religions is, if not a new issue, one that is coming into increasing prominence. Hick (1989) has done much to draw attention to it. He argues that it is not plausible to suppose that one traditional form of religious experience is veridical while others are not, and he tries to articulate a way in which many apparently conflicting forms could all be at bottom veridical, proposing to regard them as apprehending different “phenomenal” manifestations of a single “noumenal” transcendent “reality.” Not that Hick thinks all religious beliefs equally acceptable; the main criterion he proposes for the value of religious traditions and belief systems is their fruitfulness in producing morally and spiritually recognizable saints, people notably advanced in a transformation from self-centeredness to Reality-centeredness. Among the issues in the vigorous debate about Hick’s view are the adequacy of the conceptual apparatus he borrows from Immanuel Kant and whether it is compatible (as he means it to be) with a fundamentally realist and cognitivist conception of religious belief.

## PHILOSOPHY OF RELIGION [ADDENDUM]

Philosophy of religion has recently focused on a range of issues regarding God: semantic (concerning the meaning of the term *God*), metaphysical (concerning the reality and attributes of God), epistemological (concerning justified belief and knowledge regarding God's reality), and ethical (concerning the bearing of God on personal and social morality and the meaning of life). The entry by Robert M. Adams illustrates some of these issues; longer representative discussions can be found in William E. Mann (2005) and William J. Wainwright (2005). Another area of recent philosophy of religion concerns whether, and if so how, claims regarding God fit with the natural sciences. With growing recognition that the natural sciences are not deterministic, many philosophers have found room for a God who freely acts in history and in

human lives (see Draper [2005] and the exchange between Worrall and Ratzsch [2004]).

The term *God* joins *religion* as among the most elusive in English. Its uses are remarkably diverse, and this contributes significantly to the difficulty in settling many apparent disagreements regarding God. If I use the term *God* in one way, and you use it in a different way, then we may find ourselves appearing to disagree about God but actually talking at cross-purposes. For example, if I use the term in such a way that God is capable of suffering, rejection, and even incarnation, but you do not, we will diverge significantly in our questions and answers regarding God. The underlying semantic divergence regarding *God* will yield, sooner or later, divergence in claims deemed acceptable or true regarding God. As a result, philosophical illumination of one's concept of God continues to serve a valuable purpose.

One important semantic lesson is that the term *God* is typically used as a title rather than as a personal name (on which see Pike 1970). Such use can easily avoid begging the question whether God exists. The title *God* can have an intelligible use even if no one satisfies the title. The title *God*, however, does not enjoy just one understanding among its users, even its philosophical users. For instance, some philosophical writers use the title to connote a timeless transcendent agent, whereas others allow for a God in time.

Philosophers of religion have recently pursued the following longstanding question: What cognitive support, if any, is there for the claim that God exists? The question attracts a wide variety of interpretations of *cognitive support*. The most familiar understanding of cognitive support is in terms of evidence, that is, what indicates, even if fallibly and nondeductively, that a proposition is true. Evidence for the claim that God exists indicates, perhaps fallibly and only probabilistically, that it is true that God exists. Evidence can come in differing strengths and can enable a claim to be beyond reasonable doubt.

### DIVINE HIDDENNESS

We can now approach the problem of *divine hiddenness* that is beginning to occupy many philosophers of religion: If God exists, why do not all competent people have evidence that makes it beyond reasonable doubt for them that God exists? Many competent people claim not to have adequate evidence (for reasonable belief) that God exists. Some philosophers, however, deny that an all-loving God would be hidden in a way that permits rea-

sonable doubt about God's existence (see Schellenberg 2004).

### FREEDOM RESPONSE

Proponents of the Freedom Response to divine hiddenness maintain that God hides to enable people freely to love, trust, and obey God (see Hick 1985, Murray 2002). Seeking to form truly loving relationships with people, God does not coerce people to respond in a particular way. As an all-loving being, God hides to avoid coercing people to respond, and some philosophers hold that this allows for inculpable nonbelief regarding God's existence. The Freedom Response, however, prompts this question: Could not God supply less obscure self-revelation without abolishing our freedom in responding to that revelation? God could, evidently, be significantly less hidden while preserving our freedom to deny that God exists. Some revelations of God's power would overwhelm us in a way that removes our freedom, but the removal of divine hiddenness seems not to require any such overwhelming revelation.

### PROPER-MOTIVATION RESPONSE

A second response to divine hiddenness, the Proper-Motivation Response, implies that God hides to discourage a human response based on improper motives (see Pascal 1995, Swinburne 1992). According to this response, God's self-revelation without hiding would prompt us to selfish fear or arrogance. Aiming to discourage such fear and arrogance, God hides and, according to some philosophers, thereby allows for inculpable nonbelief regarding God's existence. However, the Proper-Motivation Response must face this issue: Could not God supply a less obscure self-revelation without eliciting improper motives in our response to that revelation? Must a world where God is less obscure be less susceptible to human pursuit of God that is humble and passionate? The mere fact of less obscurity in God's self-revelation seems not to undermine humble and passionate seeking after God. God could readily promote such seeking in a setting of less obscure divine revelation.

### HIDDENNESS AND SIN

A third response to divine hiddenness is that human sinfulness accounts for typical failure to appreciate the evidence of God's reality through creation, history, and conscience (see the discussions in Moroney 2000, Plantinga 2000). Some proponents hold that every competent adult who does not believe that God exists culpably fails to believe and thus that there is no need to explain how

an all-loving God could allow for inculpable nonbelief that God exists, at least among competent adults. The main problem with this response is that it offers no straightforward way for itself to be justified. We seem to lack the needed avenue to evidence to infer that, with regard to every person who does not believe that God exists, that person is culpable, owing to sin, for nonbelief. Some people cannot plausibly be diagnosed so readily.

### MULTIPURPOSE RESPONSE

A fourth response to divine hiddenness, the Multipurpose Response, acknowledges that God has various purposes in hiding and that we are not in a position to identify all of God's specific purposes in hiding (see Moser 2002). Divine hiding is sometimes a constructive effort on God's part to encourage (deeper) human focus, longing, and gratitude toward God. God thus aims to take us to our own deepest resources and their ultimate inadequacy, where we acknowledge our needing God at all times. In apprehending God's absence, we can achieve a deeper appreciation of God's presence. According to the Multipurpose Response, occasional divine hiding occurs in the context of God's main desire to have people lovingly know God and thereby to become loving as God is sacrificially loving. According to this response, God's primary aim is to include all people in God's kingdom family as beloved children under God's lovingly righteous guidance. So, God wants humans to love God and thus to treasure God, not just to believe, however reasonably, that God exists. Mere reasonable belief that God exists will not meet God's primary aim for humans. For our own benefit, according to this response, God is after something more profound and more transforming than simple reasonable belief that God exists.

### COGNITIVE IDOLATRY

If we reject or neglect transformation toward God's character of sacrificial love, we may be blinded by our own counterfeit "intelligence" and "wisdom." We will then lack the kind of filial obedience and humility appropriate to relating, cognitively and otherwise, to God. We will then have assigned the authority of God to ourselves or to some other part of creation. We would then be guilty of idolatry, the mistake of exchanging God's rightful authority for a false authority. We commit cognitive idolatry when we demand a certain sort of knowledge or evidence of God inappropriate to a filial relationship with God (on which see Moser 2002). We thereby run afoul of God's rightful authority in the cognitive domain. The Multipur-

pose Response implies that we are in no position to demand that God be revealed in a particular way.

The problem of divine hiddenness has affinities with the traditional problem of evil. One might think of inculpable nonbelief as a certain sort of evil that would not exist if there were a loving God. In any case the problem of divine hiddenness occupies many philosophers of religion in ways that bear on epistemology, semantics, and metaphysics.

## PHILOSOPHY OF RELIGION, HISTORY OF

It is not easy to say when strictly philosophical thought about religion began, for religion has always involved thought or belief of some kind. Even in other fields much of our thought is incipiently philosophical, but this is much more so in an interest that tends to be all-embracing. Religion has always had a cognitive factor, observances of various kinds had a meaning and these would often be of a far-reaching kind, involving beliefs about an afterlife or the influence upon us of beings other than those who inhabit this world. At what stage such beliefs come to be questioned, and not just accepted as a matter of course or tradition, is difficult to determine. But there is evidence of early questioning of this kind, and of the consequent defense and speculation, in some cultures, for example in India. It is a moot point how much of this we would consider strictly philosophical. But it is certain that the period, from the eighth to the fourth century BCE, which saw such an upsurge of intellectual interest and culture simultaneously (and seemingly without much mingling of cultures) in different parts of the world, produced philosophical thought of a very explicit kind, including philosophical reflection about religion.

### EASTERN TRADITIONS

**HINDUISM.** Perhaps the earliest example of philosophical reflection about religion is found in the *Upaniṣads*. These were committed to writing about the eighth century BCE but they reflect much that had been going on before. They are part of the corpus of Indian sacred writings known as the *Vedānta*. Even the earliest and simplest of these contain distinctive and shrewd anticipations of the views about life and the universe that came to be explicitly formulated in the *Upaniṣads*, and it would thus be misleading to say that religious thought began in India with the composition of the *Upaniṣads*. But it is in the body of writings known by that name that we have the first sustained and deliberate thought about religion in a form that has affinity with what we know as philosophy.

The *Upaniṣads* vary much in quality and purpose. There is also much variety within their more strictly philosophical content, but the dominant theme is that of the unity of the universe. This is sometimes thought of in a sense that eliminates all plurality, anticipating much that some mystics have held at later times. For others "the One" is involved in all things in a way which is transcendent and absolute but which leaves it vague what status is

to be accorded to finite things. This comes closer to the way God's transcendence has been understood generally in Western thought. But on occasion the *Upaniṣads* venture to be more explicit; some of their themes come close to those of G. W. F. Hegel and of post-Hegelian idealists in the nineteenth century; there is a clear insistence on the interdependence of whole and part in an all-inclusive system of reality, and this led also to speculations about the nature of the system and the function of the parts within it which suggest much that we read in idealist writings in our own times. There are also parts of the *Upaniṣads* that come closer to the Western notion of God as creator of a world of beings distinct from Himself and from one another. This is not unlike Christian theism and, in this respect, some passages of the *Upaniṣads* anticipate much which has since been central in Christian thought.

"The One breathed breathless" is a typically cryptic summing up of much of the teaching of the *Upaniṣads*. What it expresses is the profound and persistent sense of some ultimate nature of reality which escapes our understanding. The world does not wholly explain itself, it is rooted in mystery, and this means more than that there are things which are beyond our particular understanding at a certain time. All things point beyond themselves to a mystery that is in principle beyond our grasp or to some unity of things in the universe which is in some way more complete and final than the interrelations of things as we trace them in our normal understanding of the world. This is the significance of the terms that occur so often in Indian thought—"not this, not that" and "I am that." In this context these reflect a sense of some ultimate transcendent reality which is very vigorously presented in the *Upaniṣads* and whose implications are sometimes very explicitly set forth. It is indeed a very significant fact that there should be so shrewd a philosophical grasp of this notion at such an early date, and this makes the *Upaniṣads* a work of considerable significance for our understanding of religion in general. They contain also much explicit philosophical argument that is highly relevant to philosophical controversies about religion today. This covers many aspects of religion besides those that directly concern the dominant theme of the unity of all reality.

The *Upaniṣads* contain also much reflection upon our practical attitudes. This tends to be of the "world-denying" type and severely ascetic; that is not surprising where the dominant theme is the ultimate oneness of all things. But we find also in the *Upaniṣads* much emphasis on social service, on compassion, virtue, and welfare.

Even if the views adopted on such matters seem to Western eyes too strictly determined by the sense of ultimate union with the whole, and even if it is true, as even some leading Hindus have stressed, that the otherworldly feature of Indian religion has led to apathy and indifference to present concern, there is also much to be learned from the insights we find in the *Upaniṣads*, as in later Indian thought, about the true nature of compassion and selflessness.

**DAOISM AND CONFUCIANISM.** Not much later than the time the *Upaniṣads* were committed to writing, there appeared in China philosophical teaching and writing about religion which had also at the center of it a sense of some ultimate unity of all reality. This is the essential significance of the doctrines of Dao (expounded in the *Dao-de Jing* traditionally ascribed to Laozi—born 604 BCE—and in later writings like those ascribed to Liezi and Zhuangzi); and this in turn reflects a generally more basic notion that lies behind most early Chinese thought about religion, the idea of a "heaven and earth relationship." What this implies is that there is some character of reality beyond what we find in the world around us but which cannot be explicitly defined or grasped. We can only know it in its requirements and in the sense of some kind of justice operative in the universe at large. The "beyondness" of the power which works for righteousness in this way is deliberately softened; it is almost as if it could only be known from within. But this is itself a very significant fact, and the elusiveness of the influence to which our lives are subject in this way in Chinese thought is no mean indication of the subtleness of their philosophical and religious insights. It has in fact led sometimes to the view that Chinese religion, and especially Confucianism, is entirely a moral or religious system. That impression could easily be derived from *The Analects* of Confucius (551–478 BCE), since they are concerned mainly with ethical and social matters, especially those which concern the appropriate "orders" in society. But Confucianism is in fact extensively determined and overlaid by notions like that of a heaven and earth relationship mentioned above. The distinctive thing, for philosophy, about early Chinese religion and thought about religion is the shrewd sense that the nature of what lies beyond present existence and gives it meaning is best discerned by following a Way or path. The goal is, as it were, best reflected for us in the way it is to be attained. If this is not the whole truth, it is a significant pointer to it.

**BUDDHISM.** At a slightly later date we have the founding of the Buddhist religion in India. This led to the compo-

sition of the Pali Canon, containing, it is alleged, the substance of the teaching of Buddha. The canon was closed in the reign of King Aśoka (273–231 BCE) but not committed to writing until the first century BCE. It is not implausible to conclude that it does reflect fairly closely the actual teaching of the historical Buddha. The Pali Canon is of exceptional interest to philosophers today. It contains acute philosophical thinking, and some incline even to think of Buddhism as being more a philosophical system than a religion. That is certainly a mistaken impression, but we have in Buddhism a very shrewd grasp of the nature of religion as philosophy illuminates it. The purport of this has often been grievously misunderstood, not least in the assumption that Buddhism is a religion without God. The mystery of transcendent being is at the center of Buddhism and has remained so through most of its history and in its many varieties. This may not take quite the same form as in the West or find closely parallel expressions elsewhere, but it is unmistakable to anyone who knows his way about the subject.

A peculiarly distinctive feature of the doctrines of the Pali Canon is the subtle understanding of the difficulty of characterizing a reality that is “beyond” in the sense in which the infinite must be. It is in this context that we are told that we must not say that God exists or that He does not exist. At one point we have a list of sixty-two typical metaphysical questions that must not be asked. This is closely in line with much that has been maintained today in various forms of antimetaphysical philosophy, and it is strange how little appreciation there has been, on the part of recent positivists and agnostics, of how much grist of a sort there is to their mill in the doctrines of the Pali Canon. But it might all the same not be grist they could altogether accept, least of all if they fully grasped its implications in its contexts. For here we have skepticism and positivism with a difference. It springs less from a radically empiricist outlook than from a profound sense of the elusiveness of transcendent reality, and this makes much of the teaching of the Pali Canon uniquely relevant to philosophical controversies about religion today. The account of such matters as Buddha’s enlightenment reinforces this, for while this can plausibly in fact be given an atheistic interpretation, it does point suggestively to a subtle grasp of the transformation of present reality through the invasion of it by a reality of an entirely different order which beggars all description. In these and kindred ways the Pali Canon, like related further aspects of Buddhist and of Hindu thought, has close and instructive points of affinity with the cruxes of religious thought today; and this is being increasingly understood by some experts in this field.

**PHILOSOPHERS.** There has been a long line of impressive Asian thinkers who have attempted variations and refinements on the themes just outlined. Among the most important are Śankara (c. 788) and Rāmānuja (c. 1017). In recent times the more traditionalist type of Hindu thought is well represented in the works of Radhakrishnan, while we have in the very liberal writings of Śri Aurobindo an attempt at reform that is sharply opposed to the objectionably otherworldly aspect of Hinduism and that tries to come to grips with the notion of some divine disclosure which leaves the individual a free and responsible creature.

## GREECE

In the Western tradition philosophy begins with the Greeks, and to give a full indication of the course of religious philosophy in the West would be to outline the main continuous progress of philosophy from the Greeks to the present day. For almost all the main philosophical notions and the main divisions of opinion in philosophy (realist, nominalist, idealist, and so forth) have entered into religious controversy in one way or another. The matters that can be noted in the remainder of this entry must thus be highly selective.

**PARMENIDES AND HERACLITUS.** In Greek thought, as in that of the Orient, there has been a central preoccupation with the problem of the one and the many. In the work of Parmenides this took a very distinctive and influential form. He proceeded by way of analysis of the nature of thought. This he found to involve predication, the affirmation of one thing about something else. To think is to say of an identifiable *A* that it is *B*; it is some relating of terms in a system that makes the relations possible. But there is an element of exclusion in such predication. If I say that this book is blue, that precludes its being black, although of course it says nothing about its being round or square, etc. All determination, as it is put, is negation. But does not this raise peculiar problems? For negation seems to be some odd sort of affirmation of what is not the case. It appears thus to deal with what is not. But what is not, Parmenides thought, is just altogether unreal—and no one can think or affirm this. But if negation becomes impossible in these ways, affirmation appears also to stand condemned, and there seems thus to be something radically unsatisfactory about thought itself and about the world as thinking apprehends it. Parmenides concluded that it was a mistake to suppose that the universe was a system of terms in relation, of the many which change and come into being and go, and that we must therefore think of all reality as one undifferenti-

ated whole—conceived by him also as a sphere extending in the same way in all directions. There was given in this way a logical form to a profound religious sense of some ultimate all-embracing unity.

By contrast we find, in the work of other Greek philosophers, an emphatic insistence on the reality of the here and now and the world of variety and change. Protagoras took this to the length of insisting, in anticipation of much later empiricism and relativism, that nothing is real except as it appears. Neither the external world nor our moral ideas have any independent or objective reality; and this view of things received distinctive expression also in the thought of Heraclitus, who insisted that all things were in flux and that “we cannot step twice into the same river.” But this was supplemented by Heraclitus by the notion of a pattern of change in which some principle or “logos” was expressed. For him, as for Parmenides, this carried with it a poetically mystical religious undertone. The idea of fire, as a central element, functioned as a symbol of that.

PLATO. In due course Plato was to take up the problems presented in the way described above. He carefully restated and developed the difficulties that troubled Parmenides and Heraclitus and started a program of reconstruction by dealing firmly with the problem of negation. He observed that this does not involve reference to a wholly unreal, to mere nothing. It could be amply provided for within the notion of terms in relation, for to say that something is not is just to say that it is other than something else, to indicate precise location within a system of interrelations. But if thought, as involving determination of this kind, is to function accurately, the system within which it operates must be a strict and tight one. Where is this to be found? Plato thought he found it preeminently in mathematics, and he thus came to regard mathematics as the true propaedeutic to philosophy and a paradigm of its method. The realities which could be properly thought and known had thus to be quasi-mathematical ones, and they consisted of general forms or principles which were real in their own right and bestowed on all other things whatever reality those could properly claim. This left Plato with the hard problem of accounting for the particulars and the changing course of things in the world, and it is not certain that he arrived at a view of this question which contented him. He sometimes spoke of particulars imitating the forms and sometimes of their participating in the reality of the forms, but the individual and unique existent had never more than a problematic place in Plato’s philosophy.

Difficulties also arose in yet another way, for even in its more rarefied instances, as in mathematics, there appears to be something essentially inadequate about the process of relating terms in a system. Every relation, including the relation of whole to part, seems to require yet another, or another system, to make it possible. All explanations of one thing in terms of others leave us with further questions and matters unexplained—there is no natural limit to the process of thought—and for the Greeks in particular that which is without proper limit is unsatisfactory—evil, they said, is of the infinite. Plato was led in this way to the notion of some yet more perfect reality, some quite different mode of unified existence in which present imperfect relatedness disappeared, and he held that everything had its reality exhaustively determined by this ultimate nature of the universe. To this he gave the name “the Good,” and he declared that, in the sense indicated, this Good was “beyond being and knowledge.” He did not mean that it was not real, or a mere notion—far from it. But it could not be given the sort of determinate existence and intelligibility which we ascribe to the sort of entities our minds can understand and encompass.

This is the first explicit formulation in Western thought of the idea of transcendence as it came to dominate much subsequent thinking. It is evident that it owes much, not only to Parmenides’ puzzles about predication and nonbeing, but also more directly to Parmenides’ insistence on some ultimate all-encompassing unity of being. But it does not involve the elimination of all plurality. When his system seems to involve that, Plato turns back on himself in vigorous protest—as in the famous passage in the *Sophist* where he insists that there must be “place in that which is perfectly real” for “change, life, soul, understanding.” The specific forms, metaphysical as well as mathematical, had their place in the one universe in which everything derived its significance from the central all-encompassing reality of the good, and these forms lent some sort of reality to the particulars and to individual lives in the normal sense. The relation of particular to universal and of this to the Good, the ultimate supreme reality, may not have been worked out in a satisfactory way. But at least we have the notion that all we find in the world derives eventually from some one transcendent source in which all imperfection is resolved.

The formulation of these ideas owed much to the influence upon Plato of the Eleusinian mysteries and Orphic cults with which he came into contact—and also to the religiously orientated teaching of Pythagoras. In turn, it affected his teaching on what may appear to be

more specifically and recognizably religious conceptions, like his doctrine (in the *Timaeus* and the *Laws*) about the Demiurge who fashions the world according to the eternal patterns and his belief in preexistence and immortality. But it is not primarily in what he says about these more conventionally religious notions that Plato shows his main penetration or had his more abiding influence on religious thought. His notion of a system of forms held together in the transcendent unity of the Good was a more radically instructive and formative notion—although the teaching of the *Laws* and the *Timaeus* prescribed much of the form of later natural theology. It accorded best also with the element of mysticism which tempered the rationalism of his precursor to whom he was deeply indebted, namely Socrates. It is thus in the notion of the Form of the Good that Plato comes nearest to the idea of God in subsequent theism, but his approach to the subject left him no way in which his supreme and central principle of the Good could acquire the character of a person. That was precluded by the severely rationalist nature of Plato's main approach to his task and the consequent exclusion of any kind of revelation of an active concern, which could only be mediated through the actual particulars of life and history that figured in such an ambiguous and unimpressive way in Plato's philosophic outlook.

ARISTOTLE. Our next main landmark is the philosophy of Aristotle. He did not separate the universal as completely as Plato did from the particular, although it is a moot point, still much debated, how ultimate is the difference between Plato and Aristotle here. But the difference did lead in due course to notions of the union of form and matter and of mind as the informing principle of the body by which much subsequent thinking on questions of this kind was directed. For Plato the properly mental side of human life was sharply separated from the body, and along with this went a low estimate of the body—although the body was not thought to be evil, as in much subsequent teaching. The mind is apt to be thought of by Plato as imprisoned in the body and awaiting its release. On the slant given to the subject by Aristotle there is a much closer integration of mind and body and this has been the model for a great deal of later thinking about human personality and the belief in resurrection. The mind is thought to require at least some kind of body, and there are philosophers who regard mind and matter as coextensive in the universe in general. Others have taken the Platonic lead in propounding a very sharp dualism of mind and body.

In strictly religious matters the difference between Plato and Aristotle here seems to become narrow; for although we have no strict equivalent to the Form of the Good in Aristotle or the same insight into the transcendent character of the ultimate religious reality, we do have an "Unmoved Mover" whose relation to the course of events He affects is a somewhat remote and detached one. The God of Aristotle is little involved in the world; it would have been a sign of inferiority and imperfection for Him to be so. This reflected a typically Greek attitude. To be affected by something external to your self is an indication of weakness, and in Aristotle's ideal of the "Great-Minded Man" this is very marked—he will not be cruel to his inferiors just because they are beneath such notice.

The Stoics came later to pride themselves on their independence and self-sufficiency. Likewise the God of Aristotle is absorbed in contemplation of His own perfection; He takes no overt interest in other things, but He moves all other things by attraction. This is in sharp contrast with subsequent Christian teaching and represents the main way in which Christianity is "foolishness to the Greek." But the idea of an Unmoved Mover did nonetheless have a very extensive influence on later religious thought: It provided the model for the famous causal arguments for the existence of God. We have somehow to account for the world, and since we cannot account for it in terms of the way events determine one another within the world, we must have recourse to some altogether different mode of determination and explanation; and in due course this consideration became one of the main ways in which religious thinkers presented the idea that the world as we find it is dependent on some reality which is altogether "beyond" or transcendent. Here, as elsewhere, Aristotle determined very closely the style, if not always the substance, of later religious arguments.

This is evidenced specially in the way some of the further leading notions of Aristotle's philosophy, such as his distinction of potential and actual and his analysis of four types of cause and his notion of substance, became formative ideas in the religious thinking of later Christian times. It is in these ways, more than by very distinctively religious insight, that Aristotle made his main contribution to the philosophy of religion.

There is one further notion of great importance which had its place in Aristotle's system and became subsequently very influential. It is the idea of a law of nature. At times this was understood in a very relativistic way. To "follow nature" was taken to mean abiding by your own whims or impulses. It was sharply contrasted with con-

vention, and the latter came to be much derided in some quarters in the period after Aristotle and Plato in Greece—indeed earlier to some extent among the Sophists. Here we see again, in an extreme form, the ideal of being self-sufficient. This was carried by some of the Cynics and Epicureans and the early Stoics to the extent of trying to “return to nature” and doing without society and its irksome restrictions altogether—a cry that was sounded vigorously again in the seventeenth century. But it came to be realized that this policy led to absurdity and chaos, in personal life and in society; and thus the idea of “Nature” underwent complete transformation—it came to be taught that there was a nature to the universe at large (“Nature” with a capital N, as it were) and that this disclosed itself to men’s reason. This led, in the fusion of the idea of law of nature with the Roman idea of a “law of nations,” to the conception of a number of basic moral principles which were bound up with our rational nature and which, for many, further owed their firmness and objectivity to their foundation in the ultimate nature of the universe. This notion had a long and varied history and played a very important part in Christian accounts of morality and its relation to religion. It has a close affinity with the teaching of early Chinese religions and the notion of some power from beyond the world working for righteousness within it and prescribing our basic moral principles. Reflection upon this affinity can be very fruitful in seeking the way forward with such problems in the way they present themselves today.

#### EARLY AND MEDIEVAL CHRISTIANITY

The thought of early Christian times was extensively affected by Greek philosophy. This is evident even in the New Testament itself, not only in the way its authors write about matters like soul and body, but also in the central theme of “the Word” or Logos which became flesh. The Greek notion of Logos provided the basic concept in terms of which the doctrine of the Incarnation was to be understood. Directly, the concept of Logos came into philosophical thought in Christian times from the Stoics, for whom it meant originally an immanent World-Soul. But it was later combined with the Platonic idea of *nous* and so was conceived as acting in accordance with archetypal patterns. The basic problem was how is it possible to have knowledge of a strictly transcendent being, and for this a solution was sought in terms of an intermediary, in this case a logos, which was also induced in due course to fill other roles and help in the solution of further problems. These procedures came into Christian thought in the first place through the work of a gifted Jewish

philosopher of the first century, namely Philo, and it had a prominent place in the subsequent Christology of formative thinkers like the Alexandrians, of whom Origen has most interest for philosophers. But what we have in the main during early Christian centuries is not so much philosophy of religion in the strict sense as theological writings that make extensive use of philosophical concepts. There were also some theologians of this period, as there have been of later times, who resented the intrusion of philosophy into the domain of faith. Of these the most outstanding was Tertullian.

The main exception to the normal course of thought in the early Christian period was Neoplatonism. Here we revert again to a profound sense of the Oneness of the Universe in a way that puts particulars and plurality in jeopardy, as they had been to some extent in the philosophy of Plato. But some account must be given of particulars, and there was developed in this way the difficult notion of emanation. God is the ultimate unity and He transcends all the categories of thought, but finite beings exist in the form of some falling away from the original perfection. This comes to terms in some fashion with the facts of finite existence and the reality of evil that occupied the minds of thinkers of this period a great deal. But it is very hard to make sense of the notion of emanation without calling in question the all-embracing nature of the one ultimate reality. The insistence on the latter notion did, however, influence the course of mystical thought and practice extensively. It also led, as in the case of Oriental mysticism, to attempts to draw away altogether from our present existence, with its limitations and evil, and to pass beyond the world of intellect as well as sense into total union with ineffable Being.

In sharp contrast to this teaching we have the position of thinkers who reflected anew on the significance of the Hebrew-Christian doctrine of creation. The Hebrews had come early to understand the elusive and transcendent character of God, and this had found very remarkable expression in parts of the Old Testament, the most famous passage here being the story of Moses at the burning bush. But this carried with it in Hebrew thought a subtle appreciation of the way a true discernment of God’s transcendence required the recognition of our own distinctness as beings dependent on God. This sharpened, however, the question how such beings could in any way come to know God. The Hebrew answer was in terms of God’s disclosure of Himself in history and experience, and this was deepened and extended in specifically Christian claims about the work and person of Christ. In this context the problem of revelation becomes a crucial one,

and it has remained at the center of Christian philosophy at all times except when insistence on the distinctness of faith precluded all rational consideration of it.

**AUGUSTINE.** Preoccupation with the way human beings, being finite, can come to know an Infinite Being lies at the center of the more specifically philosophical parts of the writings of Augustine. In his attack on the problem Augustine gives prominence to our reflection on what we find our own souls to be like as a clue to our understanding of the relation of God to the world. He set the pattern for much subsequent reflection on our own nature and started a concern for the inward aspect of personality which persisted through formative later thinkers, such as René Descartes and George Berkeley, to such nineteenth-century theologians as F. R. Tennant and the phenomenologists and existentialists of the present day. This side of Augustine's achievement is, however, often obscured by another. For although he emphasized the distinctness and freedom of finite beings, he came in another way to put these ideas in considerable jeopardy. In seeking to account for the redemptive work of Christ he posited the notion of an initial abuse of man's freedom leading to subsequent enslavement to sin. This gave considerable impetus to a doctrine of the Fall which, although not prominent in this form in earlier Christian times, became a central theme of much later theology and Christian profession of faith. The personal experiences of Augustine and his African background are thought to have greatly influenced his view in these respects, and there have certainly been voices, like those of Pelagius in his own time and Abelard later, raised in sharp protest against the rigors of the Augustinian doctrine of humanity's sin. The doctrine of the Fall has also been invoked to simplify the problem of our knowledge of God by blunting the strictly epistemological character of the problem; this came about through emphasis on the way our own allegedly corrupted nature made us spiritually blind and stood in the way of a vision of God. In the same context the idea of a law of nature became the idea of what is practicable in the present sinful state of humankind and society by contrast with the ideal law of God. This distinction was given much prominence by St. Augustine and has been reaffirmed, in the sense in which he understood it, by his most notable followers to the present day.

**ANSELM.** The question of particulars and universals became prominent again in the controversy of realism and nominalism in the early Middle Ages. It had many implications for religious thought. For example, the view that individuals do not exist in themselves was thought to

culminate in pantheism in the sense that "all visible things pass into intellectual, and intellectual into God." This period also saw further attempts to provide a rational defense of the faith, although without denying that faith had a firm foundation of its own. An outstanding feature of this activity in philosophical thinking is the formulation of the Ontological Argument by St. Anselm. This was intended to show that sound understanding of the idea of God yields us the necessity of His existence. The idea of God, it was urged, is the idea of a being than whom nothing greater can be conceived. But a being that does not exist is inferior to one who has the additional attribute of existence. Many changes have since been rung on this argument and it is being much canvassed at the present day.

**THOMAS AQUINAS.** The most impressive achievements of the Middle Ages in religious thought came about initially through the work of Muslim scholars (Mohammad al-Ghazali and Averroes in particular) who were much concerned about the question of reason and revelation in their own faith. Among these there had also been preserved important works of Greek philosophy, especially those of Aristotle, which were not properly known by Christian scholars. There came about in this way a revival of the study of Aristotle and a new concern about the way a transcendent being could be known by limited finite ones. This culminated in the very comprehensive work of St. Thomas Aquinas, which ranged over most religious questions, seeking a synthesis of religious claims and established philosophical principles. It set up firmly one of the main forms of natural theology. For Thomas this covered two things. First we have the attempt to establish the existence of God by argument. This took the form of the famous "Five Ways." The first three of these are variations on the Cosmological Argument, as the term came to be used in due course. They seek to pass from the limited or contingent nature of finite things to an ultimate First Cause or Ground. The least elaborate, and also the most plausible, is the third way, which proceeds directly from the contingency of the world to its absolute Source without presupposing any particular view of cause and effect as we understand it. This argument, in one form or another, has been central to a great deal of subsequent philosophy of religion. Many hold today that it gets us at least very near the truth about the initial relation of God to the world and the way we know this. The other two "Ways" depend on notions of a scale of being and value and on the adaptation of things to their purposes, which are at least alien to the way we normally think about the world today—though they have their defenders.

The second prong of natural theology was that which sought, through an extremely subtle and cautious doctrine of analogy, to determine the attributes of God more precisely. It was urged that we cannot know God as He is in Himself, we can only know that He must be; and because God is a transcendent Ground of all things, He cannot be mirrored in the world He has made in the way an effect normally tells us something about its cause. Thomas and his followers were therefore well aware of the need to move very circumspectly here, and what they maintained was that God must be thought to have certain attributes, like goodness or power, in whatever way is necessary for Him to be the Author of those in the form in which they appear in the created world. In presenting this doctrine some very careful distinctions were drawn between various types of analogies. The main difficulty which this approach involves is that of determining whether anything of substance is added in this way to what is originally claimed in regarding God as a transcendent Being. There is in any case needed in addition extensive recourse to revealed truth to supply the particular affirmations of a faith like the Christian one. These truths of faith could not, according to Thomas, conflict with the truths of reason, but they go beyond them.

**WILLIAM OF OCKHAM.** The most formidable opponent of natural theology was William of Ockham, who questioned the ability of natural reason to discover in any measure the inscrutable will of God or reduce the mystery of transcendent being. His methods of procedure, involving the reduction of our postulates to the minimum that the facts require, anticipates many features of modern thought where skepticism about affirmations and alleged entities which pass beyond the facts of sensible experience and science is sometimes combined with a dogmatic affirmation of faith in which reason plays no part.

## MODERN PHILOSOPHY

Outstanding formative philosophers of the modern period, roughly the last five hundred years, were of two main sorts, rationalists and empiricists. The former, including Descartes, Benedict de Spinoza, and Gottfried Wilhelm Leibniz, had great confidence in the power of reason alone to establish ultimate metaphysical truths.

**RATIONALISM.** Descartes claimed to prove his own existence by the power of reason alone and drew a sharp distinction between mind and body. He then sought, by severely rational arguments, to prove the existence of God. Two of these arguments invoke the causal principle,

although they require also our having the idea of God; the third is a special form of the Ontological Argument; it contends that if we think of a being who does not exist we are withholding from our conception of it a "perfection," namely existence, which is essential to our conception of a perfect being. These arguments are not usually thought to succeed as they stand, but they can nonetheless be thought to be significant as indications of the insight into there having to be an ultimate reality in which essence and existence are one. They also illustrate the futility of seeking to establish the existence of such a being by arguments involving consideration of what limited finite things are like. Descartes's causal arguments are particularly illuminating in this way, as he imports into his premises, at every step in an elaborate argument, certain considerations derived from the notion of an infinite being which it is the aim of the argument to defend.

A further feature of Descartes's work is the insistence on the freedom of the individual—"liberty of indifference." This is bound up with the insistence on the distinctness of persons as nonmaterial entities. The same theme is taken up in Leibniz's monadology, in which every being is a distinct mental monad. But the genuineness of our freedom is jeopardized by Leibniz in his doctrine of preestablished harmony and the way each monad consistently unfolds in its history some destiny which its own nature prescribes for it from the start. In the ingenious monistic system of Spinoza freedom comes to be thought of in terms of accepting our place and destiny in the universe with adequate understanding and forbearance rather than in the form of genuine "liberty of indifference." Descartes's doctrine of the self as a distinct mental substance has been subjected to considerable criticism from time to time, not least at the present day. But there are many also who consider it an essential ingredient in a sound understanding of the relations of God to man and who stress, as did Descartes, the "interiority" and unextended character of the mind.

**EMPIRICISM.** Empiricism inclines to skepticism and is severely skeptical in its stricter forms. The great British empiricists did not all hold to their principle with the same consistency. We find John Locke departing from his avowed aim of showing that knowledge derives from sense impressions, not only in his theory of knowledge and his account of material and mental substances, but also in his expressly religious thought where he claimed, for example, that the existence of One Infinite Mind can be proved with the same certainty as we find in mathematics. There is much in fact in Locke's presentation of the causal argument in Chapter X, Book IV, of his *Essay*

*concerning Human Understanding* that has close relevance to controversies about the subject today. Likewise Berkeley, while dispensing with the notion of independent material substances, found in his account of the world of nature as dependent on its being perceived a firm foundation for the belief in a Divine Being on whose Mind the whole world of nature depends. To Berkeley we owe also a subtle appreciation of the distinctiveness of the way minds are known and the essential inwardness of personality which is so central a feature of religious philosophy today.

David Hume, however, was little attracted to these compromises and, although he confessed to some admiration for the argument which seeks to prove God's existence from the evidence of design in the universe, he adhered generally to a ruthlessly empiricist position. This involved total skepticism about God, immortality, and all properly religious notions. Hume contended that religion had started in a thoroughly naturalistic way with the personification of natural objects and so forth and that only at a late and sophisticated stage of culture did people arrive at some unification of religious notions and the belief in one God. His presentation of this view is delightfully lucid and it set the pattern for much of the anthropological treatment of religion later in the nineteenth century. In Hume's *Dialogues* there are also canvassed some of the main arguments that are used to support or reject religious beliefs, ranging from the general belief in God to belief in miracle.

**KANT'S CRITICISMS.** The "critical" philosophy of Immanuel Kant sought to arrest the skepticism of Hume without retreating to the strict rationalism of Descartes and his followers. Kant's main contention was that the sort of experience of the world which we undoubtedly have presupposes a unified world of objects presented to an abiding subject. The modes of unification thereby involved, the necessary conditions of experience, provided a new basis for confident belief in causality and substance, though not in the same sense as that of Descartes; but it was also implied that knowledge is confined to the world of our experience and the principles involved in this, sometimes thought to be imposed by the mind itself. This did certainly yield us the belief in an unobservable subject of experience, but nothing could be known of this beyond its being required to account for the sort of knowledge we have of the external world. There was also a tendency to isolate this inner self so completely from the external world of known reality that the functioning of the "pure self," especially as will or

active agent, became very hard to conceive and set for Kant some of his main difficulties, especially in his ethics.

The limitations involved in the alleged "critical" account of knowledge were, however, extensively corrected by Kant in his insistence that we have certain grounds for "faith," which supplements what we can strictly know. These grounds of faith are found in the operation of our practical reason or moral awareness which sets before us certain moral obligations, largely in the form of strictly universal rules, which have in turn far-reaching implications. It was urged, for example, that there is a moral requirement that justice be rewarded, but that, since the ethical motive would be impaired if we set our own happiness as the aim of moral actions, God must be postulated to guarantee the eventual relation between happiness and virtue in the universe. Freedom and immortality were similar postulates of practical reason. These contentions have been subjected to much criticism, and doubt has been cast on the success of even the limited undertaking of postulating certain principles of a unified world of experience. Religious thinkers have urged that "faith" in its Kantian form has little in common with properly religious faith and that the severely rationalist character of the appeal to postulates of practical reason neglects the distinctively religious element in religious belief. On the other hand the prominence given to moral considerations in religious thought has been widely welcomed, and many writers have sought to provide versions of the moral and teleological arguments which are not open to the difficulties of those provided by Kant.

**IDEALIST RESPONSES TO KANT.** A great deal of post-Kantian philosophy was concerned with the gap in the Kantian system between the world as we apprehend it and the ultimate or "noumenal" reality of the world as it really is. For Kant these tended to be two separate worlds, but many thought this unsatisfactory and sought in various ways to understand the ultimate reality or "thing-in-itself" as some completion of the world as we find it—a notion that is in many ways anticipated in some of Kant's own reflections. There were thus initiated various metaphysical enterprises concerned especially with finding within the world of our own experience some reliable clue to the nature of the universe as a whole. The most influential of these was that of Hegel, who found the ultimate principle of reality in reason. We cannot exhaustively understand the universe but the universe is in principle capable of being understood through and through as a system where everything has its place and nature determined by rational necessity. Others (like

Arthur Schopenhauer) gave to will the preeminent place as a metaphysical clue.

There were many variations on these themes in the nineteenth century, including the work of British idealists such as Thomas Hill Green, F. H. Bradley, and Bernard Bosanquet and of American thinkers such as Josiah Royce. Idealism became the dominant philosophical view, and within the perspective of it many views were advanced about the relation of God to the world, taking distinctive features of our own experience as the clues to what lies beyond it. This tended to leave nothing essentially or irreducibly mysterious about religion. But the leading post-Hegelian idealist, namely Bradley, argued that there were radically contradictory features of present experience which implied that the ultimate nature of the universe was suprarational. And with this emphasis we come back again to the idea of some transcendent reality on which everything depends in some way that in principle we cannot understand. It was argued also, in criticism of the more rationalist type of idealism, that it left little room for the distinctness and freedom of the individual, since all beings came to be regarded as elements or “phases” or “appearances” of an ultimate all-inclusive system—and in the same way the problem of evil became a very acute one for idealist defenders of religion.

**NATURAL THEOLOGY.** In correction of the rationalist temper of idealist philosophy many voices were raised from time to time during the nineteenth century, stressing the mystery and elusiveness of religion. The most impressive and influential of these were those of Friedrich Schleiermacher and Rudolf Otto, the former giving prominence to the “feeling of absolute dependence” in religion and the latter stressing our sense of the holy or the numinous, the *mysterium tremendum et fascinans*. Otto claimed, in sharp contrast to the earlier naturalistic theories of Hume and his nineteenth-century followers, that there was ample evidence of this sense of the holy in the rawest beginnings of religion and he sought to describe the way it became schematized and moralized to give riper and more distinctive forms of religion. Other writers sought to correct the somewhat a priori approach of idealist philosophers by resorting to what they described rather incorrectly as an empiricist defense of religion that consisted in drawing out the implications of various features of our experience. This was the form that much natural theology took in the late nineteenth century, exemplified especially in the work of F. R. Tennant. Even if this approach fails to do justice to the factor of transcendence in religion, it could nonetheless be

thought to have provided many of the ingredients of a sound understanding of religious experience.

