminated," though there remain "chromatic perceptual states," which are to be reduced to neural states.

The strengths of these views must lie in the careful analysis of what is involved in naive thought about color. If naive thought makes fundamental assumptions that are false, then error theory must be the right conclusion. But an everyday commitment to the notions of normal observers and normal conditions may (as we have seen) not be disastrous. Incoherence in everyday color thought may have to be sought elsewhere.

#### AUTONOMY VIEWS

If color experience apparently represents features of physical objects, what is to prevent us from saying that (in ordinary cases) it correctly represents features of those things, namely colors? These colors would need to be supervenient upon physical properties, though they might or might not be reducible to them. (The model might be Davidson's or Jerry Fodor's view of mental properties.) Colors would have their place in a scheme of explanation that was autonomous with respect to physics, in that its legitimacy was not dependent upon ratification by physics. And that explanatory scheme would no doubt make connections between the colors we see and the contingencies of our perceptual system—thus making those colors not only genuine features of external objects but also in a certain way subjective and relative.

The view needs to overcome the suspicions that the only genuine properties are those recognized in physics, or those intelligible from an "absolute" point of view. A defense is needed of the idea that the world (and not just the mind) can contain subjective items, and an account of

the mind's thought about such items. Until these tasks are achieved the autonomy view will at best be programmatic. If they cannot be achieved, the option seems to be an error theory. They are large tasks, central in the philosophy of mind and metaphysics, and it is a measure of the difficulty of the topic that they have taken so long to come clearly to light.

## COMBINATORY LOGIC

Combinatory logic is a branch of mathematical logic that analyzes certain processes, such as substitution, which are associated with variables. These processes are taken for granted in most formulations of logic, but they are complex, and since a fundamental part of the resulting theory is recursively undecidable the analysis is not trivial. Combinatory logic contributes to simplifying the ultimate foundations of mathematical logic and to explaining the paradoxes; it contains an arithmetic in which exactly those numerical functions that are partial recursive are representable; and it has potential applications to the deeper study of such areas as logical calculuses of higher order, computer programming, and linguistics.

Before one can define combinatory logic precisely, it is necessary to explain some notions concerning formal systems. This will be done in the next section. In the following section the definition will be given and a plan presented according to which the later sections of this article will develop the subject. Each technical term is defined by the context in which it appears in italics.

## FORMAL SYSTEMS

Consider a formal system of the following type: There is a class of formal objects, or *obs*, constructed from certain primitive *obs*, or *atoms*, by certain *operations*; each *ob* has a unique such construction. Among these operations a binary one, called *application*, is singled out. If this is the only operation, the system is called *applicative*; otherwise it is *quasi-applicative*. There is a unique unary predicate, symbolized by the sign "⊢" used as prefix; the *elementary statements* are then of the form

$$(1) \quad \vdash X,$$

where  $X$  is an *ob*. The *elementary theorems* form an inductive subclass of the elementary statements; they are generated from certain initial ones, the *axioms*, by *deductive rules*. The atoms, *obs*, elementary statements, and axioms are definite classes—that is, it can be effectively ascertained whether a proposed member of one of them is actually a member—but concerning the elementary theorems it is required only that the correctness of a derivation by the deductive rules can be effectively checked. Combinatory logic takes such a system as basis. Other sorts of system exist, but all those ordinarily used in mathematical logic can be reduced to the above type.

Assuming such a system, we observe the following conventions: The application of  $X$  to  $Y$  is symbolized as  $(XY)$ . Parentheses are omitted according to the rule of association to the left and also to the rule that outside parentheses are superfluous, so that  $XY_1Y_2Y_3$  is the same *ob* as  $((XY_1)Y_2)Y_3$ . A *combination* of given *obs* is an *ob* formed from some or all of them by application alone. The sign "≡" stands for definitional identity; "→" and "⇔" for metatheoretic implication and equivalence, respectively. Finally, "=" is defined, say, by

$$(2) \quad X = Y \Leftrightarrow \vdash QXY,$$

where  $Q$  is a specific *ob*, the axioms and rules being such that equality has the appropriate properties.

With such a formal system one associates two sorts of ontology. On the one hand, some persons insist on describing more definitely what the *obs* are; on the other hand, one may give a description of the meaning one intends for the elementary statements. The first description will be called a *representation*; the second description will be called an *interpretation*.

For a representation it is customary to state that the *obs* are words in an object language. We will not do that here—all symbols belong to the *U-language* (metalan-guage)—but it can be done quite easily for any given

object language with two or more symbols. This permits a certain freedom in regard to use and mention.

An interpretation for combinatory logic may be described as follows (this is for motivation only and does not imply a commitment to any special type of metaphysics): One associates with certain obs *contensive* (known from prior experience) notions called *interpretants*. The fact that  $Y$  is the interpretant of  $X$  will be expressed simply as  $X$  means  $Y$ . Then if  $X$  means a function and  $Y$  means a possible value for the first assignment of that function,  $XY$  will mean the result of assigning the interpretant of  $Y$  as value to the first argument of  $X$ . Thus, if  $X$  means the addition function of natural numbers and  $Y$  means the number 1, then  $XY$  will mean a form of the successor function, and if  $Z$  means the number 2, then  $XYZ$  will mean the number 3. This device reduces many-place functions to unary ones without postulating ordered pairs. An elementary statement (1) will mean that  $X$  means an asserted statement; the interpretation is a valid one when every asserted statement is true.

#### DEFINITION AND DIVISIONS OF COMBINATORY LOGIC

The usual formal systems contain a special class of obs, usually atoms, called (*formal*) *variables*. These are so named in the formalization and play a special role, such that arbitrary obs can be substituted for them (perhaps under restrictions). Variables do not have interpretants; obs containing them mean functions in which they stand for arguments. Thus, the elementary statements of *Principia Mathematica*, Sec. 1A, are not about  $p, q, r$  but about negation ( $\sim$ ) and alternation ( $\vee$ ); the interpretants of its elementary theorems state rather complex relationships, indicated by the variables, between these functions.

Let  $\mathcal{H}$  be a system as defined earlier, and let  $\mathcal{H}(x_1, \dots, x_m)$  be the system formed by adjoining  $x_1, \dots, x_m$  as variables—that is, as new atoms—without further changes. As stated above, the natural interpretant of an ob  $M$  of  $\mathcal{H}(x_1, \dots, x_m)$  is that function over  $\mathcal{H}$  whose value for arguments  $a_1, \dots, a_m$  is the result of substituting  $a_1, \dots, a_m$  for  $x_1, \dots, x_m$  respectively, in  $M$ . Let us say that an ob  $X$  of  $\mathcal{H}$  designates  $M$  when and only when

$$(3) \quad Xx_1x_2 \dots x_m = M$$

is derivable in  $\mathcal{H}(x_1, \dots, x_m)$ . The system  $\mathcal{H}$  is called *combinatorially complete* when and only when such an  $X$  exists for every  $M$ . A *constant* (that is, an ob of an  $\mathcal{H}$  containing no variables)  $X$  is called a *proper combinator* when and only when it designates a combination of variables

alone; a *combinator* is any combination of proper combinators.

*Combinatory logic* may now be defined as that branch of logic which studies combinators. This is tantamount, at least for applicative systems, to studying combinatorial completeness.

There are two methods of achieving combinatorial completeness. The first is to postulate a designator for every  $M$ . This idea leads to the *theory of  $\lambda$ -conversion*, which is discussed in the next section. It is a quasi-applicative system with bound variables. The other method is to exhibit all combinators as combinations of certain atomic ones, after which we can get along with an applicative system. This leads to *synthetic combinatory logic*, to which the rest of the article is devoted. The two approaches have been shown to be equivalent.

The subject of combinatory logic divides itself into two parts in another way. In the first part, called *pure combinatory logic*, one introduces no constant atoms except combinators and those atoms necessary to define equality and pays no attention to whether the obs have interpretants. In the second part, called *illative combinatory logic*, one introduces atoms meaning other logical notions, such as implication, quantification, and semantical categories. The question whether an ob has an interpretant, and if so, what sort of interpretant, belongs to the illative theory.

**THEORY OF  $\lambda$ -CONVERSION.** In the theory of  $\lambda$ -conversion we postulate that given  $M, x_1, \dots, x_m$ , there is an  $X$  in  $\mathcal{H}$  such that (3) holds. This  $X$ , in Alonzo Church's notation, is  $\lambda x_1 \dots x_m M$ . It suffices to postulate this for  $m = 1$ , for we can define

$$\lambda x_1 \dots x_m x_{m+1} M \equiv \lambda x_1 \dots x_m (\lambda x_{m+1} M).$$

Thus, we need only a binary operation forming  $\lambda x M$  from  $x$  and  $M$ . This operation is the only primitive operation besides application. Thus,  $x$  is a variable and is bound (in a natural extension of the usual sense) in  $\lambda x M$ . One must distinguish, just as in predicate calculus, free and bound occurrences of variables. One understands "ob of  $\mathcal{H}$ " to include any ob formed from atoms of  $\mathcal{H}$  and variables without free occurrences of variables not in  $\mathcal{H}$ . Further, given an ob  $M$ , a variable  $x$ , and an ob  $N$ , we define  $[N/x]M$  (subject to restrictions to prevent confusion of bound variables) as the ob obtained by the substitution of  $N$  for  $x$  in  $M$ .

In view of the intended interpretation, the following are acceptable (subject to the stated restrictions) as axiom schemes:

- ( $\alpha$ )  $\lambda xM = \lambda y[y/x]M,$
- ( $\beta$ )  $(\lambda xM)N = [N/x]M.$

Along with this one has the rules for equality, which give as a special case

( $\xi$ )  $M = N \rightarrow \lambda xM = \lambda xN.$

The equality relation is called *convertibility*, and “cnv” is often used instead of “=.” We call ( $\beta$ ) (as well as  $\eta$  and  $\delta$  below) a *replacement scheme*. The definition is equivalent to saying that  $X$  cnv  $Y$  when and only when  $X$  can be converted to  $Y$  by zero or more successive applications of replacement schemes in either direction. There is also defined a relation of *reducibility*, indicated by “red,” in which the replacement schemes can be used from left to right only. An ob is said to be in *normal form* when and only when no replacement scheme can be so applied to it.

There are various modifications of this system. In  $\lambda$ I-*conversion* (the original  $\lambda$ -conversion),  $\lambda xM$  is defined only when  $M$  contains a free occurrence of  $x$ ; in  $\lambda$ K-*conversion* this restriction is dropped. Again the additional axiom scheme (for  $x$  not free in  $U$ )

( $\eta$ )  $\lambda x(Ux) = U$

is acceptable from interpretations which maintain a strong extensionality principle. If it is adopted, the theory is here called  $\lambda\eta$ -*conversion*, in contrast to the original  $\lambda\beta$ -*conversion*. Finally one may introduce axiom schemes ( $\delta$ ) which single out special constants  $\delta_1, \delta_2, \dots$  and allow constants of the form  $\delta_k U_1 U_2 \dots U_{n_k}$ , where  $n_k$  is fixed by  $\delta_k$  and the  $U_j$  are in normal form, to be replaced by other constants determined in some uniform manner. Note that ( $\delta$ ) is, in principle, illative.

The various forms of  $\lambda$ -conversion have differences in interpretation. In  $\lambda$ I-reduction no component is dropped; hence, if  $X$  has a normal form, so does every part of  $X$ . This is not true for  $\lambda$ K-reduction, a disadvantage if one identifies possession of an interpretant with having a normal form. Again, if one accepts ( $\eta$ ), every ob means a function (in some sense), and sometimes this is unacceptable. However, one may prefer to make such distinctions in the illative theory.

The principal result concerning  $\lambda$ -conversion is the Church-Rosser theorem. This states that if  $X$  cnv  $Y$ , then one can find effectively a  $Z$  such that  $X$  red  $Z$  and  $Y$  red  $Z$ . Thus, two different combinations of variables are never interconvertible; this establishes consistency. In 1936, Alonzo Church and J. B. Rosser (“Some Properties of Conversion,” in *Transactions of the American Mathemat-*

*cal Society* 39, pp. 472–482) proved the theorem for  $\lambda$ I $\beta$ -conversion; it has since been extended to all forms of  $\lambda$ -conversion.

The decision problem for all equations  $X = Y$  was shown by Church in 1936 (“An Unsolvable Problem of Elementary Number Theory,” in *American Journal of Mathematics* 58, pp. 345–363) to be recursively unsolvable, as was the problem of determining whether  $X$  has a normal form. This result was the basis of Church’s later proof of the recursive unsolvability of the decision problem for predicate calculus.

Since every kind of  $\lambda$ -conversion is equivalent to a synthetic theory and vice versa, the results described below for the synthetic theory are also results of  $\lambda$ -conversion and in some cases were first so obtained.

FOUNDATIONS OF PURE SYNTHETIC THEORY. Table 1 contains a list of special combinators. The names assigned to the combinators are in the first ( $X$ ) column and the values of  $m$  and  $M$  to be used in equation (3) are in the second and third columns. The other columns will be explained later. In the various formulations certain of the combinators will be atomic; the corresponding equations (3) will then be assumed as axiom schemes in which ‘ $x_1$ ’, ‘ $\dots$ ’, ‘ $x_m$ ’ stand for arbitrary obs.

We seek to define, for arbitrary  $M, x_1, \dots, x_m$ , an  $X$  such that (3) holds. The  $X$  so defined will be  $[x_1, \dots, x_m]M$ ; this means the same thing as  $\lambda x_1 \dots \lambda x_m M$  but is a defined, not a postulated, concept. One way of defining it is to use an induction on  $m$ , as above, and then, for  $m = 1$ , an induction on the structure of  $M$ . The latter can be obtained, for instance, by defining  $X$  to be **K** $M$  when  $M$  does not contain  $x$ , to be **I** when  $M$  is  $x$ , and to be **S** $X_1 X_2$  when  $M \equiv M_1 M_2$  and we have already defined  $X_1 \equiv [x]M_1, X_2 \equiv [x]M_2$ . Such an algorithm defines all combinators in terms of **I, K, S** as atoms; the definitions are very long, but suitable modifications improve matters. The fourth column of the table gives some definitions obtained by suitably modified algorithms. Other modifications give definitions in terms of **I, B, C, S** for all cases where  $M$  actually contains  $x$ ; these are suitable for an analogue of  $\lambda$ I-conversion.

Thus, we get a definition for  $[x]M$  compatible with any of the forms of  $\lambda$ -conversion if we postulate schemes (3) as stated, together with the properties of equality. The analogues (with  $[x]M$  in place of  $\lambda xM$ ) of ( $\alpha$ ) and ( $\beta$ ) will then hold. But we do not have the analogue of ( $\xi$ ), nor do we have an extensionality principle

( $\zeta$ )  $U_1 x = U_2 x \rightarrow U_1 = U_2$

even under the restrictions that are appropriate for  $\lambda\beta$ -conversion. One can obtain these properties by adjoining a finite number of *combinatory axioms*. Examples of these axioms are

(4)  $SK = KI,$

(5)  $\Psi SK = BK.$

Given a form of  $\lambda$ -conversion, we can choose these axioms so that there is a many–one mapping of the resulting system into the  $\lambda$ -conversion and another one vice versa, such that an equation in either system is a theorem exactly when its image is in the other. Thus,  $\lambda$ -conversion and the synthetic theory are equivalent. Bruce Lercher, in 1963, extended these considerations to include ( $\delta$ ).

It is possible to define, in several ways, a combinator  $Y$  such that for any  $X$ ,  $YX = X(YX)$ . If  $\Gamma$  means negation, then  $Y\Gamma$  means the same as its own negation. For  $Y \equiv WS(BWB)$ , this is the notion at the root of the Russell paradox. Thus, in a combinatorially complete system one cannot exclude the paradoxes; one must explain them in the illative theory.

In the foregoing, equality can be taken as primitive. Then the axioms consist of the combinatory axioms, all instances of the reflexive law, and (3) (for atomic combinators); the rules are the usual rules for equality. When we press the analysis deeper so as to define equality by (2), the schemes (3) become rules; for example, that for  $S$  gives the pair of rules (one in each sense)

(6)  $\vdash U(SXYZ) \Leftrightarrow \vdash U(XZ(YZ)),$

whereas reflexivity can come from an axiom. The result is a system with a finite number of axioms (no axiom schemes) and about a dozen rules, each with one or two premises and otherwise no more complex than (6) and such that the premises uniquely determine the conclusion. There are also only a finite number of atoms—variables are used only in the metatheory—and the single operation of application. The structure is therefore very simple. But all functions of variables can be performed therein, and with suitable illative additions it can form a basis for almost any logical system.

COMBINATORY ARITHMETIC. From the formal standpoint the natural numbers are constructions from a single atom, 0, by a single unary operation,  $\sigma$ . On this basis one can develop the usual recursive arithmetic, and one can explain how to count. Assume that such a system is given, represented, say, in the words in some alphabet

TABLE 1

$X$	$m$	$M$	Definition	$FX$
<b>B</b>	3	$x_1(x_2x_3)$	<b>S(KS)K</b>	$F(F\beta\gamma)F(F\alpha\beta)(F\alpha\gamma)$
<b>C</b>	3	$x_1x_3x_2$	<b>S(BBS)(KK)</b>	$F(F\beta(F\alpha\gamma))(F\alpha(F\beta\gamma))$
<b>I</b>	1	—	—	$F\alpha\alpha$
<b>K</b>	2	—	—	$F\alpha(F\beta\alpha)$
<b>S</b>	3	$x_1x_3(x_2x_3)$	—	$F(F\alpha(F\beta\gamma))(F(F\alpha\beta)(F\alpha\gamma))$
<b>W</b>	2	$x_1x_2x_2$	<b>SS(KI)</b>	$F(F\alpha(F\alpha\beta))(F\alpha\beta)$
$\phi$	4	$x_1(x_2x_4)(x_3x_4)$	<b>B(BS)B</b>	—
$\psi$	4	$x_1(x_2x_3)(x_2x_4)$	—	—

with only one letter. These words we shall call the *natural numbers*. Further, let  $\sigma$  be the successor function,  $\delta$  the predecessor function,  $\tau$  the ordered-pair function, and  $\mu$  the operation such that for any numerical function  $f$ ,  $\mu f$  is the least  $n$  for which  $f(n) = 0$  and is undefined if there is no such  $n$ .

One can find a representation of the natural numbers as combinators; indeed, there are many choices. For any such choice let angle brackets “ $\langle \rangle$ ” symbolize the combinatory analogues of the arithmetic notions indicated within them. Thus,  $\langle n \rangle$  is, for any numeral  $n$ , the *combinatory numeral* which represents it,  $\langle + \rangle$  the analogue of addition, etc. The analogues are often not uniquely determined.

The first representation, by Church in 1933, chose  $\langle n \rangle$  so that  $\langle n \rangle f$  is the  $n$ th iterate of  $f$  (the first iterate being  $f$  itself). If one has  $K$ , then  $\langle 0 \rangle$  is  $KI$  and  $\langle \sigma \rangle$  is  $SB$ . Then  $\langle n \rangle$  is the  $Z_n$  of H. B. Curry and Robert Feys (*Combinatory Logic*). Further,  $\langle + \rangle$ ,  $\langle \cdot \rangle$ , and  $\langle e \rangle$ , where  $e(x,y) = x^y$ , have simple definitions (for example,  $\phi B$ ,  $B$ , and  $CI$ , respectively) from which their arithmetical properties follow. There are other proposals for combinatory numerals; one, made by Dana Scott in 1963, has a simple  $\langle \delta \rangle$ . For the sake of generality,  $\langle n \rangle$  is here unspecified, but a  $Z$  is postulated such that  $Z\langle n \rangle = Z_n$ . If  $\langle n \rangle \equiv Z_n$ , then  $Z \equiv I$ .

Next one can define combinators  $D$  ( $\equiv \langle \tau \rangle$ ),  $D_1$ ,  $D_2$  such that

$$D_1(Dxy) = x, D_2(Dxy) = y.$$

For instance (as Paul Bernays suggested in 1936),

$$D = [x,y,z].Zz(Ky)x.$$

For this

(7)  $Dxy\langle 0 \rangle = x, Dxy\langle \sigma n \rangle = y,$

so that  $\mathbf{D}_1$  and  $\mathbf{D}_2$  can be  $[x]x\langle 0 \rangle$  and  $[x]x\langle 1 \rangle$ , respectively. One can also define  $\mathbf{D}$  in terms of  $\langle \delta \rangle$  rather than  $\mathbf{Z}$ .

Next a combinator  $\mathbf{R}$  can be defined such that

$$(8) \quad \mathbf{R}xy\langle 0 \rangle = x, \mathbf{R}xy\langle \sigma \rangle = y\langle n \rangle(\mathbf{R}xy\langle n \rangle).$$

If  $x = \langle g \rangle$  and  $y = \langle h \rangle$ , where  $g$  and  $h$  are, respectively,  $k$ -place and  $(k + 2)$ -place numerical functions,  $\mathbf{R}xy$  can be taken as  $\langle f \rangle$ , where  $f$  is the  $(k + 1)$ -place numerical function defined by the “primitive recursion scheme” from  $g$  and  $h$ . Since the other processes of forming primitive recursive functions have combinatory analogues, definition of  $\mathbf{R}$  will ensure that  $\langle f \rangle$  is defined for any primitive recursive  $f$ .

Several definitions of  $\mathbf{R}$  exist. The first (given by Bernays in 1936) depends on the fact that  $f(n)$  can be obtained (for  $k = 0$ , as an example) by iterating  $n$  times, starting with  $\tau(0, g)$ , the function  $\phi$  such that  $\phi(\tau(x, y)) = t(\sigma x, h(x, y))$  and taking the second member. This leads to the definition (in two stages)

$$Y \equiv [u]\mathbf{D}(\langle \sigma \rangle(\mathbf{D}_2 u)) (y(\mathbf{D}_1 u) (\mathbf{D}_2 u)),$$

$$\mathbf{R} \equiv [x, y, z](\mathbf{D}_2(\mathbf{Z}zY(\mathbf{D}\langle 0 \rangle x))).$$

Another possibility is to define a combinator  $\Omega$  such that for given obs  $p, q, r$ , the ob  $t = \Omega pqr$  satisfies the conditions

$$(9) \quad t\langle n \rangle = \begin{cases} p\langle n \rangle & \text{if } r\langle n \rangle = \langle 0 \rangle, \\ qf\langle n \rangle & \text{if } r\langle n \rangle = \langle 1 \rangle, \end{cases}$$

thus:

$$Y \equiv \mathbf{D}(\mathbf{K}p)([u](q([z](u(rz)uz)))),$$

$$\Omega \equiv [p, q, r, x](Y(rx)Yx).$$

For  $p \equiv \mathbf{K}x$ ,  $q \equiv [u, z](y(\langle \delta \rangle z)(u(\langle \delta \rangle z)))$ ,  $r \equiv \mathbf{I}$ , the ob  $[x, y]\Omega pqr$  is an  $\mathbf{R}$ , different from the foregoing, satisfying (8). There are still other ways of defining  $\mathbf{R}$ . Since  $\langle \delta \rangle$  can be defined as  $\mathbf{R}\langle 0 \rangle \mathbf{K}$  and  $\mathbf{Z}$  as  $\mathbf{R}(\mathbf{K}\mathbf{I})(\mathbf{K}(\mathbf{S}\mathbf{B}))$ , we have any primitive recursive function as soon as we have either  $\mathbf{Z}$  or  $\langle \delta \rangle$  and a discrimination for  $\langle 0 \rangle$ .

We can go further. If we take  $p \equiv \mathbf{I}$ ,  $q \equiv [u, z](u(\langle \sigma \rangle z))$ , while  $r$  is a given function  $\langle g \rangle$ , then  $\Omega pqr$  is an  $\langle f \rangle$  such that  $f(n) = n$  if  $g(n) = 0$  and otherwise  $f(n) = f(\sigma n)$ . This shows that we can define  $\langle \mu \rangle$  in terms of the above  $q$  as  $[x](\Omega \mathbf{I}qx\langle 0 \rangle)$ . Consequently, every partial recursive numerical function is definable by combinators. The converse of this thesis follows by the usual arguments involving Gödel numeration.

These conclusions are not greatly affected if one restricts the system to correspond with restricted forms of  $\lambda$ -conversion. The passage from  $\eta$ -conversion to  $\beta$ -conversion hardly makes any difference. The omission of  $\mathbf{K}$  complicates things somewhat—one needs ordered triples instead of ordered pairs. But the main conclusion, that every partial recursive function is definable by combinators and vice versa, stands.

Some generalizations are known. One can define by combinators certain transformations between obs and their Gödel numbers. An extension to recursive functionals of certain types can be obtained by using an analogue of  $\langle \delta \rangle$ . There is also an extension to certain transfinite ordinal numbers.

**ILLATIVE THEORY.** By definition illative combinatory logic includes all considerations where there are atoms which neither are combinators nor are necessary to express equality. We consider here those cases in which the new atoms mean ordinary logical notions—for example,  $\Pi$  (absolute universality),  $\mathbf{P}$  (implication),  $\Xi$  (relative universality or formal implication),  $\mathbf{F}$  (functionality— $\mathbf{F}XYZ$  means that  $Z$  is a function from  $X$  into  $Y$ ),  $\Sigma$  (instantiality),  $\Lambda$  (conjunction),  $\Gamma$  (negation),  $\Theta$  (descriptive quantifier), etc. In addition, we need obs meaning semantical categories, such as  $\mathbf{E}$  (the category of all obs— $\mathbf{E}$  is definable, for example, as  $\mathbf{W}\mathbf{Q}$ ),  $\mathbf{H}$  (propositions),  $\mathbf{J}$  (individuals),  $\mathbf{M}$  (sets),  $\mathbf{N}$  (numbers), etc.

The meaning of these obs is expressed more precisely by the rules associated with them. For the first four obs these are

$$\text{RULE } \Pi: \quad \vdash \Pi X \ \& \ \vdash EU \rightarrow \vdash XU.$$

$$\text{RULE } \mathbf{P}: \quad \vdash \mathbf{P}XY \ \& \ \vdash X \rightarrow \vdash Y.$$

$$\text{RULE } \Xi: \quad \vdash \Xi XY \ \& \ \vdash XU \rightarrow \vdash YU.$$

$$\text{RULE } \mathbf{F}: \quad \vdash \mathbf{F}XYZ \ \& \ \vdash XU \rightarrow \vdash Y(ZU).$$

These rules, when relevant, are to be postulated in addition to the combinatory rules given earlier; the latter can be summarized as

$$\text{RULE Eq:} \quad \vdash X \ \& \ X = Y \rightarrow \vdash Y.$$

These notions are, of course, interdefinable; in fact, one can take as atoms either  $\mathbf{F}$ ,  $\Xi$ , or  $\Pi$  and  $\mathbf{P}$  and define the others as follows (there are two possible definitions for  $\Xi$  in terms of  $\mathbf{F}$ ):

$$\mathbf{F} \equiv [x, y, z](\Xi x(\mathbf{B}yz)),$$

$$\Xi \equiv [x, y](\Pi([z](\mathbf{P}(xz)(yz)))).$$

$$\Pi \equiv \Xi E,$$

$$\mathbf{P} \equiv \Psi \Xi \mathbf{K} = [x, y](\Xi(\mathbf{K}x)(\mathbf{K}y)),$$

$$\Xi'' \equiv [x, y](\mathbf{F}xy\mathbf{I}), \Xi''' \equiv [x, y](\mathbf{F}x\mathbf{I}y).$$

The system based on  $\mathbf{F}$  as primitive is called  $\mathcal{F}_1$ , or the theory of *functionality*; that on  $\Xi$  as  $\mathcal{F}_2$ , or the theory of *restricted generality*; and that on  $\Pi$  and  $\mathbf{P}$  as  $\mathcal{F}_3$ . With reasonable axioms, these are listed in order of increasing strength.

Although the Church–Rosser theorem shows that pure combinatory logic is consistent, in the illative theory one easily runs into contradictions. Thus, if one were to assume

$$(10) \quad \vdash \mathbf{P}(\mathbf{P}\alpha(\mathbf{P}\alpha\beta))(\mathbf{P}\alpha\beta)$$

as an axiom scheme, with the Greek letters standing for arbitrary obs, the theory would be inconsistent in the sense that (1) would hold for any  $X$ . But (10) is a thesis of the *absolute* (that is, positive intuitionistic) *propositional algebra*. Thus, it is necessary, if the theory is to contain this algebra, that (10) be a theorem scheme with a restricted range for the Greek letters. In its early stages illative combinatory logic will have axiom schemes with such restrictions. Later, perhaps, these schemes will be reduced to axioms by quantifying over a suitable category.

This requires some sort of machinery of categories or types. Such machinery is taken for granted in the usual systems of mathematical logic. It consists of four items: (a) a list of primitive categories (such as those listed above), (b) devices for forming derived categories, (c) assignments of the primitive notions to categories, (d) means for determining the categories of composite notions. Of these items (a) and (c) are special to the theory considered, but (b) and (d) are general processes which are appropriate for study in combinatory logic. Since composite obs are formed by application alone, one would expect a means of assigning a category to  $XY$  when those for  $X$  and  $Y$  are known; the general principle is that if  $X$  is a function from  $\alpha$  to  $\beta$  and  $Y$  belongs to  $\alpha$ , then  $XY$  belongs to  $\beta$ . This principle is expressed by Rule  $\mathbf{F}$ , so the basis for this generalized theory of types is  $\mathcal{F}_1$ .

From the illative standpoint one would expect that each combinator would be assigned a category depending on parameters expressing that it is a function transforming from certain sorts of categories to categories of certain other sorts. Such *functional characters* for some basic combinators of the table are listed there in the fifth column. Assignments of these characters to the atomic com-

binators would then be axiom (or at least theorem) schemes of  $\mathcal{F}_1$ . However, these schemes cannot be accepted with the Greek letters standing for arbitrary obs, for if one so accepts  $\mathbf{FW}$ , the theory is again inconsistent. Even  $\mathcal{F}_1$  has to be formulated with restrictions on the Greek letters.

The most radical restriction is the requirement that the Greek letters range over an inductive class of F-obs generated from certain otherwise unspecified atoms  $\theta_1, \theta_2, \dots$  by the operation of forming  $\mathbf{F}\alpha\beta$  from  $\alpha$  and  $\beta$ . One further restricts Rule Eq thus:

$$\text{RULE Eq}': \quad \vdash \xi X \ \& \ X = Y \rightarrow \vdash \xi Y.$$

The resulting theory is called the *basic theory of functionality*. In this theory every elementary statement will be of the form

$$(11) \quad \vdash \xi X,$$

where  $\xi$  is an F-ob and  $X$  is a combinator. The theory is demonstrably consistent. If  $X$  is a *stratified* combinator—that is, if  $X$  satisfies (3) and one can derive  $\vdash \eta M$  by Rule  $\mathbf{F}$  alone from the axiom schemes and assignments of categories to the variables—then one can derive a statement of the form (11) stating that  $X$  has the appropriate functional character. There is a converse to this which is somewhat difficult to state, but it shows that the  $X$ 's for which (11) can be derived are greatly restricted; in particular, they have a normal form.

There are several “stronger” theories of functionality with less drastic restrictions. A theory in which one uses only combinators that do not repeat variables can be constructively proved consistent without restrictions on the Greek letters. Constructive consistency proofs have been obtained for some other theories of  $\mathcal{F}_1$ .

All these systems of  $\mathcal{F}_1$  are extremely weak. To obtain stronger and natural theories one proceeds to  $\mathcal{F}_2$  (or adds assumptions to  $\mathcal{F}_1$  which are equivalent to this). In  $\mathcal{F}_2$  reasonable schemes  $\Xi\mathbf{I}, \Xi\mathbf{K}$ , etc., with Greek letters restricted to a class of “canonical obs,” can be formulated from which the corresponding  $\mathbf{FI}, \mathbf{FK}, \dots$  can be derived. Thus,  $\mathcal{F}_2$  has a deduction theorem; it also includes the absolute propositional calculus of pure implication. There is a Gentzen-like theory of “verifiability” from which it follows that certain weak forms of the illative theory are consistent.

The study of illative combinatory logic is still in its preliminary stages. Little is known, for example, about  $\mathcal{F}_3$ . It is clear that ordinary logical systems can be founded on a combinatory basis, but little has been pub-

lished along this line. On such a basis E. J. Cogan, in 1955, analyzed the foundations of Gödel's set theory and also the predicate calculus and some other calculuses; owing to an unfortunate oversight in the definition of "class," the system was inconsistent, as Rainer Titgemeyer showed in 1961, but the necessary changes are rather minor. Other investigations of this sort are in the process of development or publication. Some authors, such as F. B. Fitch, go in a somewhat different direction.

In illative combinatory logic we are dealing with concepts of such generality that we have little intuition in regard to them. This explains why proposals by competent logicians beginning with Gottlob Frege (not all combinatory, but the principle applies) have later proved inconsistent. We must, indeed, proceed by trial and error. No doubt we shall continue to find both inconsistencies in weaker systems and consistency proofs of stronger systems. In due course nonfinitary methods will be used, and much is to be expected of them. But the possibility remains that we may always be interested in systems for which neither consistency nor inconsistency is known.

Combinatory logic was inaugurated by Moses Schönfinkel in 1924. He introduced the notion of application, the combinators **B**, **C**, **I**, **K**, **S** (his *Z*, *T*, *I*, *C*, *S*), and an illative notion *U*. He showed how statements of logic could be expressed in terms of these notions, but he gave no deductive theory of them. He became ill shortly after writing the paper and was unable to do anything further in the subject. Curry, beginning in 1929, produced the first deductive synthetic theory and introduced the terminology used here. The theory of  $\lambda$ -conversion was developed by Church from 1932. Subsequent improvements were made by these authors and by Rosser, S. C. Kleene, Bernays, Fitch, and Paul Rosenbloom. The present state of the subject is the result of an interaction of the work of these authors and their students.

## COMENIUS, JOHN AMOS

(1592–1670)

John Amos Comenius, also called Komensky, the Czech philosopher of education and theologian, was born in Uhersky Brod. Comenius was a member of the Community of the Moravian Brethren (*Unitas Fratrum*) and studied Protestant theology at the universities of Herborn and Heidelberg. Shortly after his return to Moravia, the Thirty Years' War broke out. The Protestant Czechs were defeated by the Catholic Hapsburg monarchy, and Comenius became a permanent exile. Elected bishop of the *Unitas* in 1632, he considered it his main mission as a pas-

tor and as a theological writer to preserve the faith and unity of the dispersed Moravian brethren.

In his writings, which range from such topics as theology, politics, philosophy, and science (as he understood science) to linguistics and education, as well as in his personal life, he combined such contradictory strands of thought as world immanence and world transcendence, interest in science and dependence on false prophets, progressivism, and apocalyptic expectations. In order to understand this mingling of ideas, we must project ourselves into the baroque age, when so many illustrious minds were wandering from one extreme to another. Thus, despite scholastic and Calvinist influences during his years of study, Comenius's concept of the divine regime contained a notable admixture of Neoplatonic, evolutionary, mystical, and pantheistic ideas. God was for him the God of Nature as well as the God of Heaven. However, all these pantheistic leanings did not shake the foundations of Comenius's faith, and throughout his life he clung to the fundamentals of the Christian dogma. Nevertheless, it was the cosmic curiosity in Comenius's religion that opened his mind to the unfolding of the natural and humanistic sciences. Yet Comenius lacked any real understanding of science in the Newtonian sense. The generic concept under which he subsumed the new scientific pursuits was that of "Light," to be understood as both the "Light of God" and the light of reason that God has kindled in man in order to guide him on his way toward eternal truth.

No doubt a certain utopian chiliasm inspired Comenius, but he also shared with the greatest minds of his time the enthusiasm about a new discovery, the discovery of "method," understood as a form of systematic and empirical inquiry which would guarantee the harmonization between man's reason and the natural—and perhaps even the supernatural—universe. The man who impressed Comenius most of all was Francis Bacon. Through Bacon, he became convinced that the new inductive method would shed light not only on the *arcana naturae* but also on the mysteries of the human mind and of human learning. The long title of Comenius's *Great Didactic* (*Didactica Magna*) tells the reader that the author believes he has found a system to teach "all things to all men." Comenius was one of the first to grasp the significance of a methodical procedure in schooling, to project a plan of universal education, and to see the significance of education as an agency of international understanding. Often quoted are the eight principles of teaching that Comenius expounds in Chapter 9 of the *Great Didactic*, in strange analogy to what he sup-

poses to be the economy and order of the sun's functioning in the universe. Still valid in these principles is the emphasis on the interrelation between mental maturity and learning, on the participation of the student, and on the logical interconnection of the subjects in the curriculum.

Education—to be extended to both sexes, all men, and all peoples—should be crowned by a *pansophia* (encyclopedic synthesis of universal knowledge), with the aim of a *dilucidatio* (systematic interpretation) of the order of all things within the cosmic order. For the promotion of the great and worldwide mission of education, Comenius recommended a "Universal College" of the great and wise men of the whole world, and an easily constructed international language for the peace and "for the reform of the whole world" and as an "antidote to the confusion of thought."

In 1668 he dedicated a treatise, *The Way of Light* (*Via Lucis*), "to the torch bearers of this enlightened age, members of the Royal Society of London, now bringing real philosophy to a happy birth." He expressed the "confident hope" that through their endeavors "philosophy brought to perfection" would "exhibit the true and distinctive qualities of things ... for the constantly progressive increase of all that makes for good to mind, body, and estate."

## COMMON CAUSE PRINCIPLE

No correlation without causation. This is the most compact formulation of Reichenbach's Common Cause Principle (RCCP). More explicitly RCCP is the claim that if two events  $A$  and  $B$  are correlated, then either  $A$  and  $B$  stand in a causal relation,  $R_{\text{cause}}(A, B)$ , or, if  $A$  and  $B$  are causally independent,  $R_{\text{ind}}(A, B)$ , then there is a third event  $C$ , a so-called Reichenbachian common cause that brings about the correlation by being related to  $A$  and  $B$  in a specific manner spelled out in the following definition, first given by Reichenbach (1956): Event  $C$  is called a (Reichenbachian) common cause of the correlation

$$(1) \quad p(A \wedge B) - p(A)p(B) > 0$$

if the following conditions hold:

$$(2) \quad p(A \wedge B | C) = p(A | C)p(B | C)$$

$$(3) \quad p(A \wedge B | C^{\perp}) = p(A | C^{\perp})p(B | C^{\perp})$$

$$(4) \quad p(A | C) > p(A | C^{\perp})$$

$$(5) \quad p(B | C) > p(B | C^{\perp})$$

Here  $A$ ,  $B$ , and  $C$  are assumed to be elements in a Boolean algebra  $\mathcal{S}$  and they are to be interpreted as representatives of random events.  $p(A | C) = p(A \wedge C) / p(C)$  and so on denote the conditional probability of  $A$  on condition  $C$ ,  $C^{\perp}$  denotes the complement of  $C$ , and it is assumed that none of the probabilities involved is equal to zero.

RCCP is a metaphysical claim about the causal structure of the world, and it has been debated extensively in the philosophical literature whether RCCP is a valid principle. How could RCCP fail? The first step in any attempt to falsify RCCP is to display common cause incomplete probability spaces, that is, probability spaces that contain at least one correlation that does not have a common cause in the given probability space. Common cause incomplete probability spaces exist; however, the mere existence of such probability spaces does not entail that

RCCP is not valid because RCCP is not the claim that given a correlated pair  $(A, B)$  of events in  $\mathcal{S}$  there has to exist a common cause  $C$  that belongs to  $\mathcal{S}$ : RCCP is a pure existence claim, not requiring the common cause to belong to the specific set of events  $\mathcal{S}$ . If, however, one wishes to maintain the validity of RCCP against the threat posed by the existence of common cause incomplete probability spaces, one has to be able to claim that the probability space  $(\mathcal{S}, p)$  is consistently extendable into a larger probability space  $(\mathcal{S}', p')$  that does contain a common cause of the given correlation. If this can be done, one calls  $(\mathcal{S}, p)$  "common cause completable" (with respect to the given correlation). It can be shown that every common cause incomplete probability space is common cause completable with respect to any finite set of correlations in it. (It is an open problem whether common cause extendability with respect to an infinite number of correlated events also holds.)

In view of common cause completable of probability spaces, one can always defend RCCP against attempts of falsification by referring to "hidden" common causes—"hidden" in the sense of not being accounted for in the set of events  $\mathcal{S}$ . Thus any successful falsification of RCCP must require some properties of the common cause in addition to those required by Reichenbach. One such possible requirement is that different correlations have a *common* common cause. One can show that different correlations cannot in general have a common common cause—not even in case of two correlations.

Assuming that RCCP is valid, one is led to the question of whether our theories predicting probabilistic correlations can be causally rich enough to contain also the causes of the correlations. According to RCCP, causal richness of a theory  $(\mathcal{S}, p)$  would manifest in the theory's being causally closed:  $(\mathcal{S}, p)$  is called *common cause closed with respect to  $R_{\text{ind}}$* , if for every pair  $(A, B)$  of correlated events such that  $R_{\text{ind}}(A, B)$  holds, there exists a common cause  $C$  in  $\mathcal{S}$  of the correlation.

Whether a probabilistic theory is common cause closed with respect to the causal independence relation  $R_{\text{ind}}$  depends on how  $R_{\text{ind}}$  is specified. The weaker  $R_{\text{ind}}$  (i.e., the more pairs of random events are causally independent) the stronger the notion of common cause closedness with respect to  $R_{\text{ind}}$  and the more difficult it is for  $\mathcal{S}$  to be common cause closed with respect to  $R_{\text{ind}}$ . For instance no probability space with a finite set of random events can be common cause closed with respect to the weakest  $R_{\text{ind}}$  (i.e., if  $R_{\text{ind}}(A, B)$  holds for all  $A$  and  $B$ ). However if  $R_{\text{ind}}(A, B)$  is strong enough to imply that the presence of  $A$  implies neither the presence of  $B$  nor the presence of  $B^{\perp}$

(and conversely, replacing  $A$  with  $B$ ) then finite probability spaces can be common cause closed (with respect to  $R_{ind}$ )—though they are not necessarily so. EPR correlations predicted by quantum mechanics are generally viewed as ones that might not admit a common cause type explanation—if the common causes are required also to conform to relativistic causality (such common causes are called “local”).

Proving the impossibility of local common causes of EPR correlations involves two difficulties: First one has to link RCCP to quantum mechanics, which is non-trivial task since Reichenbach’s notion of common cause was defined in terms of classical probability theory, not in terms of quantum mechanics. Second one has to formulate “locality” of common causes. One can approach the first problem in two ways: (i) reformulating Reichenbach’s notion of common cause in terms of non-classical (quantum) probability spaces; (ii) representing quantum probabilities and quantum correlations in terms of classical probability theory.

Reichenbach’s notion of common cause can be reformulated in terms of non-classical probability theory, where  $\mathcal{S}$  is replaced by the lattice of projections of a von Neumann algebra and  $p$  by a state on the von Neumann algebra. The notions of common cause and of common cause completability can be adapted to the non-commutative case, and it can be shown that every non-commutative probability space also is common cause completable. Relativistic causality can also be formulated in terms of non-commutative probability spaces—the resulting theory is known as local algebraic quantum field theory. Locality of common causes of EPR correlations predicted by local quantum field theory can be defined by requiring the common causes to belong to a spacetime region located within the intersection of backward light cones of the spacelike separated regions containing the correlated observables. Whether such localized common causes exist in quantum field theory is an open problem, only partial results are known.

One can also take approach (ii) and formulate locality conditions for the hypothetical common causes of EPR correlations predicted by non-local, non-relativistic quantum mechanics—now represented in classical probability theory. These locality conditions express two sorts of independence: (i) the statistical independence of the random events of choosing measurements in the two wings of a typical correlation experiment and (ii) the statistical independence between choosing measurements in any wing and presence of any combination of the hypothetical common causes of spin correlations in different

directions. Again it is an open question whether common causes satisfying these locality conditions can exist. It is known however that the EPR correlations between outcomes of spin measurements in different directions cannot have a common common cause because the assumption of common common causes of EPR correlations in different directions implies Bell’s inequality.

## COMMON CONSENT ARGUMENTS FOR THE EXISTENCE OF GOD

Numerous philosophers and theologians have appealed to the "common consent" of humankind (the *consensus gentium*) as support for certain doctrines. Richard Hooker, for example, in his *Treatise on the Laws of Ecclesiastical Polity* appeals to this common agreement of humankind in justifying his view that the obligatory character of certain moral principles is immediately evident. Most frequently the conclusions supported in this way were those asserting the existence of God and the immortality of the human soul. In the present entry we shall confine ourselves to common consent arguments for the existence of God.

Among those who favored arguments of this kind were Cicero, Seneca, Clement of Alexandria, Herbert of Cherbury, the Cambridge Platonists, Pierre Gassendi, and Hugo Grotius. In more recent times these arguments were supported by numerous distinguished Protestant and Catholic theologians. G. W. F. Hegel did not accept the argument, but he thought that it contained a kernel of

truth. Rudolf Eisler, in his *Wörterbuch der philosophischen Begriffe*, ranks the argument fifth in importance among so-called proofs of the existence of God, and this seems an accurate estimate of its place in the history of philosophy. At the same time, J. S. Mill was probably right when he observed that, as far as the "bulk of mankind" is concerned, the argument has exercised greater influence than others that are logically less vulnerable. Although there are hardly any professional philosophers at the present time who attribute any logical force to reasoning of this kind, it is still widely employed by popular apologists for religion.

Some supporters claim relatively little. "In no form," wrote the nineteenth-century theologian Robert Flint, "ought the argument from general consent to be regarded as a primary argument. It is evidence that there are direct evidences—and when kept in its proper place it has no inconsiderable value—but it cannot be urged as a direct and independent argument" (*Theism*, p. 349). Cardinal Mercier similarly regarded the argument as "indirect or extrinsic." It does not by itself prove the existence of God, but it is a "morally certain indication that there are proofs warranting the assertion that God exists" (*A Manual of Modern Scholastic Philosophy*, Vol. II, p. 55). Father Bernard Boedder and G. H. Joyce claim a great deal more. Boedder (*Natural Theology*, p. 63) regards it as an "argument of absolute value in itself." The universal consent "of nations in the recognition of God must be deemed the voice of universal reason yielding to the compelling evidence of truth." Later, however, he admits that it is not "absolutely conclusive, except when taken in conjunction with the argument of the First Cause" (*ibid.*, p. 75). Joyce, a twentieth-century writer to whom we owe one of the fullest and clearest statements of one version of the argument, is far more sanguine. He calls it without any qualification a "valid proof of the existence of God" and seems to regard the conclusion as established with "perfect certainty."

The argument has rarely been stated by any philosopher in the form of a simple appeal to the universality of belief in God. In this form it is patently invalid and invites Pierre Bayle's comment that "neither general tradition nor the unanimous consent of all men can place any injunction upon truth." There is, on the face of it, no reason why the whole of humankind should not have been as wrong on a speculative topic as it has been on some more empirical questions on which, history teaches, it has been mistaken. The actual versions of the argument advanced by philosophers are more complicated and can be conveniently grouped into two classes. In the first we

have arguments in which the universality of belief, for reasons peculiar to this particular case, is taken as evidence either that the belief itself is instinctive or that it is due to longings or needs which are instinctive. It is then concluded, for a variety of reasons, that the belief must be true. In the second group we have arguments according to which the universality of the belief, in conjunction with the claim that believers used reason in arriving at their position, is treated as evidence for the existence of God. We shall refer to arguments of the first kind as “biological” versions and to those of the second kind as the “antiskeptical dilemma.” Whatever the shortcomings of these arguments may be, they cannot be dismissed simply on the ground that the whole of humankind may well be mistaken.

Although no doubt some of the disputes in which philosophers and others have engaged in this connection are antiquated and sometimes have a slightly preposterous ring to modern ears, other related issues are still very much with us. For example, it is still maintained by a number of influential philosophers and psychologists that people are “by nature” religious, so that the spread of skepticism and atheism is likely to lead to highly undesirable results. “It is safe to say,” writes Carl Jung about his patients, “that every one of them fell ill because he had lost that which the living religions of every age have given their followers” (*Modern Man in Search of a Soul*, p. 254). Nor are attempts lacking even in our own day to show that everybody “really” believes in God, no matter what they may say or think. In the course of evaluating various forms of the Argument from Common Consent, we shall have occasion to say something about these more contemporary issues as well.

## BIOLOGICAL FORMS OF THE ARGUMENT

**INSTINCTIVE BELIEF IN GOD.** A familiar version of the biological form of the Argument from Common Consent is found in Seneca’s *Epistulae Morales* (Letter 117):

We are accustomed to attach great importance to the universal belief of mankind. It is accepted by us as a convincing argument. That there are gods we infer from the sentiment engrafted in the human mind; nor has any nation ever been found, so far beyond the pale of law and civilization as to deny their existence.

Seneca did not elaborate on the nature of the “sentiment” that is “engrafted in the human mind,” but later writers did, especially when replying to criticisms such as John

Locke’s. In the course of his polemic against the theory of innate ideas, Locke had rejected the initial premise of the argument as plainly false. His reasons were twofold. First, he noted with regret that there were atheists among the ancients, and also, more recently, “navigation discovered whole nations among whom there was to be found no notion of a God” (*Essay concerning Human Understanding*, Book I, Sec. IV). Aside from questioning the prevalence or even the existence of unbelief, the usual reply to this kind of criticism has been to make a distinction between two senses in which an idea or a belief may be said to be innate or instinctive. Such an assertion may mean that the idea or the belief is present in the human mind at birth as an image or some other actual “content,” or it may amount to the much milder claim that it is present as a disposition to arrive at the belief when noticing certain things in the world or in oneself (usually this is stated very strongly to the effect that, when noticing the things in question, the person cannot help coming to believe in God). It is then explained that belief in God is instinctive in the latter or dispositional sense only. To avoid the charge of triviality, the defenders of the argument usually insist that because of this disposition, teaching or indoctrination is not required. Thus Charles Hodge, who makes it clear that he advocates a doctrine of the innateness of belief in God in the dispositional sense, adds that “men no more need to be taught that there is a God, than they need to be taught that there is such a thing as sin” (*Systematic Theology*, Vol. I, p. 199). “Adam,” he also writes, “believed in God the moment he was created, for the same reason that he believed in the external world. His religious nature, unclouded and undefiled, apprehended the one with the same confidence that his senses apprehended the other” (*ibid.*, pp. 200–201).

Several comments are in order here. To begin with, the theory that belief in God is innate does not become vacuous when it is stated in this way, so long as we are told what the facts are in the presence of which a human being cannot help coming to believe in the existence of God. However, when these facts are specified as the adjustments of organisms to their environment or as our experiences of duty and obligation (and these are the ones most frequently mentioned), Locke’s objection seems to be fundamentally intact. For, apart from the question of primitive tribes, a great many of the unbelievers in Western culture appear to have been fully exposed to these facts. But this does not usually move the proponents of the argument. Aside from certain rejoinders that will be discussed later, their formulations usually contain highly elastic words that make possible a speedy disposition of apparent negative instances. The

unbeliever may have been exposed to the relevant facts but not “adequately”; or he may have been exposed to them adequately, but his religious nature may have been “clouded” or “defiled”; or, contrary to outward appearances, the unbeliever may really believe, but the belief may be so faint as to be barely perceptible. This last method was adopted by Hodge when faced with the negative evidence drawn from the observations of blind deaf-mutes. Unbelievers like Ludwig Büchner had pointed to several famous cases, including that of Laura Bridgman, who either could not be brought to form an idea of God at all or who reported that, prior to instruction, no such idea had entered their minds. As far as is known, Hodge never made any empirical studies of blind deaf-mutes, but this did not prevent him from replying with full confidence. “The knowledge obtained by Christian instruction so much surpasses that given by intuition,” he assures us, that the purely intuitive knowledge of the blind deaf-mute “seems as nothing” (ibid., p. 197).

At this stage one must raise the following questions: Under what circumstances would a human being *not* possess an innate belief in God? More specifically, let us suppose that a person observes the facts of organic adjustment and experiences a sense of duty and obligation but nevertheless maintains, with all appearance of sincerity, that he does not believe in God. Under what circumstances would it be true to say that he had observed the facts adequately, that his religious nature was not clouded or defiled, but that he nevertheless had no belief in God? Unless these questions are satisfactorily answered, the argument does not really get off the ground. For it is meant to be based on an empirical premise, and the premise will not be empirical if it is retained no matter how human beings may respond to the stimuli that are supposed to activate the innate disposition to believe in God.

Waiving this difficulty, and granting that the distinction between the two senses in which a belief may be instinctive circumvents the first of Locke’s objections, the argument would still be open to his second criticism, namely, that the universality of an idea or a belief does not establish its innateness. It may well be possible, Locke argued, to account in other ways for the universal occurrence of an idea or the general agreement on a topic. The ideas of the sun and heat, he wrote, are also universal without being “natural impressions on the mind” (op. cit., Book I, Sec. 2). Locke, who was primarily concerned with the origin of the *idea* of God rather than with any question of the universality of belief in God, claimed that he could give an adequate account of how this idea arose

in the human mind without an appeal to innate ideas, and John Stuart Mill later offered a detailed account of how belief in God might be universal without being instinctive. Reasons for rejecting such accounts would have to be offered before one could infer the innateness of belief in God from its universality.

Mill, one of the few great philosophers of recent times to discuss this argument in detail, objected to it on several other grounds as well. Assuming a belief to be innate or instinctive, he asked why this should be any reason whatsoever for regarding it as true. The only justification for this transition that Mill could think of he dismissed as begging the question. This is “the belief that the human mind was made by a God, who would not deceive his creatures” (*Three Essays on Religion*, p. 156), which of course presupposes what is to be proved. Whether this is in fact the only possible justification of the inference from the innateness of a belief to its truth, Mill’s observation that the former does not by itself afford evidence for the latter seems to be very well taken. The force of his point, however, may be obscured because instinctive beliefs are frequently referred to as *a priori* and because this and related expressions are ambiguous. In this present context, calling a proposition *a priori* simply means that it was not affirmed as the result of instruction. In other contexts, and more commonly, to say that a proposition is *a priori* logically implies that it is a necessary truth and hence requires no empirical confirmation. It should be clear that if a proposition is *a priori* in the former sense, it does *not* automatically follow that it is a necessary truth or a truth at all. If an empirical or, more generally, a nonnecessary proposition were instinctively entertained, it would stand just as much in need of proof or confirmation as any other; and, except for a few defenders of the Ontological Argument, believers and unbelievers alike are satisfied that “God exists” does not express a necessary proposition.

Flint and others complained that Mill was unfair because there are versions of the argument that cannot be accused of circular reasoning. It will become clear in the next section that the antiskeptical form of the argument is in fact immune from such a criticism (and Mill was probably not familiar with it). However, it is difficult to see how the version of the biological argument which we have been discussing can bridge the transition from the instinctiveness of belief to its truth without introducing God as guarantor of the instinct’s trustworthiness.

INNATE YEARNING FOR GOD. There is, however, another version of the biological argument which can

perhaps be stated in such a way as to avoid the charge of circular reasoning. This version, moreover, has certain additional advantages over the one considered previously. “All the faculties and feelings of our minds and bodies,” writes Hodge, “have their appropriate objects; and the possession of the faculties supposes the existence of those objects.” Thus the eye, “in its very structure, supposes” that there is light to be seen, and the ear would be “unaccountable and inconceivable” without the existence of sound. “In like manner” our religious feelings and aspirations “necessitate” the existence of God (op. cit., p. 200). “The yearning for some kind of God,” in the words of Chad Walsh, a contemporary defender of the argument, “does point toward an in-built hunger in each of us—a hunger for something greater than we are.” But every other hunger has its normal gratification. This is true of physical hunger, of love and sex, and of our craving for beauty. If, similarly, our religious hunger did not have its proper gratification, it would be difficult to see “how it got built into our natures in the first place. What is it doing there?” (*Atheism Doesn't Make Sense*, p. 10).

This version of the argument escapes one of the difficulties of the version considered earlier. It can very plausibly be argued that absence of belief in God does not prove absence of a yearning for God; and in fact there are undoubtedly unbelievers who wish they could believe. But, granting that the existence of unbelievers does not prove that the wish for God's reality is not universal, this version of the argument nevertheless appears to be open to a number of fatal or near-fatal objections. To begin with, there seem to be exceptions here also. There seem to be people who not only do not believe in God but who are also devoid of any hunger for God. Furthermore, even if this hunger were universal, it might, as before, be possible to explain it on some basis other than that it is innate; or, putting the point differently, one would have to be satisfied that all such explanations are inadequate before one could conclude that it is innate. More seriously and waiving such objections as that the analogy between “religious hunger” and either physical hunger or having organs like eyes and ears is more than dubious, statements to the effect that we have eyes because there is light are objectionable on several grounds. Neither the observed facts nor contemporary biological theory warrants any such assertion. We are entitled to say that we have eyes and that there is light and that the eyes are useful because there is light, so that, other things being equal, organisms with eyes are likely to win out in the struggle for survival against organisms without eyes. Many kinds of biological variations are not similarly useful, but these are rarely noticed by proponents of the argument. When

reading the teleological formulations of these writers—Walsh's question “How did the longing get *built into* [italics added] our nature in the first place?” or Hodge's remark that “possession of the faculties *supposes* [italics added] the existence of the appropriate objects”—one can hardly avoid the suspicion that although God is not explicitly brought into the premise of the argument, these authors surreptitiously introduce a designer who supplied organisms with their native equipment in order to fit them to their environment. It might indeed be possible to establish the existence of a designer on other grounds, but in the present context the defender of the argument is guilty of circular reasoning and thus would not escape Mill's stricture. No such circularity is involved if the instinctive desire is made the basis of an argument for *immortality* after the existence of a beneficent deity has been independently established. Dugald Stewart, in his *Philosophy of the Active and Moral Powers of Man* (Edinburgh, 1828, Book III, Ch. 4), offered such an argument, observing, “whatever desires are evidently implanted in our minds by nature, ... we may reasonably conclude, will in due time be gratified under the government of a Being infinite both in power and goodness.” Stewart was not guilty of circular reasoning, since he thought that he had previously proved the existence of God by means of the Design Argument.

## THE ANTISKEPTICAL DILEMMA

**JOYCE'S ARGUMENT.** One of the most carefully developed statements of the second main form of the Common Consent Argument is found in G. H. Joyce's *The Principles of Natural Theology*. There are three stages to this form of the argument. (1) As in the biological versions, it is contended that practically all human beings, past and present, can be counted as believers in God. Here, however, it is not maintained that there are innate tendencies in human beings to believe in God. If anything, the opposite is true: people crave liberty of action and resent any being with superior authority. If, nevertheless, nearly all human beings are “perfectly certain” of the existence of their “absolute Master,” this can be so only because “the voice of reason” is so clear and emphatic: “All races, civilized and uncivilized alike, are at one in holding that the facts of nature and the voice of conscience compel us to affirm this [the existence of God] as certain truth” (op. cit., p. 179). (2) If the whole of humankind were mistaken in a conclusion of this kind, it would follow that something is amiss with man's intellect, that “it is idle for man to search for truth.” In that event, pure skepticism would be the only alternative. (3) How-

ever, all of us, unless we wish to be perverse, realize that “man’s intellect is fundamentally trustworthy—that, though frequently misled in this or that particular case through accidental causes, yet the instrument itself is sound” (ibid.). Since reason is fundamentally trustworthy, universal skepticism is not a serious alternative to the acceptance of humankind’s conclusion that God exists.

Some writers, though not Joyce, are concerned to add that on this topic great men are at one with the masses of believers. “Even for the independent thinker,” writes John Haynes Holmes, “there is such a thing as a consensus of best opinions which cannot be defied without the weightiest of reasons” (“Ten Reasons for Believing in Immortality,” in *A Modern Introduction to Philosophy*, edited by Paul Edwards and Arthur Pap, New York, 1965, p. 241). If there were no God and no afterlife, the deceived would include, in the words of James Martineau, “the great and holy whom all men revere.” Whom are we to reverence, he goes on, “if the inspirations of the highest nature are but cunningly-devised fables?” (ibid.).

Joyce is aware that the “common consent” of the human race on this subject has been challenged from two sides. To the criticism that there are unbelievers at the present time and that the history of Western countries records instances of other unbelievers, he replies that these are so few in comparison with the number of believers that they do not affect the “moral unanimity of the race,” and he adds that he never meant to claim that literally everybody who ever lived has affirmed the existence of God. To the criticism that there are primitive peoples without a belief in God or at least in one God, Joyce replies that there is in fact no race without religion and that even where there is belief in a plurality of gods, it is invariably found that “the religion recognizes a supreme deity, the ruler of gods and men” (p. 182). Joyce concedes that the supreme deity of primitive religions often lacks some of the characteristics attributed to God by Christian and Jewish monotheists. But this does not affect the argument, since “an idea of God does not cease to deserve that name because it is inadequate” (p. 181). A person may be said to believe in God if he believes in a “Supreme Being, personal and intelligent, to whom man owes honor and reverence” (ibid.), regardless of what else he also believes or fails to believe.

**OBJECTIONS TO JOYCE’S ARGUMENT.** The claim that belief in God is practically, if not indeed strictly, universal in the human race is shared by defenders of both forms of the Common Consent Argument. We shall discuss the difficulties of such a position in some detail in the next

section. Meanwhile, it should be pointed out that even if the moral unanimity of humankind on this subject is not questioned, the argument, as presented by Joyce, appears to be open to two powerful objections.

To begin with, it presupposes that all or most believers in God arrive at their belief by means of reason or the intellect. If this is not the case, then the argument clearly fails, since nothing derogatory about reason would follow if it was not the source of the mistaken conclusion. In actual fact, it seems more than doubtful that the majority of men use reason in any significant sense in arriving at belief in God or even in fortifying their belief after their original acceptance of it. In making this observation, “reason” is not used in any specially narrow sense. A person may, in a perfectly familiar and proper sense, be said to have arrived at a conclusion by means of reason without having set out any formal arguments. However, there seems to be a good deal of evidence that the majority of human beings came to their belief in God by traditional indoctrination. Nor is it particularly plausible to maintain that originally this belief was the product of reason. If reason had anything to do with it, its role, in the opinion of most contemporary psychologists, was probably quite subsidiary. Joyce’s view that man’s natural inclinations would lead to denial rather than to belief in God seems highly doubtful. There is a good deal of disagreement about the exact psychological mechanisms involved, but the majority of psychologists seem to think that man’s loneliness and helplessness, as well as his animistic propensities, incline him to belief in protective (and also hostile) cosmic powers. This does not, of course, mean that such beliefs cannot also be adequately supported by rational considerations, but it does undermine Joyce’s argument.

It should be emphasized that the view just outlined is by no means confined to antireligious psychologists. Fideistic theists would most certainly endorse these observations, as would many believers who have stressed the evil and suffering in the observable world. Indeed, most of the defenders of the biological form of the Common Consent Argument would be opposed to Joyce’s account. “Our own consciousness,” in the words of Charles Hodge (op. cit., pp. 199–200), “teaches us that this is not the ground of our own faith. We do not reason ourselves into the belief that there is a God; and it is very obvious that it is not by ... a process of ratiocination, that the mass of the people are brought to this conclusion.”

Even if this difficulty could be overcome, however, and if it were granted that human beings arrive at their belief in God by reason, Joyce’s argument would still be in

trouble. If “universal skepticism” stands for the view that human beings can never find the true answer to *any* question, then it is not implied by the rejection of the universal belief of humankind in God. All kinds of other explanations of the “universal error,” short of “the radical untrustworthiness” of human reason, seem possible and cannot be ruled out without further ado. It has, for example, been widely held by Kantians, nineteenth-century positivists, and fideists that human reason, while trustworthy as long as it deals with empirical and purely formal issues, is not fit to handle questions transcending experience.

As for the observations of Martineau and Holmes, several points are in order. To begin with, “appeals to the best opinion” are of logical force only in areas in which there are experts, as there are in physics or dentistry, for example. In this sense there is no such thing, either for the independent thinker or for anybody else, as a “consensus of best opinion” when we come to such questions as the existence of God or the immortality of the soul. Furthermore, just as there have been great men and great philosophers who believed in God, so there have also been great men and great philosophers who did not. Since presumably both groups cannot be right, we will be left with the conclusion that men who deserve to be “reverenced” are occasionally mistaken—no matter which view is taken on this subject. Finally, there is nothing about the loftiness of an “inspiration” that guarantees its truth. People whose loftiness makes them believe the best about their neighbors are probably as often mistaken as those whose lack of loftiness makes them believe the worst.

### IS BELIEF IN GOD UNIVERSAL?

Let us now turn to a discussion of the detailed objections to the premise which all forms of the Common Consent Argument share, namely, that all or practically all human beings are believers in God.

**ANTHROPOLOGICAL OBJECTIONS.** To begin with, there is a series of objections based on what is known or allegedly known about primitive tribes and about religions which are not monotheistic. We have already seen that Locke believed, on the basis of the reports of travelers, that there were whole nations without the notion of God. This view was widely advocated by anthropologists and sociologists in the nineteenth century, many of whom did not rely on the reports of others but spent long periods studying the beliefs and habits of primitive peoples at first hand. It was developed in considerable detail

by Sir John Lubbock in his pioneering work, *Prehistoric Times*, and it had the unqualified endorsement of Charles Darwin, who, in *The Descent of Man* (Ch. 3), reported confirmations in his own experience with the Fuegians. The denial that belief in God is universal was an essential part of the position of the so-called evolutionary anthropologists. They maintained that there was a gradual transition from animism, via fetishism, to a belief, first, in many gods and then, finally, in a single God. Several of these writers, however, used the word *religion* very broadly to include belief in any unseen spiritual agencies, and in this sense both E. B. Tylor (the eminent evolutionary anthropologist) and Darwin were ready to admit that *religious* belief appeared to be universal among the less civilized tribes. The philosopher Fritz Mauthner, who followed this tradition, expressed himself very strongly on the subject. In *Der Atheismus und seine Geschichte im Abendlande* (Vol. IV, Ch. 10) he accused Christian missionaries of “translation impertinence” in dragging out of aborigines the confession that they believed in a heavenly Father, when more careful investigation revealed that they did not mean anything of the kind. He also protested against the trick, as he called it, by advocates of the *consensus gentium*, of using the word *religion* ambiguously—at first in the broad sense of Tylor and Darwin, in which it may be plausible to maintain the universality of religion, and then shifting to the narrower sense, required by their argument, in which it implies belief in God or gods.

Critics of the argument have also pointed out that there are numerous tribes believing in polytheism without having in their theology one supreme deity. Hence, even if the argument were otherwise sound, it could not prove the existence of a single Supreme Being.

Finally, it has been maintained that there are religions, of which Buddhism is the most notable instance, which have no belief in God at all.