Toward the close of the nineteenth century and early in the twentieth century there appeared, however, a strong reaction against what was thought to be the facile and too liberal rationalization of religious philosophy at that time. This found expression most of all in the insistence, by Karl Barth and other eminent theologians such as Reinhold Niebuhr and Emil Brunner, on the “wholly other” character of God and the need, as they understood it, to fall back on a dogmatically orthodox theological position in which the central place was accorded to the idea of an exclusive revelation. This presented considerable difficulties, not least on the ethical side where elementary ethical principles seemed to be put in serious jeopardy. But it did give prominence again to the idea of God’s transcendence, which is a focus for controversies about religion among philosophers of the present day.

**PHILOSOPHY OF RELIGION.** The philosophy of our time has become extensively empiricist again. This trend had been preparing for some time in America in aspects of the work of William James and Charles Sanders Peirce. But it gathered its momentum in the work of the Vienna circle and those, such as Ludwig Wittgenstein, who extended its influence in England, notably at Cambridge and Oxford. Recent empiricism represents a sharp reaction against the ambitious and occasionally turgid speculations of nineteenth-century metaphysical philosophers. It set a premium on clarity and claimed to be tough-minded and down to earth. Its policy was extensively that of Hume, and it reflected much of the skepticism of the period subsequent to World War I. To Hume’s empiricism was added, however, an alleged linguistic technique which was intended, in its main early forms at least, to account for the persistence of seemingly bold nonempirical notions, like the idea of the soul or of God, by ascribing them to confusions engendered by misleading forms of speech. This set off a spate of philosophical criticism of religion aimed at showing that its basic conceptions were logically improper. This is sometimes known as the linguistic veto. A desperate attempt to save religion was undertaken by several other empiricist philosophers who seemed willing to sacrifice the strictly nonempirical elements in religion and reinterpret the main features of religious belief in terms of present experience—for example, by regarding religion as a matter of satisfying certain distinctive emotions or by identifying it, in essentials, with ethics.

There have been considerable recent variations on this theme of the attenuation of religious faith. The same method of apologetics has appealed also to many theological writers, some equating religion with morality and others finding the essence of religion in a certain depth and earnestness of our own activities. The most outstanding of these theologians have relied heavily on the work of existentialist philosophers who have brought into prominence the importance of certain searching present experiences and of deep inner aspects of them. Neither they nor their existentialist mentors are very systematic or lucid thinkers, and it is thus not very clear how far they mean to go in interpreting religion in terms of our human experience in the here and now.

**RELIGIOUS EXISTENTIALISM.** A typically elusive representative of this kind of philosophical theology was Paul Tillich. It is never quite clear whether he meant by his central conceptions of “the Ground of Being” and the “New Being” a transcendent reality (or some impact of this upon us) or some profound depth of our own experience and natures. Nor is it clear how far this skepticism about traditional beliefs, reinforced by much skepticism in the field of biblical scholarship, is meant to go; for the writers in question often give expression to seemingly skeptical views in the language of orthodoxy. The position is not made easier by considerable borrowings from phenomenological thinkers like Martin Heidegger who combine unusual perceptiveness with a veritable genius for elaborate and obscure modes of utterance.

**LINGUISTIC APOLOGETIC.** Equally uncertain and difficult is the work of certain more strictly philosophical thinkers who take their start from a new emphasis in linguistic philosophy derived largely from the later and much modified form of Wittgenstein’s work. They stress the open texture and varieties of language and, on this basis, press the claims of religious language to a status not impaired by its not complying with the conditions of ordinary language or scientific language. This leaves the door open for a cautious but less skeptical approach to religion. But the question remains how much is accomplished unless we indicate how the distinctive language of religion is to be understood and what criteria may be applied to it. There is a tendency for some linguistic apologists of religion to be content with stressing the alleged oddity of religious language and thereby also to conflate major notions, like freedom and immortality, and to leave it very unclear in what sense the various affirmations made in religion are to be understood. These writers also tend to draw much support from existentialist insistence

on the importance of formative and challenging present experiences. The details of their work, as in the case of I. T. Ramsey, is illuminating and imaginative, but it is not clear how much it can accomplish until their kind of sensitivity to religious language is accompanied by rigorous heed to the centrality and discipline of the more strictly epistemological considerations.

**RESPONSE TO EMPIRICIST CRITICISMS.** Epistemological considerations have again been uppermost in the work of a further body of recent philosophers who have taken up the challenge of empiricist and linguistic critics more boldly. They have welcomed the challenge in particular as a way of sharpening the question of the place of evidence in religious belief. They maintain that evidence is not strictly relevant to the question of the existence of God; we apprehend the necessity of God’s existence in the contingent character of everything else. This, they maintain, is the element of truth misleadingly presented in the traditional arguments. Pioneers of this position in recent philosophy are Austin Farrer and E. L. Mascall, while another severe critic of linguistic empiricism, C. A. Campbell, has arrived, by way of some modifications of Bradley’s thought, at a not dissimilar renewal of the emphasis on the suprarational character of the object of religious worship.

This takes the sting out of the challenge, given sharpness by John Wisdom and later by Antony Flew, to indicate what would count for or against the existence of God. The answer, it is said, is “nothing,” for we are not here accounting for the way the world goes or some particular feature of it, but for there being anything at all. The question “Why is there something rather than nothing?” is regarded even by some skeptical philosophers as a significant one. This new appreciation of the uniqueness of the idea of God and of God’s relation to the world has opened the way also for subtler understanding of religions other than Christianity, especially Buddhism, and with this has come a renewed philosophical interest in world religions. This is a more discerning interest than the one motivated by superficial notions of syncretism at the turn of the century.

But there has been accentuated in turn the problem of particular religious affirmations. Some have attacked this afresh through new presentations of the traditional doctrine of analogy; some, like A. C. Ewing, persist in a cautious restatement of idealism; others turn to fresh examination of the nature and sanction of religious imagery. There has also been much recourse to the analogy with our knowledge of one another, and in this con-

text it has been thought, by the present writer among others, that a fresh examination of the nature of religious experience and of features of it that could afford justification of the claim to revelation in Scriptures and history, holds the best promise of a solution of the epistemological problems of religious faith. Some who follow this course are apt to lapse from a steady epistemological study, which their initial problem requires, into a psychological or phenomenological one; but when they do so, in the case of Gabriel Marcel for example, they may nonetheless provide highly relevant material for those who manage to keep the epistemological task steadily in mind. That may also be supplemented by the perceptive analysis of those whose concern is not mainly religious or who may be strictly atheistic like Jean-Paul Sartre. The work of Maurice Merleau-Ponty is thought by many to be especially suggestive and illuminating in this way.

Consideration of religious experience may thus prove the point of convergence of many of the approaches to religion which hold most promise today of deepening our understanding of its perennial problems. Advances in fields other than strictly religious studies, most of all perhaps the study of paranormal phenomena, will have much relevance to the present tasks of the philosophy of religion; and some writers, such as H. H. Price, C. D. Broad and C. J. Ducasse, have considered closely the implications of matters like paranormal phenomena for our general view of the world and for relevance to specific questions like immortality. Psychological studies, notably those that investigate the unconscious and the unconscious matrix of conscious imagery, have considerable relevance to the philosophers' problems. A further major preoccupation of those who study the philosophy of religion today is the relation of ethics to religion, not only in the form of fresh examination of the problems of freedom and grace or of variations on the traditional "moral argument," but also in reflections on the role of moral experience within the totality of religious experience. There have likewise been fresh examinations of the claims made for mystical experience, and one writer at least, namely W. T. Stace, is prepared to defend a very extreme form of monism as the ultimate truth about the universe to which mystical experience points. Other philosophers, including some such as J. N. Findlay who took their orientation at one time from Wittgensteinian philosophy, are beginning to embark on bold—too bold?—speculative ventures in the field of religious thought.

In these ways the philosophy of religion, of which fashionable philosophers fought very shy about twenty years ago, has become again one of the liveliest interests

of philosophers. It is of considerable significance also that some of the major themes of contemporary fiction, including those that seem to have little overtly to do with religion, are found to bear closely on aspects of religion that have most importance for the philosophy of religion. In the blend of new philosophical investigations of religion, sharpened in the challenge and discipline of tough-minded philosophy, and a perceptive understanding of contemporary cultures (in their limitations as well as in their achievements) in other regards may be found a means of genuine advance in the life of religion itself which will enable it to have its place effectively in the sophistications of a developing culture and rapidly changing state of society.

## PHILOSOPHY OF RELIGION, HISTORY OF [ADDENDUM]

A remarkable revival of interest in philosophy of religion occurred during the final third of the twentieth century. The demise of logical positivism had freed philosophers of religion from their preoccupation with responding to its verificationist challenge to the meaningfulness of religious language. A narrow empiricism in epistemology ceased to play a foundational role in the philosophy of the Anglophone world. The philosophical community became more pluralistic in its views about the methods and assumptions that may fruitfully be brought to bear on the study of religion. At the same time, the philosophical community was growing in size, largely as a result of the rapid expansion of systems of higher education in

countries such as the United States. As a result of these developments, philosophical reflection on religion came to be conducted by more philosophers with a greater variety of points of view than at any time in the past. Many philosophers approached religion from within well-established traditions of thought such as pragmatism, process philosophy, phenomenology, and Thomism. Remarks on religion in the later works of Ludwig Wittgenstein inspired discussions of religious forms of life. Some philosophers cast fresh light on classical topics in philosophical theology, whereas others focused on issues that contemporary culture has made salient. This entry provides a brief survey of some of the highlights of this flowering of philosophy of religion.

Natural theology, the enterprise of giving arguments for God's existence, was among the classical topics that attracted attention. Alvin Plantinga (2000) constructed a modal ontological argument that resembles earlier arguments discussed by Charles Hartshorne and Norman Malcolm, and William Rowe (1975) set forth a cosmological argument that resembles the version proposed by Samuel Clarke. Both of these arguments are clearly valid. However, as Plantinga and Rowe point out, each of them depends on a premise that one may rationally reject, and so neither is a successful proof of God's existence. Richard Swinburne (1979) produced a probabilistic cumulative case argument for God's existence. Making use of Bayesian reasoning, he tried to show that each one of several factors such as cosmic order, the existence of consciousness, and religious experience increases the probability of God's existence. According to Swinburne, the cumulative effect of all these factors is to render theism slightly more probable than not.

A controversial challenge to the view that belief in God is irrational or in some other way improper unless it is supported by arguments or other propositional evidence was mounted by Plantinga. Many theists do not, in fact, base their belief in God on such propositional evidence. Plantinga argued that such basic belief in God can be epistemically proper under certain conditions, typically conditions pertaining to how the belief is directly grounded in experience. In later work, he has gone on to contend that basic belief in God can have a good deal of warrant, which is the epistemic characteristic enough of which converts true belief into knowledge, despite its lack of support by arguments or other propositional evidence. Plantinga describes the position for which he has argued as Reformed epistemology because he finds it suggested in the writings of John Calvin. Influenced by Wittgenstein and Thomas Reid, William Alston (1991) argued for the practical

rationality of engaging in a nonsensory perceptual practice whose outputs are beliefs about how God is manifested in the experience of the practitioner. Both Plantinga and Alston espouse views in religious epistemology according to which belief in God can have positive epistemic status even in the absence of a successful natural theology.

Of course evil constitutes a potential defeater for the positive epistemic status that theistic belief can acquire from experience. According to the logical problem of evil, the existence of an omnipotent, omniscient, and perfectly good God is logically inconsistent with the existence of evil. In his celebrated free will defense, Plantinga (2000) argued convincingly that the existence of God is consistent with the existence of evil. The main focus of debate subsequently shifted to the evidential problem of evil, according to which evils of a certain sort count as evidence that renders the existence of God improbable. An influential version of this problem formulated by Rowe (1975) started from the notion of pointless suffering, which is defined as suffering an omnipotent and omniscient being could have prevented without losing some greater good or permitting some evil equally bad or worse. Rowe maintained that instances of suffering known to us are apparently pointless and hence count as compelling evidence against the existence of God. In an attempt to rebut Rowe, Stephen Wykstra argued against concluding that such instances of suffering are apparently pointless. On his view, even if such suffering has a point because without it God cannot secure some greater good, it is very likely that its point is completely beyond our ken.

As a result of the increasing religious pluralism of modern societies, religious diversity has become a salient threat to the positive epistemic status of conflicting systems of religious belief. Major world religions disagree about even such fundamental issues as whether the ultimate religious reality is a personal deity or an impersonal absolute. John Hick proposed that our response to this situation should be to adopt the hypothesis that all the world religions are somehow in touch with a single noumenal reality to which no substantive human concepts apply. On this hypothesis, the ultimates of different world religions are equally real but merely phenomenal realities, all of which are in part products of human cultures and traditions. Opponents of Hick's proposal, such as Alston and Plantinga, have argued for the rationality of remaining within the belief systems of particular religions despite the negative impact religious diversity has on the epistemic status of such beliefs, at least for those who are sufficiently aware of the conflict to which this diversity gives rise.

Important work has also been done on several other topics. One example is the metaphysics of theism. Philosophical reflection on God's nature has produced new accounts of such divine attributes as omniscience, omnipotence, eternity, and simplicity. Another example is religious ethics. John Finnis has developed a natural law theory influenced by the thought of Thomas Aquinas; Alasdair MacIntyre has argued in favor of moral inquiry within the tradition of Aquinas; Robert Adams and Philip Quinn have formulated and defended divine command theories of moral obligation. John Caputo and Merold Westphal have played a significant role in drawing to the attention of Anglophone philosophers the religious implications of the writings of major French and German thinkers. And promising first steps have been taken toward feminist and comparative philosophies of religion.

## PHILOSOPHY OF RELIGION, PROBLEMS OF

The term *philosophy of religion* is a relative newcomer to the philosophical lexicon, but what is now so designated is as old as philosophy itself. One of the earliest spurs to philosophical reflection, in ancient Greece and elsewhere, was the emergence of doubts concerning the religious tradition; and religious beliefs and conceptions have always formed much of the staple of philosophical discussion.

If one surveys the various things philosophers have done in thinking about religion, it is difficult to find any unifying thread other than the fact that they all spring from reflection on religion. Philosophy of religion is occupied to a large extent with the consideration of reasons for and against various fundamental religious beliefs, particularly the various arguments for the existence of God. But we find many other matters treated in books that are regarded as being within the philosophy of religion. These include the nature and significance of religious experience, the nature of religion, the relation between religion and science, the nature of religious faith as a mode of belief and/or awareness, the nature of revelation and its relation to the results of human experience and reflection, the place of religion in human culture as a whole, the logical analysis of religious language, the nature and significance of religious symbolism, and possibilities for reconstructing religion along relatively non-traditional lines.

### CENTRAL AIM

Some justification can be found for grouping all these topics under the heading “philosophy of religion” if we view them all as growing out of a single enterprise, the rational scrutiny of the claims of religion—the critical examination of these claims in the light of whatever considerations are relevant—with a view to making a reasonable response to them. A highly developed religion presents us with a number of important claims on our belief, our conduct, our attitudes and feelings. It gives answers to questions concerning the ultimate source of things, the governing forces in the cosmos, the ultimate purpose(s) of the universe, and the place of man in this scheme. It tells us what a supreme being is like, what demands he makes on men, and how one can get in touch with him. It offers a diagnosis of human ills, and it lays down a “way of salvation” that, if followed, will provide a way to remedy these ills and satisfy man’s deepest needs. All this is very important. If the claims of a given religion

on these points are justified, discovering this is a matter of the greatest moment. At bottom the philosophy of religion is the enterprise of subjecting such claims to rational criticism.

It is worth noting that such claims are not made by religion in general but by particular religions exclusively and that although generally we can find claims of all these sorts in any given religion, the specific content will differ widely from one religion to another. This will have important consequences for the direction taken by the philosophizing that arises in response to each religion. This article is largely concerned with the Western tradition, and thus the philosophy of religion represented has grown out of concern with some aspect of the Judeo-Christian tradition, either through support or opposition. Philosophical reflection on a very different religious tradition will give rise to different preoccupations. Thus, Western philosophers, unlike their Indian counterparts, are much concerned with arguments for and against the existence of a supreme personal deity and with whether or not the occurrence of miracles is compatible with the reign of natural law. However, in a religious tradition like the Hindu or the Buddhist, which does not feature the notion of a supreme personal deity who has active personal dealings with his creatures, these problems do not arise. Philosophers in such a tradition, by contrast, will be concerned with trying to clarify the relation of a supreme ineffable One to the various things in the world that constitute its manifestations and with considering arguments for the ultimate unreality of the empirical world. There is, however, enough in common among different religions to ensure that all philosophy of religion will be directed to recognizably identical problems, though in very different forms.

Philosophers have raised critical questions about the justifiability and value of religious beliefs, rites, moral attitudes, and modes of experience. However, philosophers have largely focused their critical powers on the doctrinal (belief) side of religion. This selectivity might be attributed to an occupational bias for the intellectual, but there is a real justification for it. If our basic interest is in questions of justifiability, then it is natural that we should concentrate on the belief side of religion, for the justification of any other element ultimately rests on the justification of some belief or beliefs. If one asks a Roman Catholic why he goes to Mass, or what the value is of so doing, he would, if he knew what he was about, appeal to certain basic beliefs of his religion: that the universe, and all its constituents, owes its existence to and depends for its ultimate fate on a supreme personal being, God; that

man inevitably fails to live up to the moral requirements God lays down for him; that God became a man in the person of Jesus of Nazareth and suffered death in order to save man from the fatal consequences of his sinfulness; that as a part of a program designed to enable men to benefit from this, God has ordained that they should participate in the rite of the Mass, in which, in some mysterious way, they actually incorporate the body and blood of Jesus and so partake of the salvation effected through him. The ritual, as conceived by the participants, is a reasonable thing to do if and only if these beliefs are justified.

However, the attention of philosophers is generally more narrowly concentrated than this. Not all the beliefs of a given religion, not even all the beliefs considered crucial by that religion, receive equal attention. In works on the philosophy of religion, one finds little discussion of relatively special doctrines that are peculiar to a given religion, such as the virgin birth of Jesus, the divine mission of the church, or the special status of the priesthood, however important these doctrines may be for the religion in question. Instead, attention is focused primarily on what might be called the metaphysical background of the doctrinal system, the worldview of the religion—the view of the ultimate source and nature of the universe; the nature of man; man's place in the universe; the end to which man is, or should be, tending; and so on. This preferential treatment is partly due to a desire to make philosophical discussions relevant to more than one religion; for example, roughly the same worldview underlies Judaism, Christianity, and Islam. It is also partly due to a conviction that philosophical reflection will yield definite results only with respect to the more general aspects of a religious outlook. Very few philosophers have supposed that one can establish the virgin birth by philosophical argument.

It might also be argued that if we abstract from commitment to any particular religion, the worldview aspect of religion is the most undeniably significant one. Without presupposing some particular religious beliefs, it would be difficult to show that the acceptance of elaborate theological dogmas like that of the Trinity, or participation in rites, or singling out certain objects as sacred is an essential part of a fully human life. However, it can be argued on the basis of facts concerning the nature of man and the conditions of human life that human beings have a deep-seated need to form some general picture of the total universe in which they live, in order to be able to relate their own fragmentary activities to the universe as a whole in a way meaningful to them; and that a life in

which this is not carried through is a life impoverished in a most significant respect. This would seem to be an aspect of religion that is important on any religious position; and so it seems fitting that it should be at the center of the picture in a general philosophical treatment of religion.

## OTHER INVESTIGATIONS AND THE CENTRAL AIM

In presenting, defending, and criticizing arguments for and against such fundamental beliefs as the existence of a supreme personal deity, the immortality of the human personality, and the direction of the universe toward the realization of a certain purpose, philosophers are directly engaged in critical evaluation. The other major topics listed at the beginning of this article do not have exactly this status, but they are all directly relevant to rational criticism of fundamental religious beliefs. In order to conduct a systematic scrutiny of such beliefs, one must start with an adequate conception of the nature and range of religion, so that he can be sure that he is dealing with genuine religious beliefs and with those which are most fundamental for religion, and so that he will not be unduly limited by the particular interests with which he starts.

Moreover, one needs an adequate understanding of the nature of religious belief in order to filter out irrelevant considerations and arguments. The charge of irrelevancy has been most trenchantly leveled against the traditional enterprise of presenting metaphysical arguments for the existence of God by Søren Kierkegaard, who maintained that anyone who tries to give an argument for the existence of God thereby shows that he has misunderstood the special character of religious belief. Whether or not such charges are justified, the mere fact that they can be made with any plausibility shows that it is incumbent on the philosopher of religion to look into the character of religious faith and to try to determine its similarities to and differences from other modes of belief; for example, those in everyday life and in science. With an increasing realization of the way in which thought and belief are shaped by language, this kind of investigation has increasingly taken the form of an inquiry into the type of utterances that express religious belief, an attempt to make explicit the logic of religious discourse—the special ways in which terms are used in religious utterances, the logical relations between religious statements themselves and between religious statements and statements in other areas of discourse, the extent to which religious statements are to be construed as expressive of feelings or

attitudes or as directions to action, rather than as factual claims. Also, an appreciation of the extent to which language is used symbolically in religion can easily lead to a general concern with the nature and function of religious symbolism.

All the concerns listed thus far involve investigation of the relation of religion to other segments of human culture, such as science, art, and literature. The question of the relation of science and religion has a special importance for one who is critically examining religious beliefs in our society. For the last few hundred years the main challenges to religious doctrine in Western society have been made in the name of science. With respect to many segments of science, from Copernican astronomy through Darwinian biology to Freudian psychology, it has been claimed that certain scientific discoveries disprove, or at least seriously weaken, certain basic religious doctrines. Discussions of whether this ever does, or can, happen—and if so, what is to be done about it—have bulked large in works on philosophy of religion.

Philosophers of religion also investigate the nature of religious experiences because it is often claimed that such experiences provide direct warrant for the existence of God, or of other objects of religious worship. One is naturally led into a survey of the types of religious experience and into questions of their psychological bases. Finally, if a philosopher has decided that the basic beliefs of the traditional religion(s) of his society are unacceptable, he is naturally faced with the question of what to do about it. If he feels that religion is a crucially important aspect of human life, he will want to find some way of preserving religious functions in a new form. Hence, naturalistic philosophers, who reject the supernaturalistic beliefs of our religious tradition, sometimes attempt to sketch the outlines of a religion constructed on naturalistic lines. This will usually involve the substitution of some component(s) or aspect(s) of the natural world for the supernatural deity of the Judeo-Christian tradition. This may be Humanity (Auguste Comte), human ideals (John Dewey), those natural processes which make a contribution to the realization of the greatest good (H. N. Wieman), or some combination of these.

#### RELATIONS TO OTHER DISCIPLINES

The philosophy of religion is distinguished from theology and from sciences dealing with religion (such as psychology of religion and sociology of religion) in opposite ways. It is distinguished from theology by the fact that it takes nothing for granted, at least nothing religious; in the course of its examination it takes the liberty of calling

anything into question. Theology, in a narrow sense of that term, sets out to articulate the beliefs of a given religion and to put them into systematic order, without ever raising the ultimate question of their truth. The philosophy of religion is distinguished from sciences of religion by the fact that it is addressed to questions of value and justification and tries to arrive at some sort of judgment on religious claims. The psychology of religion—for instance, when pursuing strictly psychological questions—studies religious beliefs, attitudes, and experiences as so many facts, which it tries to describe and explain, without attempting to pass judgment on their objective truth, rationality, or importance.

The philosophy of religion, conceived of as an attempt to carry out a rational scrutiny of the claims made by a given religion, will always start from concern with some particular religion or type of religion and will basically aim at a judgment of that religion. It certainly is historically accurate to think of philosophy of religion as arising in this way and, furthermore, it may be taken as its common and most basic form. However, it is also possible for a philosopher to concern himself directly with the fundamental issues involved in the religious claims in question—the ultimate source of things, the destiny of man, and cosmic purpose, for example—without approaching them through the consideration of answers given to these questions by some organized religion. Benedict de Spinoza's *Ethics* is an outstanding example of this kind of investigation. Other examples are Samuel Alexander's *Space, Time and Deity* (2 vols., London, 1920) and Henri Bergson's *L'évolution créatrice* (*Creative Evolution*, New York, 1911). Whether we call philosophizing of this kind philosophy of religion is not important, but it is important to realize that these questions can be considered outside the context in which we are explicitly concerned with religion as such.

#### VARIOUS APPROACHES

One should not suppose that every philosopher of religion concerns himself with the whole range of problems. On the contrary, a given philosopher will usually restrict his attention because of his special interests, his conception of religion, and/or his general philosophical position. The second and third of these factors deserve further notice. Concerning the second, the types of problems that a given philosopher emphasizes will sometimes be influenced by the particular aspect of religion he regards as essential. Thus, the concentration on problems connected with religious belief in traditional philosophy of religion is partly due to the fact that most philosophers

of religion have thought of religion primarily as a kind of belief (although this may, in fact, be less important than other factors). W. T. Stace in *Time and Eternity*, for example, considers mystical experience to be the essence of religion. Stace concentrated his main efforts on interpreting and justifying religious doctrine conceived as basically an expression of mystical experience. On the other hand, Kierkegaard thought of religion as basically a matter of an individual maintaining a certain general stance in life, and he devoted himself to an elaborate description of a variety of such stances, combined with indirect recommendations of one of these; he rarely mentioned any of the problems customarily discussed by philosophers of religion.

The operation of the third factor, the individual's philosophical position, is more apparent and, perhaps, more powerful. A few examples, selected more or less at random, will be helpful. Philosophers who are primarily speculative metaphysicians—Plato, Thomas Aquinas, Gottfried Wilhelm Leibniz, G. W. F. Hegel, and A. N. Whitehead—naturally take very seriously the enterprise of constructing metaphysical arguments for or against the existence of God, whereas predominantly antimetaphysical philosophers—David Hume, Immanuel Kant, and Dewey—will either criticize such arguments or, as is more common in recent times, ignore them altogether. Those who subscribe to the thesis that the only proper job of philosophy is the analysis (clarification) of concepts will observe the appropriate restrictions when and if they turn their attention to religion. There is a great deal of work of this kind to be done with the concepts of God, creation, revelation, faith, and miracle, to name a few. Traditionally this has been done in connection with attempts to reach substantive conclusions on the existence of God, immortality, and other major issues, but if one thinks that conclusions on such matters cannot be attained by philosophical reflection, as analytic philosophers do, he may still seek to make explicit the concepts involved in religious belief. Such philosophizing will regard itself as a humble servant of theology or of more ordinary religious belief and will pretend to no judicial functions, except where it locates internal confusions or inconsistencies.

The influence of philosophical orientation is clearly exemplified in naturalistic philosophers, who generally rule out all supernaturalism on the basis of their general philosophical position, without giving particular supernaturalistic beliefs any detailed examination. Naturalists devote their energies to revising religious belief and prac-

tice so that they will be acceptable within a naturalistic framework.

Finally, one may consider Hegel, who devoted his lectures on the philosophy of religion to demonstrating a dialectical progression in the history of religion. This reflected Hegel's basic philosophical conviction that reality consists of the process of the Absolute coming to full self-consciousness, that this process exhibits a dialectical pattern, and that it is manifested in the history of every cultural form.

In the task of classifying the positions that have been taken in the philosophy of religion, one confronts the difficulty that not all philosophers of religion, even in a single religious tradition, are dealing with the same problems. However, there is a common task underlying all the different approaches. All philosophy of religion is ultimately concerned with arriving at a rational judgment of the religion under discussion and, if the judgment is negative, to present some sort of alternative. The initial principle of division can then be taken as the affirmative or negative character of this judgment. (This cannot be absolutely clear-cut, partly because often some part of the religion is affirmed and some is rejected, partly because it is not absolutely clear what is to be included in the religion in question.) It can then be asked of those whose judgment is affirmative what the basis of their judgment is.

One major group, which includes the great majority of philosophers of religion, presents various arguments in support of such beliefs as the existence of God and the immortality of the soul, arguments that take their start from premises that are not themselves religious doctrines and that, it is assumed, any reasonable man would accept. In other words, they attempt to support religious belief by resting it on nonreligious premises. A smaller but still considerable group regards religious belief as not needing any such support from the outside; they regard it as somehow self-justifying or at least as justified by something from within religion. Some of them (Bergson and James) suppose that the belief in the existence of God, for example, is justified by religious experience. One can directly experience the presence of God, and therefore one does not need to prove his existence by showing that he must be postulated to explain certain facts. Others regard religious faith as different from other modes of belief in such a way that it does not need support of any kind, either from argument from effect to cause or from direct experience. Kierkegaard, Emil Brunner, and Paul Tillich, for example, all take this position, though there are great differences between them. (The case of Tillich

illustrates the point that in some cases it is difficult to distinguish between those who accept the religious tradition and those who reject it. Tillich considered himself a Christian theologian, but his interpretation of Christian doctrine is so unorthodox that many feel he reconstrued it out of recognition and therefore should be classed with those who substitute a symbolic reinterpretation for traditional beliefs.)

In the other major group we can distinguish between those who simply reject traditional religion (Baron d'Holbach and Bertrand Russell) and those who in addition try to put something in its place. In the latter group we can distinguish between those who try to retain the trappings, perhaps even the doctrinal trappings, of traditional religion but give it a nonsupernaturalistic reinterpretation, usually as symbolic of something or other in the natural world (George Santayana), and those who attempt to depict a quite different sort of religion constructed along nonsupernaturalistic lines (Comte, Dewey, and Wieman).

Outside this classification are those analytical philosophers who restrict themselves to the analysis of concepts and types of utterances. We may regard them as not having a major position in the philosophy of religion, but rather as making contributions that may be useful in the construction of such a position.

### **Bibliography**

Edwin A. Burt, *Types of Religious Philosophy*, rev. ed. (New York: Harper, 1951), and Robert Leet Patterson, *An Introduction to the Philosophy of Religion* (New York: Holt, 1958), are useful introductory textbooks. A wide variety of readings in the field can be found in *Philosophy of Religion*, edited by George L. Abernethy and Thomas A. Langford (New York: Macmillan, 1962), and in *Religious Belief and Philosophical Reflection*, edited by William P. Alston (New York, 1963).

The following works are important treatments of a wide variety of topics in this area: John Baillie, *The Interpretation of Religion* (New York: Scribners, 1928); H. J. Paton, *The Modern Predicament* (London: Allen and Unwin, 1955); A. E. Taylor, *The Faith of a Moralist* (New York: Macmillan, 1930); and F. R. Tennant, *Philosophical Theology* (Cambridge, U.K.: Cambridge University Press, 1928). These works are written from a standpoint more or less sympathetic to traditional theism. For fairly comprehensive discussions from a more critical standpoint, see J. M. E. McTaggart, *Some Dogmas of Religion* (London: Arnold, 1906), and Bertrand Russell, *Religion and Science* (New York: Holt, 1935).

Works dealing with the nature and significance of religious experience include William James, *The Varieties of Religious*

*Experience* (New York: Longman, 1902), and Rudolf Otto, *The Idea of the Holy*, translated by J. W. Harvey (New York: Oxford University Press, 1958). The nature of religion is discussed in Josiah Royce, *The Sources of Religious Insight* (New York: Scribners, 1912), and in Julian Huxley, *Religion without Revelation* (New York: Harper, 1957). For the relation of religion and science, see Bertrand Russell, *op. cit.*, and Michael Pupin, ed., *Science and Religion; a Symposium* (New York, 1931). J. H. Newman, *A Grammar of Assent* (London: Burns, Oates, 1870), and Paul Tillich, *Dynamics of Faith* (New York: Harper, 1957), cover the nature of religious faith as a mode of belief and/or awareness.

In Emil Brunner, *The Philosophy of Religion from the Standpoint of Protestant Theology*, translated by A. J. D. Farrer and B. L. Woolf (New York: Scribners, 1937), the nature of revelation and its relation to the results of human experience and reflection are considered. The place of religion in human culture as a whole is dealt with in G. W. F. Hegel, *Lectures on the Philosophy of Religion*, translated by E. B. Speirs and J. B. Sanderson, 3 vols. (London: K. Paul, Trench, Trubner, 1895), and in George Santayana, *Reason in Religion* (New York: Scribners, 1905). For the logical analysis of religious language, see A. G. N. Flew and Alasdair MacIntyre, eds., *New Essays in Philosophical Theology* (London: SCM Press, 1955), and C. B. Martin, *Religious Belief* (Ithaca, NY: Cornell University Press, 1959). Edwyn Bevan, *Symbolism and Belief* (Boston: Beacon Press, 1957), and W. T. Stace, *Time and Eternity* (Princeton, NJ: Princeton University Press, 1952), discuss the nature and significance of religious symbolism. Possibilities for reconstructing religion along relatively nontraditional lines appear in Immanuel Kant, *Religion within the Limits of Reason Alone*, translated by T. M. Greene and H. H. Hudson (La Salle, IL: Open Court, 1934); John Dewey, *A Common Faith* (New Haven, CT: Yale University Press, 1934); and Julian Huxley, *op. cit.*

*William P. Alston (1967)*

## PHILOSOPHY OF SCIENCE, HISTORY OF

Philosophy of science emerged as a distinctive part of philosophy in the twentieth century. Its defining moment was the meeting (and clash) of two courses of events: the breakdown of the Kantian philosophical tradition and the crisis in the sciences and mathematics in the beginning of the century. But what we now call philosophy of science has a rich intellectual history that goes back to the ancient Greeks. It is intimately connected with the efforts made by many thinkers to come to terms with the distinctive kind of knowledge (*epistēmē*, *scientia*) that science offers. Though science proper was distinguished from natural philosophy only in the nineteenth century, the *philosophy* of natural philosophy had almost the very same agenda that current philosophy of science has.

## ARISTOTLE

Aristotle (384–322 BCE) thought that there was a sharp distinction between our understanding of facts and our understanding of the reasons for those facts. Though both types of understanding proceed via deductive syllogism, only the latter is characteristic of science, because only the latter is tied to the knowledge of causes. In *Posterior Analytics*, Aristotle illustrates this difference by contrasting the following two instances of deductive syllogism:

**Syllogism A**

Planets do not twinkle.

What does not twinkle is near.

Therefore, planets are near.

**Syllogism B**

Planets are near.

What is near does not twinkle.

Therefore, planets do not twinkle.

Syllogism A, Aristotle said, demonstrates the fact that planets are near, but does *not* explain this fact, because the syllogism does not state its causes. However, syllogism B is explanatory because the syllogism gives the *reason why* planets do not twinkle: *because* they are near. Aristotle's point was that, besides being demonstrative, explanatory arguments should also be asymmetric: The asymmetric relation between causes and effects should be reflected in an asymmetric relation between the premises and the conclusion of the explanatory arguments: The premises should explain the conclusion, and not the other way around.

For Aristotle, scientific knowledge forms a tight deductive-axiomatic system whose axioms are *first principles*, which are “true and primary and immediate, and more known than and prior to and causes of the conclusion” (71b19–25). Being an empiricist, he thought that knowledge of causes has experience as its source. But experience on its own cannot lead, through induction, to universal and necessary first principles that state ultimate causes. Nor can first principles be demonstrated, on pain of either circularity or infinite regress. So something besides experience and demonstration is necessary for knowledge of first principles. This is the process of abstraction based on intuition, a process that reveals the essences of things, that is, the properties by virtue of which a thing is what it is. Though Aristotle called first principles “definitions,” they are not verbal, but rather state the essences of things. In Aristotle's rich ontology, causes are essential properties of their effects and necessarily give rise to their effects. He thought that the logical

necessity by which the conclusion follows from the premises of an explanatory argument mirrors the physical necessity by which causes produce their effects.

## ARISTOTELIANISM

By the 1250s, Aristotle's works had been translated into Latin, either from the original Greek or through Arabic translations, and a whole tradition of writing commentaries on these works flourished. Aristotle's *Organon* was the main source on issues related to logic and knowledge. At about the same time, the first universities were founded in Paris and Oxford, and natural philosophy found in them its chief institutional home. Aristotelianism was the dominant philosophy throughout the Middle Ages, though it was enriched by insights deriving from religious beliefs and many philosophical commentaries. The new Aristotelianism put secular learning on almost equal footing with revealed truth, especially at the University of Paris.

Thomas Aquinas (c. 1225–1274) argued that science and faith cannot have the same object, since the object of science is something seen, whereas the object of faith is the unseen. He found in Aristotle's views the mean between two extremes, one being Plato's view, which demeaned experience and saw in it just an occasion in the process of understanding the realm of pure and immutable forms, the other being the Democretian atomist view, which reduced all knowledge to experience. Aristotelianism, Aquinas thought, was the golden mean. Experience is necessary for knowledge, since nothing can be in the mind if it is not first in the senses. But thought is active in that it extends beyond the bounds of sense and states the necessary, universal, and certain principles on which knowledge is based.

Aquinas inherited (and suitably modified) much of Aristotle's rich metaphysics. Aristotle, drawing a distinction between matter and form, argued that when a change takes place, the matter perdures (persists), while the form changes. He conceived of change as the successive presence of different (even opposing) forms in the substratum. Scholastic philosophers differentiated this substratum from the ordinary matter of experience and called it “prime matter” (*materia prima*). The form that gives prime matter its particular identity (making it a substance of a particular kind) they called “substantial form.” Substantial forms were individuating principles that accounted for the specific properties of bodies (which all shared the same prime matter). Aquinas added that prime matter is pure potentiality, incapable of existing by itself. He adopted the view that change (as well as

motion) was the passage from potentiality to actuality. Since a thing cannot be both actual and potential at the same time, he took it to be obvious that nothing can be the active source of its own motion, and hence that motion always requires a mover. Aquinas found solace in the Aristotelian doctrine of the first unmoved mover (the source of all motion), which immediately lent itself to being identified with God.

### THE PROBLEM OF MOTION

The status of motion was heavily debated among the Scholastics. One central Aristotelian axiom was that everything that moves requires a mover. Another central axiom was that the mover is in contact with the thing moved. This might be borne out in ordinary experience, but some cases created problems. One of them was projectile motion, and another concerned natural motion, that is, motion toward the natural place of a thing. In both cases, it is not obvious that something does the moving, let alone by being in contact with the thing moved. There was no easy way out of these problems. Underlying them was the very issue of what motion is. Is motion merely the final form momentarily attained by the moving object at any instant? Or is it something in addition, a flux or transformation of forms (in medieval terminology, *forma fluens* or *fluxus formae*)?

The radical answer to this question was sharpened by William of Ockham (c. 1280–1349), who argued that motion is nothing over and above the moving body and its successive and continuous termini. He was a nominalist who thought that only particulars exist. He denied that universals exist and claimed that general terms, or predicates, refer to concepts that apply to many particulars. He argued that the key to the problem of motion was thus held by the abstract noun “motion.” It is wrong, he claimed, to think that this and other abstract nouns refer to distinct and separately existing things. Only individual bodies, places, and forms are needed to explain what motion is. Another view came from Jean Buridan (c. 1295–1358). He argued that local motion involves *impetus*, a motive force transmitted from the mover to the moving body, which acts as an internal cause of its continued motion.

### ARGUMENT ACCORDING TO IMAGINATION

On March 7, 1277, Etienne Tempier, Bishop of Paris, issued an act condemning 219 propositions drawn from the works of Aristotle and his commentators (including Aquinas). These propositions were supposed to be in

conflict with Christian faith and in particular with the omnipotence of God. They included such claims as that the world is eternal, that God could not make several worlds, that God could not make an accident exist without a subject, that God could not move the entire cosmos in straight line. Ironically, this act opened up new conceptual possibilities that were hitherto regarded as closed. If Aristotle could err in matters theological, could he not err in matters philosophical too?

On the premise that only the law of noncontradiction constrains God’s actions, it was argued that anything that can be conceived without contradiction is possible. This led to a new type of argumentation: arguing according to the imagination (*secundum imaginationem*). If something could be consistently imagined, then it was possible. New ideas were pursued on this basis, unconstrained by claims concerning the actual course of nature (*secundum cursus naturae*). Central elements of Aristotelian doctrine were given close logical scrutiny. For instance, in the Aristotelian scheme of things, where there is no void and the entire cosmos occupies no place, it made no sense to say that the entire cosmos could move. But what if, Buridan asked, God made the whole cosmos rotate as one solid body? Freed to inquire into the logical possibility of this rotation, Buridan argued that since we can imagine it, there must be something more to motion than the moving body, its forms, and the places it acquires. For if these were all there were to motion, then, contrary to our assumption, the entire cosmos could not move, simply because there would be no places successively acquired.

Ockham pushed argument according to imagination to its limits by arguing that there is no a priori necessity in nature’s workings. God could have made things other than they are. Hence, all existing things are contingent. There are no necessary connections between distinct existences, and there is justification for inferring one distinct existence from another, Ockham forcefully argued. Accordingly, all knowledge of things comes from experience. Ockham claimed that there could never be certain causal knowledge based on experience, since God might intervene to produce the effect directly, thereby dispensing with the secondary (material) cause. Ockham thus gave a radical twist to empiricism, putting it in direct conflict with the dominant Aristotelian view.

### FIRST PRINCIPLES

The status of scientific knowledge was heavily debated in the thirteen and fourteenth centuries. John Duns Scotus (c. 1265–1308) defended the view that first principles are

knowable with certainty, as they are based only on the natural power of the understanding to see that they are self-evident, ultimately by virtue of the meanings of the terms involved in them. For him, the understanding is not caused by the senses, but only occasioned by them. Once it has received its material from the senses, the understanding exercises its own power in conceiving first principles. Interestingly enough, Scotus thought that there could be certain causal knowledge coming from experience. He asserted as self-evident a principle of induction. He held that this principle is known a priori by the intellect, since a free cause (that is, an act of a free agent) leads by its *form* to the effect that it is ordained to produce. It was then an easy step for him to extend this principle from free causes to natural causes: “Whatever happens frequently through something that is not free, has this something as its natural *per se* cause.”

Ockham disagreed with Scotus’s account of the first principles, but his central disagreement with his predecessors was about the *content* of first principles. Since he thought there was nothing in the world that corresponded to general concepts (such as universals), he claimed that first principles are, in the first instance, about mental contents. They are about concrete individuals only *indirectly* and insofar as the general terms and concepts can be predicated of concrete things. Ockham is famous for the principle known as Ockham’s razor: Entities must not be multiplied without necessity. In fact, this principle of parsimony was well-known in his time. Robert Grosseteste (c. 1168–1253) had put it forward as the law of parsimony (*lex parsimoniae*).

Ockham’s most radical follower, Nicolas of Autrecourt (c. 1300–after 1350), rejected the demand for certainty altogether and claimed that only probable knowledge is possible. He endorsed atomism, claiming that it is at least as probable as its rival, Aristotelianism. In reaction, the fourteenth-century Parisian masters—Buridan, Albert of Saxony (c. 1316–1390), and others—claimed that empirical knowledge can be practically certain and wholly adequate for natural science. For Buridan, if we fail to discover an instance of *A* that is not *B*, then it is warranted to claim that all *As* are *B*. On the basis of this principle, he defended on empirical grounds the Aristotelian claim that there is no vacuum in nature, since, he said, we always experience material bodies.