To the last of these criticisms, the customary answer is that, while the founder of such a religion may indeed not have believed in God or gods, once these religions spread, they acquired theologies—and sometimes exceedingly extravagant ones at that. Joyce, who was familiar with this objection, regarded the example of Buddhism as highly favorable to his argument. It was his contention that no religion or philosophical system which rules out belief in God “has ever succeeded in maintaining a prominent hold on any people” (p. 197). In China, Buddhism flourished, but there it became a polytheistic religion. In India, on the other hand, where the original agnostic teachings were not substantially

changed, the Buddhist creed could not hold its own and had to give way to modern Hinduism.

The existence of polytheistic religions is not, of course, questioned by defenders of the Common Consent Argument. Some, indeed, like Flint and Mercier, are willing to concede that the argument, by itself, does not favor a stronger conclusion than that God *or* gods exist. This, however, is not the usual reaction. Recent advocates of the argument have commonly challenged the entire scheme of the evolutionary anthropologists. Basing their argument largely on the work of the Austrian anthropologist Father Wilhelm Schmidt (1868–1954) and others belonging to the “theological school,” they deny that polytheism antedates monotheism and insist, furthermore, that in every polytheistic religion there is one supreme deity. According to Schmidt, the simplest peoples are also the oldest, and they are believers in a very pure monotheism. Their God possesses all the main attributes of the God of Christianity and Judaism: he is the creator of reality, he supplies the foundation of morality, and he is also omnipotent, omniscient, and supremely good. As societies became more complex, this monotheism became transformed into various kinds of animism, polytheism, and ancestor worship. Even among these later cultures, Schmidt finds “a clear acknowledgment and worship of a supreme being,” while all other “supernormal beings” are regarded as far inferior and subject to him.

It would be idle to get involved here in the controversies between Schmidt’s school and other schools of anthropology, especially since there are objections to the Argument from Common Consent which can be evaluated without taking sides on anthropological issues. Perhaps the only comment worth making is that while contemporary anthropologists are willing to credit Schmidt and other members of the theological school with some sound criticisms of the evolutionary anthropologists and with a good deal of impressive field work, the great majority of them regard his basic theories as quite unsupported by the available evidence.

**UNBELIEVERS IN THE WESTERN WORLD.** The other main challenge to the claim that belief in God is universal consists in pointing to the unbelievers in Western culture. It is admitted that unbelievers are a minority, but it is argued that they are and have for some time been too significant a minority not to affect the “moral unanimity of mankind” on this subject. This challenge and the various attempted rebuttals deserve, but have very rarely received, extended discussion.

*“Belief” redefined.* One way in which the significance of individual unbelievers may be discounted is apparent in the tendency of some Protestant writers to define “belief in God” or “religion” or both so broadly as to make it virtually impossible for a human being not to be a believer or to be religious. In our own day such writers frequently follow Paul Tillich’s definition of an atheist as someone who believes that “life is shallow” and of an irreligious person as someone who has “no object of ultimate concern.” However, the use of such definitions to do away with unbelievers achieves a victory which is purely illusory. It will now indeed be possible to call a man like Denis Diderot a believer and religious. But in the sense in which there was a dispute about the existence of unbelievers, namely, whether there are people who do not believe in the existence of what is usually understood by “God,” Diderot and countless other people will still have to be classified as unbelievers. Moreover, if the premise of the Common Consent Argument is now a true proposition, with “believer” used in the *new* sense, the conclusion established, if any, would not be the one originally aimed at. It would not show that God exists but rather, using Tillich’s redefinitions, that life is not shallow and that there are objects of ultimate concern.

*Unbelievers discounted as abnormal.* One of the favorite devices used to defend the *consensus gentium* against irritating exceptions has been the charge that unbelievers are in effect too morally or mentally defective to count as representative of human opinion. Strangely enough, this tactic was used by Pierre Gassendi, who was highly critical of Herbert of Cherbury’s argument and from whom, in view of his own independence of thought, one might have expected something better. In the course of expounding his version of the argument, Gassendi minimized the number and importance of atheists, declaring that they are either “intellectual monstrosities” or “freaks of nature.” More recently this defense was adopted by some eminent nineteenth-century Protestant theologians. Thus A. H. Strong, in a text that was widely used in Protestant seminaries, observed that just as the oak must not be judged by the “stunted, the flowerless specimens on the edge of the Arctic Circle,” so we must not take account of unbelievers in judging the nature of man (*Systematic Theology*, Vol. I, p. 56). One of the rivals of Strong’s book was Hodge’s *Systematic Theology*. Hodge was not to be outdone. A man’s hand, he reminds us, may be so hardened as to lose the sense of touch, but this does not prove that the hand is not “normally the great organ of touch.” Similarly, it is possible that “the moral nature of a man may be so disorganized by vice or by a false philosophy as to have its testimony for the existence of God

effectually silenced” (op. cit., p. 198). Human beings cannot abandon belief in God “without derationalizing and demoralizing their whole being” (p. 201); and the belief, or rather lack of belief, of such a “derationalized” and “demoralized” individual does not count.

Perhaps two brief comments will be sufficient here. First, Hodge at least is begging the question when he refers to the “false philosophy” that silences the testimony for the existence of God. The question is precisely whether this is a false philosophy. If this were already known, there would be no need for the Argument from Common Consent. Second, and more important, anybody having the slightest familiarity with the history of unbelief must surely protest that many of the outstanding thinkers of the last two centuries were avowed unbelievers. Like other mortals, they may have been frequently in error, but to dismiss them as freaks, to compare them to stunted, flowerless oaks, or to regard their moral nature as disorganized by vice is surely outrageous nonsense.

*Unbelief discounted as an illusion.* Some of those who regard the unbeliever as “unnatural” or “monstrous” do not, perhaps, wish to refer to any actual human being. This may be so because some of them also maintain that *really* everybody is a believer in God even though he may say the opposite and believe that he believes the opposite. (The strategy here is rather different from the redefinitional maneuver described above.) Hodge, for example, offers two reasons in support of such a position. First, unbelief is such an unnatural state that it cannot last. “Whatever rouses the moral nature, whether it be danger, or suffering, or the approach of death, banishes unbelief in a moment (ibid., p. 198). There seems to be an obvious answer to this. It is true that unbelievers have become converted or reconverted on occasions, but it is equally true that others have remained unbelievers right to the end of their lives. Furthermore, those who became converted must *really* have been unbelievers before their change of position, or else there would have been no conversion. To this it must be added that there are also shifts in the opposite direction, and if a person does not count as an unbeliever *at all* because he ultimately becomes a believer, then those who change from belief to unbelief will have to be counted as unbelievers exclusively.

Hodge’s second reason would probably have a much wider appeal. “It is hardly conceivable,” he writes, “that a human soul should exist in any state of development, without a sense of responsibility, and this involves the idea of God. For the responsibility is felt to be not to self, nor to men, but to an invisible Being, higher than self and higher than man” (ibid., p. 197). Hodge is certainly not

alone in taking the line that if a person is a moral creature and not lacking in sensibility, then he must be a believer in God. Even at the present time there are many people who seem to rule out a priori the possibility that a good person can be an unbeliever. To give just one illustration, Justice William O. Douglas wrote a highly laudatory preface to a recent collection of the court pleas of Clarence Darrow (*Attorney for the Damned*). Darrow had repeatedly stated and defended his agnosticism, and he never once retracted this position. Nevertheless, seeing that Darrow was such a kind and compassionate man, Douglas remarks: “Darrow met religious bigotry head-on ... but he obviously believed in an infinite God who was the Maker of all humanity.”

There are several confusions in reasoning of this kind. To begin with, the criteria which all of us employ to determine that a man is kind, that he does not lack sensibility, that he shows responsibility in his relations with other human beings—that, in short, he is a “moral person” or a good man—are quite distinct from those which we employ when determining that he is a believer in God. This at any rate must be so if the statement that all believers in God and only believers in God are good is to be, as it is usually taken to be (both by those who accept it and by those who deny it), a factual claim and not a tautology.

Second, the claim that responsibility is invariably felt not to oneself or to other men but to an invisible Being is unwarranted. Assuming that some people do on occasions feel responsibility to an invisible Being, this is certainly not true of all. If people who assure us that they feel responsible, but not to an invisible Being, are to be discounted or disbelieved, why should we count and accept the assurances of those who say that they feel responsible to the invisible Being? Moreover, it appears that the attitude, even of religious believers, is not generally in accord with Hodge’s account. If a believer borrows money and considers himself obligated to return it, he surely, like an unbeliever, regards himself as obligated to the person who lent him the money and not to anybody else. Suppose believers were asked the following question in such a situation: “If an atheistic philosopher persuaded you that God does not exist, but if otherwise the situation remained exactly the same—you needed the money badly, your friend helped you without hesitation, you promised to repay him as soon as possible, and so on—would you still consider yourself obligated to repay the loan?” It seems very doubtful that more than a handful of believers would reply that they no longer regarded themselves as obligated.

Questions about whether a person who says that he believes or disbelieves a proposition and who is apparently not lying, does really believe or disbelieve it, are complicated by the fact that “belief” is an ambiguous word. Without entering into any subtleties or attempting an elaborate analysis, it may be granted that there is nothing absurd in the suggestion that a person may sincerely regard himself as an unbeliever when in fact he is a believer, or vice versa. It is helpful in this connection to distinguish belief in terms of verbal responses and positions adopted in purely theoretical contexts from belief insofar as it is exhibited in actions and in involuntary responses, especially to critical situations.

Bertrand Russell discusses this question in a little-known essay titled “Stoicism and Mental Health.” He points out that people who say, with all appearance of sincerity, that they believe in an afterlife seem to fear their own death or regret the death of their friends as much as those who say that they do not believe in an afterlife. He explains this “apparent inconsistency” by remarking that the belief in the afterlife is in most people “only in the region of conscious thought and has not succeeded in modifying unconscious mechanisms” (*In Praise of Idleness*, paperback ed., London, 1960, pp. 133–134). Many of us, like Russell, are inclined to regard the latter, the sense in which belief is expressed in involuntary responses and not merely in theoretical contexts, as the “deeper” sense. We say that a man has reached and avows a certain conclusion, but “deep down” he really believes the opposite. It must be conceded to the defender of the Argument from Common Consent that there are people who are unbelievers in the verbal and theoretical sense but who in a deeper sense do believe in God. This is notoriously true of some who are brought up in a religious home and much later come under the influence of skeptical thinkers.

Nevertheless, the Common Consent Argument is not really helped by this admission. For, in the first place, there can be no reasonable doubt that a good many people are unbelievers in both senses; and second, not a few cases are known of believers, that is, people who sincerely believe in God in terms of their verbal and theoretical responses whose actions show them to be unbelievers “deep down.” This fact has been repeatedly stressed by religious writers when castigating some of the members of their own groups as “practical atheists.”

*Unbelief seen as a negligible influence.* Some defenders of the argument are quite ready to admit the existence of highly educated unbelievers. In other words, they question neither the genuineness of the lack of belief nor the

intellectual standing of unbelievers. However, they add to this the fact that unbelievers have failed and are bound to fail to make any major inroads on humankind at large. “We find a disposition on the part of some few philosophers to dispute the validity of the belief,” writes Boedder (op. cit., p. 68), “but nevertheless the belief has proved to be persistent and indestructible in the mass of humankind. It is this persistency among the mass of men, retained even in the teeth of skeptical opposition, on which our argument is based.”

Sometimes a comparison is made between the unbelievers and the philosophers who deny the existence of an external world or the reality of space and time but are rightly laughed off by ordinary people whose common sense is intact. Granting that the ordinary person is in some sense right as against the philosopher who denies the reality of time, to confine ourselves to one such case, the comparison seems to be very weak in more ways than one. For one thing, unbelief in matters of religion is not at all confined to professional philosophers or to people who are naturally referred to as intellectuals. Furthermore, as G. E. Moore has pointed out, the philosophers who say such things as “time is unreal” and who presumably in some sense also believe this, also say things and cannot help saying things which indicate that *they also do not believe it*. The very philosophers who say that time is unreal nevertheless use clocks, complain when their students are late, plan for the future, and engage in the same activities that the ordinary man regards as presupposing the reality of time. Nothing even remotely comparable can be found in the case of unbelievers as a class.

However, returning to the original question, it is not at all certain that unbelieving philosophers and other critics of belief in God have not significantly affected the masses. There seems to be a good deal of evidence to the contrary; but even if it were true and the impact has in fact been negligible, this could be explained quite plausibly without supposing either that belief in God is inherent or, as Boedder claims, that reason, properly used, is certain to lead to a theological conclusion.

#### ARE MEN BY NATURE “GOD-SEEKERS”?

There are philosophers and psychologists of influence who either do not believe in God at all or who, at any rate, do not favor the enterprise of buttressing belief in God by means of “proofs” but are nevertheless concerned to maintain that human beings are by nature religious—that they are, in Max Scheler’s phrase, “God-seekers.” They would point out that it is this question of “philosophical anthropology,” and not any question about the

validity of the Common Consent Argument, which is of real interest and human importance. Though perhaps invalid as a proof of the *existence of God*, the Common Consent Argument does embody an important insight about the *nature of man*.

These writers are a great deal more sophisticated than most of the traditional defenders of the argument, whose views we considered in preceding sections. They do not at all deny that, in the most obvious sense, the world is full of unbelievers, but they would add that a great many of these unbelievers feel a strong urge to worship something or somebody and therefore invent all kinds of surrogate deities. Man's "gods and demons," writes Jung, "have not disappeared at all; they have merely got new names." Those, in the words of Miguel de Unamuno, "who do not believe in God or who believe that they do not believe in Him, believe nevertheless in some little pocket god or even devil of their own." "Religious agnosticism," writes Scheler, "is not a psychological fact, but a self-deception ... it is an essential law [*ein Wesensgesetz*] that every finite spirit believes either in God or in an idol. These idols may vary greatly. So-called unbelievers may treat the state or a woman or art or knowledge or any number of other things as if they were God" (*Gesammelte Werke*, Vol. V, pp. 261–262). Scheler adds that what needs explanation is not belief in God, which is original and natural, but unbelief or, rather, belief in an idol. The situation is not infrequently compared with the sexual instinct and what we know about the consequences of its suppression. If the sexual instinct does not find natural gratification, it does not cease to be operative but becomes diverted into other and less wholesome channels. The worship of institutions and human deities is said to be a similarly pathological phenomenon.

An evaluation of this position, which amounts in effect to an endorsement of the theory of the religious instinct without inferring the existence of God from it, is not possible here because it would involve elaborate discussions of child psychology and the causation of neurosis and "alienation." Here we can only observe that in the opinion of many contemporary thinkers there is no reason whatever to suppose that human beings are "by nature" religious. In their opinion the "hunger for God," in its orthodox no less than in its newer "substitute" expressions, is invariably the result of certain deprivations and traumatic experiences. People who suffer from insufficient contact with other human beings and who do not find the natural world satisfying will tend to experience longings for something supernatural or feel a need to endow human beings with supernatural attributes.

Some of these writers would go further and maintain that traditional religion, through its life-denying morality and irrational taboos, is itself in no small measure responsible for the existence of the type of personality that displays the hunger for God. Sigmund Freud, who took this position, conceded that those in whom the "sweet—or bitter-sweet—poison," as he called religion, had been instilled early in life were unable to dispense with it later on. The same, he added, is not true of others who have been brought up more soberly. "Not suffering from neurosis," they will "need no intoxicant to deaden it."

### Bibliography

There is no full-length study in any language of the different forms of the Common Consent Argument. The major reference works contain either no entries or else very brief and unhelpful ones. Even Rudolf Eisler's "Consensus Gentium," in *Wörterbuch der philosophischen Begriffe*, 3 vols., 4th ed. (Berlin: E.S. Mittler, 1930), devotes less than a page to this subject.

The fullest defenses of the argument are found in Charles Hodge, *Systematic Theology*, 3 vols. (New York: Scribners, 1871–1873), Vol. I; Bernard Boedder, *Natural Theology* (London, 1896); and G. H. Joyce, *The Principles of Natural Theology* (London: Longmans, Green, 1923). Briefer discussions also favoring the argument are contained in A. H. Strong, *Systematic Theology*, 3 vols. (Philadelphia: Griffith and Rowland, 1907), Vol. I; Robert Flint, *Theism* (London: Blackwood, 1877); Hermann Ulrich, *Gott und die Natur*, 3 vols., 3rd ed. (Leipzig: T.O. Weigel, 1875), Vol. I; and Cardinal Mercier, *A Manual of Modern Scholastic Philosophy*, translated by T. L. and S. A. Parker, 2 vols., 3rd ed. (London: K. Paul, Trench, Trubner, 1928), Vol. II. The famous nineteenth-century biologist G. J. Romanes, in "The Influence of Science upon Religion," which forms Part I of his *Thoughts on Religion* (Chicago: Open Court, 1895), defends the biological form of the argument as proving not that there is a God but that *if* "the general order of nature is due to Mind," then the character of that Mind is "such as it

is conceived to be by the most highly developed form of religion.”

A popular contemporary statement of the biological version of the argument is advanced in Chad Walsh, *Atheism Doesn't Make Sense* (Cincinnati, n.d.). Among earlier writers, Cicero defended the argument in *De Natura Deorum*, Book II, Sec. II, translated by C. D. Yonge as *The Nature of the Gods* (London, 1892); by Herbert of Cherbury in *De Veritate*, translated by M. H. Carré (Bristol, U.K.: University of Bristol, 1937); and by Pierre Gassendi in *Syntagma Philosophicum*, in his *Opera Omnia*, edited by H. L. H. de Montmorency and F. Henri, Vol. I (Lyons: Lavrentii Anisson and Ioan, 1658).

One of the earliest criticisms of the argument was by Locke, in *Essay concerning Human Understanding* (London: Thomas Bassett, 1690), Book I. There are brief and unsystematic critical discussions in several of the works of the freethinkers of the seventeenth, eighteenth, and nineteenth centuries, including Bayle, Paul-Henri Holbach, and Büchner, but the first detailed and systematic critique is found in J. S. Mill, *Three Essays on Religion* (New York: Henry Holt, 1874). More recently, the argument has been attacked in John Caird, *Introduction to the Philosophy of Religion* (Glasgow: J. Madehose, 1880); Fritz Mauthner, *Der Atheismus und seine Geschichte in Abendlande*, Vol. IV (Stuttgart, 1923); and in two books by Josef Popper-Lynkeus: *Das Individuum und die Bewertung menschlicher Existenz* (Dresden: C. Reissner, 1910) and *Über Religion* (Vienna: R. Löwit, 1924). Popper-Lynkeus' criticisms are, for the most part, an elaboration of David Hume's remark that “the conviction of the religionists, in all ages, is more affected than real.” Hume's discussion of this topic occurs in Sec. XII of *The Natural History of Religion* (London, 1757; critical ed. with introduction by H. E. Root, London: A. and C. Black, 1956), a work which also anticipates many of the conclusions of the evolutionary anthropologists of the nineteenth century. There is a discussion, at once critical and sympathetic, in Miguel de Unamuno, *The Tragic Sense of Life in Men and in Peoples*, translated by J. E. Crawford Flitch (New York, 1921).

Two more recent works surveying the evidence concerning the religious beliefs of primitive tribes are Guy E. Swanson, *The Birth of the Gods* (Ann Arbor: University of Michigan Press, 1960), and W. J. Goode, *Religion among the Primitives* (Glencoe, IL: Free Press, 1951). Wilhelm Schmidt's theory is stated in his *The Origin and Growth of Religion*, translated by H. J. Rose (London: Methuen, 1931). A view similar to Schmidt's was expressed by Andrew Lang in various works, including *The Making of Religion* (London: Longmans, Green, 1898) and *Magic and Religion* (London: Longmans, Green, 1901). The *Anthropological Review* 2 (1864): 217–222, contains an interesting summary of an address by the Reverend F. W. Farrar, “On the Universality of Belief in God and in the Future State,” in which a great deal of evidence is presented to the effect that neither belief in God nor belief in an afterlife is universal. The discussion following Farrar's address is also reported, and most of the participants, including W. R. Wallace, fully supported Farrar's negative conclusion.

J.-H. Leuba, *The Belief in God and Immortality* (Boston: Sherman, French, 1916), presents evidence concerning belief and unbelief among academic groups in the United States in

the early years of the twentieth century. Unfortunately, there has been virtually no study in depth of religious belief and unbelief in the general population of any country.

Jung's views on the natural religious needs of human beings and the sickness of modern men who have lost their religion are stated in *Psychology and Religion* (New Haven, CT: Yale University Press, 1938) and *Modern Man in Search of a Soul*, translated by W. S. Dell and C. F. Baynes (New York: Harcourt Brace, 1933). Scheler's similar views are found in his *Vom Ewigen im Menschen*, in *Gesammelte Werke*, 4th rev. ed., Vol. V (Bern: Francke, 1954). The opposite position is defended by Sigmund Freud in *The Future of an Illusion*, translated by W. D. Robson-Scott (New York: H. Liveright, 1928), and Wilhelm Reich, in *The Mass Psychology of Fascism*, translated by T. P. Wolfe (New York: Orgone Institute Press, 1946). The views of Freud and Reich are foreshadowed in Ludwig Feuerbach, *The Essence of Christianity*, translated by George Eliot (London, 1853).

*Paul Edwards (1967)*

## COMMON SENSE

Several things can be learned about common sense from Dr. Johnson's attempt to refute George Berkeley by kicking the stone. Its philosophical incompetence is not one of them. Dr. Johnson of course misunderstood Berkeley, and his misunderstanding was not a collapse of common sense. He thought that if stones had, as Berkeley said, no “material substance” and were collections of “ideas,” a boot ought to go through them without resistance. And if Berkeley had been maintaining that solid objects were only apparently solid and were really collections of what we would ordinarily call ideas, the refutation would have been an appropriate reaction of common sense.

### THE NOTION OF COMMON SENSE

Whatever other aspects of meaning the word *sense* may retain in the compound “common sense,” it has prominently the force of sense as opposed to nonsense. In what is contrary to common sense there is always something more or less—but obviously—nonsensical. It produces the feeling, varying in strength according to circumstances, that argument is only precariously in place in dealing with it. For to deploy arguments at all *directly* against the manifestly absurd is to invest it with some intellectual dignity and to muffle its self-annihilating character. It is, moreover, to invite the suspicion that one has failed to recognize absurdity, and such failure has a very foolish look. As a man of redoubtable common sense, Dr. Johnson kept dialectic for the right occasion. He did not kick the stone formally in the name of common sense, but his action has traditionally been praised

and condemned as a piece of commonsense behavior. Yet he was demonstrating against a philosopher who was also determined to be on the side of common sense.

**BERKELEY.** Berkeley's notebooks contain the reminder to himself: "To be eternally banishing Metaphysics &c & recalling Men to Common Sense" (*Philosophical Commentaries*, No. 751). Confident that he could always secure the neutrality of common sense when he could not have its assistance, Berkeley went about his own metaphysical enterprise, which was to exhibit the dependence of physical objects on their being perceived. His *Three Dialogues* (1713) is studded with references to common sense: to opinions that are "repugnant" or "shocking" to it, to its "dictates," to the judgment of men of "plain common sense." The objections that have to be most carefully answered are those which appear to proceed from common sense. Since the issues concern mainly the world of perception, the man of common sense in the *Dialogues* is eminently the man who "trusts his senses," who will not tolerate the suggestion that the things he sees and handles are not real things but their mere representations.

The eighteenth century also brought into existence, in France and Scotland, philosophies of common sense—philosophies, to a greater or lesser degree, centered on this notion. They safeguarded what they held to be the beliefs (or "truths") of common sense by defending its authority and—in the Scottish philosophy—by exposing contraries of these beliefs to its blunt rejection.

**COMMON-SENSE BELIEFS.** It may be asked whether common sense had beliefs until philosophers engaged in its defense ascribed them to it. The *Oxford English Dictionary* lists a variety of meanings for the expression. Three of these, referring to a mental endowment, might be taken together: ordinary understanding—without which a man is out of his mind, or feeble-minded (an early meaning); ordinary, practical, good sense in everyday affairs; and the "faculty of primary truths." Ordinary understanding is not obviously, and practical, good sense is obviously not, the sort of thing that could stamp a set of beliefs with a special character. The third of these meanings is marked "philosophical." A further meaning must be noticed: "the general sense, feeling, or judgement of mankind." Here common sense seems to be a cluster of beliefs or persuasions, somehow "felt" to be true by most people. An argument drawn from common sense, in this case, would amount to an appeal to an ancient tribunal of opinion, common consent. (The most absolute modern proponent of this tribunal has probably been Lamennais, in his *Essai sur l'indifférence*, Paris, 1817–1823.)

Philosophers have frequently meant by common sense an intuitively based common consent. And the philosophers, during and after the eighteenth century, who have argued from common sense and for its beliefs have often thought of common sense in this way. They have, however, as often thought of it in a more ordinary way, as the common sense that is opposed—always at first sight, sometimes irreconcilably—to high and obvious paradox.

Can the common sense that is opposed to gross paradox properly be thought of as having beliefs, however strong? If there is some artificiality in saying that common sense has beliefs, there is none in speaking of its rejection of an opinion; the reason—it might be suggested—is that common sense does not declare itself in advance of attack upon it. The man of plain, ordinary common sense cannot readily be said, for instance, to believe that the things around him continue to exist in his absence—the idea of their not doing so does not cross his mind. But when he encounters the contrary opinion, his common sense asserts itself. On the supposition that the declarations of common sense are essentially reactive, to ascribe to it beliefs specified by what it rejects—and this the philosophers who have maintained its beliefs seem often to have intended—would be a minor linguistic innovation, justified in that it makes its commitments explicit. The supposition would have to be modified in some cases. It does not come naturally to us to speak of a *belief* in our personal identity through time, because this identity is something of which we are aware. Nevertheless, it can be argued that here also common sense has commitments which are not apparent before its reaction to various assertions.

**REACTION TO SKEPTICISM.** A philosophy of common sense is a natural reaction to the fact, or to the threat, of philosophical paradox or skepticism. The French Jesuit Claude Buffier (1661–1737) saw us as threatened, since René Descartes, with skepticism about all matters of fact beyond the range of our consciousness, the states of which cannot be doubted. What we need is unimpeachable authority for the fundamental convictions shared by all normal men about matters of fact with respect to which consciousness can give no guarantees. Common sense supplies it. It puts us into assured possession of such "first truths" as that there is an external world, that our minds are incorporeal, that we are capable of free agency. First truths have characteristic marks: No attack upon them, and no attempt to prove them, can operate from premises that surpass them in clarity or evidence. They are, and always have been, acknowledged by the vast

majority of humankind. Those who imagine they reject them act like others in conformity with them.

HUME. David Hume's work *A Treatise of Human Nature* (1739–1740) produced by reaction a more important philosophy of common sense than Buffier's. In parts of the *Treatise*—to isolate what gave the book its most generally “shocking” aspect—things were reduced to the contents of the mind and the mind to its contents. While many of Hume's conclusions are capable of a milder interpretation than they were given by his readers, Hume himself did not pretend that a number of them were anything but profoundly disturbing to our natural beliefs. At the same time he thought these beliefs had us too tightly in their grip for reasoning to be able to pry us loose. In the *Treatise* “nature” has the last word, but its meaning is left uncertain. We must submit, but whether in submitting to nature we are also submitting to truth is quite another matter. In Hume's later *An Enquiry concerning Human Understanding*, “common sense and reflection” are mentioned as correcting, in some degree, the indiscriminate doubt of an extreme skepticism, but nature and reasoning are still seen as coming into conflict. However, it should be remarked that there is another side to Hume in which these skeptical tendencies are in abeyance.

### THE “SCOTTISH SCHOOL”

REID. A central purpose of Thomas Reid's *An Inquiry into the Human Mind on the Principles of Common Sense* (1764), and of his two later books, was, with Hume kept steady in view, to defend common sense against philosophical paradox and skepticism. It was for Reid a doubly difficult undertaking; if, as he held, the truths of common sense were self-evident, how could they be denied? And again, if they were self-evident, how could they be made evident when denied?

The great source of paradoxical or skeptical repudiations of common sense, Reid thought, was an innocent-looking theory that he believed philosophers had very generally adopted in order to explain the possibility of our awareness of anything beyond the present contents of our minds. According to this theory, such awareness is secondhand, necessarily mediated by “ideas” within our minds that are representative substitutes for external things. As its implications were drawn out, the theory, Reid maintained, committed philosophers to a steadily increasing range of conflict with common sense, with no stopping before “ideas,” losing their representative character, monopolize existence. The “theory of ideas” is to be found in John Locke, needing only, Reid believed, an

unsparing logic such as Hume's to produce Hume's world. (Locke's *An Essay concerning Human Understanding* [1690], has a deceptively commonsense air; its tone is down-to-earth, and experience is set up as the source of knowledge. Locke wanted no paradoxes, and when they were approached by what he said, he was not very efficient at drawing conclusions.)

The truths of common sense cannot be made evident by deductive proofs, but, Reid maintained, there is always absurdity in opinions contrary to its dictates. His most general procedure in defending common sense was to remind us of its command over us. Common sense has so fundamentally determined the scaffolding of ordinary language that the philosopher, in trying to word an opinion which is against common sense, is liable to need another language; and his utterance is continually threatened with incoherence between its structure and its content. The beliefs of common sense govern the behavior even of those who repudiate them in opinion, and they are only fitfully repudiated even in opinion; the paradoxical or skeptical philosopher is no sooner off his guard than he is believing with, as well as acting like, other men. Reid stressed a truism about matters of common sense: They lie within “the reach of common understanding.” If this were not so, the judgment of the great bulk of humankind would carry no weight against a philosopher's superior competence. But in “a matter of common sense, every man is no less a competent judge than a mathematician is in a mathematical demonstration” (*Intellectual Powers*, Essay VI, Ch. 4). Whether or not something is a matter of common sense may well have to be investigated—prejudices shamming common sense must be exposed; what Reid denied is that the philosopher is in a better position than anyone else to pronounce on the truth of what really comes from common sense.

Many of the opinions that Reid rejected as contrary to common sense do not appear to be in conflict with the necessities of action he held common sense to impose. Thus, he attacked Berkeley as having denied the existence of a material world, but Berkeley denied that the truth of his opinion would make any changes in our experience; stones, for instance, would remain the solid objects we find them to be. Reid's limited success in vindicating the beliefs of common sense by pointing to inconsistencies between the profession and the practice of dissenters was connected with his interpretation of many of these beliefs; they presented themselves to him as containing an element that lies beyond verification by experience and that might therefore be called metaphysical. He construed, for example, our belief in the existence of a mate-

rial world as disallowing any phenomenalist account of the nature of material things, our belief in personal identity as involving a reference of all our experience to its (immaterial) subject, our belief in the freedom of our will as involving indeterminacy of choice.

**REID'S FOLLOWERS.** The notion of an appeal to common sense in great matters of philosophical dispute was crudely taken up by two of Reid's contemporaries, James Beattie (the poet) and James Oswald. When they were regarded as its representatives, the school that became associated with Reid's name could easily be spoken of as appealing to "the judgment of the crowd." Dugald Stewart (1753–1828), teaching and writing with Reid's moderation, though without his penetrating simplicity, consolidated the school's position in Scotland, and his books helped to make the influence of the ideas he shared with Reid strongly felt in France and America.

**SIR WILLIAM HAMILTON.** Sir William Hamilton (1788–1856) produced a philosophy in which doctrines of Reid and Immanuel Kant were fused into an unstable compound. It proclaimed the sovereignty of common sense and compromised its deliverances, which for Reid were necessarily objective, with an ambiguous assertion of the "relativity" of knowledge. According to Hamilton, the convictions of common sense come to us with the backing of our entire cognitive nature. They are tests of other truth; their own must be presumed, for they are too elementary to have antecedents from which they could be derived. The only possible falsification of common sense would be demonstrated inconsistency in its deliverances, and this would bring in epistemological chaos. J. S. Mill's *An Examination of Sir William Hamilton's Philosophy* (1865) gave a reactionary, obscurantist look to the authority that Reid and Hamilton claimed for common sense. The "psychological" method, which Mill opposed to their "introspective method," was damagingly designed to show how a belief—such as everyone's belief in an external world—had grown up, taking on in the process the appearance of obviousness; the psychological method would undermine the doctrine that a belief is a dictate of nature by exhibiting its natural history.

### CRITICAL COMMON SENSE

Reid and Hamilton both thought that criticism is or may be necessary in order to determine whether a belief is in fact a belief of common sense. They also held, however, that once this fact is established, it follows that the belief is true. The label "critical common sense" might be used, not too misleadingly, to distinguish from this position

those philosophical views which combine the greatest respect for common sense with the insistence or admission that at least some of its beliefs are open to critical revision.

**ARISTOTLE.** If common sense is identified with what is commonly believed and its criticism is thought of as designed to elicit and defend the truth in common beliefs, then Aristotle may be called the first common-sense philosopher. "We must," Aristotle said, "as in all other cases, set the observed facts before us and, after first discussing the difficulties, go on to prove, if possible, the truth of all the common opinions about these affections of the mind, or, failing this, of the greater number and the most authoritative; for if we both refute the objections and leave the common opinions undisturbed, we shall have proved the case sufficiently" (*Nicomachean Ethics*, 1145b2–7; cf. 1172b35–1173a2, *Eudemian Ethics* [attributed to Aristotle], 1216b26–35).

**C. S. PEIRCE.** The "Critical Common-sensism" argued for by the American philosopher Charles Sanders Peirce (1839–1914) was largely defined in relation to the views held by the Scottish school. It saw the beliefs of common sense, Peirce said, as changeless, the same for all men at all times. It rightly thought of them as having a kind of instinctive character—but instincts can undergo modification as people become civilized and civilization develops. They are not, as ordinarily held, beliefs that have been up for acceptance or rejection; they exist as lifelong "belief-habits." And they possess a logical feature in virtue of which they are doubt-resistant when criticized: They have an essential vagueness. Peirce illustrated this with "our belief in the Order of Nature." Let an attempt be made to give this belief precision, and what results will be found disputable. "But who can think that there is *no* order in nature?" (*Collected Papers*, Vol. V, p. 359).

The "Critical Common-sensist," Peirce said, tries to "bring all his very general first premisses to recognition" and to develop "every suspicion of doubt of their truth" (*ibid.*, p. 363). But the doubt he is looking for must be the real thing, not "paper" doubt; we can no more induce genuine doubt by an act of will than we can give ourselves a surprise by deciding to. "Strong thinkers" are "apt to be great breath-holders," but holding one's breath against belief is not doubting. In claiming "indubitability" for a belief of common sense, Peirce was not declaring its truth—"propositions that really are indubitable, for the time being" may "nevertheless be false" (*ibid.*, p. 347). The future holds possibilities of surprise for all our beliefs. Yet

Peirce seems to have held that though any one of our indubitable beliefs might turn out to be false, they could not all do so.

**HENRY SIDGWICK.** “Common sense organised into Science,” Henry Sidgwick (1838–1900) remarked, “continually at once corrects and confirms crude Common Sense” (*Lectures on the Philosophy of Kant*, p. 425). Sidgwick saw common sense as a great mass of ore, rich in valuable metals, that needs philosophical smelting. It must have removed “inadvertencies, confusions, and contradictions” (*ibid.*, p. 428). However, the procedures by which this is done—rigorous reflection, the adjustment of its beliefs to the assured results of science—are not alien to it. Sidgwick’s *Methods of Ethics* (1874) contains a detailed examination of the “morality of common sense,” directed toward showing its frequent vagueness, its areas of indecision, its compromises between conflicting ideas, and also toward showing how its fundamental convictions can be taken up into a form of utilitarianism that can reasonably claim the acquiescence of common sense.

**G. F. STOUT.** For G. F. Stout (1860–1944), common sense has been self-correcting in its evolution and it is still to some extent modifiable. The man in the street is not to be taken as its representative; the common sense of philosophical importance resides in the consensus of ignorant and educated belief. This unanimity is the result of a long development, during which idiosyncrasies of opinion have been worn down by mutual attrition, and mistakes—which common sense itself can see to be such—have been corrected. Common sense is less a matter of particular beliefs than “the persistence of plastic tendencies to certain most general and comprehensive views” (*Mind and Matter*, p. 11). These include such strongly metaphysical dispositions as “the tendency to find Mind in Nature generally” (*ibid.*, p. 14). When a conflict arises between common sense and some scientific or philosophical opinion, the final decision, Stout maintained, rests with common sense, “however indirectly”; for common sense must either be provided with reconciliatory explanations or be brought to see that the considerations in favor of the opinion more than cancel the presumption against it.

**RUSSELL AND BROAD.** It is convenient to mention here two contemporary philosophers who have thought that there are philosophical opinions which can be described as common sense but who have thought that some of these opinions are quite radically mistaken. Science takes common sense as its starting point, Bertrand Russell says;

it has arrived at results with regard to the nature of physical things and their relation to perception that are incompatible with parts of the “metaphysic” of common sense. One does what one can for common sense, but, according to C. D. Broad, sometimes not much is possible; nor should a philosopher feel disturbed at a break with common sense that results from seeing together facts that average people notice only separately and from taking into account other facts of which they are altogether ignorant.

### COMMON SENSE AND ORDINARY LANGUAGE

**G. E. MOORE.** G. E. Moore (1873–1958) did not think that common sense never errs. He seems often to have treated universal, or very general, acceptance as the identifying mark of a commonsense belief, and, as he mentions, things that everybody once believed have turned out to be false. He was prepared to allow that, for all he knew to the contrary, there might be many false propositions included within the vague boundaries of “the Common Sense view of the world.” Moore had no special interest in critically sifting the beliefs of common sense for truth and falsity. He was primarily interested in its massive certainties.

Moore’s paper “A Defence of Common Sense” (1925) lists sets of propositions that are as obviously true as almost any imaginable: for instance (with considerable paraphrase for the sake of brevity), propositions stating that the earth has existed for many years; that its inhabitants have been variously in contact with, or at different distances from, one another and other things; and that these facts are matters of common knowledge. According to Moore, these “truisms,” taken together, imply the truth of the commonsense view of the world in certain of its “fundamental features,” for they imply that there are material things, space, time, and other minds besides one’s own—in a clear meaning of each of the expressions “material thing,” “space,” “time,” and so on. The abstract words contain ambiguities that are absent from, for example, “The earth has existed for many years,” but Moore thought that some philosophers who have denied the existence of material things, of space, of time, or of other minds besides their own are to be understood as having expressed views incompatible with such banally obvious truths. He thus regarded them as paradoxically uttering opinions inconsistent with what they themselves know to be true. They constantly reveal this knowledge in its incompatibility with their opinions; a solipsistic

philosopher, for example, sets himself to persuade others that he alone exists.

There is very great doubt, Moore thought, about the correct “analysis,” in some important respects, of propositions of common sense that are quite certainly true. (Roughly, for Moore, the analysis of a concept or a proposition lays bare its structure by indicating the concepts it implicitly contains and the way they are combined.) Moore did not think that a phenomenalist analysis of the concept of a material thing could be ruled out as absolutely impossible. It follows that, in his judgment, a philosopher who was using the sentence “Material things do not exist” simply to word a phenomenalist doctrine and to repudiate its alternatives would not be repudiating a conviction of common sense that is manifestly true. And if this is so, it is hard to see what a philosopher could have in mind in using the words that would constitute such repudiation. By contrast, denials of the “reality” of space and time on the ground that their concepts are self-contradictory do appear to be in irreconcilable conflict with the most commonplace facts about position and distance, and about past, present, and future.

NORMAN MALCOLM. The philosophical paradoxes that Moore attacked on many different occasions are construed in Norman Malcolm’s essay “Moore and Ordinary Language” as disguised, variously motivated rejections of common language, and Moore’s defense of common sense is construed as its vindication. A philosopher declares, for instance, “We can never know for certain the truth of any empirical statement.” As interpreted by Malcolm, he is saying that it is never right to say “I know for certain” when it is *logically* possible that one is mistaken, that the words are always improperly used in this situation. Moore’s reply, characteristically translating from the abstract to the concrete, pointed out the absurdity of anyone’s suggesting, when he is sitting on a chair, that he believes he is, that he very probably is, but that he does not know it for certain. What Moore’s reply did, on Malcolm’s interpretation, was “to appeal to our language-sense,” “to make us feel how queer and wrong” it would be to speak here in the way the philosopher proposes and substitute “believe” for “know for certain” or to turn to such words as “probable” (“Moore and Ordinary Language,” p. 354).

“A philosophical paradox,” Malcolm says (pp. 359–360), “asserts that, whenever a person uses a certain expression, what he says is false.” However, from the fact that the expression has a use in ordinary language, it follows, Malcolm argues, that it is free from self-contradiction

(since a self-contradictory expression necessarily has no use) and therefore that it *can* be employed to make true statements. And this is enough to refute the paradox. Whether or not people always say something false when using these expressions becomes a matter to be settled by matter-of-fact evidence, and the paradoxical philosopher does not deal in evidence of this sort.

In Malcolm’s essay a stronger claim is made in effect for Moore’s refutations: They produce indisputably true statements employing the expressions that the paradoxes reject, for they present *paradigms* of the correct application of these expressions. And it is maintained that we could not learn the meaning of some expressions without such paradigms or standard cases; that we could not learn, for example, the meaning of “material thing” without being shown examples of material things, or the meaning of spatial and temporal expressions without acquaintance with spatial and temporal relations, or the meaning of “certain,” “probable,” “doubtful” without being introduced to the contrasted situations to which they apply. Thus, a statement denying that there is anything answering to one of these expressions must be false. Scrutiny of “the argument from paradigm cases” has been an incident in the recent shift of philosophical interest from common sense (at least under that name) to ordinary language.

LUDWIG WITTGENSTEIN. The way to philosophical paradox is opened, according to Ludwig Wittgenstein (1889–1951), when some feature of ordinary language is misconstrued as only philosophers are likely to misconstrue it. This disorder, along with such other characteristic philosophical aberrations as directionless bafflement, is to be got rid of by bringing words back from their alienation in metaphysical discourse to the familiar surroundings from which they have been abstracted and watching them at work there. Philosophers have not carelessly misunderstood ordinary language; it is waiting for them with “bewitchment” and “illusion.” In the emancipation that is achieved when one is able to “command a clear view” of the functioning of language, everything is left, but seen to be, “as it is.” Wittgenstein rarely mentioned common sense. He referred in *The Blue Book* (Oxford, 1958, p. 48) to the “common-sense philosopher” (such as Moore or Reid) who, “*n.b.*, is not the commonsense man.” The commonsense man, Wittgenstein may be taken to suggest, is man before the philosophical Fall.

## COMMUNISM

The voluntary disbanding of the communist state of the Soviet Union in 1991 was the practical defeat of a certain theory of communism as the economic, social, and political antithesis and opponent of the liberal democratic capitalist state that first emerged in the developed Western societies. According to Francis Fukuyama (1992), citing Georg Wilhelm Friedrich Hegel's theory of history, the "death of communism" marks the triumph of liberal democratic states as the paramount achievement of human history. Any further opposition to the extension of the liberal democratic model could only come in the form of regressive social movements seeking to avoid the trauma of inevitable change by clinging to ancient dogmas.

Still, as capitalism becomes the unrivaled global economic system, spilling over the bounds of the nation-state, the social and political achievements and perspectives of the liberal democracies are increasingly being jeopardized by the economic logic of capitalism itself. That the economic power of global corporations imposes demands that most nation-states ignore at their peril necessitates a reappraisal of a complacent triumphalism. In historical retrospect and freed from much of the ideological partisanship of the cold war period, it becomes clear that the challenge of communist claims of social egalitarianism and economic efficiency did much to stimulate progressive social and democratic changes in Western societies throughout the nineteenth and twentieth centuries (Hobsbawm 1994). Rather than a choice between two distinct models, it appears that the thesis of capitalism and the antithesis of communism produced in the West an evolving mixture of elements from both ideal models (Lawler 2001).

## MARX'S CONCEPTION OF THE STAGES OF COMMUNISM

Indeed, the perspective of communism as an aspect or dimension of the internal evolution of Western society was the view recommended by the foremost exponent of communism, Karl Marx, who argues that the working people "have no ideals to realize, but to set free elements of the new society with which old collapsing bourgeois society itself is pregnant" (1987, p. 355). In criticizing the conception of communism as an ideal to be realized in the future by contrast to the existing and undesirable state of affairs of the present, Marx distinguishes his "dialectical" understanding of communism from that of rival "nihilistic" theories of communism (Lawler 1994).

**NIHILISTIC AND DIALECTICAL COMMUNISMS.** The most prominent exponent of the nihilistic conception of communism, and Marx's opponent at the time of the *Communist Manifesto* (1848), was the Russian communist Nikolai Bakunin (1814–1876). In his "Appeal to the Slavs" written in 1848 while he was fleeing arrest in Germany, Bakunin writes:

Look! The Revolution is all around. It alone is powerful. The new spirit with its ability to dissolve has irrevocably penetrated humanity; it is burrowing into and overturning the deepest and darkest layers of European society. And the Revolution will not rest until it has completely destroyed the old dislocated world and created in its place a new and better world. Thus all the vigour and strength, all the certainty of triumph is in it and only in it. In it alone is life; outside it is death. (Pirumova, Itenberg, and Antonov 1990, pp. 85–86)

Marx and his partner, Friedrich Engels, rejected this utopian and nihilistic vision of creating an alternative society, however egalitarian and committed to social justice, out of the destruction of the old world. Evoking the realist historical perspective of Hegel that "[w]hat is rational is actual and what is actual is rational" (1991, p. 20), Marx argues that only by studying the real world and its actual movement is it possible to discern the internal forces and trends that bring about change, development, and transformation. Communism, he then argues, is a real movement that is actually taking place within the present capitalist society.

**TEN HOURS BILL.** For example, one of the major social events of the first half of the nineteenth century in England was the passage of a series of factory acts, including

the Ten Hours Bill, which limited the workday for women and children to ten hours. Marx describes this modest achievement as of historic significance, “It was the first time that in broad daylight the political economy of the middle class succumbed to the political economy of the working class” (1987, “Inaugural Address of the Working Men’s International Association, September 28, 1864”). In Marx’s conception the political economy of the middle class, or capitalism, is the pure, unfettered rule of private property and production for the market. Therefore, in limiting the operation of the free market for the sake of the well-being of working people, the factory acts evinced the partial triumph of communism over capitalism taking place within capitalism itself. Other such elements of communism that emerged in the industrial capitalism of the West during the nineteenth and especially the twentieth centuries included free public education, national health care plans (such as, in the United States, Medicare and Medicaid), and national pension or social security plans, as well as laws further limiting the time of the working day and establishing legal conditions for the self-organization of labor through trade unions.

From Marx’s perspective the history of Western capitalism presents evidence for the growing emergence within the evolution of capitalism of embryonic elements of an alternative society whose basic characteristics are already discernable, not from the constructions of ideal theory, but from the requirements of actual historical development. A detailed study of Marx’s thought on the nature of communism reveals six stages or phases of communist development, beginning with the factory acts and similar infusions of social consciousness into the operation of the capitalist market economy: two phases of communism within capitalism, two phases of the transition between capitalism and communism, and two phases of communism *per se* (Lawler 1998).

**DEFINITION OF COMMUNISM.** In the *Communist Manifesto*, when Marx projects the final outcome of this evolution, he formally defines communism as “an association, in which the free development of each is the condition for the free development of all” (Marx and Engels 1976, p. 506). The core idea of communism is the all-round freedom of the individual to develop latent abilities without the age-old restrictions that come from the necessities of mere physical survival. Such free development of each is the foundation of an integrally free society. When he further elaborates on this definition in his *Critique of the Gotha Program* (1875), he writes of the highest stage of the evolutionary process, the second phase of communism *per se*:

In a higher phase of communist society, after the enslaving subordination of the individual to the division of labor, and therewith also the antithesis between mental and physical labor, has vanished; after labor has become not only a means of life but life’s prime want; after the productive forces have also increased with the all-round development of the individual, and all the springs of cooperative wealth flow more abundantly—only then can the narrow horizon of bourgeois right be crossed in its entirety and society inscribe on its banners: from each according to his ability, to each according to his needs! (1989, p. 87)

The dramatic final maxim of communism, “from each according to his ability, to each according to his needs,” cited out of context as the sum and substance of Marx’s conception, appears as an unrealizable, utopian ideal. However, this definition must be comprehended as the outcome of previous stages of historical development. Distribution according to need is only possible at a certain stage or phase of historical evolution when “all the springs of cooperative wealth flow more abundantly.” And this abundance of social wealth presupposes both the alienation of labor and the alienation of this alienation—that is, the progressive emergence of creative human labor, labor that has become “not only a means of life but life’s prime want” (1989, p. 87). These conditions of a fully developed communism emerge within the previous history of market-oriented society.

**LOWER STAGE OF COMMUNISM OR SOCIALISM.** For Marx production for the market, although further limited by laws aimed at individual and social well-being, continues well past the communist revolution (initiating the transition between capitalism and communism) and into the lower phase of communism *per se*. In the lower phase of communism, often called socialism, distribution or the individual’s income is geared to the quantity and quality of the work that the individual performs. This is the principle of “bourgeois right” that arises out of the requirements of market exchange in which qualitatively different products are equalized by their economic value. Because individuals differ in terms of their needs—for example, one person is single, the other has children to support—the principle of fairness, right, or law according to which each is paid according to work performed results in inequality in real conditions of life.

In this lower phase of communism, however, bourgeois “principle and practice are no longer at logger-

heads” (1989, p. 86), as is the case in capitalism. In capitalism the principle of justice calling for “an honest day’s pay for an honest day’s work” is systematically violated by the fact that individuals do not receive according to their actual labor, but according to the value of their labor power or ability to work. While it is asserted that workers are generally paid according to the work they perform, their wages in fact tend to reflect merely the value of goods and services needed to reproduce them as workers. The difference between the wage thus determined and the value of the goods actually produced is surplus value, the basis of capitalist profit. Paying workers according to the work they actually perform, the principle of the first phase of communism, overcomes the contradiction in capitalism between abstract principle and real practice. But if bourgeois right is finally realized only in this lower phase of communism, both practical inequity and the alienation of labor nevertheless continue.

**ALIENATION OF LABOR.** The alienation of labor, first described by Marx in his early *Economic and Philosophic Manuscripts of 1844*, consists in the individual’s having to work to live, to subsist (1975). When people work only for the sake physical survival, they are subverting their essential human powers. Labor, for Marx, is the defining feature of human beings, distinguishing “the worst architect from the best of bees” (1996, p. 189)—the ability to creatively transform and channel the forces of nature to achieve distinctively human goals. The capacity for creative activity or labor arises out of the nature of the human being as a species being, that is, as a being who is directly concerned with the species as a whole. It is this connection of the individual with the human species, as epitomized in the use of language, that raises consciousness beyond the animal level of concern for (mostly) individual needs to the level of universality that constitutes reflective thought itself. Thus, while the animal is satisfied when its present hunger (and that of its immediate family) is appeased, the human individual is not content until the threat of hunger is banished in general, in terms of the future of the group and ultimately of the species as a whole.

Hence, when people survive only by selling their labor, working not to express their creative ability but to prolong their biological existence, they are alienating this distinctive feature of their humanity. Creative, essentially human, activity is barely possible where the necessities of survival force individuals to engage in repetitive physical work for up to sixteen hours per day. The distinctive human gift is squandered when children are forced into mindless labor from an early age. So when Marx exam-

ines the Ten Hours Bill, he recognizes the essential core of communist humanism: restricting the amount of time individuals are forced to work to survive and thereby freeing them, however minimally, to develop their own creative powers. Hence, one of the essential demands of the *Communist Manifesto* is free education for children and the elimination of child labor.

That much of the political platform set forth in the *Communist Manifesto* has in fact been realized in the course of the later evolution of the Western capitalist societies is therefore evidence, from Marx’s point of view, not of the triumph of capitalism, but of the incipient emergence, taking place already within capitalism itself, of what he projects as the outcome of this process, the free development of each of communist society. Only when the prime need of the majority of people is to engage in creative activity is the alienation of labor fully overcome. But the seeds of this development and its embryonic growth begin within capitalism. The historic advances of social democracies face new challenges in the early twenty-first century as an unrivaled capitalism emerges on a global scale beyond the controls of the nation-state. Capitalist economic logic implicitly pits workers of advanced countries against those of newly developing nations without centuries of struggle for the rights of the free development of each. Marx’s ringing conclusion to the *Communist Manifesto* has therefore become even more relevant: Working people of all countries, unite! (Marx and Engels 1976, p. 519)

## COMMUNISM IN THE HISTORY OF WESTERN PHILOSOPHY

**ASIATIC COMMUNISM.** Viewed in this way, communism is not an alien social theory inserted abruptly at one juncture into Western philosophy by Marx, and then given a more hospitable reception in non-Western states such as Russia and China. The communism of the Soviet Union and China reflects an altogether different historical dynamic rising out of what Marx called, in his characterization of the socioeconomic structure of this part of the world, the “Asiatic mode of production” (1989, p. 263). In this mode of production the ruler, the tsar of Russia or the emperor of China, centralizes both political and economic power in his own hands. The dynamics of Western capitalism involves, on the contrary, the relative separation of political power from economic evolution—a separation that continues, for Marx, until, with the full development of communism, “the public power will lose its political [i.e., repressive] character” (Marx and Engels 1976, p. 505). From this point of view the “cult of per-

sonality” of Joseph Stalin (1879–1953) in Russia and Mao Zedong (1893–1976) in China, with state centralization and command of the economy, reflects a kind of Asiatic communism, or a communism developing within the Asiatic mode of production, rather than the communism that Marx discerned as emerging within the womb of Western capitalism. Marx’s conception that communism and the market coexist and interpenetrate well after the communist revolution, allowing for a distinct phase of “market socialism,” diverges sharply from this “Eastern” approach to communism (Lawler 1998).

**POSSESSIVE INDIVIDUALISM.** If in terms of content Marx’s theory of communism is based on a study of Western society, in terms of philosophical form it is the outcome primarily of one of two major streams in early modern Western philosophy (Lawler 2006). One stream regards the individual as a self-interested being, urged on deterministically by desires arising out of nature, environment, and upbringing, and using reason as a means to achieve maximum individual satisfactions and advantages. The “possessive individualism” (Macpherson 1975) of the modern world sets it apart from the ancient Greco-Roman and medieval views of the individual as constituted by birth or nature for various relatively fixed social functions regarded as necessary for the good of the hierarchically ordered social whole. For the self-interested individual of modern times, the good of the social whole is a means to the individual’s own well-being. The classical expression of this trend is the *Leviathan* of Thomas Hobbes, for whom the equal restrictions imposed by the laws of the state (i.e., bourgeois right) establish the civil liberties of capitalist society, including “the liberty to buy, and sell, and otherwise contract with one another; to choose their own abode, their own diet, their own trade of life, and institute [instruct] their children as they themselves think fit; and the like” (1952, p. 113).

Adam Smith’s *Wealth of Nations* propounds an economic justification of this perspective, in which the social good or wealth of nations is the largely unintended outcome of individualistic endeavors of production for the market. But in contrast to Hobbes’s emphasis on the laws of the state, for Smith the economy is the base of the social order and the state and its laws of formally equal freedoms constitute a secondary framework. In his conception of the primacy of the economic base in relation to the political superstructure, Marx continues such economic materialism (Marx writes: “The totality of these relations of production constitutes the economic structure of society, the real foundation, on which arises a legal and political superstructure and to which correspond

definite forms of social consciousness” [1989, p. 263]). However, as seen earlier, the “political economy of the working class” or communism enters this picture when the free operation of buying and selling, and production for the market, are restricted by laws directly aimed at promoting the social good. A radically different understanding of the relation between the individual and the community is implied in the emergence of such communist laws.

**PLATO’S HIERARCHICAL COMMUNISM.** The second line of thought is continuous with the traditional ancient and medieval view that sees the deliberate promotion of the social good as the highest aim of individual flourishing. In the classical formulation of Plato the public good demands communist or communal ownership of property on the part of the ruling guardians of society to prevent them from using their positions of power for private gain. Such public good also requires the perpetuation of what Plato calls a shameful lie, that is, that the souls of individuals are composed of finer or baser metals, from gold and silver for the rulers and their children to brass and iron for the farmers and artisans and their offspring. This is a lie for Plato, because the souls of human beings are not material, and their destinies, evolving over many lifetimes, are ultimately subject to their own choices (1952, book 10, pp. 437–441). Nevertheless, for the peace and order of society it is necessary that

none of [the rulers] should have any property of his own beyond what is absolutely necessary.... Gold and silver we will tell them that they have from God; the diviner metal is within them, and they have therefore no need of the dross which is current among men, and ought not to pollute the divine by any such earthly admixture. (1952, book 3, 341)

The modern proponents of the social good are not ashamed to propagate openly their Platonic spiritualism. However, like their counterparts in the stream of possessive individualism, they reject the fixed hierarchies of the past and adopt the standpoint of free and equal individuals. But such equality they ground on the freedom of consciousness or spirit.

**DESCARTES’S EGALITARIAN COMMUNISM.** Modern egalitarian communism replaces ancient hierarchical communism by stressing the primacy of the free, self-conscious individual, whose awareness that “I think” is, for René Descartes, the foundation of modern scientific method. The self-conscious individual in the modern idealist or spiritualist tradition achieves full self-

development only by working directly for the good of others, the good of society as a whole, in such a way that each associates with the other cooperatively in rewarding activities of mutual and common endeavor. Thus, for Descartes the highest activity for the individual is the pursuit of scientific truth, and the motive of this activity is the practical application of scientific knowledge for the well-being of all. Descartes continues the medieval view of the primacy of the social whole, but abandons its aristocratic foundations in a hierarchy of social classes. Nothing is so equally distributed as reason or good sense (Descartes 1952, p. 69), and this common reason is the foundation of all science and the quest for those truths that will liberate humankind from the immense suffering that is due to ignorance and error. Each individual is capable of joining in the step-by-step ascent to truth that science elaborates as it progressively gains access to the laws of the natural and human orders. Thus, recognizing the limitations of his own individual accomplishments, Descartes begs

all well-inclined persons to proceed further by contributing, each one according to his own inclination and ability, to the experiments which must be made, and then to communicate to the public all the things which they might discover, in order that the last should commence where the preceding had left off; and thus, by joining together the lives and labours of many, we should collectively proceed much further than any one in particular could succeed in doing. (p. 69)

**METAPHYSICAL BASIS OF COMMUNISM: MATERIALISM OR SPIRITUALISM?** Descartes's metaphysical conception of the human individual as a spiritual being occupying a physical body contrasts with Hobbes's materialist view of the human being as primarily a physical being capable somehow of mental *phantasmata*. Both founders of modern philosophy appeal to the requirements of modern science. But whereas Hobbes regards the new physics of Galileo Galilei as demanding a starting point in the inertial straight-line motion of externally moved matter, Descartes sees the ultimate foundation of science in thinking itself, in the self-conscious "I" that is free to depart from the illusions of sensory perception so as to reconstruct a true picture of the world according to a step-by-step method of thought. While the possessive individualism of Adam Smith's justification of the free market correlates with this first metaphysical option, a fundamentally social orientation, anticipating Marx's theory of species being, follows from the second. It may

seem paradoxical to locate Marx's philosophical ancestry in the spiritualism of Plato and Descartes rather than the materialism of Hobbes, but Marx's materialism is a dialectical materialism that is opposed to the mechanistic materialism of Hobbes that was also influential for Smith.

Descartes's metaphysical hierarchy of spirit or consciousness over matter and the body is expressed in practical, ethical, and social requirements. The pursuit of objects that diminish when they are shared with others should be subordinated to the pursuit of objects that are not so diminished. External material wealth diminishes when shared with others, and so one tends to separate oneself from others when one pursues them. However, because one recognizes the good in others, one should freely focus one's mind on the pursuit of those goods that do not diminish when shared, such as knowledge, health, and virtue. So, in a manner reminiscent of Plato's communism, Descartes establishes the community of shared goods as taking precedence over the pursuit of material wealth:

But I distinguish between those of our goods which can be lessened through others possessing the like, and those which cannot be so lessened. ... But virtue, knowledge, health, and in general all other goods considered in themselves without regard to glory are not in any way lessened in us through being found in many others; and so we have no grounds for being distressed because they are shared by others. (1991, pp. 321–322)

When one shares one's ideas with others, one loses nothing, but enriches both oneself and others. It is a win-win situation. When, however, one pursues limited material goods, then what one person gains the other loses. Therefore, scientific philosophy prescribes a social ethics in which the pursuit of goods of the first type has precedence over pursuit of goods of the second type. So Descartes prescribes the basic maxim of a reasonable and good society: from each according to ability, in cooperation with others, and for the good of all. Therefore, a good society is one in which the creative development of each individual is freely associated with that of other individuals, and working together they promote the full development of society as a whole. But that is just Marx's definition of communism in the *Communist Manifesto*.

**LEIBNIZ'S REPUBLIC OF SPIRITS.** Similarly, Gottfried Wilhelm Leibniz's monadic human "spirits" achieve their highest development when they are aware of their harmony with one another and actively promote that

harmony. So Leibniz writes that “[s]pirits are of all substances the most capable of perfection and their perfections are different in this that they interfere with one another the least, or rather they aid one another the most, for only the most virtuous can be the most perfect friends” (1951a, p. 342). The outcome of such universal social friendship Leibniz calls, variously, the moral world, the city of God, the republic of spirits (p. 343), and “the kingdom of final causes” (1951b, p. 132).

**ROUSSEAU’S SOCIAL CONTRACT OF THE POOR.** Reflecting this latter term of Leibniz in his *Groundwork of the Metaphysics of Morals*, Immanuel Kant calls the pursuit of the “kingdom of ends” the culminating formulation of the categorical imperative. It was not primarily to Leibniz that Kant turned for his moral theory, however, but to Jean-Jacques Rousseau, whom Kant regarded as the Isaac Newton of moral science (Meld Shell 1996, 81–82). Rousseau heightens the critique of the philosophy of individual self-interest with his analysis of the Hobbesian social contract as a deceptive strategy on the part of the rich to mobilize the poor in defense of their property, for the meager concession of gaining formal political rights. He describes with sarcasm the real essence of this social contract of the rich, “You need me, for I am rich and you are poor. Let us come to an agreement between ourselves. I will permit you to have the honor of serving me, provided you give me what little you have for the trouble I will be taking to command you” (1976, p. 186). Rousseau would have appreciated the sardonic remark of the communist writer Anatole France that “[t]he law, in its majestic equality, forbids the rich as well as the poor to sleep under bridges, to beg in the streets, and to steal bread” (1894/1992, p. 550).

If the materialist philosophy of self-interest underlies this deception, Rousseau finds an alternative basis of community in the heart-felt promptings of the human soul, which the wise educator of *Émile* must nourish by turning the sympathies of youth toward the common human being, those poor and oppressed victims of the fraudulent social contract. Thus, the tutor of *Émile* counsels:

To excite and nourish this nascent sensitivity, to guide it or follow it in its natural inclination, what is there to do other than to offer the young man objects on which the expansive force of his heart can act—objects which swell the heart, which extend it to other beings, which make it find itself everywhere outside of itself—and carefully to keep away those which contract and

concentrate the heart and tighten the spring of the human *I*? (Rousseau 1979, pp. 222–223)

On such a basis an authentic social contract can be established in which what is emphasized is not the equality of formal legal and political rights (bourgeois right) but relative equality of the conditions of existence. Against the contracted “I” of the philosophy of self-interest, Rousseau emphasizes the expansive “I” that identifies with “the general will.” What distinguishes the general will from the particular will is

not so much the number of votes as the common interest that unites [the citizens], for in this institution each person necessarily submits himself to the conditions he imposes on others. . . . And asking how far the respective rights of the sovereign and the citizens extend is asking how far the latter can commit themselves to one another, each to all and all to each. (1976, p. 34)

What is crucial is the prevention of the extremes of wealth and poverty, not a mathematical or formal equality, and the means for doing this involve manifold rectifications of the existent inequalities of conditions of life, involving the use of a progressive income tax and universal public education. A society based on the principle of “each to all and all to each” is just Marx’s definition of communism in the *Communist Manifesto*.

**KANT’S KINGDOM OF ENDS.** Kant takes up Rousseau’s general will in his formulations of the categorical imperative, culminating in the conception of a “kingdom of ends,” according to which one can “abstract from the personal differences between rational beings, and also from the content of their private ends—to conceive a whole of all ends in systematic conjunction” (1956, pp. 100–101). Making it clear that he does not primarily have in mind the establishment of formal legal and political rights, Kant stresses economic relations of production and exchange of goods as an integral part of such systematic conjunction of ends or goals united under the moral consciousness. The kingdom of ends formulation of the categorical imperative asserts a systematic hierarchy of ends as follows:

What is relative to universal human inclinations and needs has a *market price*; what, even without presupposing a need, accords with a certain taste—that is, with satisfaction in the mere purposeless play of our mental powers—has a *fancy price*; but that which constitutes the sole condition under which anything can be an end in itself has not merely a relative value—that is, a

price—but has an intrinsic value—that is, dignity (p. 102).

Universal respect for the dignity of the human being establishes a community based on common humanity that economic goals must not violate and to which they should be subordinated. Kant repudiates Adam Smith's idea that if everyone pursues their individual interests, the good of all, defined in terms of quantity of goods, will take care of itself. Smith is also far from Descartes's cooperative search for truth, Leibniz's republic of spirits who "aid one another the most," or Rousseau's heart-based community whose maxim is "each to all and all to each," when he writes of the principle of the modern economy:

It is not from the benevolence of the butcher, the brewer, or the baker, that we expect our dinner, but from their regard to their own interest. We address ourselves, not to their humanity but to their self-love, and never talk to them of our own necessities but of their advantages. Nobody but a beggar chooses to depend chiefly upon the benevolence of his fellow-citizens (1952, p. 7).

In another formulation of the moral society, Kant, referring with Leibniz to the Gospels, calls the goal toward which all morality ultimately points "the highest good (the Kingdom of God)" (1993, p. 135). Leibniz and Kant interpret the Gospels as promoting a *this-worldly* kingdom based on spiritual truth, as Jesus said, "The Kingdom of God is within you" (Luke 17:21). The highest good is a unity of virtue and happiness in which happiness is "in exact proportion to morality" (Kant 1993, p. 117). That is, it is a society in which people who perform their moral duties are happy—meaning, that they have their legitimate needs and wants satisfied. Marx merely reformulates this principle for the highest stage of communism: from each according to ability; to each according to need. That is, with the realization of a society whose governing principle is the highest good, people will perform their duties as creative individuals, working in accord with the good of all, and their needs and wants will be satisfied, from the goods and services provided by society, independently of any strict measurement of their contributions. People who contribute less, materially speaking, but still perform their duty according to their ability, are able to satisfy their particular needs just as freely as those who contribute more. They do not, however, work for the sake of satisfying their needs—which for Kant constitutes heteronomy and for Marx is the general characteristic of the alienation of labor.