### THE PREROGATIVES OF EXPERIMENTAL SCIENCE

Despite their engagement with philosophical issues in natural science, thinkers such as Ockham and Scotus were

little concerned with natural science itself. They saw little role for mathematics, the science of quantity, in physics. They neglected experiment altogether. This was a drawback of their thought in relation to some earlier medieval thinkers. Grosseteste was one of the first to emphasize the role of mathematics in natural science. Roger Bacon (1214–1292) went further by arguing that all sciences rest ultimately on mathematics, that facts should be subsumed under mathematical principles, and that empirical knowledge requires active experimentation. Bacon put forward three virtues of experimental science. First, it criticizes by experiment the conclusions of all the other sciences. Second, it can discover new truths (not of the same kind as already known truths) in the fields of science. Third, it investigates the secrets of nature and delivers knowledge of future and present events.

The emphasis on the mathematical representation of nature exerted important influence on the work of the masters of Merton College in Oxford, who, in the fourteenth century, by and large put aside the philosophical issues of the nature of motion and focused instead on its mathematical representation. Walter Burley (c. 1275–c. 1345), Thomas Bradwardine (c. 1295–1349), William of Heytesbury (before 1313–1372/1373), Richard Swineshead (d. c. 1355), known as the Mertonians, most of whom were nominalists, engaged in a project to investigate motion and its relation to velocity and resistance in an abstract mathematical way. Similar research, though more concerned with the physical nature of motion, was undertaken in Paris by Buridan, Albert of Saxony, and Nicole Oresme (c. 1320–1382), known as the Paris terminists. The mathematical ingenuity of the Mertonians and the Parisians led to many important mathematical results that spread throughout Western Europe and germinated in the thought of many modern thinkers, including Galileo Galilei (1564–1642). By the end of the fourteenth century, a protopositivist movement, concerned not with the ontology of motion, but with its measurement, started to spread.

### THE COPERNICAN TURN

In *De revolutionibus orbium coelestium* (On the revolutions of the celestial spheres), Nicolaus Copernicus (1473–1543) developed his famous heliocentric model of the universe. The unsigned preface of the book, which was published posthumously in 1543, firmly placed it within the saving-of-appearances astronomical tradition favored by Plato and endorsed by many medieval thinkers. As it turned out, the preface was written not by Copernicus himself but by Andreas Osiander, a Lutheran

theologian. Copernicus emphatically refused to subscribe to this tradition. He had a *realist* conception of his theory, according to which, as Pierre Duhem put it, “a fully satisfactory astronomy can only be constructed on the basis of hypotheses that are true, that conform to the nature of things” (1908, p. 62).

Before Copernicus, the dominant astronomical theory was that of Claudius Ptolemy (c. 85–c. 165). Pretty much like Aristotle and Plato, Ptolemy had assumed a geocentric model of the universe. To save the appearances of planetary motion, he devised a system of deferents (large circles centered on the earth) and epicycles. There were alternative mathematical models of the motion of the planets (e.g., one based on a moving eccentric circle), but Ptolemy thought that since all these models saved the appearances, they were good enough. The issue of their physical reality was not raised (though at least some medieval philosophers understood these models realistically). Geometry was then the key to studying the celestial motions, but there was no pretense that the world itself was geometrical (though Plato, in the *Timaeus*, did advocate a kind of geometrical atomism). The Copernican heliocentric model, though it made the earth move around the sun, continued to use epicycles. But Copernicus argued that his theory was true. He based this thought mostly on considerations of harmony and simplicity: His own theory placed astronomical facts into a simpler and more harmonious mathematical system.

### THE BOOK OF NATURE

Galileo Galilei (1564–1642) famously argued that the book of nature is written in the language of mathematics. He distinguished between logic and mathematics. Logic teaches us how to derive conclusions from premises, but does not tell us whether the premises are true. Mathematics is in the business of demonstrating truth. Though Galileo emphasized the role of experiment in science, he also drew a distinction between appearances and reality, which set the stage for his own, and subsequent, explanatory theories of phenomena, which posited unobservable entities. He accepted and defended the Copernican system and further supported it with his own telescopic observations, which spoke against the dominant Aristotelian view that the heavens are immutable. But the possible truth of Copernicus’s theory suggested that the world might not be as it is revealed to us by the senses. Indeed, Galileo understood that the senses can be deceptive, and hence that proper science must go beyond merely relying on the senses. The mathematical theories of motion that he advanced were based on idealizations

and abstractions. Experience provides the raw material for these idealizations (frictionless inclined planes, ideal pendula), but the key method of science was extracting, via abstraction and idealization, the basic structure of a phenomenon so that it could be translated into mathematical form. Then mathematical demonstration takes over and further consequences are deduced, which are tested empirically. So Galileo saw that understanding nature requires the use of creative imagination.

Galileo also distinguished between primary qualities and secondary qualities. Primary qualities—such as shape, size, and motion—are possessed by objects in themselves and are immutable, objective, and amenable to mathematical exploration. Secondary qualities, such as color and taste, are relative, subjective, and fleeting. They are caused on the senses by the primary qualities of objects. The world that science studies is the world of primary qualities. Subjective qualities can be left out of science without any loss. Galileo set for modern science the task of discovering the objective and real mathematical structure of the world. This structure, though mathematical, was also mechanical: All there is in the world is matter in motion.

### THE INTERPRETATION OF NATURE

The emerging new science was leaving Aristotelianism behind. But it needed a new method. Better, it needed to have its method spelled out so that the break with Aristotelianism, as a philosophical theory of science, could be complete. Aristotelianism offered two criteria of adequacy for scientific method: epistemological adequacy and metaphysical adequacy. For epistemological adequacy, the scientific method had to meet some philosophical requirements as to what counts as knowledge. For metaphysical adequacy, the metaphysical presuppositions of scientific theories should coincide with the metaphysical presuppositions of philosophical theories. To different extents, the theories of scientific method developed in the seventeenth century were attempts to challenge these criteria, for they were considered more as fetters to science than enablers of its development.

In *Novum organum* (*The New Organon*; 1620/1960), Francis Bacon (1561–1626) placed method at center stage and argued that the world is knowable but only after a long process of trying to understand it—a process that begins with experience and is guided by a new method of induction by elimination. This new method differed from Aristotle’s on two counts: on the nature of first principles and on the process of attaining them. According to Bacon, the Aristotelian method (which Bacon called

“anticipation of nature”) starts with the senses and particular objects but then flies to first principles and derives from them further consequences. He contrasted this method to his own, which aims at an interpretation of nature, and which gradually and carefully ascends from the senses and particular objects to the most general principles. He rejected induction by enumeration as childish (since it takes account only of positive instances).

Bacon’s alternative proceeds in three stages. Stage 1 involves compiling a natural and experimental history to derive a complete inventory of all instances of natural phenomena and their effects. Here observation rules. Then at stage 2, one constructs tables of presences, absences, and degrees of variation. Take, for example, the case of heat, which Bacon discussed in some detail. The table of presences records all phenomena with which the nature under examination (heat) is correlated (e.g., heat is present in light, etc.). The table of absences is a more detailed examination of the list of correlations of the table of presences that seeks to find absences (e.g., heat is not present in the light of the moon). The table of degrees of variation consists of recordings of what happens to correlated phenomena if the nature under investigation (heat) is decreased or increased in its qualities. Stage 3 is induction. Whatever is present when the nature under investigation is present or increases, and whatever is absent when this nature is absent or decreases, is the *form* of this nature. The crucial element in this three-stage process is the elimination or exclusion of all accidental characteristics of the nature under investigation. On the basis of this method, Bacon claimed that heat is motion and nothing else.

Bacon’s forms are reminiscent of Aristotelian substantial forms. Yet he also claimed that the form of a nature is the law(s) it obeys. Indeed, Bacon’s view was transitional between the Aristotelian view and a more modern conception of laws of nature. Bacon, in his view of science, found almost no place for mathematics, however, though he did favor active experimentation and showed great respect for alchemists because they had laboratories. In an instance of a fingerpost, he claimed that an essential part of interpreting nature by the new method of induction consists in devising a crucial experiment that judges between two competing hypotheses for the causes of an effect. Accordingly, Bacon distinguished between two types of experiments: those that gather data for a natural and experimental history and those that test hypotheses.

## THE METAPHYSICAL FOUNDATIONS OF SCIENCE

René Descartes (1596–1650) too sought to provide an adequate philosophical foundation of science. But unlike Bacon, he felt more strongly the force of the skeptical challenge to the very possibility of knowledge of the world. So he took it upon himself to show how there could be certain (indubitable) knowledge and, in particular, how science can be based on certain first principles. Knowledge, he thought, must have the certainty of mathematics. Though Bacon was fine with some notion of virtual certainty, Descartes was after metaphysical certainty, that is, knowledge beyond any doubt. But in the end, Descartes accepted that in science a lot of things (other than the basic laws of nature) can be known only with virtual certainty. He distinguished all substances into two sorts: thinking things (*res cogitans*) and extended things (*res extensa*). He took the essence of mind to be thought and of matter extension. The vehicles of knowledge he took to be intuition and demonstration. We can be certain only of things that we can form clear and distinct ideas of or truths that we can demonstrate. Descartes tried to base his whole foundation for knowledge on a single indubitable truth, namely, “Cogito, ergo sum” (“I think; therefore I exist”). But having demonstrated the existence of God, he took God as guaranteeing the existence of the external world and, ultimately, of our knowledge of it.

Descartes was not a pure rationalist who thought that *all* science could be done a priori. Nor was he an empiricist either, obviously. He did not think that all knowledge stemmed from experience. In *Principia philosophiae* (*Principles of Philosophy*; 1644/1985), he argued that the human mind, by the light of reason alone, can arrive at substantive truths concerning the fundamental laws of nature. These laws (for instance, that the total quantity of motion in the world is conserved) are discovered and justified a priori, as they supposedly stem directly from God’s immutability. Accordingly, the basic structure of the world is discovered independently of experience, is metaphysically necessary, and is known with metaphysical certainty. But once this basic structure has been laid down, science can use hypotheses and experiments to fill in the details. This is partly because the basic principles of nature place constraints on whatever else there is and happens in the world, without determining it uniquely. The less fundamental laws of physics are grounded in the fundamental principles, but are not directly deducible from them. Hypotheses are needed to flesh out these principles. Hypotheses are also needed to

determine particular causes and matters of fact in the world, such as the shape, size, and speeds of corpuscles. It is only through experience that the values of such magnitudes can be determined. Accordingly, Descartes thought that the less fundamental laws could be known only with virtual certainty. Descartes's view of nature was mechanical: Everything can be explained in terms of matter in motion.

## NEWTON

The real break with the Aristotelian philosophical and scientific outlook occurred with the consolidation of empiricism in the seventeenth century. Empiricists repudiated the metaphysics of essences and the epistemology of rational intuition, innate ideas, and infallible knowledge. Modern philosophical empiricism was shaped by the work of three important figures: Pierre Gassendi (1592–1655), Robert Boyle (1627–1691), and Isaac Newton (1642–1727). Gassendi revived Epicurean atomism and stressed that all knowledge stems from experience. Boyle articulated the mechanical philosophy and engaged in active experimentation to show that the mechanical conception of nature is true.

Newton's scientific achievements, presented in his monumental *Philosophiæ naturalis principia mathematica* (*Mathematical Principles of Natural Philosophy*) of 1687, created a new scientific paradigm. The previous paradigm, Cartesianism, was overcome. Newton's methodological reflections became the point of reference for all subsequent discussion concerning the nature and method of science. Newton demanded certain knowledge but rejected the Cartesian route to it. By placing restrictions on what can be known and on what method should be followed, he thought he secured certainty in knowledge. His famous dictum "Hypotheses non fingo" ("I do not feign hypotheses") was supposed to act as a constraint on what can be known. It rules out metaphysical, speculative, and nonmathematical hypotheses that aim to provide the ultimate ground of phenomena. Newton took Descartes to be the chief advocate of hypotheses of the sort he was keen to deny.

His official conception of the method of science was deduction from the phenomena. He contrasted his method with the broad hypothetico-deductive method endorsed by Descartes. Newton's approach was fundamentally mathematical and quantitative. He did not subscribe to the idea that knowledge begins with a painstaking natural and experimental history of the sort suggested by Francis Bacon. The basic laws of motion, in a sense, stem from experience. They are neither true a pri-

ori nor metaphysically necessary. Newton strongly disagreed with Gottfried Leibniz (1646–1716), who thought that laws of nature are contingent but knowable a priori through considerations of fitness and perfection. The empirically given phenomena that Newton started with are laws (e.g., Kepler's laws). Then, by means of mathematical reasoning and the basic axioms or laws of motion, he drew further conclusions, for example, that the inverse-square law of gravity applies to all the planets. This kind of deduction from the phenomena has been described as demonstrative induction. It is induction, since it ultimately rests on experience and cannot deliver absolutely certain knowledge. But it is demonstrative, since it proceeds in a mathematically rigorous fashion.

## THE REVIVAL OF EMPIRICISM: LOCKE AND HUME

In his preface to *An Essay concerning Human Understanding* (1689), John Locke (1632–1704) praised "the incomparable Mr. Newton" and took his own aim to be "an Under-Labourer in clearing some Ground a little, and removing some of the Rubbish, that lies in the way of Knowledge." Locke was an empiricist and a nominalist. He thought that all ideas come from impressions and claimed that whatever exists is particular. He adopted as fundamental the distinction between primary and secondary qualities. He also drew a distinction between real essences and nominal essences. The real essence of a thing is its underlying internal constitution, based on its primary qualities. The nominal essence concerns the observable characteristics of a thing and amounts to the construction of a genus or a species. The nominal essence of gold, for instance, is a body yellow, malleable, soft, and fusible. Its real essence is its microstructure. Being a nominalist, he thought that real essences are individuals, whereas nominal essences are mere concepts or ideas that define a species or a kind. Though Locke argued that proper knowledge amounts to knowing the real essences of things, he was pessimistic about the prospects of knowing real essences. As he said, he suspected "that natural philosophy is not capable of being made a Science" (1689/1975, IV.12.10). To be sure, knowledge of nominal essences can be had, but Locke thought that this knowledge is trivial and uninteresting, since it is ultimately analytic. Even though Locke's famous book appeared after Newton's *Principia*, it is a pre-Newtonian work. It does not share Newton's optimism that the secrets of nature can be unlocked.

All empiricists of the seventeenth century accepted nominalism and denied the existence of universals. This

led them to face squarely the problem of induction. Realists about universals, including Aristotle, who thought that universals can exist only *in* things, could accommodate induction. They claimed that after a survey of a relatively limited number of instances, thought ascended to the universals shared by these instances and thus arrived at truths that are certain and unrevisable. This route was closed for nominalists. They had to rely on experience through and through, and inductive generalizations based on experience could not yield certain knowledge. This problem came in sharp focus in the work of David Hume (1711–1776).

The subtitle of Hume's *A Treatise of Human Nature* (1739/1978) was *Being an Attempt to Introduce the Experimental Mode of Reasoning into Moral Subjects*. This was an allusion to Newton's achievement and method. Hume thought that the moral sciences had yet to undergo their own Newtonian revolution. He took it upon himself to show how Newton's rules for philosophizing were applicable to the moral sciences. All ideas should come from impressions. Experience must be the arbiter of everything. Hypotheses should be looked upon with contempt. His own principles of association by which the mind works (resemblance, contiguity, and causation) were the psychological analogue of Newton's laws.

Being an empiricist, Hume argued that all factual (and causal) knowledge stems from experience. He revolted against the traditional view that the necessity that links cause and effect is the same as the logical necessity of a demonstrative argument. He argued that there can be *no* a priori demonstration of any causal connection, since the cause can be conceived without its effect and *visa versa*. Taking a cue from Nicolas Malebranche (1638–1715), he argued that there is no perception of a supposed necessary connection between cause and effect. Hume also went one step further. He found worthless his predecessors' appeals to the power of God to cause things to happen. Hume completely secularized the notion of causation. He also found inadequate, because circular, his predecessors' attempts to explain the link between causes and effects in terms of powers, active forces, and the like.

But his far-reaching point was that the alleged necessity of the causal connection cannot be empirically proved either. As he famously argued, any attempt to show, on the basis of experience, that a regularity that has held in the past *will* or *must* continue to hold in the future is circular and begs the question. It presupposes a principle of uniformity of nature. But this principle is *not* a priori true. Nor can it be proved empirically without circularity. For any attempt to prove it empirically will

have to assume what needs to be proved, namely, that since nature has been uniform in the past, it will or must continue to be uniform in the future. Hume's challenge to any attempt to establish the necessity of causal connections on empirical grounds has become known as his *skepticism* about induction. But Hume never doubted that people think and reason inductively. He just took this to be a fundamental psychological fact about human beings that cannot be accommodated within the confines of the traditional conception of Reason. Indeed, Hume went on to describe in detail some basic "rules by which to judge of causes and effects" (1739/1978, p. 173).

### KANT'S AWAKENING

Hume's critique of necessity in nature awoke Immanuel Kant (1724–1804) from his "dogmatic slumber," as he famously stated. Kant thought that Hume questioned the very possibility of science, and Kant took it upon himself to show how science was possible. He claimed that although all knowledge starts with experience, it does not arise from it. It is actively shaped by the categories of the understanding and the forms of pure intuition (space and time). The mind, as it were, imposes conceptual structure on the world, without which no experience could be possible. His central thought was that some synthetic a priori principles must be in place for experience to be possible.

Unlike Newton, Kant thought that proper science is not possible without metaphysics. Yet his understanding of metaphysics contrasted sharply with that of his predecessors. Metaphysics, Kant thought, was a science, in particular, the science of synthetic a priori judgments. Mathematics is a key element in the construction of natural science proper; without mathematics no doctrine concerning determinate natural things is possible. On these grounds, Kant argued that the chemistry of his age was more of an art than a science. The irony, Kant thought, was that though many past great thinkers (Newton in particular) repudiated metaphysics and relied on mathematics to understand nature, they failed to see that such reliance on mathematics made them unable to dispense with metaphysics. For, in the end, they had to treat matter in abstraction from any particular experiences. They postulated universal laws without inquiring into their a priori sources.

As Kant argued in his *Critique of Pure Reason* (1781/1965), the a priori source of the universal laws of nature is the transcendental principles of pure understanding. These constitute the object of knowledge in general. Thought (that is, the understanding) imposes on objects in general certain characteristics in virtue of

which objects become knowable. Phenomenal objects are constituted as objects of experience by the schematized categories of quantity, quality, substance, causation, and community. If an object is to be an object of experience, it must have certain necessary characteristics: It must be extended; its qualities must admit of degrees; it must be a substance in causal interaction with other substances. In his three Analogies of Experience, Kant tried to prove that three general principles hold for all objects of experience: that substance is permanent, that all changes conform to the law of cause and effect, and that all substances are in thoroughgoing interaction. These synthetic a priori principles make experience possible. In particular, there is the universal law of causation, namely, that “everything that happens, that is, begins to be, presupposes something upon which it follows by rule.” This is nothing like an empirical generalization. Rather, it is imposed by the mind on objects.

Yet these transcendental principles make no reference to any objects of experience in particular. In his *Metaphysical Foundations of Natural Science* (1786/1970), Kant sought to show how these principles could be concretized in the form of laws of matter in motion. Kant thus enunciated the law of conservation of the quantity of matter, the law of inertia, and the law of equality of action and reaction, and he thought that these laws were the concrete mechanical analogues of his general transcendental principles. These laws were metaphysical laws in that they determined the possible behavior of matter in accordance with mathematical rules. They determine the pure and formal structure of motion, where motion is treated *in abstracto* purely mathematically. It is no accident, of course, that the last two of these laws (the law of inertia and the law of equality of action and reaction) are akin to Newton’s laws and that the first law (the law of conservation of the quantity of matter) was presupposed by Newton too. Kant intended his metaphysical foundations of (the possibility of) matter in motion to show how Newtonian mechanics was possible. But Kant also thought that there are physical laws that are discovered empirically. Though he held as true a priori that matter and motion arise out of repulsive and attractive forces, he claimed that the laws of particular forces, even the law of universal attraction as the cause of gravity, can only be discovered empirically.

His predecessors, Kant thought, had failed to see the hierarchy of laws that make natural science possible: transcendental laws that determine the object of possible experience in general, metaphysical laws that determine matter in general, and physical laws that fill in the actual

concrete details of motion. Unlike the third kind, laws of the first two kinds require a priori justification and are necessarily true. Though philosophically impeccable, Kant’s architectonic suffered severe blows in the nineteenth and early twentieth centuries. The blows came, by and large, from science itself. Creating an explosive mixture that led to the collapse of Kant’s synthetic a priori principles were the crisis of Newtonian mechanics, the emergence of Albert Einstein’s special and general theories of relativity, the advent of quantum theory, the emergence of non-Euclidean geometries and their application to physics, Gottlob Frege’s claim that arithmetic, far from being synthetic a priori, was a body of analytic truths, and David Hilbert’s arithmetization of geometry, which proved that no intuition was necessary. It is no exaggeration to claim that much of philosophy of science in the first half of the twentieth century was an attempt to come to terms with the collapse of the Kantian synthetic a priori and to re-cast (or even cast to the wind) the concepts of the a priori and the analytic so as to do justice to developments in the sciences.

#### WHEWELL VERSUS MILL

The nineteenth century saw the culmination of Newtonian mechanics, mostly in the able hands of Pierre-Simon Laplace (1749–1827) and his followers. The Newtonian framework was extended to capture other phenomena, from optics, to heat, to electricity and magnetism. But Kant’s philosophy was very much the doctrine that almost every serious thinker about science had to reckon with. William Whewell (1794–1866) took from Kant the view that ideas (or concepts) are necessary for experience in that only through them can facts be bound together. He noted, for instance, that induction gives rise to a “new mental element.” The concept of elliptical orbit, he thought, was not already there in the astronomical data employed by Johannes Kepler, but was a new mental element added by Kepler. But, unlike Kant, he thought that history (and the history of science in particular) had a key role to play in understanding science and its philosophy. He analyzed this role in *The Philosophy of the Inductive Sciences, Founded upon Their History* (1840). Each science grows through three stages, Whewell thought. It begins with a “prelude,” in which a mass of unconnected facts is collected. It then enters an “inductive epoch,” in which the useful theories of creative scientists bring order to these facts—an act of “colligation.” Finally, a “sequel” follows, where the successful theory is extended, refined, and applied. Whewell strongly emphasized the role of hypotheses in science. Hypotheses can be proven true, he

thought, by a “consilience of inductions,” by which he meant the theoretical unification that occurs when a theory explains data of a kind different from those it was initially introduced to explain, and when a theory unifies hitherto unrelated domains. Indeed, Whewell found in the consilience of inductions a criterion of truth.

His contemporary John Stuart Mill (1806–1873) took an empiricist turn. Mill was a thoroughgoing inductivist who took all knowledge to arise from experience through induction. He even held that the law of universal causation, namely, that for every event there is a set of circumstances upon which it follows as an invariable and unconditional consequent, is inductively established. Hence, Mill denied that there could be any certain and necessary knowledge. But Mill also tried to delineate the scientific method so that it leads to secure causal knowledge of the world. In *A System of Logic, Ratiocinative and Inductive* (1843/1911) he put forward the method of agreement and the method of difference. According to the first, the cause is the common factor in a number of otherwise different cases in which the effect occurs. According to the second, the cause is the factor that is different in two cases that are similar except that the effect occurs in one, but not the other. In effect, Mill’s methods encapsulate what is going on in controlled experiments. Mill was adamant, however, that his methods work *only if* certain substantive metaphysical assumptions are in place: that events have causes, that events have a *limited* number of possible causes, and that the same causes have the same effects, and conversely.

Mill was involved in a debate with Whewell concerning the role of novel predictions. Unlike Whewell, Mill thought that no predictions could *prove* the truth of a theory. He suggested that a hypothesis could not be proved true on the basis that it accounts for known phenomena, since other hypotheses may fair equally well in this respect. He added that novel predictions cannot provide proof either, since they carry no extra weight over predictions of known facts. Mill’s target was not just the crude version of the method of hypothesis. He wanted to attack the legitimacy of the rival substantive assumption featured in Whewell’s more sophisticated view, namely, that elimination of rival hypotheses can and should be based on explanatory considerations. The difference between Mill and Whewell was over the role of substantive explanatory considerations in scientific method. The debate continues.

## CONVENTIONALISM

The inductivist tradition that flourished in England in the nineteenth century was challenged by the rise of French conventionalism. The work of Henri Poincaré (1854–1912) on the foundations of geometry raised the question of whether physical space is Euclidean. In *La science et l’hypothèse* (*Science and Hypothesis*; 1902/1952), Poincaré took this question to be meaningless, because, he suggested, one can make physical space possess *any* geometry one likes, provided that one makes suitable adjustments to one’s physical theories. Consequently, he called the axioms of Euclidean geometry “conventions” (definitions in disguise). He extended his geometric conventionalism further by arguing that the principles of mechanics are also conventions. Conventions, for Poincaré, are general principles that are held to be true but whose truth can neither be the product of a priori reasoning nor be established on a posteriori grounds. But calling general principles “conventions” did not imply, for Poincaré, that their adoption (or choice) was arbitrary. He stressed that some principles were more convenient than others. He thought that considerations of simplicity and unity, as well as certain experiential facts, could and should guide the relevant choice. Indeed, he envisaged a hierarchy of the sciences in which the axioms of Euclidean geometry and the principles of Newtonian mechanics are in place (as ultimately freely chosen conventions) so as to make possible empirical and testable physical science.

Though Poincaré took scientific theories to be mixtures of conventions and facts, he favored a structuralist account of scientific knowledge that was Kantian in origin. The basic axioms of geometry and mechanics are (ultimately freely chosen) conventions, and yet, he thought, scientific hypotheses proper, even high-level ones such as Maxwell’s laws, are empirical. Faced with discontinuity in theory change (the fact that some basic scientific hypotheses and laws are abandoned in the transition from one theory to another), he argued that there is, nonetheless, substantial continuity at the level of the mathematical equations that represent empirical and theoretical relations. From this, he concluded that the theoretical content of scientific theories is structural, by which he meant that a theory, if successful, correctly represents the *structure* of the world. In the end, the structure of the world is revealed by structurally convergent scientific theories.

## THE RISE OF ATOMISM

The beginning of the twentieth century was marked by a heated debate over atomism, an emergent scientific theory that posited unobservable entities, atoms, to account

for a host of observable phenomena (from chemical bonding to Brownian motion). Though many scientists adopted atomism right away, there was strong resistance to it by other eminent scientists. Ernst Mach (1838–1916) resisted atomism on the basis of the empiricist claim that the concept of atoms was radically different from ordinary empirical concepts, and hence problematic. Resistance to atomism was best exemplified in the writings of Pierre Duhem (1861–1916). In *La théorie physique, son objet, sa structure* (*The Aim and Structure of Physical Theory*; 1906/1954), he put forward an antiexplanationist form of instrumentalism that sharply distinguished science and metaphysics, and claimed that explanation belongs to metaphysics and not to science.

But Duhem's theory of science rested on a restricted understanding of scientific method that can be captured by the equation "scientific method = experience + logic." On this view, whatever cannot be proved from experience with the help of logic is irredeemably suspect. To be sure, theories, as hypothetico-deductive systems, help scientists classify and organize the observable phenomena. But, for Duhem, the theoretical hypotheses of theories can never be confirmed or accepted as true. At best, they can be appraised as convenient or inconvenient, empirically adequate or empirically inadequate, classifications of the phenomena. Ironically, Duhem himself offered some of the best arguments against his own instrumentalist conception of theories. The most central one comes from the possibility of *novel* predictions. If a theory were just a "rack filled with tools," it would be hard to understand how it can be "a prophet for us" (Duhem 1906/1954, p. 27).

Duhem was a strong critic of inductivism. He argued that observation in science is not just the act of reporting phenomena. It is the interpretation of phenomena in the light of some theory and other background knowledge. This thesis, known as the view that observation is theory-laden, resurfaced in the 1960s, at that time drawing on a mass of empirical evidence coming from psychology to the effect that perceptual experience is theoretically interpreted. Duhem also stressed that there can be no crucial experiments in science, since no theory can be tested in isolation from other theories (and auxiliary assumptions), and consequently, that any theory can be saved from refutation by making suitable adjustments to collateral theories or auxiliary assumptions.

### THE A PRIORI SET IN MOTION

Though battered by developments in physics and mathematics, the Kantian conception of a priori principles did find a place of sorts in the work of the neo-Kantian

school of Marburg, Germany. In *Substance and Function* (1910/1923), Ernst Cassirer (1874–1945) argued that, though mathematical structures are necessary for experience, in that phenomena can be identified, organized, and structured *only* if they are embedded in such structures, these structures need not be fixed and immutable for all time. He thought that mathematical structures, though a priori (since they are required for objective experience), are revisable yet convergent: Newer structures accommodate old ones within themselves.

But it was Hans Reichenbach (1891–1953), in *The Theory of Relativity and A Priori Knowledge* (1921/1965), who unpacked the two aspects of Kant's conception of the a priori: that a priori truths are necessarily true, and that they structure objects of knowledge. Reichenbach rejected the first aspect of a priori knowledge, but insisted that the second aspect was inescapable. Knowledge of the physical world, he thought, requires principles of coordination, that is, principles that connect the basic concepts of the theory with reality. These principles he took to structure experience. Mathematics, he thought, was indispensable precisely because it provided a framework of general rules for coordinating scientific concepts and reality. Once this framework is in place, a theory can be presented as an axiomatic system, whose basic axioms (what Reichenbach called "axioms of connection") are empirical. Against Kant, Reichenbach argued that a priori principles of coordination, though they structure objects of knowledge, can be rationally revised in response to experience. He was naturally led to conclude that the only workable notion of the a priori is one that is *relativized*.

### LOGICAL POSITIVISM

The influence of Moritz Schlick (1882–1936) on the philosophical course of events can hardly be exaggerated. Armed with the notion of convention, he and his followers, the logical positivists, tried to show that there can be no synthetic a priori at all. They extended conventionalism to logic and mathematics, arguing that the only distinction possible is between empirical (synthetic a posteriori) principles and conventional (analytic a priori) ones. In particular, though they thought that empirical science requires a logico-mathematical framework to be in place before theories can get any grip on reality, this conventional and analytic framework is purely *formal* and is *empty* of factual content. Accordingly, all a priori knowledge is analytic. Moreover, the logical positivists' conventionalist account of analyticity implies that grasping a priori (or analytic) truths requires no special faculty of intuition and that having epistemic access to a priori

(or analytic) truths presents no deep philosophical problem. Accompanying the doctrine that analytic truths are definitions or stipulations was the so-called linguistic doctrine of necessity: that all and only analytic truths are necessary. In the spirit of Hume, this doctrine excised all necessity from nature, and had already played a key role in Ludwig Wittgenstein's *Tractatus Logico-Philosophicus*.

The logical positivists adopted an empiricist criterion of meaning known as the verification principle. Nonanalytic statements, that is, synthetic empirical statements, are meaningful (cognitively significant) if and only if their truth can be verified in experience. In slogan form, the meaning is the method of verification. The logical positivists used this criterion to show that statements of traditional metaphysics were meaningless, since their truth (or falsity) made no difference in experience.

Soon after the foregoing criterion of meaning was adopted, a fierce intellectual debate started among members of the Vienna Circle, a debate that spanned a good deal of the 1930s and came to be known as the "protocol-statements debate." Protocol statements were supposed to capture the content of scientists' observations in such a basic form that they can be immediately verified. One issue was whether protocol statements are (should be) expressed in physical-object language ("The needle points to 2 on the dial") or in phenomenal language ("A black line overlies a "2" shape on a white background"). Though the balance soon turned in favor of the former, Rudolf Carnap (1891–1970), following Schlick, did toy with the idea that protocol statements need no justification, for they constitute the simplest states in which knowledge can be had. But he was soon convinced by the arguments of Otto Neurath (1882–1945) that there are neither self-justified protocol statements nor statements not subject to revision, if only because the processes that yield them are fallible. Instead of abandoning the claim that science provides knowledge, on the grounds that this knowledge cannot be certain, Carnap opted for the view that scientific knowledge falls short of certainty. Armed with Alfred Tarski's account of truth, he claimed that the truth of a scientific statement is no less knowable than the statement itself.

In the course of the 1930s, the concept of verifiability moved from a strict sense of being provable on the basis of experience to the much more liberal sense of being confirmable. The chief problem was that the strong criterion of cognitive significance failed to deliver the goods. In addition to metaphysical statements, many ordinary scientific assertions, those that express universal laws of nature, turn out meaningless on this criterion,

precisely because they are not, strictly speaking, verifiable.

According to the logical positivists, Hilbert's approach to geometry and the Duhem and Poincaré hypothetico-deductive account of scientific theories, if combined, offer a powerful and systematic way to present scientific theories. The basic principles of the theory are taken to be the axioms. But the terms and predicates of the theory are stripped of their interpretation, or meaning. Hence, the axiomatic system itself is entirely formal.

The advantage of the axiomatic approach is that it lays bare the logical structure of the theory, which can then be investigated independently of the meaning, if any, one may assign to its terms and predicates. However, as a formal system, the theory lacks any empirical content. For the theory to acquire such content, its terms and predicates have to be suitably interpreted. It was a central thought of the logical positivists that a scientific theory need not be completely interpreted to be meaningful and applicable. They claimed that it is enough that only *some* terms and predicates, the so-called observational ones, be interpreted. The other terms and predicates of the theory, in particular, those that, taken at face value, purport to refer to unobservable entities, were deemed theoretical and were taken to be only partially interpreted by means of correspondence rules. It was soon realized, however, that the correspondence rules muddle the distinction between the analytic (meaning-related) part and the synthetic (fact-stating) part of a scientific theory—a distinction that was central in the thought of the logical positivists. For, on the one hand, the correspondence rules specify (even if only partly) the meaning of theoretical terms, and on the other hand, they contribute to the factual content of the theory.

## A GHOSTLY DISTINCTION

A key idea developed in Carnap's *Logical Syntax of Language* (1934/1937) was that the development of a general theory of the logical syntax of the logico-mathematical language of science would provide a neutral framework in which scientific theories are cast and studied, scientific concepts (e.g., explanation, confirmation, laws, etc.) are explicated, and traditional metaphysical disputes are overcome. The project required a sharp analytic-synthetic distinction. Philosophical statements would be analytic (about the language of science), and scientific statements would be synthetic (about the world). A central (and stable) tenet of Carnap's was the principle of tolerance. Since the choice of a language is a conventional matter (to be evaluated only in terms of its practical fruitfulness), the

aim of philosophy of science, Carnap held, is to make clear the different language *forms* adopted by rival parties in philosophical and scientific disputes (e.g., the dispute between logicists and intuitionists in mathematics, or between realists and idealists, Platonists and nominalists, scientific realists and instrumentalists in philosophy of science). Far from being genuinely factual, these disputes, Carnap thought, center on suitable choices of a language. The principle of tolerance is thus part of Carnap's attempt to eliminate metaphysical "pseudoproblems" from the sciences. It formulates a metatheoretical standpoint in which issues of ontology are replaced by issues concerning logical syntax.

Carnap's project in *The Logical Syntax of Language* came to grief. This was the result of many factors, but prominent among them were Tarski's work on truth (which suggested that truth is an irreducibly semantic notion) and Kurt Gödel's incompleteness theorem. Though Carnap was fully aware of Gödel's limitative results, his own attempt to provide a neutral, minimal metatheoretical framework (the framework of "General Syntax" [1934/1937, pt. IV]) in which the concept of analyticity was defined fell prey to Gödel's proof that some mathematical truths are not provable within such a system.

The notion of analytic a priori truths came under heavy attack from W. V. O. Quine (1908–2000). In "Two Dogmas of Empiricism" (1951), Quine argued that the notion of analyticity is deeply problematic, since it requires a notion of cognitive synonymy (sameness of meaning) and there is no independent criterion of cognitive synonymy. Quine's chief argument against the analytic/synthetic distinction rested on the view that "analytic" was taken to mean unrevisable. If analytic statements have no empirical content, experience cannot possibly have any bearing on their truth-values. So analytic statements cannot undergo truth-value revision. But, Quine argued, nothing (not even logical truths) is unrevisable. Hence, there cannot be any analytic truths. Here Quine took a leaf from Duhem's book (and also from Carnap's book). Confirmation and refutation are holistic; they accrue to systems (theories) as a whole and not to their constituent statements, taken individually. If a theory is confirmed, then everything it says is confirmed. Conversely, if a theory is refuted, then *any* part of it can be revised (abandoned) to restore accord with experience. The image of science that emerged had no place for truths with a special status: all truths are on a par. This leads to a blurring of the distinction between the factual and the conventional. What matters for Quine is

that a theory acquires its empirical content as a whole, by issuing in observational statements and by being confronted with experience.

The cogency of Quine's attack on the a priori rests on the cogency of equating the notion of a priori with the notion of unrevisable. We have already seen a strand in post-Kantian thinking that denied this equation, while holding onto the view that some principles structure experience. It might not be surprising, then, that Carnap was not particularly moved by Quine's criticism. For he *too* denied this equation. Quine, however, did have a point. For Carnap, (a) it is rational to accept analytic statements within a linguistic framework; (b) it is rational to reject them when the framework changes; and (c) all and only analytic statements share some characteristic that distinguishes them from synthetic statements. Even if Quine's criticisms are impotent against (a) and (b), they are quite powerful against (c). The point was simply that the dual role of correspondence rules (and the concomitant Hilbert-style implicit definition of theoretical terms) made drawing this distinction impossible, even *within* a theory. Carnap spent a great deal of effort to develop the characteristic specified in (c). In the end, he had to reinvent Ramsey sentences to find a plausible way to draw the line between the analytic and the synthetic (Psillos 1999, chap. 3).

The challenge to the very possibility of a priori knowledge was a key factor in the *naturalist turn* in the philosophy of science in the 1960s. The emergence of naturalism was a real turning point in the philosophy of science, because it amounted to an ultimate break with neo-Kantianism in all its forms. By the 1960s, philosophy of science had seen the advent of psychologism, naturalism, and history of science.

## PHILOSOPHY OF SCIENCE, PROBLEMS OF

The scope of the philosophy of science is sufficiently broad to encompass, at one extreme, conceptual problems so intimately connected with science itself that their solution may as readily be regarded a contribution to science as to philosophy and, at the other extreme, problems of so general a philosophical bearing that their solution would as much be a contribution to metaphysics or epistemology as to philosophy of science proper. Similarly, the range of issues investigated by philosophers of science may be so narrow as to concern the explication of a single concept, considered of importance in a single branch of science, and so general as to be concerned with structural features invariant to all the branches of science, taken as a class. Accordingly, it is difficult to draw boundaries that neatly separate philosophy of science from philosophy, from science, or even from the history of science, broadly interpreted. But we can give some characterization of the main groups of problems if we think of science as concerned with providing descriptions of phenomena under which significant regularities emerge and with explaining these regularities. Problems thus arise in connection with terms, with laws, and with theories where a theory is understood as explaining a law and a law is understood as stating the regularities that appear in connection with descriptions of phenomena.

### TERMS

Ordinary language provides us the wherewithal to offer indefinitely rich descriptions of individual objects, and, as a matter of logical fact, no description, however rich, will exhaustively describe a given object, however simple. Science chooses a deliberately circumscribed vocabulary for describing objects, and scientists may be said to be concerned only with those objects described with the vocabulary of their science and with these only insofar as they are so describable. Historically, the terms first applied by scientists were continuous with their cognates in ordinary speech, just as science itself was continuous with common experience. But special usages quickly developed, and an important class of philosophical problems concerns the relation between scientific and ordinary language, as well as that between those terms selected for purposes of scientific description and other terms that, though applicable to all the same objects as the former, have no obvious scientific use. Scientists from Galileo Galilei to Arthur Eddington have sometimes tended to impugn as unreal those properties of things not

covered by scientific description or at least have thought that the question of which are the real properties is an important one. Certainly, it would destroy the very concept of science to suppose it possible to account for all the distinctions between things under all the descriptions of them that are feasible, but there is no recipe for selecting the scientifically relevant predicates.

In practice, terms have been chosen when there seem to be interesting and systematic patterns of change in the properties picked out by these terms—for instance, between the distance a body travels and the time it takes to do so, between the temperature and the pressure of a gas, between the density of a fluid and the deviation from a norm of a light ray passing into it, and so forth. It has often been immensely difficult to set aside manifest and cherished differences among objects and the subtle language for expressing these in favor of the spare vocabulary of science under which such seemingly crucial distinctions are obliterated, as, for example, between celestial and terrestrial objects or between “noble” and base metals.

Not only do scientific terms cut across the distinctions of common sense, but they also permit distinctions not ordinarily made and allow comparisons more precise than ordinarily demanded—for example, between differential amounts and precisely determinable degrees. For the class of terms discussed here are those that may be said to apply or not to apply to a given object by means of an act of observation rendered precise through some device of mensuration—for example, that the distance traveled is  $n$  units along a scale, that the temperature of a gas is  $n$  degrees along another scale, that the density of a fluid is  $m$  grams per cubic centimeter. The last measurement, which involves reference to different scales—namely, measures of mass and volume—is sometimes called a “derived” in contrast with a “fundamental” measurement, where only single scales are involved. But even when we speak of derived measurements, as with pressure (in terms of foot-pounds), velocity (in terms of feet per second), or stress (in terms of force per unit area), we remain within the domain of observation; the coincidence of a needle with a mark on a gauge, the angle of a balance, the appearance of a color, a bubble between lines, or a certain buzz, inform us that a given term is true or false with respect to whatever we are studying.

Philosophers may press for a further reduction of the observational language of a science to a favored idiom—for example, to a sense-datum language—but within science observational vocabulary enjoys a certain ultimacy. There are many questions as to whether observational

language, thus construed, is sufficient for the entire conduct of science, whether the whole language of science can be expressed in purely observational terms so that recourse need never be made to covert entities, hidden processes, or occult structures unamenable to direct observation and measurement. This issue cannot be fruitfully discussed until we come to the topic of theories, but it has been recognized that while observation has an essential role to play as the occasion for framing and the basis for testing scientific hypotheses, the no less important feature of measurement sets a limit on the program of thoroughgoing observationalism. For the algorithms, in connection with which it first makes scientific sense to assign numerical values and to apply scales, require use of the real number system, the class of whose values has the power of the continuum.

Hence, as Carl G. Hempel remarked, “A full definition of metrical terms by means of observables is not possible.” Nevertheless, it has been through the efforts of reductionists to assimilate the entirety of scientific language to observation terms that other sorts of terms, having logically distinct roles within science, have been discovered, and a main task in philosophy of science has been to identify and determine the relation between terms occurring at different levels, and variously related to observation, within the idiom of developed scientific theories.

## LAWS

One cannot very readily treat the syntactical features of laws in isolation from their semantic properties or, for that matter, from pragmatic considerations. Syntax here concerns the formal conditions of “lawlikeness” for sentences, and semantics concerns the truth conditions for lawlike sentences, it being customary to define a law as a true lawlike sentence. But some philosophers will reject this definition since it might rule out any sentence as having the status of a law, inasmuch as laws are not, they feel, the sorts of sentences that it makes sense to regard as admitting truth-values in the normal way or even at all; for these a law would be a lawlike sentence which has a certain use.