**IDEAL OF THE HIGHEST GOOD: A FANTASY OR AN EMERGING REALITY?** The problem with this ultimate goal of morality, Kant says, is that it seems unrealizable in the real world that one observes around oneself, that is, the world that is governed by the laws enunciated by Adam Smith and that Marx calls the "political economy of the middle class." In this empirical reality the satisfaction of needs is not based on the performance of moral duty, but on market-based laws of supply and demand that can bring misery and death to whole portions of the population as a result of changes in fashion and fad. Writing about the same time as Adam Smith, and well before the Ten Hours Bill of the next century, Kant sees no clear expressions of a countervailing "communist" tendency in the real world capable of counteracting the actual operation of the economy based on self-interest. But unless the moral principle is capable of being realized, he says, it must be "fantastic, directed to empty imaginary ends, and consequently inherently false" (Kant 1993, p. 120). The whole of Kant's moral theory as he understands it thus hangs on the empirical possibility of its being realizable. The apparent contradiction between moral ideal and empirical reality constitutes what Kant calls "the antinomy of practical reason" (pp. 199–126).

Marx again reformulates Kant when he rejects the pursuit of communism as an abstract ideal raised against the real world, as well as Hegel, who opposes the "empty ideal" of a better society and insists that "[w]hat is rational is actual and what is actual is rational" (Hegel 1991, p. 20). Kant's own solution to the problem hinges primarily on the recognition that history does in fact move in the direction of a society based on the moral ideal (Van der Linden 1988). But to justify this conception he must establish the validity of a teleological view of history. His third *Critique of Judgment*, as well as many of his historical essays, argues for this perspective. In this way Kant paves the way for the historical approach of Hegel, who sees all of human history as the expression of the dynamic of "spirit," which he defines as "'I' that is 'We,' and 'We' that is 'I'" (Hegel 1977, p. 110). Therefore, what is both actual and rational in the course of history, according to Hegel, is what Marx later calls communism (MacGregor 1984).

## COMMUNITARIANISM

In the 1980s communitarians displaced Marxists as the most prominent critics of liberal political theory. Communitarians share a belief that liberalism is excessively individualistic or atomistic, ignoring people's dependence on communal relationships. They differ in where they locate this flaw. Some criticize the liberal ideal of freedom of choice, arguing that people's ends in life are defined by their communal ties, not freely chosen (Sandel 1984). Others accept the ideal of freedom of choice, but criticize liberalism for ignoring its social and cultural preconditions (Taylor 1989). Still, others argue that moral reasoning is dependent on communal traditions, so that

liberal claims to universal validity are illegitimate (Walzer 1983, MacIntyre 1981).

Commentators sometimes distinguish between backward-looking and forward-looking versions of communitarianism (Phillips 1993). The former asserts that healthy communal bonds existed in the past, lament the decline of community as a result of the increasing emphasis on individual choice and diverse ways of life (the “permissive society”), and seek to retrieve a conception of the common good. This sort of communitarianism is difficult to distinguish from traditional conservatism and is widely criticized for ignoring the ways that most communities historically excluded women, gays, or racial and religious minorities (Frazer 1999). By contrast, forward-looking communitarians disavow nostalgia for the past, accept that individual choice and cultural diversity are now permanent features of modern life, and acknowledge that earlier forms of community were too narrow and exclusive to be retrievable today. Hence, they seek to build new bonds of community that integrate diverse groups and lifestyles, for example, by promoting forms of patriotism, democratic citizenship, or civil society that encourage people from different backgrounds to work together. A more complex version of communitarianism is backward-looking at the local level, allowing ethnic or religious communities to uphold a traditional way of life even if it requires restricting individual freedom, while adopting a forward-looking model at the national level, where the multiplicity of different groups in society must cooperate.

In response to the communitarian critique many liberals attempt to show that they, too, are sensitive to the importance of community and culture and that they can accommodate at least the forward-looking dimensions of communitarianism. Hence, a proliferation of theories of liberal republicanism, liberal patriotism, liberal multiculturalism, and liberal civil society have been witnessed. All these are intended to show that a liberal society is not exclusively individualistic and can accommodate and support a rich array of collective identities and associations, without compromising the basic liberal commitment to the protection of individual civil and political rights.

Given these developments, the original liberal-communitarian debate of the 1980s has given way to a number of new, more differentiated positions and issues. Instead of a stark choice between individualism and communitarianism, one now faces a range of debates about how to sustain bonds of moral solidarity and political community in an era of individual rights and cultural

diversity: How to build a common national identity without suppressing ethnic and religious diversity? How to nurture feelings of trust and solidarity in mass societies where people share little in common? How to foster a vibrant public sphere that encourages civic participation and democratic dialogue? How to support family life without imposing traditional gender roles? How to educate children to be public-spirited citizens without inculcating a narrow chauvinism? Communitarianism does not provide a single perspective or framework for answering these questions, and there is a growing sense that the communitarian label obscures as much as it reveals about someone’s position on them. Indeed, virtually all the major writers associated with the original communitarian critique express reservations about the label. Nonetheless, these are all questions that have been put on the agenda of political philosophy by the communitarian critique of liberalism. Communitarianism may be fading as a recognizable school of political philosophy, but communitarian concerns have come to dominate political philosophy at the start of the twenty-first century.

## COMPOSITIONALITY

The principle of compositionality is the claim that the meaning of a complex expression is determined by its structure and the meanings of its constituents. Normally the thesis is taken to be about some particular language; questions of structure and constituency are then settled by the syntax of that language. By extension, we can talk about compositionality in other representational systems—thoughts, traffic signs, musical notation, and so on—as long as they have their own syntax.

### VARIETIES OF COMPOSITIONALITY

The principle is not committed to a specific conception of syntax and semantics, which is why it can be employed in debates between proponents of different conceptions (see, by way of comparison, Partee 1984). Still, if we reject all constraints on either structure or meaning, compositionality becomes trivial. As T. M. V. Janssen (1986) has shown, we can turn any meaning function on a recursively enumerable set of expressions into a compositional one, as long as we can replace the syntactic operations with different ones. And as W. Zadrozny (1994) has shown, we can turn an arbitrary meaning function into a compositional one, as long as we replace the old meanings with new ones from which they are uniformly recoverable. But because the task of semantics is to identify a meaning assignment that respects both what our best syntax tells us about structure and what our best intuitions tell us about synonymy, these results do not show compositionality to be empirically empty (compare Kazmi and Pelletier 1998; Westerståhl 1998; Dever 1999).

Although hardly trivial, the principle as stated is rather weak. For example, consider a view, according to which the meaning of a declarative sentence  $s$  is the set of possible worlds where  $s$  is true. According to such a view, tautologies are synonymous, even though (because Rudolf presumably has some tautological beliefs and lacks others) sentences resulting from embedding tautologies in the context of “Rudolf believes that ...” are not. Intuitively, this is a violation of compositionality (compare Carnap 1947, sec. 14). Still, the semantics is *not* in conflict with compositionality as stated, because tautologies might differ structurally or in the meaning of their constituents, which could explain how embedding them may yield nonsynonymous sentences. The strengthening of the principle that is incompatible with this view requires that the meaning of a complex expression be determined by the meanings of its *immediate* constituents and the syntactic way these constituents are

combined. ( $e$  is an immediate constituent of  $e'$  if  $e$  is a constituent of  $e'$  and  $e'$  has no constituent of which  $e$  is a constituent.) Call the strengthened principle *local compositionality* and the original one *global compositionality*.

Compositionality rules out the existence of a pair of nonsynonymous complex expressions built up from synonymous constituents through identical syntactic operations within the same language. As the principle is usually construed, it says nothing about the possibility of such pair of complex expressions existing in *distinct* languages. Still, intuitively, if the Estonian sentence  $s_1$  and the Aramaic sentence  $s_2$  mean different things despite having identical syntactic structure and pairwise synonymous constituents, we should conclude that either Estonian or Aramaic is not compositional. (The same structure and the same meanings of constituents cannot *determine* more than one meaning.) If we want our principle of compositionality to yield this result, we need to strengthen it: we could demand, for example, that there be a single function for all possible human languages that maps the structure of a complex expression and the meanings of its constituents to the meaning of that complex expression (compare Szabó 2000, p. 500). Call this principle *cross-linguistic compositionality* and the original one *language-bound compositionality*.

So, there are at least four versions of the principle of compositionality: language-bound global, language-bound local, cross-linguistic global, and cross-linguistic local. The first is the weakest and it corresponds to how the principle is officially announced; the last is the strongest and it better captures what is typically taken for granted.

There are three well-known claims that are also occasionally referred to as compositionality principles. The first is the *building principle*, which states that the meaning of a complex expression is built up from the meanings of its constituents. This is a fairly strong claim, at least if we take the building metaphor seriously. For then the meanings of complex expressions must themselves be complex entities whose structure mirrors that of the sentence (compare Frege 1984 [1892], p. 193; Frege 1979 [1919], p. 255). The second is the *rule-to-rule principle*, according to which every syntactic rule corresponds to a semantic one that assigns meanings to the output of the syntactic rule on the basis of the meanings of its inputs. If we assume that an arbitrary function deserves to be called a rule, this is equivalent to language-bound local compositionality. The third is the *principle of substitutivity*, according to which if two expressions have the same meaning, then substitution of one for the other in a third

expression does not change the meaning of the third expression. Assuming that the semantics is *Husserlian*—that substitution of synonyms at a single syntactic position within a larger expression never changes the meaningfulness of the larger expression (compare Husserl 1913, p. 318)—this is also equivalent to language-bound local compositionality. (For the equivalence results, see Hodges 2001, theorem 4. If we want to insist—plausibly—that semantic rules must be at least computable, the rule-to-rule principle is stronger than language-bound local compositionality. The assumption that the semantics is Husserlian is far from trivial—it entails, for example, that because “Jacques is likely to leave” is meaningful and “Jacques is probable to leave” is not; “likely” and “probable” are not synonyms [compare Gazdar et al. 1985, p. 32].)

### FORMAL EXPRESSION

Since R. Montague (1974), it has been customary to capture compositionality formally as the existence of a homomorphism between a syntactic and a semantic algebra. Let the syntactic algebra be a partial algebra  $\mathbf{E} = \langle E, (F\gamma)_{\gamma \in \Gamma} \rangle$ , where  $E$  is the set of (simple and complex) expressions and every  $F\gamma$  is a syntactic operation on  $E$  with a fixed arity. Let  $m$  be a meaning assignment function from  $E$  to  $M$ , the set of meanings. Let  $F$  be a  $k$ -ary syntactic operation on  $E$ ; then  $m$  is  $F$ -compositional if there is a  $k$ -ary partial function  $G$  on  $M$  such that whenever  $F(e_1, \dots, e_k)$  is defined,

$$m(F(e_1, \dots, e_k)) = G(m(e_1), \dots, m(e_k)).$$

Finally, let  $m$  be compositional just in case  $m$  is  $F$  compositional for every operation of the syntactic algebra. Whenever  $m$  is compositional, it induces the semantic algebra  $\mathbf{M} = \langle M, (G\gamma)_{\gamma \in \Gamma} \rangle$  on  $M$  and it is a homomorphism between  $\mathbf{E}$  and  $\mathbf{M}$  (compare Westerstahl 1998). (For details and formal results, see Janssen 1986, 1997; Hodges 2001.) As stated, this captures language-bound local compositionality.

### ARGUMENTS FOR COMPOSITIONALITY

The argument most frequently used to support the compositionality of natural languages is the *argument from productivity*. It goes back (at least) to Frege, who claimed that “the possibility of our understanding sentences which we have never heard before rests evidently on this, that we can construct the sense of a sentence out of parts that correspond to words” (Frege 1980 [1914?], p. 79). The argument is an inference to the best explanation,

which can be expanded and rephrased without assuming that meanings are Fregean senses as follows. Because speakers of a language can understand a complex expression  $e$  that they have not previously encountered, it must be that they (perhaps tacitly) know something on the basis of which they can figure out, without any additional information, what  $e$  means. If this is so, something they already know must determine what  $e$  means. But this knowledge cannot plausibly be in general anything but knowledge of the structure of  $e$  and knowledge of the meanings of the primitive constituents of  $e$ .

If successful, the argument from productivity establishes global language-bound compositionality. To show that a language is locally and/or cross-linguistically compositional requires detailed empirical investigation. As an argument for global language-bound compositionality, it can be criticized on the ground that although we clearly do understand some complex expressions we have never heard before, it is not self-evident that we could *in principle* understand *all* complex expressions in this manner. In fact, it is hard to see how the sort of general considerations mentioned by the argument from productivity could rule out the existence of isolated *exceptions* to compositionality. (Isolated putative exceptions are often declared to be idioms. Criteria for being an idiom are controversial [compare Nunberg, Sag, and Wasow 1994].)

Besides productivity, two other features of our language comprehension are cited in support of compositionality. One is *unboundedness*: although we are finite beings, we have the capacity to understand each of an infinitely large set of complex expressions. (An example from Platts 1979, p. 47: “The horse behind Pegasus is bald,” “The horse behind the horse behind Pegasus is bald,” “The horse behind the horse behind the horse behind Pegasus is bald,” and so on.) 47. From unboundedness, productivity follows (assuming that finite beings cannot encounter infinitely many expressions), and thus this is not really an independent consideration. The other feature of language comprehension that supports compositionality is *systematicity*: that there are definite and predictable patterns among the sentences we understand. (For example, anyone who understands “The rug is under the chair” can understand “The chair is under the rug” and vice versa.) Because productivity does not follow from systematicity the argument from systematicity provides independent support for compositionality.

In fact, systematicity supports a stronger principle. The standard explanation for why understanding “black dog” and “white cat” is sufficient for understanding “black cat” and “white dog” is that we can *decompose* the

meanings of complex expressions into the meanings of their constituents and then *compose* these into meanings of other complex expressions. The best explanation for the possibility of our ability to compose the meanings of complex expressions from the meanings of their constituents is supposed to be compositionality. By parity of reasoning, the best explanation for the possibility to decompose the meanings of complex expressions into the meanings of their constituents is *inverse compositionality*: that the meaning of any complex expression determines the meanings of its lexical constituents (as well as its syntactic structure) (compare Fodor and Lepore 2002, p. 59; Pagin 2003, p. 292). Compositionality and its inverse yield the view that the meanings of complex expressions can be viewed as having a structure isomorphic to the syntactic structures of those expressions, which in turn, may capture the idea behind the metaphor of the building principle.

## COMPUTABILITY THEORY

### 0. THE INFORMAL CONCEPT

Computability theory is the area of mathematics dealing with the concept of an effective procedure—a procedure that can be carried out by following specific rules. For example, one might ask whether there is some effective procedure—some algorithm—that, given a sentence about the positive integers, will decide whether that sentence is true or false. In other words, is the set of true sentences about the positive integers decidable? Or for a much simpler example, the set of prime numbers is certainly a decidable set. That is, there are mechanical procedures, that are taught in the schools, for deciding of any given positive integer whether or not it is a prime number.

More generally, consider a set  $S$ , which can be either a set of natural numbers (the natural numbers are 0, 1, 2, ...), or a set of strings of letters from a finite alphabet. (These two situations are entirely interchangeable. A set of natural numbers is much like a set of base-10 numerals, which are strings of digits. And in the other direction, a string of letters can be coded by a natural number in a variety of ways. The best way is, where the alphabet has  $k$  symbols, to utilize  $k$ -adic notation, which is like base- $k$  numerals except that the  $k$  digits represent 1, 2, ...,  $k$ , without a 0 digit.) One can say that  $S$  is a decidable set if there exists an effective procedure that, given any natural number (in the first case) or string of letters (in the sec-

ond case), will eventually end by supplying the answer: “Yes” if the given object is a member of  $S$  and “No” if it is not a member of  $S$ .

And by an effective procedure here is meant a procedure for which one can give exact instructions—a program—for carrying out the procedure. Following these instructions should not demand brilliant insights on the part of the agent (human or machine) following them. It must be possible, at least in principle, to make the instructions so explicit that they can be executed by a diligent clerk (who is good at following directions but is not too clever) or even a machine (which does not think at all).

Although these instructions must of course be finite in length, no upper bound on their possible length is imposed. It is not ruled out that the instructions might even be absurdly long. Similarly, to obtain the most comprehensive concepts, no bounds are imposed on the time that the procedure might consume before it supplies the answer. Nor is a bound imposed on the amount of storage space (scratch paper) that the procedure might need to use. One merely insists that the procedure give an answer eventually, in some finite length of time.

Later, in section 7, more restrictive concepts will be considered, where the amount of time is limited in some way, so as to exclude the possibility of ridiculously long execution times. Initially, however, one wants to avoid such restrictions, to obtain the limiting case where practical limitations on execution time or memory space are removed.

This description of effective procedures, vague as it is, already shows how limiting the concept of decidability is. It is not hard to see that there are only countably many possible instructions of finite length that one can write out (using a standard keyboard, say). There are, however, uncountably many sets of natural numbers (by Cantor’s diagonal argument). It follows that almost all sets, in a sense, are undecidable.

The following section will look at how the foregoing vague description of effective procedures can be made more precise—how it can be made into a mathematical concept. Nonetheless, the informal idea of what can be done by effective procedure, that is, what is calculable, can be useful.

For another example, consider what is required for a string of symbols to constitute an acceptable mathematical proof. Before one accepts a proof and adds the result being proved to the storehouse of mathematical knowledge, one insists that the proof be verifiable. That is, it should be possible for another mathematician, such as the

referee of the paper containing the proof, to check, step by step, the correctness of the proof. Eventually, the referee concludes either that the proof is indeed correct or that the proof contains a gap or an error and is not yet acceptable. That is, the set of acceptable mathematical proofs should be decidable. This fact will be seen (in section 4) to have significant consequences for what can and cannot be proved. The conclusion follows that computability theory is relevant to the foundations of mathematics.

Before going on, one should broaden the canvas from considering decidable and undecidable sets to considering the more general situation of partial functions. Let  $U$  be either the set  $\mathbb{N} = \{0, 1, 2, \dots\}$  of natural numbers or the set  $\Sigma^*$  of all strings of letters—all words—from a finite alphabet  $\Sigma$ . Then a  $k$ -place partial function on  $U$  is a function whose domain is included in  $U^k = U \times U \times \dots \times U$  and whose range is included in  $U$ . And one can say that such a function is total if its domain is all of  $U^k$ .

For a  $k$ -place partial function  $f$ , one can say that  $f$  is an effectively calculable partial function if there exists an effective procedure with the following property:

- Given a  $k$ -tuple  $x$  in the domain of  $f$ , the procedure eventually halts and returns the correct value for  $f(x)$
- Given a  $k$ -tuple  $x$  *not* in the domain of  $f$ , the procedure does not halt and return a value

(Strictly speaking, when  $U$  is  $\mathbb{N}$ , the procedure cannot be given numbers, it must be given numerals. Numerals are bits of language, which can be communicated. Numbers are not. Thus, the difference between  $U = \mathbb{N}$  and  $U = \Sigma^*$  is even less than previously indicated.)

For example, the partial function for subtraction

$$f(m, n) = \begin{cases} m - n & \text{if } m \geq n \\ \uparrow & \text{otherwise} \end{cases}$$

(where  $\uparrow$  indicates that the function is undefined) is effectively calculable, and procedures for calculating it, using base-10 numerals, are taught in the elementary schools.

The concept of decidability can then be described in terms of functions: For a subset  $S$  of  $U^k$ , one can say that  $S$  is decidable if its characteristic function

$$C_S(x) = \begin{cases} \text{Yes} & \text{if } x \in S \\ \text{No} & \text{if } x \notin S \end{cases}$$

(which is always total) is effectively calculable. Here, “Yes” and “No” are some fixed members of  $U$ , such as 1 and 0 in the case of  $\mathbb{N}$ .

Here, if  $k = 1$ , then  $S$  is a set of numbers or a set of words. If  $k = 2$ , then one has the concept of a decidable binary relation on numbers or words, and so forth.

And it is natural to extend this concept to the situation where one has half of decidability: Say that  $S$  is semi-decidable if its partial characteristic function

$$c_S(x) = \begin{cases} \text{Yes} & \text{if } x \in S \\ \uparrow & \text{if } x \notin S \end{cases}$$

is an effectively calculable partial function. Thus, a set  $S$  of words—a language—is semidecidable if there is an effective procedure for recognizing members of  $S$ . One can think of  $S$  as the language that the procedure accepts.

The following is another example of a calculable partial function:

$$F(n) = \text{the smallest } p > n \text{ such that both } p \text{ and } p + 2 \text{ are prime}$$

Here, it is to be understood that  $F(n)$  is undefined if there is no number  $p$  as described; thus  $F$  might not be total. For example,  $F(9) = 11$ . It is not known whether or not  $F$  is total. Nonetheless, one can be certain that  $F$  is effectively calculable. One procedure for calculating  $F(n)$  proceeds as follows. “Given  $n$ , first put  $p = n + 1$ . Then check whether or not  $p$  and  $p + 2$  are both prime. If they are, then stop and give output  $p$ . If not, increment  $p$  and continue.” What if  $n = 10^{1000}$ ? On the one hand, if there is a larger prime pair, then this procedure will find the first one, and halt with the correct output. On the other hand, if there is no larger prime pair, then the procedure never halts, so it never gives an answer. That is all right, because  $F(n)$  is undefined—the procedure should not give any answer. (Of course,  $F$  is total if and only if (iff) the twin prime conjecture is true.)

Now suppose one modifies this example. Consider the total function:

$$G(n) = \begin{cases} F(n) & \text{if } F(n) \downarrow \\ 0 & \text{otherwise} \end{cases}$$

Here,  $F(n) \downarrow$  means that  $F(n)$  is defined so that  $n$  belongs to the domain of  $F$ . Then the function  $G$  is also effectively calculable. That is, there exists a program that calculates  $G$  correctly. That is not the same as saying that one knows

that program. This example indicates the difference between knowing that a certain effective procedure exists and having the effective procedure in one’s hands.

One person’s program is another person’s data. This is the principle behind operating systems (and behind the idea of a stored-program computer). One’s favorite program is, to the operating system, another piece of data to be received as input and processed. The operating system is calculating the values of a two-place “universal” function, as in the following example.

Suppose one adopts a fixed method of encoding any set of instructions by a single natural number. (First, one converts the instructions to a string of 0s and 1s—one always does this with computer programs—and then one regards that string as naming a natural number under a suitable base-2 notation.) Then, the universal function

$$\Phi(x, y) = \text{the result of applying the instructions coded by } y \text{ to the input } x$$

is an effectively calculable partial function (where it is understood that  $\Phi(x, y)$  is undefined whenever applying the instructions coded by  $y$  to the input  $x$  fails to halt and return an output). Here are the instructions for  $\Phi$ : “Given  $x$  and  $y$ , decode  $y$  to see what it says to do with  $x$ , and then do it.” Of course, the function  $\Phi$  is not total.

Using this universal partial function, one can construct an undecidable binary relation, the halting relation  $H$ :

$$(x, y) \in H \Leftrightarrow \begin{cases} \Phi(x, y) \downarrow \\ \Leftrightarrow \text{applying the instructions} \\ \text{coded by } y \text{ to input } x \text{ halts} \end{cases}$$

To see that  $H$  is undecidable, one can argue as follows. Suppose that, to the contrary,  $H$  is decidable. Then the following function would be effectively calculable:

$$f(x) = \begin{cases} \text{Yes} & \text{if } \Phi(x, x) \uparrow \\ \uparrow & \text{if } \Phi(x, x) \downarrow \end{cases}$$

(Notice the use of the classical diagonal construction.) (To compute  $f(x)$ , one first would decide if  $(x, x) \in H$ . If not, then  $f(x) = \text{Yes}$ . If  $(x, x) \in H$ , however, then the procedure for finding  $f(x)$  should throw itself into an infinite loop, because  $f(x)$  is undefined.) The function  $f$  cannot possibly be effectively calculable, however. Consider any set of instructions that might compute  $f$ . Those instructions have some code number  $k$ , but  $f$  has been constructed in such a way that  $f(k)$  differs from the output from the result of applying instructions coded by  $k$  to the

input  $k$ . (They differ because one is defined and one is not.) So these instructions cannot correctly compute  $f$ ; they produce the wrong result at the input  $k$ . And so one has a contradiction. That the previous relation  $H$  is undecidable is usually expressed by saying that “the halting problem is unsolvable”; that is, one cannot effectively determine, given  $x$  and  $y$ , whether applying the instructions coded by  $y$  to the input  $x$  will eventually terminate or will go on forever.

While the concept of effective calculability has been described in somewhat vague terms here, the following section will give a precise (mathematical) concept of a computable partial function. And then it will be argued that the mathematical concept of a computable partial function is the correct formalization of the informal concept of an effectively calculable partial function. This claim is known as Church’s thesis or the Church-Turing thesis. Church’s thesis, which relates an informal idea to a formal idea, is not itself a mathematical statement, capable of being given a proof, but one can look for evidence for or against Church’s thesis; it all turns out to be evidence in favor.

One piece of evidence is the absence of counterexamples. That is, any function examined thus far that mathematicians have felt was effectively calculable, has been found to be computable.

Stronger evidence stems from the various attempts that different people made independently, trying to formalize the idea of effective calculability. Alonzo Church used  $\lambda$ -calculus, Alan M. Turing used an idealized computing agent (later called a Turing machine), and Emil Post developed a similar approach. Remarkably, all these attempts turned out to be equivalent, in that they all defined exactly the same class of functions, namely, the computable partial functions!

The study of effective calculability originated in the 1930s with work in mathematical logic. As noted earlier, the subject is related to the concept on an acceptable proof. Since the development of modern computers the study of effective calculability has formed an essential part of theoretical computer science. A prudent computer scientist would surely want to know that, apart from the difficulties the real world presents, there is a purely theoretical limit to calculability.

## 1. FORMALIZATIONS

In the preceding section, the concept of effective calculability was described only informally. Now, these ideas will be made more precise (i.e., will be made part of mathe-

matics). In fact, several approaches to doing this will be described: idealized computing devices, generative definitions (i.e., the least class containing certain initial functions and closed under certain constructions), programming languages, and definability in formal languages. It is a significant fact that these different approaches all yield exactly equivalent concepts.

**TURING MACHINES.** In early 1935 Alan M. Turing was a twenty-two-year-old graduate student at King’s College in Cambridge. Under the guidance of Max Newman, he was working on the problem of formalizing the concept of effective calculability. In 1936 he learned of the work of Alonzo Church at Princeton University. Church had also been working on this problem, and in his 1936 paper “An Unsolvable Problem of Elementary Number Theory” he presented a definite conclusion: that the class of effectively calculable functions should be identified with the class of functions definable in the  $\lambda$ -calculus, a formal language for specifying the construction of functions. Moreover, he showed that exactly the same class of functions could be characterized in terms of formal derivability from equations.

Turing then promptly completed writing his paper, in which he presented a different approach to characterizing the effectively calculable functions, but one that—as he proved—yielded once again the same class of functions as Church had proposed. With Newman’s encouragement, Turing then went to Princeton for two years, where he wrote a doctoral dissertation under Church.

Turing’s paper remains a readable introduction to his ideas. How might a diligent clerk carry out a calculation, following instructions? He might organize his work in a notebook. At any given moment his attention is focused on a particular page. Following his instructions, he might alter that page, and then he might turn to another page. And the notebook is large enough that he never comes to the last page.

The alphabet of symbols available to the clerk must be finite; if there were infinitely many symbols, then there would be two that were arbitrarily similar and so might be confused. One can then without loss of generality regard what can be written on one page of notebook as a single symbol. And one can envision the notebook pages as being placed side by side, forming a paper tape, consisting of squares, each square being either blank or printed with a symbol. At each stage of his work, the clerk—or the mechanical machine—can alter the square under examination, can turn attention to the next square or the previous one, and can look to the instructions to

see what part of them to follow next. Turing described the latter part as a “change of state of mind.”

Turing wrote, “We may now construct a machine to do the work” (1936–1937, p. 251). Of course, such a machine is now called a Turing machine, a phrase first used by Church in his review of Turing’s paper in *The Journal of Symbolic Logic*. The machine has a potentially infinite tape, marked into squares. Initially, the given input numeral or word is written on the tape, but it is otherwise blank. The machine is capable of being in any one of finitely many states (the phrase “of mind” being inappropriate for a machine). At each step of calculation, depending on its state at the time, the machine can change the symbol in the square under examination at that time, can turn its attention to the square to the left or to the right, and can then change its state to another state.

The program for this Turing machine can be given by a table. Where the possible states of the machine are  $q_1, \dots, q_p$ , each line of the table is a quintuple  $\langle q_i, S_p, S_k, D, q_m \rangle$ , which is to be interpreted as directing that whenever the machine is in state  $q_i$  and the square under examination contains the symbol  $S_p$ , then that symbol should be altered to  $S_k$  and the machine should shift its attention to the square on the left (if  $D = L$ ) or on the right (if  $D = R$ ), and should change its state to  $q_m$ . For the program to be unambiguous, it should have no two different quintuples with the same first two components. (By relaxing this requirement regarding absence of ambiguity, one obtains the concept of a nondeterministic Turing machine, which will be useful later, in the discussion of feasible computability.) One of the states, say  $q_1$ , is designated as the initial state—the state in which the machine begins its calculation. If one starts the machine running in this state and examining the first square of its input, it might (or might not), after some number of steps, reach a state and a symbol for which its table lacks a quintuple having that state and symbol for its first two components. At that point the machine halts, and one can look at the tape (starting with the square then under examination) to see what the output numeral or word is.

Now suppose that  $\Sigma$  is a finite alphabet and that  $f$  is a  $k$ -place partial function on the set  $\Sigma^*$  of words. One says that  $f$  is Turing computable if there exists a Turing machine  $M$  that, when started in its initial state scanning the first symbol of a  $k$ -tuple  $\vec{w}$  of words (written on the tape, with a blank square between words, and with everything to the right of  $\vec{w}$  blank), behaves as follows:

- If  $f(\vec{w}) \downarrow$  (i.e., if  $\vec{w} \in \text{dom } f$ ), then  $M$  eventually halts, and at that time it is scanning the leftmost

symbol of the word  $f(\vec{w})$  (which is followed by a blank square).

- If  $f(\vec{w}) \uparrow$  (i.e., if  $\vec{w} \notin \text{dom } f$ ), then  $M$  never halts.

This definition can be readily adapted to apply to  $k$ -place partial functions on  $\mathbb{N}$ .

Then Church’s thesis, also called—particularly in the context of Turing machines—the Church-Turing thesis, is the claim that this concept of Turing computability is the correct formalization of the informal concept of effective calculability. Certainly, the definition reflects the ideas of following predetermined instructions, without limitation of the amount of time that might be required. (The name *Church-Turing thesis* obscures the fact that Church and Turing followed different paths in reaching equivalent conclusions.)

As will be explained shortly, Church’s thesis has by now achieved universal acceptance. Kurt Gödel, writing in 1964 about the concept of a formal system in logic, involving the idea that the set of correct deductions must be a decidable set, said that “due to A. M. Turing’s work, a precise and unquestionably adequate definition of the general concept of formal system can now be given” (Davis 1965, p. 71).

The robustness of the concept of Turing computability is evidenced by the fact that it is insensitive to certain modifications to the definition of a Turing machine. For example, one can impose limitations on the size of the alphabet, or one can insist that the machine never move to the left of its initial starting point. None of this will affect that class of Turing computable partial functions.

Turing developed these ideas before the introduction of modern digital computers. After World War II he played an active role in the development of early computers and in the emerging field of artificial intelligence. (During the war, he worked on deciphering the German battlefield code Enigma, work that remained classified until after Turing’s death.) One can speculate whether Turing might have formulated his ideas somewhat differently, if his work had come after the introduction of digital computers.

**PRIMITIVE RECURSIVENESS AND MINIMALIZATION.** For a second formalization of the calculability concept, a certain class of partial functions on  $\mathbb{N}$  will now be defined as the smallest class that contains certain initial function and is closed under certain constructions.

For the initial functions, one can take the following simple total functions:

- The zero functions, that is, the constant functions  $f$  defined by the equation:

$$f(x_1, \dots, x_k) = 0$$

- The successor function  $S$ , defined by the equation:

$$S(x) = x + 1$$

- The projection functions  $I_n^k$  from  $k$ -dimensions onto the  $n$ th coordinate,

$$I_n^k(x_1, \dots, x_k) = x_n$$

where  $1 \leq n \leq k$ .

One can form the closure of the class of initial functions under three constructions: composition, primitive recursion, and minimalization.

A  $k$ -place function  $h$  is said to be obtained by composition from the  $n$ -place function  $f$  and the  $k$ -place functions  $g_1, \dots, g_n$  if the equation

$$h(\vec{x}) = f(g_1(\vec{x}), \dots, g_n(\vec{x}))$$

holds for all  $\vec{x}$ . In the case of partial functions, it is to be understood here that  $h(\vec{x})$  is undefined unless  $g_1(\vec{x}), \dots, g_n(\vec{x})$  are all defined and  $\langle g_1(\vec{x}), \dots, g_n(\vec{x}) \rangle$  belongs to the domain of  $f$ .

A  $(k + 1)$ -place function  $h$  is said to be obtained by primitive recursion from the  $k$ -place function  $f$  and the  $(k + 2)$ -place function  $g$  (where  $k > 0$ ) if the pair of equations

$$\begin{aligned} h(\vec{x}, 0) &= f(\vec{x}) \\ h(\vec{x}, t+1) &= g(t, h(\vec{x}, t), \vec{x}) \end{aligned}$$

holds for all  $\vec{x}$  and  $t$ .

Again, in the case of partial functions, it is to be understood that  $h(\vec{x}, t + 1)$  is undefined unless  $h(\vec{x}, t)$  is defined and  $\langle t, h(\vec{x}, t), \vec{x} \rangle$  is in the domain of  $g$ .

For the  $k = 0$  case, the one-place function  $h$  is obtained by primitive recursion from the two-place function  $g$  with the number  $m$  if the pair of equations

$$\begin{aligned} h(0) &= m \\ h(t + 1) &= g(t, h(t)) \end{aligned}$$

holds for all  $t$ .

Postponing the matter of minimalization, one can define a function to be primitive recursive if it can be built up from zero, successor, and projection functions by

use of composition and primitive recursion. In other words, the class of primitive recursive functions is the smallest class that includes the initial functions and is closed under composition and primitive recursion.

Clearly, all the primitive recursive functions are total. One can say that a  $k$ -ary relation  $R$  on  $\mathbb{N}$  is primitive recursive if its characteristic function is primitive recursive.

One can then show that a great many of the common functions on  $\mathbb{N}$  are primitive recursive: addition, multiplication,  $\dots$ , the function whose value at  $m$  is the  $(m + 1)$ st prime,  $\dots$

On the one hand, it is clear that every primitive recursive function should be regarded as being effectively calculable. On the other hand, the class of primitive recursive functions cannot possibly comprehend all total calculable functions, because one can easily “diagonalize out” of the class. That is, by suitably indexing the “family tree” of the primitive recursive functions, one can make a list  $f_0, f_1, f_2, \dots$  of all the one-place primitive recursive functions. One can then consider the diagonal function  $d(x) = f_x(x) + 1$ . Then  $d$  cannot be primitive recursive; it differs from each  $f_x$  at  $x$ . Nonetheless, if one makes the list tidily, the function  $d$  is effectively calculable. The conclusion is the class of primitive recursive functions is an extensive but proper subset of the total calculable functions.

Next, one can say that a  $k$ -place function  $h$  is obtained from the  $k + 1$ -place function  $g$  by minimalization and one writes

$$h(\vec{x}) = \mu y [g(\vec{x}, y) = 0]$$

if for each  $\vec{x}$ , the value  $h(\vec{x})$  either is the number  $y$  such that  $g(\vec{x}, y) = 0$  and  $g(\vec{x}, s)$  is defined and is nonzero for every  $s < y$ , if such a number  $y$  exists, or else is undefined, if no such number  $y$  exists. The idea behind this  $\mu$ -operator is the idea of searching for the least number  $y$  that is the solution to an equation, by testing successively  $y = 0, 1, \dots$

One can obtain the general recursive functions by adding minimalization to the closure methods. That is, a partial function is general recursive if it can be built up from the initial zero, successor, and projection functions by use of composition, primitive recursion, and minimalization.

The class of general recursive functions is (as Turing proved) exactly the same as the class of Turing computable functions. And Church’s thesis therefore has the

equivalent formulation that the concept of a general recursive function is the correct formalization of the informal concept of effective calculability.

What if one tries to diagonalize out of the class of general recursive functions, as one did for the primitive recursive functions? As will be argued later, one can again make a tidy list  $\varphi_0, \varphi_1, \varphi_2, \dots$  of all the one-place general recursive partial functions. And one can define the diagonal function  $d(x) = \varphi_x(x) + 1$ . In this equation,  $d(x)$  is undefined unless  $\varphi_x(x)$  is defined. The diagonal function  $d$  is indeed among the general recursive partial functions, and hence is  $\varphi_k$  for some  $k$ , but  $d(k)$  must be undefined. No contradiction results.

The class of primitive recursive functions was defined by Gödel, in his 1931 paper on the incompleteness theorems. Of course, the idea of defining functions on  $\mathbb{N}$  by recursion is much older and reflects the idea that the natural numbers are built up from the number 0 by repeated application of the successor function. The theory of the general recursive functions was worked out primarily by Stephen Cole Kleene, a student of Church.

The use of the word *recursive* in the context of the primitive recursive functions is entirely reasonable. Gödel, writing in German, had used simply *rekursiv* for the primitive recursive functions. Retaining the word *recursive* for the general recursive functions was a, however, historical accident. The class of general recursive functions—as this section shows—has several characterizations in which *recursion* (i.e., defining a function in terms of its other values, or using routines that call themselves) plays no role at all.

Nonetheless, the terminology became standard. What are here called the computable partial functions were until the late 1990s standardly called the partial recursive functions. And for that matter, computability theory was called recursive function theory for many years, and then recursion theory. And relations on  $\mathbb{N}$  were said to be recursive if their characteristic functions were general recursive functions.

An effort is now being made, however, to change what had been the standard terminology. Accordingly, this entry speaks of computable partial functions. And it will call a relation computable if its characteristic function is a computable function. Thus, the concept of a computable relation corresponds to the informal notion of a decidable relation. In any case, there is definitely a need to have separate adjectives for the informal concept (here, *calculable* is used for functions, and *decidable* for

relations) and the formally defined concept (here, *computable*).

**LOOP AND WHILE PROGRAMS.** The idea behind the concept of effective calculable functions is that one should be able to give explicit instructions—a program—for calculating such a function. What programming language would be adequate here? Actually, any of the commonly used programming languages would suffice, if freed from certain practical limitations, such as the size of the number denoted by a variable. One can give here a simple programming language with the property that the programmable functions are exactly the computable partial functions on  $\mathbb{N}$ .

The variables of the language are  $X_0, X_1, X_2, \dots$ . Although there are infinitely many variables in the language, any one program, being a finite string of commands, can have only finitely many of these variables. If one wants the language to consist of words over a finite alphabet, one can replace  $X_3$ , say, by  $X'''$ .

In running a program, each variable in the program gets assigned a natural number. There is no limit on how large this number can be. Initially, some of the variables will contain the input to the function; the language has no input commands. Similarly, the language has no output commands; when (and if) the program halts, the value of  $X_0$  is to be the function value.

The commands of the language come in five kinds:

- (1)  $X_n \leftarrow 0$ . This is the clear command; its effect is to assign the value 0 to  $X_n$ .
- (2)  $X_n \leftarrow X_n + 1$ . This is the increment command; its effect is to increase the value assigned to  $X_n$  by one.
- (3)  $X_n \leftarrow X_m$ . This is the copy command; its effect is just what the name suggests; in particular it leaves the value of  $X_m$  unchanged.
- (4) Loop  $X_n$  and endloop  $X_n$ . These are the loop commands, and they must be used in pairs. That is, if  $\mathcal{P}$  is a program—a syntactically correct string of commands—then so is the string:

$$\begin{array}{c} \text{loop } X_n \\ \mathcal{P} \\ \text{endloop } X_n \end{array}$$

What this program means is that  $\mathcal{P}$  is to be executed a certain number  $k$  of times. And that number  $k$  is the initial value of  $X_n$ , the value assigned to  $X_n$  before

one starts executing  $\mathcal{P}$ . Possibly,  $\mathcal{P}$  will change the value of  $X_n$ ; this has no effect at all on  $k$ .

(5) While  $X_n \neq 0$  and endwhile  $X_n \neq 0$ . These are the while commands; again, they must be used in pairs, like the loop commands, but there is a difference. The program

$$\begin{array}{l} \text{while } X_n \neq 0 \\ \quad \mathcal{P} \\ \text{endwhile } X_n \neq 0 \end{array}$$

also executes the program  $\mathcal{P}$  some number  $k$  of times. Now, however,  $k$  is not determined in advance; it matters very much how  $\mathcal{P}$  changes the value of  $X_n$ . The number  $k$  is the least number (if any) such that executing  $\mathcal{P}$  that many times causes  $X_n$  to be assigned the value 0. The program will run forever if there is no such  $k$ .

And those are the only commands. A while program is a sequence of commands, subject only to the requirement that the loop and while commands are used in pairs, as illustrated. Clearly, this programming language is simple enough to be simulated by any of the common programming language, if one ignores overflow problems.

A loop program is a while program with no while commands; that is, it has only clear, increment, copy, and loop commands. Note the important property: A loop program always halts, no matter what. It is easy, however, to make a while program that never halts.

One can say that a  $k$ -place partial function  $f$  on  $\mathbb{N}$  is while-computable if there exists a while program  $\mathcal{P}$  that, whenever started with a  $k$ -tuple  $\vec{x}$  assigned to the variables  $X_1, \dots, X_k$  and 0 assigned to the other variables, behaves as follows:

- If  $f(\vec{x})$  is defined, then the program eventually halts, with  $X_0$  assigned the value  $f(\vec{x})$ .
- If  $f(\vec{x})$  is undefined, then the program never halts.

The loop-computable functions are defined in the analogous way. There is the difference, however, that any loop-computable function is total.

**Theorem.** (a) A function on  $\mathbb{N}$  is loop-computable iff it is primitive recursive.

(b) A partial function on  $\mathbb{N}$  is while-computable iff it is general recursive.

The proof in one direction, to show that every primitive recursive functions is loop-computable, involves a

series of programming exercises. The proof in the other direction involves coding the status of a program  $\mathcal{P}$  on input  $\vec{x}$  after  $t$  steps, and showing that there are primitive recursive functions enabling one to determine the status after  $t + 1$  steps, and the terminal status. Because the class of general recursive partial functions coincides with the class of Turing computable partial functions, one can conclude from the previous theorem that while-computability coincides with Turing computability.

**DEFINABILITY IN FORMAL LANGUAGES.** In his 1936 paper in which he presented what is now known as Church's thesis, Church utilized a formal system, the  $\lambda$ -calculus. Church had developed this system as part of his study of the foundations of logic. In particular, for each natural number  $n$  there is a formula  $\mathbf{n}$  of the system denoting  $n$ , that is, a numeral for  $n$ . More important, formulas could be used to represent the construction of functions. He defined a two-place function  $F$  to be  $\lambda$ -definable if there existed a formula  $\mathbf{F}$  of the  $\lambda$ -calculus such wherever  $F(m, n) = r$  then the formula  $\{\mathbf{F}\}(\mathbf{m}, \mathbf{n})$  was convertible, following the rules of the system, to the formula  $\mathbf{r}$ , and only then. An analogous definition applied to  $k$ -place functions.

Church's student, Stephen Cole Kleene, showed that a function was  $\lambda$ -definable iff it was general recursive. (Church and his student, J. B. Rosser, were also involved in the development of this result.) Church wrote in his paper, "The fact ... that two such widely different and (in the opinion of the author) equally natural definitions of effective calculability turn out to be equivalent adds to the strength of reasons ... for believing that they constitute as general a characterization of this notion as is consistent with the usual intuitive understanding of it" (Alonzo 1936, p. 346).

Earlier, in 1934, Gödel, in his lectures at Princeton, formulated a concept now referred to as Gödel-Herbrand computability. He did not, however, at the time propose the concept as a formalization of the concept of effective calculability. The concept involved a formal calculus of equations between terms built up from variables and function symbols. The calculus permitted the passage from an equation  $A = B$  to another equation obtained by substituting for a part  $C$  of  $A$  or  $B$  another term  $D$  where the equation  $C = D$  had been derived. If a set  $\mathcal{E}$  of equations allowed the derivation, in a suitable sense, of exactly the right values for a function  $f$  on  $\mathbb{N}$ , then  $\mathcal{E}$  was said to be a set of recursion equations for  $f$ . Once again, it turned out that a set of recursion equations existed for  $f$  iff  $f$  was a general recursive function.

A rather different approach to characterizing the effectively calculable functions involved definability in first-order logic over the structure of the natural numbers with addition and multiplication. Say that a  $k$ -place partial function  $f$  on  $\mathbb{N}$  is a  $\Sigma_1$ -function if the graph of  $f$  (i.e., the  $(k + 1)$ -ary relation  $\{\langle x_1, \dots, x_k, y \rangle \mid f(x_1, \dots, x_k) = y\}$ ) is definable in the structure with universe  $\mathbb{N}$  and with the operations of addition, multiplication, and exponentiation, by an existential formula (i.e., a formula consisting of a string of existential quantifiers, followed by a quantifier-free part). Then the class of partial  $\Sigma_1$ -functions coincides exactly with the class of partial functions given by the other formalizations of calculability described here. Moreover, Yuri Matijasevič showed in 1970 that the operation of exponentiation was not needed here.

Finally, say that a  $k$ -place partial function  $f$  on  $\mathbb{N}$  is representable if there exists some finitely axiomatizable theory  $T$  in a language having a suitable numerals  $\mathbf{n}$  for each natural number  $n$ , and there exists a formula  $\varphi$  of that language such that (for any natural numbers)  $f(x_1, \dots, x_k) = y$  iff  $\varphi(x_1, \dots, x_k, y)$  is a sentence deducible in the theory  $T$ . Then once again the class of representable partial functions coincides exactly with the class of partial functions given by the other formalizations of calculability described here.

## 2. BASIC RESULTS

First, one has the remarkable fact that all the formalizations of the preceding section yield exactly the same class of partial functions on  $\mathbb{N}$ . And this fact is not only remarkable, it is also reassuring, indicating that the concept captured by the formalizations—the concept of a computable partial function—is natural and significant. Moreover, it gives evidence that the concept captured by the formalizations is actually the correct formalization of the informal concept of effective calculability. That is, it gives evidence for Church's thesis (or the Church-Turing thesis). This thesis was first set forth by Church in a 1935 abstract, and then published in full in his 1936 paper. (At the time, Church was unaware of Turing's approach, but he knew of several of the other formalizations described in the preceding section.) This assertion, that computability is the precise counterpart to effective calculability, is not really a mathematical statement susceptible of proof or disproof; rather, it is a judgment that one has found the correct formalization of the one's informal concept.

The situation can be compared to one encountered in calculus. An intuitively continuous function (defined on an interval) is one whose graph one can draw without

lifting the pencil off the paper. To prove theorems, however, some formal counterpart of this notion is needed. And so one gives the usual definition of  $\varepsilon$ - $\delta$ -continuity. One should ask if the precise notion of  $\varepsilon$ - $\delta$ -continuity is an accurate formalization of intuitive continuity. If anything, the class of  $\varepsilon$ - $\delta$ -continuous functions is too broad. It includes nowhere differentiable functions, whose graphs cannot be drawn without lifting the pencil—there is no way to impart a velocity vector to the pencil. Nonetheless, the class of  $\varepsilon$ - $\delta$ -continuous functions has been found to be a natural and important class in mathematical analysis.

In a similar spirit, one can ask how accurately the formal concept of computability captures the informal concept of effective calculability. As with continuous functions, the precisely defined class (of computable functions) appears to be, if anything, too broad. It includes functions for which any procedure will, for large inputs, require so much computing time and memory (scratch paper) space as to make implementation absurd. Computability corresponds to calculability in an idealized world, where length of computation and amount of memory are disregarded. (This will be discussed further in section 7.) In any case, however, the class of computable partial functions has been found to be a natural and important class in mathematical logic.

Empirical evidence that the class of computable functions is not too narrow is provided both by the fact that the attempted formalizations (as described in section 1) have all yielded the equivalent concepts, and by the fact that no counterexample have arisen—the functions considered thus far that mathematicians have felt were effectively calculable have turned out to be computable. In the decades since 1936, Church's thesis has gained universal acceptance.

**NORMAL FORM.** In each of the formalizations described in the preceding section, one can in a straightforward way code the instructions for any computable partial function by a natural number  $e$ . In the case of Turing machines,  $e$  encodes the set of quintuples that determine the machine's operation. In the case of a function built up from the zero, successor, and projection functions by primitive recursion and minimalization,  $e$  encodes the ancestral tree describing exactly how the function is built up. In the case of while programs,  $e$  encodes the program.

**Normal form theorem.** There is a ternary computable relation  $T$  and a total computable function  $U$  with the following property: For each 1-place computable

partial function  $f$  on  $\mathbb{N}$ , there is a natural number  $e$  such that

$$f(x) = U(\mu y T(e, x, y))$$

for every number  $x$ .

Here (as elsewhere), equality has the natural meaning: Either both sides of the equation are defined and are the same, or else both sides are undefined.

One can construct the relation  $T$  (called the Kleene  $T$ -predicate) so that  $T(e, x, y)$  expresses the idea that  $e$  encodes the instructions for  $f$ , and  $y$  encodes the entire history of the step-by-step computation of  $f$  with input  $x$ , from the beginning through the final step at which the computational procedure comes to a halt. Then the function  $U$  (the upshot function) extracts from  $y$  what the answer or output is.

The normal form theorem can be extended to  $k$ -place functions. One can make a  $(k + 2)$ -ary computable relation  $T_k$  such that for each  $k$ -place computable partial function  $f$ , there is a number  $e$  such that

$$f(x_1, \dots, x_k) = U(\mu y T_k(e, x_1, \dots, x_k, y))$$

for every  $x_1, \dots, x_k$ . Moreover, one can construct  $T_k$  and  $U$  so that they are even primitive recursive.

The significance of the normal form theorem is that it allows one to form a universal partial computable function. One can define

$$\varphi_e(x) = U(\mu y T(e, x, y))$$

(where, of course,  $\varphi_e(x) \uparrow$  if the right side of the equation is undefined, which happens if there does not exist a  $y$  such that  $T(e, x, y)$ ). Then on the one hand,  $\varphi_e(x)$  is a computable partial 2-place function of  $x$  and  $e$ . And on the other hand, each 1-place computable partial function equals  $\varphi_e$  for some  $e$ . That is,

$$\varphi_0, \varphi_1, \varphi_2, \dots$$

is a complete list of all the computable partial 1-place functions.

Similarly, one can extend these ideas to  $k$ -place partial functions:

$$\varphi_e^k(x_1, \dots, x_k) = U(\mu y T_k(e, x_1, \dots, x_k, y))$$

Then

$$\varphi_0^k, \varphi_1^k, \varphi_2^k, \dots$$

is a complete list of all the computable partial  $k$ -place functions.

Whenever one has such a list, one can diagonalize out of it. One can define the set  $K$  by the condition

$$x \in K \Leftrightarrow \varphi_x(x) \downarrow$$

so that a number  $x$  (thought of as encoding a program for computing a partial function) belongs to  $K$  iff that program, given  $x$  itself as input, halts and returns a value.

Then the diagonal function

$$d(x) = \begin{cases} \varphi_x(x) + 1 & \text{if } x \in K \\ 0 & \text{otherwise} \end{cases}$$

is a total function, but it cannot equal  $\varphi_e$  for any  $e$ , because it differs from  $\varphi_e$  at  $e$ . So  $d$  is not a computable function. If  $K$  were computable, however, then  $d$  would be computable, because the partial function  $\varphi_x(x) + 1$  is computable.

One can conclude that  $K$  is not a computable set; its characteristic function  $C_K$  is not a computable function. But the partial characteristic function

$$c_k(x) = \begin{cases} 1 & \text{if } x \in K \\ \uparrow & \text{otherwise} \end{cases}$$

is a computable partial function;  $c_k(x) = 1 + 0 \cdot \varphi_x(x)$ .

**Theorem.** For a set  $A$  of numbers, the following are equivalent:

- (1) The partial characteristic function of  $A$  is a computable partial function
- (2)  $A$  is the domain of some computable partial function
- (3) For some computable binary relation  $R$ ,

$$x \in A \Leftrightarrow R(x, y) \text{ for some } y$$

(Here (2)  $\Rightarrow$  (3) because  $x \in \text{dom } \varphi_e \Leftrightarrow T(e, x, y)$  for some  $y$ . And (3)  $\Rightarrow$  (1) because one can use the function  $1 + 0 \cdot \mu y R(x, y)$ .)

A set  $A$  with the properties of this theorem is said to be computably enumerable (c.e.). The concept of a c.e. set is the formalization of the informal concept of a semidecidable set, discussed in section 0. And Church's thesis assures one that it is the correct formalization.

In the previously standard terminology mentioned earlier, a set  $A$  with the properties of the theorem was said to be recursively enumerable (r.e.). In fact, this terminol-

ogy—especially the abbreviation—has become so well established that the prospects for reform are uncertain.

The theorem extends to the case where  $A$  is a  $k$ -ary relation on  $\mathbb{N}$ ; now in part (3) the relation  $R$  is  $k + 1$ -ary. Thus, one may speak of c.e. (or r.e.) relations on  $\mathbb{N}$ .

**Unsolvability of the halting problem.** The binary relation  $\{\langle x, y \rangle \mid \varphi_y(x) \downarrow\}$  is c.e. but not computable.

This relation—the halting relation—cannot be computable lest the previous diagonal function  $d$  be computable. It is c.e., because  $\varphi_y(x) \downarrow \Leftrightarrow \exists z T(y, x, z)$ .

If one defines  $W_e = \text{dom}\varphi_e$ , then as a consequence of the normal form theorem, one has a complete list

$$W_0, W_1, W_2, \dots$$

of all the c.e. sets. The set  $K$  can be described simply as  $\{x \mid x \in W_x\}$ .

The following is not hard to see:

**Kleene's theorem.** A set is computable iff both it and its complement are c.e.

For example, the complement  $\bar{K}$  is not only noncomputable, it is not even c.e.

For another example of an undecidable set, take the set of programs that compute total functions:

$$\text{Tot} = \{e \mid \varphi_e \text{ is total}\}$$

The same argument used for  $K$  shows that Tot is not computable. Moreover, Tot is not c.e. In fact, a slightly stronger statement holds: There is no c.e. set  $P$  such that  $\{\varphi_e \mid e \in P\}$  coincides with the class of total computable functions. Thus, if  $P$  is a c.e. set of programs that compute only total functions, then there must be some total computable function with no program in  $P$ .

**Rice's theorem.** Suppose that  $C$  is a collection of computable partial 1-place functions, and let  $I$  be  $\{e \mid \varphi_e \in C\}$ . Then  $I$  is computable only in two trivial cases: when  $C$  is empty and when  $C$  is the collection of all computable partial functions.

For example, suppose one focuses attention on a particular computable partial function  $f$ . Rice's theorem asserts that one cannot always decide of a given program whether or not that program correctly computes  $f$ .

The name *computably enumerable* corresponds to yet another characterization: A set is c.e. iff there is a Turing machine (augmented with a suitable output tape) that can generate, in some order, the members of that set, one after another. More formally, a set  $S$  of natural numbers is c.e. iff it is either empty or is the range of some total computable function  $f$ , that is,  $S = \{f(0), f(1), \dots\}$ . In fact, one

can even insist that  $f$  be primitive recursive. In general the function  $f$  will not enumerate the members of  $S$  in numerical order, however (i.e.,  $f$  will not in general be an increasing function). The range of an increasing function (or even of a nondecreasing function) will always be a computable set.

It is easy to see that if  $f$  is a two-place computable partial function, then the result of holding one variable fixed (as a parameter)

$$g(x) = f(36, x)$$

is a one-place computable partial function  $g$ . Often, one needs the more subtle fact: A program for  $g$  can be effectively found from the program for  $f$  and the value of the parameter.

**Parameter theorem.** There is a total computable function  $\rho$  such that

$$\varphi_e(t, x) = \varphi_{\rho(e, t)}(x)$$

for all  $e, t$ , and  $x$ .

The analogous statement holds for more variables, that is, for an  $m$ -tuple  $\vec{t}$  and an  $n$ -tuple  $\vec{x}$  in place of  $t$  and  $x$ . The parameter theorem commonly goes by the cryptic name of the  $S$ - $m$ - $n$  theorem.

A deeper result is the following theorem, which is due to Kleene.

**Recursion theorem.** For any computable partial function  $g$ , one can find an  $e$  such that

$$\varphi_e(x) = g(e, x)$$

for all  $x$ .

Again,  $x$  can be replaced by an  $n$ -tuple  $\vec{x}$ . The proof of the recursion theorem is similar to the argument used to produce self-referential sentences in number theory, such as those used in proving Gödel's incompleteness theorem.

### 3. AXIOMATIZABLE THEORIES

The connection between computability theory and logic hinges on the fact that proofs must be effectively recognizable.

The concept of a proof is basic to logic. What exactly is a proof? As indicated in section 0, for a proof to be acceptable, it must be possible—in principle—to fill in enough steps that a hard-working graduate student (or a referee) can verify its correctness. One cannot demand that this student have the same brilliant insight that the proof's discoverer had. Nor can one demand that the stu-

dent spend an infinite amount of time checking an infinite number of cases. What one can insist is that, given a correct proof (with all the steps filled in), the student will eventually complete the verification and stand up and say, “Yes, this proof is correct.”

This is just to say, however, that the set of correct proofs must be at least semidecidable. And typically one expects that the set will even be decidable, lest the student work forever attempting to verify an incorrect proof. In an axiomatic theory, one expects to be able to tell (effectively) an axiom from a nonaxiom, and one expects to be able to determine (effectively) whether or not a rule of inference is being correctly applied.

Even with the weaker property of semidecidability, it follows that the set of theorems—the set of sentences that have proofs—is semidecidable. (Given a sentence, one could employ the brute-force procedure of going through all strings of symbols in a systematic way, spending more and more time on each, attempting to verify that it is a proof of that sentence.) That is, the set of theorems must be c.e.

More formally, assume one has a first-order language, such as the language for set theory. Formulas are (or can be made to be) strings over a finite alphabet, so the concepts of computability theory are applicable. (It is being assumed here that the language has a reasonably simple array of nonlogical symbols.) One can define a theory to be a set of sentences closed under logical consequence. In particular, for a set  $A$  of formulas adopted as axioms, one can obtain the theory  $T_A$  consisting of all sentences that are logical consequences of  $A$ .

**Theorem.** (a) If  $A$  is a computable set or a c.e. set of axioms, then the set  $T_A$  of logical consequences of  $A$  is c.e.

(b) (Craig’s theorem.) Conversely, if a theory  $T$  is c.e., then there is a computable set  $A$  of axioms such that  $T$  is the set of logical consequences of  $A$ .

Part (a) follows from the Gödel completeness theorem for first-order logic. The set of logical consequences of  $A$  is the same as the set of sentences derivable from  $A$  in the predicate calculus. If one has a machine that can generate the axioms, then one can organize a machine to generate the theorems.

Part (b) utilizes the simple fact that if one can generate the members of  $T$  in some order,

$$T = \{\tau_0, \tau_1, \tau_2, \dots\}$$

then one can generate a suitable set of axioms in increasing order:

$$A = \{\tau_0, \tau_0 \wedge \tau_1, \tau_0 \wedge \tau_1 \wedge \tau_2, \dots\}$$

So  $A$  is computable.

If one defines a theory  $T$  to be axiomatizable if there exists a computable set of axioms for it (or equivalently, if there exists a c.e. set of axioms for it), then there is the conclusion: A theory is axiomatizable iff it is c.e.

For example, the usual ZFC axioms for set theory form a computable set of axioms, so the set of theorems of ZFC is a c.e. set. At the other extreme, taking the set of axioms to be empty, one can conclude that the set of valid sentences is c.e. The set of valid sentences is, however, undecidable:

**Church’s theorem.** Assume the language has at least one two-place predicate symbol. Then the set of valid sentences is not computable.

#### 4. GÖDEL INCOMPLETENESS THEOREM

This section examines Gödel’s first incompleteness theorem, from the point of view of computability theory. As the context, first-order theories of arithmetic, that is, theories dealing with the natural numbers with the operations of addition and multiplication, will be considered. Certainly, the study of the natural numbers with addition and multiplication is a basic part of mathematics, in the real sense that it is the topic in mathematics that school children study first.

The structure that is focused on here

$$\mathfrak{N} = (\mathbb{N}; 0, S, +, \times)$$

consists of the set  $\mathbb{N}$  of natural numbers with the distinguished element 0 and the operations of successor ( $S$ ), addition ( $+$ ), and multiplication ( $\times$ ). The first-order language corresponding to this structure has quantifiers  $\forall$  and  $\exists$  ranging over  $\mathbb{N}$ , a constant symbol  $\mathbf{0}$  for the number 0, and function symbols  $\mathbf{S}$ ,  $+$ , and  $\times$  for successor, addition, and multiplication.

The set of all sentences of this language that are true in standard structure  $\mathfrak{N}$  will be called the theory of true arithmetic. Although this theory deals with basic topics, it is by no means trivial. For example, it is not hard to see that the set of prime numbers is definable in  $\mathfrak{N}$ , that is, one can write down a formula  $\pi(x)$  of the language that is satisfied in  $\mathfrak{N}$  when the number  $n$  is assigned to  $x$  iff  $n$  is prime:

$$\begin{aligned} n \text{ is prime} &\Leftrightarrow \models_{\mathfrak{N}} \pi[n] \\ &\Leftrightarrow \models_{\mathfrak{N}} \pi(n) \end{aligned}$$

where one substitutes for  $x$  the numeral  $\mathbf{n}$  for  $n$ , that is the numeral  $\mathbf{SS}\dots\mathbf{S0}$ . Using this formula  $\pi$  one can then write

down a sentence in the language that expresses the twin prime conjecture, or a sentence that expresses Goldbach's conjecture. But the truth or falsity of these conjectures remains unknown.

What can one say quantitatively about the complexity of the theory of true arithmetic? It will be seen in this section that the theory is not c.e. and hence is not an axiomatizable theory. One connection between  $\mathfrak{N}$  and computability is expressed by the result:

**Theorem.** Every computable relation over  $\mathbb{N}$  is definable in the structure  $\mathfrak{N}$ . That is, for each computable  $k$ -ary relation  $R \subseteq \mathbb{N}^k$  there is a formula  $\rho$  defining  $R$  in  $\mathfrak{N}$ :

$$\langle n_1, \dots, n_k \rangle \in R \Leftrightarrow \models_{\mathfrak{N}} \rho[n_1, \dots, n_k]$$

As an immediate consequence of this theorem, one can conclude that c.e. relations are also definable in  $\mathfrak{N}$ . This is because any c.e. relation  $Q$  is the domain of some computable relation  $R$ :

$$m \in Q \Leftrightarrow \langle m, n \rangle \in R, \text{ for some } n$$

Thus, if  $\rho(x, y)$  defines  $R$  in  $\mathfrak{N}$ , then  $\exists y\rho(x, y)$  defines  $Q$ . Moreover,  $\neg\exists y\rho(x, y)$  defines the complement  $\bar{Q}$  of  $Q$ . And by repeating the previous argument, the domain of  $\bar{Q}$  is definable.

The conclusion is that any relation over  $\mathbb{N}$  that is obtainable from the computable relations by the operations of forming the domain (i.e., projection) and forming the complement, iterated any number of times, will be definable in the structure  $\mathfrak{N}$ . (The converse is also true; these are exactly the definable relations; see section 6.)

In particular, the set  $\bar{K}$  is definable in  $\mathfrak{N}$ , where  $K$  is the c.e. but noncomputable set constructed earlier. That is, there is some formula  $\kappa(x)$  that defines  $K$ , so that  $\neg\kappa(x)$  defines  $\bar{K}$  and

$$n \in \bar{K} \Leftrightarrow \neg\kappa(n) \text{ is true in } \mathfrak{N}.$$

It follows from this, however, that the set of sentences (of the language) true in  $\mathfrak{N}$  cannot be semidecidable, lest equivalence yield an effective procedure for recognizing membership in this. Thus, one comes to the conclusion that truth in arithmetic is not a c.e. concept:

**Theorem.** The set of sentences true in  $\mathfrak{N}$  is not c.e.

(An elaboration of this argument would give Tarski's theorem: The set of sentences true in  $\mathfrak{N}$ , when converted to a set of natural numbers, is not definable in  $\mathfrak{N}$ .)

This theorem, with the previous section, asserts that the theory of true arithmetic is not axiomatizable. So any axiomatizable subtheory fails to give all of true arithmetic.

**Gödel's incompleteness theorem.** For any axiomatizable subtheory  $T$  of true arithmetic, one can find a true sentence that is not derivable in  $T$ .

In fact, here is how one can find that true, undervivable sentence. Let

$$J = \{n \mid T \vdash \neg\kappa(n)\},$$

the set of numbers that  $T$  "knows" are in  $\bar{K}$ . Because  $T$  is axiomatizable (and hence c.e.), the set  $J$  is c.e., and so  $J = W_j$  for some number  $j$ . Moreover,  $J$  is a subset of  $\bar{K}$  so it cannot be all of that set; there is a number in  $\bar{K}$  that is not in  $J$ . In fact,  $j$  is such a number.

That is, the sentence  $\neg\kappa(j)$  is a true sentence ( $j$  is really in  $\bar{K}$ ) that  $T$  does not prove ( $T$  does not know that  $j \in \bar{K}$ ). Thus, the sentence  $\neg\kappa(j)$  is a specific witness to  $T$ 's incompleteness.

And what might this sentence  $\neg\kappa(j)$  say? Interpreted in  $\mathfrak{N}$  it speaks of numbers and their sums and products. One can give it a more interesting translation, however:

$$\begin{aligned} \neg\kappa(j) \text{ says } & j \in \bar{K} \\ & \text{i.e., } j \notin W_j \\ & \text{i.e., } j \notin J \\ & \text{i.e., } T \nvdash \neg\kappa(j) \end{aligned}$$

That is, the witness (the true unprovable sentence) asserts, in a sense, its own unprovability!

The conclusion is that the computability theory approach to Gödel's incompleteness theorem, based on c.e. sets, is not so different from the more traditional approach, which uses a diagonal construction to produce a sentence asserting, in a sense, its own unprovability.

## 5. DEGREES OF UNSOLVABILITY

Some unsolvable problems are more unsolvable than others. To make sense of this idea, one can employ the concept of relative computability.

Consider a fixed set  $B$  of natural numbers. Then a partial function  $f$  should be considered effectively calculable relative to  $B$  if there is a procedure that computes  $f$  and is effective except that it is allowed to appeal to an "oracle" for  $B$ . An oracle for  $B$  can be thought of as a device that, given a number  $x$ , responds by saying whether or not  $x$  is in  $B$ .

Any of the formalizations of calculability given in section 1 can be augmented to incorporate such an oracle. For example, in the case of primitive recursive functions, one can simply add the characteristic function of  $B$

as a new initial function. As before, the various formalizations give exactly the same class of partial functions. Thus, one may speak unambiguously of computability relative to a set  $B$ .

Of course, if  $B$  is a computable set, however, the computability relative to  $B$  is simply equivalent to computability. For a noncomputable set, however, some noncomputable functions will become computable relative to  $B$  (the characteristic function of  $B$ , for one).

The concept of relative computability was introduced by Turing in a 1939 paper. At first glance, it seems an odd concept, combining as it does the most constructive approach to functions (that of computability) with the least constructive approach (that of a magical oracle). It is to Turing's credit that he perceived the value of the concept.

For sets  $A$  and  $B$  of natural numbers, one can say that  $A$  is computable *in*  $B$ , or that  $A$  is Turing reducible to  $B$  (written  $A \leq_T B$ ) if the characteristic function of  $A$  is computable relative to  $B$ . That is, saying that  $A \leq_T B$  implies that membership in  $A$  is no harder to decide than is membership in  $B$ . The  $\leq_T$  relation is transitive and is reflexive on  $\mathcal{P}\mathbb{N}$  (i.e., it is a preordering). Informally, transitivity of  $\leq_T$  corresponds to connecting machines in series. Consequently, the symmetric version

$$A \equiv_T B \Leftrightarrow A \leq_T B \text{ and } B \leq_T A$$

is an equivalence relation on  $\mathcal{P}\mathbb{N}$ , and  $\leq_T$  gives a partial ordering of the equivalence classes. These equivalence classes are called degrees of unsolvability, or simply degrees.

There is a least degree  $\mathbf{0}$ , the class of the computable sets. Each degree must be a countable collection of sets (because there are only countably many programs), and so there are  $2^{\aleph_0}$  equivalence classes altogether. Any two degrees have a least upper bound. The earlier construction of a noncomputable set  $K$  can be relativized:

$$x \in B' \Leftrightarrow \varphi_x^B(x) \downarrow$$

(where  $\varphi_x^B$  is the partial function computed, relative to  $B$ , by the program  $e$ ). Then the degree of  $B'$  is strictly larger (under  $\leq_T$ ) than the degree of  $B$ ; thus, there is no largest degree.

The set  $B'$  is called the jump of  $B$ . Thus, the jump operation can be applied to a set to obtain a set of higher degree, and this operation can be iterated:

$$B <_T B' <_T B'' <_T B''' <_T \dots$$

The degrees are not linearly ordered. It is possible to construct simultaneously sets  $A$  and  $B$  in such a way as to sabotage each machine that might reduce one set to the other. In fact, much more is true; one can construct  $2^{\aleph_0}$  degrees that are all incomparable to each other under the ordering.

One can define a degree to be c.e. if it contains a c.e. set. These degrees are of particular interest because they are the degrees of axiomatizable theories. The least degree  $\mathbf{0}$  is the degree of the decidable theories. Earlier, a non-computable c.e. set  $K = \{x \mid \varphi_x(x) \downarrow\}$  was constructed. So the degree of  $K$ , denoted  $\mathbf{0}'$ , is a c.e. degree greater than  $\mathbf{0}$ . The halting problem for Turing machines (regarded as a set of integers) also has degree  $\mathbf{0}'$ . It is not hard to show that  $\mathbf{0}'$  is the largest c.e. degree: for every c.e. degree  $\mathbf{a}$  one has  $\mathbf{a} \leq_T \mathbf{0}'$ . (Thus, any c.e. set of degree  $\mathbf{0}'$  is  $\leq_T$ -complete for c.e. sets, in the sense that every other c.e. set is computable in it.)

A number of undecidable axiomatizable theories turn out to have degree  $\mathbf{0}'$ : the validities of predicate calculus (with at least a binary predicate symbol), first-order Peano arithmetic, ZF set theory (if consistent), and others.

In 1944 Emil Post raised the question whether there were any c.e. degrees other than  $\mathbf{0}$  and  $\mathbf{0}'$ . This question, which became known as Post's problem, was finally answered in 1956 (two years after Post's death), independently by Richard Friedberg (in his Harvard senior thesis) and by A. A. Mučnik (in the Soviet Union). They showed that intermediate c.e. degrees do indeed exist, and in great profusion. Gerald Sacks later showed that any countable partial ordering can be embedded—as a partial ordering—in the partial ordering of c.e. degrees.

Although the natural axiomatizable theories have turned out to have either degree  $\mathbf{0}$  or degree  $\mathbf{0}'$ , Solomon Feferman showed that every c.e. degree contains some axiomatizable theory.

There is a simpler way in which questions about membership in one set might be effectively reducible to questions about another set. One can define  $A$  to be many-one reducible to  $B$  (written  $A \leq_m B$ ) if there is a total computable function  $f$  such that

$$x \in A \Leftrightarrow f(x) \in B$$

for all natural numbers  $x$ . The idea is that each question " $x \in A$ ?" about  $A$  is reduced by  $f$  to one question about  $B$ . Moreover, if there is such a reduction function  $f$  that is one to one, then one can say that  $A$  is one-one reducible to  $B$  (written  $A \leq_1 B$ ). Clearly,

$$A \leq_1 B \Rightarrow A \leq_m B \Rightarrow A \leq_f B$$

and in general neither arrow can be reversed. Again, both  $\leq_1$  and  $\leq_m$  are preorders, so the corresponding symmetric relations

$$A \equiv_1 B \Leftrightarrow A \leq_1 B \ \& \ B \leq_1 A \text{ and } A \equiv_m B \Leftrightarrow A \leq_m B \ \& \ B \leq_m A$$

are equivalence relations on  $\mathcal{P}\mathbb{N}$ , and the equivalence classes (the one-one degrees and the many-one degrees) are partially ordered. John Myhill showed that if  $A \equiv_1 B$ , then there is a total computable permutation of  $\mathbb{N}$  taking  $A$  onto  $B$ .

It is not hard to make a c.e. set that is  $\leq_1$ -complete for c.e. sets, that is, every c.e. set is one-one reducible to it. In fact,  $K$  is such a set.

## 6. DEFINABILITY IN ARITHMETIC

As in section 4, let

$$\mathfrak{A} = (\mathbb{N}; 0, S, +, \times)$$

be the standard structure for arithmetic, consisting of the set  $\mathbb{N}$  of natural numbers with the distinguished element 0 and the operations of successor, addition, and multiplication. In this structure, what sets (or relations or functions) are definable by first-order formulas? In section 4 it was noted that every computable relation is definable in arithmetic, and section 5 used the fact that some non-computable sets (such as  $\overline{K}$ ) are also definable. Now, one can approach the matter more systematically.

Say that a relation (on  $\mathbb{N}$ ) is arithmetical if it is definable in  $\mathfrak{A}$ . Of course, only countably many relations can be arithmetical, because there are only countably many formulas. One wants to classify these relations, according to the quantifier depth of the defining formulas.

From section 2 it is known that a relation  $A$  is c.e. iff it is the domain of some computable relation  $R$ :

$$\bar{m} \in A \Leftrightarrow R(\bar{m}, n) \text{ for some } n.$$

If  $\rho(x_1, \dots, x_k, y)$  defines  $R$ , then the formula  $\exists y \rho(x_1, \dots, x_k, y)$  defines  $A$ , so that  $A$  is “one quantifier away” from being computable. One can say that such relations  $A$  are  $\Sigma_1$ . (Yuri Matijacevič showed in 1970 that in fact every c.e. relation is definable by an existential formula, that is, one of the form

$$\exists y_1 \dots \exists y_l \rho(x_1, \dots, x_k, y_1, \dots, y_l)$$

where  $\rho$  is quantifier-free, but that fact is not needed here.)

Next, call a relation  $\Sigma_2$  if it is definable by a formula

$$\exists y_1 \forall y_2 \rho(x_1, \dots, x_k, y_1, y_2)$$

where  $\rho$  defines a computable relation. Call a relation  $\Sigma_3$  if it is definable by a formula

$$\exists y_1 \forall y_2 \exists y_3 \rho(x_1, \dots, x_k, y_1, y_2, y_3)$$

where  $\rho$  defines a computable relation), and so forth.

The dual concept, where one reverses existential and universal quantifiers, gives the  $\Pi_k$  relations. That is, call a relation  $\Pi_1$  if it is definable by a formula

$$\forall y \rho(x_1, \dots, x_k, y)$$

call it  $\Pi_2$  if it is definable by a formula

$$\forall y_1 \exists y_2 \rho(x_1, \dots, x_k, y_1, y_2),$$

call it  $\Pi_3$  if it is definable by a formula

$$\forall y_1 \exists y_2 \forall y_3 \rho(x_1, \dots, x_k, y_1, y_2, y_3),$$

and so forth, where in each case  $\rho$  defines a computable relation.

Then the  $\Pi_k$  relations are exactly the complements of the  $\Sigma_k$  relations. In effect, one is measuring how far away a relation is from decidability.

By adding vacuous quantifiers, one sees that any  $\Sigma_k$  relation is both  $\Sigma_{k+1}$  and  $\Pi_{k+1}$ . And every definable relation appears somewhere in this hierarchy, because it will be definable by a prenex formula, the quantifier-free part of which always defines a computable (in fact primitive recursive) relation.

For example, the set  $\{e \mid \varphi_e \text{ is total}\}$  of programs of total functions is  $\Pi_2$ , because  $\varphi_e$  is total iff  $\forall m \exists n T(e, m, n)$ . By Kleene’s theorem, a relation is computable iff it is both  $\Sigma_1$  and  $\Pi_1$ . The set  $K$  is  $\Sigma_1$  but not  $\Pi_1$ . And in analogy to this fact, one can, for each  $k$ , construct a set that is  $\Sigma_k$  but not  $\Pi_k$ . Thus, letting the noun  $\Sigma_k$  denote the collection of all  $\Sigma_k$  relations, one has proper inclusion in both of the chains

$$\Sigma_1 \subset \Sigma_2 \subset \Sigma_3 \subset \dots$$

$$\Pi_1 \subset \Pi_2 \subset \Pi_3 \subset \dots$$

and in both cases the union of the chains is exactly the class of arithmetical relations. One can say that these chains define the arithmetical hierarchy.

From the point of view of the arithmetical hierarchy, one can obtain Tarski’s theorem that the theory of true arithmetic is not arithmetical:

**Tarski's theorem.** The set of sentences true in  $\mathfrak{N}$ , regarded as a set of numbers, is not definable in  $\mathfrak{N}$ .

Let  $T$  be the set of true sentences. It suffices to show, for each  $k$ , that  $T$  cannot be  $\Sigma_k$ . Let  $A$  be a set that is arithmetical but not  $\Sigma_k$  (as indicated, there is such a set, and one can even make it  $\Pi_k$ ). Then  $A$  is definable by some formula  $\alpha(x)$  and

$$n \in A \Leftrightarrow \alpha(n) \in T$$

which shows that  $A \leq_m T$  (where  $T$  has been identified with the corresponding set of numbers). That is, for some total computable function  $f$  (which substitutes numerals into  $\alpha$ ),

$$n \in A \Leftrightarrow f(n) \in T.$$

If, contrary to one's hopes,  $T$  were  $\Sigma_k$ , then the previous line would let one conclude that  $A$  is also  $\Sigma_k$ , which it is not.

There is also a connection between the arithmetical hierarchy and relative computability, as in section 5. The following result extends the fact that a relation is  $\Sigma_1$  iff it is c.e.

**Post's theorem.** (a) A relation is  $\Sigma_2$  iff it is c.e. in  $\emptyset'$ , the jump of the empty set.

(b) More generally, a relation is  $\Sigma_{k+1}$  iff it is c.e. in  $\emptyset^{(k)}$ , the  $k$ th jump of the empty set.

## 7. FEASIBLE COMPUTABILITY

Up to now, this entry has approached computability from the point of view that there should be no constraints on the time required for a particular computation, or on the amount of memory space that might be required. The result is that some total computable functions will take a long time to compute. If a function  $f$  grows rapidly, then for large  $x$  it will take a long time simply to generate the output  $f(x)$ . There are also, however, bounded functions that require a large amount of time.

To be more precise, suppose one adopts one of the formalizations from section 1 (any one will do), and one defines in a reasonable way the "number of steps" or the "time required" in a computation. (Manuel Blum converted the term *reasonable* into axioms for what a *complexity measure* should be.) Then Michael Rabin showed that for any total computable function  $h$ , no matter how fast it grows, one can find another total computable function  $f$  with range  $\{0, 1\}$  such that for any program  $e$  for  $f$  (i.e.,  $f = \varphi_e$ ), the time required for  $e$  to compute  $f(x)$  exceeds  $h(x)$  for all but finitely many values of  $x$ . (The

function  $f$  is constructed in stages, in such a way as to sabotage any fast program that might try to compute  $f$ .)

Is there a more restricted concept of "feasibly computable function" where the amount of time required does not grow beyond all reason, where the amount of time required is an amount that might actually be practical, at least when the input to the function is not absurdly large? To this vague question, an exact answer has been proposed.

One can call a function  $f$  polynomial-time computable (or for short, P-time computable) if there is a program  $e$  for  $f$  and a polynomial  $p$  such that for every  $x$ , the program  $e$  computes  $f(x)$  in no more than  $p(|x|)$  steps, where  $|x|$  is the length of  $x$ .

This definition requires some explanation and support. If  $f$  is a function over  $\Sigma^*$ , the set of words over a finite alphabet  $\Sigma$ , then of course  $|x|$  is just the number of symbols in the word  $x$ . If  $f$  is a function over  $\mathbb{N}$ , then  $|x|$  is the length of the numeral for  $x$ . (Here, one comes again to the fact that effective procedures work with numerals, not numbers.) So if one uses base-2 numerals for  $\mathbb{N}$ , then  $|x|$  is about  $\log_2 x$ .

Moreover, there was vagueness about exactly how the number of steps in a computation was to be determined. Here the situation is encouraging: The class of P-time computable functions is the same, under the different reasonable ways of counting steps.

Back in sections 0 and 1 there was the encouraging fact that many different ways of formalizing the concept of effective calculability yielded exactly the same class of functions. As remarkable as that fact is, even more is true. The number of steps required by one formalization is bounded by a polynomial in the number of steps required by another. For example, there exists a polynomial  $p$  (of moderate degree) such that a computation by a Turing machine that requires  $n$  steps can be simulated by a loop-while program that requires no more than  $p(n)$  steps. Consequently, the concept of a P-time computable function is robust: One can get the same class of functions, regardless of which formalization from section 1 is employed. To be sure, the degrees of the polynomials will vary somewhat, but the class of P-time functions is unchanged.

Encouraged by this result, and inspired in particular by 1971 work of Stephen Cook, people since the 1970s have come to regard the class of P-time functions as the correct formalization of the idea of functions for which computations are feasible, without totally impractical running times.

By analogy to Church's thesis, the statement that P-time computability corresponds to feasibly practical computability has come to be known as Cook's thesis or the Cook-Karp thesis. (The concept of P-time computability appeared as early as 1964 in work of Alan Cobham. Jack Edmunds in 1965 pointed out the good features of P-time algorithms. Richard Karp in 1972 extended Cook's work.)

So what are the P-time computable functions? They form a subclass of the primitive recursive functions. All the polynomial functions are P-time computable, as are some functions that grow faster than any polynomial. There is, however, a limit to the growth rate of P-time computable functions, imposed by the fact that printing an output symbol takes a step. That is, there is the following growth limitation property: If  $f$  is computable in time bounded by the polynomial  $p$ , then  $|f(x)| \leq |x| + p(|x|)$ . This prevents exponential functions from being P-time computable; there is not enough time to write down the result.

Often, P-time computability is presented in terms of acceptance of languages (i.e., sets of words). Where  $\Sigma$  is the finite alphabet in question, consider a language  $L \subseteq \Sigma^*$ . One can say that  $L \in P$  if there is a program and a polynomial  $p$  such that whenever a word  $w$  is in  $L$ , then the program halts on input  $w$  (i.e., it "accepts"  $w$ ) in no more than  $p(|w|)$  steps, and whenever a word  $w$  is not in  $L$ , then the program never halts on input  $w$  (i.e., the program does not accept  $w$ ). This is equivalent to saying that the characteristic function of  $L$  is P-time computable, because one can add to the program an alarm clock that rings after time  $p(|w|)$ . For example, it is now known that the set of prime numbers (as a set of words written in the usual base-10 notation) belongs to P.

Of course, if the characteristic function of  $L$  is P-time computable, then so is the characteristic function of its complement,  $\bar{L}$ . That is,  $P = \text{co-P}$ , where co-P is the collection of complements of languages in P.

Informally,  $L$  is in P if  $L$  is not only a decidable set of words, but moreover there is a fast decision procedure for P—one that can actually be implemented in a practical way. For example, finite graphs can be coded by words over a suitable finite alphabet. The set of two-colorable graphs (i.e., the set of graphs that can be properly colored with two colors) is in P, because it is fast to check that the graph has no cycles of odd length. The set of graphs with an Euler cycle is in P, because it is fast to check that the graph is connected and that every vertex has even degree.

What about three-colorable graphs or graphs with Hamiltonian cycles? Here, there are no known fast decision procedures, but there are weaker facts: Given a proper coloring with three colors, it is fast to verify that it is indeed a proper coloring. Given a Hamiltonian cycle, it is fast to verify that it is indeed Hamiltonian. Both three-colorable graphs and Hamiltonian graphs are examples of languages that belong to a class known as NP.

One way to define NP is to use nondeterministic Turing machines. (The acronym NP stands for *nondeterministic polynomial time*.) Back in section 1 the definition of a Turing machine demanded that a machine's table of quintuples be unambiguous, that is, that no two different quintuples have the same first two components. By simply omitting that demand, one can obtain the concept of a nondeterministic Turing machine. A computation of such a machine, at each step, is allowed to execute any quintuple that begins with its present state and the symbol being scanned. Then, one can say that  $L \in \text{NP}$  if there is a nondeterministic Turing machine  $M$  and a polynomial  $p$  such that whenever a word  $w$  is in  $L$ , then *some* computation of  $M$  starting from input  $w$  halts in no more than  $p(|w|)$  steps, and whenever a word  $w$  is not in  $L$ , then no computation of  $M$  starting from input  $w$  ever halts. (An accepting computation can be thought of as having made a number of lucky guesses.)

There is an equivalent, and somewhat more workable, characterization along the lines of  $\Sigma_1$  definability:  $L \in \text{NP}$  iff there is binary relation  $R \in P$  and a polynomial  $p$  such that for every word  $w$ ,

$$w \in L \Leftrightarrow \exists y[|y| \leq p(|w|) \text{ and } R(w, y)].$$

Another example of a language in NP is SAT, the set of satisfiable formulas of sentential logic. The truth-table method for determining whether a formula with  $n$  sentence symbols is satisfiable involves forming all  $2^n$  lines of the formula's truth table and looking to see if there is a line making the formula true. This is not, however, a feasible algorithm, because  $2^{80}$  microseconds greatly exceeds the age of the universe. If one (nondeterministically) guesses the correct line of the table, however, then one can quickly verify that the formula is true under that line.

There is a clear analogy between computable and c.e. sets on the one hand, and P and NP on the other hand. The computable sets are decidable; the sets in P are decidable by fast algorithms. And c.e. sets are one existential quantifier away from being computable; sets in NP are one existential quantifier away from being in P. Moreover, there are c.e. sets that are complete with respect to  $\leq_m$ ; there are NP sets with a similar property. One can say that

$L_1$  is P-time reducible to  $L_2$  if there is a P-time computable (total) function  $f$  that many-one reduces  $L_1$  to  $L_2$ . The following result was proved independently by Cook (1971) and Leonid Levin (1973):

**Cook-Levin theorem.** SAT is in NP, and every NP language is P-time reducible to SAT.

In other words, SAT is NP-complete. Karp showed that many other NP languages (three-colorable graphs, Hamiltonian graphs, and others) are NP-complete.

P VERSUS NP. How far does the analogy between NP and c.e. go? It is known that there are noncomputable c.e. sets, and a set is computable iff both it and its complement are c.e. While it is clear that  $P \subseteq NP \cap \text{co-NP}$  (i.e., every language in P is in NP, as is its complement), it is not known whether  $P = NP$ , or if NP is closed under complement.

The diagonalization that produces a noncomputable c.e. set can be relativized in a straightforward way to show that for any fixed oracle  $B$ , there is a set  $B'$  that is c.e. in  $B$  but not computable in  $B$ . Might some diagonal argument produce a set in NP that was not in P? Would that argument then relativize? The definitions of P and NP extend easily to  $P^B$  and  $NP^B$ , where the computations can query the oracle  $B$  (in one step).

In a 1975 paper, Theodore Baker, John Gill, and Robert Solovay showed that there are oracles  $B$  and  $C$  such that on the one hand  $P^B = NP^B$  and on the other hand  $P^C \neq NP^C$ . This result suggests that the P versus NP question is difficult, because whatever argument might settle the question cannot relativize in a straightforward way. It has also been shown that if one chooses the oracle  $B$  at random (with respect to the natural probability measure on  $\mathcal{P}\mathbb{N}$ ), then  $P^B \neq NP^B$  with probability 1.

The P versus NP question remains the outstanding problem in theoretical computer science. In recognition of this fact, the Clay Mathematics Institute is offering a million-dollar prize for its solution.

## 8. ANALYTICAL HIERARCHY

The ideas in section 5 can be utilized to consider partial functions that take as input not only numbers (or words over a finite alphabet), but sets of numbers or, more generally, functions from  $\mathbb{N}$  to  $\mathbb{N}$ . One can think of the computational procedure as being given a set or a function if it is given an oracle for it.

Let  $\mathbb{N}^{\mathbb{N}}$  be the set of all total functions from  $\mathbb{N}$  to  $\mathbb{N}$ . For a function  $\alpha$  in  $\mathbb{N}^{\mathbb{N}}$ , a calculation can query an oracle for  $\alpha$  by giving it a number  $n$ . The oracle then supplies (in one step) the number  $\alpha(n)$ . For example, the partial func-

tion whose value at  $\alpha$  is the least  $n$ , if any, for which  $\alpha(n) = 0$  is a computable partial function on  $\mathbb{N}^{\mathbb{N}}$ . One can broaden the concept of computability to include partial functions that take as inputs  $k$  numbers and  $l$  members of  $\mathbb{N}^{\mathbb{N}}$ , and produce numbers as outputs.

For definiteness, suppose that  $f$  is a partial function on  $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$ . Informally,  $f$  is effectively calculable if there exists an effective procedure that, when given a number  $x$  and an oracle for an  $\alpha$  in  $\mathbb{N}^{\mathbb{N}}$ , eventually halts and returns the correct value  $f(x, \alpha)$  if this is defined, and never halts if  $f(x, \alpha)$  is undefined. As before, the various formalizations in section 1 all can be adapted to incorporate inputs from  $\mathbb{N}^{\mathbb{N}}$ . One can thereby obtain the concept of a computable partial function on  $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$ .

The basic results of section 2 can be adapted to this broader situation. An essential point is that any one computation takes finitely many steps before producing its output and so can make use of only finitely many values from the given oracles. To obtain a normal form theorem, one again needs to adopt a way of encoding an entire step-by-step history of a computation when a program  $e$  is given an input number  $x$  and an oracle  $\alpha$ . It is natural to do this in such a way that, where  $y$  is the number encoding the history, the oracle is asked for values  $\alpha(t)$  only for  $t < y$ . Let  $\bar{\alpha}(y)$  be a number encoding the finite sequence  $\alpha(0), \alpha(1), \dots, \alpha(y-1)$  consisting of the first  $y$  values of  $\alpha$ .

For the Kleene  $T$ -predicate, one now needs for  $T(e, x, s, y)$  to say that  $e$  encodes a program, and  $y$  encodes the step-by-step history of the computation that program produces on input  $x$ , where the oracle supplies values according to the sequences coded by  $s$ . This is a decidable property of  $e, x, s$ , and  $y$ .

**Normal form theorem.** There is a 4-ary computable relation  $T$  on  $\mathbb{N}$  and a total computable function  $U$  with the following property: For each computable partial function on  $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$ , there is a natural number  $e$  such that

$$f(x, \alpha) = U(\mu y T(e, x, \bar{\alpha}(y), y))$$

for every  $x$  and  $\alpha$ .

Analogous results hold for partial computable functions with more arguments. It is interesting to note that because  $U$  and  $T$  have only natural numbers as arguments, computability on  $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$  can be characterized in terms of computability on  $\mathbb{N}$ .

As before, one can define a subset of  $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$  to be computable if its characteristic function is computable. Informally, this means that one has an effective decision procedure that, given  $\langle x, \alpha \rangle$ , decides whether or not it is in

the set. Of course, the decision procedure will be able to utilize only finitely much information about  $\alpha$  before rendering a verdict. Because of this fact, any computable set will be both open and closed in the natural topology on  $\mathbb{N} \times \mathbb{N}^{\mathbb{N}}$  (where  $\mathbb{N}$  has the discrete topology and  $\mathbb{N}^{\mathbb{N}}$  has the product topology).

Moreover, one can define the c.e. sets to be the ones whose partial characteristic function is a computable partial function. From the normal form theorem, it follows that if  $Q$  is c.e., then there is a computable ternary relation  $R$  on  $\mathbb{N}$  such that

$$Q(x, \alpha) \Leftrightarrow \exists y R(x, \bar{\alpha}(y), y)$$

for every  $x$  and  $\alpha$ . Any such set  $Q$  will be open in the natural topology.

In section 6 the connection between computability and definability in arithmetic was examined. The definable relations formed a hierarchy, where the place of relation in the hierarchy ( $\Sigma_k$  or  $\Pi_k$ ) depended, roughly, on how many quantifiers away from being computable it was.

Now, one can extend those ideas to second-order definability in arithmetic, where besides quantifiers over  $\mathbb{N}$ , quantifiers over  $\mathbb{N}^{\mathbb{N}}$  can be used. One can start with

$$\Sigma_0^1 = \Pi_0^1 = \text{the class of arithmetical relations.}$$

Furthermore, one can define  $\Sigma_{k+1}^1$  to consist of relations definable from  $\Pi_k^1$  relations by prefixing existential quantifiers over  $\mathbb{N}^{\mathbb{N}}$ . Similarly, one can define  $\Pi_{k+1}^1$  to consist of relations definable from  $\Sigma_k^1$  relations by prefixing universal quantifiers over  $\mathbb{N}^{\mathbb{N}}$ . Finally, one can define  $\Delta_k^1$  to be  $\Sigma_k^1 \cap \Pi_k^1$ .

As with the arithmetical hierarchy, one has proper inclusion in both of the chains

$$\Sigma_1^1 \subset \Sigma_2^1 \subset \Sigma_3^1 \subset \dots$$

$$\Pi_1^1 \subset \Pi_2^1 \subset \Pi_3^1 \subset \dots$$

and in both cases the union of the chains is exactly the class of relations that are second-order definable in  $\mathfrak{N}$ . One can say that these chains define the analytical hierarchy.

## COMPUTATIONALISM

Computer science has been notably successful in building devices capable of performing sophisticated intellectual tasks. Impressed by these successes, many philosophers of mind have embraced a computational account of the mind. *Computationalism*, as this view is called, is committed to the literal truth of the claim that the mind is a computer: Mental states, processes, and events are computational states, processes, and events.

### THE BASIC IDEA

What exactly are computational states, processes, and events? Most generally, a physical system, such as the human brain, implements a computation if the causal structure of the system—at a suitable level of description—mirrors the formal structure of the computation. This requires a one to one mapping of formal states of the computation to physical state-types of the system. The mapping from formal state-types to physical state types can be called an *interpretation function*  $I$ .  $I$  allows a

sequence of physical state-transitions to be seen as a computation.

An example should make the central idea clear. A physical system computes the addition function if there exists a one-to-one mapping from numbers to physical state types of the system such that any numbers  $n$ ,  $m$ , and  $n+m$  related as addends and sums are mapped to physical state types related by a causal state-transition relation. In other words, whenever the system goes into the physical state specified under the mapping as  $n$ , and then goes into the physical state specified under the mapping as  $m$ , it is caused to go into the physical state specified under the mapping as  $n+m$ .

Traditionally, computational processes have been understood as rule-governed manipulations of internal symbols or representations—what computer scientists call *data structures*. Though these representations typically have meaning or semantic content, the rules apply to them solely in virtue of their structural properties, in the same way that the truth-preserving rules of formal logic apply to the syntax or formal character of natural language sentences, irrespective of their semantic content. Computationalism thus construes thinking as a type of mechanical theorem-proving.

Computationalism has been the predominant paradigm in cognitive psychology since the demise of behaviorism in the early 1960s. The failure of behaviorism can be traced in no small part to its refusal to consider the inner causes of behavior—in particular, the capacity of intelligent organisms to represent their environment and use their representations in controlling and modulating their interactions with the environment. Computationalism avoids this failing, explaining intelligent behavior as the product of internal computational processes that manipulate (construct, store, retrieve, and so on) symbolic representations of the organism's environment.

Many philosophers of mind find computationalism attractive for two reasons. First, it promises a physicalistic account of mind; specifically, it promises to explain mental phenomena without positing any mysterious non-physical substances, properties, or events. Computational states are physically realized in the computer; they are just the physical states specified by the mapping  $I$ . Computational operations, as noted, are purely mechanical, applying to the objects in their domain—typically, symbols—in virtue of their structural properties. Moreover, computationalism, if true, would show how it is possible for mental states to have both causal and representational properties—to function as the causes of behavior, and to be about things other than themselves. Mental states, on

this view, are relations to internal symbols, and symbols have a dual character: They are both physically constituted, hence causally efficacious, and bearers of meaning.

A second reason why philosophers of mind find computationalism attractive is that it promises a nonreductive account of the mind. A serious problem with reductive physicalist programs—such as central state identity theory—is that they are overly chauvinistic; they seek to identify mental state-types, such as pain, with their specific physical (i.e. neural) realization in humans, thus denying mentality to systems that lack human physiology. Functionalists, by contrast, take it to be a contingent fact about mental states and processes that they are realized in neural matter; these same mental processes may, in other creatures or devices, be realized in other ways (e.g., in a silicon-based circuitry). According to functionalism, it is the causal organization of a system—rather than its intrinsic physical makeup—that is crucial to its mentality. Computationalism endorses—and affords a precise specification of—the basic idea of functionalism. The computational characterization given by  $I$  provides an abstract characterization of that causal organization for a given system. Computational explanation is itself a species of functional explanation; it provides an analysis of a cognitive capacity in terms of the organized interaction of distinct components of the system, which are themselves functionally characterized—that is, described abstractly in terms of what they do rather than what they are made of.

A commitment to computationalism by philosophers of mind has frequently taken the form of a commitment to a computational construal of the *Representational Theory of Mind* (hereafter, RTM-C), which is an account of propositional attitudes, such states as beliefs, desires, hopes, fears, and so on. According to RTM-C, propositional attitudes are relations to internal representations—for example, to believe that  $P$  is to bear a certain relation to a token of an internal representation that means that  $P$ . Each attitude type is construed as a distinct computationally characterizable relation to an internal representation; thus, believing is one type of computational relation, and desiring another. The RTM-C has been advertised, by, for example, Jerry Fodor in *Psychosemantics* (1987), as a scientific vindication of the commonsense practice of explaining a subject's behavior by appealing to his or her propositional attitudes. If true, it would underwrite the practice of individuating propositional attitudes along two distinct dimensions, by *attitude* and by *content*. Subjects can hold various attitudes toward a single proposition; they may believe, doubt, or

fear that the conflict in the Middle East will never be resolved. And subjects bear the same relation—belief, say—to many different propositions. On the RTM-C, the various attitudes correspond to distinct computational operations, and distinct data structure-types over which these operations are defined have distinct contents. The transparency of the relation between the commonsense explanatory scheme and the underlying computational realization of human psychology is an attractive feature of the view. However, it may also seem rather surprising that the two explanatory structures are virtually isomorphic. (Imagine if commonsense physics had anticipated the basic explanatory structure of quantum physics.)

The RTM-C is a heavily committed empirical hypothesis about the nature of the mind. Unlike computationalism, which claims simply that the mind is a computer, RTM-C purports to specify in broad outline the computational architecture of the mental processes that produce behavior. Computationalism is therefore compatible with the falsity of RTM-C. Is there any reason to believe RTM-C? It has been claimed that existing work in computational cognitive science provides empirical support for the RTM-C. Fodor (1987) points out that computational models of human cognitive capacities construe such capacities as involving the manipulation of internal representations. Psycholinguistic theories, for example, explain linguistic processing as the construction and transformation of structural descriptions, or *parse trees*, of the public language sentence being processed. It should be noted, however, that in order for a psychological theory to provide support for the RTM-C—for the claim that to have an attitude A toward a proposition P is to bear a computational relation R to an internal structure that means that P—it is not sufficient that the theory posits computational operations defined over internal representations. The posited representations must have appropriate contents—in particular, they must be interpreted in the theory as the contents of attitudes that one is prepared to ascribe to subjects independently of any commitment to the RTM.

For example, consider a psycholinguistic theory that explains a subject's understanding of the sentence "the dog bit the boy" as involving the construction of a parse tree exhibiting the constituent structure of the sentence. The theory supports the RTM only if there are independent grounds for attributing to the subject the content ascribed to the parse tree. There may be grounds for attributing to the subject a belief in a certain distal state of affairs—that a specific dog bit a specific boy—but this is not the content ascribed to the parse tree by the psy-

chological theory. The parse tree's content is not even of the right sort. It does not represent a distal state of affairs; it represents the constituent structure of the sentence comprehended. The psycholinguistic theory supports the RTM only if the subject has propositional attitudes about the grammatical constituents of the sentence, such things as noun phrases and determiners. Such attitudes may be attributed to subjects as a consequence of the acceptance of the RTM-C, but these attitudes would not provide independent empirical support for the view.

### SOME GENERAL ISSUES

Developments in computer science in the 1980s, in particular, the construction of *connectionist* machines—devices capable of performing cognitive tasks but without fixed symbols over which their operations are defined—have necessitated a broadened understanding of computation. Connectionist processes are not naturally interpretable as manipulations of internal symbols or data structures. Rather, connectionist networks consist of units or nodes whose activation increases or decreases the activation of other units to which they are connected until the ensemble settles into a stable configuration. Because connectionist networks lack symbols, they lack the convenient "hooks" to which, in the more traditional *classical* models, semantic interpretations or meanings are attached. Semantic interpretations, in connectionist models, are assigned either to individual units (in localist networks), or, more commonly, to patterns of activation over an ensemble of units (in distributed networks). Therefore, representation in connectionist devices is, in one respect, not as straightforward as it is in classical devices, because it is not as transparent which states or structures of the device count as *representations*. But issues concerning how the interpreted internal states or structures acquire their meaning—in other words, how a given semantic interpretation is justified—are fundamentally the same for the two kinds of machines.

Connectionist networks have had some success modeling various learning tasks—most notably, pattern-recognition tasks. There is continuing discussion within cognitive science about whether connectionist models will succeed in providing adequate explanations of more complex human cognitive capacities without simply implementing a classical or symbol-based architecture. One issue, originally raised by Jerry Fodor and Zenon Pylyshyn (1988), has turned on whether connectionist networks have the resources to explain a putative property of thought—that cognitive capacities are systemati-

cally related. For example, subjects can think the thought *the dog bit the boy* only if they can think the thought *the boy bit the dog*. A classical explanation of *systematicity* would appeal to the constituent structure of representations over which the operations involved in these capacities are defined—these representations contain the same constituents, just differently arranged. Connectionists, of course, cannot provide this sort of explanation—their models do not contain structured representations of the sort that the explanation requires.

Whether systematicity constitutes a decisive reason to prefer classical over connectionist cognitive models depends on several unresolved issues: (1) how pervasive the phenomena really is. It is certainly not true generally that if one can entertain a proposition of the form  $aRb$ , then one can entertain  $bRa$ . One can think the thought *the boy parsed the sentence* but not *the sentence parsed the boy*; (2) whether classical cognitive models are in fact able to provide real explanations of the systematic relations holding among cognitive capacities, rather than simply a sketch of the form such explanations would take in classical models. A real explanation of the phenomena would require, at least, the specification of a compositional syntax for the internal system of representation, something that classicists have so far been unable to provide; and (3) whether connectionist models are in fact unable to explain the systematic relations that do hold among cognitive capacities.

While strong claims have been made on both sides of this dispute, the question remains open. If it turns out that the mind has a connectionist architecture, then it would be expected that a perspicuous account of this architecture would reveal many cognitive capacities to be systematically related. For example, a characterization of the state of the network that consists in an English speaker's understanding of the sentence "the dog bit the boy" would cite the activation levels of various nodes of the network. The subject's understanding of the sentence "the boy bit the dog" would, presumably, activate many of the same nodes, and the explanation for the systematic relation between these two states would appeal to a dynamical account of the network's state transitions. These nodes would not be *constituents* of the subject's thought(s), in the sense required by classical models. And yet the relation between the two thoughts would not be merely accidental but instead would be a lawful consequence of general features of the network's architecture.

Questions such as whether connectionist devices will prove capable of modeling a wide range of complex cognitive capacities, and whether the best explanation of

human cognitive capacities will advert to connectionist or classical computational processes, are properly understood as issues within computationalism. It should be noted, however, that the majority of philosophers committed to computationalism tend to interpret computation in classical terms, claiming that mental processes are manipulations of symbols in an internal code or language of thought. (See Jerry Fodor's *The Language of Thought* [1975] for the most explicit account of this view.) For this reason, and for ease of exposition, this entry will continue to refer to computational processes as manipulations of internal representations.

Computationalism requires a *psychosemantics*—that is, an account of how the postulated internal representations (or, in connectionist devices, states of the network) acquire their meaning. In virtue of what fact does a particular data structure mean *snow is white* rather than  $2+2=4$ ? The meanings of natural language sentences are fixed by public agreement, but internal symbols must acquire their meanings in some other way. Philosophers committed to computationalism (and, hence, typically to physicalism) have assumed that an appropriate semantics for the language of thought must respect a "naturalistic constraint," the requirement that the conditions for a mental representation's having a particular meaning must be specifiable in nonintentional and nonsemantic terms. There have been various proposals for a naturalistic semantics. *Information-based* theories identify the meaning of a mental representation with the cause of its tokening in certain specifiable circumstances. *Teleological* theories hold that the meaning of a mental representation is determined by its biological function, what it was selected for.

No proposal is without serious problems, and the difficulty of accounting for the possibility that thoughts can *misrepresent* is the most widely discussed. But the difficulty of specifying naturalistic conditions for mental representation does not undermine computationalism itself. Cognitive scientists engaged in the business of developing computational models of cognitive capacities seem little concerned with the naturalistic constraint, and their specifications of semantic interpretations for these models do not obviously respect it. (See Frances Egan [1995] for argument.) There is no reason to think that the physicalistic bona fides of computational models are thereby impugned.

## SUCSESSES AND OBSTACLES

As a hypothesis about the nature of mind, computationalism is not uncontentious. Important aspects of the

mental have so far resisted computational analysis, and computational theorists have had little to say about the nature of conscious experience. While computers perform many intellectual tasks impressively, no one has succeeded in building a computer that can plausibly be said to feel pain or experience joy. It is possible that consciousness requires an explanation in terms of the biochemistry of the brain. In other words, the computational strategy of prescinding from the neural details of mental processes may mean that conscious phenomena will escape its explanatory net.

If conscious mental phenomena resist computational analysis, then the computational model of mind cannot be said to provide a general account of the human mind; however, the model may still provide the basis for a theory of those cognitive capacities that do not involve consciousness in any essential way. Cognitive psychologists have applied the computational model to the study of language processing, memory, vision, and motor activity, often with impressive results. Domain-specific processes—such as syntactic processing and early vision—have proved most amenable to computational analysis. It is likely that the information available to these processes is tightly constrained. So-called *modular* processes lend themselves to computational treatment precisely because they can be studied independently of the rest of the cognitive system. One does not need to know how the whole mind works to characterize the relatively simple interactions involved in these processes. The idea that perceptual processes are modular, at least up to a certain point, is well supported. Modular processes tend to be more reliable—they take account of information in the input before being influenced by the system's beliefs and expectations. This is especially important for the perception of novel input. And modular processes are faster—the process does not have to find and retrieve relevant information from memory for the processing to proceed. Ultimately, of course, perceptual processes will have to be integrated with the rest of the system if they are to provide a basis for reasoning, belief formation, and action.

Perceptual mechanisms, as characterized by computational accounts, typically rely on physical constraints—that is, on general information true of the subject's environment—to aid the recovery of perceptible properties of that environment. This information is assumed to be available only to the process in question—not stored in memory, and hence not available to the system for reasoning tasks. For example, the *structure from motion* visual mechanism, characterized by Shimon Ullman in

*The Interpretation of Visual Motion* (1979), computes the structure of objects in the scene from information obtained from relative motion. The mechanism computes the unique rigid structure compatible with relatively minimal input data (three distinct views of four non-coplanar points in the object), in effect making use of the fact that objects are rigid in translation. Without the assumption of rigidity, more data is required to compute an object's shape. Whether or not Ullman's model accurately describes the human visual system, the general strategy of positing innate assumptions about the environment that simplify the processing is methodologically sound, given that perceptual mechanisms may be assumed to be adaptations to that environment.

Domain-general processes—such as decision making and rational revision of belief in response to new information—have so far resisted computational treatment. Their intractability is due in part to the fact that general constraints on the information that may be relevant to solutions are difficult, if not impossible, to specify. A system capable of passing the *Turing test*—the requirement that it convince an interlocutor that it is a person for a short period of time—must have access to a vast store of information about the world, about how agents typically interact with that world, and about the conventions governing conversation among agents in the world. All this information must be stored in the system's memory. At any point in the conversation, the system must be capable of bringing that information to bear on the selection of an appropriate response from the vast number of meaningful responses available to it. Human agents, of course, have no trouble doing this. The relevant information is somehow just there when it is needed. The task for the computational theorist is to characterize how this vast store of information is represented in the system's memory in such a way that relevant information can be accessed efficiently when needed. This formidable technical problem is known in the field of Artificial Intelligence (AI) as the *knowledge representation problem*.

A related problem, known in AI circles as the *frame problem*, concerns how a system is able to continuously update its knowledge store as the world around it changes. Every change has a large number of consequences. For example, the typing of the previous sentence on this author's computer requires the provision of a plausible example of the generalization just typed. It also changes the arrangement of subatomic particles in the room, yet it doesn't affect the Dow Jones industrial average or the price of crude oil. The author needs to keep track of some of these consequences, but most can and

should be ignored. How, then, does the author update her knowledge store to take account of just those changes that are relevant (for her) while ignoring the vast number that are not? Unless the frame problem can be solved, or otherwise sidestepped, computationalism has a slim chance of providing a general account of human cognitive capacities.

## GENERAL OBJECTIONS

Opponents of computationalism have offered arguments purporting to show that the human mind cannot be a computer. One class of objection, typified by Roger Penrose's *The Emperor's New Mind* (1989), takes as its starting point Kurt Gödel's result that any formal system powerful enough to do arithmetic can yield a sentence that is undecidable—that is, a sentence such that neither it nor its negation is provable within the system. A human observer, the argument continues, can see that the undecidable sentence is true; therefore, the human's cognitive abilities outstrip that of the machine. For the argument to establish that human minds are not machines it would have to demonstrate that human cognitive abilities simultaneously transcend the limits of all machines. No version of the argument has succeeded in establishing this strong claim.

A second objection claims that any physical system, including a rock or a piece of cheese, may be described as computing any function, thus computationalism's claim that the human mind is a computer is utterly trivial. If everything is a computer, then computationalism reveals nothing interesting about the nature of mind. The following is John Searle's version of the argument in *The Rediscovery of the Mind* (1992). Recall that to characterize a physical system as a computer is to specify a mapping from formal states of a computation to physical state-types of the system. Take some arbitrary function, say the addition function, and some physical system, say a particular wall. Though the wall appears to be in a constant state, it is known that the wall is made up of atoms in continuous motion. Its physical state is constantly changing. The microphysical state of the wall at time  $t_1$  can be interpreted as *two* and its microphysical state at time  $t_2$  as *three*, and its microphysical state at time  $t_3$  as *five*. And similarly for other combinations of addends and sums. Under this interpretation the physical state transitions of the wall implement the addition function. The wall is an adder!

It is possible, in the above sense, to describe any physical system as computing any function. This does nothing, however, to damage computationalism's claim

that the mind is a computer. There are significant differences between the interpretation function under which the wall is an adder, and the interpretation function under which a hand calculator is an adder. One important difference is that in order to know how to interpret the wall's states as sums one has to compute the addition function oneself. The triviality argument does point to an important task for theorists concerned with the foundations of computational cognitive science—namely, specifying the adequacy conditions on interpretation that allow a computational characterization of a physical system to be predictive and explanatory of the system's behavioral capacities.

A third objection to computationalism has been made by John Searle in his 1980 article "Minds, Brains, and Programs." According to Searle's *Chinese Room* argument, genuine understanding cannot be a computational process. The manipulation of symbols according to rules that operate only on their structural properties is, according to Searle, a fundamentally unintelligent process. The argument, which many have found unconvincing, is formulated explicitly for classical computational models—yet if Searle is right it would apply to any mechanical model of the mind, and hence to connectionist models as well.

It is unlikely that a philosophical argument of the sort discussed in this section will prove computationalism false. Computationalism is a bold empirical hypothesis about the nature of mind that will be evaluated by the explanatory fruit it bears. There is reason for cautious optimism, though substantial progress needs to be made on some formidable technical issues before theorists of mind can be confident that computationalism is true.

## COMPUTER ETHICS

Computer ethics is a branch of applied ethics that considers ethical issues raised or significantly amplified by computer technology. The field is sometimes referred to by other terms such as "cyberethics," "information ethics," "information communications technology ethics," "global information ethics," and "Internet ethics." But, whatever the field is called, the computer remains the essential technological feature. Although some computing technology, for example the abacus, is centuries old, computer ethics has developed as a philosophical field with the advent of modern, digital, electronic computing. Modern computing technology, which includes hardware, software, and networks, is highly flexible and powerful. Computers can be programmed and in some cases trained to perform a wide range of functions. Because of this logical malleability computers carry out numerous and diverse applications in society. Computer chips are ubiquitous. They are embedded in everyday items such as cars and clothing, toys and tools, and pets and people.

Communication that depends upon computer technology has grown dramatically through widespread use of the cell phones, global positioning systems, and the Internet. In the early twenty-first century, people in developed countries live in computationally revolutionized and informationally enriched environments. Because computing has become so integrated in society, computer ethics has expanded dramatically to issues involving most activities within society including education, law, business, government, and the military.

Through its extensive growth computer ethics is a field of applied ethics that intersects and affects virtually all other branches of applied ethics.

Computer ethics is interesting philosophically, not merely because computing technology is widely used, but because the application of computing technology raises intriguing conceptual issues and serious ethical problems for society. This happens frequently because computers are logically malleable and can be configured to perform old tasks in new ways and to accomplish strikingly new tasks. When computing technology is deployed in novel ways, ethical guidelines for its use are frequently unclear or nonexistent. This creates policy vacuums that may be accompanied by conceptual confusions about how to understand the computerized situation adequately. Hence, computer ethics typically demands doing more than routinely applying ethical principles to ethical issues in computing. Rather computer ethics requires an analysis of the nature and impact of the computing technology and the corresponding formulation and justification of policies for the ethical use of such technology. Listing all of the subject matter of computer ethics would be difficult as the field continues to expand as the application of computing grows, but broadly speaking traditional areas of investigation and analysis include privacy, property, power, security, and professionalism.

Because computers rapidly store and search vast amounts of information, privacy has been an ongoing concern of computer ethics. Personal information in medical documents, criminal records, and credit histories is easily retrieved and transmitted to others electronically, and as a result individuals are vulnerable to the improper disclosure of sensitive information and to the introduction of unknown errors into their records. The threat to privacy has been increasing in part because computing technology enables an enormous amount of information gathering to occur in subtle and undetectable ways. Internet stores track purchases of individuals and place cookies on personal computers inconspicuously. Computerized cameras in satellites, public places, private establishments, and personal cell phones record without notice. Computers utilizing global-positioning satellites routinely track locations of vehicles. Spyware installed on computers surreptitiously surveils the computing activities of unsuspecting users. In general, personal information can be collected from many sources and potentially assembled in databases that can be further merged, matched, and mined to construct profiles of the lives of individuals. Many fear that the widespread use of computers to collect information is creating a panopticon

society in which too many details of individual lives are known by others, leaving people with dramatically reduced levels of privacy. Philosophical analyses of the nature of privacy, the policies to protect privacy, and the justifications for privacy are more important than ever.

Property is also a major issue within computer ethics. This has become increasingly important because of the significant growth in hardware and software and the computerization of many popular products including art, photos, music, movies, and games that are produced, transmitted, and portrayed using a digital format. Because digital information can be copied so easily and accurately, the extent to which digital products should be owned and protected is heavily debated. Some libertarians on this issue argue that “information wants to be free” and that traditional intellectual property restrictions should not apply. For instance, those in the open source software movement advocate licensing that permits the free redistribution of software and requires accessibility to a program’s source code so that it can be tested and improved by others. Those who advocate the ownership of intellectual digital property argue that with ownership comes pride and profit incentive that will generate digital products that otherwise would never be produced.

Debates over the rights of ownership raise many difficult philosophical issues. What is it that is owned and how should it be protected? A computer disk itself does not have much value; it is the information on the disk that matters. Information seems to be nothing more than an idea and ideas are not normally given intellectual property protection. As an example, consider again computer programs. Computer programs are algorithmic and hence mathematical in nature. This suggests that computer programs, like the Pythagorean theorem, should not be owned at all. However, computer programs generally are fixed in a tangible medium and are lengthy, original human expressions. As such they are appropriately covered by copyright protection. Yet, in their operation on machines computer programs are often novel, useful, nonobvious processes and hence are properly patentable. How, or even whether, computer programs should be protected depends largely on one’s philosophical analysis of the nature of computer programs and on a justification of protecting intellectual property.

The basic philosophical issues of computerized property extend well beyond computer programs to every product in digital form. A movie that costs millions of dollars to make can be copied at no significant cost. If a movie is copied illegally using the Internet, to what extent should various contributors be held accountable—the

person downloading the copy, the person who maintains a directory on the Internet informing people where copies are located, the person who makes a digital version available for others to copy, the company that makes the software specifically designed to copy movies easily over the Internet, or the Internet service provider?

Computers can create and shift relationships of power. Because computers allow individuals to perform tasks more easily and to accomplish some activities that they could never do without them, those who have access to computers have access to power. As a consequence, an obvious social concern is the disparity in advantage of those who have access to computing, for example in school, over those who do not. Unequal distribution of power may require ethical countermeasures to ensure fairness. To what extent, for example, should disabled citizens be assured of equal access to computing technology? To some degree the Internet has helped to correct this imbalance of power and even shift power toward the individual. For a modest fee individuals can advertise personal items for sale on the Web to a large audience. Politicians who are not well connected to an established political group can run an Internet campaign to express their ideas and to solicit funds. Independent hotel operators can unite through an Internet reservation service to compete with the larger hotel chains.

But the Internet’s ability to shift power to the individual allows one person to solicit children to arrange illicit sexual encounters, to send spam e-mails to millions of people, and to spread viruses and worms. Moreover, Internet power shifts can sometimes result in making the strong even stronger. Large corporations can outsource jobs to cheaper labor markets and dominant militaries can enhance their capabilities with computerized communication and weapons. These power shifts raise philosophical questions about what the new relationships should be. One of the most important power questions is who should govern the Internet itself.

The issue of rights and responsibilities of individuals on the Internet is complex because the Internet that supports the Web is worldwide. Different countries have different laws and customs and therefore have different concerns about the Web. Any given country may have great difficulty enforcing its concerns with information coming and going beyond its borders. Consider differences with regard to free speech as just one example. France and Germany have been concerned about prohibiting hate speech. China has targeted political speech. In the United States the focus has been largely on controlling pornography over the Internet. Even within a coun-

try's borders free speech often raises perplexing conceptual issues. For instance, should pornography that utilizes virtual children be regulated differently than pornography displaying actual children? But, even assuming agreement on the law, how does a country stop or punish a violator of free speech on the Internet who is located in some remote location in the world? Should the law be change to accommodate the realities of the Internet?

Not surprisingly security is as a fundamental problem on the Internet. Computer users can act from a distance over networks and thereby can accomplish goals without being observed. Hackers can break into computers and remove or alter data without being detected. Ordinary citizens can use tools on the Web to gather information from public documents in order to steal the identities of others. Terrorists can disrupt entire networks that control vital resources such as the electric power grid. The lack of security on the Internet is reminiscent of Plato's story of the ring of Gyges that allowed a shepherd to act invisibly. Plato posed the question, Why should someone be just if he can get away with being unjust? Plato's question is not just an abstract theoretical issue given the availability of current computer technology. If an Internet user can act unjustly and get away with it, why should he or she not do it?

Many people who design and operate computing systems regard themselves as computing professionals. But, given that anyone, regardless of educational background, can be hired to do computing, what does it mean to claim that someone is a computing professional? To what standards, including ethical standards, should computing professionals adhere? Although several codes of ethics have been offered to clarify what duties and responsibilities computer professionals have, professional responsibility has been difficult to establish for at least two reasons. First, unlike medicine and law, the field does not have a tradition of professional qualifying examinations and licensing, and therefore enforcement of any code of ethics is difficult. Second, the nature of computing itself makes the assessment of responsibility difficult. Computer programs are often enormously complex, written by dozens of people, and incomprehensible to any one person. Moreover, such large computer programs are brittle in that a tiny, obscure error can shatter the performance of the entire system under certain conditions. To what extent should computing professionals be regarded as liable when such difficult to predict errors lead to major failures or even catastrophic results?

Although traditionally computer ethics has focused on the ethics of computing situations, a philosophically

rich part of the field is computational ethics that considers the impact computing has or theoretically may have on ethics itself. Philosophical issues in this area include questions such as: In what ways can ethical decision making be properly assisted by computational methods? In principle, could a computer ever make appropriate ethical decisions? Could computer implants in humans enhance and possibly alter human values? And, could a computer, or perhaps a robot, ever have rights or moral responsibilities?

## COMPUTING MACHINES

Any thorough discussion of computing machines requires the examination of rigorous concepts of computation and is facilitated by the distinction between mathematical, symbolical, and physical computations. The delicate connection between the three kinds of computations and the underlying questions "What are machines?" and "When are they computing?" motivate an extensive theoretical and historical discussion. The relevant outcome of this discussion is formulated at the beginning of section 3.

The paradigm of the first kind of computation is given when a human calculator determines, by finitely many and mathematically meaningful steps, the values of number-theoretic functions for particular arguments. The informal concept of such effectively calculable functions is thought to be captured by Kurt Gödel's concept of general recursive functions. The latter notion was introduced in 1934 and arose in an intellectual context that

includes the contemporaneous development of David Hilbert's program as well as earlier steps toward modern logic and abstract mathematics.

Alan M. Turing and Emil Post initiated in 1936 a shift from mathematically meaningful steps to basic, not further analyzable ones that underlie mathematical computations. They investigated symbolic processes carried out by human calculators and proposed essentially the same model of symbolic computation that is mathematically presented now by a Turing machine. Turing took, however, an additional, most significant step: He devised a universal machine that can execute the program of any Turing machine, and he had it carry out the necessary symbolic operations. This construction allowed him to prove the effective unsolvability of the halting and decision problems.

The physical details of how a universal machine could actually be constructed did not matter for Turing's theoretical investigations in 1936, but obviously did when he was involved in designing and building an Automatic Computing Engine (ACE). In modern digital computers controlled physical processes are used to realize, efficiently, the stepwise operations of a universal machine. That seems to be true even for quantum computing. In analog computing physical processes are used in a different way. However, independently of the mode of the physical computation, the question can be raised, whether there are physical processes that are carried out by a computing machine, but do not fall under Turing computations.

## 1. MATHEMATICAL COMPUTATIONS

Human calculating provides a rich prehistory for the development of machines that can take over routine computational tasks. This prehistory points to the pervasive impact computing machines will develop: from the broadly intellectual and socioeconomic to the highly focused scientific. Before coming to the technological challenge of building machines that mimic processes on symbolic configurations, one has to address the problem of determining the nature of such processes and those aspects that are crucial for their machine implementation. After all, physical representations of the symbolic configurations are needed, and machines have to perform on them physical operations that correspond to the symbolic ones.

**1.1. PREHISTORY.** In the sixteenth and seventeenth centuries Wilhelm Schickard, Blaise Pascal, Gottfried Wilhelm Leibniz, and others constructed mechanical

calculators to carry out basic arithmetical operations. The calculatory roots go back, however, not just to ancient Greece but also to Egypt and Mesopotamia; important developments took place also in China, India, and in many different parts of the world under Arab influence. It is no accident for the evolution of computing that algebra and algorithm etymologically come from the same Arab source: the title of a widely used book and the agnomen of its author (Muhammed ibn Musa al-Kwarizmi).

The construction of mechanical calculators is *prima facie* narrower than the development of other scientific tools and yet it was pursued as having, potentially, a much broader impact through the intimate connection of computing with mathematics and logic. That was clearly sensed and expressed with great expectations by Leibniz. Of course, there had been aids to computation in the form of neatly arranged configurations of pebbles, for example. Another efficient aid had been the Chinese abacus that allows, via a good representation of natural numbers, the human calculator to add, subtract, multiply, and divide through strictly local manipulations of beads. The configurations of the abacus serve as the representation of input, intermediate results, and output of the calculation; they are essentially aids to memory.

The difference between abacus-like devices and mechanical calculators (as developed by Schickard, Pascal, and Leibniz) is formulated in an illuminating way by Charles Babbage:

Calculating machines comprise various pieces of mechanism for assisting the human mind in executing the operations of arithmetic. Some few of these perform the whole operation without any mental attention when once the given numbers have been put into the machine.

Others require a moderate portion of mental attention: these latter are generally of much simpler construction than the former, and it may also be added, are less useful. (1864/1994, p. 30)

The abacus certainly requires a moderate portion of mental attention, whereas Babbage's difference engine is perfectly in line with the development of automatic computing machines. The difference engine was intended to determine the values of polynomials for given arguments by the method of finite differences; the results were to be printed by the machine and to create reliable tables useful for astronomy and navigation. The evolution of the difference engine brought to light the economic importance of computing and the consequent governmental

support of related research. (The British government sponsored Babbage's work; the Swedish government supported the work of Georg Edward Scheutz, who was inspired by a description of Babbage's machine and constructed a difference engine in 1834; an improved version was built between 1851 and 1853 with funds from the Swedish Academy.)

Babbage took later another important conceptual step when developing his analytical engine. He followed the lead of Joseph Marie Jacquard, who had used "cards with holes" as a means of programming a loom to weave intricate patterns. Babbage devised, but never fully constructed, a programmable computing machine with a rather modern organization. In chapter 8 of *Passages from the Life of a Philosopher*, Babbage writes after having described the process of the Jacquard loom:

The analogy of the Analytical Engine with this well-known process is nearly perfect. The Analytical Engine consists of two parts:

1. The store in which all the variables to be operated upon, as well as all those quantities which have arisen from the result of other operations, are placed.
2. The mill into which the quantities about to be operated upon are always brought. Every formula which the Analytical Engine can be required to compute consists of certain algebraical operations to be performed upon given letters, and of certain other modifications depending on the numerical value assigned to those letters. (1864/1994, p. 89)

Evidently, *store* corresponds to the memory and *mill* to the central processing unit of a contemporary computer. The programming constructs in Babbage's design are of such a general character that, Robin Gandy (1980) asserts, the number theoretic functions that are Babbage calculable are precisely those that are Turing computable.

The generality of computational issues, beyond their connection with arithmetic and analysis, is emphasized through the algebraic treatment of logic in the hands of George Boole, Augustus De Morgan, Charles Sanders Peirce, and Ernst Schröder, among others. In this line of research the decision problem was formulated and considered as a central issue. Even in the traditional Aristotelian presentation of logic computational features were considered to be significant by Raymundus Lullus and, importantly, by Leibniz in his project of constructing a universal language and an appropriate calculus ratiocinator. A logical machine in that tradition was built by William Stanley Jevons and described in the *Proceedings of the Royal Society* for January 20, 1870. Finally, it should

be mentioned that Gottlob Frege claimed in *Grundgesetze der Arithmetik* (1893) that in his logical system "inference is conducted like a calculation," but continued, "I do not mean this in a narrow sense, as if it were subject to an algorithm the same as ... ordinary addition and multiplication, but only in the sense that there is an algorithm at all, i.e., a totality of rules which governs the transition from one sentence or from two sentences to a new one in such a way that nothing happens except in conformity with these rules."

Within mathematics at that time, Leopold Kronecker insisted on the decidability of mathematical notions and the calculability of functions. These logical and mathematical developments were joined in formal mathematics, when Hilbert exploited the effective metamathematical description of formal theories (in his consistency program) and shifted effectiveness requirements from mathematics to metamathematics. It is here that modern computability theory found its ultimate motivation through the emphasis of the decision problem (*Entscheidungsproblem*) in the Hilbert School and the systematic articulation of the significance of Gödel's incompleteness theorems; both issues required a rigorous mathematical concept of effective method or mechanical procedure. Though these issues could have been addressed in their formulation for symbolic configurations, it took a detour through the calculability of number theoretic functions to arrive at sharp mathematical notions.

1.2. UNIFORM CALCULABILITY. Richard Dedekind formulated in his 1888 essay "Was sind und was sollen die Zahlen?" the general concept of a primitive recursive function and proved that all these calculable functions can be made explicit in his logicist framework. Dedekind's idea for the proof was very abstract, namely, to show the existence of unique solutions for functional equations of the form

$$\psi(0) = \omega,$$

$$\psi(\varphi(n)) = \theta(\psi(n)),$$

where  $\omega$  is an element of  $\mathbb{N}$ ,  $\varphi$  is the successor function, and  $\theta$  an arbitrary given function from  $\mathbb{N}$  to  $\mathbb{N}$ . This general point recurs in the early 1920s, for example, in the work of Hilbert, Thoralf Skolem, and Jacques Herbrand. However, the existence of solutions is no longer to be guaranteed by abstract logicist or set theoretic considerations, but by the availability of suitable calculation procedures. Implicit in these discussions is the specification of the class PR of primitive recursive functions. Hilbert's 1925 essay, "On the Infinite," defines this class inductively,

in almost the standard contemporary form, by specifying initial functions and closing under the definitional schemas of composition and primitive recursion. One shows by an easy inductive argument that the values of primitive recursive functions can be determined by an effective procedure for any given argument. All primitive recursive functions are in this sense calculable, but there are calculable functions that are not primitive recursive. Hilbert discussed an example due to Wilhelm Ackermann prominently already in 1925.

Herbrand viewed the Ackermann function in 1931 as finitistically calculable. In his systems of arithmetic he considered different classes  $F$  of finitist functions for which recursion equations were available. The defining axioms for the elements in  $F$  had to satisfy in particular this calculability condition, which had to be proved by finitist means, “We must be able to show, by means of intuitionistic [i.e., finitist] proofs, that with these [defining] axioms it is possible to compute the value of the functions univocally for each specified system of values of their arguments” (letter to Gödel in *Gödel’s Collected Works V*, p. 15). The issue of characterizing classes of finitistically calculable functions was crucial for Herbrand’s reflections on Gödel’s second incompleteness theorem and its impact on Hilbert’s program. Inspired by Herbrand’s formulation, Gödel defined in his Princeton lectures of 1934 the class of general recursive functions; its definition no longer depends on the problematic concept of finitist provability.

Gödel’s class of functions includes all primitive recursive functions and those of the Ackermann type. Assume, Gödel suggests, you are given a finite sequence  $\psi_1, \dots, \psi_k$  of known functions and a symbol  $\phi$  for an unknown one. Then substitute these symbols “in one another in the most general fashions” (*Gödel’s Collected Works I*, p. 368) and equate certain pairs of the resulting expressions. If the selected set of functional equations has exactly one solution, consider  $\phi$  as denoting a “recursive” function; the definition of general recursive functions is obtained by insisting on two restrictive conditions. The first stipulates a standard form of certain terms, whereas the second condition demands that for every 1-tuple  $k_1, \dots, k_l$  there is exactly one  $m$  such that  $\phi(k_1, \dots, k_l) = m$  is a derived equation. The set of derived equations is specified inductively. The basic clauses guarantee that all numerical instances of a given equation as well as all true equalities  $\psi_{ij}(x_1, \dots, x_n) = m$  are derived equations. The rules that allow steps from already obtained equations to additional ones are formulated as follows:

(R.1) Replace occurrences of  $\psi_{ij}(x_1, \dots, x_n)$  by  $m$ , if  $\psi_{ij}(x_1, \dots, x_n) = m$  is a derived equation;

(R.2) Replace occurrences of  $\phi(x_1, \dots, x_l)$  on the right-hand side of a derived equation by  $m$ , if  $\phi(x_1, \dots, x_l) = m$  is a derived equation.

Gödel emphasized two central features in his definition when comparing it to Herbrand’s: first, the precise specification of mechanical rules for carrying out numerical computations in a uniform way; second, the formulation of the regularity condition requiring calculable functions to be total, but without insisting on a finitist proof of that fact.

1.3. NORMAL FORM AND THE  $\mu$ -OPERATOR. Using Gödel’s arithmetization technique to describe provability in the equational calculus Stephen Cole Kleene analyzed the class of general recursive functions in 1936. The uniform and effective generation of the derived equations allowed him to establish an important theorem that is called now Kleene’s normal form theorem: *for every recursive function  $\phi$  there are primitive recursive functions  $\psi$  and  $\rho$  such that  $\phi(x_1, \dots, x_n)$  equals  $\psi(\epsilon y. \rho(x_1, \dots, x_n, y) = 0)$ , where for every  $n$ -tuple  $x_1, \dots, x_n$  there is a  $y$  such that  $\rho(x_1, \dots, x_n, y) = 0$ .* The latter equation expresses that  $y$  is (the code of) a computation from the equations that define  $\phi$  for the arguments  $x_1, \dots, x_n$ ;  $\epsilon y. \rho(x_1, \dots, x_n, y) = 0$  provides the smallest  $y$ , such that  $\rho(x_1, \dots, x_n, y) = 0$ , if there is a  $y$  for the given arguments (it yields 0 otherwise). Finally, the function  $\psi$  considers the last equation in the given computation and determines the numerical value of the term on the r.h.s of that equation, which is a numeral and represents the value of  $\phi$  for the given arguments  $x_1, \dots, x_n$ . This theorem, or rather its proof, is remarkable: it allows to establish equivalences of different formulations with great ease; what is needed for the proof is only that the inference or computation steps are all primitive recursive.