It is commonly supposed that a universally quantified conditional sentence— $(x)(Fx \supset Gx)$ —is the simplest form with which a lawlike sentence may be expressed. The chief syntactical problems arise, however in connection with the nonlogical terms  $F$  and  $G$ . For an important class of cases these will be observational, so that it is in principle possible to determine whether a given instance is both  $F$  and  $G$ , and the law is generally based upon some

known favorable instances, Yet there are cases in which the terms satisfy observational criteria, in which there are a large class of favorable instances and no known counterinstances, and still the appearance of these terms in a lawlike sentence  $L$  disqualifies  $L$  as a law even if it is true. Such terms are unduly restricted in scope, whereas it is thought that the terms suitable for laws should be unrestricted in scope. “All the hairs on my head are black” employs the restrictive term “the hairs on my head” and thus is disqualified as a law.

A criterion sometimes advanced for identifying restrictive terms as antecedents in possible laws is that if the requisite universal conditional supports a true counterfactual, it is a law, but if the counterfactual is false, as (with reference to a certain white hair) “If that hair were on my head, it would be black” is false, then the corresponding sentence is not a law, and the term is restricted. However, this criterion begs the question insofar as it seems that counterfactuals must be analyzed in terms of general laws; at any rate, the analysis of counterfactuals, as well as the basis for distinguishing true from false counterfactuals, remains to be given by philosophers. In what sense “the hairs on my head” is restrictive, whereas *ravens* in “All ravens are black” is not, is difficult to specify, though the former does refer to a specific object (my head) and it is believed that the terms in a law must not make such references. This restriction, however, makes Johannes Kepler’s laws laws in name only and forestalls the possibility of any laws for the universe as a whole. And though Kepler’s laws may be retained since they are derivable from laws that employ unrestricted and generally referential terms, the laws of the universe hardly could be thus derived; moreover, it could be argued that “All the hairs on my head are black” might be derivable from some general laws of hirsuteness, making use only of purely qualitative predicates. Thus, precise and rigorous criteria for lawlikeness are difficult to specify.

If the terms of a lawlike sentence  $L$  must be unrestricted,  $L$  cannot be known as true through induction by finite enumeration; since there must in principle always be uninspected instances under  $F$ , the law  $(x)(Fx \supset Gx)$  cannot be known true no matter how many known favorable instances there are. Of course, laws are not always (and perhaps not even often) inductive generalizations from large samples—Galileo’s laws, for instance, were based upon few observations indeed—and it has been maintained by anti-inductivists (chiefly Karl Popper and his followers) that observations function as tests rather than inductive bases for laws; in this view laws need not be generalizations from observation but only be in prin-

ciple falsifiable on the basis of observation. Some lawlike sentences may be known false, at least to the extent that they admit of observational consequences, but often the antecedent of a lawlike sentence is sufficiently hedged with *ceteris paribus* riders, to which we may add indefinitely, that one need not surrender a law save as an act of will.

This suggests that the criteria for accepting a lawlike sentence as a law are more complex than either inductivists or their opponents have recognized, and an instrumentalist position may be taken, in accord with which laws are neither true nor false but serve as instruments in the facilitation of inference—“inference-tickets,” as Gilbert Ryle put it. In this view, as Stephen Toulmin pointed out, the question is not “Is it true?” but “When does it hold?” Here laws are regarded not as sentences about the world but as rules for conducting ourselves in it, and semantic considerations thus yield to pragmatic ones in that there is surely some agreement that a criterion for accepting  $L$  as a law is that it should, in conjunction with information, furnish successful predictions. Whether, in addition, a successful law is true and, if so, in what sense it is true other than that it successfully enables predictions cannot be discussed independently of larger philosophical considerations.

Many laws in science are statistical in form, but the suggestion that a law may be truly scientific and yet affirm a merely probable connection among phenomena has been offensive to scientists and philosophers with antecedent commitments to determinism as a metaphysical fact or a scientific ideal. For these nothing less than deterministic (nonstatistical) laws are ultimately tolerable, so that statistical laws, while countenanced as interim makeshifts, are, ideally, to be replaced in every instance with deterministic ones. As a program, however, the projected reconstruction of statistical laws and the theories that contain them has encountered an impressive obstacle in the quantum theory of matter, upon which the whole of atomic physics is based, for the laws here are demonstrably irreducible to deterministic form.

To be sure, there is a logical possibility that quantum theory could be replaced in toto. But there is no way—for instance through the discovery of hidden variables—in which its laws may be rendered deterministic, and since there is scant evidence for any alternative and the evidence for quantum theory is overwhelming, most members of the scientific community are reconciled to an obdurate indeterminism at the core of one of its most fundamental theories. If the quantum theory should be true, certain events are objectively probable, or indeter-

ministic; that is, they are probable independently of the state of our knowledge or ignorance.

An epistemological sense of probability, connected with our concepts of induction and confirmation, is not incompatible with determinism; we may even speak of the probability of a deterministic law, meaning that relative to our evidence its degree of confirmation is equal to a number between 0 and 1. It is nonepistemological probability, according to which we could conceivably be certain that a given event were objectively probable, which is allegedly repugnant to determinism. It should be pointed out, however, that indeterministic laws may be deterministic in at least the sense that the values of certain probability variables are precisely determined by the values of other variables. At any rate, the extent of incompatibility between determinism and indeterministic laws and the precise explication of the two kinds of probability are topics of continuing philosophical investigation and controversy.

Laws are believed to play an important role in explanation as well as in prediction. It has been maintained that a necessary condition for explaining an event *E* consists in bringing *E* under the same general law with which it could have been predicted. Hempel regards the temporal position of the scientist vis-à-vis the event as the sole difference between explaining and predicting that event. This symmetry has been challenged (notably by Israel Scheffler), but we might still maintain Hempel's thesis by distinguishing among laws. Not every law used in prediction has explanatory force if we think of explanations as causal explanations, for causal laws do not exhaust the class of scientific laws, which also includes functional expressions of covariation among magnitudes, statistical laws, and so on, all of which are used in predicting. Even so, it has been questioned whether even causal explanation requires the use of causal laws, either in science or in history or the social sciences, where this controversy has been chiefly focused.

Be this as it may, the explanation of particular events has less importance in science proper than the explanation of regularities, and it is therefore the explanation of laws that characterizes scientific achievement in its most creative aspect. This brings us to theories, for it is commonly held that to explain a law *L* is to derive *L* from a theory *T* when *T* satisfies certain conditions.

## THEORIES

Let us characterize a law all of whose nonlogical terms are observational as an empirical law. A theory may be regarded as a system of laws, some of which are empiri-

cal. Not every empirical law is part of a theory, nor are all the laws of a theory empirical, for some of a theory's laws employ theoretical terms, which are nonobservational. Theoretical terms, if they denote at all, refer to unobservable entities or processes, and it is with respect to changes at this covert level that one explains the observed regularities as covered by empirical laws. Thus one explains the regularities covered by the Boyle–Charles law (all the terms of which are observational) in terms of the (unobservable) behavior of the gas molecules of which the gas is theoretically composed. The status of theoretical terms (and the theoretical entities they would designate if they designated anything) has been the subject of intense philosophical investigation. It is not mere unobservability—Julius Caesar is at this point in time unobservable though his name is not a theoretical term—but unobservability in principle that characterizes these entities; it is unclear whether there would be any sense in speaking of observing, say, Psi-functions, electrons, fields, super-egos, and the like. Moreover, the behavior of theoretical entities, supposing the theory to be true, is (as with certain fundamental particles) often so grossly disanalogous to the behavior of the entities they are invoked to explain that our ordinary framework of concepts fails to apply to them.

Yet theoretical terms seem deeply embedded in scientific language. Empiricist strategies of eliminating them by explicit definition in observational language or of tying them to observation by reduction sentences have failed, although there exist techniques by which they may be formally replaced with striking ease. William Craig demonstrated that any theory containing both theoretical and observational predicates may be replaced with another employing only observational ones but yielding, nevertheless, all the observational theorems (or empirical laws) of the original. Craig's result, however, has not been a victory for empiricism; the reasons for this are somewhat obscure, but it is due in part at least to the realization that theoretical terms play a role and have a meaning in terms of the total structure of the theory and therefore cannot be neatly extricated to leave anything to be called a "theory." Indeed, it often happens that rather than theoretical terms being defined in observational terms, observational terms are defined with reference to the theoretical vocabulary, so that one must, in effect, master the theory in order to make the relevant observations.

With the elaboration of a theory, however, the inferential route from observation to (predicted) observation becomes complex (there may be many intervening steps and intermediate computations) and far removed from

the simple universal conditional used to represent a law. A theory, in Hempel's words, "may be likened to a complex spatial network [which] floats, as it were, above the plane of observation and is anchored to it by rules of interpretation." Theories, that is, impinge upon experience as wholes but not in all their parts, and the rules of interpretation, or correspondence, which permit them to be applied, are not part of the theory; indeed, the same formal theoretical network might, through different interpretations, have application to different domains of experience.

We may think of a theory as a formal system distinguishable, in principle, from its interpretation, regarding the former (in R. B. Braithwaite's terms) as a calculus and the latter as its model. In point of scientific history and practice, however, model and calculus emerge together. The distinction first began to be clear through the advent of non-Euclidean geometries and the consequent agitated question of which was physically descriptive, and geometry, perhaps because it has been almost paradigmatic of axiomatic systems, has served as a pattern, at least for analytical purposes, for the calculi of theories generally. Thus, philosophers think of theories as employing primitive and derived terms, primitive and derived sentences, satisfying explicit formation and transformation rules, and the like. But whether, apart from the purposes of philosophical representation, actual scientific theories exhibit axiomatized form and whether axiomatization is even a desideratum for scientific theory-formation are moot points.

At any rate, the framing of theories in the course of history has almost always involved some intuitive model on the scientist's part, the pattern of thought being (whether this is or is not the "logic of discovery" that N. R. Hanson suggested) this, that the regularities for which explanation is sought would hold as a matter of course if certain states of affairs (those postulated by the theory) held in fact. Whether the theoretical states do hold in fact is, of course, the immediate question, and it is through the obligation to provide an answer that the scientific imagination is disciplined. Without the formal means of deriving testable consequences from a theory, the theory would merely be ad hoc, and one wants more than the mere deduction of the laws that the theory was intended to explain. Indeed, it is by and large the ability of a theory to permit derivations far afield from its original domain that serves as a criterion for accepting a theory, for in addition to the obvious fruitfulness such a criterion emphasizes, such derivations permit an increasingly broad and diversified basis for testing the theory. The

great theories in the development of science—Isaac Newton's, Albert Einstein's, Paul Dirac's—have brought into a single comprehensive system great numbers of phenomena not previously known to have been connected.

It is impossible to say, of course, whether the whole of scientific knowledge might someday be embraced in a single unified theory, but piecemeal assimilation of one theory to another is constantly taking place, and the conceptual issues that arise through such reductions are of immense philosophical interest. The careful elucidation of the logic of scientific reduction—of thermodynamics to mechanics, of wave and matrix mechanics—draws attention to features that lie, far more obscurely, within the oldest philosophical problems and controversies: problems of emergence, of natural kinds, of free will and determinism, of body and mind, and so on. The treatment of these questions is often not so much philosophy of science proper as the philosophical interpretation of science, in which the philosophy of science serves as a technique of philosophical clarification, illuminating topics remote from the conceptual issues of science as such.

### **Bibliography**

The literature on the philosophy of science is immense and often technical. Many influential papers are anthologized in *Philosophy of Science*, edited by Arthur C. Danto and Sidney Morgenbesser (New York: Meridian, 1960), and in *Readings in Philosophy of Science*, edited by Herbert Feigl and May Brodbeck (New York: Appleton-Century-Crofts, 1953). The following may be consulted as representative and excellent discussions. On preliminary definition of the field see R. B. Braithwaite, *Scientific Explanation* (Cambridge, U.K.: Cambridge University Press, 1953), pp. 1–9, and Israel Scheffler, *The Anatomy of Inquiry* (New York: Knopf, 1963), pp. 3–15. On the observational bases of science see Carl G. Hempel, *Fundamentals of Concept Formation in Empirical Science* (Chicago: University of Chicago Press, 1952), especially pp. 20–50, and Scheffler, *op. cit.*, pp. 127–222. On measurement see Ernest Nagel "Measurement," in Danto and Morgenbesser, *op. cit.*, pp. 121–140. On laws see C. F. Presley, "Laws and Theories in the Physical Sciences," in Danto and Morgenbesser, *op. cit.*, pp. 205–215; Ernest Nagel, *The Structure of Science* (New York: Harcourt Brace, 1960), especially pp. 29–78; and Stephen Toulmin, *Philosophy of Science* (London: Hutchinson, 1953), pp. 57–104. On the nonlogical terms of laws see Carl G. Hempel and Paul Oppenheim, "The Logic of Explanation," in Feigl and Brodbeck, *op. cit.*, pp. 319–352. On laws and

falsifiability see Karl Popper, *The Logic of Scientific Discovery* (New York: Hutchinson, 1959), pp. 27–48. On explanation see Hempel and Oppenheim, op. cit. On the parity between explanation and prediction see Scheffler, op. cit., pp. 43–88. On theories see Braithwaite, op. cit., pp. 50–114; Nagel, *The Structure of Science*, op. cit., pp. 79–152; Presley, op. cit., pp. 215–225; Toulmin, op. cit., pp. 105–139. On Craig’s theorem see Carl G. Hempel, “The Theoretician’s Dilemma,” in *Minnesota Studies in the Philosophy of Science*, edited by Herbert Feigl et al., Vol. II (Minneapolis: University of Minnesota Press, 1958), and Scheffler, op. cit., pp. 193–203. On the logic of discovery see N. R. Hanson, *Patterns of Discovery* (Cambridge, U.K.: Cambridge University Press, 1958), passim. On reduction of theories and related issues, see Nagel, *The Structure of Science*, pp. 336–397.

Arthur C. Danto (1967)

## PHILOSOPHY OF SEX

In the last quarter of the twentieth century a distinct, new subarea of philosophy came to life, the philosophy of sex. Many philosophical books and professional journal articles on various aspects of sex appeared in print during this period; university-level courses devoted substantially or entirely to the philosophy of sex proliferated, as did textbooks for these courses (the first, the anthology *Philosophy and Sex*, was published in 1975, edited by Robert Baker and Frederick Elliston); and in 1977 a professional organization, The Society for the Philosophy of Sex and Love, was founded.

The new philosophical investigation of sexuality emerged partially in concert with second-wave feminism’s critique of both the politics of sexual difference, including gender discrimination, and the politics of sexual desire and behavior, including widespread social and legal contempt for the sexual preferences and lifestyles of gays, lesbians, transsexuals, and the transgendered. But the philosophy of sex was (and has been) historically and thematically separate from any particular ethical, political, metaphysical, or religious perspective. Indeed, the discipline encompasses a host of viewpoints, schools, approaches, and methods, as shown by its eclectic teaching and research materials, for example, Igor Primoratz’s collection *Human Sexuality* (1997) and Alan Soble’s encyclopedia *Sex from Plato to Paglia* (2005).

By the early twenty-first century, scholars working in the philosophy of sex had exhumed much of its history, although many figures and movements remained to be explored. They had also written about numerous conceptual, ontological, ethical, and political matters. In addition to “sexual activity” and “sexual desire,” perhaps the

two fundamental concepts (or phenomena) of the area, subjects investigated included marriage (same- and other-sex), fidelity and adultery, consent and coercion, seduction, exploitation, sexual objectification, sexual harassment, rape, date and acquaintance rape, pornography, prostitution (and other sex work), sexual perversion, incest, pedophilia, group sex, masturbation, sexual orientation, sadomasochism, and sex with and without love, commitment, or psychological intimacy (casual sex, promiscuity). Analytic, existentialist, phenomenological, poststructuralist, postmodernist, evolutionary, conservative, liberal, feminist, Marxist, and diverse religious philosophers have all had their say.

## A HISTORY OF THE PHILOSOPHY OF SEX

The philosophical discussion of sex in the West began with the ancient Greek philosopher Plato (427–347 BCE). His dialogues *Symposium* and *Phaedrus*, which are about *eros* (identified in the former work as a powerful passion to possess the good and beautiful), are provocative, astute, and an indispensable foundation for anyone interested in pursuing the philosophy of sex. Although Plato’s student Aristotle (384–322 BCE) had little to say about *eros*, he meditates at length in his *Nicomachean Ethics* (books 8, 9) about *philia* (friendship-love), arguing that genuine friends improve each other’s virtue and want the good for each other for each other’s sake. Those who engage in research in the philosophy of sex commonly also study the related phenomena of love and friendship. Furthermore, the philosophy of sex generates its most instructive results when approached interdisciplinarily, that is, when it pays attention not only (and most obviously) to the psychology of sex and love but also to the sociology and history of mating practices and marriage forms, the anthropology of sexual and fertility rites and rituals, and the anatomical, physiological, and genetic findings of biomedical science.

Between antiquity and the twenty-first century, many philosophers, theologians, and others in the humanities made significant contributions to the richness of the philosophy of sex. Among the figures who made a lasting impact is St. Augustine (354–430), the Bishop of Hippo (in North Africa). Augustine was a profound thinker about sex and the human condition, as can be seen in his *The City of God* (for example, book 14), in which he expresses apprehension (as Plato did) about the threat to self-mastery and individual contentment by the forcefulness of the sexual impulse. Also noteworthy are the people with whom Augustine had theological dis-

putes over the nature of the prelapsarian sexuality of Adam and Eve and the effects on sexuality of the Fall: on the one side, the radically more sexually ascetic St. Jerome (the translator of a Latin Vulgate bible, in 380) and, on the other, the much more sexually relaxed Pelagians, including Julian (c. 386–454), Bishop of Eclanum—battles recounted well by Princeton University historian of religion Elaine Pagels (1988). Innumerable later medieval theologians were also important (see Brundage 1987), from Peter Abelard and his student, lover, and wife Heloise, whose tragic lives and impassioned letters are lessons in ardent sexual desire and an equally ardent Christianity, to St. Thomas Aquinas, tutored by Albertus Magnus (who also set about to merge Catholicism with Aristotle). In his stupendous *Summa theologiae* (1265–1273), Aquinas formulated a natural law theory that eventually (1879) became the authoritative foundation of Catholic teaching about sexuality.

After the medievalists, there came, from 1500 to 1900, a stream of colorful scholars: the skeptic Michel De Montaigne (1533–1592), author of the famous essay “On Friendship” and the lesser known “Of the Power of the Imagination,” on sexuality; the French mathematician and rationalist philosopher René Descartes, whose last book (1649) was *The Passions of the Soul*; the Scottish empiricist philosopher David Hume, who proposed in his monumental *A Treatise of Human Nature* (1739–1740) that the amorous passion “betwixt the sexes” was composed of three discordant elements: kindness, lust, and a response to beauty (2.2.11); the Englishman Thomas Hobbes (life in the state of nature, he wrote in 1651, is “solitary, poor, nasty, brutish, and short” [*Leviathan*, sec. 1.13]), who contended in his earlier “Human Nature” (sec. 9.15) that sexual desire is actually composed of two distinct desires, a desire to be sexually pleased by the other person and (as anomalous as it sounds) a desire to please the other; his adversary, a defender of the state of nature, Jean-Jacques Rousseau (1712–1778), who promulgated terrifying warnings about the evils of self-abuse (the solitary vice) in his autobiography, *Confessions*, and in a treatise devoted to educational techniques, *Emile*; the philosopher and physician Bernard Mandeville, who, in *A Modest Defence of Publick Stews* (1724), praised prostitution in part because it prevented self-abuse, or so he was convinced; the bachelor Immanuel Kant (1724–1804), who alleged that sexual love not combined with “human love” is merely an appetite that, when satisfied, discards the other person like a lemon sucked dry (*Lectures on Ethics* 1997, Ak 27:384); the Marquis de Sade, whose inventory of acrobatic and monstrous sexual feats in *120 Days of Sodom* (c. 1785) proclaims that “anything goes,”

and who died in the Charenton insane asylum; G. W. F. Hegel, who, wielding dialectical logic in “On Love” (1797–1998), claimed that during sex (only during good sex?) “consciousness of a separate self disappears, and all distinction between the lovers is annulled” (p. 307); the Danish Christian-existentialist philosopher Søren Kierkegaard, whose brilliant “Diary of a Seducer” and portrayal of the aesthetic/sensual and ethical stages of life in *Either/Or* (1843) began the decade-long analysis of his broken engagement with his beloved Regine Olsen; a German fan of Kant, Arthur Schopenhauer (1788–1860), whose nineteenth-century metaphysics, philosophy of mind, and deification of the reproductive function of sexuality in *World as Will and Representation* uncannily anticipated both Charles Darwin and Sigmund Freud; Karl Marx and Friedrich Engels, whose *Communist Manifesto* (1848) equated being a prostitute and being a bourgeois wife, an idea far from dead among contemporary feminist scholars; John Stuart Mill, the author of the definitive feminist treatise *Subjection of Women*, who employed, in *On Liberty* (1859), his liberal utilitarianism to exonerate Mormon polygyny and pimps or brothels; and, closer to the fin-de-siècle, a German fan of Schopenhauer, Friedrich Nietzsche, who, with myriad scattered, sharp aphorisms about the sexes to his credit, still failed to negotiate benignly his crush on the vamp Lou Salomé and ended up dying in an insane asylum.

After Plato and Augustine, philosophical deliberation about sex became less urgent. With the exception of the thorough Thomas and the obsessed Sade, those mentioned above did most of their philosophy in epistemology, ontology, ethics, economics, and political theory, writing only sporadically on sexuality. The twentieth century, however, witnessed an outpouring of candid, sometimes shocking, inquiries into human sexuality. First was Sigmund Freud’s *Three Essays on the Theory of Sexuality* (1905), which audaciously challenged myths about childhood sexual innocence and postulated that human sexual nature was polymorphously perverse. Freud’s legacy includes the maverick psychoanalyst Jacques Lacan (1901–1981), who explored sex and language, and Lacan’s Slovenian student Slavoj Žižek, who has explored nearly everything, from the role of power in human sexuality to cultural variations in the technology of toilets. Later came Bertrand Russell’s *Marriage and Morals* (1929), which combined a prescient and formidable feminism with a well-reasoned critique of marital sexual fidelity. *Marriage and Morals*, called a “lecherous” book by some, cost Russell an appointment at the City University of New York. Then, during the thick of World War II (1943), Jean-Paul Sartre’s *L’être et le néant* was published. Sartre

unabashedly exposed the “bad faith” of the woman who allows an unwelcome male hand to remain on her knee without so much as a mild squawk. In sexual interactions, for Sartre, we always desire to capture the freedom of the other. That endeavor, however, is doomed to failure; consequently, he argued, sexual relations reduce to masochism or sadism.

Soon afterwards appeared *Le deuxième sexe* (*The Second Sex*) by Simone de Beauvoir, Sartre’s long-standing companion, with its primordial yet fertile feminist accounts of love, sex, and gender: “One is not born, but rather becomes, a woman” (p. 267). Beauvoir’s “Must We Burn Sade?” helped garner for the Divine Marquis a persisting scholarly interest. Coming before and after Sartre and Beauvoir were some social philosophers—Wilhelm Reich (1897–1957), Herbert Marcuse (1898–1979), Erich Fromm (1900–1980), and Norman O. Brown (1913–2002)—who tried to solder an alliance between Freud’s psychology and Marx’s humanist economics in the name of liberating sexuality from oppressive Victorian morality and twentieth-century political tyranny. (Marcuse’s *Eros and Civilization* [1955] is a worthy successor to Freud’s 1930 *Civilization and Its Discontents*.) Outside philosophy, Alfred Kinsey and his associates at Indiana University stirred up a hornet’s nest by investigating in the late 1940s the extent of homosexual and other atypical sexual behaviors in America.

More recently, New York University philosopher Thomas Nagel domesticated Sartrean insights and fashioned from them, in “Sexual Perversion” (1969), an H. P. Gricean theory of psychologically natural human sexuality. It is routinely acknowledged that this essay inaugurated contemporary philosophy of sex. It was followed almost immediately by a swarm of sophisticated discussions and rebuttals that also boosted the field, including essays by Sara Ruddick, Robert C. Solomon, Janice Moulton, Jerome Shaffer, Robert Gray, and Alan Goldman. In his wide-ranging and erudite *Sexual Desire: A Moral Philosophy of the Erotic* (1986), politically conservative British philosopher Roger Scruton rehabilitated nearly everything traditional, from sexual fidelity in marriage to Rousseau’s condemnation of the solitary vice and, in an already sexual-orientation sensitive climate, Scruton fearlessly raised doubts about homosexuality. In *Sex and Reason* (1992), law professor and Judge Richard Posner expounded a no-nonsense, pragmatic/utilitarian ethical and legal philosophy of sex, and articulated what we should expect sexually from *homo economicus* (e.g., male pederasty tends to increase in locales in which there is a relative scarcity of women).

Another law professor and political philosopher, Catharine MacKinnon, after her early innovative writings on sexual harassment, dramatically escalated (along with Andrea Dworkin) the feminist battle against sexism. In *Feminism Unmodified: Discourses on Life and Law* (1987) and *Toward a Feminist Theory of the State* (1989), she argued that women’s consent to sex in patriarchy is chimerical, implying that all heterosexual intercourse is rape. A third philosopher with legal training, John Finnis, joined by other New Natural Lawyers and the Catholic theologian Germain Grisez, overhauled Thomistic philosophy of sex. Finnis defended, in the *Notre Dame Law Review* (1994), the crucial but, for many critics, dubious moral distinction between the permitted coital acts of a sterile heterosexual couple and the prohibited sexual acts of a lesbian or gay couple.

This distinction in Catholic ethics has affinities with another one, well worth contemplating, between (illicit) heterosexual coitus in which procreative potential is deliberately impeded by contraceptive devices and (licit) intercourse that is unlikely to be procreative because the couple has deliberately restricted engaging in the act to the infertile period in the wife’s cycle (see Anscombe 1976, Wojtyła 1981, and Noonan 1986). The unconventional feminist Camille Paglia frankly told university women, in *Sex, Art, and American Culture* (1992), that if they go to fraternity parties and willingly drink excessively, it is partially their own foolish fault if their panties come down on a billiard table—thereby adding the cool voice of a humanist public intellectual to the often tempestuous debate in philosophical and legal circles about date and acquaintance rape.

Of special significance is the French Renaissance man Michel Foucault, who caused a thunderstorm among philosophers, historians, and social theorists of sex with the three volumes of his *Histoire de la sexualité* (1976–1984). Foucault sparked “genealogical” studies informed by the heuristic idea that not only are patterns of sexual desire and behavior socially engineered but also that the very concepts of our sexual discourse are “socially constructed.” (He was in part reacting against the discourse of “natural” sexuality found in Reich and Marcuse.) Foucault influenced feminism, gender studies, queer theory, and the debate about the resemblance and continuity, or lack of them, between ancient same-sex relationships and their contemporary counterparts. (These questions are pursued in the collections edited by Edward Stein, by Nussbaum and Sihvola, and by David Halperin and his colleagues. This venture is sharply criticized by Paglia in “Junk Bonds and Corporate Raiders,” in

her *Sex, Art, and American Culture*.) One contested issue is whether homosexuality as a sexual orientation was first recognized in 1869 when the Magyar sexologist Károly Mária Benkert coined a word for it (“homosexuality”), a word unknown to the ancients, who could very well have invented it had they deemed that doing so was philosophically, socially, or medically meaningful. It was late nineteenth-century European sexology that detected value in picking out and labeling a class of persons as homosexual.

### CONCEPTUAL ANALYSIS

Related to the question of the “birth” of the modern homosexual, there is the analytic task of defining “sexual orientation” and each of the various sexual orientations. It seems that neither sexual orientation in general nor any specific sexual orientation can be adequately understood in terms solely of behavior. Because there are many reasons and motives to engage in sex, and many intentions and desires are involved, outward behavior might not reveal anything interesting about a person’s core sexual psychology (orientation). A closeted gay male who engages in coitus with his wife to impregnate her does not thereby make or declare himself heterosexual; the frustrated straight male in prison who reluctantly succumbs to mutual masturbation does not thereby become gay; the prostitute who participates in sexual acts with both the male and the female of a couple who has hired her for an evening is not thereby bisexual; an abstinent person who engages in no sexual activity, not even self-abuse, does not necessarily have an “asexual” orientation but may be heterosexual, homosexual, bisexual, or polysexual. What the examples suggest is that preferred sexual activity, or activity that one would engage in purely out of desire and for no other reason, is a better indicator of sexual nature than behavior, which might be induced by nonsexual motives. Counterfactual questions such as “What would you prefer to do, given your druthers and all real-life obstacles eliminated?” as well as straightforward questions about sexual fantasies, perhaps those entertained during the solitary vice, and about what a person finds arousing in anticipation (even if not during the anticipated act itself) are more revealing of sexual psychology than an accounting of acts performed. Orientation, then, is largely understood in terms of what sexual desire attaches to and the sources of sexual pleasure. But what are sexual desire and sexual pleasure?

Among the central concepts in the philosophy of sex are sexual desire, sexual activity, sexual pleasure, sexual perversion, sexual arousal, and sexual satisfaction.

Philosophers have worked on these concepts, striving to provide clear analyses of them as well as illumination about the role and significance of sexual desire, and the others, in human life. Analytic philosophy of sex attempts to indicate, for example, how sexual desire is different from other kinds of desires; to explain how acts can be specifically sexual instead of some other kind of act; to discover what it is that makes a feeling or sensation one of sexual pleasure; and to determine what meaning, if any, can be given to the idea that some sexual acts (but not others) are unnatural or perverted. In the process of analyzing these central concepts, philosophers of sex have discerned or proposed that understanding any one of them might require understanding some other central concept. A chief case is sexual activity, which might be defined as activity that aims to satisfy sexual desire, or is motivated by sexual desire, or is intended to produce (or does produce) sexual pleasure. These candidate analyses seem to be on the right track, yet they all suffer from the same apparent defect.

The principal problem is that if sexual activity is defined as activity that is motivated by sexual desire or is intended to yield sexual pleasure (which works well for many paradigmatic instances), there are activities that are presumably sexual, are not uncommon, and yet are not captured by these or similarly fashioned definitions. Acts performed by a prostitute may produce pleasure for the paying client or are done by him to satisfy his sexual desires, but these definitions cannot explain why the acts of the prostitute (e.g., fellatio or coitus) are still sexual for her, assuming, which is plausible, that she participates for payment and not out of sexual desire for her client and that she derives no sexual pleasure from what she does or has done to her. The problem is not only that, given this type of analysis, the single act that the client and the prostitute perform together might be a sexual act for the client but not for the prostitute. The conundrum, more specifically, is that the feature (if any) in virtue of which her contribution to the act is sexual is not clear. It might be proposed that sexual activity be analyzed, instead, in terms of the involvement of salient sexual body parts—say, the genitals. If so, acts performed by a prostitute are sexual when and because her genitals are involved. But “involves the genitals” (or any other body part) seems neither necessary nor sufficient for an act to be sexual: some sexual acts are not genital (rubbing the breasts) and some acts that involve the genitals are not sexual (a gynecological exam). Perhaps “sexual body part” should be analyzed in terms of “sexual activity” (a body part is sexual exactly on those occasions when it is employed in a sexual act) rather than the other way around.

Analytic philosophy also tackles “derivative” sexual concepts, a large group of concepts (or phenomena) that include reference to sexuality. Derivative concepts that philosophers have attended to include adultery, jealousy, sexual harassment, casual sex, promiscuity, seduction, flirting, cybersex, and sexual fantasy.

Intriguing questions can be asked about adultery, in addition to standard moral questions, which are also explored by philosophers of sex. Does a nonmarried person who engages in sexual activity with a married person commit adultery? (In the law, the answer varies by jurisdiction.) Does a person commit adultery if she believes falsely that her spouse is deceased? Is adultery altogether a physical act or could desires and fantasies be not only adulterous in spirit but adultery itself? (See Matthew 5:28.) Some claim that in vitro fertilization, if carried out with donor (nonspousal) sperm, constitutes adultery. Can such a judgment be sustained? Casual sex and promiscuity, too, suggest questions beyond the ethical: For how many partners over what period of time is the judgment “promiscuous” accurate? Can one engage in casual sex with one’s spouse? (Theologians argue that marital sex can be unchaste. Perhaps in this way it can be casual.) What distinguishes promiscuity from casual sex? Are there moral or perfectionist criticisms that can be made about casual sex and promiscuity other than condemning them for the absence of love, marriage, or commitment? There are difficulties in defining “sexual harassment”—what counts as a sexual advance, an improper sexual comment, or hostile work environment?—and explaining what is wrong with it, when (if) it is wrong—as sexual discrimination, immoral sexual conduct, or misuse of power, authority, or institutional position?

Seduction poses the analytic problem of carving out distinct logical space between rape, on the one side, and completely consensual sexual activity, on the other, and hence may pose novel ethical questions beyond those that apply to the other cases. But the moral issues concern not only the perpetrator of seduction. What about the person who welcomes and encourages being seduced, perhaps to be reassured of attractiveness or power? Sexual fantasy is a ubiquitous human phenomenon that suggests provocative questions: Does sexually fantasizing about a person “use” that person in any robust sense? Is it possible to criticize morally a person who fantasizes sexually about a third party during sexual activity with a partner, while not objecting to sexual fantasy *tout court*? What is the relationship between fantasy and sexual desire: Do we fantasize about something (or someone) because we

desire it or do we desire it because we have fantasies about it? Jealousy, because of its intentional structure (its dependence upon beliefs), might arise in response to a fantasy. Is the fault with sexual jealousy (if it is faulty) exhausted by its being caused by a false belief or one arrived at negligently? Or can sexual jealousy be deplored because it frequently betrays a wrongful attitude of owning another person?

Cybersex highlights the intentionality of sexuality, because cybersexual arousal depends exquisitely on beliefs about unseen persons; it forces us to ask why another person’s body is apparently so important—or not so important, after all—in sexual experiences, which also raises questions about masturbation; and cybersex makes us ponder whether some sexual activity—and therefore, for example, some adultery—may involve no physical touching in the ordinary sense (as does telephone sex). Similarly, flirting might be a sexual activity that falls somewhere between faithfulness and infidelity. To which is it closer? Does this depend on with whom one flirts, why, or the extent to which one is tempted or willing to turn flirting into physical contact? Flirting is interesting also because it is occasionally misread, conveying to some optimistic or deluded recipients an explicit invitation to engage in sex instead of registering merely as playful or teasing. As a result, flirting might sometimes precipitate date or acquaintance rape.

The derivative concept “rape” has long presented special problems. One controversial matter is whether rape should be defined in terms of the absence of consent or the presence of force. This has implications for how the occurrence of rape is established in a court of law. The choice is difficult: A force definition of rape might place too much emphasis on whether or to what extent a woman resists, which many see as irrelevant. A consent criterion implies that tough issues about mens rea become important: Did the accused believe that the woman had consented, even if she didn’t; is the accused liable for something he might or should have believed but did not believe (that is, that consent was absent)? The difference between a force and a nonconsent criterion may be illustrated with acquaintance rape. A force criterion tends not to classify such acts as rape, whereas proponents of a nonconsent criterion argue that rape includes all nonforcible yet nonconsensual sex (see McGregor 2005). Further, like prostitution, rape seems to provide a counterexample to the analytic proposal that sexual activity be understood in terms of sexual desire or sexual pleasure.

Perhaps because both prostitution and rape are activities that involve coercion or are not engaged in (fully) voluntarily, they resist being characterized as sexual acts in terms of desire or pleasure. Indeed, it has been argued, on various grounds, that rape is not a sexual activity at all. (Maybe this point applies to prostitution as well.) If a woman, a virgin, is raped and does not thereby, automatically, lose her virginal sexual status, she has not taken part in a sexual activity, at least not one that was sexual for her. But the derivative concept “virginity” and similar notions—abstinence, chastity, celibacy—require careful analysis in their own right. Are they merely a matter of behavior or anatomical characteristics or does state of mind play a role, and how? Another issue concerns the extension of “rape,” which accentuates problems in spelling out the meaning of coercion or consent and in deciding why and when coerced or nonconsensual sex is wrong. Suppose a man badgers his wife for sex until she acquiesces, and they engage in sexual activity even though she much prefers not to. Has she been coerced and therefore raped, and is this the reason the act is morally stained? Perhaps badgering does not amount to coercion, but it is still morally suspect. By contrast, some would say that even if the badgering coerces her into sex, it is not especially morally objectionable. Or suppose a woman hints to her husband, “No sex until you buy me that fur coat.”

## HUMANS AND OTHER ANIMALS

One debate in the philosophy of sex concerns the relevance of animal sexuality for understanding and judging human sexuality. Some philosophers, for example Thomas Aquinas in *Summa contra gentiles* (chap. 122, sec. 6), argue from observations of animal sexual behavior to the nature of human sexuality and draw ethically conservative conclusions. These philosophers emphasize (a subset of) that which is common between humans and animals. For example, many animals engage in sexual relations only to reproduce and that, too, is what is significant about human sexuality. Then there are philosophers—those who are sympathetic to sociobiology or evolutionary psychology are among them—who similarly stress what is common to animals and humans, yet draw ethically liberal conclusions. We are fundamentally animals and that fact should not be ignored or minimized; the robust sexuality that is due to our animal nature is suppressed at our peril.

What may distinguish the first group of philosophers from the second is the animal species invoked in drawing conclusions about humans. If one selects as the argu-

ment’s observational basis monogamous birds (swans) and mammals (wolves), different conclusions will emerge than if one selects more sexually adventuresome species (dogs, the bonobo). The question—Which is the right animal model?—is murky, although similarity of DNA, testicle size, and other traits are potentially useful links. (Why even assume that the same animal model will be the right one for both human males and females?) Regardless, we must avoid the circularity of arguing that a species is the right model because these creatures are remarkably like humans—unless our methodology is a sophisticated “reflective equilibrium.” Further, once we select some animal species from which to argue, we must take the “bad” with the “good”: The aggression, dominance, promiscuity, and oddness (e.g., urolagnia in some llamas) of animal sexuality, along with its attractive features, have to be extrapolated to humans as well. Against both the conservative and the liberal who argue from animal sexuality to ethics, it can be protested that doing so commits the naturalistic fallacy. What cannot be excluded is that comprehensively studying animals can tell us something about human nature. It is a dangerous leap from there to ethics.

Some philosophers, by contrast, even though acknowledging that humans, as embodied, are undeniably in part animals, perceive sharp discontinuities or differences of kind, not degree, between animals and humans. There are physiological differences such as concealed ovulation and the absence of oestrus in human females that have extensive implications for sexual psychology and behavior. But more striking is the human cerebral cortex and hence cognitive differences between humans and animals. This view can also be taken in an ethically conservative or liberal direction. Conservatives—Scruton, for one, and many theologians—say that humans have mind or soul, something that lifts us above animals, so that even if we have animal urges, we can and should transcend them. Behaving in a humanly civilized fashion is to be accomplished by virtue of our spirit and for the sake of our spirit. But the discontinuity is also compatible with liberal sexual ethics. Nagel, in formulating his theory of psychologically natural human sexuality, emphasizes the differences between animal and human sexuality that result from the nearly unique faculties of the human mind, primarily intentionality and self-consciousness (which also figure prominently in Scruton’s philosophy of sex). Yet Nagel comfortably embraces Millian liberal sexual ethics.

Further, for social constructionists animal and human sexuality are of course different, and nothing

much is to be gained by comparing them. Human sexuality and sexual discourse vary as much as human culture varies, whereas animals have (by and large) no culture or language that might construct their sexuality or their (nonexistent) conceptions of it. The sociobiologists and their philosophical sympathizers retort: Yes, society constructs much of human sexuality, but human sexuality (to use E. O. Wilson's metaphors) is a twig bent at birth; it is on a leash, tied ultimately to a biological post, a substrate upon which society can work—and which it requires in order to work—its constructionist miracles. As suggested by the mixed results of the medical management of intersex conditions (neonates of ambiguous sex), the social cannot make everyone male, female, straight, or gay. How much of human sexual nature is due to animal biology, and how much to culture, is as difficult to resolve as analogous nature-nurture quandaries about the contribution of race or biological sex on various skills and personality traits. Often these disputes are replaced by (prematurely, perhaps, but not altogether baselessly) brute political machinations, à la Plato's Thrasymachus in the *Republic*.

One reason for looking at animal sexuality is that this knowledge may serve as a guide to what human sexuality would be like were it not for social interference, that is, in the absence of all cultural influence (although, unlike Freud, social constructionists do not speak of the cultural as an "interference" but as necessarily constitutive). It does not strain the imagination to conceive of cultureless animals as expressing pure state-of-nature sexuality. If humans arrange their sexuality consistently with what is seen among animals (by peeling back various social influences), we can have some faith that we are not too far away from humanly natural, healthy, satisfying sexuality. Such thinking builds on an absorbing and plausible thought, that animal sexuality cannot in any way be unnatural or "perverted." If nothing about morality can be learned from animal sexuality, at least we can get glimpse of normality. There is probably too much Rousseauvian utopianism in this thinking, and of course such a view remains vulnerable to the hitch of which animal model confers the best insight into "normal" humanity. Alternatively, well-founded speculation about the sexuality of prelapsarian Adam and Eve might, for some theologians, supply that information. The Garden of Eden is their Hobbesian state of nature.

## SEXUAL PERVERSION

As far as popular culture and ordinary folk are concerned, the terms "[sexual] perversion," "[sexually] perverted,"

and "[sexual] pervert" are not problematic, even if they might not always be in good taste and cause distress to those singled out. "Sexual" is bracketed because "pervert" in ordinary talk implies that the domain of discourse is the sexual. (At least, that is the default position.) By contrast, some philosophers, psychologists, and other academics have argued that "sexual perversion" is outmoded, ontologically groundless, confused, offensive, unscientific, not applicable to anything in human sexual behavior, and hence happily dispensable. Despite the counsel of philosophers and other experts that "perversion" be extirpated from the language, ordinary people use it unflinchingly, as does the Religious Right. The American Psychiatric Association (APA) no longer officially uses "perversion" to refer to sexual disorders but has, since 1980, opted for the clinical "paraphilia," even if an ordinary person's list of perversions is nearly identical to the paraphilias listed in the *Diagnostic and Statistical Manual of Mental Disorders (DSM)*. ("Paraphilia" is not a total improvement. It is an unlikely group that includes "Philadelphia," "philanthropy," "philosophy"—and "paraphilia.")