Hilbert and Paul Bernays had introduced in the first volume of their *Grundlagen der Mathematik* (1934) a  $\mu$ -operator that functioned in just the way the  $\epsilon$ -operator did for Kleene. The  $\mu$  notation was adopted later by Kleene and is still being used in computability theory. Indeed, the  $\mu$ -operator is at the heart of the definition of a new class of number theoretic functions, the so-called  $\mu$ -recursive functions, and the normal form theorem is the crucial stepping stone in proving that this class of functions is co-extensional with that of Gödel’s general recursive ones. The  $\mu$ -recursive functions are specified inductively in the same way as the primitive recursive ones, except that a third closure condition is formulated:

if  $\rho(x_1, \dots, x_n, y)$  is  $\mu$ -recursive and for every  $n$ -tuple  $x_1, \dots, x_n$  there is a  $y$  such that  $\rho(x_1, \dots, x_n, y) = 0$ , then the function  $\theta(x_1, \dots, x_n)$  given by  $\mu y. \rho(x_1, \dots, x_n, y) = 0$  is also  $\mu$ -recursive.

Gödel's concept characterized a class of calculable functions that contained all known effectively calculable functions. Footnote 3 of the Princeton lectures seems to express a form of Alonzo Church's thesis. In a letter to Martin Davis of February 15, 1965, Gödel rejected that interpretation, "The conjecture stated there only refers to the equivalence of 'finite (computation) procedure' and 'recursive procedure.' However, I was, at the time of these lectures, not at all convinced that my concept of recursion comprises all possible recursions; and in fact the equivalence between my definition and Kleene's ... is not quite trivial" (Davis 1982, p. 8). At that time in early 1934 Gödel was equally unconvinced by Church's proposal that effective calculability should be identified with  $\lambda$ -definability; he called the proposal "thoroughly unsatisfactory." That was reported by Church to Kleene on November 29, 1935. In the following year Gödel observed the absoluteness of general recursive functions: If the value of a general recursive function can be computed in a finite or even transfinite type extension of arithmetic, then it can be computed already in arithmetic. Gödel added this important observation to his 1936 paper *On the Length of Proofs* and viewed it as providing evidence that an important and stable class of functions had been isolated. The next section presents considerations of some of the pioneers, obviously including Gödel, as to their reasons why the mathematically rigorous notion of machine computation introduced by Turing, and not general recursiveness, was ultimately viewed as providing the correct concept of mechanical procedure.

## 2. CONCEPTUAL ANALYSIS

Returning to the beginning, one notices a shift from effective mathematical calculations to mechanical operations of a machine. Church maintained in 1935 that the former are properly captured by the calculations involving general recursive functions. Clearly, if one has appropriate machines that allow the calculation of the base functions and mimic composition, recursion, and minimization, then all recursive functions and thus all effectively calculable ones are seen to be machine computable. Gödel argued in exactly that way in his 1936 paper and drew broader conclusions. He asserted that the characteristics of his equational calculus "are exactly those that give the correct definition of a computable function." He expanded that assertion by, "That this really is the correct

definition of mechanical computability was established beyond any doubt by Turing" (*Gödel's Collected Works III*, p. 168). The equivalence between general recursiveness and Turing computability is taken to support this claim.

**2.1. CHURCH'S THESIS.** Almost a year after his conversation with Gödel, Church came back to his proposal in a letter to Bernays dated January 23, 1935; he conjectured that the  $\lambda$ -calculus may be a system that allows the representability of all constructively defined functions. When Church wrote this letter, he knew that all general recursive functions are  $\lambda$ -definable; the converse was established in collaboration with Kleene by March 1935. This mathematical equivalence and the quasi-empirical adequacy of  $\lambda$ -definability provided the background for the public articulation of Church's thesis. Church announced it in a talk contributed to the meeting of the American Mathematical Society in New York City on April 19, 1935, but formulated it with general recursiveness, not  $\lambda$ -definability as the mathematically rigorous notion.

In his 1936 paper Church restated his proposal for identifying the class of effectively calculable functions with a precisely defined class. To give a deeper analysis Church discussed, in section 7 of his paper, two methods of characterizing the effective calculability of number-theoretic functions. The first of these methods uses the notion of algorithm, and the second employs the notion of calculability in a logic. He argues that neither method leads to a definition that is more general than recursiveness. These arguments have a parallel structure, and this entry discusses only the one pertaining to the second method. Church considers a logic  $L$ , that is a system of symbolic logic whose language contains the equality symbol  $=$ , a symbol  $\{ \} ( )$  for the application of a unary function symbol to its argument, and numerals for the positive integers. He defines, " $F$  is *effectively calculable* if and only if there is an expression  $f$  in the logic  $L$  such that:  $\{f\}(\mu) = \nu$  is a theorem of  $L$  iff  $F(m) = n$ ; here,  $\mu$  and  $\nu$  are expressions that stand for the positive integers  $m$  and  $n$ ." Church claims that  $F$  is recursive, assuming that  $L$  satisfies a certain step condition that amounts to requiring the theorem predicate of  $L$  to be recursively enumerable. The claim follows immediately by an application of the  $\mu$ -operator; the argument parallels that for Kleene's normal form theorem.

The general concept of calculability is thus explicated by that of derivability in a logic, and Church uses the step condition to sharpen the idea that within such a logical formalism one operates with an effective notion of immediate consequence. The thesis is thus appealed to

only in a special case. Given the crucial role this condition plays, it is appropriate to view it as a normative requirement: The steps of any effective procedure (governing derivations of a symbolic logic) must be recursive. If this requirement is accepted and a function is defined to be effectively calculable as above, then Church's step-by-step argument proves that all effectively calculable functions are recursive.

Church gave two reasons for the thesis, namely, (1) the quasi-empirical observation that all known calculable functions are general recursive and (2) the mathematical fact of the equivalence of two differently motivated notions. A third reason comes directly from the 1936 paper, the step-by-step argument from a core conception. However, Church and Gödel found in the end Turing's machine model of computation much more convincing. Church's 1937 review of Turing's paper for the *Journal of Symbolic Logic* asserts that Turing computability has the advantage over general recursiveness and  $\lambda$ -definability of "making the identification with effectiveness in the ordinary (not explicitly defined) sense evident immediately" (pp. 42–43)

2.2. FINITE MACHINES. Church's more detailed argument for the immediate evidence starts out as follows:

The author [Turing] proposes as a criterion that an infinite sequence of digits 0 and 1 be "computable" that it shall be possible to devise a computing machine, occupying a finite space and with working parts of finite size, which will write down the sequence to any desired number of terms if allowed to run for a sufficiently long time. As a matter of convenience, certain further restrictions are imposed on the character of the machine, but these are of such a nature as obviously to cause no loss of generality—in particular, a human calculator, provided with pencil and paper and explicit instructions, can be regarded as a kind of Turing machine.

He then draws the conclusion, "It is thus immediately clear that computability, so defined, can be identified with ... the notion of effectiveness as it appears in certain mathematical problems" (pp. 42–43). Why Turing's notion should convey this immediate conviction Church does not explain; the step from a computing machine "occupying a finite space and with working parts of finite size" to Turing machines is not deepened.

Gödel commented on Turing's notion in his 1951 Gibbs lecture publicly for the first time and made remarks similar to Church's. He explores there the impli-

cations of the incompleteness theorems, not in their original formulation, but in a "much more satisfactory form" that is "due to the work of various mathematicians." He stresses, "The greatest improvement was made possible through the precise definition of the concept of finite procedure, which plays such a decisive role in these results" (*Gödel's Collected Works III*, p. 304). There are, Gödel points out, different ways of arriving at a precise definition of finite procedure, which all lead to exactly the same concept.

However, and here is Gödel's substantive remark on Turing, "The most satisfactory way ... [of arriving at such a definition] is that of reducing the concept of finite procedure to that of a machine with a finite number of parts, as has been done by the British mathematician Turing" (*Gödel's Collected Works*, pp. 304–305). Gödel does not expand on this brief remark. In particular, he gives no hint of how reduction is to be understood or why the concept of such a restricted machine is equivalent to that of a Turing machine. At this point, it seems, the ultimate justification lies in the pure and perhaps rather crude fact that finite procedures can be reduced to computations of finite machines.

In a deep sense, neither Church nor Gödel seem to have recognized the distinctive character of Turing's analysis, that is, the move from arithmetically motivated calculations to general symbolic processes that underlie them. Most importantly in the given intellectual context, these processes have to be carried out programmatically by human beings: the *Entscheidungsproblem* had to be solved by humans in a mechanical way; it was the normative demand of radical intersubjectivity between humans that motivated the step from axiomatic to formal systems. For this reason Turing brings in human computers and exploits the limitations of their processing capacities, when proceeding mechanically. The Turing machine is in the end nothing but, as Gandy (1980) puts it, a codification of the human computer.

2.3. COMPUTERS. One can call a human computing agent who proceeds mechanically a *computer*; such a computer operates on finite configurations of symbols and, for Turing, deterministically so. At issue is then, how does one step from calculations of computers to computations of Turing machines? Turing explores, as he put it, the extent of the computable numbers (or, equivalently, of the effectively calculable functions) by considering two-dimensional calculations in a child's arithmetic book. Such calculations are reduced to symbolic steps on linear configurations of such a simple character that a

Turing machine operating on strings (instead of letters) can carry them out. Turing's argument concludes, "We may now construct a machine to do the work of the computer. ... The machines just described [string machines] do not differ very essentially from computing machines as defined in §2 [letter machines], and corresponding to any machine of this type a computing machine can be constructed to compute the same sequence, that is to say the sequence computed by the computer" (*The Undecidable*, p. 138).

It is important to recall Turing's goal of isolating the basic steps of computations, that is, steps that need not be further subdivided. This leads to the demand that the configurations, which are operated on, must be immediately recognizable by the computer. Combined with the evident limitation of the computer's sensory apparatus, this demand motivates convincingly two restrictive conditions:

(B) (*Boundedness*) There is a fixed finite bound on the number of configurations a computer can immediately recognize

(L) (*Locality*) A computer can change only immediately recognizable (sub-) configurations

Turing's considerations, sketched earlier, lead rigorously from operations of a computer on linear configurations to operations of a letter machine and can be generalized to other syntactic or graphic configurations. It should be noted that these constraints apply to Turing machines, but are violated by Gödel's equational calculus, as the replacement operations naturally involve terms of arbitrary complexity.

Turing's analysis secures the generality of mathematical results (e.g., of the incompleteness theorems) and their conclusiveness (e.g., of the undecidability of predicate logic) by respecting the intellectual context that appealed to effective operations carried out by humans without invoking higher mental capacities. It was after all the decision problem, the *Entscheidungsproblem* in the title of Turing's 1936 article, that motivated Turing's work. Its positive solution required "a procedure ... that permits—for a given logical expression—to decide the validity, respectively satisfiability, by finitely many operations." Hilbert and Ackermann gave that formulation (pp. 72–73) in their book *Grundzüge der theoretischen Logik* (1928) and considered the decision problem as the main problem of mathematical logic. Why that problem should be considered as the main problem of mathematical logic is stated clearly in their remark, "The solution of this general decision problem would allow us to decide, at least in

principle, the provability or unprovability of an arbitrary mathematical statement" (p. 86). Taking for granted the finite axiomatizability of set theory or some other fundamental theory in first-order logic, the general decision problem is solved when that for first-order logic has been solved.

A negative solution of the decision problem required, however, a rigorous characterization of finite procedures and a proof that none of them answers Hilbert and Ackermann's demand. Turing did both, as he gave a convincing conceptual analysis, established the effective unsolvability of the halting problem (or rather of the equivalent printing problem), and showed how to reduce it to the decision problem. Thus, if the latter were effectively solvable, then the halting problem would be; but as it is not, one has a contradiction. The proof of the unsolvability of the halting problem makes crucial use of a particular Turing machine, the universal machine U that, when presented on its tape with the program of a Turing machine M and an input, executes M's program for that input. This particular machine will play a special role in the next section.

### 3. PHYSICAL REALIZATION

For the further considerations, the most significant outcome of the previous historical and conceptual examination can be restated sharply as follows: Turing's notion of machine computation is obtained by an analysis of symbolic calculations carried out by computers. To put it negatively, Turing's notion is not obtained by an independent analysis of physical devices with the goal of, first, defining a general notion of machine and, second, introducing an appropriate concept of computation for such machines. It was only in 1980 that Gandy gave an analysis of machines and the deterministic computations they can carry out. This is presented in the second subsection below and will be followed, in the last subsection, by a description of the special features of quantum computers. However, what amounts to the physical implementation of Turing's universal machine U is discussed first. That is an absolutely central step in the development of modern computing machines and was taken in intricately intertwined ways, it seems, by Turing and John von Neumann; their work shaped the architecture of modern computers.

3.1. IMPLEMENTING U. In the years following World War II Turing worked on various aspects of the design and the actual building of a practical version of his universal machine U. During the last three months of 1945

he wrote a remarkable document titled *Proposal for Development ... of an Automatic Computing Engine (ACE)* and connected, in a lecture to the London Mathematical Society of February 20, 1947, the work on the ACE explicitly with his early theoretical work:

Some years ago I was researching on what might now be described as an investigation of the theoretical possibilities and limitations of digital computing machines. I considered a type of machine which had a central mechanism, and an infinite memory which was contained on an infinite tape. ... It was essential in these theoretical arguments that the memory should be infinite. It can easily be shown that otherwise the machine can only execute periodic operations. Machines such as the ACE may be regarded as practical versions of this same type of machine. (Turing 1947, pp. 106–107)

Turing characterized the ACE in his lecture as a typical large-scale electronic digital computing machine. From a mathematical perspective, Turing viewed being digital as the most relevant property of the ACE, since digital machines can work to any desired degree of accuracy and are not restricted, as analog machines are, to a particular type of computational problem.

From a practical point of view, the property of the ACE to be an electronic machine Turing considered as extremely important: it was to guarantee high speed and thus make it possible to execute complex procedures. The latter possibility requires, beyond the speed of basic operations, an appropriate organization of the machine, so that it can proceed fully automatically—without having to interact with a human operator—while executing a procedure. Turing emphasized, alluding to his universal machine:

It is intended that the setting up of the machine for new problems shall be virtually only a matter of paper work. Besides the paper work nothing will have to be done except to prepare a pack of Hollerith cards in accordance with this paper work, and to pass them through a card reader connected with the machine. There will positively be no internal alterations to be made even if we wish suddenly to switch from calculating the energy levels of the neon atom to the enumeration of groups of order 720. It may appear somewhat puzzling that this can be done. How can one expect a machine to do all this multitudinous variety of things? The answer is that we should consider the machine as doing some-

thing quite simple, namely carrying out orders given to it in a standard form which it is able to understand. (Turing 1946, p. 21)

In the 1947 lecture he made the connection to the universal machine explicit; after discussing memory extensively, he claims that digital computing machines such as the ACE are just “practical versions of the universal machine.” He continues, “There is a certain pool of electronic equipment, and a large memory. When any particular problem has to be handled the appropriate instructions for the computing process involved are stored in the memory of the ACE and it is then ‘set up’ for carrying out that process.”

The requirements for building a universal machine can in the end only be satisfied, if the machine is not only digital and electronic but also large scale, as it involves demands for “storage of information or mechanical memory.” Indeed, Turing pointed out already in the ACE Report that “the memory needs to be very large indeed.” The principled as well as the practical issues of implementation overlapped at this point with developments in the United States. Indeed, Turing recommended reading his report “in conjunction with J. von Neumann’s *Report on the EDVAC*.” (Herman H. Goldstine [1972] and Andrew Hodges [1983] present complementary views on the tenuous connection between the two projects; a balanced perspective is given by Hodges [1983, pp. 555–556, note 5.26.]

von Neumann completed a first draft of his report on June 30, 1945; the report emerged out of work with the group of J. Presper Eckert and John Mauchly at the Moore School of Electrical Engineering (University of Pennsylvania, Philadelphia). The group had built one of the first electronic calculators, the Electronic Numerical Integrator and Computer (ENIAC) and was evaluating a new memory system for a second, more sophisticated calculator, the Electronic Discrete Variable Calculator (EDVAC). The demand for a large, readily accessible memory emerged out of computational practice, namely, the need to have fast access to instructions, but also to fixed constant parameters and statistical data. That was to be achieved by storing them in the machine; von Neumann writes, “The device requires a considerable memory. While it appeared, that various parts of this memory have to perform functions which differ somewhat in their nature and considerably in their purpose, it is nevertheless tempting to treat the entire memory as one organ” (Goldstine 1972, p. 194).

von Neumann shifted the attention from the technological problems of having a larger memory to logical ones concerning the basic structure of machines with a central control mechanism and extensive memory. This structure is discussed in detail by Goldstine (1972, pp. 204–210).

A higher level of generality was attained in the Electronic Computer Project at the Institute for Advanced Study at Princeton University; this project was begun in March 1946 and directed by von Neumann. The resulting IAS Computer can be viewed as a prototype of all modern computers (the “von Neumann machine”). Its basic architecture, however, is similar to that of the ACE; it is the balance between arithmetical and fundamental logical operations that is distinctive. Goldstine describes the issue as follows:

The work of Post and Turing made it very clear that from the point of view of formal logics there was no problem to devise codes which were “in abstracto adequate to control and cause the execution of any sequence of operations which are individually available in the machine and which are, in their entirety, conceivable by the problem planner.” The problem is of a practical nature and is closely allied to that connected with the choice of elementary operations in the arithmetic organ. (1972, p. 258)

Turing and von Neumann made different compromises between simplicity of basic machine operations and complexity of programs needed to execute mathematical or symbolic procedures. These choices were obviously informed not only by their different computational experience and goals but also by their broader philosophical outlook. (That is movingly described by Hodges [1983, pp. 320–333].)

3.2. DISCRETE MACHINES. Turing’s *U* can be realized within practical limits by physical devices, and one can raise the question whether these devices are just doing things faster than humans can do, or whether they are in a principled way computationally more powerful. Church, as recalled earlier, asserted in 1937 that finite machines are essentially Turing machines; in Gödel’s remarks (from 193? and 1951) that assertion is taken for granted. The claim seems to be plausible, but it does require an argument. On the one hand, there may be physical systems that do not obey the same restrictions as computers and consequently may be able to carry out computations not possible for a computer. On the other hand, there may be physically grounded limits for

machines in the same way that there are psychologically based constraints for computers.

The character of individual computational steps was at the heart of the conceptual analysis. Because of physical constraints, such steps cannot be accelerated unboundedly or be made arbitrarily complex (Mundici and Sieg 1995, §3). However, there seems to be the possibility of sidestepping these constraints by using with massively parallel operations. Cellular automata, introduced by Stanislaw Ulam and von Neumann, operate in parallel; they do not satisfy the boundedness condition (**B**), as the configurations affected in a single computation step are potentially unbounded. They can simulate universal Turing machines and yield discrete simulations of complex physical processes. Konrad Zuse, for example, reflected on digital formulations of physics in his essay *Rechner der Raum* (1967). Edward Fredkin advocated the use of (reversible) cellular automata in physics and conjectured in his *Digital Mechanics* “that there will be found a single cellular automaton rule that models all of microscopic physics; and models it exactly” (1990, p. 254). The interested reader should consult Rolf Herken (1988), Tommaso Toffoli and Norman Margoulis (1987), and, of course, Stephen Wolfram (2002).

Gandy addresses the issue of parallel machine computations in his essay “Church’s Thesis and Principles for Mechanisms” (1980), where he proposes a particular mathematical description of discrete mechanical devices and their computations. He then follows Turing’s three steps of pertinent analysis, articulation of constraints, and proof of a reduction theorem. The central and novel aspect of Gandy’s formulation lies in the fact that it incorporates parallelism in complete generality. Cellular automata fall directly under Gandy’s formulation. And yet, the reduction theorem shows that everything calculable by a device satisfying the constraints, a Gandy machine, is already computable by a Turing machine. Here is a sketch of the main considerations.

Gandy (1980) introduces the term *discrete mechanical device* to make it vivid that his analysis is not at all concerned with analog devices, but rather with machines that are discrete and proceed step-by-step by step from one state to the next. Gandy considers two physical constraints as fundamental for such devices: (1) a lower bound on the size of atomic components and (2) an upper bound on the speed of signal propagation. Together, these constraints guarantee what the sensory limitations guarantee for computers, namely that in a given unit of time there is a bound on the number of different observable configurations and of possible actions

on them. However, the incorporation of massive parallelism into the mathematical description takes in Gandy's essay a substantial amount of complex mathematical work. In Wilfried Sieg's "Calculations by Man and Machine: Conceptual Analysis" (2002), Gandy machines are axiomatized as special discrete dynamical systems, and this presentation makes clear that they are radical generalizations of Turing machines: the latter modify one bounded part of a state, whereas the former operate in parallel on arbitrarily many bounded parts to arrive at the next state of the system.

Discrete computing machines in the broadest sense, when only constrained by physically motivated boundedness and locality conditions, do not reach beyond the computational power of Turing machines; that is the general moral. Every mathematical model of physical processes faces at least two questions: How accurately does the model capture physical reality, and how efficiently can the model be used to make predictions? It is distinctive for modern developments that, on the one hand, computer simulations have led to an emphasis of algorithmic aspects of scientific laws and that, on the other hand, many physical systems are being considered as computational devices, but under what conditions can a physical system really be viewed in that way? To have one important data point for reflections on this question, this entry will now look at the case of particular quantum systems.

**3.3. QUANTUM COMPUTERS.** Suppose one has a photon that impinges on a beam splitter and then propagates via two different paths. Quantum theory describes the photon as going partly into each of these two components. The state of the photon is given by the superposition of the two states associated with the two components of the original beam. Any observation of the photon, however, results in either the whole photon or nothing at all. This implies that after a measurement (1) the photon changes its state from being partly in one beam and partly in the other to being entirely in one of the beams, and (2) any interference effect is lost since one of the beams no longer enters into the description of the photon. If a second beam splitter combines the two beams, then the photon will be observed with probability one in a single beam. This certainty is because of quantum interference. Quantum computation arises from the possibility of exploiting a multiplicity of parallel computational paths in superposition as well as quantum interference to amplify the probability of correct outcomes of computations.

As the photon can be in a coherent superposition of being in two beams, the basic unit of quantum information, a *qubit* (from quantum bit), is a two-state system that can be prepared in a superposition of the two logical states 0 and 1. If a computational state can be reached through several alternative paths, then its probability is the squared modulus of the sum of all the probability amplitudes for the constituent paths. (Probability amplitudes determine probabilities and these have to add up to one for any quantum computational state.) Since the probability amplitudes are complex numbers, they may cancel each other and produce destructive interference or enhance each other and produce constructive interference.

Imagine a computation that starts in the input state 0 and reaches the output state in two steps. Suppose a computational step can mimic the action of a beam splitter and generate a superposition of two intermediate output states, 0 and 1 with probability amplitudes  $c_0 = i/\sqrt{2}$  and  $c_1 = 1/\sqrt{2}$ . Then the probability of each output is the same:  $|c_0|^2 = |c_1|^2 = 1/2$ . However, if the output state is measured after two computational steps, then the probability of the output 1 is one: The action of a beam splitter can be perfectly simulated by quantum computing operations that have no classical analogs. One of these is the  $\sqrt{\text{NOT}}$ , which when applied twice results in the logical operation *NOT*.

Since quantum mechanics describes a state transformation by means of a unitary operator, any quantum computing operation is a unitary transformation on qubits. The description of a quantum Turing machine (*QTM*) is derived from a Turing machine, but using quantum theory to define the operations carried out by the computer, which is now a physical system. Quantum interference allows a *QTM* to act on coherent superpositions of a given state and evolves them via unitary operators into other superpositions, from which the next state results with a certain probability. Any unitary operation on  $n$  qubits can be decomposed into simple operations on one or two qubits.

A collection of  $n$  qubits constitutes a quantum register of size  $n$  (the analogue of a Turing machine tape). A quantum register of two qubits can store all four numbers  $|00\rangle$ ,  $|01\rangle$ ,  $|10\rangle$ ,  $|11\rangle$  in superposition. Adding qubits increases the storage capacity of the register exponentially: given a quantum register of size  $L$ , a *QTM* can in one computational step perform the same mathematical operation on  $2^L$  numbers; a classical machine has to repeat the same computation  $2^L$  times or has to use  $2^L$  different processors working in parallel. However, if one

tries to read a number out of a superposition of the  $2^L$  output states, then one sees just one randomly chosen number. Only after an appropriate number of computational steps can one obtain a single final result that depends—in constructive ways—on all  $2^L$  intermediate results.

This is how quantum algorithms work. Grover's algorithm, as an example, can determine an element from an unsorted list of  $N$  items in approximately  $\sqrt{N}$  steps. A classical algorithm that scans the entries one by one requires on average  $N/2$  steps. Another quantum algorithm, due to Peter Shor, can factorize large integers efficiently. Here, the difference in performance between the quantum and classical algorithms seems exponential. Quantum algorithms solve some important problems more efficiently than classical ones, but they do not increase the class of computable functions.

If, using Ludwig Wittgenstein words, Turing machines are humans who calculate, then quantum Turing machines are physical systems that calculate. What made this shift possible was Deutsch's analysis leading to the assertion, "Every finitely realizable physical system can be perfectly simulated by a universal Turing computing machine operating by finite means" (Deutsch 1985, p. 99). Following David Deutsch (1985), a computing machine operates by finite means if: (1) only a finite subsystem is in motion during anyone step; (2) the motion depends only on the state of a finite subsystem; and (3) the rules that specify the motion can be given finitely in the mathematical sense (e.g., by an integer). "Turing machines," Deutsch asserts, "satisfy these conditions, and so does the universal quantum computer" (p. 100). Thus, boundedness conditions also play a significant role in characterizing the computation of a quantum system.

#### 4. CONCLUDING REMARKS

Computing machines have taken over the tasks of computers and transcend in important ways (e.g., of power and efficiency) human computational capacities. The takeover has two bases: (1) aspects of physical or intellectual reality have a finite symbolic representation, and (2) machines can take on (part of) the effective manipulation of the physical tokens involved in a representation. The latter may consist of just simulating the mechanical steps in human operations, as Turing machines do, or it may involve complex physical processes that are used in a different way, as in the case of quantum computers, when a suitable theoretical description allows them to perform a massively parallel calculation, so to speak, in a single step.

The concrete technological and scientific challenges of building a quantum computer seem enormous. Broad issues surrounding computing machines in general are multifarious and reach from the mathematically fundamental to the methodologically problematic. Can representations, for example, contain infinite components? Are there physical processes that can be viewed as computations, but do not fall within the Turing limits? What is the conceptual nature of analogue computations? Do they have to have a mathematical description that allows a calculable determination? What are the critical physical issues concerning measurement?

The ultimate challenge, articulated by Turing, is to have machines exhibit intelligence. Implementing the universal machine  $U$  meant for Turing to build a machine with discipline; producing intelligence required in addition initiative. Here, then, is the core of Turing's challenge, "Our task is to discover the nature of this residue as it occurs in man, and to try and copy it in machines" (*Gödel's Collected Works*, p. 125). Computing machines have become in their modern form scientific tools to explore, in particular, one's own intellectual nature.

#### Bibliography

The classical 1936 papers by Church, Kleene, Post, and Turing are all reprinted in *The Undecidable: Basic Papers on Undecidable Propositions, Unsolvability Problems, and Computable Functions*, edited by Martin Davis (Hewlett, NY: Raven Press, 1965). Gödel's papers are all available in his *Collected Works*. 5 vols. (New York: Oxford University Press, 1986–2003). Turing's papers from the late 1940s are collected in *Mechanical Intelligence*, edited by D. C. Ince (Amsterdam, Netherlands: North-Holland, 1992). The classical textbook presenting the Turing-Post development of computability theory is Martin Davis's *Computability and Unsolvability* (New York: McGraw-Hill, 1958). Finally, the references to von Neumann's papers and reports are all in Goldstine (1972).

## COMTE, AUGUSTE

(1798–1857)

Auguste Comte was a French positivist philosopher. Positivism may be viewed as either a philosophical system and method or as a philosophy of history. In the latter aspect, Comte's work was almost an early history of science. He has a good claim to having originated the new science of sociology; certainly, he coined the term. His political philosophy, elaborated on the basis of his positive sociology, was a noteworthy attempt to reconcile science with religion, and the ideals of the Revolution of 1789 with the doctrine of the counterrevolution of his own time. His influence on nineteenth-century thought was strong, he had numerous disciples, such as Émile Littré, and sympathetic supporters, such as John Stuart Mill. His ideas still have important meaning and interest.

### LIFE

Comte was born in Montpellier, France. Although his family were ardent Catholics, he announced at the age of fourteen that he had "naturally ceased believing in God." At this time he also seems to have abandoned his family's royalism and to have become a republican.

Comte's relations with his family were strained throughout his life. His mother, twelve years older than her husband, clutched at the son. She once wrote asking for word from him "the way a beggar asks for bread to sustain life" threatening that he would know what he had lost only when she was dead. His father and sister constantly complained of ill health; the latter appears to have suffered from hysteria. Comte portrayed them all as covetous and hypocritical and accused them of keeping him in financial distress. The facts, however, suggest that they did what they could for the son and brother whom they loved and admired but found so strange. It is necessary, in order to understand Comte's philosophy and polity, to comprehend his family's compelling influence on him. Although he rejected the ties to his parents and sister (he also had a brother), with their Catholic royalism and their strong emotional demands, these ties reasserted themselves in altered form in his later life and thought. These same family bonds also become important in understanding his nervous breakdown.

EDUCATION. Two events are outstanding in Comte's early life: his attendance at the École Polytechnique and his service as secretary to Claude-Henri de Rouvroy, Comte de Saint-Simon. The École Polytechnique, founded in 1794 to train military engineers and rapidly transformed into a general school for advanced sciences, was the product of both the French Revolution and the rise of modern science and technology, and it became the model for Comte's conception of a society ordered by a new elite. Although he was there for only a short period, from 1814 to 1816, he immersed himself in the scientific work and thought of such men as Lazare Carnot, Joseph Lagrange, and Pierre Simon de Laplace. Indeed, it was Lagrange's *Analytical Mechanics* that inspired Comte to expound, by means of a historical account, the principles animating each of the sciences.

Expelled from the École at the time of its royalist reorganization, Comte remained in Paris instead of returning home, as his parents desired. He came under the influence of the *idéologues* (Comte de Volney, Pierre-Jean Georges Cabanis, and Comte Destutt de Tracy) and, through his wide reading, of the political economists Adam Smith and J. B. Say, as well as of such historians as David Hume and William Robertson. Of major importance was the Marquis de Condorcet, whom Comte called "my immediate predecessor," and whose *Sketch for a Historical Picture of the Progress of the Human Mind* provided an outline of history in which developments in science and technology played a prominent role in humankind's rise through various stages to a period of enlightened

social and political order. Then, in August 1817, he became secretary to Saint-Simon. This crucial relationship lasted seven years, until it dissolved in acrimony.

**COMTE AND SAINT-SIMON.** The question of what Comte owed his patron, and what he added to the latter's ideas, is vexed. Both men were responding to the same intertwined challenges of the French, scientific, and industrial revolutions. Both sought a science of human behavior, called social physiology by Saint-Simon, and both wished to use this new science in the effort to reconstruct society. Saint-Simon, the older man, had priority in some of the ideas: He was first to announce the law of the three stages, talked of organic and critical periods, and called for a new industrial-scientific elite. Moreover, Comte's early work, including the fundamental opusculé, "Prospectus des travaux scientifiques nécessaires pour réorganiser la société," appeared as the last part of a work that also included two of Saint-Simon's writings.

However, Comte's development of the ideas—for example, the encyclopedic range of data with which he supported the idea of the three stages—went far beyond Saint-Simon and ultimately established a qualitative difference in their systems. Further, where Saint-Simon hoped to deduce his new social science from existing knowledge, such as the law of gravitation, Comte saw each science as having to develop its own method. Comte also perceived that such a development came historically; that is, only in the course of the progress of the human mind. And whereas Saint-Simonianism evolved toward a vague socialism, Comte's thought emerged as a philosophical or scientific position.

**LATER LIFE.** After the angry break with Saint-Simon, Comte, who could never obtain a satisfactory university post, supported himself primarily by tutoring in mathematics. Gradually, beginning in 1826, he also lectured on his new philosophy to a private audience composed of many of the outstanding thinkers of his time: Henri Marie de Blainville the physiologist, Jean Étienne Esquirol the psychologist, Jean Baptiste Joseph Fourier the mathematician, and others. From these lectures came Comte's major work, the six-volume *Cours de philosophie positive* (1830–1842).

Meanwhile, Comte entered into connubial arrangements, which were only later formalized in a macabre religious ceremony (Comte was then in the midst of his nervous breakdown) insisted upon by his mother. Although Comte was nursed back to health by his wife, the marriage was unhappy and was finally dissolved in

1842. Two years later, Comte met Mme. Clothilde de Vaux and fell deeply in love, and from this love may have come his new emphasis on a universal religion of humanity. In any case, after the *Cours*, which forms the core of Comte's positivism—the part that had the most influence on subsequent philosophers—came such various attempts to set up the religion of humanity as the *Système de politique positive* (1851–1854), and the *Catéchisme positiviste* (1852). In 1857, worn out from his labors, Comte died in wretchedness and isolation. Behind him he left only his monumental attempts at synthesis of many of the most important intellectual strands of his period.

## POSITIVE PHILOSOPHY

Comte's positive philosophy emerged from his historical study of the progress of the human mind—the western European mind. India and China, he claimed, had not contributed to the development of the human mind. Indeed, by mind he really meant the sciences: astronomy, physics, chemistry, and physiology (biology). Mathematics, for Comte, was a logical tool and not a science.

**THE THREE STAGES.** The history of the sciences shows that each goes through three stages: the theological, the metaphysical, and the positive. The progress of each field through the three stages is not only inevitable but also irreversible; it is, in addition, asymptotic—that is, we always approach, but never obtain, perfect positive knowledge.

Briefly, Comte's view of each of the three stages is as follows: In the theological stage, man views everything as animated by a will and a life similar to his own. This general view itself goes through three phases; animism, or fetishism, which views each object as having its own will; polytheism, which believes that many divine wills impose themselves on objects; and monotheism, which conceives the will of one God as imposing itself on objects. Metaphysical thought substitutes abstractions for a personal will: Causes and forces replace desires, and one great entity, Nature, prevails. Only in the positive stage is the vain search for absolute knowledge—a knowledge of a final will or first cause—abandoned and the study of laws "of relations of succession and resemblance" seen as the correct object of man's research.

Each stage not only exhibits a particular form of mental development, but also has a corresponding material development. In the theological state, military life predominates; in the metaphysical state, legal forms achieve dominance; and the positive stage is the stage of industrial society. Thus, Comte held, as did G. W. F.

Hegel, that historical development shows a matching movement of ideas and institutions.

According to Comte, the first science to have gone through the triadic movement was astronomy, whose phenomena are most general and simple, and that affects all other sciences without itself being affected. (For instance, chemical changes on Earth, while they affect physiological phenomena, do not affect astronomical or physical phenomena.)

**METHODOLOGY.** In the *Cours*, Comte attempted to demonstrate, by a mass of detail, that each science is dependent on the previous science. Thus, there can be no effective physics before astronomy, or biology before chemistry. Further, the history of the sciences reveals the law that as the phenomena become more complex (as biological phenomena are more complex than astronomical), so do the available methods by which those phenomena may be treated—for example, the use of comparative anatomy in contrast to simple observation of planetary movement.

In this part of his work, Comte demonstrated the real power and flexibility of his approach. In contrast to René Descartes, who saw only one right method of conducting the reason—the geometrical method—Comte believed that each science develops by a logic proper to itself, a logic that is revealed only by the historical study of that science. He explicitly named Descartes as his predecessor and claimed to have fulfilled Descartes’s work by studying the mind historically instead of merely abstractly. In Comte’s view, the logic of the mind cannot be explained in a priori fashion, but only in terms of what it has actually done in the past. In this respect, Comte’s position implies a fundamental revolution in philosophy.

Himself a mathematician, Comte objected to the overextended use of mathematics. In his view, mathematics was simply one tool among many. He admitted that while in principle all phenomena might be subject to mathematical treatment, in practice those phenomena far up the scale in complexity, such as biology or his hoped-for new science of sociology, were not amenable to such an approach. On the other hand, Comte sharply dissociated the positive method from the inquiry into first causes; as we have seen, this would be metaphysical, not positive, knowledge.

**Observation.** The first means of scientific investigation, according to Comte, is observation. We observe facts, and Comte would agree with the logical positivists of our day that a sentence that is not either a tautology or an assertion of empirical facts can have no intelligible

sense. However, by the observation of a fact, Comte—perhaps more sophisticated than many of his latter-day followers—did not mean having a Humean sensation or a complex of such sensations. He meant an act of sensing that was connected, at least hypothetically, with some scientific law. Comte admitted that the simultaneous creation of observations and laws was a “sort of vicious circle” and warned against the perverting of observations in order to suit a preconceived theory. However, he insisted that the task of the scientist was to set up hypotheses about invariable relations of phenomena, concomitantly with their verification by observation.

**Experimentation.** After observation, understood in this sense, experimentation is the next available method. Since it can be resorted to only when the regular course of a phenomenon can be interfered with in an artificial and determinate manner, the method is best suited to physics and chemistry. In biology, interestingly enough, Comte suggested that disease—the pathological case—while not determined beforehand, could serve as a substitute for experimentation.

**Comparison.** For the more complex phenomena of biology and sociology, the best available means of investigation is comparison. In biology this might be comparative anatomy. In social science, the method might take the form of comparing either coexisting states or consecutive states: The first method anticipated anthropology; the latter comprised historical sociology.

**SOCIOLOGY.** Comte described the study of consecutive social states as a “new department of the comparative method.” This “new department” was the final science to be developed by man, and the only one that had not yet entered the positive stage: sociology. As the last phenomena to be considered as falling under invariant laws, social phenomena were the ones that would give meaning to all the rest. Only by perceiving through the new science of sociology that man is a developing creature who moves through the three stages in each of his sciences could we understand the true logic of his mind.

Comte acknowledged both Baron de Montesquieu and Condorcet as his predecessors in the science of sociology, for they, too, had perceived that social phenomena appear to obey laws when correctly considered. However, the task of bringing sociology into the positive stage, or at least up to its threshold, was performed by Comte alone. He officially announced the advent of the new science in the fourth volume of the *Cours*, 47th lesson, when he proposed the word *sociologie* for what Lambert Adolphe Jacques Quételet had named *physique sociale*.

*Statics and dynamics.* Comte divided sociology into two parts: statics and dynamics. Social statics is the study of political-social systems relative to their existing level of civilization; that is, as functioning cultural wholes. Social dynamics is the study of the changing levels of civilization; that is, the three stages. The division into statics and dynamics is merely for analytic purposes: The distinction is one between two different ways of organizing the same set of social facts (just as, for example, in biology students of comparative anatomy and of evolution classify the same facts in different ways).

*Order and progress.* Statics and dynamics, then, are branches of the science of sociology. To this classification, Comte added a division between order and progress, which he conceived as abstractions about the nature of the society studied by sociology. (He further complicated the matter by using the terms *organic* and *critical* or *negative* to describe various periods.) Thus, order exists in society when there is stability in fundamental principles and when almost all members of the society hold similar opinions. Such a situation prevailed, Comte believed, in the Catholic feudal period, and he devoted numerous pages to analyzing the ideas and institutions of medieval social structure.

In contrast to the concept of order, and using images that remind one of the Hegelian dialectic, Comte posited what he called the idea of progress. He identified this progress with the period bounded by the rise of Protestantism and the French Revolution. What was now needed, Comte told his readers, was the reconciliation or synthesis of order and progress in a scientific form. Once a science of society had been developed, opinions would once again be shared and society would be stable. According to Comte, people did not argue over astronomical knowledge, and, once there was true social knowledge, they would not fight over religious or political views. Liberty of conscience, Comte declared, is as out of place in social thought as in physics, and true freedom in both areas lies in the rational submission to scientific laws.

The gradual becoming aware of and understanding of these invariable laws was what Comte meant by progress. (One of these invariable laws, incidentally, was that society must develop in a positive direction.) Thus, in the Middle Ages, when society found its order in terms of shared religious ideas, sociology was in the theological stage, and the French Revolutionary period witnessed the emergence of the metaphysical stage. As has been explained, Comte denigrated the period of progress, from the rise of Protestantism to the French Revolution, while from the point of view of social dynamics, he had to

praise the progressive movement toward positivism that took place during this “negative” period. Comte’s classification was neither always clear nor consistent.

**POLITICAL PHILOSOPHY.** Comte’s sociology was overly intertwined with his conception of the right polity. In Comte’s view, society had broken down with the French Revolution. The Revolution had been necessary because the old order, based on outdated “theological”—Catholic—knowledge, no longer served as a respectable basis for shared opinions; it had been undermined by the progress of the sciences. The Revolution itself offered no grounds for the reorganization of society because it was “negative” and metaphysical in its assumptions. The task, therefore, was to provide a new religion, and a new clergy, that could once again unify society. Comte’s solution was a science on which all could agree. In place of the Catholic priesthood, Comte proposed a scientific-industrial elite that would announce the “invariable laws” to society. It was a bold effort to synthesize the old regime (as conceived by Comte) and the Revolution, and to meet the problems of a modern industrial society with the insights about the need for order and shared certainty that were revealed in the theological-feudal period. These insights, religious in nature and intuitive in form, were now to be reformulated by Comte and his followers in terms of positive science.

**POSITIVE RELIGION.** Comte, in responding to the actual problems of his time, was also working out a synthesis of two bodies of thought. Montesquieu and Condorcet have already been mentioned as the sources of Comte’s conception of social statics and social dynamics. Comte’s views on organic and critical periods, and his dislike of Protestantism as negative and productive only of intellectual anarchy, were undoubtedly derived from the Catholic counterrevolutionary thinkers Vicomte de Bonald and Comte Joseph de Maistre, whom he began to read around 1821. It was Bonald, in fact, who first announced that one did not argue over social truths any more than one argued over the fact that 2 plus 2 equals 4, and de Maistre stated that Protestantism is a negative ideology. Comte rewarded de Maistre by putting his name in the calendar of positivist saints.

Now the positivist calendar was a product of Comte’s increasing turn from his earlier mainly philosophical and scientific interests to a form of mysticism. Comte appointed himself the high priest of a new religion of humanity. The new “religion”—based on Comte’s positive science—had its holy days, its calendar of saints (which included de Maistre, Adam Smith, Frederick the

Great, Dante Alighieri, and William Shakespeare), and its positive catechism. It was nontheistic, for Comte never reverted to a belief in God or in Catholic dogma. As an effort to replace the Catholic religion with a new version of the cult of reason of 1793, it is of great interest, but it was not this aspect of Comte's work that influenced such important figures as Littré and J. S. Mill and it is not what is generally meant when one speaks of Comte's Positivism.

**EDUCATIONAL THEORY.** It was on the basis of the earlier, rather than the later, parts of his work that Comte sought to regenerate education. To know a given science, Comte believed, one must know the sciences anterior to it. According to this scheme, the sociologist must first be trained in all the natural sciences, whose knowledge has already gone through the three stages and become positive. (A by-product of this approach to education was Comte's conviction that the proposed method of studying would aid each science by suggesting answers to its problems from other fields.) Positive education was a necessary foundation for the positive polity, as well as for the positive sociology.

**COMTE AND SOCIALISM.** To round off this presentation of Comte's thought, a brief word is in order on the relationship of his views to the emerging proletarian movement. The goal of Comte's polity was never the affluent society, although he believed that every social measure ought to be judged in terms of its effect on the poorest and most numerous class. He sought, instead, a moral order, with the positive religion enjoining everyone "to live for others." The two classes from which Comte expected the greatest moral influence were women and proletarians, and he relied on their respective charms and numbers to soften the selfish character of the capitalists. In this way, class conflict would be abolished, and the owners of industry would be moralized instead of eliminated. Comte was against the abolition of private property; on the other hand, he joined Karl Marx in attacking the individualist attitudes and behavior of the property-owning classes. In this context, it is interesting to note that Marx, who claimed not to have read Comte until 1866, when he judged his work "trashy," had as a friend the Comtian Professor E. S. Beesly, who chaired the 1864 meeting establishing the International Workingmen's Association.

### CRITICISM AND ASSESSMENT

Against Comte's entire system, various criticisms may be lodged. J. S. Mill took Comte to task for not giving a place

in his series of sciences to psychology (instead, Comte concentrated on phrenology) and commented that this was "not a mere hiatus in M. Comte's system, but the parent of serious errors in his attempt to create a Social Science."

Perhaps there is a connection between Comte's disregard of introspective psychology and his unquestioned faith in the possibility of an ultimate positive stage of society and knowledge. For example, Comte did not even consider the question of how we can be sure that the positive stage is the last one. Since the human mind and its logical procedures, in Comte's own view, can be known only in terms of experience, it is at least theoretically possible that another stage might be reached. And how can we be sure that, although the positive method has been extended to all natural phenomena, it can be extended to human phenomena? Even if we grant this—and admittedly it is an appealing and useful assumption—does the discovery of laws regulating human phenomena put us in possession of a final science of humanity? At this point, are we not still without a science of ethics, a science that will tell us with complete positive certainty what end to pursue? Comte considered none of these questions, nor, with his neglect of introspective psychology, the further question of whether man's moral disposition is necessarily improved by the pursuit of science.

On another level, both Comte's sociology and his political philosophy can be criticized as embodying a wrong view of scientific procedure. In his best moments, he knew that science proceeds by free inquiry and constant redefinition of its "laws." However, in setting up a scientific elite, who were to announce fixed and stable laws to society, he betrayed his own insight. The polemic needs of his polity—ordered, organic, and positive—triumphed over the philosophic and scientific method he had so painstakingly elaborated in the *Cours*.

Along this same line of criticism, Comte can be charged with serious errors of fact. His anti-Protestant, pro-Catholic feelings led him to make sweeping and unexamined statements, such as that Protestantism was "anti-scientific" (a conclusion supported, perhaps, by Martin Luther's views, but undermined, for example, by the Puritan involvement in the Royal Society) and that Catholicism was a nonaggressive religion. Thus, speaking of the Crusades, Comte asserted, as a matter of fact: "All great expeditions common to the Catholic nations were in fact of a defensive character." Throughout his work, especially in the last three volumes of the *Cours*, which are devoted to his sociology rather than to the natural sciences, similar remarks are to be found.

Yet, with all the criticisms of either a conceptual or factual nature that can be leveled against Comte's position, one must not lose sight of his essential contributions. He did grasp the notion that knowledge in the various sciences is unified and related. His law of the three stages, while too rigid and schematized, did point to the different ways of viewing the world and to the fact that men at different stages of history have emphasized one way of ordering society more than another. And, most important, Comte did prepare the way for a new science, sociology, that would help study the interrelations of men in society and how these interrelations change in the course of history.

### Bibliography

There is no critical edition of Comte's works. His most important writings, all published in Paris unless otherwise stated, are as follows: *Opuscules de philosophie sociale 1819–1828* (1883), which includes the 1822 "Plan des travaux scientifiques nécessaires pour réorganiser la société"; *Cours de philosophie positive*, 6 vols. (1830–1842), and Harriet Martineau's English condensation of *Cours*, *The Positive Philosophy of Auguste Comte*, 2 vols. (London: John Chapman, 1853), which was personally approved by Comte; *Discours sur l'esprit positif*, prefixed to the *Traité philosophique d'astronomie populaire* (1844); *Discours sur l'ensemble du positivisme* (1848); *Calendrier positiviste* (1849); *Système de politique positive*, 4 vols. (1851–1854), translated by J. H. Bridges, Frederic Harrison, et al. as *The System of Positive Polity*, 4 vols. (London: Longmans, 1875–1877); *Catéchisme positiviste* (1852), translated by Richard Congreve as *The Catechism of Positive Religion* (London: John Chapman, 1858); *Appel aux conservateurs* (1855); and *La synthèse subjective* (1856).

In addition, see P. Valat, ed., *Lettres d'Auguste Comte à M. Valat* (1870); *Lettres d'Auguste Comte à John Stuart Mill, 1841–1846* (1877); *Testament d'Auguste Comte* (1884); *Lettres à des positivistes anglais* (London: Church of Humanity, 1889); *Correspondance inédite d'Auguste Comte*, 4 vols. (1903–1904); and *Nouvelles Lettres inédites. Textes présentés par Paulo E. de Berredo-Carneiro* (1939).

The most important work on Comte, essential to a study of his intellectual development, is Henri Gouhier, *La jeunesse d'Auguste Comte et la formation du positivisme*, 3 vols. (Paris: Vrin, 1933–1941). The same author's *La vie d'Auguste Comte*

(Paris: Gallimard, 1931) is the best biography. For an analysis of Comte's philosophical ideas, J. S. Mill, *Auguste Comte and Positivism* (London: Trubner, 1865) is still obligatory. See also Thomas Whittaker, *Comte and Mill* (London: A. Constable, 1908); Lucien Lévy-Bruhl, *La philosophie d'Auguste Comte* (Paris: Alcan, 1900), translated by Kathleen de Beaumont-Klein as *The Philosophy of Auguste Comte* (New York: Putnam, 1903); Émile Littré, *Auguste Comte et la philosophie positive* (2nd ed., Paris: Hachette, 1864); J. Delvolvé, *Reflexions sur la pensée comtienne* (Paris: Alcan, 1908); and Pierre Ducassé, *Méthode et intuition chez Auguste Comte* (Paris: Alcan, 1939).

On Comte's religious attitudes, see George Dumas, *Psychologie de deux Messies positivistes: Saint Simon et Auguste Comte* (Paris: Alcan, 1905).

Jean Lacroix, *La sociologie d'Auguste Comte* (Paris: Presses Universitaires de France, 1956) is one of the most interesting books on Comte. For a critical view of Comte's sociology in relation to morality, H. B. Acton, "Comte's Positivism and the Science of Society," in *Philosophy* 26 (October 1951) is valuable.

Treating Comte as a historian of science are Paul Tannery, "Comte et l'histoire des sciences," in *Revue générale des sciences* 16 (1905), and George Sarton, "Auguste Comte, Historian of Science," in *Osiris* 10 (1952). In this connection, John C. Greene, "Biology and Social Theory in the Nineteenth Century: Auguste Comte and Herbert Spencer," in *Critical Problems in the History of Science*, edited by Marshall Clagett (Madison: University of Wisconsin Press, 1959) is interesting. Frank Manuel, *The Prophets of Paris* (Cambridge, MA: Harvard University Press, 1962), Ch. 6, and F. A. Hayek, "Comte and Hegel," in *Measure* 2 (1951), are rewarding; the Hayek article treats Comte as a historicist.

**Bruce Mazlish (1967)**

## CONCEPTS

Concepts are customarily regarded as intermediaries between mind and world. They are the basic elements of thoughts and the tools by which one classifies things. Concepts are central to the philosophy of mind, and they are often implicated in theories of meaning. There are also some who think that philosophical method is largely a matter of conceptual analysis. There is considerable consensus on the importance of concepts, and, to a lesser extent, on the roles that concepts play, but beyond that there is rampant disagreement. For example, philosophers disagree about the ontology of concepts, the acquisition of concepts, and the content of concepts. In the twentieth century, psychologists began to weigh into these debates, and since the 1970's, much theorizing about concepts has been informed by interdisciplinary dialogue. This entry surveys dominant theories.

## WHAT ARE CONCEPTS FOR?

Within philosophy concepts are most often defined as the elements or ingredients of thoughts. Concepts are for thinking. When one ascribes a thought, such as “aardvarks are nocturnal,” one typically assumes that the bearer of that thought has a concept of aardvarks and a concept corresponding to the property of being nocturnal. It is sometimes said that a concept is to a thought as a word is to a sentence, but this formula can mislead, because some philosophers do not believe that thought is language-like. However, even those who resist the view that thought is language-like may be attracted to one crucial point of analogy: concepts are believed to be combinable. Those who possess a concept of aardvarks can form the thought that aardvarks are nocturnal, the thought that aardvarks are quadrupeds, or the thought that aardvarks are insectivores, assuming possession of these other concepts. Gareth Evans (1982) suggests that it is a condition on concept possession (“the generality constraint”) that, if a person can have the thought that *a* is *F*, then that person should also be able to form every other thought of the form *a* is *X*, where *X* ranges over the concepts in that person’s conceptual repertoire. Some philosophers think there may be restrictions (e.g., of intelligibility) on combination, but most agree that thought formation through conceptual combination is a central function of concepts.

A second function of concepts is categorization. Many philosophers think that concepts are the primary tools by which one determines that something falls into a category. One knows that two things are both turtles in virtue of having a turtle concept. Historically, some philosophers have reserved the word *concept* and closely related words for general kinds. On this usage there can be a concept of turtles, in general, but not a concept of a particular turtle, say Yertle. Other philosophers tend to say that there can be concepts of individuals and that concepts can be singular as well as general. When one identifies an individual, one can think of that as an act of categorization, broadly construed: One categorizes that individual as belonging to a class with one member. Concepts are implicated in the categorization of kinds and individuals.

Concepts are sometimes said to have a function in inference. This third function often works in concert with the second. One uses concepts to draw inferences about the things that one categorizes. If one encounters a shovel, one can infer that it is used for digging. The knowledge that shovels are used for digging is said, by many, to be contained in one’s concept of shovels. Thus,

when one applies the concept to some thing, one can use the concept to infer facts about that object.

Concepts are also widely presumed to play a role in linguistic meaning. For some, concepts simply are the meanings of words or components of meanings. On this view concepts are expressed when one uses words. Some philosophers’ (especially those who favor reference-based semantic theories) concepts are not meanings. But these authors usually concede that concepts play a central role in the epistemology of language. One comes to understand a word by associating it with a concept. On either approach concepts and language will be closely related.

A fifth function of concepts is related to the other three, but is potentially dissociable. Concepts are said to be representations; they refer to things. Some theories of concepts encompass theories of reference. In this sense, concepts are intermediaries between mind and world.

There is controversy about what concepts are for, but the items on the preceding list are widely accepted. Concepts are usually postulated to play all or some of the preceding roles.

## SOME ISSUES OF CONTROVERSY

In describing some of the functions of concepts, a few places of controversy have already been indicated. There are a number of other controversies that deserve special mention.

One issue concerns ontology. It is widely agreed that concepts are intermediaries between mind and world, but where do they reside? One possibility is that they are timeless *abstracta*. This view has been especially popular among those who identify concepts with word meanings. Many semantic theorists believe that meaning enjoy some autonomy from psychology. On this view the meaning of a word does not depend on the images or ideas any individual happens to possess. Others are attracted to this view because they regard concepts as a specification of the essential properties of the things to which they refer.

The concept of a triangle, on this view, might be a geometric definition. Triangles had that definition before anyone discovered it. In contrast, there are philosophers who locate concepts inside the head. On this approach a concept is a mental representation, which plays a causal role in information processing. Others regard concepts as psychological, but eschew talk of mental representations. For example, one might say that a concept is a skill or ability or an operation on mental representations. Immanuel Kant (1997) says concepts are rules for constructing or organizing images. In between those who say

that concepts are abstract and those who say they are psychological, there are social theories of concepts, according to which concepts supervene on human practices. What matters is not the contents of any individual's mind, but socially distributed patterns of deference, normative demands, and reason-giving behavior. There is room for uniting all these ontological perspectives into a single theory. For example, one could say that individuals have mental representations (psychological concepts) of community-enforced rules (social concepts) that dictate which timeless, essential properties their thoughts denote (abstract concepts).

Among those who think that concepts are mental representations, there are significant disagreements about representational format. Some think concepts are words in language-like mental code ("the language of thought hypothesis"), others claim they are mental images ("imagism"), and still others say they are weighted connections or patterns of activation in neural networks ("connectionism").

Those who think that concepts are mental representations also disagree about how concepts are attained. Some think that many concepts are innate, and some think that few or none are innate. There are controversies about how learned concepts are acquired. Concepts might be copied from experience, they might be abstracted, they might be learned by strengthening associations, or they might be acquired using a more deliberative procedure, such as the formation and testing of hypotheses. The innateness question is sometimes posed as a question of which concepts are primitive. Many philosophers believe that some concepts are primitive and others are assemblies or inferential networks built up from these. (When two concepts are combined to form a third, they are said to be "features" of that third concept.) Primitive concepts are often thought to be innate, so debates about this issue can sometimes be characterized as debates about how many primitives one has. Historically, however, some philosophers have assumed that many complex concepts are innate as well (such as the concept of God or of identity).

Those who think that concepts are abstract or otherwise external to individual minds sometimes talk about concepts using a definite article, "The concept of X." Those who think that concepts are mental representations are less likely to talk this way, leaving open room that different people may have different concepts of the same thing. There may be exceptions to this rule. It is natural to speak of technical concepts with a definite article ("The concept of natural selection") because there is

sometimes just one correct formulation. In addition, some philosophers think concepts are individuated by their referents. On this view any concepts of the same thing will count as being the same concept. Hence, it would always make sense to talk about concepts using the definite article.

Another controversy surrounds the relationship between concepts and language. Besides the question of whether concepts are meanings (hence, whether language depends on concepts), there is a question of whether concepts depend on language. This conclusion has been defended by Ludwig Josef Johann Wittgenstein, Michael Anthony Eardley Dummett, and Donald Davidson. The arguments often turn on the claim that having concepts requires recognizing that thoughts and inferences can be mistaken, which depends in turn on belonging to a language community whose members give and demand reasons for utterances. In contrast, many think that concepts can be possessed without language, and, indeed, Jerry A. Fodor (1975) argues that language learning would be impossible without prior possession of concepts.

All these controversies are significant, but the main issue dividing competing theories of concepts has to do with content. Philosophers disagree about what information one knows in virtue of possessing concepts. One knows a great deal about many categories, but many philosophers believe that only some of this knowledge is conceptually constitutive. Some of this knowledge belongs to one's concepts, and the rest merely belongs to one's conceptions, where conceptions are thought to be more ephemeral and idiosyncratic than concepts. Theories of concepts can be distinguished by where they draw the concept-conception divide.

## THE CLASSICAL THEORY

One theory of concepts has been so dominant in the history of philosophy that it has been dubbed "the classical theory." The name is apt, because the theory is championed by Plato. In classical theory, concepts are definitions: They specify conditions that are individually necessary and jointly sufficient for the categories they designate. In his dialogues Plato tries to uncover definitions of concepts such as justice, knowledge, piety, and love. On this approach specifying a concept of justice is a matter of specifying what it is to be just. It is unclear whether Plato thinks concepts are abstract entities or mental entities. He claims that people categorize things by recalling a life in a world of ideal forms, which they inhabited before life in the terrestrial world. Possessing a

concept is a matter of intuiting, through memory and reflection, the essence of these ideal forms.

Many philosophers have assumed that some version of the classical theory is correct. Kant (1997) says that concepts are rules that determine the conditions of category membership. He also suggests that many concepts contain other concepts, like houses made from bricks, and in the *Prolegomena to Any Future Metaphysics That Will Be Able to Come Forward as Science, with Selections from the Critique of Pure Reason* (1997) he introduces the term *analytic* to refer to judgments whose predicate concepts are contained in their subject concepts. These judgments are, in effect, true by definition, as opposed to synthetic judgments, which are not true by definition, but must be discovered.

Gottlob Frege (1960) uses the term *concept* (*Begriff*) to refer, narrowly, to the concepts expressed by predicates, but he uses a more encompassing term *sense* (*Sinn*) to refer to the components of thoughts, and each of these, he suggests, can be identified with a descriptive content that determines reference. Frege insists that senses are abstract entities; if they were in the head, he thought they could not serve as the shared meanings of words. Inspired by Frege, Christopher Peacocke (1992) claims that concept possession involves the mastery of inferences, which play a central role in determining reference.

Rudolf Carnap (1956) claims that the concepts used in ordinary thought and talk are riddled with imprecision and that they need to be replaced by concepts that are explicitly defined. Analytic truths are stipulated, and hence immune from empirical refutation.

Defenders of the classical theory disagree about how concepts are attained. Plato obviously thinks concepts are innate, and Carnap thinks explicated concepts must be learned. For many classical theorists, some are innate and others are learned.

The classical theory has been criticized in various ways. Willard Van Orman Quine (1981) argues that the distinction between analytic and synthetic truths is unprincipled, because any putatively analytic claim could be revised under empirical pressure, if, for example, such a revision would be the most conservative way to alter a prevailing theory to accommodate new evidence. Hilary Putnam (1975) argues that definitions are not essential for reference; one can think about natural kinds (e.g., tigers, gold, and water) even if no one grasps the conditions that are necessary and sufficient for falling in the categories. Ludwig Wittgenstein (1953) argues that concepts often lack catchall definitions; instead, concepts

group things together on the basis of family resemblances (games are his famous example). Psychologists support Putnam and Wittgenstein by showing that people rarely know the defining features of a category. Georges Rey (1983) counters that the psychological objections presuppose that concepts are in the head and readily available to consciousness—some classical theorists are willing to deny both assumptions.

## CONCEPT EMPIRICISM

Plato does not say much about how concepts are mentally represented. Aristotle has more to say. He says that every concept is accompanied by an image. This idea inspired subsequent empiricist philosophers to propose that concepts are perceptual in nature. This basic claim is the essence of concept empiricism. Scholastic philosophers say that nothing is in the intellect that is not first in the senses. The British empiricists, such as John Locke (1799) and David Hume (1778), say that concepts are derived from percepts. Hume says concepts are simply copies of percepts or combinations of copied percepts, and Locke proposes that many concepts are acquired through abstraction from percepts (though there is some disagreement about what he and his scholastic predecessors meant by abstraction).

Concept empiricists differ in several ways from typical classical theorists. First, many concept empiricists are imagists, whereas many classical theorists are not. Concept empiricists usually say that concepts are mental representations (the British empiricists use the term *ideas*), whereas classical theorists often say they are abstracta. Concept empiricists emphasize learning, whereas traditional classical theorists assume that many concepts are innate. Concept empiricists claim that concepts refer either by resemblance or by causal relations to their referents, whereas classical theorists usually assume that concepts refer by satisfying lists of defining conditions.

Nevertheless, there are theories that straddle the border between the classical theory and concept empiricism. The verificationist theories of concepts advanced by Carnap (1956) and other logical positivists are a case in point. For a verificationist, concepts consist in conditions that are necessary and sufficient for reference, but these conditions are specified in observational vocabulary; a concept refers to that which satisfies perceivable conditions of verification.

Concept empiricism is widely believed to face serious objections. One has to do with the concepts of abstract categories. There seem to be concepts of virtue, truth, substance, cause, and being, yet none of these things has

any characteristic appearances. If concepts were all derived from perception, it would be hard to explain how people think about these things. Concept empiricists reply by either arguing that people do not have concepts of these things, or by reducing these concepts to perceptual features. Both strategies are hard to pull off.

Another objection is put forward by Kant (1997). He argues that one's capacity to perceive presupposes the possession of certain concepts (including concepts of time and space), which could not be derived from experience. Contemporary psychologists also argue that there is empirical evidence for innate concepts, which are evidently in place before experience, such as the concept of physical object or of number.

### PROTOTYPE THEORY

When the classical theory came under attack in the middle of the twentieth century, new alternatives were sought. One alternative, already mentioned, was Wittgenstein's (1953) family resemblance account, according to which one comprehends categories by means overlapping features rather than a catchall definition. This suggestion spawned the emergence of the cluster theory, which identified concepts with features that are not individually necessary for category membership but sufficient when a sufficient number are in place. No one feature may suffice for being a game, and no one feature is necessary, but bring a few features together and one has a game. In effect, the cluster theory is a similarity theory of concepts; it says that one categorizes by looking for similarities with familiar instances.

In psychology, dissatisfaction with the classical theory and inspiration from Wittgenstein (1953) gave rise to the prototype theory. On this approach categorization is also a matter of assessing similarity to a set of features that are not individually necessary for category membership. Prototype theorists do not construe concepts as unwieldy clusters, but as summary representations capturing just those features that are most typical of the category. A prototype is a representation of features that are highly frequent, salient, and diagnostic for category membership. The prototype for the category bird might include features such as flies, has feathers, has a beak, and sings. Following Putnam (1975), philosophers sometimes use the term *stereotypes* for much the same thing. Psychologists, notably Eleanor Rosch and Carolyn Mervis (1975), support the postulation of prototypes by showing that people categorize prototypical category members faster, learn to recognize them earlier, and list prototypical features first when asked to describe a category.

Prototype theorists usually assume that concepts are mental representations, but they diverge on the format of these mental representations. Some say they are made up of images, some say they are patterns in connectionist networks, and some say they are lists of features coded in a language of thought. Like some concept empiricists, prototype theorists argue that concepts are often learned by abstracting from particular category instances, but prototype theorists do not always assume that concepts are grounded in perceptual experience. There can be prototypes for categories that are difficult to discern perceptually, such as a prototypical analytic philosophy paper, a prototypical democracy, or a prototypical lie.

Prototypes are often used in categorization, but some psychologists and philosophers argue that they should not be equated with concepts. One objection is that similarity to a prototype is not necessary for categorization and reference; a shaved, mute, tailless, three-legged dog is completely unlike the dog prototype but still falls under the category. Similarity to a prototype is also not sufficient for categorization and reference: a duck decoy is no duck. Another objection is that prototypes do not combine together compositionally: the prototype for a compound concept is often unlike the prototype for its parts. Pet fish prototypically live in bowls, but neither pets nor fish prototypically live in bowls. Fodor (1998) argues that concepts must combine compositionally to explain that one can generate an unbounded number of novel thoughts from a finite stock of concepts. For similar reasons, prototypes may violate Evans's Generality Constraint (1982), which implies that concepts can be freely recombined; someone might know the prototypes for red fruit and long hair without knowing the prototypes for red hair and long fruit.

### THE THEORY THEORY AND HOLISM

Unconvinced by prototype theory, some psychologists developed an alternative, which is associated with the following basic tenets. First, not all concepts are alike; one must distinguish animal concepts, artifact concepts, psychological concepts, mathematical concepts, concepts of physical objects, and so on. Each of these classes is governed by different "folk theories" that comprise small collections of basic principle; for example, folk biology explains that animals have hidden genetic essences, and folk physics explains that solid objects cannot pass through each other. Second, some folk theories lead one to postulate defining essences (as in the case of folk biology), but, unlike classical theorists, psychologists do not assume that these essences are known to those who pos-

tulate them; this is called psychological essentialism. Third, each of the concepts within one of these classes may contain causal and explanatory features besides prototypical features; for example, a concept of birds may contain the belief that wings enable flight. Together, these tenets suggest that concepts are like scientific theories: they divide into domains, they postulate hidden features, and they play a role in explanation. The approach has been dubbed the *theory theory*.

Most theory theorists assume that some rudimentary folk theories are innate, but they disagree about which ones. They also disagree about whether one's innate theories remain intact over development, or whether they undergo significant transformations, akin to conceptual revolutions in science. On the latter view adult concepts may be incommensurable with the concepts of children and infants.

The theory theory has been primarily developed by psychologists, but related ideas can be found in philosophy. Quine's (1981) critique of the analytic-synthetic distinction has led some to believe that the basic units for understanding any given category is an entire theory. Quine differs from most psychologists in three respects: He does not claim that theories are insulated from each other (perturbations in one may have ripple effects); he does not claim that theories are mentally represented in the head (Quine is a behaviorist); and he assumes that theories are learned (one's initial sorting behavior is driven by superficial similarities). Still, one might appropriate Quine's ideas into a psychological theory by proposing that each concept is a mental representation individuated by its place in a complete network of mental representations. This would be a holistic theory of concepts.

Critics of the theory theory and holism worry that these approaches entail that concepts are rarely shared. If two people have different theories, then they have different concepts, and their ability to communicate and to obey the same psychological laws becomes difficult to explain. It is also unclear whether these approaches can explain how concepts are combined to form thoughts, because theories are too cumbersome to easily combine together.

### INFORMATIONAL ATOMISM

The theory theory and holism pack a lot of information into concepts. Some philosophers prefer the opposite strategy. Fodor (1998) argues that just about every lexical concept (a concept expressed by a single word) is primitive: a primitive concept is one that is not individuated by

its relation to any other. This is called atomism. Instead, concepts are individuated by their referents, and concepts refer by falling under the nomic control of properties; roughly, a cow concept refers to cows because it is a law that encounters with cows and causes cow concepts to be tokened. This is called informational semantics.

Informational atomism is unlike all the theories considered so far, because all the others assume that most lexical concepts are complex. A primary advantage of informational atomism is that it can explain how concepts are recombined compositionally. If concepts are primitive symbols, then they can retain their identity when combined, just as words retain their shape when placed into sentences. Concepts can also be easily shared on this view: Two people have the same concept if they have symbols that are under nomic control of the same properties regardless of any difference in their beliefs.

These advantages come at cost. If lexical concepts are primitive, then they cannot be used to explain the inferences one draws or the way one categorizes. For a thoroughgoing atomist, someone could possess a concept of bachelors without knowing that they are male or unmarried. Atomism has also been associated with radical concept nativism. Many philosophers assume that primitive concepts are innate and that complex concepts are learned; if all lexical concepts are primitive, then all are innate. Fodor (1981) used to embrace this consequence, and Fodor (1998) now argues that primitive concepts can be learned.

### PHILOSOPHY AS CONCEPTUAL ANALYSIS

Beginning with Plato, one of the dominant methods for doing philosophy has been philosophical analysis. Practitioners begin with a specific concept and reflect on its content. In so doing, they hope to reveal not only how one thinks about the referent of that concept but also what the essence of that referent is. By reflecting on the concept of virtue, for example, one might reveal what it is to be virtuous. The viability of this method depends on which theory of concept is correct. If concepts are definitions, conceptual analysis can reveal the essence of things. But if concepts are merely assemblies of typical features, incomplete and revisable theories, or semantically primitive symbols, then conceptual analysis cannot reveal the essence of things. There is as yet no consensus on which theory of concepts is right, but at stake is the methodology of philosophy itself.

## CONDILLAC, ÉTIENNE BONNOT DE (1714–1780)

Étienne Bonnot de Condillac was one of the French *philosophes*, known primarily for his development of the doctrine of "sensationism." According to this doctrine, not only all of one's thoughts but even the basic operations on these thoughts derive from sensation.

Condillac was born on September 30, 1714, in Grenoble, one of five children of Gabriel Bonnot, vicomte de Mably, and Catherine de la Coste. He took the name of Condillac after his father purchased an estate of that same name in 1720. Condillac was born with poor eyesight that prevented him from reading before the age of twelve, and he was considered in his childhood to possess only limited intellectual abilities. However, in 1730 he took up residence with his brother, the abbé de Mably, in Lyon to attend the Jesuit college there, and in 1733 he went to Paris to study at the Sorbonne, where he later became a seminarian at Saint-Sulpice. Condillac defended his thesis in theology in 1739, and he took holy orders around 1741, though he subsequently devoted himself more to study than to pastoral work. Indeed, he was said to have celebrated Mass only once in his life. While in Paris Condillac frequented the salons and was exposed to the views of John Locke and Isaac Newton. He was influenced in particular by Locke's critique of innatism and Newton's method of explaining phenomena in terms of simple general principles drawn from experience.

Condillac was well connected in French Enlightenment circles. His cousin was Jean Le Rond d'Alembert, coauthor of the *Encyclopédie, ou Dictionnaire raisonné des sciences, des arts et des métiers* (1751–1765), and he was a friend of the other coauthor, Denis Diderot, as well as of Jean-Jacques Rousseau. The entries of the *Encyclopédie* on "Mémoire (*Métaphysiq*)," "Réflexion (*Logique*)," and "Signe (*Métaphysiq*)" reflect the influence of Condillac's views on these topics. The first of his philosophical writings was the *Essai sur l'origine des connaissances humaines* (Essay on the Origin of Human Knowledge), which was

published anonymously in 1746, after Diderot had helped him find a publisher. Around this time Condillac corresponded with the French scientist Pierre-Louis Moreau de Maupertuis, who was then the president of the Royal Prussian Academy in Berlin.

In 1746 Condillac submitted an essay on Gottfried Wilhelm Leibniz's theory of monads to a competition sponsored by the academy (it was not selected for the prize), and he was elected to this organization in 1749. Also in 1749 Condillac published his *Traité des systèmes* (Treatise on Systems), a critique of the metaphysics and methodologies of philosophers such as René Descartes, Nicolas Malebranche, Benedict (Baruch) de Spinoza, and Leibniz. He published his second main philosophical work, *Traité des sensations* (Treatise on Sensations), in 1754. The following year he published *Traité des animaux* (Treatise on Animals), a work that emphasizes the differences between human and animal souls, and "Extrait raisonné" of the *Traité des sensations*. In 1755 he also produced a "Dissertation sur la liberté" (Dissertation on Liberty), appended to the *Traité des sensations*, that addresses the issue of human freedom.

In 1758 Condillac became tutor to the young Prince of Parma, grandson of Louis XV. He spent nine years in Parma, during which time he wrote with the help of his brother the multivolume *Cours d'Etudes* (Course of Study), which was published in 1775. He returned to Paris in 1768, when he became a member of the Académie française, but left Paris again in 1773 to take up residence at the chateau de Flux, near Beaugency, which his niece had purchased for him. After that time he published a work on commerce in 1776 and a textbook on logic, which the comte Stanislas Félix Potocki had requested for his Polish schools in 1780. On August 3, 1780, Condillac died at his chateau after a return from a trip to Paris. He left behind an unfinished manuscript, *La langue des calculs* (The Language of Calculation), which was first published in 1798.

## MIND AND SENSATIONS

**RELATION TO LOCKE.** In his *Essai* Condillac acknowledged his great debt to Locke's *Essay concerning Human Understanding*, and in particular to the attack there on innate ideas and to Locke's empirical investigation of the origin of human thought. This debt is reflected in the subtitle of the English translation of the *Essai*: "A Supplement to Mr. Locke's Essay." Even so, Condillac argued explicitly against Locke that one can know with certainty that the mind that is the subject of thought is an indivisible and immaterial substance wholly distinct from body

(2001, I.i.§6, pp. 12f). In later years Condillac was especially concerned to distance himself from the materialism of more radical French Enlightenment figures such as Julien Offray de La Mettrie and Paul-Henri Thiry, Baron d'Holbach. In the *Essai* Condillac also distinguished himself from Locke by emphasizing the possibility that when separated from the body one's mind can derive knowledge independently of the senses. However, he noted that in one's present condition, that is, after the fall from the biblical state of innocence that the first humans experienced, the human mind is wholly dependent on the body, to the extent that one can have no thought that does not have a sensory origin. In Condillac's terms, all of one's thoughts are simply "*sensations transformées*."

Condillac's dualism informs his conclusion that sensations are modification of an immaterial mind. In his *Essai* he also claimed to follow Locke in holding that there are no sensory impressions in one's mind of which one is not conscious. Indeed, at one point he used this same point against the account in Locke's *Essay* of shape perception. This account addresses the speculation of Locke's friend, William Molyneux, that a man born blind would on recovering sight not be able to immediately distinguish a cube from a sphere by vision alone, without the aid of touch. Locke accepted this conclusion and claimed on the basis of this hypothetical case that one's perception of three-dimensional shapes involves not only sensations of light and color but also judgments that alter these sensations "without our taking notice of it." Condillac objected that the phenomenology of shape perception belies this account. One's sensations of light and colors render one immediately conscious of a three-dimensional world. Condillac did mention the 1729 report to the Royal Society in London by the English surgeon William Cheselden that subjects who had blinding cataracts removed could not recognize shapes. But he proposed that this result was due simply to the fact that the subjects were overwhelmed by the new sensory information and thus were unable to focus properly on the shapes (2001, I.vi.§16, p. 110).

**RELATION TO BERKELEY.** In a 1749 *Lettre sur les aveugles* (Letter on the Blind) Diderot charged that Condillac's *Essai* had failed to respond adequately to an idealism in George Berkeley that precludes any awareness of an external material world. Condillac in effect responded to this charge by attempting in his *Traité des sensations* to give an account of one's perception of the extended world that does not simply assume from the start that such a world exists. He introduced the example of a slowly animated statue to illustrate the manner in which one comes to per-

ceive the external world. This statue is supposed to possess initially only the sense of smell and to perceive this smell merely as an aspect of itself, and not as part of an external world (*Traité des sensations* I.i.2). Even when the statue comes to sense colors, the colors themselves are not considered as constituting distinct shapes. It is only with the sense of touch that the statue acquires an awareness of objects in space and attributes various sensible qualities to such objects (III.iii.§2). Here, Condillac abandoned his view in the *Essai* that one senses shapes by means of the sensations of light and color alone. He also granted in the *Traité*, in effect, that one is not immediately aware of everything in one's sensations. Even though sensations of color are shaped, one cannot recognize the shapes until one comes to associate colors with various tactile sensations.

In a supplement to his 1756 *Lettres à un Américain*, Joseph Adrien Lelarge de Lignac objected that, by allowing in the *Traité* that one has color sensations that are themselves extended, Condillac illicitly attributed to spirits a quality that pertains to bodies alone. In his "Lettre de M. l'abbé de Condillace à l'auteur des Lettres à un Américain," first published the same year, Condillac responded that colors are considered as manners of being of the mind only with respect to their chromatic features, and not with respect to their extension or shape. On the view in the *Traité*, one can recognize the colors as marking out shapes only when one associates them with tactile sensations and, on that basis, attributes the shapes to external objects. But there is still the question whether the color sensations themselves are extended, however one might consider them. Here, Condillac could perhaps draw on Berkeley's view in his *Principles of Human Knowledge* (1710) that extension exists in the mind not "by way of mode or attribute" but "by way of idea." There is still Berkeley's challenge that the extension that exists by way of idea can in no way "resemble" any purported extra-mental extension. But it is not clear that Condillac was too concerned to respond to this sort of challenge given the skeptical suggestion in his writings that one cannot know for certain whether any object exists external to mind and, if any does, what the nature of such an object is (*Traité des sensations* IV.v).

## MENTAL OPERATIONS AND SIGNS

In his introductory remarks in the *Essai* Condillac claimed to have found a "fundamental fact of experience" that explains all operations involved in human knowledge, a fact that consists in "the connection of ideas, either with signs or among themselves" (2001, p. 5). An

important part of Condillac's sensationism is his claim that not only the ideas but even their connections with signs or among themselves derive from sensation. He focused in particular on the initial connections forged through imagination, memory, and reminiscence. Imagination occurs when a perception is recalled at the sight of an object. This operation is possible because of an association between the object and perception set up by attention to their conjunction in experience. The attention is itself developed by associations of perceptions with sensations of pleasure and pain. Memory is a more developed operation that involves the recall not of the perception itself, but only of certain signs or circumstances associated with the object. Thus, memory is an imagination of these signs. Finally, reminiscence is the most developed of the operations, which involves not merely the formation of previously experienced perceptions, as in imagination, or previously experienced signs, as in memory, but also the recognition that the recalled perceptions or signs were experienced in the past. The ability so to recognize itself depends on the previous exercise of the imagination and memory.

In the *Essai* Condillac distinguished among three kinds of signs involved in the development of memory and reminiscence. The first two, accidental and natural signs, are not initially recognized as signs. Accidental signs are simply objects that have been experienced with certain circumstances, whereas natural signs are merely one's instinctual reactions to certain experiences. These two become signs only when they are actually associated with the circumstances or experiences. Instituted signs are those that one has chosen to induce thoughts. Though not required for the exercise of imagination and memory, the use of instituted signs allows one to have control over these operations. Such control in turn allows for the development of further rational operations such as abstraction and judgment that according to Condillac are not present in brute animals but are unique to humans.

In a 1752 letter to Maupertuis Condillac wrote that though he had tried to show in the *Essai* how the progress of the mind depends on language, "I was mistaken and gave too much to signs" (1947–1951, vol. 2, p. 536). The mistake here is indicated by Condillac's comment in a 1747 letter to Gabriel Cramer that his work was "not clear enough" on the point that natural and arbitrary signs "are the first principles of the development and progress of the operations of mind" (1953, p. 86). Condillac had of course indicated the importance of these kinds of signs in the *Essai*, but his mistake seems to have consisted in distinguishing them too greatly from instituted signs

involved in language. This would explain why he chose to focus in his *Traité* on the nature of sensation and mental operations before the start of language. There, even a statue without language is held to be capable of constructing a rich awareness of a spatially extended world on the basis of primitive sensory experience.

## LANGUAGE AND ACTION

In the *Essai* Condillac criticized Locke for addressing the topic of words only after he had provided an account of ideas and mental operations. He insisted that the use of words is in fact “the principle that develops the seed of all our ideas” (2001, p. 8). Though the discussion in the *Traité* indicates that Condillac came to have a greater appreciation of one’s prelinguistic abilities, he never relinquished the view that language is crucial for the development of mind. Whereas Descartes and Locke both suggested that thoughts or ideas are prior to and condition the use of language, Condillac insisted that it is the use of language that makes higher-order thoughts and mental operations possible. Here, one has a historical precedent for the “linguistic turn” in twentieth-century analytic philosophy.

Among the higher-order operations that require the use of language, Condillac singled out in particular a reflection that allows the mind to detach itself from current perceptions and apply itself to different objects. The *Essai* introduces the objection that the claim that this operation depends on language seems to be circular, since the use of instituted signs itself requires the abilities involved in reflection. Condillac responded to this objection that the nonlinguistic use of signs prepares the way for the mental operations required for the use of language and that these operations in turn make possible the development of reflection. He compared this relation between reflection and language to the discovery of algebraic signs by means of mental operations that had sufficient exercise to prepare the way for this discovery, but that were more primitive than the sort of mathematical thought that could not have occurred without this discovery (2001, II.i.§4, p. 115).

In the *Essai* Condillac claimed that spoken language derives from a “language of action” that involves voluntary control over nonlinguistic signs. He took the fact that such control develops over time to show that even the will derives from sensation. Still, he also seems to have indicated in the “Dissertation sur la liberté” that the freedom to direct attention is an original mental ability (1947–1951, vol. 1, p. 316). His sensationism thus appears to entail not that the will itself as a capacity derives from

sensation, but that the employment of the capacity so derives. The employment of the will is made possible in particular by the habits that the instinctual use of natural and artificial signs produces.

Noam Chomsky claims to find in Antoine Arnauld and Claude Lancelot’s *Grammaire générale et raisonnée, ou La grammaire de Port-Royal* a doctrine that posits innate “universal grammar” responsible for language (compare Arnauld and Lancelot 1966 and Chomsky 1966). The historical accuracy of this characterization is a matter of dispute (e.g., see the critical review of Chomsky in Aarsleff 1982, pp. 101–119), but what is undeniable is that Condillac offered an alternative to this sort of linguistics that attempts to explain language in terms of prelinguistic instincts and habits. This alternative was a particularly important influence for one of the classic texts in the field, Johann Gottfried Herder’s *Abhandlung Über den Ursprung der Sprache* (1772).

## CONDITIONALS

Conditionals are sentences like the following:

- (1) If Oswald did not kill Kennedy, then someone else did
- (2) We will not go on the trip if it rains tomorrow
- (3) If Oswald had not killed Kennedy, then someone else would have
- (4) We would be playing tennis if it were not raining

Conditionals are often believed to be analyzable into a two-place sentence connective and two constituent sentences, the antecedent (the sentence introduced by "if") and the consequent. (Thus, [3] may be analyzed into a binary connective ["If it had been the case that ... , then

it would have been the case that ..."] and the constituent sentences "Oswald did not kill Kennedy" and "someone else did [kill Kennedy].")

Many philosophers believe that there is an important difference between conditionals like (1) and (2) (which are commonly called "indicative conditionals"), and those like (3) and (4) (called "subjunctive" or "counterfactual"). Following Ernest W. Adams (1970), one can motivate this idea by considering (1) and (3). Suppose that you think that Oswald killed Kennedy, acting alone, and that no one else ever thought of committing this crime. You reject (3). But you accept (1): If you are wrong in thinking that Oswald did it, then someone else must be the culprit. Thus, it can be perfectly reasonable to assign different truth-values to the two conditionals. This indicates that an indicative conditional cannot in general have the same meaning as the corresponding counterfactual. Now suppose that this observation is combined with the suggested analysis of conditionals into two constituent sentences and a binary connective. Since (1) and (3) have the same constituent sentences, it is natural to conclude that their difference in meaning must result from a difference in meaning between the conditional connectives contained in the two sentences. The connective occurring in indicative conditionals, it seems, must differ semantically from the one found in counterfactuals.

This line of reasoning can be resisted in a number of ways. In particular, even if (1) and (3) belong to semantically different kinds of conditional, it is not obvious that the line between the two kinds coincides with that between indicative conditionals and counterfactuals. For all the argument shows, some indicative conditionals might have to be classified with (3) or some counterfactuals with (1), and under the influence of Vic H. Dudman (1984) some philosophers argue that indicative conditionals like (2) belong to the same class as (3).

Nonetheless, the standard view has it that conditionals are to be classified into indicatives and counterfactuals, and this entry will focus on theories that rest on this classification. The symbol " $\rightarrow$ " will be used for the indicative and " $\square \rightarrow$ " for the counterfactual conditional connective.

### INDICATIVE CONDITIONALS

Two of the main approaches to indicative conditionals will be considered.

**THE EQUIVALENCE THESIS.** Consider the mode of inference

(5) either  $B$  or not- $A$ ; therefore, if  $A$ , then  $B$ ,

which is instantiated by the argument “Either the butler is guilty, or Fred lied about the ice pick. Therefore, if Fred said the truth, then the butler is guilty.” This form of inference might appear to be valid. If it is, then an indicative conditional must be true whenever its antecedent is false and whenever its consequent is true. Moreover, it seems plausible that these are the only cases in which the conditional is true. It cannot be true if it has a true antecedent but a false consequent. (If someone says, “If it rains, she won’t come,” and it rains but she does come, then the utterance is not true.) This suggests that “ $A \rightarrow C$ ” is true if and only if either  $A$  is false or  $C$  is true. In other words, “ $A \rightarrow C$ ” has the same truth-conditions as the so-called material conditional, “ $A \supset C$ .” This claim is sometimes called the “equivalence thesis.”

It is well known that the equivalence thesis yields many seemingly absurd consequences. For instance, it makes (6) come out true, since (6) has a false antecedent and a true consequent:

(6) If Kennedy survived Oswald’s assassination attempt, then he died in the assassination attempt.

Yet (6) does not seem to be assertable.

One strategy for dealing with such apparent counterexamples originates in work by Paul Grice (1991): According to the equivalence thesis, knowledge that  $A$  is false or that  $C$  is true is sufficient for knowing that “ $A \rightarrow C$ ” is true. But if one’s belief in the truth of a conditional rests solely on one’s knowledge of the truth-values of its constituents (as in the case of [6]), then there is little point in asserting the conditional. For one could convey more information with fewer words by simply uttering the consequent, or the negation of the antecedent (as the case may be). If one utters the conditional anyway, then the audience, trusting the speaker not to do something pointless, will conclude that the speaker has reasons for believing the conditional that go beyond knowledge of the truth-values of its constituents. The utterance of the conditional would therefore be misleading, and the conditional, although true, is unassertable. When confronted with (6), one notes that it would be a mistake to assert it. This accounts for the feeling that there is something wrong with uttering the conditional. This impression can thus be explained without denying that the conditional is true.

The Gricean account has come in for criticism, but even if it is correct and apparent counterexamples to the equivalence thesis can be explained away, one may wonder whether the thesis is sufficiently well motivated. The

previous argument for it rests on the assumption that the inference schema (5) is valid. But this premise has been questioned, because of apparent counterexamples to (5), such as “You will meet nobody, or at least not many people. Therefore, if you meet many people, then you will meet nobody.”

The equivalence thesis can be supported in other ways, however: It is the simplest of all candidate truth-conditional theories of indicative conditionals. And Frank Jackson (1987, chapter 2) argues that, although the equivalence theorist must concede that an indicative conditional’s degree of assertability can differ from its probability of truth, the equivalence thesis can be used to explain the assertability-conditions and can be supported by appeal to this explanatory power.

**THE RAMSEY TEST.** Another approach to the semantics of indicative conditionals originates in a footnote in a paper by Frank P. Ramsey (1990, p. 155, n. 1) and has been developed in detail by Adams (1975). It starts from the idea, which is sometimes called the “Ramsey test,” that the degree to which a speaker ought to accept “ $A \rightarrow C$ ” equals the person’s subjective conditional probability  $P(C|A)$  (i.e.,  $P(A \text{ and } C) / P(A)$ ), provided that  $P(A)$  is not zero so that  $P(C|A)$  is defined. (On other versions of this account,  $P[C|A]$  measures the degree to which the speaker should regard the conditional as assertable. The discussion below will focus on the acceptability-conditional version of the thesis.) This hypothesis is strongly supported by its ability to predict pre-theoretical intuitions about individual conditionals. Suppose that I am about to cast a fair die. My probability that I will throw a six given that I will throw an even number is one-third, and this is also the degree to which I accept, “I will throw a six if I throw an even number.”

One might be tempted to try to explain why the degree of acceptability of “ $A \rightarrow C$ ” equals  $P(C|A)$  by the assumption that

(7) a conditional “ $A \rightarrow C$ ” expresses a proposition, and the probability that this proposition is true equals  $P(C|A)$  in all probability distributions for which  $P(C|A)$  is defined.

However, David K. Lewis shows that (7) is false (he proves this and some stronger results in his 1991a and 1991b). Instead of stating the proof, this entry will point in a nonrigorous and informal way in the direction of the reason why (7) is false (this seems more intuitively helpful than a formal proof):

Let each point of the rectangle in Figure 1 stand for a possible world, and let the rectangle as a whole represent

FIGURE 1

the totality of possible worlds. Propositions can be represented by the regions containing all and only the points that stand for worlds in which these propositions are true. One can model a belief system by distributing one kilogram of mud over the rectangle: If  $P(X)$  equals  $p$  in the belief system one intends to represent, then one places  $p$  kilograms of mud on the region representing the proposition  $X$ . Every possible way of distributing the mud corresponds to some probability distribution. If (7) were true, then there would have to be some region, namely the one representing the proposition expressed by " $A \rightarrow C$ ," that bears an amount of mud equal to  $P(C|A)$ , that is, to the ratio of the amount on the  $A \& C$  region and that on the  $A$  region, whenever  $P(A)$  is not zero. However, it is easy to make it plausible that there is no such region. Assume that  $P(C|A)$  equals one-half, which is to say that there is the same (nonzero) amount of mud on the  $A \& C$  region as on the  $A \& \sim C$  region. This is information about the relative amounts of mud on the two regions, and as such it tells one next to nothing about the absolute amount on any specific region. In particular, it seems intuitively plausible that, contrary to (7), there is no region that must be loaded with exactly half a kilogram of mud whenever the  $A \& C$  region and the  $A \& \sim C$  region bear the same (nonzero) amount of mud.

These considerations suggest that there is no one region whose amount of mud equals the ratio of the amount of  $A \& C$  mud and the amount of  $A$  mud whenever this ratio is defined. However, it might be that, whenever the mud is distributed in such a way that the ratio is defined, there is some region whose amount of mud equals the ratio, though it is a different region in different cases. (Note the difference in the scopes of the quantifiers.) Hence, as Bas van Fraassen (1976) points out, for all the argument of the last paragraph shows, it could be that an indicative conditional " $A \rightarrow C$ " expresses a propo-

sition and that its probability of truth equals  $P(C|A)$  whenever this conditional probability is defined, but that the proposition expressed by the conditional varies systematically with the speaker's belief system. Philosophers have attempted to extend Lewis's proof so as to rule out this possibility.

As an alternative to finding truth-conditions that fit the Ramsey test, one might give up the idea that indicative conditionals express propositions and make the Ramsey test itself the centerpiece of one's semantic account. Such a theory raises two questions: (1) What account can be given of the meanings of compound sentences that embed indicative conditionals, such as "Either Fred will give you the money if you ask him, or he is more avaricious than Susie"? If indicative conditionals lack truth-values, then one cannot assign a meaning to this sentence using the usual truth-functional construal of the disjunction operator. However, as Allan Gibbard (1981, pp. 234–236) argues, that a nonpropositional account of indicative conditionals does not assign meanings to all compounds of conditionals might be a good thing. For many such compounds are so hard to understand that one may doubt that they have any clear meanings. (Consider "If Fred arrived yesterday if it rains tomorrow, then Susie was in Paris last week.") The thesis that indicative conditionals lack truth-conditions may explain such difficulties of interpretation. (2) The usual criterion for the acceptability of an inference form relates to whether it preserves truth, that is, to whether the conclusion of an instance of it must be true if the premises are true. If indicative conditionals cannot be true or false, then this criterion cannot be applied to inferences involving such conditionals. Adams (1975, chapter 2) tackles this problem by defining a new and independently motivated criterion of acceptability that is more widely applicable. According to this criterion, an inference must preserve probability, in a sense that Adams makes precise as follows: Call  $1-P(A)$  the "uncertainty" of the proposition  $A$ ; the uncertainty of a conditional " $A \rightarrow C$ " equals  $1-P(C|A)$ . An inference preserves probability just in case there is no probability distribution in which the uncertainty of the conclusion exceeds the sum of the uncertainties of the premises. Classically valid arguments satisfy this condition, as do intuitively acceptable inferences involving indicative conditionals.

## COUNTERFACTUALS

Counterfactuals are used to analyze a wide range of philosophically important concepts, such as dispositions, causation, laws of nature, knowledge, practical rationality

(counterfactuals are used in decision theory), and freedom of action (“She would have acted differently if she had chosen to do so”). Theories of counterfactuals are of interest in part because they may make it easier to understand and evaluate counterfactual accounts of other notions.

**GOODMAN’S ACCOUNT.** In the seminal paper “The Problem of the Counterfactual Conditional” (1991) Nelson Goodman proposes an account of roughly the following form for a certain important class of counterfactuals:

(8) “ $A \square \rightarrow C$ ” is true just in case  $C$  follows from  $A$ , the laws of nature, and suitable true supplementary premises.

This account fits the ordinary-life practice of evaluating counterfactuals well. In determining what would have happened to a certain match if it had been struck on a specific occasion, one needs to draw on knowledge of the particular circumstances, such as the knowledge that (D) the match was dry and (O) oxygen was present, and of the law that (L) dry matches start to burn when struck in the presence of oxygen. These items of knowledge, when combined with the assumption that the match was struck, entail that (B) it burned. This justifies the conclusion that the match would have burned if it had been struck.

Which truths count as “suitable supplementary premises” in the sense of (8)? Clearly, not every truth does. When evaluating the counterfactual “If the match had been struck ...,” one cannot regard the truth that it was never struck as a suitable ancillary premise. More generally, if the antecedent is both self-consistent and consistent with the laws, then the suitable auxiliary premises must be consistent with the antecedent plus laws. Otherwise, the antecedent combined with the laws and the supplementary premises would entail everything, so that every counterfactual with the relevant antecedent would come out true—an unwelcome result if the antecedent is consistent.

This condition of consistency does not suffice as a criterion for the suitability of a truth as ancillary premise. For there are different sets of truths that meet the consistency constraint, and depending on which of them one regards as the set of suitable auxiliary premises, different counterfactuals come out true. If one uses (D) and (O) as supplementary premises in evaluating the conditional about the match, one can draw on one’s knowledge that (L) is a law to conclude that the match would have burned if it had been struck. Availing oneself instead of

(O) and ( $\sim B$ ) as auxiliary premises, one can (again using [L]) establish that the match would not have been dry if it had been struck.

The task of stating conditions for a truth’s suitability as supplementary premise is central to Goodman’s project. After discussing the issue at length, he ends up proposing that a truth  $P$  is suitable only if  $P$  is cotenable with the antecedent of the conditional, where this means: It is not the case that  $P$  would have been false if the antecedent had been true. (For instance, [ $\sim B$ ] is not cotenable with “the match was struck,” since if the latter sentence had been true, ( $\sim B$ ) would have been false. But [D] and [O] would still have been true and are therefore cotenable.) Since this criterion is formulated in counterfactual terms, it renders Goodman’s theory circular—a problem of which Goodman is vividly aware. As will become clear below, more recent work on counterfactuals promises to deliver a solution.

**THE POSSIBLE-WORLD ACCOUNT.** In the late 1960s and early 1970s another account of counterfactual conditionals was developed by Robert C. Stalnaker (1991b) and Lewis (1973). Lewis neatly expresses the core idea: “*If kangaroos had no tails, they would topple over*” seems to me to mean something like this: in any possible state of affairs in which kangaroos have no tails, and which resembles our actual state of affairs as much as kangaroos having no tails permits it to, the kangaroos topple over” (1973, p. 1).

More formally, the theory is formulated in terms of possible worlds. A possible world in which the antecedent of a counterfactual is true is called an “antecedent-world.” One can state the theory (in a somewhat simplified form) by saying that a counterfactual is true just in case its consequent is true in those antecedent-worlds that are most similar to the actual world.

Stalnaker’s and Lewis’s accounts differ in a number of ways. First, Stalnaker intends his theory to cover both indicative conditionals and counterfactuals, whereas the scope of Lewis’s account is restricted to counterfactuals. Second, according to Stalnaker’s truth-conditions, but not according to Lewis’s, there is always one most similar possible antecedent-world. In consequence, Stalnaker’s theory validates the principle of conditional excluded middle, ( $A \square \rightarrow C$ ) or ( $A \square \rightarrow \sim C$ ), whereas Lewis’s account does not.

It is an advantage of the possible-world account that it can explain some noteworthy logical features of counterfactuals, namely the failure of a number of inference

**FIGURE 2**

schemata that are valid for the material and strict conditionals, such as the following:

- $A \Box \rightarrow B \therefore \sim B \Box \rightarrow \sim A$  (Contraposition)
- $C \Box \rightarrow B, B \Box \rightarrow A \therefore C \Box \rightarrow A$  (Hypothetical syllogism)
- $B \Box \rightarrow A \therefore (B \& C) \Box \rightarrow A$  (Strengthening the antecedent)

To see that these modes of inference are invalid, consider the following counterexamples:

- (Even) if Mary had qualified for the tournament, she (still) would not have won it. Therefore, if she had won the tournament, she (still) would not have qualified for it.
- If Hoover had been born a Russian, he would have been a communist. If Hoover had been a communist, he would have been a traitor. Therefore, if Hoover had been born a Russian, he would have been a traitor (Stalnaker 1991b).
- If we had told them about our plan, they would have been delighted. Therefore, if we had told them about our plan and its likely result, they would have been delighted.

The possible-world account explains the failure of these inference rules, as Figure 2 will render clear. Let the dot labeled “@” stand for the actual world, let the other points in the rectangle represent the other possible worlds, and let the smaller and greater spatial distances

between the points represent smaller and greater degrees of similarity between the corresponding worlds. As before, propositions can be represented by regions within the rectangle. In the situation depicted, *B* is true in the possible *A*-worlds most similar to the actual world; but  $\sim A$  is not true in the most similar possible  $\sim B$ -worlds. Hence, while “ $A \Box \rightarrow B$ ” is true, “ $\sim B \Box \rightarrow \sim A$ ” is false. This shows that contraposition is invalid. Moreover, “ $C \Box \rightarrow B$ ” and “ $B \Box \rightarrow A$ ” are true while “ $C \Box \rightarrow A$ ” is false, and “ $B \Box \rightarrow A$ ” is true while “ $(B \& C) \Box \rightarrow A$ ” is false, so that the diagram also represents counterexamples to hypothetical syllogism and strengthening the antecedent.

If the antecedent of a counterfactual is impossible, then there are no possible antecedent-worlds, so that it is vacuously true that the consequent is true in all the most similar possible antecedent-worlds. The possible-world account therefore entails that all counterfactuals with impossible antecedents are true. But that is implausible: Most philosophers would agree that Willard Van Orman Quine could not have been a hippopotamus, but it does not seem right to say that, if Quine had been a hippopotamus, he would have been a reptile. According to Daniel Nolan (1997) and others, this problem can be remedied if impossible worlds are allowed to figure in the account alongside possible worlds. On this view, impossible worlds are ordered by their comparative similarity to the actual world, just as possible worlds are. A counterfactual “ $A \Box \rightarrow C$ ” with impossible antecedent is true just in case *C* is true in the most similar impossible *A*-worlds. Such an account, however, requires an ontology of impossible worlds, which not all philosophers are happy to accept.

**SIMILARITY BETWEEN WORLDS.** The notion of similarity between worlds that is used in the analysis of counterfactuals cannot be the one that governs ordinary offhand judgments about overall similarity. This was shown by Kit Fine (1975) among others. Fine used (9) as his example:

(9) If Nixon had pressed the button, there would have been a nuclear catastrophe.

(9) sounds correct. But offhand it may seem that an antecedent-world devastated by a nuclear explosion is much less similar to the actual world than an antecedent-world in which the signal disappears in the wire after the button-pressing, so that no harm is done. If the notion of offhand similarity were used in analyzing counterfactuals, the account would yield the incorrect verdict that (9) is false and that everything would have been fine if Nixon had pressed the button.

What are the standards of similarity that govern counterfactuals? Many philosophers who address this question assume that different standards are relevant in different contexts of utterance. This assumption is motivated by examples like the following (which is taken from Jackson 1977, p. 9): Frank is in a room on the tenth floor of a building. There is nothing that could break the fall of someone jumping out of the window. It seems safe to say that Frank would get badly hurt if he were to jump. But suppose that Frank says: "I would never jump from a tenth-floor window, unless I had made sure that there was a safety net. So, if I were to jump, a net would be in place, and I would be fine." Frank's reasoning might convince his audience that his counterfactual is true. And yet his conditional seems to be incompatible with the one stated before. The most obvious diagnosis is that the truth-conditions of counterfactuals are context-dependent. In some contexts worlds in which Frank jumps despite the absence of a net count as more similar than those in which he places a net below the window before jumping. In other contexts it is the other way around.

Some of those who take the truth-conditions of counterfactuals to be context-dependent (notably Lewis 1979), believe that there is such a thing as a default assignment of truth-conditions to them, an assignment that hearers choose when interpreting the utterance of a counterfactual unless their presumption in favor of it is removed by distinctive features of the context. That seems plausible enough in the example of the last paragraph: If presented with the case out of the blue and asked for a judgment, one would say that Frank would get badly hurt if he were to jump. It requires some stage-setting (like that provided by Frank's utterance) to create a context in which it seems right to say that he would be fine.

Attempts to describe the default truth-conditions of counterfactuals often start from a special case: counterfactuals whose antecedents are false and describe nominally possible matters of particular local fact. (9) can serve as an example. Pre-theoretical intuitions about this conditional seem to furnish two data points:

(1) *Counterfactual dependence is temporally asymmetrical.* If Nixon had pressed the button, then later on things would have been different from what they were actually like; but matters until shortly before the button-pressing would have been just as they actually were. The most similar antecedent-worlds must therefore be just like the actual world until a short time before the button-pressing, but might be different afterward.

(2) *Laws support counterfactuals.* If Nixon had pressed the button, then events would still have conformed to the actual laws of nature. The most similar antecedent-worlds must therefore be ones that evolve in accordance with the laws of the actual world. In particular, if the missile system is set up in such a way that the actual laws guarantee that button-pressing leads to a nuclear explosion, then there is a nuclear catastrophe in the most similar antecedent-worlds.

Suppose that determinism is true. In that case at least one of the principles (1) and (2) stands in need of some qualification. For determinism entails that every initial segment of the history of the actual world, together with the laws, determines the entire rest of history, and thus determines that Nixon does not press the button. This implies that no antecedent-world can both perfectly conform to the actual laws and be like the actual world throughout some initial segment of its history. Some philosophers (e.g., Lewis 1979) choose to solve this problem by allowing that the most similar antecedent-worlds contain violations of the actual laws, while others allow for backward counterfactual dependence over arbitrarily long periods of time (e.g. Bennett 1984; but see Bennett 2003, §80).

Note that Goodman's problem of specifying which truths are suitable supplementary premises resurfaces on the possible-world theory, in the shape of the question: Which of the actual matters of particular fact must obtain in an antecedent-world for it to count among the most similar? An account of the similarity relation will address this question and, if successful, will at last provide a non-circular solution to Goodman's problem.

## CONDORCET, MARQUIS DE

(1743–1794)

Marie-Jean-Antoine-Nicolas Caritat, Marquis de Condorcet, the French mathematician, historian of the sciences, political theorist, and social reformer, was one of the youngest of the Encyclopedists and the only prominent one to participate actively in the French Revolution. He was born in Ribemont in Picardy and was educated by the Jesuits at the Collège de Navarre. Admitted to the Académie des Sciences in 1769 on the basis of his early mathematical writings, he was elected its perpetual secretary in 1776 and ably depicted the progress of the sciences to a wide public in the customary eulogies (*Éloges*) of deceased academicians, which he presented in this position.

A protégé of Jean Le Rond d'Alembert, for whom Condorcet's election to the Académie Française in 1782 was regarded as a personal triumph, and of Baron de l'Aulne Turgot, who called him to the directorship of the mint during his abortive reforming ministry, Condorcet was active in the prerevolutionary campaigns for economic freedom, religious toleration, legal reform and the abolition of slavery. After his marriage to Sophie de Grouchy in 1786 their salon became one of the most brilliant and influential of the prerevolutionary period. He took part in the opening debates of the French Revolution as a member of the municipal council of Paris and was a convinced republican by the time he was elected to the Legislative Assembly in 1791. Prominent in this assembly, he directed his most sustained efforts toward the elaboration of a project for public education that had great influence on the eventual establishment of the French educational system.

In the National Convention, Condorcet's opposition to the death penalty led him to cast his vote against the execution of Louis XVI (he voted for the supreme penalty short of death). He then undertook the task of drawing up a draft constitution for the new republic, but although accepted by the committee on the constitution, his liberal

constitutional scheme—commonly known as the Girondin constitution of 1793—shared the unfortunate fate of the group with which it was associated. In July 1793, Condorcet's indignant defense of his constitution against that prepared by the Jacobins led to his denunciation and flight into hiding. He spent his remaining months of life secluded in Paris, working on the *Sketch for a Historical Picture of the Progress of the Human Mind* (*Esquisse d'un tableau historique des progrès de l'esprit humain*), published posthumously in 1795. He left his asylum in March 1794 and was arrested and imprisoned at Bourg-la-Reine, near Paris. He died during the first night of his imprisonment, either from exhaustion or from a self-administered poison.

### PROBABILITY AND SOCIAL SCIENCE

It has often been assumed that Condorcet's increasing preoccupation with social and political affairs, if not the result of a sense of frustration with his mathematical investigations, was at least accompanied by a waning interest in them. Quite the reverse is true. Condorcet's experience at the Académie des Sciences fostered a sense of the power of science to elucidate even the realm of social behavior. His mathematical endeavors were intimately bound up with his fundamental intellectual concern. He aimed to bring to social questions the attitudes and methods of the physical sciences, thereby welding the broken elements of the moral and political sciences into a new social science, which he regarded as the necessary condition of a rational political and social order.

Condorcet seized upon the calculus of probabilities as the essential epistemological connection between the physical sciences and the science of man. All the truths of experience are merely probable, he argued. In the social sciences the observation of facts may be more difficult and their order less constant. The results of the social sciences may therefore be less probable than those of the physical sciences. But Condorcet maintained that the probability of all statements of experience can be expressed and evaluated mathematically within probability theory. Thus, while the statements attained by the social sciences may on occasions be less probable than those of the physical sciences, in Condorcet's view the mathematical estimate of their respective probabilities is equally certain. The meteorologist cannot be certain that it will rain tomorrow, for example, but if on the basis of his observations he can estimate the probability of its doing so as  $x:1$ , then he can be certain that there is a probability of  $x:1$  that it will rain tomorrow. Similarly, the economist, who cannot be certain that the standard of

living will continue to rise, can in theory arrive at a certain mathematical estimate of the probability of its doing so.

The significance of this argument can be best assessed in terms of the earlier epistemological claims to certainty made by René Descartes on behalf of the mathematical and physical sciences. Condorcet accepted the skeptic's evaluation of the physical sciences as being merely probable. But in arguing that probabilities in the physical sciences (like those in the social sciences) can be evaluated with mathematical certainty, he remained in a sense fundamentally Cartesian. Not only did he hold to the idea of certainty as the criterion of acceptable knowledge, but he also accepted mathematics as the paradigm of certain knowledge (although even this certainty is based in the last analysis, he was occasionally prepared to argue, on the observed constancy of the operation of the human mind). Condorcet's argument in this respect ranks with that of Giambattista Vico as one of the major eighteenth-century attempts to establish the validity of social science. But whereas Vico turned away from the mathematical and physical sciences in search of a historical and organic conception of his new science, Condorcet's probabilistic evaluation of the physical sciences served to integrate them with the science of man in an essentially mathematical conception of science. For Condorcet, the mathematician was able, by using the calculus of probabilities, to subject to the certain evaluation of mathematics even those areas of knowledge condemned by Descartes as untrustworthy. The calculus of probabilities provided a sure means of estimating the validity of our opinions and the probability of our expectations; it bound the moral and physical sciences together on a sliding scale of probabilities which could at all stages be evaluated with mathematical certainty.

Condorcet developed this conception in two very different works. In the first, the *Essay on the Application of Analysis to the Probability of Majority Decisions* (*Essai sur l'application de l'analyse à la probabilité des décisions rendues à la pluralité des voix*, 1785), he set out to discover by means of the calculus of probabilities under what conditions there will be an adequate guarantee that the majority decision of an assembly or tribunal is true. In one of its applications he envisaged such an analysis as the means of solving a perennial problem of liberal thought, that of reconciling the claims of an elite to exercise special responsibilities in the process of decision making with the general principle of universal or majority consent. But the obscure mathematics of the essay and its inevitable reliance on unverifiable assumptions as to the probable

truth or error of the opinions of individuals composing social bodies have left it largely ignored by those interested in Condorcet's political theory. More recently, social mathematicians interested in elucidating the relationship between individual and collective choice (whether political or economic) have been able to disengage from the probabilistic framework of this work a theoretical model of collective decision making that is remarkably modern in its implications and approach. (See Black [1958] and Granger [1954]).

The *Essai sur l'application de l'analyse* was intended to convince academicians of the validity of Condorcet's contention that the moral and political sciences can be treated mathematically. The unfinished "Tableau général de la science, qui a pour objet l'application du calcul aux sciences morales et politiques" (General View of the Science Comprising the Mathematical Treatment of the Moral and Political Sciences) was meant for a different audience. It appeared in 1793 in a popular journal that sought to initiate citizens of the new French republic into the social science, or the art of the rational conduct of politics. Condorcet saw the new social mathematics (*mathématique sociale*) as a common, everyday science of conduct ("une science usuelle et commune," *Oeuvres*, Vol. I, p. 550) that would provide the essential foundation of a democratic, but rational, politics. He viewed man in all his conduct as a gambler. Each individual automatically and instinctively balances the probability of one opinion against that of another, the desired goal of a proposed action against its probable results. The mathematical science of man was intended not only as an objective description of social behavior but also as a scientific basis for individual conduct that would enable people to substitute for habitual and instinctive modes of thought and action the precise evaluation of reason and calculation. Social mathematics, coupled with an exact language based on precise philosophical analysis of our ideas, would free human beings from instinct and passion and restore the empire of reason in social affairs. It formed the essential link between scientific advance and moral progress, for evil, as Condorcet remarked, was far more often the result of an erroneous calculation of interest than the product of violent passion.

## IDEA OF PROGRESS

In the *Sketch for a Historical Picture of the Progress of the Human Mind*, Condorcet turned to history for a demonstration of the power of reason and calculation in social affairs. The *Sketch* was only the hastily written introduction to a larger work on the history of science and its

impact upon society which Condorcet had been contemplating for many years. Some of the fragments of this unfinished work are of considerable philosophical interest. One outlined a project for a universal, symbolic language of the sciences; another elaborated a decimal system of classification addressed to the much-debated problem of scientific classification. But it is with the *Sketch* itself that Condorcet's name and influence have been chiefly associated, and it is with that work—often regarded as the philosophical testament of the eighteenth century—that Condorcet bequeathed to the nineteenth century the fundamental idiom of its social thought, the idea of progress.

The aim of the *Sketch* was to demonstrate man's progressive emancipation, first from the arbitrary domination of his physical environment and then from the historical bondage of his own making. Condorcet shared with other eighteenth-century theorists a view of progress that depended ultimately upon man's cumulative ability to combine sensations and ideas (in the manner revealed by sensationalist psychology) to his own satisfaction or advantage. This Promethean psychological capacity functioned in the same manner in the human race as in the individual; it proceeded by way of a natural, self-revealing logic or "method," from the fundamental data of sense experience to the most general principles of the moral and physical sciences. Condorcet's main concern, therefore, was less to explain the growth of reason in itself—this growth was posited as natural—than to point to the destruction of the obstacles that had inhibited that growth or diverted the historical development of the mind from the natural logic of ideas.

Condorcet's hopes for future progress rested on two conclusions. First, he was convinced that the obstacles which had in the past threatened the advance and dissemination of reason—elitism and tyranny on the one hand; popular prejudice, ignorance, and social and political subjection, on the other—were finally being destroyed under the joint impact of scientific, technological, and political revolution. Second, he believed that the discoveries of sensationalist psychology had made it possible to articulate the natural and fundamental principles of the social art, or science, and he drew from the doctrine of the rights of man—grounded upon the "facts" of man's sensate nature—a comprehensive outline of the principles of liberal democracy that it would be the purpose of the social art to implement.

Although this belief in indefinite future progress was based on the general assertion that observation of past events warrants extrapolation as to the probable future,

Condorcet was not a strict historical determinist. Humans are subject to the general laws of physical nature, he maintained in an unpublished introduction to the *Sketch*, but they have the power to modify these laws and turn them to their own advantage. Although this power is feeble in the individual, when exercised by humankind collectively and over a long period, it can balance the forces of nature and can even be regarded as the work of nature itself. For if nature has endowed humankind collectively with the capacity to learn from experience, to understand its laws, and to modify their effects, the progressive emancipation of humans from nature is itself natural, and the growth of freedom is a natural law. The *Sketch* not only demonstrated the power of the social art but also made clear that it could succeed only as a communal and democratic art. It is this emphasis upon the collective experience and achievements of humankind, this concern with the “most obscure and neglected chapter of the history of the human race” (*Sketch*, Barraclough translation, p. 171)—namely, the progress of the mass of the people in society—that links Condorcet’s view of history with his conception of social science.

## CONFIRMATION THEORY

Predictions about the future and unrestricted universal generalizations are never logically implied by our observational evidence, which is limited to particular facts in the present and past. Nevertheless propositions of these and other kinds are often said to be confirmed by observational evidence. A natural place to begin the study of confirmation theory is to consider what it means to say that some evidence *E* confirms a hypothesis *H*.

### INCREMENTAL AND ABSOLUTE CONFIRMATION

Let us say that *E* raises the probability of *H* if the probability of *H* given *E* is higher than the probability of *H* not given *E*. According to many confirmation theorists, “*E* confirms *H*” means that *E* raises the probability of *H*. This conception of confirmation will be called incremental confirmation.

Let us say that *H* is probable given *E* if the probability of *H* given *E* is above some threshold. (This threshold remains to be specified but is assumed to be at least one half.) According to some confirmation theorists, “*E* confirms *H*” means that *H* is probable given *E*. This conception of confirmation will be called absolute confirmation.

Confirmation theorists have sometimes failed to distinguish these two concepts. For example, Carl Hempel

(1945/1965) in his classic “Studies in the Logic of Confirmation” endorsed the following principles:

- (1) A generalization of the form “All  $F$  are  $G$ ” is confirmed by the evidence that there is an individual that is both  $F$  and  $G$ .
- (2) A generalization of that form is also confirmed by the evidence that there is an individual that is neither  $F$  nor  $G$ .
- (3) The hypotheses confirmed by a piece of evidence are consistent with one another.
- (4) If  $E$  confirms  $H$  then  $E$  confirms every logical consequence of  $H$ .

Principles (1) and (2) are not true of absolute confirmation. Observation of a single thing that is  $F$  and  $G$  cannot in general make it probable that all  $F$  are  $G$ ; likewise for an individual that is neither  $F$  nor  $G$ . On the other hand there is some plausibility to the idea that an observation of something that is both  $F$  and  $G$  would raise the probability that all  $F$  are  $G$ . Hempel argued that the same is true of an individual that is neither  $F$  nor  $G$ . Thus Hempel apparently had incremental confirmation in mind when he endorsed (1) and (2).

Principle (3) is true of absolute confirmation but not of incremental confirmation. It is true of absolute confirmation because if one hypothesis has a probability greater than  $\frac{1}{2}$  then any hypothesis inconsistent with it has a probability less than  $\frac{1}{2}$ . To see that (3) is not true of incremental confirmation, suppose that a fair coin will be tossed twice, let  $H_1$  be that the first toss lands heads and the second toss lands tails, and let  $H_2$  be that both tosses land heads. Then  $H_1$  and  $H_2$  each have an initial probability of  $\frac{1}{4}$ . If  $E$  is the evidence that the first toss landed heads, the probability of both  $H_1$  and  $H_2$  given  $E$  is  $\frac{1}{2}$ , and so both hypotheses are incrementally confirmed, though they are inconsistent with each other.

Principle (4) is also true of absolute confirmation but not of incremental confirmation. It is true of absolute confirmation because any logical consequence of  $H$  is at least as probable as  $H$  itself. One way to see that (4) is not true of incremental confirmation is to note that any tautology is a logical consequence of any  $H$  but a tautology cannot be incrementally confirmed by any evidence, since the probability of a tautology is always one. Thus Hempel was apparently thinking of absolute confirmation, not incremental confirmation, when he endorsed (3) and (4).

Since even eminent confirmation theorists like Hempel have failed to distinguish these two concepts of

confirmation, we need to make a conscious effort not to make the same mistake.

## CONFIRMATION IN ORDINARY LANGUAGE

When we say in ordinary language that some evidence confirms a hypothesis, does the word “confirms” mean incremental or absolute confirmation?

Since the probability of a tautology is always one, a tautology is absolutely confirmed by any evidence whatever. For example, evidence that it is raining absolutely confirms that all triangles have three sides. Since we would ordinarily say that there is no confirmation in this case, the concept of confirmation in ordinary language is not absolute confirmation.

If  $E$  reduces the probability of  $H$  then we would ordinarily say that  $E$  does not confirm  $H$ . However, in such a case it is possible for  $H$  to still be probable given  $E$  and hence for  $E$  to absolutely confirm  $H$ . This shows again that the concept of confirmation in ordinary language is not absolute confirmation.

A hypothesis  $H$  that is incrementally confirmed by evidence  $E$  may still be probably false; for example, the hypothesis that a fair coin will land “heads” every time in 1000 tosses is incrementally confirmed by the evidence that it landed “heads” on the first toss, but the hypothesis is still extremely improbable given this evidence. In a case like this nobody would ordinarily say that the hypothesis was confirmed. Thus it appears that the concept of confirmation in ordinary language is not incremental confirmation either.

A few confirmation theorists have attempted to formulate concepts of confirmation that would agree better with the ordinary concept. One such theorist is Nelson Goodman. He noted that if  $E$  incrementally confirms  $H$ , and  $X$  is an irrelevant proposition, then  $E$  incrementally confirms the conjunction of  $H$  and  $X$ . Goodman (1979) thought that in a case like this we would not say that  $E$  confirms the conjunction. He proposed that “ $E$  confirms  $H$ ” means that  $E$  increases the probability of every component of  $H$ . One difficulty with this is to say what counts as a component of a hypothesis; if any logical consequence of  $H$  counts as a component of  $H$  then no hypothesis can ever be confirmed in Goodman’s sense. In addition Goodman’s proposal is open to the same objection as incremental confirmation: It allows that a hypothesis  $H$  can be confirmed by evidence  $E$  and yet  $H$  be probably false given  $E$ , which is not what people would ordinarily say.

Peter Achinstein (2001) speaks of “evidence” rather than “confirmation” but he can be regarded as proposing an account of the ordinary concept of confirmation. His account is complex but the leading idea is roughly that “*E* confirms *H*” means that (i) *H* is probable given *E* and (ii) it is probable that there is an explanatory connection between *H* and *E*, given that *H* and *E* are true. The explanatory connection may be that *H* explains *E*, *E* explains *H*, or *H* and *E* have a common explanation. Achinstein’s proposal is open to one of the same objections as absolute confirmation: It allows evidence *E* to confirm *H* in cases in which *E* reduces the probability of *H*. Achinstein has argued that this implication is in agreement with the ordinary concept, but his reasoning has been criticized, for example, by Sherrilyn Roush (2004).

It appears that none of the concepts of confirmation discussed by confirmation theorists is the same as the ordinary concept of evidence confirming a hypothesis. Nevertheless, some of these concepts are worthy of study in their own right. In particular, the concepts of incremental and absolute confirmation are simple concepts that are of obvious importance and they are probably components in the more complex ordinary language concept of confirmation.

## PROBABILITY

All the concepts of confirmation that we have discussed involve probability. However, the word “probability” is ambiguous. For example, suppose you have been told that a coin either has heads on both sides or else has tails on both sides and that it is about to be tossed. What is the probability that it will land heads? There are two natural answers: (i)  $\frac{1}{2}$ ; (ii) either 0 or 1 but I do not know which. These answers correspond to different meanings of the word “probability.” The sense of the word “probability” in which (i) is the natural answer will here be called inductive probability. The sense in which (ii) is the natural answer will be called physical probability.

Physical probability depends on empirical facts in a way that inductive probability does not. We can see this from the preceding example; here the physical probability is unknown because it depends on the nature of the coin, which is unknown; by contrast the inductive probability is known even though the nature of the coin is unknown, showing that the inductive probability does not depend on the nature of the coin.

There are two main theories about the nature of physical probability. One is the frequency theory, according to which the physical probability of an event is the relative frequency with which the event happens in the long

run. The other is the propensity theory, according to which the physical probability of an event is the propensity of the circumstances or experimental arrangement to produce that event.

It is widely agreed that the concept of probability involved in confirmation is not physical probability. One reason is that physical probabilities seem not to exist in many contexts in which we talk about confirmation. For example, we often take evidence as confirming a scientific theory but it does not seem that there is a physical probability of a particular scientific theory being true. (The theory is either true or false; there is no long run frequency with which it is true, nor does the evidence have a propensity to make the theory true.) Another reason is that physical probabilities depend on the facts in a way that confirmation relations do not. Inductive probability does not have either of these shortcomings and so it is natural to identify the concept of probability involved in confirmation with inductive probability. Therefore we will now discuss inductive probability in more detail.

Some contemporary writers appear to believe that the inductive probability of a proposition is some person’s degree of belief in the proposition. Degree of belief is also called subjective probability, so on this view, inductive probability is the same as subjective probability. However, this is not correct. Suppose, for example, that I claim that scientific theory *H* is probable in view of the available evidence. This is a statement of inductive probability. If my claim is challenged, it would not be a relevant response for me to prove that I have a high degree of belief in *H*, though this would be relevant if inductive probability were subjective probability. To give a relevant defense of my claim I need to cite features of the available evidence that support *H*.

In saying that inductive probabilities are not subjective probabilities, we are not denying that when people make assertions about inductive probabilities they are expressing their degrees of belief. Every sincere and intentional assertion expresses the speaker’s beliefs but not every assertion is about the speaker’s beliefs.

We will now consider the concept of logical probability and, in particular, whether inductive probability is a kind of logical probability. This depends on what is meant by “logical probability.”

Many writers define the “logical probability” of *H* given *E* as the degree of belief in *H* that would be rational for a person whose total evidence is *E*. However, the term “rational degree of belief” is far from clear. On some natural ways of understanding it, the degree of belief in *H*

that is rational for a person could be high even when  $H$  has a low inductive probability given the person's evidence. This might happen because belief in  $H$  helps the person succeed in some task, or makes the person feel happy, or will be rewarded by someone who can read the person's mind. Even if it is specified that we are talking about rationality with respect to epistemic goals, the rational degree of belief can differ from the inductive probability given the person's evidence, since the rewards just mentioned may be epistemic. Alternatively, one might take "the rational degree of belief in  $H$  for a person whose total evidence is  $E$ " to be just another name for the inductive probability of  $H$  given  $E$ , in which case these concepts are trivially equivalent. Thus if one takes "logical probability" to be rational degree of belief then, depending on what one means by "rational degree of belief," it is either wrong or trivial to say that inductive probability is logical.

A more useful conception of logical probability can be defined as follows. Let an "elementary probability sentence" be a sentence that asserts that a specific hypothesis has a specific probability. Let a "logically determinate sentence" be a sentence whose truth or falsity is determined by meanings alone, independently of empirical facts. Let us say that a probability concept is "logical in Carnap's sense" if all elementary probability sentences for it are logically determinate. (This terminology is motivated by some of the characterizations of logical probability in Carnap's *Logical Foundations of Probability*.) Since inductive probability is not subjective probability, the truth of an elementary statement of inductive probability does not depend on some person's psychological state. It also does not depend on facts about the world in the way that statements of physical probability do. It thus appears the truth of an elementary statement of inductive probability does not depend on empirical facts at all and hence that inductive probability is logical in Carnap's sense.

It has often been said that logical probabilities do not exist. If this were right then it would follow that inductive probabilities are either not logical or else do not exist. So we will now consider arguments against the existence of logical probabilities.

John Maynard Keynes in 1921 published a theory of what we call inductive probability and he claimed that these are logical. Frank Ramsey (1926/1980) criticizing Keynes's theory, claimed that "there really do not seem to be any such things as the probability relations he describes." The main consideration that Ramsey offered in support of this was that there is little agreement on the values of probabilities in the simplest cases and these are

just the cases where logical relations should be most clear. Ramsey's argument has been cited approvingly by several later authors.

However, Ramsey's claim that there is little agreement on the values of probabilities in the simplest cases seems not to be true. For example, almost everyone agrees with the following:

- (5) The probability that a ball is white, given only that it is either white or black, is  $\frac{1}{2}$ .

Ramsey cited examples such as the probability of one thing being red given that another thing is red; he noted that nobody can state a precise numerical value for this probability. But that is an example of *agreement* about the value of an inductive probability, since *nobody* pretends to know a precise numerical value for the probability. What examples like this show is merely that inductive probabilities do not always have numerically precise values.

Furthermore, if inductive probabilities are logical (i.e., non-descriptive), it does not follow that their values should be clearest in the simplest cases, as Ramsey claimed. Like other concepts of ordinary language, the concept of inductive probability is learned largely from examples of its application in ordinary life and many of these examples will be complex. Hence, like other concepts of ordinary language, its application may sometimes be clearer in realistic complex situations than in simple situations that never arise in ordinary life.

So much for Ramsey's argument. Another popular argument against the existence of logical probabilities is based on the "paradoxes of indifference." The argument is this: Judgments of logical probability are said to presuppose a general principle, called the Principle of Indifference, which says that if evidence does not favor one hypothesis over another then those hypotheses are equally probable on this evidence. This principle can lead to different values for a probability, depending on what one takes the alternative hypotheses to be. In some cases the different choices seem equally natural. These "paradoxes of indifference," as they are called, are taken by many authors to be fatal to logical probability.

But even if we agree (as Keynes did) that quantitative inductive probabilities can only be determined via the Principle of Indifference, we can also hold (as Keynes did) that inductive probabilities do not always have quantitative values. Thus if there are cases where contradictory applications of the principle are equally natural, we may take this to show that these are cases where inductive probabilities lack quantitative values. It does not follow

that quantitative inductive probabilities never exist, or that qualitative inductive probabilities do not exist. The paradoxes of indifference are thus consistent with the view that inductive probabilities exist and are logical.

How can we have knowledge of inductive probabilities, if this does not come from an exceptionless general principle? The answer is that the concept of inductive probability, like most concepts of ordinary language, is learned from examples, not by general principles. Hence we can have knowledge about particular inductive probabilities (and hence logical probabilities) without being able to state a general principle that covers these cases.

A positive argument for the existence of inductive probabilities is the following: We have seen reason to believe that a statement of inductive probability, such as (5), is either logically true or logically false. Which of these it is will be determined by the concepts involved, which are concepts of ordinary language. So, since competent speakers of a language normally use the language correctly, the wide endorsement of (5) is good reason to believe that (5) is a true sentence of English. And it follows from (5) that at least one inductive probability exists. Parallel arguments would establish the existence of many other inductive probabilities.

The concept of probability that is involved in confirmation can appropriately be taken to be inductive probability. Unlike physical probability, the concept of inductive probability applies to scientific theories. And unlike both physical and subjective probability, the concept of inductive probability agrees with the fact that confirmation relations are not discovered empirically but by examination of the relation between the hypothesis and the evidence.

## EXPLICATION OF INDUCTIVE PROBABILITY

Inductive probability is a concept of ordinary language and, like many such concepts, it is vague. This is reflected in the fact that inductive probabilities often have no precise numerical value.

A useful way to theorize about vague concepts is to define a precise concept that is similar to the vague concept. This methodology is called explication, the vague concept is called the explicandum, and the precise concept that is meant to be similar to it is called the explicatum. Although the explicatum is intended to be similar to the explicandum, there must be differences, since the explicatum is precise and the explicandum is vague. Other desiderata for an explicatum, besides similarity

with the explicandum, are theoretical fruitfulness and simplicity.

Inductive probability can be explicated by defining, for selected pairs of sentences  $E$  and  $H$ , a number that will be the explicatum for the inductive probability of  $H$  given  $E$ ; let us denote this number by " $p(H|E)$ ." The set of sentences for which  $p(H|E)$  is defined will depend on our purposes.

Quantitative inductive probabilities, where they exist, satisfy the mathematical laws of probability. Since a good explicatum is similar to the explicandum, theoretically fruitful, and simple, the numbers  $p(H|E)$  will also be required to satisfy these laws.

In works written from the 1940s to his death in 1970, Carnap proposed a series of increasingly sophisticated explications of this kind, culminating in his *Basic System of Inductive Logic* published posthumously in 1971 and 1980. Other authors have proposed other explicata, some of which will be mentioned below.

Since the value of  $p(H|E)$  is specified by definition, a statement of the form " $p(H|E) = r$ " is either true by definition or false by definition, and hence is logically determinate. Since we require these values to satisfy the laws of probability, the function  $p$  is also a probability function. So we may say that the function  $p$  is a logical probability in Carnap's sense.

Thus there are two different kinds of probability, both of which are logical in Carnap's sense: Inductive probability and functions that are proposed as explicata for inductive probability. Since the values of the explicata are specified by definition, it is undeniable that logical probabilities of this second kind exist.

## EXPLICATION OF INCREMENTAL CONFIRMATION

Since inductive probability is vague, and  $E$  incrementally confirms  $H$  if and only if  $E$  raises the inductive probability of  $H$ , the concept of incremental confirmation is also vague. We will now consider how to explicate incremental confirmation.

First, we note that the judgment that  $E$  confirms  $H$  is often made on the assumption that some other information  $D$  is given; this information is called background evidence. So we will take the form of a fully explicit judgment of incremental confirmation to be " $E$  incrementally confirms  $H$  given  $D$ ." For example, a coin landing heads on the first toss incrementally confirms that the coin has heads on both sides, given that both sides of the coin are the same; there would be no confirmation if the back-

ground evidence was that the coin is normal with heads on one side only.

The judgment that  $E$  incrementally confirms  $H$  given  $D$  means that the inductive probability of  $H$  given both  $E$  and  $D$  is greater than the inductive probability of  $H$  given only  $D$ . Suppose we have a function  $p$  that is an explicatum for inductive probability and is defined for the relevant statements. Let “ $E.D$ ” represent the conjunction of  $E$  and  $D$  (so the dot here functions like “and”). Then the explicatum for “ $E$  incrementally confirms  $H$  given  $D$ ” will be  $p(H|E.D) > p(H|D)$ . We will use the notation “ $C(H, E, D)$ ” as an abbreviation for this explicatum.

The concept of incremental confirmation, like all the concepts of confirmation discussed so far, is a qualitative concept. For each of these qualitative concepts there is a corresponding comparative concept, which compares the amount of confirmation in different cases. We will focus here on the judgment that  $E_1$  incrementally confirms  $H$  more than  $E_2$  does, given  $D$ . The corresponding statement in terms of our explicata is that the increase from  $p(H|D)$  to  $p(H|E_1.D)$  is larger than the increase from  $p(H|D)$  to  $p(H|E_2.D)$ . This is true if and only if  $p(H|E_1.D) > p(H|E_2.D)$ , so the explicatum for “ $E_1$  confirms  $H$  more than  $E_2$  does, given  $D$ ” will be  $p(H|E_1.D) > p(H|E_2.D)$ . We will use the notation “ $M(H, E_1, E_2, D)$ ” as an abbreviation for this explicatum.

Confirmation theorists have also discussed quantitative concepts of confirmation, which involve assigning numerical “degrees of confirmation” to hypotheses. In earlier literature the term “degree of confirmation” usually meant degree of absolute confirmation. The degree to which  $E$  absolutely confirms  $H$  is the same as the inductive probability of  $H$  given  $E$  and hence is explicated by  $p(H|E)$ .

In later literature, the term “degree of confirmation” is more likely to mean degree of incremental confirmation. An explicatum for the degree to which  $E$  incrementally confirms  $H$  given  $D$  is a measure of how much  $p(H|E.D)$  is greater than  $p(H|D)$ . Many different explicata of this kind have been proposed; they include the following. (Here “ $\sim H$ ” means the negation of  $H$ .)