The fundamental problem about sexual perversion is distinguishing natural from unnatural sexuality. In carrying out this task, it is necessary to explain not only how certain sexual behaviors (desires, preferences) are perverted but also how they are sexual to begin with. For example, if being potentially procreative is the feature that defines sexual activity, then being nonprocreative cannot be a mark of the sexually perverted, because whatever is not procreative is not sexual. (The acts might still be "nonsexually [or fill in the blank] perverted.") Or if sexual activity is defined as activity that tries to satisfy sexual desire and sexual desire is defined, in turn, as desire for physical contact with another human being, the perversions cannot be sexual, because they typically do not involve desire for that contact: consider the wide variety of fetish objects that excite men. Some would call it special pleading or ad hocery, whereas others would see it as a stroke of genius, to say that the fetishist does desire physical contact with a person, unconsciously, and achieves that in a psychologically safe way by substituting the fetish object.

Philosophers and psychologists have tried, with unclear success, to formulate theories about sexual perversion. An obvious contender, that only potentially reproductive sexual acts—acts that are reproductive in their anatomical and physiological forms—are natural, and all others perverted, has seemed plausible to many thinkers (Catholics and some evolutionists, mostly) but

implausible to others. Certainly, being nonprocreative is a property that many (preanalytically) perverted sexual acts share: zoophilia, cross-dressing, exhibitionism, voyeurism, klismaphilia, necrophilia, urolagnia, sado-masochism.

But analyzing perversion as nonprocreative sexuality is not straightforward. Some nonprocreative sexual acts are not especially, or at all, perverted: masturbation (solitary or mutual) and oral sex to orgasm. And some purportedly perverted acts (cross-dressing, light sadomasochism) for some people often or regularly culminate in heterosexual intercourse, as if functioning as foreplay. Also note that both vertical (parent-child) and horizontal (sibling-sibling) incest can be procreative, yet many have thought them considerably unnatural (or maybe only repulsive). The sexual practices that are supposed to be subsumed under the label “perversion” or “paraphilia” are extraordinarily diverse, other than being nonprocreative, so finding common, essential features may be doomed—a reason to dispatch the concept. We could still investigate, without using “perversion,” behaviors that are unusual, bizarre, harmful, or are done compulsively or exclusively, in preference to every other sexual activity (which category may well include a narrow interest in heterosexual coitus). That “unusual,” “bizarre,” and “harmful” are to a greater or lesser extent evaluative or culturally bound is why these features of sexual acts cannot be used to develop an objective, scientific, universally sound theory of sexual perversion. Social constructionists applaud this result.

Another question about sexual perversion has to do with its morality. The Roman Catholic position, that what is perverted is for that reason sinful, has not won over many secular adherents. “Premodern” philosophy of sex, which derives from the older Plato, Augustine, and Aquinas, understands sexual perversion teleologically as behavior that is incompatible with the (perhaps divinely ordained) species design. Premoderns frequently add that in virtue of this deviation, deliberately performed sexually perverted acts are immoral. But perhaps not every deviation is wrong. Mutual masturbation, cunnilingus, and fellatio, which in themselves are nonprocreative and hence unnatural, might be permissible when they function as preparation for heterosexual marital coitus. “Modern” philosophy of sex dates from the late nineteenth century and the rise of scientific sexology (e.g., Iwan Bloch, Magnus Hirschfeld, Richard Krafft-Ebing, Havelock Ellis, Freud). Some modern philosophers of sex retain the biological, teleological account of perversion,

whereas others (Freud, Nagel) replace that with a more sophisticated psychological account.

What the two branches of modern philosophy of sex share is a refusal to judge perverted sex immoral merely because it is perverted. Many modern philosophers of sex have reached, instead, for the evaluation “psychologically unhealthy.” It is worthwhile to think of premodern judgments of sinfulness as superseded by modern judgments of sickness, as social authority residing over sexual perversion passed from the clergy and organized religion to the physician and biomedical science. The fate of homosexuality illustrates this progression, from being condemned as sin by all Western religions to being deprecated as sickness (although excused, in keeping with the medical model) by most Western psychology and psychiatry through the mid-twentieth century. But in 1973, the APA removed homosexuality from its list of mental disorders in *DSM*, thereby helping to usher in “postmodern” philosophy of sex, according to which no nonharmful, consensual sexual behaviors are perversions, sinful, or sick, but alternative sexual choices. The APA has not gone completely postmodern. It still classifies some innocuous sexual practices (fetishism, transvestism) as sexual mental disorders.

The American Psychiatric Association distinguishes between sexual dysfunctions and the paraphilias, which, even though they involve unusual or bizarre sexual desires or acts, do not necessarily involve inadequate functioning of the sexual organs. When homosexuality was still a mental sexual disorder, there was no doubt that gay men could sport firm erections and did not suffer from ejaculatory problems merely in virtue of their orientation. In addition to premature ejaculation, an inability to achieve or maintain an erection, insufficient lubrication, and pain during coitus, the APA includes as a dysfunction “Hypoactive sexual desire disorder,” a deficit or absence of sexual desire that causes psychic distress or interpersonal (e.g., marital) problems (*DSM-IV*, sec. 302.71). Critics have pointed out that the clinical judgments that a person has too little sexual interest and is bothered too much by a perceived lack of desire are routinely influenced by all manner of social factors that seem irrelevant to a diagnosis of mental disorder. The *DSM* also lists a more extreme variant, “Sexual Aversion Disorder” (sec. 302.79), but (asymmetrically) contains no “hyperactive sexual desire disorder.” The APA did, however, briefly flirt with Patrick Carnes’s innovation, “sexual addiction” (a type of obsessive-compulsive promiscuity), as a sexual mental disorder, which was included only in the revised version of *DSM-III* (1987). Speaking of naturally pleasurable sexual activity as “addic-

tive” is highly disputable, as is whether promiscuity (such as homosexuality) is sinful, sick, or a mere variation in human sexuality.

## SEXUAL USE

Being unnatural is of course not the only way sexual activity might go astray morally. In the Kantian tradition, the central way that sexual activity is morally wrong is when one person uses another person sexually, treating the other as a means or object, thereby violating the second formulation of the categorical imperative. Coercing another person, as in rape or quid pro quo sexual harassment (boss to employee: “Have sex with me or you’re fired”), or deceiving someone in order to obtain sexual relations (an identical twin sliding into the bed of his brother’s wife) are frequently cited cases of treating another person as a means. On a Kantian view, and on some utilitarian views (such as Mill’s), it is necessary for the moral permissibility of a sexual event that all parties furnish free and informed consent. Other instances of possible use are difficult to settle; even among confirmed Kantians, exactly what treating another person as a means or an object amounts to has long been disputed. One disagreement between conservative and liberal Kantians is over whether an adult’s consent is sufficient (*ceteris paribus*) for the morality of sexual activity. Kant answered “no,” arguing that sexual activity avoided mere use in, and only in, marriage, or that marriage made mutual sexual use permissible. (How to interpret Kant is an issue for Kant scholarship. See *Lectures on Ethics*, Ak 27:388.)

In this respect many conservative Kantians, such as Karol Wojtyła (Pope John Paul II, 1920–2005), have followed Kant, insisting that mutual consent alone neither eliminates nor blesses the mutual use in sexual relations that must occur if the persons are not married (although some conservatives would be satisfied were sexual relations confined to a genuinely committed even if nonmarital relationship). In any event, Kant and the conservative Kantians need to explain—a challenging task—how the additional ingredient, marriage or commitment, changes sexual activity from mere mutual use to something morally permissible, and why only commitment or marriage and nothing else (say, consent) has the ability to do this. For liberal Kantians, mutual consent is powerful enough by itself to make sexual acts permissible in the absence of marriage. The presence of consent, they argue, satisfies the demand of the second formulation of the categorical imperative for the reciprocal acknowledgment by each person of the rational autonomy (the humanity) of the other. In virtue of consent, much sex is permissible

that is condemned morally by Kantian and other conservatives: same-sex sexual acts, group sex, casual sex (say, between strangers), even adultery if all parties consent. Consent is sufficient only *ceteris paribus* for the liberal Kantian and the Millian utilitarian because third parties might be harmed or have their legitimate interests disregarded by the consensual sex of others (as often happens in adultery). For some conservative Kantians, mutual consent to use each other not only is not sufficient, but makes for an especially morally corrupt situation, for they take, as did Kant, the often slighted part of the second formulation seriously: one may not treat the humanity in one’s own person merely as a means. This is what one does to oneself—willingly makes an object of oneself—when consenting to be sexually used by another person, even if that use is mutual. It is an interesting question how it might be decided whether mutual consent cancels or compounds the moral faults of mere use.

The opposite of sexual objectification is sexual personification, which occurs when, to mention the key instance, a person or a couple gives a name to an erotic body part. (Christening the genitals is an important theme in D. H. Lawrence’s *Lady Chatterley’s Lover*.) An example of nonsexual personification might be worshipping an idol, a golden lamb, treating a mere material symbol of the Almighty as if it were the Almighty. Personification can be understood as raising something’s ontological status or treating it as if had a higher status. This is what happens when a couple gives proper names to their genitals, treating them as persons. In objectification, by contrast, one person reduces (or attempts to reduce) the ontological status of another. If a person manipulates another so that a goal of the first person is thereby attained, the first has used the second, has treated him or her as a mere material object, in that the second’s personhood-defining feature, rational autonomy, has been minimized or ignored. One person is acting toward another as if the latter were no more ontologically elegant than an inanimate thing or a subhuman animal. In sexual objectification, even if there is no coercion or deception, a person is treated as a usable object fundamentally capable of (only) satisfying another’s sexual desire. It is often claimed, by both Kantian conservatives and many feminist philosophers, that this is exactly what is morally wrong with prostitution and pornography: women are not respected fully as the persons they are but are seen and treated only or primarily as consumable and fungible providers of sexual pleasure, even when they consent to participate. Some theorists go further, claiming that these considerations apply as well to the institution of heterosexual marriage.

## PORNOGRAPHY AND PROSTITUTION

Arguments about consent occur when philosophers, legal theorists, political activists, and women and men sex-industry workers discuss pornography and prostitution. If consent is present in a given instance of prostitution (which can be defined, but not unproblematically, as exchanging sexual activity for compensation), if neither the client nor the provider of sexual services is subject to coercion or is deceived, or if those hired to perform sexual acts in front of a camera (a type of prostitution) in the production of pornography (variously definable, notoriously with difficulty) have, similarly, freely and with reasonably full and relevant information agreed to do so, the issue still arises whether their consent is sufficient. In this debate, one side (the liberal, the libertarian, perhaps the Milton Friedman capitalist) points out that if consent is sufficient for other kinds of paid labor, from slinging slop in a fast food pub and collecting garbage to executing proctological examinations and fighting in a volunteer army, there can be no objection to a person's engaging in sex for payment. Anything is fodder for the market or, at least, nothing differentiates selling sexual services and performing other tasks that some people, but not all, find too repugnant or risky to undertake even for substantial financial compensation. The other side (some conservative theologians, Marxists, and feminists) insists, however, that sexuality is "different," that it does or should involve a quality of intimacy that is undermined by its being bought and sold, or that it is demeaning when sexuality is the means of making a living, or that sexuality is metaphysically or anthropologically too crucial an aspect of human personality or identity to be commodified. Doing so entails an immeasurable cheapening of humanity. Whether these claims about how sexuality differs from other aspects of human life are culturally bound (hence not so compelling?) or are deep, sustainable philosophical truths about the human person is unclear. Note that if they are overblown, exaggerating the significance of sexuality in an overall picture of the human person, it might be more difficult to explain why rape is an especially grievous harm (see Murphy 1994).

However, that women sex-industry workers participate consensually is debatable. There are various reasons, often advanced by feminists and Marxists, for doubting that the consent of the women who make pornography or sell sexual services is genuine (see, e.g., MacKinnon's *Only Words*). They might have been indoctrinated to devalue themselves and their sexuality or have been as children victims of sexual abuse, and in either case, they may be exceptionally vulnerable to being manipulated into pros-

titution and the production of pornography. Further, to the extent that women who participate in these activities come from the lower economic levels of society, the lure of making decent money despite lacking education or vocational training can be coercive, if their alternatives are even more dismal. The possibility of compulsion may be greater when the women, in addition to being relatively impoverished, are members of a disparaged ethnic minority or have dependent children. Their dire need creates a situation in which being offered money for sexual activity is coercive, even if engaging in those sexual events seems to them, at the moment, a small sacrifice of their sexual integrity.

It might also be argued that because women are willing to sell sexual services in either prostitution or pornography, this is by itself evidence that something is amiss in their rational autonomy; doing such things is not what someone "in her right mind" would choose to do. Several responses to this account of the plight of women sex-industry workers have been advanced. One rebuttal is that it overstates the victimization of women and underestimates their strength and resourcefulness. Another is that citing financial need as coercive may imply too much. Most people who sell their labor have financial needs, are in no position to refuse to work, and they, too, would have to be described as coerced. Finally, there are women who relish the opportunity to make good money in the sex industry and would not describe their situation as one in which they are pressured into doing something they prefer not to do.

## CONCLUSION

Our personal understandings of the nature of sexuality and its significance in our lives, public discussion of ethical, religious, and social issues, and technical matters about sex that arise in medicine, social science, and the law—all these can profit from philosophical study. Students who take courses in the philosophy of sex are exposed to material they are unlikely to encounter elsewhere, material that gives them an opportunity to scrutinize their beliefs about sexuality and habitual behaviors. The law benefits from the philosophical analysis of concepts such as rape, harassment, and consent; theology is in a position to learn from the elaboration of theories of natural human sexuality and the examination of the conceptual connection between the goodness of the natural and the goodness of human actions; social scientific surveys of the frequency of sexual activity (by age, education, ethnicity, and other parameters) and the extent of non-heterosexual sexual orientations depend on analyses of

“sexual activity,” “sexual desire,” and “sexual preference” and effective ways of identifying and counting or measuring them; the pronouncements of psychiatry and medicine on sexual health, both physical and mental, can be (and have been) improved by the deliberations of philosophers who investigate the concepts of sexual perversion and mental illness. The philosophy of sex has proven that it is no idle enterprise.

## PHILOSOPHY OF SOCIAL SCIENCES

The “philosophy of social sciences” comes in three varieties, as the metaideology, the metaphysics, and the methodology of the disciplines involved. The metaideology looks at how far different, traditional legitimations of social sciences succeed. The metaphysics looks at questions having to do with what social science posits—what things it says there are—and at how far those posits are consistent with more or less commonplace beliefs. And the methodology looks at questions regarding the nature of observations, laws, and theories in social science, the logic of induction and confirmation, the requirements of understanding and explanation, and so on.

### METAIDEOLOGY

The social sciences were conceived and pursued, from the very beginning, under the influence of ideals (particularly of scientific objectivity and progress) deriving from the eighteenth-century enlightenment (Hawthorn 1976). The first social scientists were economists and sociologists, as we would call them today, and they were self-consciously concerned about producing something that would count, not as philosophy, not as literature, not as common sense, but as science: as a project faithful to the image forged by natural science.

The scientific intention—the intention to make science—has remained characteristic of work in the social sciences. It puts social scientists, paradoxically, under an obligation of an ideological kind: the obligation to show that the sort of analysis they pursue is of a properly scientific kind. The metaideology of social science interrogates and assesses the ideologies whereby the social sciences try to legitimate what they do, to show that what they do is genuinely scientific in character.

Broadly speaking, there are three main ideologies that have been invoked—individually or in various combinations—by social scientists in the scientific legitimation of their enterprise. Each of these marks a feature that putatively distinguishes social science from mere common sense, mere social lore. The first ideology hails social science as an explanatory enterprise of culturally universal validity; the second as an enterprise that is interpretatively neutral, not being warped by people’s self-understanding; and the third as an enterprise that enjoys evaluative independence: value-freedom. The universality, neutrality, and independence claimed are each meant to establish social science as objective, and therefore scientifically respectable, in a way in which common sense is

not; each notion offers an explication of what scientific objectivity involves. Some approaches in the metaideology of social science, particularly those of a postmodern cast (Rosenau 1992), reject all three ideologies out of hand: They reject any notion of objectivity in the area (others consider them one by one, under the assumption that they may come apart).

Social lore is always lore about a particular social milieu and culture, and an aspiration to cultural universality, if it can be vindicated, would certainly give social science a distinctive status. Such an aspiration is supported in a variety of traditions: among anthropologists and sociologists of a Durkheimian cast, among many Marxist scholars, and among those economists who think that all human behavior, and the patterns to which it gives rise, can be explained by reference to *homo economicus*.

But the metaideologists of social science have claimed many reasons to question the possibility of any universalist, or at least any straightforwardly universalist, theory. Hermeneutic philosophy, which has long been dominant in Germany, and the analytical tradition sponsored by the work of the later Ludwig Wittgenstein both suggest that any explanation of human behavior has to start with the culturally specific concepts in which people understand their environment and cannot aspire, therefore, to a substantive universality (McCarthy 1978, Winch 1958). The debate on these questions ranges widely, encompassing issues of cultural and other forms of relativism (Hollis and Lukes 1982).

Social lore is not only particularistic, it is also designed to represent people as subjectively understandable or interpretable. We, the local consumers of such lore, know what it is like to be creatures of the kind represented and know how we would go about communicating with them. The second, and perhaps least persuasive, ideology of social science suggests that this disposition to represent people as subjectively understandable comes of a limited perspective that social science transcends. It suggests that social science can aspire to an objective explanation of people’s behavior without worrying about whether the explanation fits with their self-understanding: without being anxious to ensure that it makes native sense of them and facilitates interpersonal communication. The ideology suggests that social science, in the received phrases, can aspire to a form of *Erklären*, or explanation, that need not service the needs of interpersonal *Verstehen*, or understanding.

Metaideologists of social science have claimed many reasons to question this aspiration to *Verstehen*-free

explanation. Hermeneutic and Wittgensteinian thinkers both reject the idea that people can be properly understood without facilitating communication (Winch, 1958). And the many philosophers who follow the lead of Donald Davidson on interpretation argue that there is no interpreting human subjects without representing them as more or less rational and more or less interpersonally scrutable (Macdonald and Pettit 1981).

Social lore is often evaluatively committed as well as particularistic and oriented to subjective understanding. It takes a form premised on an evaluative characterization of the status quo. Thus, it may characterize the beliefs and explain the behavior of rulers on the assumption that the regime they sustain is unjust. The third and most common legitimating ideology of social science, one associated in particular with the German sociologist Max Weber, holds that in this respect—and perhaps in this respect only—social science can do scientifically better than social lore. It can acknowledge that the agents in the society have evaluative beliefs, and it can take account of these in its explanation of what they do, without itself endorsing any such beliefs; it can be objective, in the familiar sense of remaining uncommitted on evaluative questions.

Metaideologists of social science have also sought reasons to doubt this claim, but the debate has been confused by differences over what sorts of evaluative commitments would really be damaging to the pretensions of social science. The critique of social science on the grounds of not escaping a commitment to value has been nurtured by the appearance, in the later part of the century, of a variety of realist positions on the nature of value. If values are taken to be objective features of the world, then a social scientist's beliefs as to what those features are may well affect their interpretation of how certain subjects think and act; interpretation, after all, is bound to be influenced by the interpreter's view of the subject's environment (Hurley 1989, chap. 5; Macdonald and Pettit 1981, chap. 4; Taylor 1981).

The metaideology of social science may concern itself with other issues: for example, whether the models used in social science, in particular within economics, are really empirical, scientific models and not just pieces of mathematics or exercises in a conversational rhetoric (Hausman 1991, McCloskey 1985, Rosenberg 1992). These issues are not discussed here.

## METAPHYSICS

The metaphysics of social science usually takes it as granted that there is no society without individual inten-

tional agents: without subjects who apparently act, other things being equal, on the basis of their beliefs and desires (Pettit 1993, pt. 1). The question that metaphysics raises bears on what more we should include in our metaphysical stock-taking of society; and on how the more we should include, if there is any, relates to individual intentional subjects.

There are two aspects of social life that are particularly relevant to this question. There is the social interaction between individuals in virtue of which various relationships get formed: relationships involving communication, affection, collaboration, exchange, recognition, esteem, or whatever. And there is the social aggregation of individual attitudes and actions in virtue of which various institutions get established: These institutions will include common instrumentalities such as languages, cultures, and markets; groups such as the club, union, or party, whose essence it is to have a mode of collective behavior; groups that may have only a nonbehavioral collective identity such as genders, races, and classes; and shared resources of the kind illustrated by museums, libraries, and states.

The metaphysics of social science concerns itself both with issues raised by interaction and with questions associated with aggregation, specifically with social interaction and aggregation. (On the definition of "social," see Ruben 1985.)

On the side of interaction the main issue in social philosophy is that which divides so-called atomists from nonatomists (Taylor 1985). The atomist holds that individual human beings do not depend—that is, non-causally or constitutively depend—on social relationships for the appearance of any distinctive, human capacities. The nonatomist holds that they do. The atomist defends an image of human beings under which they come to society with all the characteristic properties that they will ever display; social life does not transform them in any essential manner. The nonatomist denies this, believing that it is only in the experience of social relationships that human beings come properly into their own.

The debate between atomists and nonatomists has centered on the connection between thought and language. Atomists have taken their lead from Thomas Hobbes, who argues that, however useful language is for mnemonic, taxonomic, and communicative purposes, thinking is possible without speech, even without any inchoate form of speech. Nonatomists have tended to follow Jean-Jacques Rousseau and the Romantic tradition with which he is associated—a tradition also encompassing Johann Gottfried Herder and G. W. F. Hegel—in

arguing, first, that language is social and, second, that thought requires language.

The atomist tradition has been dominant in English-speaking philosophy, while the nonatomist has had a considerable presence in France and Germany. One source of nonatomism in the English-speaking world has been the work of the later Wittgenstein, in which it is suggested that following a rule—and, therefore, thinking—is possible only in the context of social practices and relationships (Wittgenstein 1968). This very strong nonatomist thesis may also be weakened, so that the claim is that following a rule of a characteristic kind—say, a suitably scrutable kind—requires such a social context (Pettit 1993, chap. 4). Another source of nonatomism in recent English-speaking philosophy has been the argument that the content of a person's thoughts is fixed, not just by what goes on in his head, but by the linguistic community to which he belongs and to which he aspires to remain faithful (Burge 1979, Hurley 1989).

What now of the issues generated by the aggregative aspect of society? There are a number of interesting questions raised by the aggregative structure of society, some having to do with the reducibility of aggregative theory to theory of a more psychological cast, others having to do with the status of aggregative individuals and the standing of the causal relevance we ascribe to such entities (Gilbert 1992, James 1984, Ruben 1985, Tuomela 1996). Perhaps the most pressing question, however, is whether the entities that appear with the social aggregation of individual attitudes and actions give the lie to our ordinary sense of intentional agency: whether it means that, contrary to appearances, we are in some way the dupes of higher-level patterns or forces (Pettit 1993, chap. 3). The individualist, to use a name that also bears further connotations—see under “Methodology”—denies that aggregate entities have this effect; the nonindividualist insists that they do.

One extreme sort of individualism would say that intentional agency is not compromised by any aggregate, social entities, because in strict truth no such entities exist. A more plausible form of the doctrine would say that while there are indeed a variety of aggregate entities, there is nothing about those entities that suggests that our received, commonplace psychology is mistaken. No doubt, there are aggregate regularities associated with such entities: For example, a rise in unemployment tends to be followed by a rise in crime; the fact that something is in an organization's interest generally means that agents of the organization will pursue it; and so on. But the individualist will argue that those regularities do not signal

the presence of forces unrecognized in commonplace psychology or the operation of any mechanism—say, any selection mechanism—that belies the assumptions of that psychology. That the regularities obtain can be explained within that psychology, given the context in which the relevant agents find themselves and given their understanding—perhaps involving relevant aggregate-level concepts—of that context.

## METHODOLOGY

There are two sorts of methodological questions raised in the philosophy of social science: first, questions imported from the methodology of natural science having to do with such matters as observations and laws and theories, realism and nonrealism in theory interpretation, statistical inference, confirmation, and explanation; second, questions that arise only, or arise distinctively, within the social sciences. Perhaps the two major questions of the latter kind bear on whether it is good explanatory practice to follow the individualistic and economistic assumptions, respectively, that characterize much social science. Here the emphasis will be on the issues of individualism and economism.

The methodological individualist, as characterized in the literature, is associated with a number of more or less outlandish doctrines: for example, that individuals each play indispensable roles, so that things would always have been significantly different if the actual individuals had not been around or if they had not done the things they actually did; that individuals are unaffected by their circumstances, or their relationships with one another, in the things they come to think and want; or that all social facts can be expressed in terms of a nonsocial psychology and that all social laws can be derived from the laws of such a psychology.

Methodological individualism is better understood, however, as a doctrine that has more clearly had respectable defenders as well as opponents: specifically, as the doctrine that it is always good explanatory practice to try to explain social events in terms of finer-grain, individualistic factors rather than by reference to aggregative antecedents. Such an explanatory individualism has been defended by Jon Elster (1985). He argues that aggregative antecedents are causally relevant in virtue of the causal relevance of individual factors and that staying at the aggregative level means leaving the productive mechanism in a black box; it amounts to a willful neglect of relevant facts.

Suppose that we have found a good aggregative explanation of some social phenomenon: say we find that

secularization is explained adequately by urbanization or a rise in crime by a rise in unemployment. We gain further information about the causal history of such a phenomenon as we are informed about the individual-level factors at work in producing secularization or crime. But it may still be that the aggregative story gives us equally important causal information. It may be, for example, that while we learn more about the detail of the actual causal process in going individualistic we learn more about what would be enough to ensure an increase in secularization or crime—that there should be urbanization or unemployment—in spotting the aggregative connections. After all, we might have known the individual-level explanations without having come to recognize the aggregative connections. Perhaps the right line is neither explanatory individualism nor explanatory nonindividualism but explanatory ecumenism (Jackson and Pettit 1992).

The second question bears on whether it is a good explanatory strategy in social science to make economic assumptions about individual agents: to assume, as economists tend to do, that agents are rational in the way they form and reform their preferences and that their preferences are generally egoistic in character. There are lots of persuasive arguments for following an economic strategy: arguments that point to the precision in model building and prediction that economic assumptions allow (Becker 1976). But it seems manifest, on the other hand, that the economic story is not the whole truth about human beings (Hollis 1977). For example, it is surely obvious that most of us do not make our decisions on the self-concerned, calculative basis that that story would seem to suggest.

But this consideration may not be decisive against economicism. For what is possible is that while agents often do not calculate economically, they tend sooner or later to give up on patterns of behavior that are not at least comparatively satisfactory in economic terms (Pettit 1993, chap. 5). Perhaps the fact that a pattern of behavior satisfies such economic constraints is necessary to explain the resilience, if not the actual production and reproduction, of the behavior.

## PHILOSOPHY OF STATISTICAL MECHANICS

Probabilistic modes of description and explanation first entered into physics in the theory of statistical mechanics. Some aspects of the theory that are of interest to the general philosopher of science are the nature of probability and probabilistic explanations within the theory, the kind of intertheoretical relation displayed between this theory and the nonprobabilistic theory it supplants, and the role to be played in scientific explanations by the invocation of cosmological special initial conditions. In addition, this theory provides the framework for attempts to account for the intuitive sense that time is asymmetric by reference to asymmetric physical processes in time.

### HISTORY OF THE THEORY

It was in the seventeenth century that thinkers first realized that many material systems were describable by a small number of physical quantities related to one another by simple laws—for example, the ideal gas law, relating the volume, temperature, and pressure of a gas.

It was soon understood that a fundamental notion was that of equilibrium. Left alone, systems might spontaneously change the value of their parameters, as when a gas expands to fill a box. But they would soon reach an unchanging final state, that of equilibrium. And it was realized that this process was asymmetrical in time, in that systems went from earlier non-equilibrium states to later equilibrium states, but not from earlier equilibrium states to later states of non-equilibrium.

Studies of steam engines initiated by S. Carnot showed that stored heat could be converted to mechanical work, but only by a process that converted stored heat at a higher temperature to residual heat at a lower temperature. This result was made mathematically elegant by R. Clausius, who introduced the notion of entropy as a measure of heat's ability to be converted into external work into physics. That heat was a form of stored energy and that the total amount of energy in heat and work was conserved became a fundamental principle of physics, as did the idea that energy could spontaneously only go from a more ordered to a more a less orderly state. These results were formalized in the First and Second Laws of Thermodynamics. But why were these laws true?

The latter half of the nineteenth century and the beginning of the twentieth saw the development of an intensive debate about the place of thermodynamics within the more general sciences that dealt with dynam-

ics and with the constitution of matter. P. Duhem, E. Mach, and others argued that the laws should be understood as autonomous principles. But others sought an account of heat as the hidden energy of motion of the microscopic constituents of matter. This was later understood for gases in terms of a simple model of molecules in free motion except for collisions among them. The early work on kinetic theory of W. Herepath and J. Waterston, followed by work of A. Kronig, made this a rich area for theoretical exploration. J. C. Maxwell and L. Boltzmann discovered laws governing the distribution of velocity of the molecules in the equilibrium state, and they developed a law governing how such distributions changes as a system in nonequilibrium approached equilibrium, at least for the simple system of a nondense gas.

The theory of approach to equilibrium soon met with profound objections. J. Loschmidt pointed out that the apparently demonstrated time-asymmetrical approach to equilibrium was hard to understand in light of the fact that the laws governing the underlying dynamics of the molecules allowed for the time reverse of each possible process to be possible as well. Later H. Poincaré showed that the kind of systems being dealt with would, except possibly for exceptional initial conditions in a class of probability zero, return over infinite time infinitely often to states arbitrarily close to their initial states. Once again this seemed incompatible with the monotonic increase of entropy described by thermodynamics and apparently deduced from the dynamics in kinetic theory.

Both Maxwell and Boltzmann introduced probabilistic elements into their theory. The equilibrium distribution might be thought of as the most probable distribution of the molecules in space and in velocity. Alternatively, in an approach later systematically developed by J. W. Gibbs, equilibrium values might be calculated by computing the average of macroscopic features over all possible distributions of the molecules. Both Maxwell and Boltzmann also argued that approach to equilibrium should also be thought of probabilistically. Maxwell discussed the possibility of a “demon” who could, by inspecting molecules one by one, change an equilibrium state of a system to a nonequilibrium state without doing external work on the system. Critics such as S. Burbury and E. Culverwell noted that the introduction of probabilistic notions was not sufficient by itself to overcome the puzzles of reversibility and recurrence.

In his last view of the theory, Boltzmann, following his assistant Dr. Scheutz, offered a time-symmetrical version of the theory. On this view, isolated systems spend most of their life near equilibrium over very long periods

of time. There would be occasional fluctuations away from equilibrium. A system found in a nonequilibrium state would probably be closer to equilibrium both in the past and future. Our local region of the universe, a universe that as a whole was itself in equilibrium, was one such fluctuation. Scientists could only exist in such a nonequilibrium region because only such a region could support sentient creatures. Why do we find our local world approaching equilibrium in the future and not in the past? Because the time direction of increase in entropy determined the future just as the local direction of gravitational force determined the down spatial direction.

In an important study of the foundations of the theory in 1910, P. and T. Ehrenfest (1959) surveyed the basis of the theory as understood in different ways by Maxwell, Boltzmann and Gibbs. They also offered an important interpretation of Boltzmann's equation describing approach to equilibrium in which the solution of the equation described not the inevitable or even probable behavior of an individual system but rather the sequence of states that would be found dominant at each time in a collection of systems all of whose members started in the same macroscopically nonequilibrium condition.

## PROBABILITY AND STATISTICAL EXPLANATION

Probability is characterized formally by simple mathematical postulates, the additivity of probabilities over disjoint sets of events being the most important of these. Philosophers have long debated the interpretation of probability. Some interpretations are subjectivist, taking probabilities to be measures of partial belief. Others are logical, holding probabilities to represent partial entailments. Other interpretations are objectivist. Some varieties of this last are frequency, limits of frequency, or dispositional interpretations.

At least one proposal (by E. Jaynes) has held that the probabilities in statistical mechanics are subjective, or rather of a kind of logical sort resting upon a principle of indifference. Most interpreters of statistical mechanics hold to objectivist interpretations of probability, but even among them there is much debate. Are the probabilities somehow dependent on the underlying dynamical laws, as ergodic approaches suggest? Or are they reflective of a deeper lawlike structure of tychistic chance, as Albert suggests, referring to Ghirardi-Rimini-Weber (GRW) stochastic theories introduced in the interpretation of quantum mechanics? Or is it the case, rather, that the

probabilities have an autonomous place within the theories requiring their independent postulation?

Philosophers analyzing statistical explanations have usually focused on uses of probabilistic explanation in everyday circumstances or in the application of statistics to such fields as biology. Here some suggestions have been that high probability is explanatory, that increased probability is what matters, or that explanations are only genuinely probabilistic when pure tychistic chance is relevant.

In statistical mechanics explanation in the nonequilibrium theory has many aspects that fit familiar patterns of statistical explanation as analyzed by philosophers. Within the theory the main areas of controversy are over the nature and rationale for the particular kind of probabilistic explanation that does justice to the empirical facts. In the equilibrium theory a kind of transcendental use of probability in the statistical explanations offered by ergodic theory is quite unlike the usual kind of causal-probabilistic explanations familiar in other contexts.

## THE THEORY OF EQUILIBRIUM

Boltzmann and Maxwell developed a standard method for calculating the equilibrium values of the macroscopic parameters of a system. This became formalized by Gibbs as the method of the microcanonical ensemble. Here a probability distribution is placed over the microstates possible for the system, given its constraints. For each microstate the values of the macroscopic parameter are calculable. One takes as the observed equilibrium values the average value of these parameters calculated over all the possible microstates, using the stipulated probability distribution. But why does the method work? What rationalizes the choice of probability distribution and the identification of average values with equilibrium quantities?

Boltzmann argued that the method could be partly justified if one thought of equilibrium values as average values over an infinite time as the system changes its microstates under dynamic evolution. Another component of this way of thinking is a claim that, given the large numbers of molecules in a system, average values would coincide with overwhelmingly most probable values for a macroscopic parameter. Boltzmann and Maxwell argued that one could identify such time averages with so-called phase averages, calculated using the posited probability distribution over the microscopic conditions possible for the system, if one thought of any one system as going through all possible microstates compatible with the macroscopic constraints on the system as time went on.

This became formalized by the Ehrenfests in the form of the Ergodic Hypothesis.

Early versions of the Ergodic Hypothesis were provably false. Weaker versions, such as the claim that the microstate of the system would come arbitrarily close to every possible microstate over infinite time, were impossible to demonstrate and could not support the equality of time and phase averages even if true.

These early ideas gave rise to the mathematical discipline of ergodic theory. The results of J. von Neumann, and, in stronger form, those of G. Birkhoff, showed that for certain idealized dynamical systems, except for a set of initial conditions of zero probability in the standard probability distribution, the time average of quantities calculated from the microstate of the system over infinite time would, indeed, equal the phase average of that quantity calculated using the standard-probability distribution over all possible microstates of the system.

But did any realistic models of a system meet the conditions needed for these theorems to hold? Many decades of work, culminating in that of Sinai, showed that a familiar model of a dilute gas, hard spheres in a box, was a model of an ergodic system. On the other hand, important work in theoretical dynamics showed that more realistic models of the gas would necessarily fail to be strictly ergodic (the KAM theorem). So any hope of applying ergodicity to rationalize the standard theory would require subtle reasoning involving the fact that the system was composed of vast numbers of molecules and might be, therefore, “ergodiclike.”

From ergodicity many consequences follow. Except for a set of initial points of probability zero, infinite time averages of a phase quantity will equal the phase average of that quantity. For any measurable region of the phase space, the proportion of time spent by the system in that region over infinite time will equal the probabilistic size of that region. Most important is the following: Boltzmann realized that the standard probability distribution was invariant over time under the dynamics of the system. But could there be other such time invariant distributions? If the system is ergodic, one can show that the standard distribution is the unique time-invariant distribution, which assigns zero probability to regions assigned zero probability by the standard distribution.

These results provide us with a kind of transcendental rationale for the standard equilibrium theory. Equilibrium is an unchanging state. So if we are to identify macroscopic features of it with quantities calculated by using a probability distribution over the microstates of

the system, this probability distribution should be unchanging under the dynamics of the system. Ergodicity shows us, with a qualification, that only one such probability distribution, the standard one, will do the trick.

But as a full rationale for the theory, ergodicity must be looked at cautiously. Real systems are not genuinely ergodic. We need to simply swallow the claim that we may ignore sets of conditions of probability zero in the standard measure. And the kind of rationale we get seems to ignore totally the place of equilibrium as the end point of a dynamic evolution from nonequilibrium conditions.

## THE THEORY OF NONEQUILIBRIUM

Maxwell and Boltzmann found equations describing the approach to equilibrium of a dilute gas. Later a number of other such kinetic equations were found, although attempts at generalizations to such situations as dense gases have proved intractable.

But how can such equations, whose solutions are time asymmetric, possibly be correct if the underlying dynamics of the molecules are symmetrical in time? Careful analysis showed that the Boltzmann equation depended upon a time-asymmetrical assumption, the *Stosszahlansatz*. This posited that molecules had their motions uncorrelated with one another before, but not after, collisions. Other forms of the kinetic equations made similar assumptions in their derivation. Two general approaches to deriving such equations are that of the master equation and the approach that works by imposing a coarse graining of cells over the phase space available to the system and postulating fixed transition probabilities from cell to cell. But the time-asymmetrical assumption must be imposed at all times and might even be inconsistent with the underlying deterministic dynamics of the molecules.

Many attempts have been made to understand the kinetic equations and to resolve the paradoxes. Some of these explore how an initial probability distribution over a collection of systems can, in a “coarse-grained” sense, distribute itself over the increased phase volume available to a system. This way of looking at things was first described by Gibbs. The coarse-grained spreading of the probability distribution is taken to represent the approach to equilibrium of the system. This interpretation fits with the understanding of the solution curve of the Boltzmann equation outlined by the Ehrenfests.

To show that such spreading of the initial probability distribution occurs, one relies upon the underlying dynamics and generalizations of the results of ergodic

theory. Systems can be characterized as randomizing in a variety of senses of increasing strength such as being a mixing system, a K-system, or a Bernoulli system. Then one can rely upon the model of the system—hard spheres in a box, for example—and the dynamics to show the system randomizing in the specified sense. This approach often relies upon many idealizations, such as calculating what happens in the infinite time limit. And the results often depend upon the use of unrealistic models of systems. For these reasons the applicability of the results to real systems and their real finite time behavior requires care.

Crucially these results, following as they do from the time-symmetrical dynamics, cannot by themselves introduce time asymmetry into the account. To do that one must make a time-asymmetrical assumption about how the initial probability distribution over the microstates of the system is constrained. This problem was studied by N. Krylov and others. Krylov's solution was a kind of nonquantum uncertainty principle applicable to the preparation of systems. Others look for the solution in cosmological facts, as we shall later note. Still others seek to modify the underlying dynamics by postulating some time-asymmetrical fundamental physical principle in play, such as the time-asymmetrical GRW stochastic field proposed in some interpretations of quantum mechanics.

There are ways of trying to understand an approach to equilibrium quite at odds with the mixing approach just described. O. Lanford, for example, has produced a "rigorous derivation of the Boltzmann equation." Going to an idealized limit, the Boltzmann-Grad limit, Lanford imposes an initial probability distribution, and then shows that with probability one systems will evolve for a short time as described by the Boltzmann equation. Because the results can be proved only for very short times—less than the mean free time to the first collision—their applicability to the real world is again in question. As usual, interesting issues about time asymmetry arise, here in the form of the choice of the initial probability distribution.

## IRREVERSIBILITY

Why is it that, although the underlying dynamic principles are symmetrical in time, the thermodynamic laws describe a world asymmetrical in time, a world in which entropy spontaneously increases in one time direction but not the other? Merely introducing probabilities into the account by itself will not provide the grounds for understanding the physical origins of irreversibility.

Throughout the history of thermodynamics and statistical mechanics, the suggestion has been repeatedly made that the source of thermodynamic time asymmetry lies in the existence of some time-asymmetrical law governing the underlying dynamics. The recent invocation of time asymmetric GRW stochastic influences is the latest such proposal.

Sometimes it has been suggested that the entropic increase experienced by an "isolated" system is to be accounted for in terms of the fact that systems can never really be fully causally isolated from their external environment. Even the most carefully insulated system, for example, has its molecules' motion influenced by gravitational forces exerted by matter outside the system. Whether the fact that isolation is an idealization is really relevant to thermodynamic time asymmetry has been much debated. Of great importance to this debate is the existence of systems that seem to show the usual macroscopic entropic increase familiar from thermodynamics, but which are systems sufficiently isolated from their surrounding environments such that a simple external trigger can have their microstates follow a reverse course, with the system recurring to its original nonequilibrium state—spin-echo experiments, for example. For these systems seem to show that a kind of entropic increase cannot be accounted for in terms of external interference with the system.

As noted above, it was Boltzmann's assistant, Dr. Scheutz, who first suggested a cosmological solution to the problem. Scheutz suggested that the universe as a whole is in a time-symmetrical equilibrium state, with our local portion of the cosmos in a rare fluctuation away from equilibrium. Such a region would be very likely, from a time symmetrical probabilistic perspective, to evince higher entropy in one time direction but lower entropy in the other direction of time, since it is unlikely to be at the turning point of maximal deviation from equilibrium. Boltzmann then supplemented this with his assertion that the very meaning of the future is that is the time direction in which entropy is increasing.

Current cosmological theories describe a very different sort of universe, one that, to the best of our knowledge, is in an overall nonequilibrium state and that has entropic increase in the same time direction in all its regions. In current Big Bang cosmology the universe is said to be spatially expanding from a singularity some tens of billions of years ago. Some theorists take the thermodynamic time asymmetry to have its roots in the cosmic expansion. The more general opinion is that this cannot be correct, since, according to the prevailing but

not universal opinion, even if the universe began to contract, entropy would continue to increase.

In the dominant opinion, rather, the source of entropic increase is found in a special physical condition of the universe just after the Big Bang. In these accounts the matter of the universe is taken to be, at that early date, in thermal equilibrium. But matter is thought to be smoothly distributed in space. This is a very low entropy state because of the fact that gravity, unlike intermolecular forces in a gas, is a purely attractive force. The theory goes on to propose a clumping of matter into dense galactic clusters, galaxies, and stars, leaving most of space almost devoid of matter. This results in an enormous increase in spatial-gravitational entropy. Matter so clumped goes into a lower entropy state than its original equilibrium, since it now consists of hot stars in cold interstellar space. The general increase of entropy from the Big Bang onward is then accounted for by positing both the usual time-symmetrical probability assumptions and initial low entropy for the universe as a whole.

One question that then arises is why the initial state should be one of such low entropy. Here one is up against the usual perplexities that arise if we ask for an answer to a why question about “the initial state of everything.” Why is such a low-probability state the one we find? Should one posit many universes, of which our low-probability case is a rare example? Here one is reminded of the speculation of Scheutz about our region of the universe just being an improbable sample from the whole. Can one explain why we find ourselves in such a universe by some version of the anthropic principle, first used by Boltzmann to explain why we find ourselves in a low-entropy region of his speculated high-entropy universe? Can one attribute probabilities to initial singular states or to universes at all? Here one thinks of the criticism offered by D. Hume of the teleological argument for the existence of God.