Difference measure:  $p(H|E.D) - p(H|D)$

Ratio measure:  $p(H|E.D) / p(H|D)$

Likelihood ratio:  $p(E|H.D) / p(E|\sim H.D)$

Confirmation theorists continue to debate the merits of these and other measures of degree of incremental confirmation.

## VERIFIED CONSEQUENCES

The remainder of this entry will consider various properties of incremental confirmation and how well these are captured by the explicata  $C$  and  $M$  that were defined above. We begin with the idea that hypotheses are confirmed by verifying their logical consequences.

If  $H$  logically implies  $E$  given background evidence  $D$ , we usually suppose that observation of  $E$  would incrementally confirm  $H$  given  $D$ . For example, Einstein’s general theory of relativity, together with other known facts, implied that the orbit of Mercury precesses at a certain rate; hence the observation that it did precess at this rate incrementally confirmed Einstein’s theory, given the other known facts.

The corresponding explicatum statement is: If  $H.D$  implies  $E$  then  $C(H, E, D)$ . Assuming that  $p$  satisfies the laws of mathematical probability, this explicatum statement can be proved true provided that  $0 < p(H|D) < 1$  and  $p(E|D) < 1$ .

We can see intuitively why the provisos are needed. If  $p(H|D) = 1$  then  $H$  is certainly true given  $D$  and so no evidence can incrementally confirm it. If  $p(H|D) = 0$  then  $H$  is certainly false given  $D$  and the observation that one of its consequences is true need not alter this situation. If  $p(E|D) = 1$  then  $E$  was certainly true given  $D$  and so the observation that it is true cannot provide new evidence for  $H$ .

If  $H$  and  $D$  imply both  $E_1$  and  $E_2$ , and if  $E_1$  is less probable than  $E_2$  given  $D$ , then we usually suppose that  $H$  would be better confirmed by  $E_1$  than by  $E_2$ , given  $D$ . The corresponding explicatum statement is: If  $H.D$  implies  $E_1$  and  $E_2$ , and  $p(E_1|D) < p(E_2|D)$ , then  $M(H, E_1, E_2, D)$ . Assuming that  $p$  satisfies the laws of probability, this can be proved true provided that  $0 < p(H|D) < 1$ . The proviso makes sense intuitively for the same reasons as before.

If  $H$  and  $D$  imply both  $E_1$  and  $E_2$  then we usually suppose that  $E_1$  and  $E_2$  together would confirm  $H$  more than  $E_1$  alone, given  $D$ . The corresponding explicatum statement is that if  $H.D$  implies  $E_1$  and  $E_2$  then  $M(H, E_1, E_2, E_1, D)$ . It follows from the result in the previous paragraph that this is true, provided that  $p(E_1, E_2|D) < p(E_1|D)$  and  $0 < p(H|D) < 1$ . The provisos are needed for the same reasons as before.

These results show that, if we require  $p$  to satisfy the laws of probability, then  $C$  and  $M$  will be similar to their explicanda with respect to verified consequences and, to that extent at least,  $C$  and  $M$  will be good explicata. In addition these results illustrate in a small way the value of explication. Although the provisos that we added make

sense when one thinks about them, the need for them is likely to be overlooked if one thinks only in terms of the vague explicanda and does not attempt to prove a precise corresponding result in terms of the explicata. Thus explication can give a deeper and more accurate understanding of the explicandum. We will see more examples of this.

### REASONING BY ANALOGY

If two individuals are known to be alike in certain respects, and one is found to have a particular property, we often infer that, since the individuals are similar, the other individual probably also has that property. This is a simple example of reasoning by analogy, and it is a kind of reasoning that we use every day.

In order to explicate this kind of reasoning, we will use “*a*” and “*b*” to stand for individual things and “*F*” and “*G*” for logically independent properties that an individual may have (for example, being tall and blond). We will use “*Fa*” to mean that the individual *a* has the property *F*; similarly for other properties and individuals.

It is generally accepted that reasoning by analogy is stronger the more properties that the individuals are known to have in common. So for *C* to be a good explicatum it must satisfy the following condition:

$$(6) C (Gb, Fa.Fb, Ga).$$

Here we are considering the situation in which the background evidence is that *a* has *G*. The probability that *b* also has *G* is increased by finding that *a* and *b* also share the property *F*.

In the case just considered, *a* and *b* are not known to differ in any way. When we reason by analogy in real life we normally do know some respects in which the individuals differ, but this does not alter the fact that the reasoning is stronger the more alike *a* and *b* are known to be. So for *C* to be a good explicatum it must also satisfy the following condition. (Here *F'* is a property that is logically independent of both *F* and *G*.)

$$(7) C (Gb, Fa.Fb, Ga.F'a. \sim F'b).$$

Here the background evidence is that *a* has *G* and that *a* and *b* differ in regard to *F'*. The probability that *b* has *G* is increased by finding that *a* and *b* are alike in having *F*.

Another condition that *C* should satisfy is:

$$(8) C (Gb, Ga, F'a. \sim F'b).$$

Here the background evidence is merely that *a* and *b* differ regarding *F'*. For all we know, whether or not some-

thing has *F'* might be unrelated to whether it has *G*, so the fact that *a* has *G* is still some reason to think that *b* has *G*.

In *Logical Foundations of Probability* Carnap proposed a particular explicatum for inductive probability that he called *c\**. In *The Continuum of Inductive Methods* he described an infinite class of possible explicata. The function *c\**, and all the functions in Carnap’s continuum, satisfy (6) but not (7) or (8). Hence none of these functions provides a fully satisfactory explicatum for situations that involve more than one logically independent property.

Carnap recognized this failure early in the 1950s and worked to find explicata that would handle reasoning by analogy more adequately. He first found a class of possible explicata for the case where there are two logically independent properties; the functions in this class satisfy (6) and (8). Subsequently, with the help of John Kemeny, Carnap generalized his proposal to the case where there are any finite number of logically independent properties, though he never published this. A simpler and less adequate generalization was published by Mary Hesse in 1964. Both these generalizations satisfy all of (6)-(8).

Carnap had no justification for the functions he proposed except that they seemed to agree with intuitive principles of reasoning by analogy. Later he found that they actually violate one of the principles he had taken to be intuitive. In his last work Carnap expressed indecision about how to proceed.

For the case where there are just two properties, Maher (2000) has shown that certain foundational assumptions pick out a class of probability functions, called *P<sub>p</sub>*, that includes the functions that Carnap proposed for this case. Maher argued that the probability functions in *P<sub>p</sub>* handle reasoning by analogy adequately and Carnap’s doubts were misplaced.

For the case where there are more than two properties, Maher (2001) has shown that the proposals of Hesse, and Carnap and Kemeny, correspond to implausible foundational assumptions and violate intuitive principles of reasoning by analogy. Further research is needed to find an explicatum for inductive probability that is adequate for situations involving more than two properties.

### NICOD’S CONDITION

We are often interested in universal generalizations of the form “All *F* are *G*,” for example, “All ravens are black,” or “All metals conduct electricity.” Nicod’s condition, named after the French philosopher Jean Nicod, says that generalizations of this form are confirmed by finding an indi-

vidual that is both *F* and *G*. (Here and in the remainder of this entry, “confirmed” means incrementally confirmed.)

Nicod (1970) did not mention background evidence. It is now well known that Nicod’s condition is not true when there is background evidence of certain kinds. For example, suppose the background evidence is that, if there are any ravens, then there is a non-black raven. Relative to this background evidence, observation of a black raven would refute, not confirm, that all ravens are black.

Hempel claimed that Nicod’s condition is true when there is no background evidence but I. J. Good argued that this is also wrong. Good’s argument was essentially this: Given no evidence whatever, it is improbable that there are any ravens, and if there are no ravens then, according to standard logic, “All ravens are black” is true. Hence, given no evidence, “All ravens are black” is probably true. However, if ravens do exist, they are probably a variety of colors, so finding a black raven would increase the probability that there is a non-black raven and hence disconfirm that all ravens are black, contrary to Nicod’s condition.

Hempel was relying on intuition, and Good’s counterargument is intuitive rather than rigorous. A different way to investigate the question is to use precise explicata. The situation of “no background evidence” can be explicated by taking the background evidence to be any logically true sentence; let *T* be such a sentence. Letting *A* be “all *F* are *G*,” the claim that Nicod’s condition holds when there is no background evidence may be expressed in explicatum terms as

$$(9) C(A, Fa.Ga, T).$$

Maher has shown that this can fail when the explicatum *p* is a function in  $P_I$  and that the reason for the failure is the one identified in Good’s argument. This confirms that Nicod’s condition is false even when there is no background evidence.

Why then has Nicod’s condition seemed plausible? One reason may be that people sometimes do not clearly distinguish between Nicod’s condition and the following statement: Given that an object is *F*, the evidence that it is *G* confirms that all *F* are *G*. The latter statement may be expressed in explicatum terms as:

$$(10) C(A, Ga, Fa).$$

This is true provided only that *p* satisfies the laws of probability,  $0 < p(A|Fa) < 1$ , and  $p(Ga|Fa) < 1$ . (This follows from the first of the results stated earlier for verified consequences.) If people do not clearly distinguish between

the ordinary language statements that correspond to (9) and (10), the truth of the latter could make it seem that Nicod’s condition is true.

### THE RAVENS PARADOX

The following three principles about confirmation have seemed plausible to many people.

(11) Nicod’s condition holds when there is no background evidence.

(12) Confirmation relations are unchanged by substitution of logically equivalent sentences.

(13) In the absence of background evidence, the evidence that some individual is a non-black non-raven does not confirm that all ravens are black.

However, these three principles are inconsistent. That is because (11) implies that a non-black non-raven confirms “all non-black things are non-ravens,” and the latter is logically equivalent to “all ravens are black,” so by (12) a non-black non-raven confirms “all ravens are black,” contrary to (13).

Hempel was the first to discuss this paradox. His initial statement of the paradox did not explicitly include the condition of no background evidence but he stated later in his article that this was to be understood. The subsequent literature on this paradox is enormous but most discussions have not respected the condition of no background evidence. Here we will follow Hempel in respecting that condition.

The contradiction shows that at least one of (11)-(13) is false. Hempel claimed that (11) and (12) are true and (13) is false but his judgments were based on informal intuitions, not on any precise explicatum or use of probability theory.

Our preceding discussion of Nicod’s condition shows that (11) is false, contrary to what Hempel thought. On the other hand, our explicata support Hempel’s view that (12) is true and (13) is false, as we will now show.

In explicatum terms, what (12) says is: If *H*’, *E*’, and *D*’ are logically equivalent to *H*, *E*, and *D* respectively, then  $C(H, E, D)$  if and only if  $C(H', E', D')$ . The truth of this follows from the assumption that *p* satisfies the laws of probability.

Now let “*F*” mean “raven” and “*G*” mean “black.” Then (13), expressed in explicatum terms, is the claim  $\sim C(A, \sim Fa, \sim Ga, T)$ . Maher has shown that this need not

be true when  $p$  is a function in  $P$ ; we can instead have  $C(A, \sim Fa, \sim Ga, T)$ . This happens for two reasons:

- (a) The evidence  $\sim Fa, \sim Ga$  reduces the probability of  $Fb, \sim Gb$ , where  $b$  is any individual other than  $a$ . Thus  $\sim Fa, \sim Ga$  reduces the probability that another individual  $b$  is a counterexample to  $A$ .
- (b) The evidence  $\sim Fa, \sim Ga$  tells us that  $a$  is not a counterexample to  $A$ , which a priori it could have been.

Both of these reasons make sense intuitively.

We conclude that, of the three principles (11)-(13), only (12) is true.

### PROJECTABILITY

A predicate is said to be “projectable” if the evidence that the predicate applies to some objects confirms that it also applies to other objects. The standard example of a predicate that is not projectable is “grue,” which was introduced by Goodman (1979). According to Goodman’s definition, something is grue if either (i) it is observed before time  $t$  and is green or (ii) it is not observed before time  $t$  and is blue. The usual argument that “grue” is not projectable goes something like this: A grue emerald observed before  $t$  is green, and observation of such an emerald confirms that emeralds not observed before  $t$  are also green. Since a green emerald not observed before  $t$  is not grue, it follows that a grue emerald observed before  $t$  confirms that emeralds not observed before  $t$  are not grue; hence “grue” is not projectable.

The preceding account of the meaning of “projectable” was the usual one but it is imprecise because it fails to specify background evidence. Let us say that a predicate  $\phi$  is absolutely projectable if  $C(\phi b, \phi a, T)$  for any distinct individuals  $a$  and  $b$  and logical truth  $T$ . This concept of absolute projectability is one possible explicatum for the usual imprecise concept of projectability. Let “ $Fa$ ” mean that  $a$  is observed before  $t$  and let “ $Ga$ ” mean that  $a$  is green. Let “ $G'a$ ” mean that either  $Fa.Ga$  or  $\sim Fa.\sim Ga$ . Thus “ $G'$ ” has a meaning similar to “grue.” (The difference is just that  $G$  uses “not green” instead of “blue” and so avoids introducing a third property.) Maher has proved that if  $p$  is any function in  $P$ , then “ $F$ ”, “ $G$ ”, and “ $G'$ ” are all absolutely projectable. It may seem unintuitive that “ $G'$ ” is absolutely projectable. However, this result corresponds to the following statement of ordinary language: The probability that  $b$  is grue is higher given that  $a$  is grue than if one was not given any evidence whatever. If we keep in mind that we do not know whether  $a$  or  $b$  was observed before  $t$ , this should be intuitively acceptable. So

philosophers who say that “grue” is not projectable are wrong if, by “projectable,” they mean absolute projectability.

Let us say that a predicate  $\phi$  is projectable across another predicate  $\psi$  if  $C(\phi b, \phi a, \psi a.\sim \psi b)$  for any distinct individuals  $a$  and  $b$ . This concept of projectability across another predicate is a second possible explicatum for the usual imprecise concept of projectability.

It can be shown that if  $p$  is any function in  $P$ , then “ $G$ ” is, and “ $G'$ ” is not, projectable across “ $F$ .” So philosophers who say that “grue” is not projectable are right if, by “projectable,” they mean projectability across the predicate “observed before  $t$ .”

Now suppose we change the definition of “ $Ga$ ” to be that  $a$  is (i) observed before  $t$  and green or (ii) not observed before  $t$  and not green. Thus “ $G$ ” now means what “ $G'$ ” used to mean. Keeping the definitions of “ $F$ ” and “ $G'$ ” unchanged, “ $G'a$ ” now means that  $a$  is green. The results reported in the preceding paragraph will still hold but now they are the opposite of the usual views about what is projectable. This shows that, when we are constructing explicata for inductive probability and confirmation, the meanings assigned to the basic predicates (here “ $F$ ” and “ $G$ ”) need to be intuitively simple ones rather than intuitively complex concepts like “grue.”

## CONFUCIUS (551–479 BCE)

Confucius (Kong Qiu) is one of the early Chinese philosophers and the founder of the ethical teaching known as Confucianism. He was born in a time of political, social, and spiritual crisis that had shattered the tra-

ditional way of life as well as the view of a world based on the conventions of ritual propriety (*li*) and the religion of Heaven (*tian*). The hierarchies of the patriarchal feudal system of the Zhou had fallen into decay, giving way to a new social mobility, and because of this, a small but influential middle class emerged. Its members became the clients of private teachers who imparted the knowledge needed in a society that ascribed increasing importance to individual capability instead of descent.

Confucius (a transcription of Kong fuzi—teacher Kong) was one of these teachers. He probably taught the practical "six arts" (writing, mathematics, ritual propriety, music, charioteering, and archery) and dealt with the texts handed down from the past that he is said to have edited and that constitute the core of the later Confucian classics. However, as documented by his "Collected Words" (*Lunyu*, a later compilation), the main focus of his teaching is morality. Confucius dedicates himself to an ideal of education that transcends the social boundaries and roles the disciples would possibly play in their present and later life—the ideal of becoming a gentleman (*junzi*), a truly moral person in solidarity with the community and rooted in self-respect. This endeavor is again embedded in the quest for a still higher goal: To rescue "this culture" from the flood in which it was drowning, and to "change the world" that had lost the dao, the right way (*LY* 9.5, 18.6).

To find a solution for the world in a time when tradition was in crisis enforced a reflection on the established norms in order to reconstruct and rescue their true meaning (*zheng ming*). This gives a philosophical ring to Confucius's ethics. He finds one of the paradigmatic answers to the challenge China's intellectuals were facing: How to redefine humankind's position in a world that had lost its foundation, without the possibility for reiterating the past. His answer is the internalization of ethics as a new basis for the ethical life, which entails both constant self-reference of the individual and norm reflexivity. It has always remained a Confucian conviction that there must be ethical rather than legal or organizational solutions to the basic problems of human existence; that morality must have primacy over all other concerns, also over politics; and that the human being as its agent is capable of moral cultivation. This makes the Confucian position distinct both from the Daoist return to nature and the legalist social engineering.

The general structure of ethics of the *Lunyu* may be described as comprising three steps: (1) In view of the sobering conditions of the time, the "gentleman" turns away from society; he no longer trusts public reputation

(LY 12.20) and the opinions of the majority (13.24, 15.28); and he is constantly prepared to be misjudged and not acknowledged by others (1.1, 1.16, 14.30, 15.19). He then (2) *turns into his inner self* where in private seclusion he develops self-respect (5.16, 13.19) as the basis for autonomous action and, given the absence of a strong religious backing of ethics, the ultimate reason for being moral. Through regular self-reflection and critical self-examination (1.4, 5.27, 12.4, 15.21) he safeguards the purity of his intentions, which, if necessary, will enable him to, as Confucius is quoted in the *Mengzi*, “withstand thousands or tens of thousands” (2a:2). However, in a final step, the moral actor (3) consciously “overcomes himself” and *returns* to society (*ke ji fu li*) (LY 12.1). He thus accepts his responsibility as a moral authority in the interest of the common good, rather than simply trying to stay “clean” in a world where “the *dao* does not prevail” (18.7), far away from the ideal of the “great community” (*da tong*, attributed to Confucius in *Liji* 9).

Return to society implies the critical acknowledgment of the given ethos of a hierarchical world dominated by the principle of male seniority. Without the handed-down rules of propriety (*li*) the human being would be without a firm “standing” (*li*) (LY 8.8, 16.13, 20.3). However, the traditional canon of normative orientations is reconsidered and realigned to a new organizing center—humaneness (*ren*). Humaneness has “to start from oneself” rather than from external guidance (12.1); it is ideally followed for its own sake rather than for reasons of utility (4.2); and it is universally valid, even when one is among barbarian tribes (13.19).

Humaneness is explicated differently, however, in the *Lunyu*, the most conspicuous variants being its affective reading as love (12.22) and its cognitive reading as the golden rule (5.12, 6.30, 12.2, 15.23), the maxim that “consists of one word and can be practiced through all one’s life” (15.24) and the “one that goes through all” (4.15). By humaneness in terms of the golden rule, the direct reciprocal relationship with the generalized “other” becomes one of the two complementary dimensions of ethics along with the concrete role orientation.

Confucius’s ethics thus promises a “mean” comprising personal integrity and social integration, allowing one to keep faith with the conventional ethos while not surrendering to it. The “gentleman” as its protagonist will fulfill the duties owed to family and society and at the same time, “harmonious, but not conformist” (13.23), maintain a moral watchfulness and inner independence.

It was possible, however, to adopt this ethics with different accents, also because of the vagueness of many

*Lunyu* passages and the opacity of its structure. The conflict of opinions about the true teaching of the master, the attempts to regain the original spirit lost in the course of its effective history, as well as Confucius’s critique as a rebel, a ritualist, and a moralist out of touch with reality, apparently started shortly after his death. The debate still continues in the twenty-first century, with deontological, pragmatist, aestheticist, communitarian, and religious interpretations competing with each other.

## CONNECTIONISM

“Connectionism” is an approach within cognitive science that employs neural networks, rather than computer programs, as the basis for modeling mentality. A connectionist system, or neural network, is a structure of simple neuronlike processors called nodes or units. Each node has directed connections to other nodes, so that the nodes send and receive excitatory and inhibitory signals to and from one another. The total input to a node determines its state of activation. When a node is on, it sends out signals to the nodes to which it has output connections, with the intensity of a signal depending upon both (1) the activation level of the sending node and (2) the strength or “weight” of the connection between it and the receiving node. Typically at each moment during processing, many nodes are simultaneously sending signals to others.

When neural networks are employed for information processing, certain nodes are designated “input” units and others as “output” units, and potential patterns of activation across them are assigned interpretations. (The remaining nodes are called “hidden units.”) Typically a “problem” is posed to a network by activating a

pattern in the input nodes; then the various nodes in the system simultaneously send and receive signals repeatedly until the system settles into a stable configuration; the semantic interpretation of the resulting pattern in the output nodes is what the system currently represents, hence its “answer” to the problem. Connectionist systems are capable of “learning” from “experience” by having their weights changed systematically in a way that depends upon how well the network has performed in generating solutions to problems posed to it as a training regimen. (Typically the device employed is not an actual neural network but a simulation of one on a standard digital computer.)

The most striking difference between such networks and conventional computers is the lack of an executive component. In a conventional computer the behavior of the whole system is controlled at the central processing unit (CPU) by a stored program. A connectionist system lacks both a CPU and a stored program. Nevertheless, often in a connectionist system certain activation patterns over sets of hidden units can be interpreted as internal representations with interesting content, and often the system also can be interpreted as embodying, in its weighted connections, information that gets automatically accommodated during processing without getting explicitly represented via activation patterns.

Connectionist models have yielded particularly encouraging results for cognitive processes such as learning, pattern recognition, and so-called multiple-soft-constraint satisfaction (i.e., solving a problem governed by several constraints, where an optimal solution may require violating some constraints in order to satisfy others). For example, Terry Sejnowski and Charles Rosenberg trained a network they called NETalk to convert inputs that represent a sequence of letters, spaces, and punctuation constituting written English into outputs that represent the audible sounds constituting the corresponding spoken English. (The phonetic output code then can be fed into a speech synthesizer, a device that actually produces the sounds.)

Philosophical discussion of connectionism has largely centered on whether connectionism yields or suggests a conception of mentality that is importantly different from the conception of mind-as-computer at the core of classical cognitive science. Several different nonclassical alternatives have been suggested; each has been alleged to fit well with connectionism, and each has been a locus of debate between fans and foes of connectionism. Three proposed interpretations of connectionism deserve specific mention.

On one view, the key difference between classical models of mental processes and connectionist models is that the former assume the existence of languagelike mental representations that constitute a so-called language of thought (LOT), whereas the latter supposedly favor representations that are alleged to be inherently non-languagelike in structure: namely, activation patterns distributed over several nodes of a network, so-called activation vectors. On this interpretation connectionism shares with classicism the assumption that cognition is computation over mental representations—that cognitive transitions conform to rules for transforming representations on the basis of their formal structure, rules that could be formulated as an explicit computer program. (In connectionist systems the rules are wired into the weights and connections rather than being explicitly represented. In classical systems some rules must be hard wired; and there may be—but need not be—other rules that are explicitly represented as stored data structures.) The key difference allegedly turns on the languagelike or non-languagelike structure of mental representations.

This construal of connectionism fits naturally with the idea that human cognition involves state transitions that are all essentially associative—in the sense that they reflect statistical correlations among items the system can represent and can be analyzed as the drawing of statistical inferences. Many fans of connectionism, including Patricia Churchland and Paul Churchland, evidently see things this way and tend to regard connectionism as breathing new life into associationism. Prominent foes of connectionism, notably Jerry Fodor and Zenon Pylyshyn, also see things this way; but they regard the link with associationism as grounds for maintaining that connectionism is bound to founder on the same general problem that plagued traditional associationism in psychology: namely, inability to account for the rich semantic coherence of much human thought. To overcome this problem, Fodor and Pylyshyn maintain, cognitive science must continue to posit both (1) mental representations that encode propositional information via languagelike syntactic structure and (2) modes of processing that are suitably sensitive to syntactic structure and are thereby sensitive to propositional content.

A second interpretation of connectionism claims that connectionist models do not really employ internal representations at all in their hidden units (and, a fortiori, do not employ internal representations with languagelike structure). This view has been defended—by Rodney Brooks, for example—on the grounds that puta-

tive representations in connectionist systems play no genuine explanatory role. It has also been defended—for instance, by Hubert Dreyfus and Stuart Dreyfus—on the basis of a Heideggerian critique of the notion of mental representation itself. The approach goes contrary to the views of most (but not all) practicing connectionists, who typically posit internal representations in connectionist models and assign them a central explanatory role.

A third interpretation assumes the existence of internal mental representations; and it does not deny—indeed, the version defended by Terence Horgan and John Tienson resolutely affirms—that mental representations often have languagelike structure. It focuses instead on the classical assumption that cognition is computation (see above). This third approach maintains (1) that much of human cognition is too rich and too subtle to conform to programmable rules and (2) that connectionism has theoretical resources for potentially explaining such non-algorithmic cognitive processing. The approach stresses that there is a powerful branch of mathematics that applies naturally to neural networks: dynamical systems theory. According to this anticomputational construal of connectionism, there can be cognitive systems—subservable mathematically by dynamical systems, which in turn are subservable physically by neural networks—whose cognitive state transitions are not tractably computable. In other words, mental activity in these systems is too refined and too supple to conform to programmable rules. Humans are alleged to be such cognitive systems, and connectionism (so interpreted) is held to yield a more adequate picture of the mind than the classical computational picture.

One objection to this third interpretation of connectionism alleges that cognitive state transitions in a connectionist system must inevitably conform to programmable rules, especially since neural networks are simulable on standard computers. Another objection, directed specifically at the version that retains language-like representations, alleges that the LOT hypothesis is intelligible only on the assumption that cognition is computation.

In much of the early philosophical debate between proponents and opponents of connectionism, the first interpretation was largely taken for granted. But as competing interpretations get articulated, defended, and acknowledged, philosophical discussion of connectionism and its potential implications becomes richer.

## CONSCIENCE

Doubtless from the earliest times in which groups established social customs, or mores, and enforced them, members of such groups who were tempted to violate these mores could almost feel the disapproval of their fellows and hear in their own minds a protesting outcry, perhaps some primitive equivalent of "No!" or "Don't!" In the early eighteenth century such inner voices or feelings were described as edicts of one's moral sense or of one's "conscience." This kind of account of these restraining influences became explicit with the development of faculty psychology, which involved the view that there are different faculties of the human mind responsible for different capacities or abilities which the mind seems to exhibit. Reason was thought of as the rational faculty, emotion as a passional one, and volition as a faculty that enables us to reach decisions and make choices. The moral faculty was thought by some, the earl of Shaftesbury and Francis Hutcheson, for example, to operate through feelings. For instance, a feeling of repugnance would tend to be aroused by the thought of doing any-

thing immoral—anything in violation of the mores—and a feeling of approval by the thought of acting virtuously.

In contrast with this moral-sense type of theory, Samuel Clarke and Richard Price, among others, thought that it must be something akin to reason or the understanding which enabled us to distinguish right from wrong. Joseph Butler termed this faculty of the mind “conscience,” and in more recent times this term has become the common one.

Modern behaviorists, to be sure, would not write of conscience as a mental faculty; they refer instead to “learned modes of reaction to stimuli.” When one has been conditioned to respond in certain standard ways which are widely and strongly approved, one tends to find that one can break with such approved behavioral norms only after a genuine struggle and a stiff volitional conflict. In any case, whether we speak of the voice of conscience or of the voice of our group or of learned blockage and interference patterns, we often find that there are inhibitions to be overcome before we can break with the mores of our peers.

It has been suggested that a policeman, upholding the law, functions as a kind of government-supported externalized conscience. His mere presence in uniform suffices to warn us not to break, for example, the speed law that we are already bending a bit. Even animals below the human level can be trained to feel the force of such an externalized conscience. Cats, for example, can be trained not to sleep on the couch when humans are in the room. But it is difficult, to say the least, to teach them not to do so when no human observer is present to their senses. With human children and adults, by contrast, it is possible to develop an internalized conscience, which, even in the absence of all enforcers, will remind them, and even stimulate them strongly, not to do certain prohibited actions and to do certain required ones. The driver who stops his car at red traffic lights only when he sees or suspects that an officer is nearby has, like the cat, only an externalized conscience about this type of act, whereas one who habitually stops is, as we say, acting conscientiously—obeying, perhaps unconsciously, his internalized conscience.

That “the voice of conscience” is often effective seems clear, but it is also clear that it can and often does lose its effectiveness. A dutiful son may well adopt many of the mores of his father for a time and then gradually abandon them. If a person persists in violating his conscience, it will grow decrepit, bother him less and less effectively, and it may soon cease to deter him at all.

## CONSCIENCE AS A RELIABLE GUIDE

As children many of us were taught that the voice of conscience is the voice of God and, hence, completely reliable. Some would claim, in more sophisticated terms, that although God gave us free will and does not infringe upon our freedom of choice, he nevertheless continues to lend us moral support. He gives us, through conscience, a means for distinguishing right from wrong. If we follow the guidance of conscience, we shall do our duty and act rightly. If we act contrary to its deliverances, we shall surely act wrongly.

There are, however, many difficulties with this kind of account and, indeed, with any other which claims that conscience is a sufficient guide to moral conduct.

First, the consciences of different people, whether members of the same or of different societies, often differ radically. Conscientious objectors to war and volunteers for wartime service usually disagree strongly as to the rightness of a given war. Cannibals do not share the conscientious objections to eating human flesh that vegetarians do, and both these groups differ from those who feel it is morally permissible to eat animal but not human flesh.

Second, there seem to be exceptions to all the edicts of conscience. Even within groups whose members share, say, a conscientious prescription against deliberately taking a human life, the exceptions that the various consciences allow to individuals vary greatly from one person to another. Lev Tolstoy, and presumably some Quakers, would insist that his conscience forbids the taking of a human life under any conditions. By contrast, although many of us verbally would fully accept the commandment not to kill, we would be likely in practice to find ourselves approving some acts of killing, for example in self-defense or in defense of others, and disapproving of some avoidances of killing, for example in a very deserving mercy case.

Third, conscience fails to provide guidance for many important and even some crucial moral questions. Many problems that we confront are so complex that we frankly have very little idea, and certainly no confirmed judgment or deliverance of conscience, as to which alternative is most worthy of being chosen. In many such cases, where getting adequate knowledge in the time available before a decision must be reached is impossible, we know in advance that we would be only too happy to do what is right if we could identify, with some reasonable degree of probability, the right alternative. A situation of this sort must frequently arise for people who cannot pass the

decision on to someone else. The president of the United States, for example, cannot avoid the responsibility for important decisions that must be made—very often on vastly less evidence than he would like to have. Similarly, there are many difficult problems to be decided by those of us who are less highly placed, problems where the decision will not indeed be world-shaking but where it will affect a number of lives in important ways. We often sweat with the desire to solve a difficult problem in the right way but are unable, in the time available before a decision must be taken, to find out which way is the right way. In complicated cases the relatively simple prescriptions of conscience tend to prove quite inadequate.

It is not that the prescriptions of our conscience are worthless; they are often of value in reminding us of the moral views which have been taken by other members of our peer group. Awareness also of the edicts that spring from the consciences of others with different backgrounds not infrequently throws light on our own problem. But in complicated and novel cases, the edict of another's conscience cannot provide us with certain knowledge as to what ought to be done.

#### SOURCES OF DELIVERANCES OF CONSCIENCE

Psychologists, anthropologists, and other social scientists have gathered empirical evidence as to various sources of the deliverances of conscience. Many of the edicts of our conscience seem to have come to us while we still rested at our mother's knee. These were usually simple in form but quite effective for many years. Others came from our fathers, from teachers, from preachers, from lecturers and writers, from friends whom we respected. This wide variety of the sources of the edicts that now emanate apparently from our own consciences explains many things about them: their vagueness, their variability, their changing authority over us. As suggested by behaviorists, at least some of them rest on conditioned responses instilled in us at an early age by repetitions we no longer remember.

Examination of a particular edict of conscience throws significant light on "our inner voices." Suppose we warn our sons, ages four and six, to stay off a railway trestle near our home. We say with great emphasis, "*Never* go out on that trestle, no matter what." One day the younger boy pursues his gay red ball onto the trestle. The older boy rushes to him and pulls him off the trestle just before a train crosses it. Will we punish him for breaking our "absolute" rule? Obviously not. Our consciously instilled rule, now a command of conscience, has its values, posi-

tive and negative. It needs supplementation as soon as increasing maturity permits rational consideration. And to this phase anyone who has attained knowledge and discretion should surely move on.

#### UNIVERSALIZABILITY OF MORAL PRESCRIPTIONS

Since the edicts of conscience have pedestrian empirical sources and are subject to exceptions, it was natural for Immanuel Kant to insist, through his categorical imperative, that every valid moral principle must hold universally: "So act that you can will the maxim or principle of your action to be a universal law, binding on the will of every rational being." This requirement has two facets. First, for an act to be moral it must be done not on whim or impulse or as a mere reflex response to stimuli, but in accordance with some moral principle or maxim. Second, this principle must be one that the agent is willing to have universally adopted. This requirement that a person should act only on a principle that he is willing to have universally adopted seems to introduce undesirable psychological factors that might tend to vary radically from one person to the next. Thus, a pessimist like Arthur Schopenhauer might approve of universal suicide and be willing to have everyone else do so, whereas an optimist might be willing to have everyone work toward increasing the population. Such a formulation of the universalizability principle would thus lead to incompatible moral edicts.

To eliminate such psychological factors and to state the principle in a way closer to Kant's intent, Richard M. Hare urges that a moral principle, to be applicable to a person *A*, must also be applicable in like circumstances to any similar person *B*. Although Hare's intent seems clear, he does not specify the degree of similarity required. Complete identity would make the principle useless. On the other hand, it seems clear that Hare was not suggesting, for example, that because it is right for *A* to make love to his wife, it is also proper that *B*, who is like *A* in various respects, should also make love to Mrs. *A*. Perhaps the universalizability thesis is best stated as follows: If it is right for *A* to do an act of kind *X* in a set of circumstances *C*, then it is right for any *B* who is like *A* in all relevant respects to do an act of kind *X* in circumstances like *C* in all relevant respects. So stated, the principle is analytically and thus necessarily true. But whether we can ever know in practice that both sets of circumstances and both agents are alike in all relevant respects is highly doubtful. It would be difficult, if not impossible, even to specify these respects. But we do know what is meant by this pre-

scription, and we sometimes know with a fair degree of probability that the required likenesses are present.

Because the universalizability principle is analytic, it is necessarily true. But it is an “If ... then ...” statement: If *A* should do *X* in *C*, then *B* should do *Y* in *D*, where the similarities between *A* and *B*, *C* and *D*, and *X* and *Y* meet the requirements previously mentioned. Quite aside from the difficulties of knowing whether or not these requirements are met, the statement tells us only that if its antecedent is true, its consequent is also true. But to know the antecedent to be true—that *A* ought to do *X* in *C*—we must turn to experience for an answer. To know anything to be good on the whole, we must know if its existence (or occurrence) is preferable to its nonexistence. To know any act to be right, we must know that no possible alternative is preferable to it. Such preferability presupposes empirical knowledge of values. The possibility of such knowledge is a matter of controversy, but many, including the present writer, believe it to be attainable.

## CONSCIOUSNESS

The term *consciousness* refers to several distinct, but related phenomena that figure in the mental functioning of people and other creatures.

### KINDS OF CONSCIOUSNESS

One of these phenomena is closely tied to simply being awake. An individual is conscious if it is awake and responsive to sensory stimulation; a person or other creature that is asleep, in a coma, or knocked out is not conscious.

There are also other phenomena we refer to as consciousness. One is conscious *of* something if one senses or perceives the thing or has some suitable thought about it; being conscious of something is being aware of that thing. Because we use a grammatical object to specify what somebody is conscious of, it is convenient to call this phenomenon *transitive consciousness*, as against an individual's being awake and responsive to sensory input, which we can call *creature consciousness* (Rosenthal 1990).

We sometimes describe the states one is aware of as constituting one's current mental life as a stream of consciousness. But there are, in addition, thoughts, desires, feelings, and perceptions that occur outside that stream of consciousness, of which one is wholly unaware. Even though one is unaware of these states, they are nonetheless part of one's mental functioning. We call the states that occur in somebody's stream of consciousness *conscious*, in contrast with those of which that individual is wholly unaware. This is a third use of the term *conscious*. Because consciousness of this sort is a property of mental states, such as thoughts, desires, feelings, and perceptions, we can call it *state consciousness*.

Sometimes we focus deliberately and attentively on some feeling or perception we have; such focused awareness of our mental states is called *reflective*, or *introspective consciousness*. And we call the explicit consciousness of the self to which these states belong *self-consciousness*.

There is disagreement about what connections hold among these several kinds of consciousness. Some theorists hold that an individual cannot be creature conscious—that is, awake and responsive to sensory stimulation—unless at least some of its mental states are conscious. Doubtless that is true for ordinary humans; people are never conscious without being in some conscious states. But, if perceptions and feelings can occur without being conscious, there is in principle no reason why some creatures might be awake and responsive to

sensory stimulation even though none of their feelings, perceptions, or other mental states are conscious states.

Not all theorists, however, accept that feelings, perceptions, thoughts, and desires can occur without being conscious. Even Sigmund Freud (1961), who championed the idea of unconscious desires and thoughts, drew the line at qualitative states, such as sensations and feelings. All feelings, he held, are conscious, though we can loosely characterize feelings as unconscious when one is unclear or mistaken about what they are about.

Others, such as Thomas Nagel (1974) and John R. Searle (1990, 1992), accept that nonconscious states occur that function in ways similar to conscious feelings, perceptions, and thoughts, but deny that those nonconscious states are full-fledged feelings, perceptions, or thoughts.

It is also a matter of some controversy whether mental states are conscious in virtue of one's being conscious *of* those states. Earlier writers, such as René Descartes (1984–1991) and John Locke (1975), always described the states we now call conscious as states that one is conscious of. But, because they also held that we are conscious of all our mental states, they saw no need to use the term *conscious* to mark a distinction between those mental states we are conscious of and those we aren't. When, in the late nineteenth century, it became widely accepted that individuals are in some mental states of which they are wholly unaware, the term *conscious* came to mark the contrast between those mental states one is conscious of and those one is not.

Though not all theorists agree that a mental state's being conscious involves one's being conscious of that state, that has long been the dominant view.

### QUALITATIVE CONSCIOUSNESS

Mental states fall into three broad groups. Some, such as beliefs, thoughts, desires, hopes, and expectations, have intentional content that can be described by a sentential clause. Thinking is always thinking *that* something is the case; the clause beginning with *that* specifies what it is that one thinks. Similarly with one's desires, hopes, and expectations. The intentional content, described by a *that* clause, specifies what it is that one desires, hopes, or expects.

Pains and other sensations, by contrast, have no intentional content, but instead exhibit some qualitative character, such as the quality of painfulness or the color qualities of visual sensations. A third group of states includes emotions and perceptions, which exhibit both qualitative character and intentional content.

Many theorists hold that the consciousness of qualitative states is something different from the consciousness of other mental states, and that it demands special treatment. Giving an informative theoretical account of qualitative consciousness, on their view, faces special difficulties.

Thus Ned Block (1995) has urged that qualitative states exhibit a special kind of consciousness, which he calls *phenomenal consciousness*, or *phenomenality*. A state has phenomenal consciousness, according to Block, if there is something it is like to be in that state, which happens only when the state has some qualitative character. There is nothing it is like simply to think or believe something, even when one's thought or belief is conscious. Phenomenal consciousness occurs only with states that have qualitative character.

Block (1995) distinguishes a state's having phenomenal consciousness from its having what he calls *access consciousness*. A state is access conscious if its content is poised to figure in reasoning and in the rational control of action and speech. Some qualitative states, which exhibit phenomenal consciousness, also exhibit access consciousness; intuitively, they are the qualitative states one is conscious of. By contrast, when a state is phenomenally conscious but not access conscious, one is wholly unaware of the state. And there is often compelling empirical or theoretical reason to think that qualitative states of which one is unaware do occur (see the next section in this entry).

Block's notion of access consciousness echoes Daniel C. Dennett's (1993) idea that a state's being conscious consists in its having "cerebral celebrity," that is, if it has a widespread effect on memory and on the control of behavior. It also accords with the cognitive theory of consciousness advanced by the psychologist Bernard J. Baars (1988), on which a state is conscious if it occurs in a global workspace that maximizes its connections with other states and behavior.

## PROBLEMS ABOUT QUALITATIVE CONSCIOUSNESS

A state's being access conscious consists in its having suitable connections with other states and with behavior. So the notion of access consciousness invites a functionalist account (Lewis 1972, Putnam 1975), on which a state's mental properties are a matter of such connections. Many theorists, however, deny that any such an account can work for qualitative consciousness. They insist that, because conscious qualitative character is an intrinsic

property of sensations, it cannot be understood in terms of connections that sensations have with other things.

**EXPLAINING CONSCIOUS QUALITIES.** The new physics pioneered in the seventeenth century by Galileo Galilei, Descartes, and Isaac Newton holds that we can explain the nature and behavior of physical objects only insofar as we can describe them in mathematical terms. Since commonsense physical qualities, such as color and sound, seem to resist mathematical description, some have followed Locke in construing such properties as powers to cause the corresponding mental qualities. But conscious mental qualities also resist mathematical description, and it may seem that no parallel move is possible for them. Many conclude that conscious mental qualities lie outside the reach of physical explanation, and possibly, therefore, any informative explanation. Thus, Locke argued that sensations either are nonphysical states or, if they are states of material bodies, they must be "superadded" to those bodies by God.

In a somewhat similar spirit, Joseph Levine (2000) has argued that there is an "explanatory gap" that blocks any intelligible explanation of conscious qualitative states in terms of physical processes. Similarly, Nagel (1974) has argued that none of the available naturalist theories of mind can explain what it's like for one to be in a mental state. And David Chalmers (1996) has described as the "hard problem" of consciousness the question why relevant brain processes are accompanied by qualitative consciousness at all, and why particular brain events are accompanied by specific types of mental quality.

Levine has urged that, though we cannot explain qualitative consciousness in physical terms, qualitative consciousness might nonetheless be physical in nature. Others conclude instead that qualitative consciousness cannot have a physical nature, arguing that any such physical nature would make possible a physical explanation of qualitative consciousness. And Colin McGinn (1991) has argued that, though consciousness is physical in nature, we lack the cognitive capacity to understand how that is possible.

It is unclear, however, that the considerations used to support these views are compelling. We rely on well-developed theories to draw systematic connections among things in nature. Even the most ordinary connections among natural processes seem surprising and unintelligible without any commonsense theory to provide context, and come to seem rational only when subsumed by some suitable theory. So it may be that the ties between conscious mental qualities and brain processes now

seem unintelligible only because we still have no well-developed theory that links them. But by itself, that current lack gives us no reason to doubt that we will some day have such a theory. And coming to have one would likely overcome any prior intuitive concerns about explaining qualitative consciousness, just as physics and chemistry have made intuitively acceptable various explanations of our commonsense world that would previously have seemed outlandish.

Introspection may also seem to support intuitive doubts about whether rational explanation of conscious qualitative character is possible, since introspection provides no clue about how such an explanation might proceed. But we have no reason to think that introspection would help here; introspection can at most tell us about the qualities themselves, not how they connect with other things.

**THE KNOWLEDGE ARGUMENT.** Frank Jackson (1982, 1986) has argued that conscious qualitative states are not physical because, even if one knew everything physical there is to know about our psychological and neural functioning, one would not thereby know what it's like for one to be in particular qualitative states. Jackson imagines a neuroscientist who knows everything physical about visual functioning but has never seen anything except in black, white, and gray. Still, Jackson argues, this neuroscientist, on consciously seeing red for the first time, would learn something new, namely, what it's like for one to see red. Since the neuroscientist already knew everything physical about seeing red, the new knowledge of it what it's like for one to see red cannot be knowledge of something physical.

Jackson (2003) has since repudiated this argument, maintaining now that what it's like for one to see red is purely a matter of intentional content. This view is a version of representationalism, which is discussed later in this entry. Others have responded differently to Jackson's original argument, urging that what one would learn on first consciously seeing red is not factual knowledge, but only a kind of acquaintance (Churchland 1985) or an ability to recognize the quality in question (Lewis 1990; cf. Loar 1997).

**QUALITIES AND CONSCIOUSNESS.** Some theorists contend that qualitative states of which we are in no way conscious cannot occur. Indeed, the very term *qualia* (singular *quale*) is often applied to mental qualities with the implication that such qualities cannot occur without being conscious. But there is compelling reason to

hold that mental qualities do occur outside our stream of consciousness.

Individuals sometimes perceive things without being at all aware that they are doing so. In so-called masked priming experiments (Marcel 1983), subjects briefly exposed first to one visual stimulus and then to another may consciously see only the second. Nonetheless, it is plain that subjects do see the first stimulus, since it affects subsequent behavior in ways characteristic of seeing those stimuli. Thus, subjects who report seeing only the second stimulus can nonetheless make strikingly accurate guesses about the first.

There are other such cases. Individuals with lesions in the cortical area primarily responsible for vision may be wholly unaware of seeing a stimulus and yet guess about its visible character, again with great accuracy, exhibiting what Lawrence Weiskrantz (1997) has called blindsight. These individuals see stimuli, but are not in any way conscious of seeing them. And subliminal perceiving, of which one is wholly unaware, sometimes occurs even in everyday situations.

Not only do qualitative states sometimes occur without being conscious; there are circumstances in which we are conscious of ourselves as being in qualitative states that are different from those we are actually in. John Grimes (1996) reported that subjects will continue to see a highly salient object as unchanged in color or other respects if the relevant changes occur during a saccade, since no visual input reaches the brain during saccades. A subject may thus attentively look at something red but be conscious instead of seeing green. Such a subject would presumably have a sensation of red, despite being conscious of having a sensation of green. Our consciousness of our qualitative states can sometimes be strikingly inaccurate.

According to Block (1995), cases of qualitative states that occur outside our stream of consciousness are phenomenally conscious states that lack access consciousness. Access consciousness makes the difference, he urges, between qualitative states of which we are intuitively aware and those of which we are not. But it's likely that even qualitative states that intuitively occur in one's stream of consciousness sometimes lack access consciousness, on Block's official definition. Visual states near the periphery of our visual field are conscious but are not, without some shift in attention, poised to figure in any general way in reasoning and the rational control of action and speech. Similarly with other perceptual states that lie outside our focus of attention but are nonetheless part of our stream of consciousness. It is

likely that access consciousness has more to do with attention than with consciousness.

**QUALITY INVERSION** Qualitative states figure in perceiving. There is a distinctive mental quality that occurs when one sees something red and a different quality when one sees something green; similarly for perceptible properties accessible by modalities other than vision. That raises the question whether particular mental qualities might play different perceptual roles from one individual to another, or even different roles in the same individual at different times. The question is not about the slight variations in the way people see things, which are detectable in standard ways, but about whether particular mental qualities could play different perceptual roles in ways undetectable by others.

Locke held that such inversion of mental qualities is at least conceivable, and many contemporary theorists share that view. This idea very likely reflects a conviction that mental qualities are individuated solely by the way one is conscious of them, that is, by how they appear to consciousness. If any other factors do figure in the individuation of mental qualities, those factors would enable the detection in others of inversion in the perceptual roles of their mental qualities.

But if mental qualities were individuated only by how we are conscious of them, they would differ only in the way they appear to consciousness. And then mental qualities could not occur without being conscious. Indeed, the evidence that mental qualities do occur without being conscious provides ways of determining their occurrence independent of consciousness. So, that evidence also suggests that any conceivable quality inversion would have to be detectable. It is therefore likely that any satisfactory way of individuating mental qualities will rely on their role in perceiving, independent of whether that perceiving occurs consciously (Rosenthal 2005).

## CONSCIOUSNESS AND INTENTIONALITY

As noted earlier, intentional states, such as thoughts, desires, doubts, and expectations, occur both consciously and not consciously.

Freud posited intentional states that are not conscious as the best explanation of various otherwise inexplicable conscious thoughts and desires and various bits of behavior. Thus, a person may do just those things and have just those conscious thoughts and desires that we would expect if the person also had certain other thoughts and desires. And, if the person is unaware of

being in those other thoughts and desires, we can best explain the behavior and conscious states by supposing that the person has those thoughts and desires, but they are simply not conscious. Such reasoning again invites a functionalist account of intentional states, on which the intentional properties of a state is a matter of its connections with other states, behavior, and sensory stimulation. But even apart from a functionalist account, it is widely accepted that intentional states with particular contents have characteristic causal connections with other intentional states and with behavior, and that is all Freud's argument requires. Such reasoning is compelling, moreover, independent of the special kinds of case that interested Freud.

Experimental work in social psychology shows that subjects sometimes report having beliefs or desires that would make sense of a situation or conform to social expectations, despite compelling evidence that these subjects do not actually have those beliefs and desires (Nisbett and Wilson 1977). Not only are we sometimes unaware of our thoughts and desires; in such confabulatory cases we are conscious of ourselves as having thoughts and desires that we do not have.

Searle (1990) has argued that intentional states, properly so called, cannot occur without being conscious. As he notes, one's thoughts and desires always represent things in terms of some aspects and not others; Oedipus had a desire to marry a particular woman, but his desire did not represent that woman as his mother. And, as Oedipus's case illustrates, how one's intentional states represent the things they are about makes a difference both to one's mental life and one's behavior.

According to Searle, the way one's intentional states represent things cannot make a difference to one unless those states are conscious. He concludes that genuine thoughts and desires cannot occur without being conscious. But the way one's thoughts and desires represent things can make a difference to one even if those states are not conscious. A thought or desire need not be conscious to affect one's other intentional states and one's behavior, and it will affect those things differently depending on the way it represents things. Genuine intentional states can occur without being conscious.

## THEORIES OF CONSCIOUSNESS I

Theories of consciousness often rely on the traditional idea that a state's being conscious involves one's being conscious in some way *of* that state. States of which one is in no way conscious are not conscious states. When we are conscious of something, moreover, we can tell others

about it. So a standard test for whether somebody is in a conscious state is whether that person can report being in the state. If somebody can report having a particular thought, feeling, or perception, that state is conscious; if the person cannot report being in the state, it is not. This rule of thumb underlies typical methodology in experimental psychology no less than everyday practice.

But the commonsense observation that mental states are states of which we are conscious goes only so far. A theory of consciousness must also specify how it is that we are conscious of those states. One important feature of our consciousness of those states was highlighted by Descartes, who insisted that we are immediately conscious of our mental states. When we are conscious of a mental state, it seems that nothing mediates between that state and our awareness of it. A theory of consciousness must explain this sense of immediacy in the way we are aware of our conscious states.

**INNER SENSE.** We also seem to be immediately conscious of things when we perceive them; nothing seems to mediate between the things we perceive and our perceptions of them. This encourages the hypothesis, advanced by Locke, Immanuel Kant (1998), and others, that mental states are conscious because we sense or perceive them. A thought, feeling, or perception is conscious because one is aware of that state by way of some faculty of inner sense, or some internal monitoring mechanism that involves the higher-order perceiving of that state. This theory has traditionally been the most widely held explanation of consciousness; contemporary advocates include David M. Armstrong (1978) and William G. Lycan (1996).

But there are difficulties with this theory. Sensations and perceptions always exhibit some qualitative character; sensing a red object, for example, involves a sensation's having a mental quality of red, as against a mental quality of blue, green, and so forth. Our consciousness of our mental states, however, does not involve any qualitative character. This is obvious when the state we are aware of is a thought or desire, which itself has no qualitative character; plainly, no mental quality figures in the way we are conscious of those intentional states.

Qualitative character does figure when we are conscious of sensations and perceptions. But these mental qualities are just the qualities we are conscious of our sensations and perceptions as having. As Aristotle (1993) noted, there are no higher-order qualities in virtue of which we are conscious of our qualitative mental states, in the way the mental quality of red enables us to see red objects. Our higher-order awareness of our conscious

states may resemble perceiving in other ways, but qualitative character is so central to perceiving that no form of awareness that fails to involve mental qualities can count as perceiving.

Inner-sense theorists often urge that the higher-order sensing or perceiving they posit serves the function of monitoring our mental states, much as perceiving monitors external objects and bodily conditions. But perceiving is not the only way that the mind might monitor itself. And cases of confabulatory awareness, which Richard E. Nisbett and Timothy DeCamp Wilson have demonstrated, do not in any case fit neatly with a model based on monitoring.

**INTRINSIC THEORIES.** But we need not appeal to inner sense to capture the apparent immediacy of our consciousness of many mental states. If our awareness of our conscious states were internal to those states themselves, nothing could mediate between a state and one's awareness of it; such consciousness would be intrinsic to each conscious state. This theory, advanced by Franz Brentano (1973) and possibly Aristotle, also has a number of contemporary advocates.

But the intrinsic theory also faces difficulties. There are thoughts and desires that we sometimes have consciously and other times not. A sensation that results from a particular stimulus may be conscious if that stimulus occurs alone, but not conscious if the very same stimulus is followed in a suitable way by a second, masking stimulus (Marcel 1983). It is unclear how we can explain such variation if consciousness is literally built into our mental states.

The problem is particularly pressing when one particular state passes between being conscious and not being conscious. Some perceptual or bodily sensations that are not very intense may be conscious or not depending on where one focuses one's attention. But, since shifts in attention are extrinsic to particular sensations, such shifts should leave consciousness unaffected if consciousness is indeed an intrinsic aspect of mental states.

Brentano held that consciously hearing something makes us conscious of two things: the sound one hears and the hearing itself. And he maintained that we are conscious of the hearing in the way that having a thought about something makes us conscious of that thing, even when we don't perceive it. The intentional content of hearing something, according to Brentano, makes us conscious both of the thing heard and the hearing itself.

Perhaps hearing can have two intentional objects in this way. But there are other cases for which Brentano's

model does not work. Doubting something does not make one conscious of the thing one's doubt is about. Consider, then, a case of doubting that it is raining. Even if one's doubt is about both the rain and the state of doubting itself, that will not make one conscious of the doubting. A mental affirmation that one has that doubt would make one conscious of the doubting. But that mental affirmation could not be intrinsic to the doubting, since no mental state involves more than one mental attitude. Similar considerations apply to wondering about something, and many other mental attitudes.

Inner sense and Brentano's intrinsic theory both sought to explain the way our awareness of our conscious states is immediate. But all we really need to explain is why such awareness appears to be immediate, since we do not know that it actually is. Indeed, perceiving is also subjectively unmediated, but we know that there is much that actually mediates between our perceptions and the things we perceive. So the same may well be so with the way we are aware of our conscious states. Despite the subjective impression of immediacy, there may well be mediation we are not subjectively aware of. All we need to explain is the subjective sense of immediacy, and neither the analogy with perceiving nor the intrinsic theory is required for that.

**HIGHER-ORDER THOUGHTS.** On Brentano's intrinsic theory, every conscious state makes us conscious of itself, in much the way that having a thought about something makes one conscious of that thing. This theory cannot work, at least for cases like doubting and wondering. Inner sense, by contrast, faces the difficulty that, because the awareness of our conscious states does not involve higher-order mental qualities, that awareness cannot be sensing or perceiving. This suggests combining features of the two theories so as to avoid the difficulties of each. Perhaps we are aware of our conscious states by having thoughts about them, as Brentano urged, but those thoughts are distinct from the states we are conscious of, as inner sense maintains about the higher-order perceptions it posits.

This appeal to higher-order thoughts that are distinct from the mental states they make us conscious of avoids the foregoing difficulties that face inner sense and Brentano's theory. The higher-order-thought theory, advanced by David M. Rosenthal (1986, 1990, 2005) and others, also allows for an explanation of the subjective immediacy of our awareness of our conscious states; the theory can require that these higher-order thoughts are independent of any conscious inference. If we are

unaware of any inference on which a higher-order thought relies, we will be unaware of any mediation between the states we are aware of and our awareness of them. So, such awareness will be subjectively unmediated. Indeed, we would seldom be aware of these higher-order thoughts, since a third-order thought would be needed for any second-order thought to be conscious. And our typically being unaware of our higher-order thoughts would enhance the subjective sense that our consciousness of our mental states is immediate.

Critics have urged two major difficulties for this theory. One involves the possibility that higher-order thoughts will sometimes misrepresent what mental states we are in. But it is arguable that consciousness does sometimes misrepresent things, as in the confabulatory cases noted earlier. And there are very likely psychological pressures that prevent such misrepresentation from becoming too extreme.

Nonetheless, some have insisted that such misrepresentation cannot occur, in effect relying on the traditional idea, advanced by Descartes, Locke, and others, that the mind is transparent to itself. But there is compelling reason to reject that transparency claim. Confabulatory consciousness and other phenomena show that consciousness does occasionally mislead us; moreover, others sometimes know what we are thinking and feeling better than we ourselves do. Consciousness is neither infallible nor exhaustive.

Another challenge to the higher-order-thought theory pertains specifically to conscious qualitative states. How can higher-order thoughts, which themselves lack qualitative character, result in qualitative states' being conscious? How can simply having a thought result in there being something it is like for one to be in a qualitative state?

This challenge echoes the concern that an explanatory gap may make it impossible to understand how conscious mental qualities could arise as a result of particular neural events. Put most generally, the concern is how conscious qualities can result from anything else. But as noted earlier, connections among things in nature seem intelligible only when we have a well-established theory that subsumes those connections. Since higher-order thoughts are seldom conscious, introspection cannot tell us whether they result in conscious qualities. But it may be that the connections higher-order thoughts have with the thoughts we have about the things we perceive result in our being conscious of the mental qualities that figure in such perceiving.

In any case, no alternative theory has a response to this challenge that is at all satisfactory. By itself, simply positing that our awareness of qualitative states is intrinsic to those states does nothing to explain why there is something it is like for one to be in those states. And inner sense faces a regress, since it could help only if the higher-order perceptions themselves had conscious mental qualities, and we would then need to explain what gives rise to those higher-order conscious qualities.

## THEORIES OF CONSCIOUSNESS II

The foregoing theories differ about whether our awareness of our conscious states is intrinsic to those states or external to them, and about whether that awareness is due to our perceiving those states or to our having thoughts about them. But there are other issues about which theories differ as well.

**DISPOSITIONAL THEORIES.** Peter Carruthers (2000) has argued that a state's being conscious does not require the actual occurrence of a higher-order thought, but only a disposition for such a higher-order thought to occur. Carruthers urges that having an actual higher-order thought for each conscious state would result in cognitive overload, unlike one's merely being disposed to have higher-order thoughts.

But there is no reason to think that our cortical resources cannot accommodate actual higher-order thoughts, and dispositions would themselves make substantial cortical demands. Nor is it obvious that dispositions will do. Since being disposed to have a thought about something does not make one conscious of anything, merely being disposed to have a higher-order thought would not make one aware of one's mental states. Carruthers seeks to meet this difficulty by endorsing the view that the intentional content a state has is partly a matter of what other states it is disposed to cause. So, when a state is disposed to cause a higher-order thought, that very state has higher-order content, which makes one conscious of that state. But, since the state itself has the higher-order content, this view faces the same difficulties that tell against Brentano's theory.

**REPRESENTATIONALISM.** Some have sought to meet the challenge about conscious mental qualities by denying that there are any. According to representationalism, we are never conscious of any mental qualities, but only the perceptible properties of physical objects, and the states in virtue of which we are conscious of them are purely intentional states. When we see something red, on

this view, the only quality we are aware of is the redness of the thing seen; we are not in addition aware of some mental red. Advocates of this view, such as Gilbert Harman (1990), Dennett (1991), Fred Dretske (2000), Armstrong, and Lycan, point out that we never seem to be conscious of two distinct qualities of red, nor to switch from being conscious of the redness of physical objects to being conscious of a mental quality of the seeing itself. Descartes also espoused a form of representationalism, since he regarded all mental phenomena as having only intentional properties, and construed sensations either as purely intentional states or as nonmental bodily states.

But, as Wilfrid Sellars (1963), Sydney Shoemaker (1996), and Rosenthal (2005) have argued, perceptual sensations resemble and differ in ways that reflect the similarities and differences among perceived physical properties. And it is natural to construe the properties in virtue of which those sensations resemble and differ as mental qualities. When we introspectively attend to our qualitative states, moreover, we sometimes become conscious of the relevant qualities *as* qualities of our experiences. So it may well be that we are, after all, often aware of mental qualities that our qualitative states exhibit.

Some theorists, such as Dretske (1993) and Searle (1992), reject the idea that a mental state's being conscious is a matter of one's being conscious of that state. A state's being conscious, on their view, does not involve some higher-order awareness of that state. Rather, according to Dretske (1993), a state is conscious if, in virtue of one's being in that state, one is conscious of something. This is sometimes called a first-order theory of consciousness, in contrast to theories that posit some higher-order awareness.

This account faces a difficulty, however. Perceptions sometimes occur without being conscious. But it is arguable that even those perceptions make us conscious of things. If perceiving something primes one for some conscious state or some behavior, then one was conscious of the thing one perceived even if it did not seem to one that one perceived it. On Dretske's (1993, 2000) view, however, any state in virtue of which one is conscious of something is conscious. And that has the unwelcome result that even the perceptions we seem subjectively not to have are conscious.

Searle (1992) holds that we can subjectively draw no distinction between a conscious state and one's consciousness of it. He concludes that no higher-order awareness figures in a state's being conscious. But when we focus introspectively on our conscious states, we are often aware both of the state thus scrutinized and of the

scrutinizing itself. And even if we could not draw that distinction subjectively, we might still have sound theoretical reasons to insist on it.

**DENNETT'S THEORY.** Dennett (1991) has developed an important theory of consciousness, which emphasizes cases in which consciousness misrepresents what mental states we are in. Visual information that is not central to our focus of attention can be highly degraded, but still we seem subjectively to see things in sharp detail throughout our field of vision. Dennett argues that consciousness extrapolates from available visual information to create a full picture of the environment, in effect filling in missing visual information and providing missing details.

In thus distinguishing the way consciousness represents things from our actual visual states, Dennett's (1991) view resembles higher-order theories, on which our higher-order awareness of mental states is distinct from the states themselves, and so can misrepresent them. But Dennett rejects such higher-order views, arguing that there is no distinction between the way things appear and our awareness of how they appear. So, he construes the divergence between consciousness and visual states not in terms of two mental levels—perceiving and our consciousness of perceiving—but rather as the difference between the way things consciously appear and the subpersonal neural events in virtue of which things appear that way.

Dennett shares with the higher-order-thought theory a view of consciousness as a kind of self-interpretation. On both views we interpret ourselves as being in various commonsense psychological states. But, unlike higher-order-thought theorists, Dennett denies that we are actually in any of the commonsense psychological states we interpret ourselves as being in. The only states that figure in psychological functioning are subpersonal neural events of content fixation, complex patterns of which subserve such functioning.

Searle (1992) and Dennett (1991, 1993) both reject any distinction between the mental states one is in and one's awareness of those states, but they do so for different reasons. Searle rejects that distinction because he holds that we cannot draw it subjectively. Dennett, by contrast, maintains that the psychological states we are conscious of ourselves as being in do not actually occur. But it is arguable that suitable patterns of the subpersonal events of content fixation Dennett countenances actually constitute the mental states of commonsense psychology. If so, we can distinguish between those commonsense mental states and our higher-order awareness of them.

## NEURAL CORRELATES, FUNCTION, AND THE SELF

Whether or not conscious qualitative states are physical in nature, few doubt that something specific in brain functioning correlates with qualitative consciousness. This has led to speculation about what that neural correlate of consciousness (NCC) is.

According to Francis Crick and Christoph Koch (1990) the NCC involves the occurrence of synchronized neural oscillation of 35 to 75 hertz in sensory cortex, a synchrony sufficient for a vigorous coalition of neurons firing together. One thing that favors this hypothesis is that such synchronized neural oscillation seems to figure in the way different qualitative properties are bound together in conscious experience. As Anne Treisman (1986) has shown, visual qualities pertaining to color, shape, motion, and orientation occur independently in the early stages of visual processing; so there is a *binding problem* of explaining how they come together in conscious experience. But these qualities are bound together even when qualitative states are not conscious. So, the neural factors operative in such binding may not be the same as those responsible for qualitative consciousness, and synchronized oscillation may subserve only binding, independent of consciousness.

Mental functioning plays a variety of roles, allowing animals to negotiate their way in the world and to satisfy various needs and desires. What, then, is the specific function of consciousness? The answer depends on which kind of consciousness is at issue. Creature consciousness, which consists in an animal's being awake and responsive to sensory stimulation, plainly functions to enable an animal to satisfy needs and avoid danger. Similarly with transitive consciousness, which consists in a creature's being conscious of various things.

State consciousness, by contrast, consists in a state's occurring in a creature's stream of consciousness, and it is somewhat less clear what function this has. A mental state's function depends on its causal connections with other states and with behavior and sensory stimuli, and the causal properties of thoughts and desires are mainly a matter of their intentional content, whether or not they are conscious. Similarly, the causal properties of qualitative states depend on their mental qualities; visual sensations of red interact causally in ways suitably different from visual sensations of green, again whether or not they are conscious. So it is unclear what additional function might result from these states' being conscious.

One standard answer is that such consciousness functions to enhance reasoning and planning; perhaps decisions and thinking will be more rational if one is conscious of one's thoughts and desires. This idea underlies Block's (1995) claim that a state is access conscious if its content is poised to figure in the rational control of action and speech, Baars's (1988) related suggestion that conscious states occur in a global workspace, and Dennett's (1993) that consciousness is cerebral celebrity.

But many thoughts and desires have global effects on other states and on behavior even when they are not conscious. And even when planning and thinking is not conscious, it often is rational, as when we solve problems by sleeping on them. Indeed, this is just what we should expect if the causal potential of thoughts and desires depends mainly on their intentional content. There is, moreover, compelling evidence that we are conscious of our decisions only after those decisions have been made (Libet 1985), so that being conscious of those decisions cannot affect whether we make them.

According to Dretske (1993), any state in virtue of which one is transitively conscious of something is a conscious state. So on that view, the function of state consciousness coincides with that of transitive consciousness. But if, instead, a state is conscious just in case one is in some suitable way conscious of that state, the function of state consciousness will rather be whatever function is added by one's being thus conscious of the state. And that may be relatively marginal.

When we introspect our mental states by deliberately and attentively focusing on them, we are conscious of the states we introspect as states of ourselves, and we are in that way conscious of ourselves as centers of consciousness. There are several questions about the nature of such self-consciousness. David Hume (1978) urged that, though we are aware of many of our mental states, we are not aware of anything in addition to those states which we might call a self. Hume was operating with a perceptual model of awareness, and it is plain that we do not perceive such a self. But we are sometimes conscious of things not only by perceiving them, but also by having thoughts about them as being present. So having higher-order thoughts to the effect that one is in various mental states will make one conscious of oneself as being in those states, and hence conscious of the self to which those states belong.

As Descartes and Kant stressed, our mental states are conscious in a way that seems to involve an important unity; we are conscious of them as all being states of a single unitary self or center of consciousness. It is not obvi-

ous whether some actual unity underlies this appearance of conscious unity (see Marcel 1993, Rosenthal 2005). But even explaining that subjective appearance requires more than simply explaining the consciousness of the relevant mental states.

## CONSCIOUSNESS IN PHENOMENOLOGY

For Edmund Husserl, the two basic features of consciousness are intentionality and temporality. Intentionality means that all consciousness is directed to some object. The thesis that consciousness is temporal means not only that all conscious states have a temporal location but that each of them has within itself a temporal structure and that the temporal structure of consciousness is the basis for all other determinations of consciousness and its objects.

Husserl's philosophical method proceeds through an analysis of conscious life. However, because all consciousness is intentional, the analysis of the forms and structures of various kinds of consciousness (including volitional, emotional, and evaluative, as well as theoretical) is also the appropriate way to analyze the essential forms and structures of various kinds of objects. Because Husserl also believes that consciousness involves at least implicit self-consciousness of one's own mental states, the focus on consciousness shifts the analysis to a sphere that is immediately and directly given in reflection and is therefore the source of apodictic certainty, the transcendental ego. In later works Husserl qualifies this assertion by pointing out that self-givenness even for ideal objects never necessarily involves absolute certainty, so that all purported givenness requires reconfirmation. He also turns his attention to the sphere of passive synthesis, whose results may be directly given to us, while the operations that originally generate them are not, so that a phenomenological reconstruction or intentional analysis is necessary to reveal sedimented or initially hidden and prepredicative elements of consciousness.

Jean-Paul Sartre considered himself a philosopher of consciousness during the first half of his career. He subscribed to the Cartesian ideal of the cogito as the starting point of philosophy and placed a premium on the apodictic evidence it yielded. But he valued consciousness as much for its freedom and spontaneity as for its epistemological translucency. In fact, it was the relevance of translucency to moral responsibility that led him to deny both a transcendental ego and the Freudian unconscious and to posit a "prereflective *Cogito*."

In his *The Imaginary* Sartre describes imaging consciousness as the locus of "negativity, possibility, and lack." Because we are able to "hold the world at bay" and "derealize" perceptual objects imagistically, he argues, we are free. Imaging consciousness becomes paradigmatic of consciousness in general (being-for-itself) in *Being and*

*Nothingness*. Adopting Husserl's thesis that all consciousness is intentional, he insists that this intentionality is primarily practical, articulating a fundamental project that gives meaning/direction (*sens*) to our existence.

Sartre makes much of the prereflective self-awareness that accompanies our explicit awareness of any object, including our egos as reflective objects. Because we are always implicitly self-aware, it is unnecessary to seek self-consciousness in an endless infinity of reflections on reflections or to chase after a subject that cannot be an object (the transcendental ego). The unblinking eye of prereflective consciousness makes possible both bad faith and its overcoming through what he calls "purifying reflection," the authentic "choice" to live at a creative distance from one's ego.

Husserl's students such as Aron Gurwitsch and Ludwig Landgrebe and most of the subsequent figures within the phenomenological tradition such as Martin Heidegger and Maurice Merleau-Ponty built upon Husserl's and Sartre's insights into the importance of self-awareness, intentionality, and temporality—often under other names—but they also stress the prepredicative and the practical nature of this awareness as well as its limitations. Hence they avoid the term "consciousness" for the most part because of its association with Cartesian aspirations to complete self-transparency and absolute autonomy in human knowledge and action that they reject.

## CONSEQUENTIALISM

As a name for any ethical theory or for the class of ethical theories that evaluate actions by the value of the consequences of the actions, “consequentialism” thus refers to classical utilitarianism and other theories that share this characteristic.

Classical utilitarianism, in the philosophies of Jeremy Bentham, John Stuart Mill, and Henry Sidgwick, was consequentialist, judging actions right in proportion as they tended to produce happiness, wrong as they tended to produce pain. In the nineteenth and early twentieth centuries much of the criticism of utilitarianism was directed at the hedonistic value theory on which the ethical theory was founded. Some philosophers, such as G. E. Moore, agreed with the claim of utilitarianism that acts are right insofar as they produce good consequences, wrong as they produce bad consequences, but put forward a richer theory of value, claiming that other things besides pleasure and pain are of intrinsic value and disvalue. Such theories were sometimes labeled ideal utilitarianism. The term *consequentialism* is now used in a generic sense to include both hedonistic and nonhedonistic theories.

The term was probably introduced into usage by Elizabeth Anscombe in “Modern Moral Philosophy” (1958), an essay in which she claims that there is little difference between strictly consequentialist theories and other moral theories from Sidgwick on that permit forbidden acts to be overridden by consequentialist considerations. For example, W. D. Ross, who was an intuitionist in opposition to utilitarianism, even “ideal” utilitarian-

ism, believed that a prima facie wrong action, such as the deliberately unjust punishment of an innocent person, could be outweighed by some consequentialist consideration such as the national interest. One contrast with consequentialism, then, is absolutism, the claim that there are some actions that are never right, whatever the consequences.

In the most usual usage of *consequentialism* as a term for ethical theories, however, it is contrasted, not only to absolutism, but to any theory, such as Kantianism, intuitionism, virtue ethics, rights theories, and so on, that does not in some way make consequences the determinant of right and wrong. The consequences may be considered indirectly. Distinctions have been made between act utilitarianism, which judges acts right or wrong according to the consequences of the particular act, case by case, rule utilitarianism, which judges acts right or wrong according to whether the acts are in accord with or in violation of a useful rule—that is, a rule whose general practice would have good consequences (or better consequences than any feasible alternative rule)—and motive utilitarianism, which judges acts right or wrong if stemming from a motive that, as a motive for action, generally has good consequences. These distinctions carry over to consequentialism as a generic category of ethical theories, and one can speak of act consequentialism, rule consequentialism, and so on. Consequentialist theories can also have a place for virtues and for rights, if the inculcation of certain virtues or the respect for certain rights has good consequences. But for the consequentialist the virtues or rights are not ultimate. Their value is dependent upon their contribution to good consequences.

Abstracting from the alternative theories of value, there are still important controversies regarding consequentialist theories. Some are problems of measuring consequences or making interpersonal comparisons, whatever the theory of value, but these cannot be addressed in the abstract. Another is the theory of responsibility. One prominent criticism of consequentialism, stated, for example, by Bernard Williams (1973), is that it does not adequately distinguish between positive and negative responsibility. The claim is that consequentialism is indifferent between states of affairs that are produced by what an agent does and those that occur because of what someone else would do that the agent could prevent. It becomes an agent’s responsibility to prevent someone else from doing harm as well as not to do harm oneself. Related to this is the claim that consequentialism undermines agent integrity. For example, someone opposed to research in chemical and biological

warfare might be required to engage in such research to prevent someone else from doing it more zealously. Another criticism is that if it is formulated as a “maximizing” theory, requiring the maximization of best consequences, consequentialism goes beyond the limits of obligation. For example, one would be morally obligated to spend one’s wealth and income on others as long as there is anyone who could benefit more than oneself.

There are four basic kinds of responses that the consequentialist can make to these criticisms. One is to stick to the theory, saying that these things are morally demanded, even if not generally recognized in our selfish and self-centered society, as Peter Singer (1971–1972) argues concerning famine relief. Another is to challenge the implications of the examples, claiming that for moral agents to focus energy and attention on their own lives with integrity to their own principles has better consequences than doing otherwise. A third strategy for a non-hedonist is to attempt to avoid some of these objections by enriching the theory of value, such as to claim that integrity is something that is intrinsically valuable. A fourth strategy is to modify the structure of the theory. Michael Slote (1984) has argued in favor of a “satisficing” rather than a maximizing theory. Samuel Scheffler (1982) has proposed a “hybrid” theory that permits an agent either to maximize best consequences or to pursue the “agent-centered prerogative” of not always doing so.

## CONSERVATION PRINCIPLE

Conservation principles tell us that some quantity, quality, or aspect remains constant through change. Such principles already appear in ancient and medieval natural philosophy. In one important strand of Greek cosmology, the rotation of the celestial orbs is eternal and immutable. In optics at least from the time of Euclid (fl. c. 300 BCE), when a ray of light is reflected, the angle of reflection is

equal to the angle of incidence. According to some versions of the medieval impetus theory of motion, impetus permanently remains in a projected body (and the associated motion persists) unless the body is subject to outside interference. Such examples abound.

In the seventeenth century, conservation principles began to play a central role in scientific theories. Galileo Galilei, René Descartes, Christian Huygens, Gottfried Leibniz, and Isaac Newton founded their approaches to physics on the principle of inertia—the principle that a body will undergo uniform rectilinear motion unless interfered with. A multitude of other conservation principles gained currency during the seventeenth century—some still with us, some long ago left behind.

Descartes is an interesting example of an author who attempted to derive all of his physical principles from conservation laws (1991 [1644], esp. pt. 2, secs. 36–42). Descartes believed that the principles of his physics could be derived from the God's immutability, supplemented only by very weak assumptions about the existence of change in the world. He claimed, in fact, that we ought to postulate the strongest conservation laws consistent with such change. These laws were that God preserves at all times the total quantity of motion in the world (the quantity of motion of a body being the product of its volume and its speed), that each thing remains in the same state in every respect unless interfered with, and that in collisions the quantity of motion gained by one body is balanced by the quantity of motion lost by the other. The rest of his physics was supposed to follow from these principles alone.

The most remarkable of seventeenth-century analyses of conservation principles is contained in Huygens's essay on elastic collisions (1977). Huygens began by assuming that if two collinearly moving bodies of equal size move toward one another with equal speeds, in the resulting collision they simply exchange velocities. He then showed that it follows from the principle of Galileian relativity—that an experiment has the same outcome whether performed in a laboratory at rest or in a laboratory in uniform rectilinear motion—that whatever the initial velocity of such bodies, the result of a collision is always that velocities are simply exchanged. Huygens went on to analyze collisions between bodies of unequal size, again relying heavily on Galileian relativity. Among the consequences of his analysis were a number of conservation laws for systems of particles interacting only via elastic collisions: that the center of gravity of such a system undergoes uniform rectilinear motion, that the total kinetic energy of such a system is constant in

time, and that the relative velocities ( $mv$ ) of a pair of colliding particles is unchanged by a collision.

In a sense that will be spelled out below, the principle of Galileian relativity is a symmetry principle. So one of the things that Huygens accomplished was to show that from a symmetry principle one could deduce conservation principles. For an extensive class of physical theories—essentially, all of classical (or nonquantum) physics—it is now possible to establish a deep connection between symmetry principles and conservation laws. The balance of the discussion here provides an elementary introduction to the ideas relevant to understanding this connection.

## SYMMETRY

At the most abstract level, a structure is a set of objects instantiating some set of properties and relations. A symmetry of a given structure is a permutation of the set of objects of the structure that leaves invariant all the properties and relations involved in the structure. For any structure, the identity map on its set of objects is, trivially, a symmetry.

For example, suppose that three points have relative pair-wise distances of three, four, and five units. Then there is no nontrivial symmetry that preserves these distances. But if the points instead form the vertices of an equilateral triangle, there will be several nontrivial symmetries, such as any transformation that interchanges two vertices while leaving the third fixed. We will be interested here in dynamic symmetries. As an intuitively plausible example, ordinary translation and rotation in space should be symmetries of any decent physical theory set in Euclidean space. Note that this does not mean that every translation or rotation will be a symmetry of the states allowed by the theory: The theory might treat the behavior of a finite number of point masses, in which case no configuration of the material points could be invariant under any nontrivial translation or under more than finitely many rotations. Rather, in such a case the invariance of the theory amounts to this: The dynamics of the theory is indifferent to the location or orientation of the system in Euclidean space, in that a translation or rotation of any state allowed by the theory will not change the dynamic evolution predicted by the theory, so long as the evolution of the new state is described relative to coordinate axes that have also been translated or rotated.

It's necessary to make all of this a bit more precise. Specifying a physical theory typically involves specifying a set of physically possible states and a dynamics defined on this space of states. Most often, the states involved will

be possible instantaneous states of the system, such as the instantaneous positions and momenta of a set of particles, or the values of some field and of its time derivative at each point of space. These states will be collected together to form a space with some interesting mathematical structure (there is no need to be very specific about this structure at this stage). For convenience, a strict form of determinism will be assumed, under which the dynamics is given by the rule that if the state of the system at a given time is  $a$ , then its state  $t$  units of time later will be  $b$ , which we write as  $a \xrightarrow{t} b$ . A symmetry of this dynamics,  $S$ , will be a one-to-one mapping from the state space onto itself that leaves invariant all of the structure defined on this space, including the arrow relation. So  $a \xrightarrow{t} b$  if and only if  $S(a) \xrightarrow{t} S(b)$ .

### THE HAMILTONIAN APPROACH

Remarkably, almost all the equations of motion that arise in classical physics can be derived within the mathematical framework of Hamiltonian mechanics.

Consider the Newtonian  $n$ -body problem ( $n$  point masses interacting according to Newton's law of gravitation). We construct the phase space for this problem, the space of dynamically possible states of the particles. Choosing a point in this  $6n$ -dimensional abstract space amounts to specifying the position and momentum of each of the  $n$  particles (collision states with two or more particles coinciding in position are ruled out a priori, since the expression for the force of gravitational attraction between coincident particles is ill defined). Now, by the nature of the Newtonian equation of motion ( $F = ma$ ), specifying the positions and momenta of the particles at some initial time suffices to determine their positions and momenta at other times (indeed, at all other times, unless a collision or other singularity occurs). So the dynamic content of the theory takes this form: Specifying a point in the phase space determines a curve in the phase space through that point—the idea being that if the given point represents the state of the system of  $n$  particles at time  $t = 0$ , then the curve tells us which points of the phase space represent states of the system at earlier and later times. These curves have the following nice feature: They partition the phase space, in the sense that exactly one curve passes through each point of the phase space (that at least one curve passes through each point follows from the dynamic content of the theory; that no more than one does so is a reflection, roughly speaking, of the determinism of this theory).

At the heart of the Hamiltonian approach lie three insights: (1) The phase space of the system, just in virtue

of being a space of possible positions and momenta, carries a natural mathematical structure called a “symplectic form” (a closed nondegenerate two-form). (2) This structure allows the association to each nice real-valued function on the phase space of a family of curves that partitions the phase space. (3) The curves encoding the dynamics of the theory are thus associated with the Hamiltonian for the theory—the function that assigns to each point in phase space the total energy of the corresponding physical state (here the total energy is the sum of the kinetic energy and the gravitational potential energy).

These insights carry over to underwrite a Hamiltonian treatment of a vast assortment of classical (or non-quantum) physical theories. To develop a Hamiltonian treatment, consider the space of initial data for the equations of motion, and take this as the phase space of one's theory, showing that it comes equipped with a natural symplectic form (or generalization thereof) that allows one, in general, to pass from a function on the phase space to a set of curves partitioning the phase space—and in particular to pass from the Hamiltonian function assigning to each state its total energy to the curves on the phase space encoding the dynamic content of the equations of motion of the theory. This strategy works for rigid bodies, systems of moving particles subject to many sorts of constraints, many field theories, and some theories of material continua such as fluids and elastic bodies.

### SYMMETRIES IN THE HAMILTONIAN APPROACH

So under the Hamiltonian approach, a theory consists of a phase space (representing the possible dynamic states of the theory) equipped with a symplectic form (or generalization) and a Hamiltonian function. Below, this symplectic form will be referred to as the geometrical structure of the phase space, although it is important to keep in mind that this structure is different in kind from the sort of metric structure that is normally treated in geometry.

A symmetry of a Hamiltonian theory is a one-to-one mapping from the phase space onto itself that preserves the geometric structure of the phase space and the Hamiltonian. Because these latter two objects are smooth, it follows that symmetries are continuous and differentiable to all orders.

In the  $n$ -body problem, for instance, all symmetries are smooth maps from the phase space onto itself that correspond to some combination of the following actions: (a) shifting by some fixed amount the positions

of all particles in the Euclidean space in which they move; (b) rotating the orientation of the system of particles in Euclidean space by some fixed amount; (c) shifting the temporal origin by some fixed amount (that is, associating each state with the state that normally precedes or follows it by the given amount of time); (d) applying related discrete symmetries, such as a mirror reflection of the positions of the particles or an interchange of negative and positive senses of time.

Because each symmetry of a Hamiltonian theory leaves invariant all of the structure on the phase space that was used to define the dynamics, it also leaves invariant the curves that encode the dynamics—as we should expect from our general account of dynamic symmetries above. (The operation of a Galileian boost is not a symmetry in the present sense. Boosting a system does not leave its Hamiltonian invariant. A boost changes the kinetic energy of each particle and in general alters the total kinetic energy of the system, while leaving the potential energy of the system unchanged. But Galileian boosts do leave invariant the set of dynamic curves of the  $n$ -body problem.)

### NOETHER'S THEOREM

A remarkable consequence of the geometric structure of the phase space is that in any Hamiltonian system, the Hamiltonian is constant along each curve encoding the dynamics. That is, the total energy of the system is a conserved quantity of the dynamics: If one state evolves into another, each has the same total energy.

Are there additional conserved quantities—functions on our phase space that are constant along the curves encoding the dynamics? To find them, consider any one-parameter continuous family of symmetries of a Hamiltonian system closed under composition—such as the family of spatial translations by a varying amount in a given direction in the  $n$ -body problem. What happens if we allow such a family to act on a point in the phase space of a Hamiltonian system? To find out, we construct a curve in the phase space that describes how each symmetry in our one-parameter family acts on the initial state. By performing this operation for each point in the phase space, we construct partitions the phase space. For the sort of theories that arise in practice, we can then find a nice function on our phase space that the geometric structure associates with this family of curves. From the geometric structure and from the fact that the family of curves in question arises via the action of a family of symmetries that preserve the Hamiltonian, it follows that this function will itself be a constant of motion of the physi-

cal theory under consideration—that this new function, associated with our one-parameter family of symmetries, is constant along each of the dynamic curves associated with the Hamiltonian of our theory.

In this way, for any well-behaved Hamiltonian theory, we can construct a conserved quantity corresponding to each one-parameter family of symmetries of the theory. Indeed, we can find as many functionally independent conserved quantities as there are dimensions in the complete family of symmetries of the theory. In the case of the  $n$ -body problem, we find seven conserved quantities: the Hamiltonian, the components of the total linear momentum of the system, and the components of the total angular momentum of the system. These conserved quantities correspond, respectively, to the invariance of the system under time translations, to its invariance under spatial translations in each direction, and to its invariance under rotation.

These insights derive from work of Emmy Noether in 1918 (1971), though they assume a somewhat different form in her work, since she worked in the Lagrangian framework rather than the Hamiltonian framework.

## CONSERVATISM

Conservatives hold that the aim of political arrangements is to make a society good, that a society is good if those

living in it can make good lives for themselves, and that good lives are satisfying for oneself and beneficial for others. The political arrangements that make such lives possible are discovered by historical reflection, which discloses various enduring traditions. People participate in them because they conceive of good lives in terms of the beliefs, values, and practices these traditions provide. Conservatism is not an uncritical defense of all traditions but only ones that have endured because people have found participation in them satisfying and beneficial. The justification or criticism of traditions, therefore, is based on their success or failure in fostering good lives. Conservatism has different versions depending on the views held about history, values, the relation between individuals and their society, and between human nature and evil. Conservatives agree that these are the pivotal political topics and that political arrangements should be based on the views held about them, but they disagree about what these views should be.

## HISTORY

Conservatives believe that the starting points of political thought should be the prevailing political arrangements, rather than a hypothetical contract, a theory about an ideal society, a conception of the common good for all of humanity, or some basic value that always overrides any other value that may conflict with it. Some conservatives, however, believe that it is not a coincidence that certain political arrangements have been historically conducive or detrimental to good lives. They hold that there is a metaphysical explanation of their success or failure: the existence of a moral order in reality. Lives are good if they conform to this moral order and bad if they do not, and the same is true of political arrangements. These conservatives recognize that there are serious disputes about whether the order is (a) hierarchical—having The Good at its pinnacle, as supposed by the ancient Greek philosopher Plato, (b) providential, embodied in natural law, as held in the thirteenth century by Saint Thomas Aquinas and his many followers since then, or (c) an unfolding of the dialectic of clashing forces culminating in the final unity of reason and action, as claimed by Georg W. F. Hegel in nineteenth-century Germany. They nevertheless all assume that there is a moral order. Their task is to find out what it is, or, if it has already been revealed in some canonical text, to find out how it should be interpreted. Disputes about these matters are taken to show only the infirmity of human understanding or motivation, not that the existence of the moral order is doubtful.

The historical record of societies whose political arrangements have been based on a supposed moral order, however, is most alarming. They have tended to indoctrinate unwilling or uninformed people, leaving them no opportunity for choice. Such societies have not been freer of misery than less dogmatic ones. But they have added the misery peculiar to themselves of recognizing authorities who have claimed privileged access to the true and the good and thought that only human shortcomings stand in the way of good lives. This was taken by them to justify coercion, silencing dissenters, and indoctrinating the rest. Many conservatives, such as Edmund Burke in the eighteenth century and Michael Oakeshott in the twentieth, have rejected this approach to politics because of its grave dangers.

Other conservatives, such as the Frenchman Joseph de Maistre (1753–1821), deny that the right political arrangements can be justified by reason. It makes no difference to them whether the proffered reasons are metaphysical, scientific, or historical. They believe that all reasons are ultimately based on assumptions accepted on faith. Their rejection of reason as a guide, however, leaves them with the problem of deciding what political arrangements they ought to favor. The solution they have offered is to be guided by their faith and perpetuate existing arrangements because familiarity makes them safer than untried alternatives.

The problems of this approach are as evident from the historical record as those of the preceding one. Faith breeds dogmatism, persecution of those who hold other faiths or none at all, and it provides no justification for regarding political arrangements based on one faith as better than contrary ones based on other faiths. Moreover, the perpetuation of political arrangements on account of their familiarity makes their improvement virtually impossible because even flawed familiar ones will be judged preferable to dangerous unfamiliar possibilities.

An alternative to relying on a moral order or on faith is the fallibilism of the Frenchman Michel de Montaigne in the sixteenth century, the Scottish David Hume in the eighteenth century, and, closer to our times, George Santayana (1863–1952) and Oakeshott. They do not deny that there may be a moral order, only that reliable knowledge of it can be had. They find the historical evidence testifying to humans' fallibility much more convincing than the success of efforts to overcome it. They think that the claims of revelation, canonical texts, or putative eternal verities stand in need of persuasive evidence. But the available evidence is as questionable as the claims based

on it. Fallibilists believe that it is far more prudent to look to the historical record of various political arrangements than to endeavor to justify or criticize them by relying on metaphysical speculations or faith, either of which is more dubious than the historical record.

Fallibilism, however, does not commit conservatives to the denial that it is possible to adduce reasons for or against political arrangements. What they deny is that good reasons must be universal and timeless. They reject the fideistic repudiation of reason, accept the importance and desirability of being as reasonable as possible, and claim that political arrangements should be based on the historical evidence available for them. Fallibilists want political arrangements to be firmly rooted in the experiences of the people who are subject to them. Since these experiences are inevitably historical, it is to their history that these conservatives look for evidence. Thus they avoid basing political arrangements on metaphysical speculation about what lies beyond experience and suspecting reasonable evaluations because of a global distrust of reason.

It seems, then, that the most defensible conservative belief about history is the fallibilist one. There is a presumption in favor of the enduring political arrangements of a society because their endurance is *prima facie* reason for supposing that they foster satisfying and beneficial lives. In the absence of contrary reasons, the enduring political arrangements ought to be maintained. It is possible, of course, that the arrangements have endured because of coercion or manipulation. If the case for change is based on cogent evidence that the arrangements have endured for reasons other than fostering good lives, then it should be seriously considered. But if the case is inspired merely by metaphysical, contractarian, fideistic, or utopian speculations, then much stronger reasons are needed before they could mount a reasonable challenge to political arrangements that have stood the test of time and attracted the allegiance of many people.

## VALUES

Commitment to political arrangements that make good lives possible requires a view about what makes lives good. But there are countless valued activities, obligations, virtues, and satisfactions, countless ways of combining them and evaluating their respective importance, and so there seem to be countless ways in which lives can be good. Conservatives, therefore, must have a view about the diversity of values because the arguments for or against particular political arrangements depend on it. The problem is that there are three incompatible views

about the diversity of values: absolutist, relativist, and pluralist.

Absolutists believe that the diversity of values is apparent, not real. They concede that there are many values, but they think that there is a universal standard that can be used to rank them. This standard may be a highest value, such as Plato's Good; the tranquility of ancient Greek and Roman Stoics; the love of God postulated by Saint Augustine, the fifth-century Bishop of Hippo; or the idea of general happiness advanced by nineteenth-century English Utilitarians. Other values, then, can be ranked on the basis of their contribution to the realization of the highest value. Or the standard may be a principle, like the Ten Commandments of the Old Testament, the Golden Rule of the New Testament, or the categorical imperative formulated by the German philosopher Immanuel Kant in the eighteenth century. If a choice needs to be made among different values, the principle will determine which ought to take precedence. Contemporary absolutists—for instance, the English John Finnis, the American Germain Grisez, and the German-American Eric Voegelin—argue that some political arrangements are preferable to others because they conform more closely to the universal standard than the alternatives. However, the candidates for a universal standard are also numerous and face the same problems as the values whose diversity is supposed to be diminished by them. Absolutists acknowledge this problem and explain it in terms of human shortcomings that prevent people from recognizing the true standard. The history of religious wars, persecutions, and tyrannies, aiming to rectify human shortcomings, testifies to the dangers inherent in this explanation.

Relativism is opposed to absolutism. Relativists regard the diversity of values as real: There are many values; many ways of combining and ranking them; and there is no universal standard that could be appealed to in resolving disputes about them. A good society, however, requires some consensus about values, and political arrangements should reflect this consensus. If the consensus changes, the arrangements should change as well. According to relativists, then, what counts as a value and how important it is depends on the consensus of a society. A value is what is valued in a particular context; all values, therefore, are context-dependent.

Values and the political arrangements that reflect them can be reasonably justified or criticized, but, relativists believe, the reasons that can be given for or against them count as reasons only within the context of a society. Since reasons ultimately rest on the prevailing con-

sensus, they will not and are not meant to persuade outsiders. The ultimate appeal of relativists is to point at their arrangements and say: This is what we do here. If relativism takes a conservative form, as in Burke, or in the nineteenth-century Germans Johann Gottfried Herder and Wilhelm Dilthey, it often results in the romantic celebration of national identity, of the spirit of a people and an age, of the shared landscape, historical milestones, ceremonies, stylistic conventions, manners, and rituals that unite a society.

Relativism may seem to avoid the dangers of dogmatism and repression that threaten absolutism, but it is, in fact, equally prone to them. That the values of a society are not thought to be binding outside of it does not mean that the values of other societies will be regarded tolerantly. Because the world is full of people and societies whose values are inimical to the relativist's, there is good reason to guard jealously the relativist's values. Furthermore, if the justification of the values of a society is the prevailing consensus, then any political arrangement becomes justifiable, provided a sufficiently large consensus favors it. Slavery, female circumcision, the maltreatment of minorities, child prostitution, the mutilation of criminals, blood feuds, bribery, and any other noxious political arrangement may be exempted from censure on the grounds that it happens to be valued in its context.

These pitfalls of absolutism and relativism make them unreliable guides to the evaluation of political arrangements. It is with relief, then, that some conservatives in the last and present century—for instance, Oakeshott, Gordon Graham, and John Kekes—have turned to pluralism as an alternative to these flawed views. Pluralists are in partial agreement and disagreement with both absolutists and relativists. According to pluralists, there is a universal standard, but it applies only to values that must be protected by all political arrangements if they are to foster good lives. This standard is universal and minimal. It is possible to establish with reference to it some values required by all good lives, but not all the values that may make lives good. This leads to recognizing some political arrangements as necessary and to allowing a generous plurality of possible political arrangements beyond the necessary minimum. The standard accommodates part of the universalism of absolutism and part of the contextualism of relativism.

The source of pluralism's standard is human nature. To understand human nature sufficiently for the purposes of this standard does not require scientific research or commitment to some metaphysical belief or to natural law. It is enough for it to concentrate on normal people in

a commonsensical way. It will then become obvious that good lives depend on the satisfaction of basic physiological, psychological, and social needs such as nutrition, shelter, rest, companionship, self-respect, the hope for a good or better life, the division of labor, justice, predictability in human affairs, and so forth. The satisfaction of these basic needs is a universal requirement of all good lives, whatever may be their social context. If the political arrangements of a society foster their satisfaction, it is reasonable to support them; if they hinder their satisfaction, it is reasonable to reform them.

If absolutists merely asserted and relativists merely denied this requirement, then the former would be right and the latter wrong. But both go beyond this point: absolutists hold that all the values that make lives good are to be evaluated by a universal standard and relativists deny that there is any universal standard at all. Pluralists think that the minimum requirements of human nature set a universal standard, but beyond it there is a plurality of values, of ways of ranking them, and of good lives that embody these values and rankings. According to pluralists, then, the political arrangements of a society ought to protect minimum requirements of good lives and foster a plurality of values beyond the minimum.

The combination of pluralism and conservatism provides two important possibilities. The first is the justification of political arrangements that protect the minimum requirements and the criticism of political arrangements that violate them. This possibility sets the goal of political action and makes possible reasonable comparisons among different societies on the basis of how well they protect the conditions on which all good lives depend. This version of conservatism avoids the objection to relativism that it sanctions any political arrangement so long as a large consensus supports it. The second is that the best guide to the political arrangements a society ought to have beyond the minimum is the history of the society because it is most likely to provide the evidence for or against the prevailing political arrangements. This second possibility avoids the dangers of dogmatism and repression that beset absolutism.

The political arrangements favored by this version of conservatism are based on a familiar list of values: justice, freedom, the rule of law, order, legal and political equality, prosperity, peace, civility, happiness, and so forth. There is likely to be a significant overlap among the lists conservatives, liberals, and socialists may draw up. But there will also be a significant difference: conservatives are genuine pluralists, whereas the liberal and socialists are not. Liberals and socialists are committed to regarding

some of these values as more important than the others. What makes them liberals or socialists is their claim that when the values they favor conflict with others on the list, then the favored ones should prevail. If they did not claim this, they would cease to be liberals or socialists. Conservatives reject this approach. Their concern is to protect the whole system of these values. This sometimes requires favoring a particular value over another, sometimes the reverse. Conservative pluralists hold this to be true of all values. They differ from liberals and socialists in refusing to make an a priori commitment to resolving conflicts in favor of any particular value in the prevailing system of values.

### INDIVIDUALS AND SOCIETY

Good lives must be satisfying and beneficial, but these requirements often conflict because satisfying lives may not be beneficial and beneficial lives may not be satisfying. This raises the question of which requirement should be dominant, and it has far-reaching political consequences how it is answered. Some twentieth-century conservatives—for instance, Friedrich von Hayek, Shirley Letwin, and Robert Nozick—favor individual autonomy over social authority. Their position is virtually indistinguishable from classical liberalism or libertarianism. Other conservatives—such as James Fitzjames Stephen in nineteenth-century England, Voegelin, and the twentieth-century English thinker Roger Scruton—think that social authority should prevail over individual autonomy, if they conflict. As before, there is an intermediate view between these two extremes, namely, that of twentieth-century traditionalist conservatives, represented, among others, by Oakeshott, the American Edward Shils, and Kekes.

Conservatives who stress autonomy at the expense of authority face two serious problems. First, they assume that good lives must be autonomous and cannot involve the recognition of some form of authority over oneself. If this were so, no military or devoutly religious life, no life in static, traditional, hierarchical societies, no life that involves the subordination of individual will and judgment to what is regarded as a higher purpose could be good. This would require regarding of the vast majority of lives outside of modern Western societies as bad. The mistake involved is to slide from the reasonable view that autonomous lives may be good to the unreasonable view that a life cannot be good unless it is autonomous. Second, if a good society is one that fosters good lives, then the precedence of autonomy over authority cannot be right, since autonomous lives may be frustrated or harm-

ful. It is obvious that social authority must prevail over the autonomy of fanatics, criminals, fools, and so on.

The problems of authoritarianism are no less serious. There is no guarantee that if social authority prevails over individual autonomy, the resulting lives will be satisfying. Lives cannot be pronounced satisfying by some authority. Whether they actually are satisfying must ultimately be judged by the individuals themselves. Their judgments, of course, may be influenced by social authority. But no matter how strong that influence is, it cannot override the judgment of individuals in finding what satisfies them. As the lamentable historical record shows, however, this has not prevented countless religious and ideological authorities from stigmatizing individuals who reject their prescriptions as heretics, pagans, maladjusted, or sinful. The result is a repressive society whose dogmatism is reinforced by specious moralizing.

How, then, is the question to be answered? There is no need to insist that either individual autonomy or social authority should systematically prevail over the other. Both are necessary for good lives, but neither is sufficient. Instead of engaging in futile arguments about their comparative importance, it is far more illuminating to understand that they are interdependent aspects of the same underlying activity of individuals trying to make good lives for themselves. The connecting link between them is tradition.

A tradition is a set of customary beliefs and practices that have endured from the past to the present and attracted the allegiance of people so that they wish to perpetuate it. Traditions may be religious, horticultural, scientific, political, stylistic, moral, aesthetic, commercial, medical, legal, military, educational, architectural, and so on. They permeate human lives. When individuals aim at a good life, part of what they are doing is deciding which traditions they should participate in. They may make conscious, deliberate, clear-cut yes-or-no choices, or they may unconsciously, unreflectively fall in with familiar patterns, or they may be at various points in between. The bulk of the activities of individuals concerned with living in ways that strike them as good is composed of participation in the various traditions of their society.

Participation involves the exercise of autonomy. Individuals choose and judge; their wills are engaged; they learn from the past and plan for the future. But they do so in the frameworks of various traditions that authoritatively provide them with a range of choices, with matters that are left to their judgments, and with standards that within a tradition determine what choices and judgments are reasonable or unreasonable. Their exercise

of autonomy is the individual aspect of their conformity to their tradition's authority, which is the social aspect of what they doing. They act autonomously by following the authoritative patterns of the traditions to which they feel allegiance. When a Catholic goes to confession, a violinist gives a concert, or a football player scores a touchdown, then the individual and the social, the autonomous and the authoritative, the traditional pattern of doing it and an individual doing it are inextricably mixed. To understand what is going on in terms of individual autonomy is as one-sided as it is to do so in terms of social authority. Both play an essential role, and understanding what is going on requires understanding both the roles they play. Traditionalism rests on this understanding, and it is the political response to it to maintain political arrangements that foster participation in the various traditions that have endured in a society.

Traditions may be vicious, destructive, stultifying, nay-saying, and thus detrimental to good lives. Part of the purpose of political arrangements is to draw distinctions among traditions that are unacceptable (like slavery), suspect but tolerable (like pornography), and worthy of encouragement (like university education). Traditions that violate minimum requirements of good lives should be prohibited. Traditions that have shown themselves to make questionable contributions to good lives should be tolerated but not encouraged. Traditions whose record testifies to their importance for good lives should be cherished.

The obvious question is who should decide which tradition is which and how that decision should be made. Traditionalist conservatives say that the decision should be made by those who are legitimately empowered to do so through the political arrangements of their society and they should make the decisions by reflecting on the historical record of the tradition in question. From this three corollaries follow. First, those who are empowered to make the decisions ought to be able to view the prevailing political arrangements from a historical perspective. The process works well if it empowers people who are not ill-educated, preoccupied with some single issue, inexperienced, or have qualifications that lie in some other field of endeavor. Traditionalist conservatives are clearly not populists. Second, a society that proceeds in this manner is pluralistic because it fosters a plurality of traditions. It does so because it sees as the justification of its political arrangements that they foster good lives, and fostering them depends on fostering the traditions participation in which may make lives good. Third, the society is tolerant because it is committed to having as many traditions as

possible. Its political arrangements place the burden of proof on those who wish to proscribe a tradition. If a tradition has endured, if it has the allegiance of enough people to perpetuate it, then there is a *prima facie* case for it. That case may be, and often is, defeated, but the initial presumption is in its favor.

This outlook leads traditionalists to favor limited government. They do not think that the purpose of its political arrangements is to impose a conception of a good life. The political arrangements of a limited government interfere as little as possible with the traditions that flourish among people subject to it. The purpose of its arrangements is to enable people to live as they please, not to force them to live in a particular way. One of the most important ways of accomplishing this is to have a wide plurality of traditions as a bulwark between individuals and the government that has power over them. Traditionalist conservatives thus believe that a good society should have political arrangements that balance the claims of individual autonomy and social authority. This balance is maintained by the mediation of the traditions of a society that make autonomy possible and provide many of the forms it might take.

#### HUMAN NATURE AND EVIL

Conservatives tend to take a dim view of progress. They are not so foolish as to deny that great advances in pure and applied science have changed human lives for the better. But they have also changed them for the worse. Advances have been both beneficial and harmful. They have certainly enlarged the stock of human possibilities, but the possibilities are for both good and evil, and new possibilities are seldom without new evils. Evil is an obstacle to the betterment of the human condition. Unjust war, genocide, tyranny, torture, terrorism, the drug trade, concentration camps, racism, the murder of religious and political opponents, easily avoidable epidemics and starvation are some familiar and widespread evils. If evil is understood as serious unjustified harm caused by human beings, then the conservative view is that the prevalence of evil is a permanent condition that cannot be significantly altered.

The prevalence of evil reflects not just a human propensity but also a contingency that influences what propensities people have and develop. The propensity for evil is itself a manifestation of deeper, more pervasive influences, which operate through genetic inheritance, environmental factors, the crimes, accidents, pieces of good or bad fortune, the historical period, society, family, and so on. The same contingency also affects people

because others, whom they love, depend on, and with whom their lives are intertwined in other ways, are as subject to it as they are themselves.

Pessimistic conservatives, such as Thomas Hobbes in seventeenth-century England and Niccolo Machiavelli in sixteenth-century Florence, think that the prevalence of evil reveals that human nature is basically evil. Optimistic conservatives, such as Hume and Oakeshott, reject pessimism because they think that the right sort of political arrangements will make evil less prevalent. Opposed to both are realistic conservatives—for example, Montaigne, Stephen, and Santayana—who hold that whether the balance of good and evil propensities and their realization by people tilts one way or another is a contingent matter over which individuals and their political arrangements have insufficient control.

Realistic conservatives do not think that the human condition is devoid of hope, but they have no illusions about the limited control a society has over its future. Their view is not that evil propensities are uncontrollable. Rather, human beings have both good and evil propensities and neither they nor societies can exercise sufficient control to make good propensities reliably prevail over evil ones. The right political arrangements help of course, just as the wrong ones make matters worse. But even under the best political arrangements a great deal of contingency remains and it places beyond human control much good and evil. The chief reason for this is that the efforts to control contingency are themselves subject to the very contingency they aim to control. And that, of course, is the fundamental reason why realistic conservatives doubt the possibility of significant improvement of the human condition.

Realistic conservatives do not believe that it is a matter of indifference what political arrangements are made. Political arrangements cannot guarantee the victory of good over evil, but they can influence how things go. Whether that is sufficient at a certain time and place is itself a contingent matter insufficiently within human control. The attitude that results from realizing this combines the acceptance of the fact that not even the best political arrangements guarantee good lives with the motivation to make political arrangements as good as possible.

This view accounts for another significant difference between conservative and liberal or socialist politics: the insistence of conservatives on the importance of political arrangements that hinder evil. This difference is a result of the conservative rejection of the optimistic belief, shared by liberals and socialists, that the prevalence of

evil is the result merely of bad political arrangements, which tend to corrupt people, and if political arrangements were good, evil would be much less prevalent. Realistic conservatives reject this optimism. They do not think that evil is prevalent merely because of bad political arrangements. They ask why political arrangements are bad. And the answer must be that political arrangements are made by people, and they are bound to reflect the propensities of their makers. Bad political arrangements are ultimately traceable to evil human propensities. Since the propensities are subject to contingencies over which human control is insufficient, there is no guarantee that political arrangements can be made good. Nor that, if they were made good, they would be sufficient to hinder evil.

Conservatives insist, therefore, on the necessity and importance of political arrangements that hinder evil: moral education, the enforcement of morality, the treatment of people according to what they deserve, the importance of swift and severe punishment for serious crimes, and so on. They oppose the prevailing attitudes that lead to agonizing over the criminal and forgetting the crime, the absurd fiction of a fundamental moral equality between habitual evildoers and their victims, guaranteeing the same freedom and welfare-rights to good and evil people, and so forth. Conservatives think that the aim of justice is to uphold the rule of law that assures that people get what they deserve.

Political arrangements that are meant to hinder evil are liable to abuse. Conservatives know and care about the historical record that testifies to the dreadful things that have been done on the many occasions when such arrangements have gone wrong. The remedy, however, cannot be to refuse to make the arrangements; it must be to learn from history, and try hard to avoid their abuse. Conservatives know that in this respect, as in all others, contingency will be a permanent obstacle to success. But this is precisely the reason why political arrangements are necessary for hindering evil. Realistic conservatives face the worst and try to deny scope to it, rather than endeavor to build a Utopia on optimistic illusions.

## OVERVIEW

The most reasonable version of conservatism is fallibilist, pluralist, traditionalist, and realist. It avoids metaphysical and fideistic dogmatism. It denies that the content of good lives is given by a system of absolute values; accepts that good lives have some universal albeit minimal, requirements; and holds that some, but not all, values are context-dependent. It recognizes that both individual

autonomy and social authority are necessary for good lives, and resolves their conflicts by balancing their claims. It rejects both optimism based on utopian illusions and pessimism that registers only human corruption. It sees human nature as having both good and evil propensities and strives for political arrangements that foster the first and curb the second. Conservatism is a view of politics guided by history and aiming at the betterment of society within the limits set by the contingency of life and human imperfection.

## CONSTRUCTIVISM, MORAL

Moral constructivism is a metaethical view about the nature of moral truth and moral facts (and properties), so called because the intuitive idea behind the view is that such truths and facts are human constructs rather than objects of discovery. More precisely, constructivism involves both a semantic thesis about moral sentences and a two-part metaphysical thesis about the existence and nature of moral facts and properties. According to the semantic thesis, ordinary moral sentences purport to be fact-stating sentences and thus purport to be genuinely true or false. And, according to the metaphysical thesis, there are moral facts whose existence and nature are in some sense dependent upon human attitudes, agreements, conventions, and the like. Thus, constructivism represents a metaethical view in partial agreement with versions of moral realism. Like the realist, the constructivist is a so-called cognitivist (descriptivist)—moral sentences have descriptive content and thus purport to be genuinely fact stating. Again, like the realist, the constructivist accepts the view that there are moral facts that serve as the truth makers of true moral sentences. But unlike the realist, the constructivist rejects the idea that there are moral facts (and properties) that are independent of human attitudes, conventions, and the like.

It is useful to distinguish between simple and sophisticated versions of constructivism as well as between non-relativist and relativist versions. Simple versions of constructivism are represented by certain views that would construe moral truth in terms of the actual attitudes of individuals or actual agreements within cultures about matters of moral concern. More sophisticated versions of constructivism construe moral truths (and associated moral facts and properties) in terms of the hypothetical attitudes of individuals or perhaps hypothetical agreements among members of a group reached under suitably constrained circumstances. Nonrelativist versions of constructivism maintain that all individuals and groups whose attitudes, agreements, and so forth provide the basis for moral truths and facts do or would accept the same set of basic moral norms with the result that there is a single set of moral truths and facts. Usually, such views are wedded to some version or other of sophisticated constructivism.

Thus, a version of the ideal-observer view of moral truth—according to which basic moral truths are represented by the moral norms that would be accepted by an ideal observer, where the notion of an ideal observer is so characterized that all ideal observers will agree on the same set of basic moral norms—is a version of sophisticated nonrelativist constructivism. Relativist versions of constructivism allow that there may be more than one individual or group with differing attitudes and agreements that serve as the basis for different (and conflicting) sets of basic moral norms. Versions of moral relativism, according to which moral truths and facts are a matter of what basic moral norms a culture in fact accepts, represent versions of simple, relativistic constructivism; versions of relativism, according to which moral truths and facts are a matter of what would be accepted under conditions that are ideal for choosing such norms, represent sophisticated relativistic versions of constructivism. Versions of the ideal-observer view are relativistic if they allow that there can be ideal observers who would accept different (and conflicting) sets of moral norms. So-called Kantian constructivism of the sort elaborated and defended by John Rawls, which appeals to choices made by hypothetical individuals behind a veil of ignorance (a version of contractarianism), is yet another sophisticated and apparently nonrelativistic constructivist view.

Constructivism, at least in its sophisticated versions, is supposed to capture what is plausible about moral realism, leaving behind what is problematic about realist views. Thus, constructivism can accommodate quite well

certain “objective pretensions” of commonsense moral thinking. Some of these pretensions have to do with the form and content of moral discourse. A good many moral sentences are in the declarative mood (e.g., “Abortion, except in cases of rape and incest, is wrong”) and are thus naturally interpreted as genuinely fact-stating sentences. Moreover, some such sentences appear to make references to (putative) moral facts and properties (e.g., “The evil of American slavery was partly responsible for its demise as an institution”). Other objective pretensions have to do with such activities as moral deliberation, debate, and argument. These critical practices are seemingly aimed at arriving nonarbitrarily at true or correct moral views, ones that would ideally resolve intrapersonal and interpersonal conflict and uncertainty about moral issues. Like realism, constructivism is attractive in apparently being able to accommodate such objective pretensions of ordinary moral discourse. Moreover, it attempts to accommodate these features without endorsing the sorts of metaphysical commitments to independently existing moral properties and facts countenanced by the realist. In short, at least certain versions of constructivism boast a robust notion of moral objectivity without problematic metaphysical commitments.

One serious challenge to constructivism is represented by the argument from moral error. According to constructivism, moral truths and associated facts are to be understood in terms of the attitudes and agreements of individuals and groups. However, if we take ordinary moral discourse and argument seriously, then since such discourse and argument presuppose that there are right answers to moral questions whose correctness outstrips any actual or even ideal set of attitudes or agreements, the constructivist view cannot be correct. To understand this objection more clearly, it will be useful to distinguish between basic and nonbasic moral truths and facts. Basic moral truths and facts are of a quite general sort, properly expressed by moral principles, and are the direct objects of choice by those under ideal conditions of moral thought and deliberation. Nonbasic moral truths and facts are those truths and facts that, in some sense, follow from the basic ones together with nonmoral information.

Now the constructivist can allow for certain sorts of errors in moral judgment. For instance, simple moral relativism can allow that individuals and groups can be mistaken about particular moral judgments owing to misinformation about particular cases or perhaps to faulty reasoning from basic moral principles to concrete cases. This kind of moral relativism, however, cannot allow for error at the level of actual agreements, since

such agreements constitute basic moral truths. The sophisticated constructivist can allow for error at the level of communal agreement, since it is possible on such views that the actual agreements of actual groups are at odds with those hypothetical choices constitutive of moral truth on this sort of view. However, the sophisticated constructivist cannot allow for error at the level of choice made under ideal conditions—call this “deep moral error.” After all, the constructivist construes such choice as constitutive and not just evidence of basic moral truths and facts. But, so the objection goes, given our critical practices, we can sensibly raise questions about the truth of those moral principles and norms that are chosen under ideal circumstances. This indicates that moral truth is one thing and the norms and principles chosen even under the most ideal of circumstances is another. Hence, constructivism, in both its simple and sophisticated versions, is not acceptable.

In response, the constructivist can perhaps block the argument from moral error in the following way. First, the constructivist can note that it is dubious that our critical practices presuppose that deep moral error—error at the level of choice under ideal conditions—is possible. After all, our commonsense critical practices are not finely tuned to subtle differences in metaethical positions, and, in particular, common sense does not (so the constructivist might plead) make any distinction between the sort of realist objectivity that presupposes the possibility of deep moral error and a kind of constructivist objectivity that denies this possibility. Can we, for instance, really make sense of the idea that we might be mistaken about such basic moral principles as one that prohibits torture for fun? Furthermore, the constructivist can question the basic move featured in the argument from moral error—that is, the move from (1) it is quite sensible to raise questions about choices that purport to be made under ideal conditions to (2) an explanation of this phenomenon requires moral realism. Granted, the supposed gap between the truth of moral principles on the one hand and choice of such principles under ideal conditions on the other is one way to explain how we can sensibly raise questions about the truth of moral judgments made under ideal conditions, but this is not the only way to make sense of such critical stances.

The constructivist can note that in the context of everyday discussion where we have to judge whether or not to accept the moral judgments of others, one can sensibly raise questions about some judgment by raising questions about the judger herself. After all, whatever is involved according to the constructivist in being ideally

well situated for choosing basic moral principles, it is not likely to involve features of the judger and her situation that are easy to detect. For example, part of being ideally well situated would seem to require having all sorts of factual information, being free from certain forms of bias, and properly weighing the interests of parties affected by the choice of principles. But it is difficult to determine that someone has satisfied these and other relevant desiderata for being well situated. So, even if it is not possible for someone who really is well situated to be mistaken in moral judgment, it is possible for critics who acknowledge that such error is not possible to raise sensible questions about the truth of a person’s moral judgment. Hence, although the constructivist cannot allow for the possibility of deep moral error, she can plausibly argue that our commonsense critical practices do not presuppose that deep moral error is possible. Moreover, she can go on to accommodate the idea that it makes sense to criticize those who are ideally situated. The constructivist, it would appear, can plausibly respond to the argument from moral error.

## CONSTRUCTIVISM AND CONVENTIONALISM

“Conventionalism” and “constructivism” are kindred, often overlapping positions, asserting that the subject matter of some area of inquiry is not fully mind-independent. Conventionalism and constructivism are not well-defined names of positions but labels adopted—as often by critics as by advocates—to emphasize one positive aspect of positions in a wide range of areas; consequently, these terms group together a variety of positions with varying motivations. In general, the label “conventionalism” is applied to positions that claim the truths in some area are so in virtue of the conventions of a linguistic or conceptual scheme, while “constructivism” emphasizes that a position assigns to the cognitive faculties of humans some role in “making” the objects or facts in the area in question.

### CONVENTIONALISM

Conventionalists claim either that the truths of some subject matter—such as mathematics or logic, or of a certain sort, such as necessary truths, or some dispute, such as whether Euclid’s parallel postulate holds of our physical world—are matters of convention rather than of how the world is independent of mind. Some extreme versions of conventionalism take the fact that it is a matter of convention what our words mean (we could have used *cat* to designate Napoleon Bonaparte) to show that all truth is conventional. However, its being a convention that “Napoleon” names Napoleon hardly makes it conventional that Napoleon was defeated at Waterloo. An interesting conventionalism must assert something more than the conventionality of word meaning and must rest on something more than wild inference from it.

One area in which conventionalism is familiar, though controversial, is necessary truth. This was one cornerstone of logical positivism; from the seeming a priori nature of necessary truths, the positivists argued (some would say claimed) that since a priori knowledge cannot be of (mind-independent) facts, necessary truths must be analytic, which they understood as true by definition. Given that mathematics is also a priori, their argument was applied there as well. This sort of epistemological argument is typical of conventionalist views: Arguing that our methods for ascertaining what is so in some area could not give us knowledge of a mind-independent world, they claim that this knowledge would not be problematic on the assumption that what is fundamentally under investigation are our conventions. Some

sorts of conventionalism are also supported by metaphysical considerations such as naturalistic concerns about what, in the mind-independent world, could make for the relevant sort of truth. This sort of argument is common to necessary truths, mathematics, ethics, and other areas with normative import; plainly, such arguments need to be supplemented with an account of how it is that conventions can provide the relevant features.

Saul Kripke’s arguments that there are necessary truths that are a posteriori—and, so, not analytic—seemed to some to undermine conventionalism about necessity (Kripke 1980). It has, however, been argued that conventions could explain the necessity of these truths without the truths themselves being analytic—that is, true by convention (Sidelle 1989). This may indicate that in general conventionalism, with respect to a subject matter, does not require that all target truths themselves be analytic but only that conventions be responsible for the features that purportedly cannot be adequately handled within a realistic interpretation.

Aside from the claim that certain truths are so by convention, another common conventionalist position is that some dispute is a conventional rather than factual matter. Jules Henri Poincaré’s famous conventionalism about geometry is of this sort. He claims that the choice among systems of geometry, for describing the physical world, is not an issue of which is true but of which is most convenient or useful. By adopting any of them, we could modify our physics so as to have equally full and correct descriptions of the world; indeed, this last claim is the basis for his view that the issue is conventional rather than factual. Rudolf Carnap offers a similar view about ontological disputes between, for instance, phenomenalists and materialists. Both of these views illustrate that “conventional” does not as such imply “arbitrary,” as pragmatic differences may be quite genuine; we can also see that the plausibility of conventionalism in some area depends largely on how implausible it is to claim that the issue, or truth in question, is a matter of mind-independent fact.

On a more local level, some disputes can appear “purely verbal,” as perhaps whether some politician is conservative. When this is plausible, the issue may be said to be a matter of convention or choice rather than fact. The conventionalism of Poincaré, Carnap, and others is akin to this, only in a wider application. In book 3, chapters 7 and 11, of his *Essay*, John Locke speculates that many of the “great disputes” are of this sort.

As applied to areas in which the truths are well established (mathematics or logic, for instance), conventional-

ism is fundamentally a deflationary interpretive position, urging that we not mistake the metaphysical status of these truths. Applied to areas of controversy—ontological or essentialist claims, or whether whales are fish—conventionalism claims that disputes here can only be over what our conventions in fact are, or what they should be, either pragmatically or perhaps morally. In either case, if conventionalism is right, our focus and methods of investigation—and certainly our understanding of what is at stake—for the questions at hand would probably require alteration.

## CONSTRUCTIVISM

Thomas Kuhn, by virtue of his *The Structure of Scientific Revolutions*, may be considered constructivism's leading protagonist of the mid-to-late twentieth century, despite not adopting the label himself and expressing unease at having it assigned to him. He writes of scientists within different paradigms—roughly, methodological and theoretical traditions or frameworks—as studying different worlds and of their paradigms as in “a sense ... constitutive of nature” (Kuhn 1970, p. 110, chaps. 10, 13), at least suggesting a constructivism about the world studied by science. Kuhn's major concerns are epistemological; he argues that scientific procedure is deeply theory laden and encodes ontological and theoretical commitments that it is incapable of testing. How, then, can such a method give us knowledge of the world? Those who see a constructivist in Kuhn have him answer that the world under investigation is itself partly a product of the investigating paradigm. This puts Kuhn in the tradition of Immanuel Kant, except that the features we “impose” upon the phenomenal world are not (as for Kant) necessary for the possibility of experience, but, rather, contingent features of current science. It is important to note that, even as interpreted, this constructivism does not have scientists making the world out of whole cloth with their paradigms; rather, there is something mind-independent that “filters through” the conceptual apparatus of the paradigm. This is a central difference between constructivism and idealism. The object of scientific study is, however, not this mind-independent world, but rather that which results “through the filter.”

Other philosophers, as well as historians and sociologists of science, have taken the supposedly arational or nonobjective features guiding scientific judgment to establish that scientific truth is relative to one's background theory or paradigm. This is sometimes then articulated as the view that these theories or paradigms in part “make” the objects of study—that is, as constructivism.

Indeed, many positions that formerly would have simply been called relativist came, in the late twentieth century, to be called constructivist by their protagonists; arguments in their support tend to be of the familiar relativist sort and thus have the same strengths and problems. It should be noted that neither constructivism nor conventionalism need take a relativistic form.

Another philosopher associated with constructivism is Nelson Goodman, due largely to his *Ways of World-making*. Goodman argues that no sense can be made of the notion “the (one) way the world is”; rather, there are lots of ways the world is, depending on the conceptual apparatus one brings. This sort of position is found in many philosophers since Kant, often argued on the trivial ground that one cannot describe or investigate the world without using a system of representation, therefore (*sic*) the world investigated is not mind-independent but partly constructed by our conceptual scheme. This is sometimes added to, or confused with, the relativistic considerations mentioned above. What needs to be explained is how we are supposed to get this substantive conclusion from the banal premise. Why can't the objects represented by the elements of a system of representation—by the name “Tabby,” say—be wholly and utterly mind-independent? And even if we add the fact that there can be different schemes of representation, why can it not simply be that they pick out different features of a mind-independent reality? What gives Goodman his special place is that he supplements this argument with the claim that different schemes may be such that their claims conflict with each other, but there can be no grounds for maintaining that one is correct and the other not. Goodman uses as examples the claims that the planets revolve around the sun and that the sun and other planets revolve around Earth. Both, he claims, must be judged as correct (within the appropriately formulated total systems), but they cannot simply be seen as two notationally different descriptions of a single world (thus differing from Poincaré's conventionalism). The success of this argument depends on whether one can simultaneously make out that these claims genuinely do conflict with each other and that, so understood, neither of them can be judged to be true while the other is false.

## PROSPECTS

While both Kuhn and Goodman offer relatively global constructivist positions, there are constructivists about essences, moral and aesthetic properties, mathematical objects, and in principle anything. The same is true of conventionalism. Both conventionalism and construc-

tivism are motivated primarily by negative considerations against a realistic understanding of the subject matter in question; this is sometimes supplemented with positive arguments that by understanding the matter as concerning our conventions or choices we can get a better explanation of the phenomena at hand. Often, the negative arguments are very quick and fail to fully consider the range of options available to realists (Scheffler [1966] presents good discussion), and sometimes they fail to consider whether their positive proposals actually fare any better. Plainly, the plausibility of these positions depends on how well these arguments can be made out, and this may vary drastically across the different subject matters for which conventionalist and constructivist proposals have been offered. Additionally, if these positions are even to be candidates for serious consideration, defenders must be prepared to offer further proof. Conventionalists must specify some sense in which that which is purportedly so by convention would have been otherwise had our conventions been different, and constructivists must describe some sense in which the purportedly constructed objects would not have existed without our input.

## CONTENT, MENTAL

Beliefs, desires, perceptions, and other mental states and events are said to possess content. We attribute such states and events with sentences such as

(1) Arabella believes that the cat is crying.

(1) contains a propositional attitude verb ("believes") and a sentence complement ("the cat is crying"). The verb specifies a type of mental state (belief), and the complement sentence indicates the content of the state. On most accounts this content is the proposition expressed by that sentence. Propositions have been variously conceived as abstract entities composed of modes of presen-

tation, sets of possible worlds, sets of synonymous sentences, and structured entities containing individuals and properties. All these accounts agree that propositions determine truth conditions. Some mental states and events (e.g., desiring to visit Paris) seem to have contents that are not propositions. However, for most of the current discussion, contents will be identified with propositions and contentful mental states with mental states that possess truth conditions.

Both natural-language sentences and mental states possess contents. The relation between content properties of the two items is controversial. Some philosophers think that natural-language expressions derive their contents from mental states, while others hold that, at least in some cases, the dependency goes the other way. In any case, it is plausible that there are mental states whose contents cannot be expressed or cannot be completely expressed by sentences of English (or other natural languages). For example, the full propositional content of a person watching the sun set is only partially captured by an attribution such as “A sees that the sun is setting.” Also, some of the states posited by cognitive psychology and the mental states of animals plausibly have contents that fail to correspond to any contents expressible in English.

Content apparently endows mental states with a number of remarkable features. First, they or their constituents refer to extramental reality. When a person perceives that the sun is setting her perception refers to and thus puts her into contact with the sun. Second, they seem to be essentially normative. For example, a person ought to believe that the sun is setting only if the sun is setting, and if she believes that the sun is setting she ought not believe that the sun is not setting. Third, they apparently cause other mental states and behavior in virtue of their contents. For example, Arabella’s belief that the cat is crying causes her to feed it. Fourth, a person can apparently know the contents of her own thought a priori and with an authority available only to her.

It is difficult to see how anything can exemplify all these features. The problem is especially difficult for philosophers who endorse naturalism, the view that all genuine properties are constituted by or realized by properties that are mentioned in true theories of the natural sciences. Content properties are *prima facie* so different from physical and biological properties as to raise the question of whether they are natural properties.

Hilary Putnam (1975) and Tyler Burge (1979) described thought experiments that have been taken to have important consequences for the nature of mental contents. Putnam imagined two thinkers, Oscar and

twin-Oscar, who are identical with respect to their intrinsic neurophysiological properties but whose environments differ. Specifically, Oscar shares our environment, but twin-Oscar lives on twin-earth where the abundant substance that quenches thirst, fills the twin-earth oceans, and so forth is not H<sub>2</sub>O but XYZ. H<sub>2</sub>O’s and XYZ’s superficial properties are identical, and the two substances are indistinguishable without chemical analysis. Putnam claims that, while Oscar’s sentence “Water is wet” and the thought he expresses with it are about H<sub>2</sub>O, the same sentence in twin-Oscar’s language and the thought he expresses with it are about XYZ. The two thoughts differ in their propositional contents, since one is true if and only if (iff) H<sub>2</sub>O is wet and the other iff XYZ is wet. Putnam supports these conclusions with the intuition that, were Oscar and twin-Oscar to learn that the substances each refers to with the word *water* differ in their chemical natures, they would agree that their utterances of “Water is wet” possessed different truth conditions.

Putnam’s thought experiment has been taken to establish the truth of content externalism, the thesis that the individuation conditions of mental content are partially external to the thinker. The point generalizes to other mental states whose contents are the same as the contents of sentences containing natural-kind terms such as *water*. Burge described further thought experiments that he thinks show that practically all thoughts expressible in natural language are externally individuated, and others have argued that all mental states that express extramental truth conditions are externally individuated (LePore and Loewer 1986).

Some philosophers (Fodor 1987, Loar 1987) react to content externalism by granting that mental states possess externally individuated contents but adding that they also possess narrow contents that are not externally individuated. Oscar’s and twin-Oscar’s beliefs possess the same narrow content. Philosophers sympathetic to narrow contents raise a number of considerations. One is the Cartesian intuition that thinkers in the same intrinsic state have the same mental lives. It seems essential to our conception of a mental life that it possess content, so there must be some kind of content that such thinkers share. The other consideration is that the causal powers of Oscar’s and twin-Oscar’s mental states seem to be, in an important way, the same. Jerry Fodor (1987) claims that if these causal powers involve the states’ contents, then that content must be narrow.

Whether or not these considerations are persuasive, it has proved difficult to formulate a satisfactory notion of narrow content. If natural-language sentences express

only externally individuated contents, then we do not attribute narrow content with sentences such as (1). While identity of intrinsic neurophysiological states is sufficient for identity of narrow content, it is not a plausible necessary condition. To adopt it as such would make it enormously unlikely that two people have ever shared the same narrow content state and impossible for a state to maintain its content in the course of reasoning. While some proposals for necessary and sufficient conditions for identity of narrow content have been forthcoming (Fodor 1987), there is little agreement concerning whether they are correct or, for that matter, whether a notion of narrow content is even needed.

Externalism seems to be in tension with our having a priori knowledge of the contents of our thoughts (Boghossian 1989). If the content of the thought (e.g., that water is wet) is individuated in part by external factors, then it seems that a person could know that she is thinking this thought only if she knows that those external factors obtain, and thus it is implausible that such knowledge is a priori. One response to this is to grant that we have a priori knowledge only of narrow contents. But a number of philosophers (Burge 1988, Warfield 1994) have responded that the tension is only apparent. Burge claims that judgments of the form "I am now thinking that water is wet" are self-verifying, since one cannot make the judgment without thinking the thought that the judgment is about. If this is correct, then externalism and a priori knowledge of content are not always incompatible. But such self-verifying thoughts seem to be a very special case of the thoughts whose contents we seem able to know a priori. It is likely that little progress concerning the epistemology of content can be made without an account of the nature of contentful mental states.

The dominant view in the philosophy of mind is that contentful mental states are functionally individuated internal states. Some philosophers (Dretske 1981, Fodor 1987) posit that these states are partially constituted by mental representations that are the bearers of propositional content. Mental representations are conceived of as picturelike (mental images), maps, or linguistic expressions. One view (Fodor 1979) is that mental representations are expressions in a language of thought, *Mentalese*. On this account thinking that the cat is crying involves tokening a *Mentalese* sentence with the content that the cat is crying. The thought inherits its content from the semantic properties of its constituent sentence, which in turn obtains its content from the semantic properties of its constituent expressions. Fodor identifies concepts with *Mentalese* expressions. So, for example, possessing the

concept cat is being able to token a *Mentalese* expression that refers to cats. Some philosophers (Peacocke 1986) have argued that the contents of perceptual states are nonconceptual. If so, then the contents of these states are not borne by *Mentalese* expressions.

The nature of the bearers of mental content is best seen as an empirical issue. Fodor (1987) cites the fact that thought is productive and systematic as support for the language-of-thought hypothesis. Productivity is the capacity to produce complicated thoughts by combining simpler thoughts, and systematicity involves being able to think thoughts that are systematically related to each other, as are the thoughts that Bill loves Newt and that Newt loves Bill. Fodor argues that the language-of-thought hypothesis provides the best explanation of these phenomena, since languages are productive and systematic. Further, cognitive scientists have constructed theories of cognitive processes, language comprehension (Pinker 1994), perception (Marr 1982), and so forth that involve subpersonal contentful mental representations. For example, on one such theory understanding a natural-language sentence involves tokening a representation of its grammatical structure. These representations are not accessible to consciousness and have contents that are not usually available as the contents of a person's beliefs.

There have been various attempts to specify conditions in virtue of which mental states or mental representations possess their contents. Some of these are attempts to naturalize content properties. Following are brief descriptions of the main proposals.

According to interpretationist theories (ITs; Davidson 1984, Lewis 1974) our practices of interpreting one another partially constitute the contents of mental states. On Donald Davidson's approach interpretation is constrained by principles of rationality and charity. These principles say, roughly, that a person's mental states are generally rational and her beliefs are generally true. According to Davidson the evidential base for an assignment of contentful mental states to a person consists of her dispositions to hold true sentences under various conditions. She believes that  $p$  (desires that  $p$ , etc.) iff assignments of content to her sentences and to her mental states that systematize these holding true dispositions and that conform to the principles of charity and rationality assign to her the belief that  $p$  (desire that  $p$ , etc.).

On ITs, content properties are holistic, since whether or not a person exemplifies a particular contentful mental state depends on what other mental states she exemplifies and on their relations to each other and to environmental conditions. Davidson's IT is externalist,

since a state's content is partially determined by relations to environmental conditions. But his account does not provide a naturalistic account of content, since it explains content in terms that presuppose content: holding true, rationality, truth. The primary difficulty with extant ITs is their vagueness. No one has formulated the principles of rationality and charity with sufficient clarity to permit an evaluation of proposed ITs.