The second law of thermodynamics is not concerned, of course, with the entropy change of the entire cosmos, but rather with the parallel in time-entropic increases of small systems temporarily causally isolated from their external environments. The study of the connection between cosmic entropy increase and that of the “branch systems” was initiated by H. Reichenbach. Many of the arguments in the literature claiming to derive changes of entropy of branch systems that are parallel in time to the entropy increase of the cosmic whole are badly flawed, but a reasonable inference can likely be constructed using probabilistic posits that themselves do not smuggle time asymmetry into the derivation.

## THERMODYNAMICS AND STATISTICAL MECHANICS

We often speak of an older theory being reduced to a newer theory, and it is often said that thermodynamics has been reduced to statistical mechanics. But, as we have learned in general, the relation of older theory to newer theory may be of some complexity and some subtlety.

Thermodynamics, traditionally, was not a theory framed in probabilistic terms. Its laws, especially the second law, could not be exactly true, as Maxwell noted, in the light of the new probabilistic account. Alternative ways of dealing with this problem are available. One way is to stick with traditional thermodynamics and offer an account of the relation between newer and older theory that is far from a simple derivation of the latter from the former. Another possibility is to use the new knowledge of the probabilistic aspects of thermal phenomena to construct a novel statistical thermodynamics that imports probabilistic elements directly into the older theory.

There must be a high degree of complexity in the relations between the concepts of the older theory—such as volume, pressure, temperature and entropy—and those of the newer theory—such as concepts dealing with molecular constitution, the dynamics governing the molecules, and probabilistically framed concepts dealing either with the distribution of states of constituents of the individual system or with the distribution of microstates of systems in a collection of systems characterized by some macroscopic parameters.

Consider, for example, thermodynamic entropy. Associated with it are many distinct entropy concepts in statistical mechanics. Boltzmann entropy, for example, is defined as the fluctuating property of an individual system, defined in terms of the actual spatial and momentum distribution of the molecules of the system at a time. Gibbs’s entropies, on the other hand, are defined in terms of some probability distribution imposed over some imagined ensemble of systems characterized by some specified constraints. To make matters even more complicated, there is Gibbs’s fine-grained entropy, defined by the probability distribution alone and useful for describing the equilibrium states of systems, and Gibbs’s coarse-grained entropy, whose definition requires a specification of some coarse-grained partition of the phase space as well as the probability distribution, and whose place is in characterizing the approach to equilibrium of nonequilibrium systems. Other notion of entropy, such as those defined in terms of topology rather than measure theory, exist as well.

None of this complexity shows that one is wrong in thinking that in some appropriate sense, statistical mechanics explains the success of thermodynamics or that it might be plausible to speak of a reduction of thermodynamics to statistical mechanics. The complexity and subtlety of the relations between the two theories informs the philosopher of science of just how varied and complicated such reductive relations might be.

Philosophers outside the field of philosophy of physics might take some interest in the relationship that thermodynamics bears to the underlying physical description of the systems to which thermodynamic concepts are applied. A material object composed of atoms or molecules, for example, can exist in equilibrium with a system of electromagnetic radiation, leading physicists to speak of both such systems as having a common temperature. What this shows is that concepts such as entropy and temperature have a kind of functional role, with their meanings fixed by the place they play in a theory that is applicable to physical systems of many different kinds. This bears some analogy with the claim, so familiar in the philosophy of mind, that mental terms are functional and that mental states are multiply realizable in physical systems of varied natures.

## THE DIRECTION OF TIME

The claim that our very notion of the asymmetry of time is rooted in entropic asymmetries of physical systems in time was first made by Boltzmann, as we have noted. The claim has often been repeated but remains controversial. Much needs to be done to provide a completely convincing case that our deepest intuitions about the difference between past and future are somehow grounded in entropic asymmetries.

A first question relates to what an entropic theory of the direction of time is claiming. It certainly cannot be that we find out which direction of time is the future by somehow checking up directly on the entropic behavior of systems around us, for that claim has little plausibility. So what does the claim come down to?

What intuitively distinguishes future from past? We think we have a direct insight into which of a pair of events is later than the other. We take it that we have asymmetric epistemological access into past and future, there being memories and records of the past and not of the future. We usually take it that causation goes from an earlier event as cause to a later event as effect. We are anxious about future events but not about past events, although we may regret the latter. We often think of the past as being over and done with and hence not subject to

change, whereas the future is open to many possibilities. Some philosophers have argued that past events have determinate reality, whereas there is no such thing as a determinate being to the future.

The most plausible version of the entropic theory of the direction of time is best understood by looking at the analogy introduced by Boltzmann. What lies behind our intuitions that space is distinguished by an asymmetry because one direction is down and its opposite up? Surely it is the existence of gravitational force that fully accounts for the down-up distinction. It is gravity that explains why rocks fall down and, in our atmosphere, flames and helium balloons go up. Even the fact that we can tell, directly and without using our sensory awareness of the external world, which direction is down is explained in terms of the local direction of gravitational force. For it is the behavior of fluids in our semicircular canals that tells us which way is up, and the behavior of that fluid is entirely explained in terms of its gravitationally induced weight. In regions of the universe with no gravitational field, there is no distinction between the up and the down direction to be drawn.

The entropic theorist of the direction of time argues that the situation is exactly analogous to the case of down directionality and gravity. The claim is that we can account for all the intuitive differences by which we distinguish past from future by a scientific account at whose core are entropic asymmetries in the behavior of systems in time. If there were regions of the cosmos in which entropic changes were antiparallel to one another in time, the entropic theorist claims, the inhabitants of such regions would take opposite directions of time to be the future direction of time. And in regions of the cosmos in equilibrium, there would be no past-future distinction, although, of course, there would still be opposite directions in time.

There have been numerous proposals, starting with the seminal work of H. Reichenbach, to try to justify the claim that it is, indeed, entropic change that lies at the heart of any explanation of why we have memories and records of the past and not of the future, of why we think of causation as going from past to future, of why we have differential concerns about past and future, and of why we think of the past as determinate but think of the future as an open realm of mere possibilities. Despite much important work on this problem, however, the very possibility of constructing such entropic accounts remains controversial.

## PHILOSOPHY OF TECHNOLOGY

The philosophy of technology brings logical, metaphysical, epistemological, ethical, and political philosophical questions to bear on the making and using of artifacts. The particular balance among these questions will differ within related regionalizations of philosophy, such as the philosophy of science or the philosophy of art. In the philosophy of technology, for instance, epistemology typically plays a lesser role than in the philosophy of science but a greater role than in the philosophy of art. Any philosophical assessment of technology is thus partially defined by its own inner balance in relation to philosophy as a whole.

### HISTORICAL EMERGENCE

Although limited discussions of *techne* and associated or derivative phenomena can be found in ancient, medieval, and early modern philosophy, it was not until the late nineteenth and early twentieth centuries that technology, as something distinct from technics or technique, became a subject for theoretical examination. Among the earliest contributing texts, the mechanical engineer Franz Reuleaux's *Theoretische Kinematik* (1875) developed an extended conceptual analysis of different types of tools and machines. More generally, Ernst Kapp's *Grundlinien*

*einer Philosophie der Technik* (1877), in the first book to use "philosophy of technology" in its title, outlined a theory of culture grounded in technics understood as the extension and differentiation of human anatomy and physiology. The hammer, for instance, functions as an extension of the fist, the camera as an extension of the eye, and the railroad as an extension of the circulatory system; and vice versa, the fist can be said to be like a hammer, the eye like a camera, and rail lines like blood vessels. Elaborations of this view of technology as organ projection are representative of a school of what Carl Mitcham (1994) calls engineering philosophy of technology, an approach that was further developed in the work of thinkers as diverse as the Russian Peter Englemeier, the German Friedrich Dessauer, the Frenchman Gilbert Simondon, and the Spaniard Juan David García Bacca (all of whom have been largely ignored in Anglo American philosophy).

The research engineer Dessauer, for instance, developed a neo-Kantian critique of the transcendental possibility of technological invention that sees technology as bringing noumenal power into the world. Dessauer was also instrumental in promoting philosophical discussion within the Verein Deutscher Ingenieure (VDI; Society of German Engineers). The psychologist Simondon explored relations among parts, artifacts, and technical systems and the evolutionary manifestation of what he called technicity. The engineer Englemeier and the philosopher García Bacca both saw technological change engendering world-historical transformations that were at once humanizing and transcending of the merely organically human. Additional contributions to this school can be found in theoretical discussions about cybernetics and artificial intelligence. Also illustrative of achievements in engineering-oriented philosophy of technology are the scientific philosopher Mario Bunge's (1985) systematic metaphysics, epistemology, and ethics of technology and the engineer Billy Vaughn Koen's (2003) brief for engineering as the one right method for problem solving.

In its emergence, however, philosophy of technology was more commonly associated with what might be called a counterphilosophy that interprets technology not as extending but as encroaching on or narrowing the dimensions of human experience. Following Immanuel Kant's attempt "to deny [scientific] *knowledge*, in order to make room for *faith*," this humanities philosophy of technology has sought to limit technological thought and practice to make room for human culture in all its rich diversity. A case in point is the public intellectual Lewis

Mumford's (1967) criticism of what he calls monotechnics, the technics of power, in contrast to poly- or biotechnics. The problem with monotechnics is that it promotes the pursuit of physical power and control at the expense of other aspects of human flourishing such as friendship and art. For Mumford the "myth of the machine" is to think that power is the source of all human benefit. In fact, it constitutes an unrealistic narrowing of human activity. Some version of this argument has been promoted especially by the continental European philosophical tradition in the works of José Ortega y Gasset (1939), Martin Heidegger (1954), and Jacques Ellul (1954). Indeed, even more broadly, the relation between technology and life—whether in the sense of *zoe* (organic existence) or *bios* (human flourishing)—has become one of the most crucial issues in both the metaphysics and ethics of technology.

Until the latter half of the twentieth century, the argument for delimitation had the unintended side effect of relegating technology to marginal status in professional philosophy. Only as technology became more than an engineering interest or a social problem has it begun to be a mainstream topic in philosophy. One of the challenges in the twenty-first century will be to pursue the professional development of philosophical reflection on technology in ways that bridge the oppositions inherent in its bimodal historical origins without compromising their basic if divergent concerns.

### ETHICAL AND POLITICAL ISSUES

Because of their prominence in public affairs, the philosophy of technology properly highlights ethical and political issues. Indeed, contemporary work in practical or applied ethics—as in nuclear, environmental, biomedical, and computer ethics—emphasizes the moral challenges of technology, although in ways that sometimes reduce the field to an aggregate of different ethics for different technologies. Such subspeciation can deprive ethics of possible synergistic strengths. Access equity issues, for instance, occur in both biomedicine and computers, and the concepts and principles for dealing with one might well inform or enhance the other. Speaking generally, then, one can identify at least six competing and overlapping interpretations of technology as an ethical or political problem. Three of these arose initially before World War II, although they have continued to cast a shadow of concern, often in new and distinctive forms.

First, there is a problem of the just distribution of technological products and powers—that is, technology as a political issue. Since the Industrial Revolution the

social-justice question has found numerous expressions in authoritarian and democratic regimes, in developing and developed countries. Authoritarian regimes have often justified themselves as acting to promote access to technological benefits against entrenched special scientific, technical, or corporate interests or against those whose commitment to equality undermines the invention and production of goods and services. Democratic regimes have placed more emphasis on promoting equality by means of due process and regulatory agencies. One aspect of due process that has been given special philosophical attention concerns the legal protocols to promote free and informed consent, extending the concept from human experimentation to engineering at large (Martin and Schinzinger 2005).

With the engineered design of new products and processes social justice issues have often taken special form in association with some otherwise morally neutral concepts. The advent of electronic computer and Internet communications, for instance, has helped impart ethical significance to questions of privacy and the so-called "digital divide." Additionally, according to Ulrich Beck (1992), concerns for the fair distribution of goods and services were, during the late twentieth century, superseded by those dealing with the fair distribution of dangers and risks, thus giving social justice debates a special twist. One of the strongest criticisms of some of the resulting twists and turns has been Kristin S. Shrader-Frechette's (1991) careful dissecting of the antidemocratic assumptions of much risk-cost-benefit analysis.

Second is the problem of the alienation of workers from their labor in the industrial means of production, which has been presented especially by Marxists as an economic and by some non-Marxist social scientists as a psychological issue. Langdon Winner's (1977) analysis of the theory of autonomous technology or the idea that technology as resistant to human control is a more general statement of the issue. Critical theory work by Herbert Marcuse (1964) and Andrew Feenberg (1991, 1999) extended the classic Marxist discussion into situations reconfigured by consumerist culture and globalization. Opposing Marcuse's pessimism about transformation, Feenberg (especially 1995) has been more optimistic about alternative possibilities. Environmentalists, however, have further argued that technology in general alienates human beings from nature.

Don Ihde's (1990) phenomenology of the technolifeworld offers another take on this issue through an analysis of human—technology—world relations. Two fundamental types of such engagements are instrumental

relations, in which the technology is integrated into the human sensorium as its extension (the blind man's cane), and hermeneutic relations, in which the technology becomes part of the world to be interpreted (a thermometer). Both engagements manifest an invariant structure that amplifies some aspect of the world (exact metric of temperature) while simultaneously reducing others (general sense of climate). The former tends to bring humans closer to the world, the latter to distance (or alienate) them from it.

Third is the problem of the destruction or transformation of culture by modern science and technology—either directly through new weapons and forms of military conflict or indirectly through the impact of new means of transportation, communication, and media. The destruction of World War I, the most violent in human history, was a manifestation of technology that only became worse during World War II with the development of nuclear weapons. The long cold war practice of nuclear deterrence and the early twenty-first-century challenges of terrorism present special problems for learning to manage the destructive potential in technology.

Between the two world wars concern for the more indirect technological transformation of culture took on special salience, as variously illustrated by the cultural lag theory of the American sociologist William Fielding Ogburn, the elegiac ruminations of the Catholic theologian Romano Guardini, or the active nihilistic enthusiasms of Ernst Jünger. In the latter half of the twentieth century the issue found small-scale manifestation in personal efforts to come to terms with new choices (e.g., in diet, drugs, and consumer lifestyle options) and large-scale manifestation in debates about the dynamics of sociotechnical change (e.g., the role of technology in economic development and technological determinism versus social constructionism). Questions can also arise about the transformed character of cultural life under the influence of information and image technologies, from television to the Internet and virtual reality machines.

Since World War II three more issues have emerged to ethical and political prominence. One is that of democratic participation. An anticipatory version of this issue emerged in interwar proposals for technocracy. For some theorists (such as Thorstein Veblen) rule by technical elites offered a better alternative than rule by economic or political elites. However, in the postwar revival of democratic theory, and with recognition that technology (like law) is a creation that also influences the creators, it was argued that the principle of “no taxation without repre-

sentation” should be extended to “no innovation without representation” (Goldman 1992). Winner, for instance, describes “technologies as forms of life” and calls for the abandonment of “technological somnambulism” (1986, p. 10) in favor of public debate about the design of technological projects as diverse as highway bridges, tomato harvesters, and nuclear power plants. Efforts to determine how such democratic participation should be structured both within communities of technical expertise and in the negotiations between technical experts and the non-technical public have been the subject of ongoing debates (see Sclove 1995).

Fifth is the industrial pollution of the natural environment, which has contributed to attempts to develop an appropriate environmental or ecological ethics. What is the difference between artifice and nature—and the moral status of wilderness or the nonhuman environment? As nature is humanly transformed, to what extent should contemporary technological action take into account the welfare of future generations, whether human or nonhuman? What is the relation between values that are divided between the anthropocentric and ecocentric, extrinsic or instrumental and intrinsic?

Another morally relevant concept, closely related to issues of both participation and environmentalism, is that of unintended consequences. To what extent are scientists and engineers responsible for the unexpected and perhaps even unforeseeable results of their technological actions? Two attempts to deal with the plethora of environmental issues, especially in relation to the challenge of unintended consequences, are those associated with sustainable development and the precautionary principle—with competing interpretations of both becoming major themes of moral and political deliberations.

Finally, there is the issue of responsibility: How are humans to respond ethically to the power placed in their hands by modern technology? Such a question has personal, professional, and policy dimensions. At the personal level, quantitatively and qualitatively enhanced choices, with expanding knowledge production relevant to such choices (scientific research and consumer reports), place existential pressures on individuals to increase conscious reflection. The principle of free and informed consent appears to require not only that medical professionals inform the subjects of human experimentation about the risks and benefits of their participation but also that medical patients of all sorts become reflective participants in their own treatment—and that consumers of any technological goods or services weigh multiple costs and benefits as if they were

engineers designing their lives. Are such demands both reasonable and possible?

At the professional level, scientists and engineers, falling under similar existential pressures to expand the conscious exercise of responsibility, have formulated codes of conduct for technical practices related to both research and design. In engineering ethics, for instance, the primacy of protecting public safety, health, and welfare is now a well-established general principle. In what sense, however, are engineers qualified to make such judgments? Does technical expertise provide any basis for determining appropriate levels of public safety, health, or welfare?

Finally, at the level of public policy, responsibility takes two closely related forms. Policy for science and technology seeks out the best ways to fund or regulate developments in science and technology. Science and technology for policy searches for the best ways to bring scientific knowledge to bear on political decision making while making technological power most effectively available for political action. Responding to and exemplifying these dual drives scientific and technological research agencies such as the U.S. National Science Foundation, the Human Genome Project, and the National Nanotechnology Initiative have created specific programs to promote ethical reflection on the creation and use of new scientific knowledge and technological products, processes, and systems.

Again speaking broadly, it is possible to identify two fundamental attitudes toward this spectrum of ethical and political issues. One attempts to explain modern technology as rooted in human nature and culture (engineering philosophy of technology), the other interprets modern technical methods and effects as deformations of human action, however preferable in particular instances to those of nature (humanities philosophy of technology). The engineering approach in its expansive confidence calls in one way or another for more and better technology, the humanities approach in its restrictive questioning for some relinquishment or delimitation of technology. The tensions between such alternative attitudes repeatedly come to the fore in analysis of such key concepts as privacy, risk, participation, and the environment, and in assessments of new opportunities in virtual reality construction, biotechnological design, and nanotechnological research and development.

There is also a tendency for the engineering school to make alliances with the Anglo American analytic tradition in philosophy, and for the humanities school to find a convenient partner in the European phenomenological tradition. The former, viewing technology as a complex

amalgam of artifacts, knowledge, activities, and volitions, each with diverse structural features scattered across historical epochs and societal contexts, prefers to deal on a case-by-case basis with one technology after another. The latter strives for bolder generalizations about technology as a whole, at least across each historical or societal context. From the phenomenological perspective, too great an emphasis on individual technological rocks can obscure the extent to which such geological specimens are constituents of mountains extended in both space and time.

## METAPHYSICAL ISSUES

The attempt to speak of *technology* rather than *technologies* rests on an attempt to identify some inner or essential feature of diverse technologies. This hypothetical essential feature may be termed *technicity*. One can then immediately note that, before the modern period, technicity was at a minimum scattered throughout and heavily embedded within a diversity of human engagements, and indeed that philosophy took a stand against any separating of technicity from its embedding context. Plato's argument in the *Gorgias* is precisely an argument against disembedding *techne* from social or cultural contexts and traditions, not to mention ideas of the good. For Aristotle, *techne* is an intellectual virtue, and thus properly subordinate to the flourishing of human nature. What is distinctive about modern philosophy, by contrast, is the attempt, beginning with Galileo Galilei, Francis Bacon, and René Descartes to disembed technics from particular human activities, to study them in systematic ways, and thus to create technology.

John Stuart Mill in his *Logic* (1843) already assumes the success of this disembedding project when he explains the practical value of science. For Mill the rationality of any art is grounded in a corresponding science.

The art proposes to itself an end to be attained, defines the end, and hands it over to the science. The science receives it, considers it as a phenomenon or effect to be studied, and, having investigated its causes and conditions, sends it back to art with a theorem of the combinations of circumstances by which it could be produced. Art then examines these combinations or circumstances, and according as any of them are or are not in human power, pronounces the end attainable or not.

(*LOGIC*, BOOK 6, CH. 12, SECTION 2)

Remarkably, Mill's analysis does not recognize art (or traditional technics) as including any knowledge of means. Art is concerned solely with determining an end, to achieve which it deploys appropriate means as determined by science. It is the scientific study of means that constitutes what even during Mill's lifetime was coming to be called technology. Modern technicity may thus be defined as a systematic or scientific study of means that suspends examination of ends. Does such an approach have distinctive social and cultural implications, independent of any particular technologies and contexts?

Among the first philosophers to analyze such a disembedding of means from ends was Ortega. In the English translation of his *La rebelión de las masas* (1929), Ortega writes that "[t]hree principles have made possible [the] new world: liberal democracy, scientific experiment, and industrialism. The two latter may be summed up in one word: technicism" (1939, p. 56). Ortega himself actually uses the word *técnica*, but the term *technicism* is significant, and this in fact constitutes one of its first English occurrences with this sense. (Before the 1930s, *technicism* simply meant excessive reliance on technical terminology. The previous decade Max Scheler used the cognate *Technizismus* to name the industrial ethos.)

As part of a further "Meditación de la técnica" (1939), Ortega outlined a historical movement from the chance inventions that characterize archaic societies, through the trial-and-error techniques of the artisan, to the scientific technologies of the engineer. According to Ortega, the difference between these three forms of making lies in the way they create the means to realize a human project—that is, in the kind of technicity involved. In the first epoch, technical discoveries are accidental; in the second, techniques emerge from intuitive skill. In both instances they are preserved and elaborated within the confines of myth and craft traditions. In the third, however, the engineer undertakes scientific studies of technics and, as a result, "prior to the possession of any [particular] technics, already possesses technics [itself]" (*Obras*, 5:369). It is this third type of technicity that constitutes modern technicism (and here Ortega himself uses the term *tecnicismo*).

But technicism, understood here as the science of how to generate all possible technical means, disembedded from any lived making and using, creates a unique challenge. Before the modern period human beings were commonly limited by circumstances, within which they inherited a way of life and the technical means to achieve it. Now, however, they are given in advance many possible

ways to live and a plethora of technical means but little in the way of a substantive vision of human flourishing. "To be an engineer and only an engineer is to be everything possibly and nothing actually," all form and no content (*Obras*, 5:366). There is in the midst of modern technicism what Ortega describes as a hidden ethical challenge to imagination and choice. Insofar as people can be anything they want, why should they take the trouble to be any one thing at all? Will not some extranatural motivation (not to say fanaticism) not be needed to help Buridan's cyborgs select among (rejecting some) the equally liberal options that surround them?

According to Heidegger modern technology is a challenge not just to ethics but to ontology. For Heidegger (1954) scientific technics constitutes a new kind of truth: truth not as correspondence, not as coherence, and not as functional knowledge, but as disclosure or revelation. Technology discloses Being in a historically unique way: as *Bestand* or resource. A castle constructed with traditional technics on a cliff overlooking the Rhine makes more fully present than before the stone that invests the landscape with its particular contours, while it sets off the curve of the river against the backdrop of its walls and towers. It invites people to settle near and experience the particularities of this place. By contrast, a poured concrete, hydroelectric power station compels the river to become an energy resource and converts the landscape into, not a place of human habitation, but a machine for the generation of electricity. It encourages people to draw on its energy for multitasking business in production and travel. The distinctly modern technicity that manifests itself in the disclosure of nature as resource Heidegger names *Gestell* (enframing).

*Gestell* at first sight appears to be a human work, something human beings in the course of history have chosen to practice for their own benefit. It gives them power over nature. However, as it digitalizes nature physically (dimensioned vectors), geographically (longitude and latitude), chemically (molecules, atoms, and subatomic particles), and biologically (genetic mapping), it also transforms language (computer signal processing) and art (pixel imaging) so that impact outstrips original intentions. Hidden in the midst of *Gestell* is Being as event, that which lets this dominating transformation come to pass. *Gestell* is at once destiny and, precisely because it appears so clearly to be the result of a human activity, an obscuring of the transhuman imparting of a destiny that is its ground.

In the same year that Heidegger's *Die Frage nach der Technik* appeared, Jacques Ellul published *La Technique*,

later translated into English as *The Technological Society* (1954). For Ellul, too, what is happening is something transhuman, or at least transindividual, the emergence of a new social order in which people give themselves up to the systematic analysis of actions into constituent means that are then evaluated in terms of output/input metrics. The scientific analysis of techniques extends technoscientific methods into economics, politics, education, leisure, and elsewhere creating what he calls the technical milieu. After the milicux of nature and of society, technology is the third great epoch of human history. Ellul's characterology of this new reality—describing its rationality, artificiality, self-directedness, self-augmentation, indivisibility, universality, and autonomy—reveals the technical milieu as something more than simply human. Although more hospitable to human biological existence, it nevertheless also manifests certain inexorable laws of artifice (such as those of economics). Just as the natural milieu once provided a framework for human life, a differentiated but overriding order to which human beings adapted in a variety of ways, so now a much more homogeneous technical milieu presents itself, not simply as a realm of freedom that human beings have constructed, but as that which also constructs and constrains them even when they fail to recognize it.

### FROM METAPHYSICS TO ETHICS

Efforts to make phenomenological metaphysics fruitful for ethics can be found in the work of two German American philosophers, Hans Jonas and Albert Borgmann. Jonas's (1966) work begins with a fundamental inquiry into the phenomenon of life, arguing that in the organic world there emerges a new kind of being. For Jonas the key features of human inner life (introspection and subjectivity) are present in embryo in the most primitive organisms, and in metabolism there emerges the primordial form of freedom. In metabolism a detachment enters the world insofar as being becomes distinguished from physical identity. However, in the materialism of modern science this unique reality is easily overlooked. Adopting a teleological approach to ontology, Jonas argues that only from the perspective of the more fully realized freedom manifest in humans can the reality of the organic as a whole be recognized for what it is. On this ontological basis Jonas (1984) undertakes an extended philosophical scrutiny of the technological projects of nuclear weapons and biomedical health care. In the presence of technical powers to end or alter human life Jonas reformulates the Kantian categorical imperative as: "Act so that the effects of your action are compatible with the permanence of

genuine human life" (p. 11). Such a reformulation of the fundamental deontological principle constitutes an attempt at the re-embedding of technology in moral philosophy.

More broadly and in sustained dialogue with a range of discussions about the place of technology in human affairs, Borgmann's (1984) work draws a fundamental distinction between two kinds of artifice and action. On the one side are technological devices that obscure their inner functions to deliver without engagement commodities for easy and effortless consumption. This constitutes what Borgmann calls the device paradigm, an ideal type at which the products and processes of modern technology aim. On the other are focal things and practices whose workings are more transparent and that demand of their users some reordering of interests if they are to be used. The model for the first is the central heating system that only needs its thermostat set, for the second the wood-fired hearth.

In a series of studies arguing the nondeterminist importance of material culture to ethics and politics, Borgmann (1992, 1999) calls on citizens in the high-tech world to reconsider their ways of life to develop a deeper sense for the possibilities of human flourishing in the midst of liberal options for self-determined self-fulfillment. For Borgmann the ideal is not a forced return to the past but a voluntary recovery of the commanding presence of things in the technological present. As he concludes in a volume devoted to the critical assessment of his thought:

Science makes reality ever more transparent, and technology makes it more and more controllable. But at the end of our inquiries and manipulations there is always something that reflects rather than yields to our searchlight and presents itself as given to us rather than constructed by us. It is intelligible not because we have seen through it or designed it but because it speaks to us [in the form of] an unforethinkable and uncontrollable reality. (Higgs, Lights, and Strong 2000, pp. 368–369)

It is such a reality to which human flourishing is ultimately in thrall even in the midst of its highest exercises of insight and mastery.

### EPISTEMOLOGICAL ISSUES

Epistemology has often been treated as a stepchild in the philosophy of technology family of philosophical interests. Technological forms of knowledge are commonly

thought to be derivative of scientific knowledge, so that any attempt to bring the theory of knowledge to bear in the examination of technology has regularly been part of a discussion of the relation between technology and science. At the same time this common privileging of science has been philosophically criticized, although the criticism has taken different forms in the European phenomenological and in the Anglo American analytic philosophical traditions.

From a phenomenological perspective the argument has been that technology is not so much applied science as science is theoretical technology. In his historico-philosophical studies of the scientific and technological revolutions of the seventeenth century and after, for instance, Jonas (1974) argues that from its origins modern science was animated by a technological interest that gives it an inherently applicable or technological character. Related studies of the dependency of science on technological instrumentation, from Galileo's telescopes to particle accelerators and PCR (polymerase chain reaction) machines (e.g., see Ihde 1991), suggest that science might even be described as applied technology. This approach to the epistemology of technology has parallels with the pragmatic tradition of conceiving scientific knowledge in fundamentally instrumentalist terms (see Hickman 2001). The Venezuelan phenomenologist Ernesto Mayz Valle- nilla (2004) likewise offers a more Husserlian-based but complementary effort to describe the unique epistemological features of what he calls meta-technical instruments.

From the analytic perspective there has been more of an effort to identify distinctive types of knowledge operative in technology. Summarizing the results from such an approach, Mitcham (1994) draws attention to at least four types of distinctly technological knowledge: sensorimotor skills, technical maxims (including rules of thumb and recipes), descriptive laws or technological rules (which take an "if A then B" form), and technological theories (either grounded in scientific theory or bringing scientific method to bear on human-technology interactions). German philosophers of technology such as Hans Lenk, Gunter Ropohl, and Bernhard Irrgang, all associated with the VDI promotion of philosophical reflection on technology, are pursuing efforts to develop epistemological analyses of the engineering sciences. And Joseph C. Pitt (2000) makes a determined effort to identify the distinctive forms of technological and engineering knowledge, drawing especially on the careful analyses of aeronautical engineering history by Walter G. Vincenti

(1990) to argue that engineering design possesses its own cognitive features.

Important issues for any theory of technological knowledge remain the characterization of whatever basic epistemic criteria might be analogous to those operative in science such as truth, simplicity, coherence, and explanation. There may be distinctive technological forms of such criteria. But two major candidates for uniquely technological criteria are effectiveness and efficiency. Certainly, many propositions of engineering knowledge are assessed in terms of effectiveness and efficiency more than truth or explanation. A further epistemological challenge is to explicate the distinctive character of models and modeling in the technological and engineering contexts. The relevance of such epistemological analyses nevertheless remains of problematic relevance to ethics and politics.

#### EMPIRICAL, ANTHROPOLOGICAL, AND POLICY TURNS

Concern for the adequacy of metaphysical definitions of technology—and perhaps exhaustion with endless ethical and political difficulties (with hopes that new approaches might prove more fruitful)—has given rise to what has been called an empirical turn in the philosophy of technology. As advocated by the Dutch philosophers Peter Kroes and Anthonie Meijers, this program argues that "philosophical reflection should be based on empirically adequate descriptions reflecting the richness and complexity of modern technology" (2000, p. xix) and promotes a greater analysis of what technologists and engineers actually do over any extended exegesis of texts, whether those of other philosophers of technology or even engineers and technicians. As such, a natural alliance has developed with social constructivist approaches to science, technology, and society studies in the pursuit of richer metaphysical or ontological understandings of artifacts, epistemological analyses of technical practice, and even ethical decision making among professional engineers. From the perspective of Jozef Keulartz et al. (2002), this also provides a solid opportunity for advancing a pragmatist ethics for technological culture.

Two topics of prominence in the empirical turn from the interpretation of texts to the interpretation of technical artifacts have been those of design and function. Design is often identified as the essence of engineering, and there have been numerous technical studies of design methodology. At the same time engineering design must be distinguished from aesthetic design as well as design by means of evolutionary processes in nature. Even

within the realm of engineering design, studies such as those by Vincenti (1990), Louis Bucciarelli (1994), and Richard Buchanan and Victor Margolin (1995) have very different implications for assessing proposals for consumer, green, sustainable, or participatory design. With regard to technical functions, analyses have focused on the relation between functions in organisms, social institutions, and artifacts; on the relation between functional and physical descriptions of artifacts; and on the extent to which functions are determined by design or use.

A different sense for new beginnings has emerged in relation to prospects in the development of the new fields of bioengineering and biotechnology—especially when applied to humans. The leader in this case is the medical scientist and philosopher Leon Kass, the chair of the Bush administration's President's Council on Bioethics. In his turn Kass has tried to go outside the boundaries of standard bioethics in at least four ways: to promote thinking that enrolls more than professional bioethicists, that does more than piecemeal or specialized analyses, that references human nature as a norm, and that builds toward policy results. As in *Beyond Therapy: Biotechnology and the Pursuit of Happiness* (2003), Kass et al. at the council seek to raise broad issues about what it means to be human in the presence of possibilities for the reengineering not just of the external world but of the inner world of human birth, growth, and experience. He has been especially concerned about the possibilities for the deformation of humanity not from above by totalitarian governmental use of technology but from below by positive consumer endorsement of behaviors that would from a traditional perspective be assessed as temptations.

Beyond the policy-oriented work of Kass and colleagues, policy questions have become increasingly central not just as aspects of ethical responsibility but as issues in their own right. What precisely is technological policy, as opposed to technological politics? Does policy decision making take different forms in relation to science and to engineering? How are policies to be formulated and assessed?

The extent to which these turns in the philosophy of technology will define its future are questions that the professional community must examine. Any such examination will also need to include a self-criticism that considers the special responsibilities of a regionalization in philosophy that, more than the philosophy of science or of art, has as part of its heritage public responsibilities and a large measure of ethical concerns.

Carl Mitcham (1996, 2005)

## PHONOLOGY

“Phonology” is the branch of linguistics concerned with the articulatory and auditory domain of grammar—that is, with the theory of what John Langshaw Austin (1962) called phonetic acts. Its subject matter links with but is distinct from that of syntax, semantics, and pragmatics. It covers the forms in which the sounds of words are kept in memory and the manner in which the motions of speech organs are shaped by grammar.

Unlike syntax, semantics, and pragmatics (but like closely related morphology), phonology has been largely ignored by philosophers. On the whole, philosophers consider the fact that natural languages are primarily spoken rather than written as of little interest for what Michael Dummett (1986) calls a “philosophical explanation” of language. This attitude stems largely from the mistaken but widely held view that spoken signs are arbitrary sounds whose individuating traits are those of noises. On that view, utterances contemplated apart from their semantic and syntactic features are merely tokens of acoustical types, bereft of grammatical properties, fully described by the physics of noises, and available for human communication simply because humans can perceive and produce them; there is nothing intrinsically linguistic about them. Nor is this attitude an accident. Historically, philosophers have had little incentive to reflect on the sound of language. Most belong to traditions that admit no crucial differences (except perhaps those that pertain to pragmatics) between natural lan-

guages and notational systems developed by scientists, mathematicians, or philosophers for the elaboration of their theories. Such notational systems have a syntax and a semantics of sorts, but they have no phonology. Their constituent elements are typically spatial ideographs that share little with the phonological structures of natural languages. Studying language with such a bias offers few reasons, if any, to focus on what is spoken rather than written. It can, however, entrap one in a false conception of linguistic signs, so false, in fact, as seriously to weaken philosophic doctrines built on it.

Phonology rests on a series of presumptions—each supported by a vast body of observations—that together entail that the sounds of natural languages are not arbitrary human noises, on a par with grunts or snorts, whose individuating attributes lie entirely outside the domain of grammar.

The first such presumption is that when people acquire a word they memorize the underlying phonological representation of that word, a representation that defines—but often only partially—how the word is pronounced. These representations have the structure of linearly arrayed discrete timing positions that are assigned pointers to articulatory organs (lips, blade of tongue, dorsum of tongue, root of tongue, velum, vocal cords) implicated in the pronunciation of the word, and pointers to actions these organs execute during speech. The first timing position for the English *pin*, for instance, points to the lips, the vocal cords, the velum, full closure of the first, stiffening of the second, and nonlowering of the third.

A second presumption is that these pointers (called phonological features) on timing positions are drawn from a finite repertoire, common to all languages, and that they are combined within and across timing positions in rule-governed ways. Some rules are common to all languages and reflect innate linguistic endowments, others are language specific and reflect the influence of linguistic exposure. No language, for instance, avails itself of nasal snorts. French admits rounding of the lips in combinations of features that English excludes (thus the sound *ü* in French but not in English). Korean, unlike English (except for *h*), admits aspiration in underlying phonological representations. German, unlike English, admits initial sequences corresponding to sounded *k* followed by sounded *n*. All languages assemble features in similar (three-dimensional-like) structures.

A third presumption is that underlying phonological representations, in isolation or when compounded in complex words, are subject to rule-governed processes that add, subtract, or modify phonological features,

which group them into syllables, feet, and prosodic words, which assign stresses and (in some languages) tones, and which ultimately yield final articulatory instructions, so-called surface phonological representations related to, but often very different from, the underlying representations in memory. Processes of this sort account for the fact that, for example, *leaf* occurs as *leavz* (with *v* instead of *f*) in the plural, or that *serene* is pronounced differently when alone than when a constituent of *serenity*, or that *p* gets aspirated in *pin* though not in *spin*. The details of these rules, the manner of their application, the universality of their formats, and the options fixed by different languages are all objects of intense research and controversies. But the evidence in behalf of their reality seems irrefutable.

Phonology is of philosophic interest, not only because it brings into question analogies between contrived notational systems and natural languages, but also because it raises conceptual issues of its own. Two can be mentioned here.

First, individual spoken utterances are analyzable in both acoustical and phonological terms. No generalizable exact correspondences between these two analyses are known. None may be forthcoming. For instance, nothing acoustical corresponds to word division. How can this dualism be reconciled? Is there a cogent sense in which the objects of speech production are the same (or belong to the same types) as those of speech perception? Offhand, the problem resembles that raised by other events amenable to multiple descriptions. But in this case solutions must be attuned to much that is already understood about both phonology and acoustics. It is not a simple task.

Second, phonological theory associates multiple representations with each utterance—including an underlying representation and a surface one—and it describes them all in the same notation. Surface representations can be conceptualized as instructions (or intentions) to move articulators in certain ways; their ontological status, though unclear, is at least comparable to that of other familiar cases. Not so the other phonological representations. They do not have familiar analogues. The semantic domain of phonological notation therefore cannot be ontologically homogeneous. Furthermore, part of that domain is deeply perplexing.

## PHYSICALISM

Physicalism, of which materialism is a historical antecedent, is primarily an ontological doctrine concerning the nature of reality and, specifically, mental reality. It is the view that reality is ultimately constituted or determined by entities—objects, events, properties, and so on—that are physical. This thesis is often combined with a claim about the explanatory supremacy of physical theory (physics).

Any formulation of physicalism raises the question, What is meant by "physical"? It is difficult to formulate a conception of the physical that is neither too strong, making physicalism obviously false, nor too weak, making physicalism trivially true. For example, what is physical may be simply identified through the language of physics. However, a problem arises over the conception of physics appealed to. Current physics seems too narrow because future extensions of physics would not count as physical; but the idea of a completed physics is too indeterminate because there is no clear idea of what that physics might include. One could attempt to characterize the physical in more general terms such as having spatial location or

being spatiotemporal. However, this threatens to make physicalism trivially true because mental phenomena seem clearly to have spatial location in virtue of having subjects—persons—who have bodies. It may be preferable to appeal to the idea of a completed physics. Although at any particular time people may not know exactly what is physical and what is not (because they may not know whether they have completed physics), nevertheless what is physical is all and only what a completed physics countenances.

There are two main types of physicalist theses. First, there is eliminative materialism, or physicalism. According to this there are not, and never have been, any mental entities, events, properties, and so forth. Strictly speaking, this is not a view about the nature of mental reality. Second, there is a group of doctrines that fall under the general heading of identity theories, some of which are stronger than others. These can be divided into two main categories. The stronger doctrines may be called type-type identity theories, or type physicalist theories (Armstrong 1968, Lewis 1966, Place 1956, Smart 1959), and the weaker doctrines may be called token identity theories, or token physicalist theories (Davidson 1970, Macdonald 1989, Macdonald and Macdonald 1995).

Physicalist theories need to account for at least two different kinds of mental phenomena. First, there are the sensations, such as color experiences, pains, tingles, itches, and the like, which are typically, and perhaps essentially, identified in terms of how they feel to their subjects. Then there are the intentional states or events, such as beliefs, hopes, desires, and thoughts, which are typically, and perhaps essentially, identified in terms of their intentional contents, or their "aboutness." For example, a person's belief that water is transparent has the intentional content, *water is transparent*; a content that represents the world around that person in a certain way, irrespective of whether the world happens to be that way. One of the biggest difficulties for physicalism is accounting for both of these kinds of mental phenomena. In the late twentieth and early twenty-first centuries, philosophers have expressed skepticism as to whether a thoroughgoing physicalist position is possible, and have maintained that physicalism (either token, or type) is true of at most one of these two kinds of mental phenomena (Chalmers 1996, Kim 1998).

### TYPE PHYSICALISM

Consider any mental phenomenon, such as being in pain now, or thinking right now that water is transparent. It is possible to talk about this phenomenon as an individual

occurrence of a certain kind in the mental life of a person and discuss its properties. It is also possible to talk about the kind of phenomenon—pain, or the thought that water is transparent—of which this event is an individual instance. Physical phenomena too can be discussed in both of these ways. Type physicalism is the view that the mental types, properties, or kinds under which mental phenomena fall are identical with physical types, properties, or kinds. For example, pain—that type of phenomenon, occurrences of which are individual pains—is identical with some single type of physical phenomenon such as C-fiber stimulation.

Type physicalism has its origins in the doctrines espoused by the logical positivists and central-state materialists (Place 1956, Smart 1959). It is a strong form of physicalism because it is reductionist. Many who endorse it believe that nothing short of it counts as a proper physicalism. They argue that even if it is in practice impossible for sentences containing mental terminology to be translated into or replaced by sentences containing physical and topic-neutral terminology, any view that holds that all mental phenomena are physical phenomena, but mental properties or kinds are not physical properties or kinds, is not worthy of the name “physicalism.”

**THE FIRST OBJECTION TO TYPE PHYSICALISM.** Type physicalism suffers from two serious objections. The first, from phenomenal properties, specifically concerns sensations such as color experiences, pain, afterimages, and the like. It is that phenomena of these kinds or types have “felt” properties, such as being reddish, stabbing, or vivid, whereas phenomena of physical types do not. Given this, and given Leibniz’s principle of the indiscernibility of identicals, it follows that sensation types are not identical with physical types because the phenomena that fall under them do not share all of the same properties. A variant of this objection focuses on the distinctive point of view a subject has on its own experiences: A subject knows what it is like to have experiences in a way that others do not, and this subjective mode of access reveals the phenomenal aspect of the experience, whereas an “other”-oriented point of view does not (Nagel 1974).

One response is to argue that the problem is purely conceptual and does not threaten physicalism, which is an ontological view about what sorts of things there are in the world, not a view about concepts (Levine 2001, Loar 1997, Tye 1999). Consider the type-type identity expressed by “Brain State B is the red-feeling sensation.” To the objection that such identities are false because first-person access to experiences reveals them to have

properties that physical states do not have, the response is that the apparent difference in properties arises from the distinctive nature of human experiential (or phenomenal) concepts alone. Certain concepts, such as the concept *red-feeling sensation* (or *reddish sensation*), are ones that can only be possessed by being put into direct contact with experiences that fall under them, without the mediation of other information or concepts that one might have of those states. Because the phenomenal concept *red-feeling sensation* enables subjects to be put in direct contact with their own red-feeling experiences in a way in which no concept of Brain State B could do, it puts them in a position to recognize directly and in an immediate way their own phenomenal red-feeling experiences. Possession of the concept *Brain State B* could not put any subject in a position to recognize directly and in an immediate way its own red-feeling experiences. So, even having met the experiential requirement on the possession of the concept *red-feeling experience*, a subject might be under the illusion of thinking that the red-feeling sensation has a property that Brain State B lacks. Whether or not this response succeeds depends on whether, in acquiring a new concept, such as the concept *red-feeling sensation*, one learns a new fact about the world that one did not know before, despite being in possession of the concept *Brain State B*.

**THE SECOND OBJECTION TO TYPE PHYSICALISM.** The second objection to type physicalism is that from multiple realizability. This claims that mental kinds or properties may be realized in physically diverse types of ways, hence there is no single physical property with which a given mental property may be identified. The point is that even if each mental property were in fact to be realized by a single physical one, it is possible for it to be realized by physically diverse ones. The reason is that the introspective and behavioral basis upon which attributions of mental properties are typically made is silent on the potential internal physical realizers of them. Given the claim that identical things are necessarily identical, the mere possibility that a given mental property should be realized by a physical property other than that which in fact realizes it is sufficient to refute the claim that that mental property is identical with any physical property that may realize it. This objection is not independent of a modal argument that trades on the thesis that identical things are necessarily identical (Kripke 1980). This begins with the conceivability of a mental state type’s existence in the absence of any physical type of state, and argues that, because what is conceivable is possible, it is possible that mental state types could exist in the absence of any

physical state type. The argument concludes that, because it is possible that mental types should exist in the absence of any type of physical phenomenon, mental state types are not identical with any type of physical phenomenon. A version of this argument is held to be particularly decisive against type physicalism with respect to sensation states.

One response is to argue that mental types are identical with disjunctions of physical types. For example, pain may not be identical with C-fiber stimulation, but it may be identical with the disjunctive property, C-fiber stimulation, or A-fiber stimulation, or ... , and so on (properties picked out by predicates formed by disjoining predicates that pick out all the possible physical realizers of mental properties). However, it is unclear whether these are bona fide properties. They do not have a unity of their own, viewed from a physical perspective; and it is arguable that a reason is needed, apart from the fact that they all realize a given mental property, to think that they are properties in their own right (Macdonald 1989).

Against this, it might be claimed that because any given mental *predicate* may correlate with an indefinite number of physical *predicates*, this may pose problems for formulating laws connecting mental with physical properties; but it does not follow that there is not a single physical *property* that is the extension of a given mental predicate. Mental properties are identical with the physical properties picked out by disjunctive physical predicates, but their autonomy is secured by their participation in real regularities, and so they do have a unity of their own, despite being identical with disjunctive physical properties (Antony 2003).

In a similar but more radical vein, it might be claimed that although there are mental and physical predicates, there really are only physical properties, so there are no type-type identities of any kind that might be problematic for physicalism (Kim 1998). This reductionist response avoids the problem of multiple realizability altogether, but only by taking an eliminativist stand on mental properties. Alternatively, it might be claimed that the only type-type identities licensed by physicalism are species-specific (as in, for example, that expressed by “pain in humans is identical with C-fiber stimulation”). None of these claims is unproblematic: the first, because it threatens to make mental properties non-nomic, which seems to undermine the commitments of type physicalism; the second, because it is eliminativist; and the third, because it leaves questions such as “What makes pain in humans and pain in dogs both pain?” unanswered.

## TOKEN PHYSICALISM

Many consider one or the other of the above objections to be decisive against type physicalism and have opted instead for a weaker view: token physicalism. According to this, each individual mental event or phenomenon is identical with some physical event. One influential version of this is the view known as anomalous monism (Davidson 1970). Token physicalism is compatible with the multiple realizability of mental properties by physical ones because it is not committed to the view that each individual occurrence of a given mental kind is identical with an occurrence of the same type of physical phenomenon. It also appears to avoid the objection from phenomenal properties in its original form because it can concede that mental kinds have associated with them felt aspects with which no physical kinds are associated. To the objection that mental events are not identical with physical events because it is no part of the nature of any physical event that it have a felt aspect, the following reply can be made. If token physicalism is true, no physical event is essentially of a mental type; but given that it is of a given mental type, it has what is essential to being of that type. Thus, if this pain is identical with this C-fiber stimulation, then it is not essentially a pain. However, given that it is, as it happens, a pain, it has (though not essentially) what is essential to being of that type, namely being felt.

Without an explanation of how mental types relate to physical ones, token physicalism threatens to succumb to the charge that it is dualist because it countenances the existence of nonphysical properties or types. A common strategy is to advance a supervenience doctrine concerning the relation between mental and physical properties, according to which physical properties, although distinct from mental ones, in some sense determine them (Hellman and Thompson 1975). There are many varieties of supervenience theses. One difficulty is in finding a thesis strong enough to do justice to the claim that physical properties determine mental ones without being so strong as to entail identities between mental and physical properties or types, and with these, reducibility. Another, related problem, is explaining how it could be that mental types or properties supervene on physical ones in a way that dispels the worry that mental properties have no causal powers of their own.

## PHYSICOTHEOLOGY

"Physicotheology" is the aspect of natural theology that seeks to prove the existence and attributes of God from the evidence of purpose and design in the physical universe. The argument is very ancient, but it is from the Greeks that its medieval and modern forms principally spring. Socrates revolted against the materialist tendencies of earlier philosophers, and his pupil Plato sought to show that the order and harmony exhibited in the world sprang from the action of mind. Plato argued that since matter cannot move itself, motion is evidence of the presence of mind in nature. All the activity and change in the world have their origin in a supreme mind that moves itself and creates subordinate souls or gods, the heavenly bodies. The outer sphere of the universe is set in motion by the direct action of the changeless, transcendent God. Aristotle expounded more emphatically a teleological or purposive view of nature in which the members of the hierarchy of natural classes in the universe seek to realize their beings according to their stations. This perspective presupposes a rational design, a universal aspiration to fulfillment, and in one passage Aristotle describes God as the perfect being whom all things desire.

The theological aspects of Greek views of nature passed into later science and were readily translated into Christian thought. The animistic view of natural knowledge may be seen in the work of Galen (second century), for whom the processes of the human body are divinely planned. During the earlier medieval period the natural world appeared to the eye of faith to be a scene of symbols and ciphers veiling moral and spiritual doctrines. Later medieval philosophers were fond of discerning marks of providential direction in the operations of nature, and Thomas Aquinas rests one of his proofs of the existence of God upon the cooperation of all types of natural objects to make the order of the world and the pointing of that order to an intelligent author who devised it. There was abundant recourse to this argument during the later Middle Ages.

### SEVENTEENTH CENTURY

The golden age of the Argument from Design was the two centuries following the rise of science in the seventeenth century, and it took place principally in England. The new philosophy of nature abandoned belief in the intrinsic teleology of physical objects. In place of the analogy with a creator of living organisms or an artist creating works of beauty it substituted the analogy of an inventor and manufacturer of elaborate machines. The new scientists combined faith in the sovereignty of God in nature and belief in the mechanistic bases of phenomena by conceiving the deity as the skillful contriver of instruments, a consummate engineer.

In England the doctrine was promoted by two trends of thought, the Baconian gospel of controlled observation and the revival of Greek atomism. The Baconian method inspired groups of inquirers in London and Oxford to collect a mass of detailed information in which they saw the confirmation of their religious faith; and it was the descriptions of the zoologists and botanists, such as Nehemiah Grew and Francis Willoughby, that strikingly illustrated the marvelous skill of the Creator. The second doctrine, the atomic, or corpuscular, theory of matter, incurred charges of materialism and atheism from moralists because of its association with Epicurean atomism, and in order to divide themselves from these imputations the virtuosi were intent on attaching theological conceptions to the elements of the material world. They were also acutely sensitive to the materialist dangers in the dualist philosophy of René Descartes. Neither their religion, which formed the frame of all their thought, nor their reason, which saw the marks of purpose and planning in nature, allowed them to accept the idea that the

world originated in the chance combination of material atoms. Ralph Cudworth, in his *True Intellectual System of the Universe* (1678), spoke for all the experimental philosophers when he argued at length that greater perfections and higher degrees of being cannot possibly arise out of senseless matter. The ancient metaphysics of cause, securely rooted in Christian theology, precluded any doctrine of natural evolution, and it is interesting to observe that when writers on biology mentioned the hypothesis that creatures have been produced by “millions of trials,” as did John Ray, the hypothesis was dismissed with scorn. Species had been finally and completely created. There was no conceivable alternative to the Argument from Design.

ROBERT BOYLE. The Argument from Design was expounded with eloquence by Robert Boyle (1627–1691). In his multifarious researches he was concerned with the evidence of benevolent and ingenious contrivance in nature and found on all sides “curious and excellent tokens and effects of divine artifice.” But first we may notice the way in which he associated the atomic view of matter with supernatural power. In embracing the corpuscular or mechanical philosophy, he writes, he is far from supposing with the Epicureans that atoms accidentally meeting in an infinite vacuum were able by themselves to produce a world and all its phenomena. The philosophy he pleads for teaches that in the beginning God gave motion to matter and so guided the motions of its parts as to “contrive them into the world he designed they should compose,” establishing those rules of motion that we call the laws of nature (*The Excellence and Grounds of the Mechanical Philosophy*, 1674). In *The Origin of Forms and Qualities* (1666) he explains that the diversity of bodies must arise from motion and that motion in the beginning was from God, for it is not inherent in matter.

In the realm of animate nature Boyle points to numerous instances of ingenious design, such as the human eye, and he constantly speaks of organisms as engines or machines. For him an animal as a whole is an engine, and each part of it is a subordinate engine excellently fitted for some subordinate use. Here he reverts to a famous analogy that in a simpler context goes back to Cicero and even to Xenophon, the analogy of organisms and the world with clocks and watches. In Boyle’s day, clocks were the most complex examples of machines available for comparison, and he takes a celebrated clock as a model of the machine of the world, the cathedral clock at Strasbourg, in which “the several pieces making up that curious Engine are so fram’d and adapted, and are

put into such motion, as though the numerous wheels and other parts of it knew and were concerned to do its Duty” (*The Usefulness of Experimental Natural Philosophy*, 1663). The popularity of the analogy between a watchmaker and the author of nature in the following age issued largely from the writings of Boyle.

**ROBERT HOOKE.** During the early years of the Royal Society proofs of design multiplied. Robert Hooke’s *Micrographia* (London, 1665) disclosed the astonishing beauty and ingenuity of the minute creatures revealed by the microscope, and in his Cutlerian lectures he spoke of the divine providence that in the eye “has so disposed, ordered, adapted, and empowered each part so to operate as to produce the wonderful effects which we see.”

**JOHN RAY.** Before the end of the century there appeared treatises by the greatest zoologist of the age that were wholly devoted to the evidences in nature of the existence of God. John Ray’s *The Wisdom of God Manifested in the Works of Creation* was first published in London in 1691, enlarged in three later editions before Ray’s death in 1705, and reprinted more than twenty times by 1846. In the preface he declares that his discourse will serve to demonstrate the existence of the Deity and illustrate his principal attributes, his infinite power and wisdom. He proceeds to show the futility of attributing the world to the operation of chance events; it manifests all the marks of deliberate creation. Inanimate bodies are reviewed in order, the system of the stars and their planets, and the services performed for animals and man by water, air, fire, meteors, rain, and winds. Passing to regions of life, he ascends through the vegetable and animal kingdoms, discovering everywhere a complex arrangement of parts that contribute to the welfare of the plant or animal and to the uses of man.

Ray was too close an observer of nature to accept the crude doctrine that organisms are complex machines constructed by a divine watchmaker. His physicotheology borrowed from Cudworth the theory of plastic nature or vital force by which the growth, adaptation, and instinctive activities of living creatures are directed. This plastic virtue acts sympathetically, without reason, informing the movements of material bodies. Ray therefore diluted his physicotheology with an immaterial energy, a form of animism. But the plastic nature is nonetheless a subordinate instrument of divine providence, although it transcends the operations of local motion. Its relative independence of the immediate direction of God allowed Ray to meet a cardinal difficulty in the Argument from Design; he could accept the aberrations of nature without

making the Deity responsible for them. Faced with this problem, Boyle has preserved his mechanistic view of creation by asserting that the irregularities we find in nature may serve ends that lie concealed in God’s unsearchable wisdom.

Ray presided over the subsequent course of the Argument from Design, and theologians drew freely on his *Wisdom of God in Creation*. They studied also his *Three Physico-theological Discourses* (London, 1692), which supports the biblical narratives of the creation, the deluge, and the final dissolution of the world by arguments from natural philosophy.

**ISAAC NEWTON.** The appearance of Isaac Newton’s *Principia* in 1687 had provided the argument with a great deal of new material. Natural theology became absorbed by the cosmology of the *Principia*, and preachers and poets acclaimed the almighty hand that “poised, impels and rules the steady whole.” Newton’s great treatises offered at many points notable arguments for the belief that the universe is the work of an intelligent being; indeed, Newton told Richard Bentley that in writing the *Principia* he had had an eye upon arguments for a belief in a deity, and in the *Opticks* he declared that the main business of natural philosophy was to deduce causes from effects until we arrive at the First Cause, which cannot be mechanical. In the *General Scholium* added to the second edition of the *Principia* and in the *Queries* of the Latin translation of the *Opticks* (1706), he set forth the religious conceptions that underlay his mathematical physics of the universe. Why is it, he asks, that all planets move the same way in concentric orbits? What prevents the stars from falling on one another? And, with a glance at the evidence of Boyle and Ray, how, he asks, did the bodies of animals come to be contrived with so much art? Whence, in short, arose all that order and beauty that we see in the world? Does it not appear that there is a Being incorporeal, living, intelligent, and omnipresent, who created the world?

For Newton, however, the admirable system of nature was not imposed by the deity upon an infinitely complex material mechanism; immaterial forces were introduced into the heart of the mechanism of nature. Newton asserted the atomic theory of matter in the manner of Boyle: It seemed probable that God in the beginning formed matter in solid, massy, hard, impenetrable, movable particles, but the forces that cause the particles to cohere and to form larger bodies are immaterial. It is not the business of experimental philosophy to discuss the nature of these forces, but it is clear that they provide

the world with its structure and order. They could not have arisen from chaos by the mere laws of nature; the wonderful uniformity of the planetary system, for example, must be the effect of choice and must proceed from the counsel and dominion of an intelligent and powerful Being.

Other fundamental principles of Newton's system of physics are associated with theology. Absolute space is immovable, homogeneous, indivisible, and distinct from matter; like other thinkers of the time, Newton accorded space some of the attributes of God. He described infinite space as the boundless sensorium of the omnipresent God, whereby he perceives all things. Motion also presupposes a metaphysical agent, for if the motion of moving bodies is derived from the impact of bodies already in motion, some other principle was necessary for putting bodies in motion in the first instance and for conserving the motion of those in movement. The agent must be an all-powerful immaterial being, for pressure is constantly brought to move bodies throughout the universe. Furthermore, the variety of motion is always decreasing because at every impact between bodies, some motion is lost. It must be renewed by an immaterial power.

## EIGHTEENTH CENTURY

The natural theology of Newton crowned the Argument from Design, and by the beginning of the eighteenth century the main stock of theory and of evidence on which the argument relied had been provided. Numerous writers repeated and enforced the case pronounced by John Locke that the works of nature everywhere sufficiently evidence a Deity. Prominent among those who vindicated the conclusions of the great men of the seventeenth century were the Boyle lecturers in the series instituted in Boyle's will with the purpose of confuting atheism. The lectures were inaugurated in 1692 by Richard Bentley, a renowned scholar who corresponded with Newton while preparing the lectures. In his letters to Bentley, Newton maintained that there are many features of the universe that cannot be explained in terms of mechanical principles, and he went on to assert that the cause that constructed the planetary system cannot be blind and fortuitous but must be one very skilled in mechanics and geometry. Bentley faithfully reported these opinions in the lectures.

**CLARKE AND LEIBNIZ.** The second Boyle lecturer was the celebrated Samuel Clarke, who delivered the course called "A Demonstration of the Being and Attributes of God" in 1704, an excellent survey of the accepted picture,

with some fresh touches. His famous correspondence with Gottfried Wilhelm Leibniz on natural theology was published in 1717; he probably received advice from Newton in composing his replies, and the letters further reveal Newton's position on such important topics as the divinity of space. But the vital interest of this correspondence is the conflict between Leibniz's conception of nature as mechanical, determined, self-sufficient, and self-perpetuating and the doctrine, defended by Clarke, of God's providential guidance of the world. Leibniz rejected the Newtonian contention that God corrects aberrations of the cosmic order, such as certain inequalities of planetary motions, as a watchmaker cleans and mends a watch—a view that implies that the creation of the system was imperfect and that God is lacking in foresight. Clarke, on his part, accused Leibniz of restricting the liberty of God to act as he will, independently of the laws of nature; indeed, but for his constant intervention, the world would lapse into chaos. The doctrine of supernatural intervention began to recede from the physics of astronomy and found its home before the end of the century in the realms of geology and biology.

**JOSEPH BUTLER.** The deists, in their war against revelation, caught at the notion that God, having created the world in the distant past, had left it to the action of the laws of nature. Deism provoked a stream of hostile pamphlets and treatises, but orthodox churchmen who opposed deism continued to harp on law, order, and design and the divine artificer. The greatest of these apologists was Bishop Butler. *The Analogy of Religion* (1736) shows that he had closely studied Newton, but his natural theology rises above that of other writers of the age in its candid recognition of the defects of nature, which he ascribes to our ignorance of God's purposes.

Another Boyle lecturer was William Derham, whose *Physico-theology* (London, 1713) and *Astro-theology* (London, 1715) rehearsed the testimony of Ray and of Newton at prodigious length, with some superficial reflections of his own. Many other utterances must be passed over. It is interesting to observe the large number of writers who discussed Clarke's (and Newton's) theology of space.

**DAVID HUME.** In the later years of the eighteenth century, natural theology encountered the penetrating criticism of David Hume, although few scientific theologians were shaken by it. In the *Dialogues concerning Natural Religion*, published posthumously in 1779, Hume exploded the logic of the Argument from Design, especially in the form in which it was presented by the disci-

ples of Newton, such as the Scottish mathematician Colin Maclaurin. Hume confronted the analogy between the maker of a machine and the maker of the world with the point that while scientists like Nicolas Copernicus and Galileo Galilei made fruitful use of reasoning by analogy, the associations between cause and effect that provided the material of their arguments were derived from observation. The inference from machines and their makers to a world and its maker is not parallel. Order, arrangement, or the adjustment of final causes is not by itself any proof of design, but only insofar as it has been seen to be produced by design; since we have no experience of the invention and production of a world or of nature, we cannot maintain that an orderly universe must arise from thought or art. For all that we can know a priori, matter may contain the source of order within itself.

Hume attacked this argument by a *reductio ad absurdum*. If we are confined to speculative, a priori explanations of the origins of the world, they can lead to disturbing conclusions. Some natural philosophers have found nature to resemble an organism, a vegetable or an animal, and its origin ought to be ascribed to generation and vegetation rather than to reason or design. When the analogy with the manufacturers of machines is pressed, we might infer that several deities combine in contriving and framing the world. Hume now introduced fatal evidence against the belief in a benevolent Creator. The curious artifices of nature embitter the life of every living being. “The whole presents nothing but the idea of a blind nature, impregnated by a great vivifying principle, and pouring forth from her lap, without discernment or parental care, her maimed and abortive children.” Faced with these difficulties the defender of traditional doctrine in the *Dialogues* is compelled to admit that belief in a beneficent Creator of the world cannot be rationally sustained. The sources of such a belief are “temper and education,” and the defender of the Argument from Design falls back on utilitarian supports; belief in divine design promotes morality.

## NINETEENTH CENTURY

Hume’s *Dialogues concerning Natural Religion* failed to confound the deep-seated prepossessions of the natural theologians, nor were they discomposed by the refutation of the Argument from Design by Immanuel Kant in the *Critique of Pure Reason* (1781).

**WILLIAM PALEY.** At the turn of the century the argument was revived in William Paley’s *Natural Theology* (1802). It marks the apotheosis of the analogy between a

watch and a natural object, opening, in fact, with the discovery of a watch lying on a heath. The instrument must have been made by a being who comprehended its construction and designed its use. If we suppose that the watch contains a mechanism by which it can produce another watch (a supposition that exhibits the deficiency of the mechanical analogy), our admiration of the maker’s skill will increase. Paley proceeds to describe numerous examples of natural contrivances, drawn from anatomy, physiology, botany, and entomology: the eyes of fish, animals, and men, the construction of the ear, the webbed feet of water birds, the elongated tongue of the woodpecker, and a catalog of other instances. These marvels of adaptation prove the existence of a superhuman designer, God. As for the suffering that nature displays, Paley attempts to minimize the spectacle; the pain of animals, he thinks, is exaggerated, and their happiness outweighs their pain. Even venomous bites and the preying of one species on another are shown to be necessary features of benevolent design.

**BRIDGEWATER TREATISES.** Leading men of science in this period duly acknowledged the action of divine providence in natural phenomena. In geology John Playfair and Sir Charles Lyell discovered in the adjustment of the strata of the earth to the accommodation of living creatures clear proofs of divine foresight, and James Prescott Joule saw in the interconvertibility of natural forces evidence of the sovereign will of God. The most sustained defense of the Argument from Design was advanced in the Bridgewater Treatises of the 1830s. Eight men of science, four of whom were clergymen, were chosen to discharge the intentions of the earl of Bridgewater to explore “the Power, Wisdom and Goodness of God, as manifested in the Creation.” These writers added a wealth of new information from astronomy, physics, chemistry, and anatomy to the old theses of Ray and Derham, and they outstripped Paley in showing how all aspects of nature have been thoughtfully arranged for the comfort of the world’s inhabitants and especially for man. John Kidd, Regius professor of medicine in the University of Oxford, in *On the Adaptation of External Nature to the Physical Condition of Man* (London, 1833); Peter Roget, secretary to the Royal Society, in *On Animal and Vegetable Physiology Considered in Relation to Natural Theology* (London, 1834); and William Buckland, professor of geology at Oxford, in *On Geology and Mineralogy* (London, 1836), showed how climates have been fitted to the character of the various races of humankind, horses invented for man’s transport, minerals for his adornment, and water for his ablutions. In short, much of the reasoning of these

writers recalls that of the lady who praised the goodness of the Creator in causing a great river to flow through the main cities of Europe.

Sir Charles Bell, the most distinguished physiologist of the time, in his *The Hand, Its Mechanism and Vital Endowments as Evincing Design* (London, 1833), argues that species were successively created to fit the conditions of geological epochs, changes in their anatomy being deliberately shaped to meet the circumstances of the creatures' life. Man is the center of a magnificent system, which has been prepared for his reception by a succession of revolutions affecting the whole globe, and the strictest relation is established between his intellectual capacities and the material world. The celebrated William Whewell, in his *Astronomy and General Physics considered with Reference to Natural Theology* (London, 1833), makes play with the ambiguous sense of the word *law*, a common procedure among scientific theologians of the period, confusing the idea of uniform sequence with the idea of legal and moral law; the confusion arose from Whewell's demonstration that the laws of nature, terrestrial and celestial, provide evidence of selection, design, and goodness. The tenacity and ingenuity with which the scientists vindicated the sovereignty of God over nature are illustrated in Charles Babbage's *Ninth Bridgewater Treatise* (London, 1837), where by means of his calculating machine he proves mathematically that miraculous interruptions of scientific laws can be predicted, and that the Being who called the laws into existence must have chosen them with the breaches of continuity in view.

The Bridgewater Treatises marked the final stage of the general confidence of men of science in the old natural theology, although religious thinkers long continued, and still continue, to appeal to it. However, when the treatises appeared the classical form of the Argument from Design was weakening. Whewell had difficulty in understanding the bearing of cosmology upon the support and comfort of sentient creatures, and geologists, led by James Hutton and Lyell, were abandoning the view that there had been sudden changes in the crust of Earth, occasioned by the mediation of God. The catastrophic picture of geological change was yielding to the uniformitarian view in which the laws operating at present could in the slow process of ages have caused all the changes of the past. The range of natural law in time and space was being extended, but the scientists failed to account for the processes by which fresh species had originated, and faith in the periodic agency of the Creator was encouraged.

**CHARLES DARWIN.** Charles Darwin opened a notebook on the transmutation of species in 1837, and in the unpublished "Essay on Species" of 1844 he proposed the machinery by which new species might result from the natural selection of fortuitous variations. The notion of special creations, he recorded in his private notebook, explains nothing, and the Essay concluded with a forceful *reductio ad absurdum* of the Argument from Design. *The Origin of Species* (1859) brought a wealth of material to substantiate the theory of natural selection in the evolution of species and in adaptations of the organs of living creatures to their circumstances, and it is interesting to see Darwin using the same examples that Paley did to show evidence of contrivances resulting not from purpose but from chance. By abolishing both transcendent and immanent teleology, Darwin undermined the ground on which physicotheology had stood since the seventeenth century. Yet in the last chapter of the *Origin* Darwin himself assumed a First Cause, though not a beneficent one, and he declared in 1873 that the impossibility of conceiving that this great and wondrous universe arose through chance seemed to him the chief argument for the existence of God. In the end, however, Darwin became a complete agnostic, as is shown most clearly in the unexpurgated edition of his *Autobiography* (first published in 1958).

**J. S. MILL.** In his *Three Essays on Religion*, published posthumously in 1874, J. S. Mill allowed some value to the Argument from Design, for the world contains marks of deliberate contrivance, and our experience of such devices is associated with an intelligent mind. Mill here seems to have exposed himself to Hume's objections against arguing from cases within the world to the world as a whole. But Mill recognized many features of the world that are incompatible with beneficent design, and he thought that God may be a limited Being circumscribed by matter and force. Mill maintained that if Darwin's doctrine of evolution were shown to be valid it would greatly weaken the evidence for the work of a divine intelligence in nature.

**SUPPORT FROM SCIENTISTS.** Other scientists contrived to fit the theory of natural selection into the frame of divine purpose. Samuel Houghton, a fellow of the Royal Society, described expressions of supernatural intentions in his book *Principles of Animal Mechanics* (London, 1873). Another book that exercised great influence was Professors P. G. Tait and Balfour Stewart's *The Unseen Universe* (1875), in which it was contended that science upheld the ideas of religion on the transcendental

world and its connection with the physical world. A succession of eminent scientists proclaimed that nature is the sacred book of God. The most popular and, it must be added, most muddle-headed work that applied evolution to theistic principles was Henry Drummond's *Natural Law in the Spiritual World* (1883). The tendency of these scientific writers was to assert the view that Darwin's theory had deepened and widened the belief in the operation of purpose in nature, a view that was characterized as misplaced zeal by those who stood more closely to Darwin's findings.

A number of physicists of the period also employed classical versions of the design argument. The Celestial Engineer was reinstated by O. M. Mitchell in his widely read *The Orbs of Heaven* (4th ed., London, 1853) at the middle of the century, in which, after the manner of Newton, the deity is invoked to secure the stability of the solar system. It was a notion of the earlier apologists that the identical character of the fundamental materials of the physical world in all parts of the natural order indicated the action of an intelligent maker. The idea had been adopted by Sir John Herschel in his *Study of Natural Philosophy* (1830), and it was now revived by the greatest mathematical physicist of the age, James Clerk Maxwell. At the meeting of the British Association in 1873, he pointed out that every type of molecule in the universe is identical with every other type; a molecule of hydrogen, whether it occurs in Sirius or in Arcturus, executes its vibrations in precisely the same time. No theory of evolution accounts for this identity, for the molecule is not subject to change. Its similarity to other molecules proves that it is the product not of chance but of design. It is a manufactured article, and because they are the work of a Creator, the foundation stones of the material universe remain, whatever catastrophes may occur in the heavens. Even the argument from miracles reappeared in the *Natural Theology* (London, 1891) of a later mathematical physicist, Sir George Stokes: "If the laws of nature are in accordance with God's will, he who willed them may will their suspension." Stokes assumed that God's action in nature cannot be detected within the laws of physics but by interventions from beyond. *Natural Theology* embraces the arguments of physicotheology in the period.

A monumental exposition in a modern setting of the Argument from Design appeared in *Philosophical Theology* (London, 1928–1930) by F. R. Tennant. Recent discussions of the argument have abandoned the old mechanical analogies and have dwelled on the evidence for various types of vitalism in biology. On these views

evolution is guided no longer from outside but by directive activities within organisms. In the human psychosocial phase of evolution these self-directed activities point toward moral ends; history becomes the education of humankind in the fulfillment of God's design. Teleological doctrines of this kind have drawn support from philosophers such as Samuel Alexander and A. N. Whitehead, who contend that the universe is informed by an immanent *nisus* to divinity. Present theological discussions, however, ignore natural theology, and for contemporary linguistic philosophers the Argument from Design possesses no validity whatsoever and is logically and morally indefensible, although it may serve to heighten religious emotions.

## PHYSICS, PHILOSOPHY OF

See *Philosophy of Physics*

## PHYSICS AND THE DIRECTION OF TIME

Our experience of the temporality of things seems to be an experience of a radically asymmetric feature of the world. Although we do know some things about what the future will be like, we have an access to past events that is not given to us of events in the future. We take ourselves as having memories of the past but not of the future and as having records of the past but not of the future. In our explanatory accounts of what happens in the world, we explain present and future by reference to what happened in the past, but we typically do not explain the past by referring to the future. We take it that there is causation in the world—that events determine one another to occur. But, intuitively, we think of causation and determination as directed from past to future. We have distinctive *attitudes* to past and future. Of the past we may have regrets, for example, but our concern for the future will be rather things such as anxiety or anticipation. So profound are these apparent differences between past and future that they are often promoted into the realm of deep metaphysics. Sometimes it is argued that the past is *fixed*, subject to some version or another of immutability, whereas the future remains merely a domain of open possibilities. In an even more extreme view it is argued that what is past has a *determinate reality* whereas the future remains a realm to which we cannot even attribute any kind of determinate being.

One might take these asymmetric features of time as irreducible, primitive properties of the world. And one might take our awareness of these features as somehow direct and not further explicable. Alternatively, one might argue for some basic, asymmetrical, metaphysical aspect of time as grounding all the asymmetries discussed above. For example, there are proposed *branching* models of the world in which a tree of possibilities is constantly pruned into a single actuality as time goes on and the present moves inexorably into the future. One problem with any such model is the need to respect the results of modern physics, especially special and general relativity, so as to reconcile the usual assumption in the metaphysical models of a unique global present with the denial of any such objective feature of the world in the relativistic accounts of spacetime. Another alternative would be to take a temporally asymmetric notion of causation as primitive and argue that all the other intuitive asymmetries follow from the fundamental asymmetry of causation.

## NATURALISTIC THEORIES OF TIME ASYMMETRY

On the other hand, one could seek for some *naturalistic* account of the temporal asymmetries. Here, one looks at what our best available scientific theories tell us about the actual physical structure of the world in the hopes of finding some physical process characterized by fundamental physics that could serve to *ground* or *explain* the existence and nature of the fundamental temporal asymmetries. Much work has been done in this direction, but more needs to be done to make such a naturalistic account fully convincing. It is to this approach that this entry is directed.

Physics presents us with a *paradox*. Although most of its fundamental laws are often alleged to be time-reversal invariant and unable, it is therefore claimed, to ground any fundamental asymmetry in time of processes in the world, physics also describes a number of alleged time-asymmetric features of the world at a very general level. Measurement processes in quantum mechanics are often alleged to be asymmetric in time. We see radiation out-bound in spherical waves from accelerated charged particles but not spontaneous collapsing spheres of radiation converging on a particle and accelerating it. Subtle experiments seem to show that some of the interactions of the elementary particles show asymmetries in time that may, indeed, require positing a fundamental law governing them that itself describes a lawlike asymmetry in time for the world. Most importantly, thermodynamics seems to reveal to us a world that is time asymmetric. A metal bar hot at one end and cold at the other when kept in isolation becomes uniformly warm all over. But an isolated uniformly warm bar does not spontaneously become hot at one end and cold at another.

A naturalistic account of the *direction of time* requires more than finding some physical process that is time asymmetric. It also requires even more than finding a fundamental process that has such time asymmetry. Suppose the weak interactions of the elementary particles obey a time-asymmetric law. How would such a fact be of any use in accounting for our intuitive sense that there are records and memories of the past and not of the future, or that causation proceeds from past to future, or that the past is determinate and fixed and the future a realm of mere possibilities? What is needed from a naturalistic theory of the direction of time is some appropriate connection between the physical facts introduced in the account as grounding the direction of time and those features that characterize our intuitive, deeply rooted sense of the asymmetry of time.

## THERMODYNAMIC ASYMMETRIES

The thermodynamic asymmetries, being pervasive elements of our everyday experience, provide the most promising physical basis for a naturalistic account of the direction of time. Here, two fundamental questions must be explored: (1) Why does the world show these deep asymmetries in time of physical processes? (2) How could the existence of these asymmetric processes account for the intuitive asymmetries we attribute to the world in time? Neither question is trivially answered.

The contemporary explanation of the thermodynamic laws starts with the realization that macroscopic objects are composed of a vast number of microscopic constituents. Macroscopic thermodynamic properties, then, are thought of as grounded in such microscopic features of a system as the total energy of its microscopic constituents or the average energy of some one of these. The microscopic constituents are assumed to obey the standard dynamical laws, originally classical dynamics and now quantum mechanics. How the system behaves, then, will depend upon these laws and upon whatever initial conditions are possessed by the microscopic constituents, with the system also subject to such macroscopic constraints as exist (such as a gas being confined to a box).

Probabilistic methods were soon invoked to deal with the behavior of the vast number of microscopic constituents. These led to such theories as the kinetic theory of gases and the more abstract statistical mechanics. One consequence of this new viewpoint was a rethinking of the thermodynamic laws to allow for such possibilities as fluctuations away from the equilibrium state, even for an isolated system. A deep conceptual problem for this theory is the understanding of why the probabilistic posits that are made, and that work so well for prediction and explanation, hold in the world. Are they brute posits to be otherwise unexplained? To what degree can they be extracted from the dynamical laws governing the behavior of the microscopic constituents? Need the fundamental dynamical laws be modified to find an appropriate explanation for the fundamental probabilistic posits (and, perhaps, to solve other outstanding problems as well, such as the nature of the measurement process in quantum mechanics)? Another crucial question is the degree to which the probabilistic posits can be shown consistent with the underlying dynamics and the degree to which they can be weakened with the empirical results still forthcoming.

Furthermore, arguments that have existed from the early days of the theory indicate that introducing proba-

bility into the theory is not, by itself, enough to ground a theory of the direction of time. Probabilistic considerations would suggest that the world we live in should be a world where all systems are at equilibrium, not at all like the world we actually live in with its vast pool of nonequilibrium systems and its parallel movement from nonequilibrium to equilibrium of temporarily isolated systems. In addition, to obtain the desired nonequilibrium results in the theory, the theory's probabilistic posits must be applied in a temporally asymmetric way, being taken as correctly applicable to temporally initial, but not to temporally final, states of isolated systems.

### COSMOLOGICAL CONSIDERATIONS

From early days of the theory, cosmology has been invoked as providing the needed supplementary posits. Ludwig Boltzmann's assistant Scheutz suggested the possibility that the cosmos was, in general, in equilibrium, with the part of it with which we were familiar in a local (if large from our perspective) fluctuation away from equilibrium. Our local cosmos, then, was in equilibrium in the past and will be again in the future. Boltzmann added the *anthropic* observation that we could not find ourselves in one of the pervasive equilibrium regions of the cosmos since such a region could not support the flows of energy necessary for life. To this Boltzmann added the additional proposal that the reason we found our region heading toward equilibrium in the future time direction and not in the past time direction is that our very meaning of the *future* direction of time was that the future time direction was determined by that temporal direction in which our local region of the cosmos had a succession of states closer to equilibrium (of higher entropy).

Current cosmology, insofar as it is a discipline open to observation and empirical test, is doubtful of this early cosmological speculation. The current model, rather, is of a universe (at least as far as we know) that is distinctly unsymmetrical in time. In particular, it is posited that there is a singularity in which the cosmos is all *at a single spatial point* in the past time direction some tens of billions of years ago, the so-called Big Bang cosmology.

Even accepting this model of the universe is not enough to get the thermodynamic asymmetries out of the cosmology. Instead, it is generally agreed, one must make a specific assumption about the Big Bang state of the cosmos, that it is a low-entropy, that is, a highly nonequilibrium, state. The usual posit is that the space of the world at the Big Bang is highly smooth, this being for gravitational force the low-entropy condition. The idea is that as

matter clumps from uniformly distributed into stars (and galaxies, etc.), the matter, initially in thermal equilibrium, becomes highly nonuniform and in a grossly nonequilibrium state, with hot stars radiating out to cold space. The decrease in the matter's entropy is continually being paid for by the great increase in the entropy of the spatial distribution that has gone from uniform to clumped.

The idea, then, is that the universe as a whole must be posited to have an initial highly nonequilibrium starting point. It is this posit that must be added to the standard probabilistic assumptions to get us the result of a predicted nonequilibrium condition for the world as we find it, and a predicted, temporally asymmetric, approach to equilibrium in the future and not into the past, for system temporarily isolated from their environments. Here the grand cosmic initial condition is being invoked to generate the temporal asymmetry unobtainable from the allegedly time-symmetric dynamical laws alone. Getting the result about the temporarily isolated subsystems of the universe requires a little more, in the form of a demonstration that from the temporally asymmetric behavior of the universe as a whole one can derive, with either no additional temporally asymmetric assumptions at all or with some posited additional asymmetry of dynamics, parallel increase of entropy of so-called *branch systems* in the same time direction in which the entropy of the cosmos as a whole is increasing.

### FROM ASYMMETRIES IN TIME TO THE DIRECTION OF TIME

But then there is the second question noted above as well. Why should we think that this pervasive asymmetry of physical systems in time has anything to do with our intuitive sense of the asymmetry of time itself? Once again, the mere fact that there is some asymmetry in time of systems of the world, even a lawlike temporal asymmetry, is not enough to establish the naturalist's claim. What else is required?

Boltzmann hinted at an answer in his famous paper "On Zermelo's Paper 'On the Mechanical Explanation of Irreversible Processes'" where he claimed that what we took to be the future direction of time was just the direction of time in which the entropy of our local portion of the universe was on the increase. In that paper he drew a trenchant analogy between the temporal case and an intuitive spatial asymmetry accounted for by gravity. Originally we might think of space as being asymmetric, with one direction being *down* and its opposite *up*. Eventually, though, we realize that what we call the *down* direction is just the direction of the local gravitational

force. On antipodal points of the earth, the local *downward* directions are directed oppositely to one another. And in a region of space in which there was no gravitational force, there would be no downward direction. Just so in a region of the universe not in equilibrium, Boltzmann maintained, the direction of time in which entropy was increasing would be the future time direction, and in a region of the universe at equilibrium, there would be no future direction of time and no past direction (although there would still be two oppositely directed directions of time).

What makes Boltzmann's remarks about gravity and *down* so plausible? It is the fact that we have in gravity and its consequences a complete explanation of all the facts that we take as distinguishing the downward direction of space from all the other directions. Down is the direction in which, for example, rocks fall. We even have an explanation, invoking the fluid in our semicircular canals, of how it is that we can tell without external observation which direction is the downward one.

The analogous argument in the case of the direction of time would require a sustained argument to the effect that it is the existence of the asymmetric processes of systems in the world described by thermodynamics, and explained by statistical mechanics combined with cosmology, that provides a full explanatory account of all those features of the world that we take as marking out an asymmetric nature to time. What would need explaining is why we have memories and records of the past and not of the future, why we take causation as going from past to future and not the other way around, why we think of the past as fixed and determinate and of the future as a realm of possibility, and, also, of how it is that we think we can tell, without inference, of any pair of events which is the earlier and which the later.

Sometimes it is claimed that the entropic theory of time direction is supported by the fact that we cannot tell of a film of events whether it is being run in the right or the wrong direction except by reference to entropic facts portrayed by the film. Sometimes it is argued against the entropic account that we can tell of events in the world what their order is in time without noting any entropic features of them. Both arguments are misguided. What would be required of an entropic account would be some kind of explanation of all the intuitive asymmetries that constitute our sense of the direction of time, not a demonstration that our judgments of time order are always inferences from directly observed entropic facts.

A number of tentative suggestions have been made in this direction. Hans Reichenbach suggested that records

might be analyzed as causal interventions that induced a macro low-entropy change into what would otherwise be a macro high-entropy state. But many records do not fit his paradigm. There is no fully developed extant argument to the effect that the very existence of records, and presumably those mental records we call memories, can have their time asymmetry directly accounted for by the entropic asymmetry of processes in time.

One might argue that such intuitive asymmetries as the direction of causation and the difference in *fixedness* of past and future are derivative from the asymmetry of records, our taking as the fixed and the determining that which we can know to be the case from records. Or, alternatively, one might try to directly account for the asymmetry of causation out of entropic-like facts. An example of that can again be found in a tradition stemming from Reichenbach where it is noted that spatially separated correlated events can often have their correlation explained by some common past event casually connected to both correlated events but not by any such correlating event in the future of the correlated pair (the so-called *fork* asymmetry). Another approach stems from David Lewis. Here, causation is analyzed in terms of counterfactual conditionals. It is suggested that the fact that an event has a numerous extended range of effects in its future, but not in its past, grounds our intuition that there are forward looking but not *back tracking* counterfactual assertions that we accept, and that this underlies our intuitions about the time asymmetry of the causal relation.

Even though no fully worked-out account of these sorts exists, the naturalistic approach to the direction of time remains the only plausible alternative to *metaphysical* accounts. The latter remain hard to explicate, and it is hard to understand how they might provide new insights into the intuitive asymmetries of time. The former, in its usual thermodynamic version, is at least clear in its intentions and of an intrinsic plausibility. The further pursuit of this naturalistic program is well worthwhile.

## PIAGET, JEAN (1896–1980)

Jean Piaget, the psychologist and philosopher, was born in Neuchâtel, Switzerland. He studied zoology at the university there and in 1918 received his doctorate for a thesis on the subject of land mollusks in the Valais Alps. He then studied psychology for a year at Zürich and, from 1919 to 1921, abnormal psychology, logic, and the philosophy of science at the Sorbonne. From 1921 to 1925, he was director of studies at the Institut J.-J. Rousseau (now the Institut des Sciences de l'Éducation) in Geneva; he was its assistant director from 1929 to 1932 and became codirector in 1932. In 1925 he was appointed professor of philosophy at the University of Neuchâtel; in 1929, professor of the history of scientific thought at the University of Geneva; and in 1940, professor of experimental psychology and director of the psychological laboratory at

Geneva. He served as professor of child psychology at the Sorbonne from 1952 to 1963. From 1955 to 1980 he was director of the Centre International de l'Épistémologie Génétique at Geneva. Piaget also took an active interest in international educational projects. He was director of the Bureau International de l'Éducation from 1929 to 1967 and was associated with UNESCO as its assistant director general.

## THOUGHT

Although Piaget is usually considered a psychologist working in the field of child thought, his interests were always, broadly speaking, philosophical. As a young man he read widely in philosophy, and while in Paris he studied with André Lalande and Léon Brunschvicg. Even his earliest work, which appeared between 1925 and 1932, dealt with such topics as thought, causality, moral judgment, and the development of language. His logical and epistemological interests show themselves particularly in his later studies, starting about 1937. By means of simple, although highly ingenious experiments, Piaget set out to make a detailed investigation of the way in which logical, mathematical, and physical concepts develop in the individual. He thus studied experimentally many of the concepts and principles that philosophers had discussed in the past on a purely a priori level. Piaget would say that what he was really doing in this work was reexamining the whole question of the Kantian categories. This reexamination formed for him the basis of a new discipline that he called genetic epistemology.

In a series of studies Piaget examined in some detail the development not only of abstract concepts such as classes, relations, and numbers but also of physical concepts like space, time, speed, atomism, conservation, and chance, all of which he has regarded as constructed from our behavioral activities. In starting from the facts of observable child behavior rather than from adult introspections (or sensations), Piaget differed from such thinkers as Ernst Mach, Karl Pearson, and Bertrand Russell by the importance he attached to the part played by overt activities in building up the conceptual machinery of thought. Throughout his work Piaget placed considerable emphasis on the pragmatic aspect of logical and mathematical operations, as, for example, the way we actually handle symbols and formulas. From this point of view Piaget's account bears a marked resemblance to the views of Jules Henri Poincaré and the intuitionists; the construction of number, for example, had for Piaget a definite psychological aspect.

**ABSTRACT CONCEPTS.** Piaget believed that logical and mathematical notions first show themselves as overt activities on the part of the child and only at a later stage take on a conceptual character. They are to be conceived as internalized actions in which things are replaced by signs, and concrete actions by operations on these signs. Rational activity occurs in the child when his trial-and-error gropings attain a definite pattern of order that may be inverted in thought. At this rational stage, if the child makes a mistake in performing a task, he is able to return to his starting point. This characteristic of thought that enables us to reverse a train of ideas or actions Piaget calls "reversibility." It is the basis of our ability to perform mental experiments, as well as the psychological foundation of the deductive process.

Piaget contended that the more elementary forms of logical behavior in which the child compares, distinguishes, and orders the objects around him are largely concerned with the creation of concrete classificatory and relational systems. It is from these systems that we develop our later, more abstract, logical and mathematical modes of thinking. Piaget would rather not speak of the intuition of number before the child has developed logical concepts of invariance and has thereby grasped the operation of reversibility. The transition to number occurs in the child just when his activities of classifying and ordering objects take on the form of simple logical systems. What emerges from Piaget's experimental researches is that numerical concepts in their psychological development are ultimately based on simple logical notions. There is thus some resemblance between the way number comes to be constructed in a child's thought and the attempt on a purely normative plane by Russell and others to define number in logical terms.

**PHYSICAL CONCEPTS.** Among the other concepts studied by Piaget, those of time and space are of particular philosophical relevance. Immanuel Kant, for example, believed that these concepts were objects of an a priori intuition. Piaget, however, found that the abstract notion of time arises at a relatively late stage; at first time is connected with space. For example, the child first confuses the notion of age with that of height or other visible signs of age. As far as space is concerned, his ability to make spatial judgments is initially fairly rudimentary. He can differentiate between open and closed figures but has difficulty in distinguishing one shape from another. He is also incapable of imagining a perspective other than his own. Only at a later stage is he able to take account of several relations at once (before and behind, right and left)

and to coordinate them into a general system of perspectives.

**PERCEPTION.** For Piaget learning played an important part not only in the elaboration of intellectual structures but also in the field of perception. It is this that distinguishes his view from that of the Gestalt psychologists. For the latter, the perceptual constancies of shape and size belong directly to the perceived objects and are independent of age and ability. For Piaget, however, perception of figures is built up as a result of a series of random eye and other muscular movements, which are gradually corrected. The young child does not attribute a constant size or even identity to the objects around him. Piaget believed that the logical forms of activity that emerge in child behavior, namely classifying, relating, and so forth, arise as a result of his trial-and-error activities.

Piaget's views on perception have certain philosophical implications. In the past, he points out, philosophers have assumed a definite psychology of perception in their epistemologies. A good example of this is John Locke's sensationalism, in which it is assumed (1) that empirical facts are passively given in perception and (2) that they correspond to a certain range of linguistic expressions that designate them. For Piaget, however, even the notion of an object, one of the simplest forms of perceptual invariants, requires a definite learning process. Before the child is able to use linguistic expressions to refer unequivocally to definite objects, he must first have developed concrete classificatory and relational activities. Even the simple statement, "This is green," implies the acquisition of such skills and hence cannot be regarded as a reference to a simple perceptual datum. When we talk intelligently of green, this presupposes that we have learned to classify objects according to their color and to differentiate one color from another.

**BEHAVIOR AND LOGIC.** Piaget's work might be dismissed as philosophically irrelevant by philosophers of a Platonic turn of mind. It might be said that philosophical discussions of conceptual thinking are largely concerned with questions of validity and not with questions of origin. Piaget does not deny that logical notions as they appear in purely formal discussions differ from those occurring in ordinary thought. However, he asserts (1) that even our simpler kinds of intellectual performance have a logical character about them, which we can study formally, and (2) that when the logician constructs logical systems, performs deductions, tests for validity, and so on, his logical behavior can be studied in the same direct way as that of the child or unsophisticated adult. Piaget

also believed that it may be illuminating to compare the simpler logical structures inherent in our behavior with the purely formal systems constructed by the logician, as we may find some continuity between them.

## Bibliography

### WORKS BY PIAGET

Piaget was a prolific writer, and among the numerous volumes he wrote, the following have a specifically logical or philosophical character:

*Le jugement et le raisonnement chez l'enfant*. Paris, 1924.

Translated by M. Warden as *Judgment and Reasoning in the Child*. New York: Harcourt Brace, 1928.

*Le langage et la pensée chez l'enfant*. Paris, 1924. Translated by M. Warden as *The Language and Thought of the Child*. New York: Harcourt Brace, 1926. 2nd ed. translated by M. Gabain. London, 1932.

*La représentation du monde chez l'enfant*. Paris: Alcan, 1926. Translated by J. Tomlinson and A. Tomlinson as *The Child's Conception of the World*. New York: Harcourt Brace, 1929.

*La causalité physique chez l'enfant*. Paris, 1927. Translated by M. Gabain as *The Child's Conception of Physical Causality*. New York: Harcourt Brace, 1930.

*Le jugement moral chez l'enfant*. Paris: Alcan, 1932. Translated by M. Gabain as *The Moral Judgment of the Child*. New York: Harcourt Brace, 1932.

*La genèse du nombre chez l'enfant*. Paris, 1941. Written with A. Szeminska and translated by C. Gattegno and F. M. Hodgson as *The Child's Conception of Number*. New York: Humanities Press, 1952.

*Le développement des quantités chez l'enfant*. Paris, 1941. Written with B. Inhelder.

*Le développement de la notion du temps chez l'enfant*. Paris: Presses Universitaires de France, 1946.

*Les notions de mouvement et de vitesse chez l'enfant*. Paris: Presses Universitaires de France, 1946.

*La représentation de l'espace chez l'enfant*. Paris: Presses Universitaires de France, 1948. Written with B. Inhelder and translated by F. J. Langdon and J. L. Lunzer as *The Child's Conception of Space*. New York: Humanities Press, 1956.

*La géométrie spontanée chez l'enfant*. Paris: Presses Universitaires de France, 1948. Written with B. Inhelder and A. Szeminska and translated by E. A. Lunzer as *The Child's Conception of Geometry*. New York: Basic, 1960.

*La genèse de l'idée de hazard chez l'enfant*. Paris: Presses Universitaires de France, 1951.

*De la logique de l'enfant à la logique de l'adolescent*. Paris: Presses Universitaires de France, 1955. Translated by Anne Parsons and Stanley Milgram as *The Growth of Logical Thinking*. New York: Basic, 1958.

*La genèse des structures logiques élémentaires*. Paris, 1959. Written with B. Inhelder.

### WORKS ON PIAGET

There have been few philosophical discussions of Piaget's work, but W. Mays, "The Epistemology of Professor Piaget," in *PAS* (London, 1953–1954) compares his epistemology with the views of contemporary philosophers. C. Parsons in "Inhelder and Piaget's 'The Growth of Logical Thinking: II. A Logician's Viewpoint,'" in the *British Journal of Psychology* (1960), criticizes Piaget's logic from a theoretical standpoint. John H. Flavell in *The Developmental Psychology of Jean Piaget* (Princeton, NJ: Van Nostrand, 1963) gives a good summary of Piaget's work from a psychological point of view. The book contains an excellent bibliography of primary and secondary sources. W. Mays, "How We Form Concepts," in *Science News* (1954) gives a simple introduction from a more philosophical viewpoint.

K. Lovell in *The Growth of Basic Mathematical Concepts in Children* (London, 1961) provides an introduction to Piaget's ideas from an educational standpoint. Z. P. Dienes in *Building up Mathematics* (London, 1960) shows how Piaget's work has influenced the introduction of new methods in the teaching of school mathematics.

### OTHER RECOMMENDED WORKS

## PICO DELLA MIRANDOLA, COUNT GIOVANNI (1463–1494)

Count Giovanni Pico della Mirandola, the Renaissance philosopher, was born in Mirandola, near Modena. He was a younger son in a family of feudal lords who ruled the small territory of Mirandola and Concordia in northern Italy. He seems to have received at an early age his first humanistic training in Latin and, perhaps, in Greek. Being destined by his mother for a career in the church, he was named papal protonotary at the age of ten and began to study canon law at Bologna in 1477. Two years later he began the study of philosophy at the University of Ferrara, which he continued at the University of Padua from 1480 to 1482.

After a number of journeys that took him to Paris and repeatedly to Florence, Pico studied Hebrew and Arabic under the guidance of several Jewish teachers and in 1486 composed 900 theses, offering to defend them in Rome the following year in a public disputation to which he invited scholars from all parts of Europe. When some of these theses met with objections from various theologians, Pope Innocent VIII appointed a committee to have them examined. As a result of the investigation 7 theses were condemned as unorthodox, and 6 more were declared to be dubious. When Pico published a defense of these 13 theses, the pope condemned all 900, although Pico had signed an act of submission. Pico fled to France, where he was arrested in 1488 on the request of papal envoys.

Upon the intervention of several Italian princes Pico was released from prison by King Charles VIII. He returned to Italy and was allowed by the pope to settle in Florence, under parole, as it were, and under the personal protection of Lorenzo de' Medici. Except for a few short visits to Ferrara, Pico spent the remainder of his life in Florence and there wrote, or began to write, his most important works, remaining in close touch with the circle of the Medici, with the Platonic Academy of Marsilio Ficino, and with Girolamo Savonarola. In 1493 he was acquitted of all ecclesiastical censures and restrictions by Alexander VI. He died in 1494 on the very day (November 17) on which Charles VIII of France made his entry into Florence after the expulsion of Piero de' Medici.

Pico's numerous writings reflect the wide range of his interests. He composed Italian and Latin poems of which only some have survived. A number of his humanistic letters were published posthumously, as was his famous *Oration*, originally composed for the projected

disputation. To the scholastic aspect of his work we may assign the 900 theses (1486) and especially the *Apologia* (1487), his defense of the condemned theses. Another early work is his lengthy commentary on the Platonic love poem of his friend Girolamo Benivieni (1486). His mature philosophical works include the *Heptaplus* (1489), a sevenfold interpretation of the first verses (1:1–27) of Genesis, and his *De Ente et Uno* (On Being and Unity), written in 1491 but published posthumously. His most extensive work is his *Disputationes Adversus Astrologiam Divinatricem* (Disputations against Astrology), in twelve books, published posthumously. To this we may add a few short religious and theological writings and several fragments of a commentary on the Psalms that have been preserved in a number of scattered manuscripts and are still for the most part unpublished.

A characteristic document of Pico's attitude on history and philosophy from his earlier years is his correspondence with Ermolao Barbaro (1485). Barbaro, a distinguished Venetian humanist and student of the Greek texts of Aristotle, had stated in a letter to Pico that the medieval philosophers were uncultured and barbarous and did not deserve to be read or studied. Pico replied in a long letter in which he praises and defends the medieval philosophers and insists with great eloquence that what counts in the writings of philosophers is not their words but their thoughts. Unlike Barbaro and many other humanists who despised the scholastic philosophers for their lack of elegance and classical learning, Pico is willing to recognize the solidity of their thought and to learn from them whatever truth they may have to offer. The line between humanism and Scholasticism, rhetoric and philosophy, is thus clearly drawn, and Pico, although deeply imbued with humanist learning, throws his weight on the side of Scholasticism or, at least, of a synthesis of both sides. Many years after Barbaro and Pico died, Philipp Melancthon wrote a reply to Pico's letter in defense of Barbaro's position.

### SYNCRETISM

Pico's defense of the scholastic philosophers was merely a special instance of a much broader historical and philosophical attitude that has been rightly emphasized as his syncretism. Pico was convinced that all known philosophical and theological schools and thinkers contained certain valid insights that were compatible and hence deserved to be restated and defended. This was the underlying idea of his projected disputation, for the 900 theses relied on the most diverse sources—Hermes Trismegistus, Zoroaster, Orpheus and Pythagoras, Plato and Aris-

tole and all their Greek followers and commentators, Avicenna and Averroes and other Arabic philosophers, Thomas Aquinas and John Duns Scotus and several other medieval Latin thinkers, and the Jewish kabbalists.

In using all these sources, Pico wished to emphasize his basic conviction that all of these thinkers had a genuine share in philosophical truth. His notion of a universal truth in which each of the schools and thinkers participates to some extent constitutes an attempt to deal with the apparent contrasts and contradictions in the history of philosophy. It may be compared with the positions of the ancient eclectics and of G. W. F. Hegel, yet it differs from both of them. For Pico truth consists in a large number of true statements, and the various philosophers participate in truth insofar as their writings contain, besides numerous errors, a number of specific statements that are true. That this was Pico's intent we may gather from the second part of his *Oration* and from a passage in the *Apologia* that repeats it almost verbatim. He insists that he is not bound by the doctrines of any master or school but has investigated all of them. Instead of confining himself to one school, he has chosen from all of them what suits his thought, for each has something distinctive to contribute.

Pico's syncretism presupposes that of Ficino, who had proposed a theory of natural religion; had traced the Platonic tradition back to Hermes, Zoroaster, and other early theologians; and had insisted on the basic harmony between Platonism and Christianity. Yet Pico made these notions part of a much wider and more comprehensive synthesis. He explicitly includes Aristotle and all his Greek, Arabic, and Latin followers, and he adds to these previously known sources the Jewish kabbalists, with whom he became acquainted through his Hebrew studies, thus being probably the first Christian scholar to use kabbalistic literature. This attitude toward Aristotelianism and kabbalism clearly distinguished Pico from Ficino and other predecessors; it was to find further development in Pico's own later thought and to exert a strong influence on the philosophy of the sixteenth century. Pico's broad syncretism has been rightly praised by several historians as a steppingstone to later theories of religious and philosophical tolerance.

Pico's use of kabbalism consisted not so much in accepting specific kabbalist theories as in gaining recognition for kabbalism in general. Some of the theories that he seems to have borrowed from kabbalist authors were not necessarily of kabbalistic origin, such as the scheme of the three worlds—elementary, celestial, and angelic—which he uses for the first three sections of his *Heptaplus*.

Pico accepted the claim made by the followers of kabbalism that their writings were based on a secret tradition that went back, at least in oral form, to biblical times. Kabbalism thus acquires a kind of authority parallel to that of the Bible and similar to that held by Hermes and Zoroaster in the eyes of Ficino and Pico. Moreover, Pico applied to kabbalism a principle that had been used for the Old Testament by all Christian writers since St. Paul: He tried to show that the kabbalistic tradition, no less than the Hebrew Scripture, was in basic agreement with Christian theology and hence could be taken as a prophecy and confirmation of Christian doctrine. With this argument he laid the foundation for a whole tradition of Christian kabbalism that found its defenders in Johannes Reuchlin, Giles of Viterbo, and many other thinkers in the sixteenth and later centuries.

In Pico's own work the kabbalistic influence is most noticeable, after the time of the 900 theses, in his *Heptaplus* and in his fragmentary commentary on the Psalms. In a manner that goes far beyond the usual medieval scheme of the four levels of meaning Pico assigns to the text of Scripture a multiple meaning that corresponds to the various parts of the universe. He also uses the kabbalistic method of scriptural interpretation, which assigns numerical values to the Hebrew letters and extracts secret meanings from the text by substituting for its words other words with comparable numerical values.

The other distinctive aspect of Pico's syncretism, his tendency to assume a basic agreement between Plato and Aristotle, also remained one of his major preoccupations during his later life. We know that he planned to write an extensive treatise on the agreement between Plato and Aristotle. The idea that Plato and Aristotle were in basic agreement, although differing in their words and apparent meaning, was not new with Pico. We find it in Cicero, who probably took it from his teacher Antiochus of Ascalon. It is also attributed as a program to Ammonius Saccas, the teacher of Plotinus, and endorsed by Boethius. We may also compare certain trends in recent scholarship that have attempted to bridge the gap between Plato's dialogues and Aristotle's extant later writings by interpolating the oral teaching of Plato and the lost early writings of Aristotle.

Pico's approach is known to us through his *De Ente et Uno*, a small treatise composed toward the end of his life and the only surviving fragment of his projected larger work on the harmony of Plato and Aristotle. The question he discusses is whether being and unity are coextensive, as Aristotle maintains in the tenth book of the *Metaphysics*, or whether unity has a broader diffusion

and higher status than being, according to the view of Plotinus and other Neoplatonists. Following the scholastic doctrine of the transcendentals, Pico sets out to defend the position of Aristotle. He then tries to prove that Plato did not hold the opposite view, as claimed by the Neoplatonists. In support of his claim Pico cites a passage from Plato's *Sophist* and dismisses the testimony of the *Parmenides*, arguing that this dialogue is merely a dialectical exercise.

In the course of his discussion Pico sharply distinguishes between being itself and participated being, and it is thus possible for him to maintain that God is identical with being in the first sense but above being in the second. The harmony between Plato and Aristotle that Pico tries to establish turns out to be Aristotelian, at least in its wording, but in another sense it is neither Platonic nor Aristotelian, and the distinction between being itself and participated being is evidently indebted to the same Neoplatonists whom Pico tries to refute on the major issue of the treatise. As a result Pico's position was criticized, on the one side, by Ficino, who, in his commentary on the *Parmenides*, defended Plotinus and, on the other, by the Aristotelian Antonio Cittadini, who formulated a series of objections that were answered first by Pico himself and then by his nephew and editor Gianfrancesco Pico.

Another aspect of Pico's syncretism is his treatment of classical mythology. An allegorical interpretation of the myths of the Greek poets had been developed by the ancient Stoics and Neoplatonists, and for them it had been a device for reconciling pagan religion with philosophical truth. When the medieval grammarians continued to interpret the classical poets in this manner, they minimized the pagan religious element and emphasized the implied universal, or even Christian, truth that would justify the study of these authors. The method was taken over and further developed by the humanists and Ficino. Pico tends to be even more elaborate in his discussion and interpretation of ancient myths, especially in his commentary on Benivieni's love poem. Here he repeatedly mentions his plan to write a treatise on poetic theology, a work that probably remained unwritten. Pico apparently intended to construct a detailed system of the theology implicit in the myths of the ancient poets and thus to include them in his universal syncretism.

## DIGNITY OF MAN

Much more famous than the ideas thus far discussed is Pico's doctrine of the dignity of man and his place in the universe. The *Oration*, in which this doctrine is developed, is probably the most widely known document of

early Renaissance thought. In many editions the work is titled "Oration on the Dignity of Man," but this title properly belongs only to the first part of the oration; the original title was simply *Oration*. Man and his dignity are often praised by the early humanists, and some of them dedicated entire treatises to the subject. The topic was taken up by Ficino, who assigned to the human soul a privileged place in the center of the universal hierarchy and made it, both through its intermediary attributes and through its universal thought and aspirations, the bond of the universe and the link between the intelligible and the corporeal world. In his *Oration* Pico went beyond Ficino in several ways. He did not discuss the question merely in passing or in the context of a large work dedicated to other subjects but displayed it prominently in the opening section of a short and elegant speech. Moreover, he lays the accent not so much on man's universality as on his freedom; instead of assigning to him a fixed though privileged place in the universal hierarchy, he puts him entirely apart from this hierarchy and claims that he is capable of occupying, according to his choice, any degree of life from the lowest to the highest. He has God tell Adam:

Neither a fixed abode nor a form that is thine alone, nor any function peculiar to thyself have We given thee, Adam, to the end that according to thy judgment thou mayest have and possess what abode, what form, and what functions thou thyself shalt desire. Constrained by no limits, in accordance with thine own free will, in whose hand We have placed thee, thou shalt ordain for thyself the limits of thy nature.... Thou shalt have the power to degenerate into the lower forms of life, which are brutish. Thou shalt have the power, out of thy soul's judgment, to be reborn into the higher forms, which are divine.

These words have a modern ring, and they are among the few passages in the philosophical literature of the Renaissance that have pleased, almost without reservation, modern and even existentialist ears. It is not absolutely certain that they were meant to be as modern as they sound, and it is hard to believe what has often been said—that when Pico wrote them, he had denied or forgotten the doctrine of grace. After all, the words are attributed to God and are addressed by him to Adam before the Fall. Yet they do contain an eloquent praise of human excellence and of man's potentialities, and they receive added vigor when we think of what the reformers,

and even great humanists like Michel Eyquem de Montaigne, were to say about man's vanity and weakness.

Some scholars have tried to minimize Pico's praise of human dignity and regard it as a piece of mere oratory. This view is refuted by the testimony of the *Heptaplus*, a work written several years later and for an entirely different purpose. Here again, Pico places man outside the hierarchy of the three worlds—the angelic, celestial, and elementary—treats him as a fourth world by himself, and praises him and his faculties, although within a more obvious theological context.

Pico's insistence on man's dignity and liberty also accounts, at least in part, for his attack on astrology, to which he dedicates his largest extant work, probably composed during the last few years of his life. The *Disputationes Adversus Astrologiam Divinatricem* is full of detailed astronomical discussions and displays an amazing mastery of the astrological and antiastrological literature of previous centuries. It has often been hailed by historians as a landmark in the struggle of science against superstition. In fact, Pico does state that the stars act upon sublunar things only through their light and heat, not through any other occult qualities that may be attributed to them, and this statement sounds very sober, if not necessarily modern. Moreover, we learn that even a scientist such as Johannes Kepler at least modified his initial belief in astrology under the influence of Pico's treatise.

In Pico's time, however, the belief in astrology was more than a superstition, and the rejection of it was not necessarily scientific. As a general system astrology was closely linked with the scientific cosmology of the age and hence widely accepted not only by quacks but also by serious thinkers. There is no evidence that Pico was especially guided by scientific considerations in his polemics against astrology, and we must face the fact that he accepted natural magic while rejecting astrology. We happen to know that his work against astrology was composed as a part of a larger work he planned to write against the enemies of the church. The basic impulse of his attack was religious and not scientific, and he indicates more than once what his chief objection to astrology was—the stars are bodies, and our selves are spirits; it cannot be admitted that a corporeal and, hence, lower being should act upon a higher being and restrict its freedom.

Pico's conception of the relation between philosophy and religion is also significant. He became increasingly concerned with religious problems during his later years, a development in which his shock at the papal condemnation of his theses and the influence of Savonarola must have played a part. The fact appears in the religious and

theological content of several of his later writings and in the religious motivation of his treatise against astrology. It also finds an unexpected expression in certain passages of the *De Ente et Uno*, a work that deals fundamentally with a very different problem. Here Pico tells us that God is darkness and that philosophical knowledge can lead us toward God only up to a certain point, beyond which religion must guide us. Unlike Ficino, Pico seems to regard religion as a fulfillment of philosophy; religion helps us to attain that ultimate end for which philosophy can merely prepare us.

Pico did not live long enough to develop his ideas into a coherent system. Fragmentary as his work was, it had wide repercussions for a long time. His universal syncretism came closer to subsequent efforts at formulating a universal religion than that of any of his predecessors, including Ficino. His study of Hebrew and Arabic, although not entirely without precedents, served as a widely known example and gave a powerful impulse to these studies in Christian Europe, leading to a study of the Hebrew Scripture and to many new translations of Jewish and Arabic texts. His study of the kabbalah started a broad and powerful current of Christian kabbalism, which flourished throughout the sixteenth century and included many distinguished scholars and thinkers. In his attempt to harmonize the traditions of Platonic and Aristotelian philosophy, of Hermetic and kabbalistic theology, and of the various strands of Arabic and scholastic thought with one another and with Christian doctrine, Pico pointed the way toward intellectual freedom and a universal truth that stands above the narrow limits of particular schools and traditions.

**See also** Antiochus of Ascalon; Aristotelianism; Aristotle; Averroes; Avicenna; Boethius, Anicius Manlius Severinus; Cicero, Marcus Tullius; Duns Scotus, John; Ficino, Marsilio; Hegel, Georg Wilhelm Friedrich; Humanism; Italian Philosophy; Kabbalah; Kepler, Johannes; Melancthon, Philipp; Montaigne, Michel Eyquem de; Neoplatonism; Pico della Mirandola, Gianfrancesco; Plato; Platonism and the Platonic Tradition; Plotinus; Pythagoras and Pythagoreanism; Renaissance; Stoicism; Thomas Aquinas, St.

## Bibliography

### WORKS BY PICO

Three volumes of a critical edition of Pico's works by Eugenio Garin have appeared: *De Hominis Dignitate, Heptaplus, De Ente et Uno, e scritti vari* (Florence: Vallecchi, 1942) and *Disputationes Adversus Astrologiam Divinatricem*, 2 vols. (Florence: Vallecchi, 1946–1952). For the other works

(especially the *Conclusiones*, *Apologia*, and *Letters*) one of the numerous editions of Pico's works must be used. The earliest and best was published in Bologna (1496); the most accessible is the Basel edition of 1572. For additional letters and texts see Léon Dorez, "Lettres inédites de Jean Pic de la Mirandole," *Giornale storico della letteratura italiana* 25 (1895): 352–361, and Eugenio Garin, *La cultura filosofica del Rinascimento italiano* (Florence: Sansoni, 1961). A few of Pico's letters and short religious works, along with the biography of Pico by his nephew, were translated by Sir Thomas More as *Pico, His Life by His Nephew*, edited by J. M. Rigg (London, 1890). The commentary on Benivieni was translated by Thomas Stanley in 1651 and later appeared as *A Platonick Discourse upon Love*, edited by Edmund G. Gardner (Boston: Merrymount Press, 1914).

There is a modern English version of the *De Ente et Uno*, translated by Victor M. Hamm as *Of Being and Unity* (Milwaukee, WI: Marquette University Press, 1943), and no less than three versions of the *Oration—The Very Elegant Speech on the Dignity of Man*, translated by Charles G. Wallis (Annapolis, MD: St. John's Book Store, 1940); *Oration on the Dignity of Man*, translated by Elizabeth L. Forbes in *The Renaissance Philosophy of Man*, edited by Ernst Cassirer, Paul Oskar Kristeller, and John H. Randall Jr. (Chicago: University of Chicago Press, 1948), and published separately with the Latin text (Lexington, KY, 1953); and *Oration on the Dignity of Man*, translated by A. Robert Caponigri (Chicago: Gateway, 1956). The correspondence with Ermolao Barbaro was translated by Quirinus Breen as "Giovanni Pico della Mirandola on the Conflict of Philosophy and Rhetoric," *Journal of the History of Ideas* 13 (1952): 384–426.

#### WORKS ON PICO

For Pico's thought the chief monograph is Eugenio Garin, *Giovanni Pico della Mirandola* (Florence: Le Monnier, 1937). Important is Ernst Cassirer's "Giovanni Pico della Mirandola," *Journal of the History of Ideas* 3 (1942): 123–144, 319–346. See also Giovanni Semprini, *La filosofia di Pico della Mirandola* (Milan, 1936); Eugenio Anagnine, *G. Pico della Mirandola* (Bari, Italy: Laterza, 1937); Pierre Marie Cordier, *Jean Pic de la Mirandole* (Paris: Nouvelles Éditions Debresse, 1957); E. Monnerjahn, *Giovanni Pico della Mirandola* (Wiesbaden, Germany: Steiner, 1960); and Eugenio Garin, *Giovanni Pico della Mirandola* (Mirandola, Italy, 1963).

For Pico's sources see Pearl Kibre, *The Library of Pico della Mirandola* (New York: Columbia University Press, 1936). For the condemnation of his theses see Léon Dorez and Louis Thuasne, *Pic de la Mirandole en France* (Paris: Leroux, 1897). For his scholastic background see Avery Dulles, *Princeps Concordiae: Pico della Mirandola and the Scholastic Tradition* (Cambridge, MA: Harvard University Press, 1941). For the *De Ente et Uno* and its background see Raymond Klibansky, "Plato's *Parmenides* in the Middle Ages and the Renaissance," *Mediaeval and Renaissance Studies* 1 (1941–1943): 281–330. For his kabbalism see Joseph L. Blau, *The Christian Interpretation of the Cabala in the Renaissance* (New York: Columbia University Press, 1944); F. Secret, *Le zôhar chez les kabbalistes chrétiens de la Renaissance* (Paris, 1958) and "Pico della Mirandola e gli inizi della Cabala cristiana," *Convivium*, n.s. 25 (1957): 31–47.

For Pico's influence on the iconography of Renaissance art see Edgar Wind, *Pagan Mysteries in the Renaissance* (New Haven, CT: Yale University Press, 1958).

Several long papers by Eugenio Garin, Robert Weiss, Paul Oskar Kristeller, and Frances A. Yates are included in *L'opera e il pensiero di Giovanni Pico della Mirandola nella storia dell'umanesimo. Convegno internazionale, Mirandola, 15–18 settembre 1963*, 2 vols. (Florence: Nella Sede dell'Istituto, 1965).

## PICO DELLA MIRANDOLA, GIANFRANCESCO (1469–1533)

Gianfrancesco Pico della Mirandola was the nephew of the great Florentine humanist Giovanni Pico della Mirandola. He, like his uncle, became interested in the reform movement of Girolamo Savonarola (1452–1498) that was centered in the Convent of San Marco. The younger Pico della Mirandola moved into the convent and joined the group of scholars who took part in the daily discussions of philosophy and religion. His uncle moved into the convent in 1492 and placed his library there. Among the manuscripts brought to the convent by Pico della Mirandola and other scholars were five manuscript copies of Sextus Empiricus. Savonarola became interested in making these texts in Greek available to modern readers and asked two of his monks to begin preparing an edition of the writings of Sextus. This project never came to fruition, but some of it seems to be incorporated in the younger Pico della Mirandola's own publications.

He edited his uncle's work on astrology that was left in 1494, after Pico della Mirandola had died. He himself authored another work criticizing astrology, as did Savonarola. Pico della Mirandola was writing in praise of Savonarola up to the moment when the latter was arrested, tried, and burned at the stake. Thereafter, his disciples had to flee for their lives. Pico della Mirandola went back to his ancestral home of Mirandola, Italy, and struggled for about ten years to secure control of his family's property.

He wrote on a variety of philosophical and theological subjects, supporting the views of his teacher, Savonarola. In 1520 he published the first presentation of Greek skepticism in modern times, *Examen vanitatis doc-*

*trinae gentium et veritatis Christianae disciplinae: Distinctum in libros sex, quorum tres omnem philosophorum sectam universim: reliqui Aristoteleam et Aristoteleis armis particulatim impugnant: Ubicunque autem Christiana et asseritur, et celebratur disciplina* (Examination of the vain doctrine of the gentiles and the true Christian teaching). The work was apparently written over at least fifteen to twenty years. Besides presenting arguments and analyses out of Sextus, it also contains a text by John Philoponus and Hasdai Crescas. It is curious that Pico della Mirandola includes the material from Crescas, which had not yet been published and only circulated in Hebrew manuscript. He may have gotten a text and its translation from Judah León Abrabanel (c. 1460–c. 1521), with whom he was in contact. Pico della Mirandola's skeptical work did not have wide circulation. It is cited by several people writing on philosophical topics, but it does not seem to have encouraged people to look further into skeptical thought. He was read by Gentian Hervetius (1499–1584), the translator of Sextus, and probably by Francisco Sanches, Pierre Gassendi, and Gottfried Wilhelm Leibniz. The more serious impact of Sextus on modern thought had to await the presentation of his doctrines in Michel Eyquem de Montaigne's writings.

## PIETISM

Since the seventeenth century "Pietism" has been an important movement within German Protestantism, and it is still influential in some parts of Germany. It began as a reaction against the formal and conventional character that appeared in Protestantism in the aftermath of the Reformation. Pietism opposed on the one hand the intellectualism implicit in the orthodox tendency to equate faith with the giving of assent to correct doctrine, and on the other, the tendency to identify Christianity with conformity to the ecclesiastical establishments that had been set up in various parts of Germany. By stressing experience, feeling, and personal participation as essential to a true Christian faith, Pietists hoped to bring new life into the Lutheran Church. One can point to similar movements in other parts of Christendom, in the English-speaking world the movement most akin to Pietism was Methodism.

The founder of German Pietism was Philipp Jakob Spener (1635–1705). Influenced by the extreme Protestant sect of Jean de Labadie, he undertook the task of raising the devotional level of his congregation in Frankfurt am Main and eventually, he hoped, of German Protestantism as a whole. Devotional meetings in his home were the beginnings of the famous *collegia pietatis*. At its meetings his sermons were considered, the New Testament was expounded, and there was conversation on religious topics. Spener gave clear expression to the aims of his movement in *Pia Desideria* (Frankfurt am Main, 1675), in which he laid down six goals to be realized: (1) greater study of the Bible but with the aim of personal devotion rather than academic competence; (2) a serious commitment to Martin Luther's belief in the priesthood of all Christian believers, so that the laity might really participate in the life of the church instead of merely conforming outwardly; (3) a realization that Christianity is a practical faith rather than an intellectual belief and that this faith expresses itself in love; (4) corresponding to this, a new style in apologetics and controversy that must aim not so much at intellectual conviction as at winning the allegiance of the whole man; (5) following from the last two points, the reorganization of theological education in order to lay stress on standards of life and conduct rather than on academic achievement; (6) the renewal and revitalizing of preaching as an instrument for building up a genuine piety among the people.

Spener continued to advocate his views in many other writings, including *Das geistliche Priesterthum* (1677), *Des thätigen Christenthums Nothwendigkeit*

(1679), *Die allgemeine Gottesgelehrtheit aller gläubigen Christen und Rechtschaffenen Theologen* (1680), *Klagen über das verdorbene Christenthum* (1684), *Natur und Gnade* (1687), and *Evangelische Glaubenslehre* (1688), which were all published at Frankfurt. He became engaged in stormy controversies, both attracting supporters and arousing opposition. Through the support of the elector of Brandenburg, the University of Halle became a center for Pietist views. Spener himself seems to have been a reasonable man who avoided the extravagances of some of his followers and performed a genuine service for the Lutheran Church.

Also important in the history of Pietism is August Hermann Francke (1663–1727). He taught at the University of Halle and is noteworthy for his development of the practical emphasis of Pietism. He founded a school for the poor and an orphanage and also took an interest in the cause of foreign missions. Like Spener, he encountered opposition, especially among some of the theologians, because of his indiscriminate attacks on intellectualism and his depreciation of the academic disciplines in the interests of devotion and philanthropy. Francke, however, had his supporters and was favored by King Frederick William I of Prussia. Mention should also be made of Count Nikolaus Ludwig von Zinzendorf (1700–1760), a pupil of Francke, who spread the spirit of Pietism to Holland, England, and North America by founding communities there. He maintained close relations with John Wesley and the Methodists. Like the other Pietists, he stressed feeling and personal devotion in what seems to have been a mixture of mysticism and emotionalism.

The chief characteristics of Pietism can be seen from this sketch of its origins and early history. It made claims for the affective and sometimes also the conative aspects of religion, in devotion and in practical service, at the expense of the cognitive element. While this may have been a healthy corrective to a sterile dogmatic orthodoxy, it tended to lead to dangerous excesses. Its insistence on intense inward experience could easily lead to the emotionalism that is common in evangelical religion and to the contempt for intelligence and common sense that sometimes accompanies it. The moralistic tone encourages utopianism. Some of those who have been caught up in the enthusiasm of Pietism have underrated the complexities of the moral life and the limitations of what is possible for man; as a result they have shared with the Methodists a belief in perfectionism. Apart from these dangerous excesses, Pietism has contended for the breadth of the human spirit and guarded against too narrow a rationalism. That the tenets of Pietism can receive

a sober formulation worthy of respectful consideration is shown above all by the work of F. D. E. Schleiermacher, whose analysis of religion in terms of the feeling of absolute dependence is a direct reflection of the Pietist tradition in Germany.

The influence of Pietism on philosophy is largely indirect. The Pietists themselves tended to be antiphilosophical, but their spirit and teaching became part of the German heritage and eventually influenced even philosophy. This influence showed itself above all in the rise of *Lebensphilosophie* of which the religious variety, as expressed in the work of Rudolf Christoph Eucken, comes nearest to being a philosophical version of Pietism. Yet even the nonreligious varieties of this philosophy probably owe something to the anti-intellectualism that Pietism has encouraged.

## PISAREV, DMITRI IVANOVICH (1840–1868)

Dmitri Ivanovich Pisarev, the Russian literary critic and social philosopher, was educated at St. Petersburg Uni-

versity (1856–1861). His studies were interrupted by a nervous breakdown requiring four months of institutionalization. At this time he twice attempted suicide. Pisarev was imprisoned from 1862 to 1866 for his outspoken criticism of the tsarist regime. He drowned while swimming in the Baltic Sea, under circumstances that suggest suicide, at the age of twenty-eight.

Pisarev called himself a “realist” and praised “fresh and healthy materialism,” but his own philosophical position was a sense-datum empiricism. In his early writings on ethics and social philosophy, in the years 1859 to 1861, he advocated the “emancipation of the individual person” from social, intellectual, and moral constraints but particularly stressed the preservation of the wholeness of human personality in the face of the fragmenting pressures of functional specialization and the division of labor.

Among the constraints that the free individual must discard are those resulting from “the timidity of his thought, caste prejudices, the authority of tradition, the aspiration toward a common ideal” (*Polnoye Sobraniye Sochineniy*, Vol. I, Col. 339). Pisarev declared that common ideals have “just as little *raison d’être* as common eyeglasses or common boots made on the same last and to the same measure” (Col. 267). Eyes differ, feet differ, individuals differ; hence eyeglasses, boots, and ideals (for “every ideal has its author”) should be individually fitted. Pisarev’s moral relativism anticipated contemporary emotivist or noncognitivist doctrines in ethics—the claim that moral judgments are expressions of individual taste or preference. “When it is a matter of judging port or sherry,” Pisarev wrote, “we remain calm and cool, we reason simply and soundly . . . , but when it is a question of lofty matters, we immediately . . . get up on our stilts. . . . We let our neighbor indulge his taste in hors d’oeuvres and desserts, but woe unto him if he expresses an independent opinion about morals” (Col. 266).

In his later writings Pisarev adopted a utilitarian ethics modified by the principle of “economy of intellectual energies.” In the situation of cultural and intellectual deprivation of Russia at mid-century, he argued, the greatest-happiness principle precludes such luxuries as esoteric art that can be enjoyed “only by a few specialists” and abstruse science that is “in its very essence inaccessible to the masses” (Col. 366).

## PLANCK, MAX

(1858–1947)

The German physicist Max Planck was the discoverer of the quantum of action, also called Planck’s constant. Born in Kiel, he studied physics and mathematics at the University of Munich under Philipp von Jolly and at the University of Berlin under Hermann von Helmholtz and Gustav Kirchhoff. After receiving his Ph.D. at Munich (1879), he taught theoretical physics, first in Kiel, then (starting in 1889) in Berlin, as Kirchhoff’s successor. “In those days,” he wrote later, “I was the only theoretician, a physicist *sui generis*, as it were, and this circumstance did not make my *début* so easy.” At this time Planck made important, and indeed quite fundamental, contributions to the understanding of the phenomena of heat, but he received hardly any attention from the scientific community: “Helmholtz probably did not read my paper at all. Kirchhoff expressly disapproved of its contents.” The spotlight was then on the controversy between Ludwig Boltzmann and the Wilhelm Ostwald–Georg Helm–Ernst Mach camp, which supported a purely phenomenological theory of heat. It was via this controversy, and not because of the force of his arguments, that Planck’s ideas were finally accepted. “This experience,” he wrote, “gave me an opportunity to learn a remarkable fact: a new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die.”

Nevertheless, the discovery of the quantum of action in 1900, for which Planck received the Nobel Prize in physics (1918), was a direct result of these earlier studies. In 1912 Planck became permanent secretary of the (then)

Prussian Academy of Sciences, a post that he retained with only minor interruptions for the rest of his life. He used this position with excellent judgment for furthering the international collaboration of all scientists. From 1930 to 1935 he was president of the Kaiser-Wilhelm-Institut, which later became the Max-Planck-Institut.

Politically Planck was conservative, loyal to the Prussian ideas of the state and of honor, and loyal to Wilhelm II. During World War I he more than once expressed his devotion to the cause of the German people united in battle, and he received the order of “pour le mérite,” one of the highest orders of Wilhelm’s Germany. However, he opposed the Nazi regime. He defended Albert Einstein, first against his scientific opponents, then against his political enemies. Despite severe criticism by Johannes Stark, Phillip Lenard, and Ernst Müller, he continued to defend Einstein and other Jewish scientists (such as Walther Nernst) even after 1933. He later personally demanded of Adolf Hitler that those scientists who had been imprisoned be freed; as a consequence he was removed as president of the Physical Society, was refused the Goethe Prize of the city of Frankfurt (he was awarded it after the war, in 1946), and finally was forced to witness the execution of his only son, who had been connected with the German resistance. Antiquated as some of his political ideas may have been, he nevertheless put individual justice above all and defended it even at the risk of his own life. At the end of the war he was rescued by the Allied forces. He spent the last years of his life in Göttingen.

### APPROACH TO SCIENCE

Planck’s research was guided by his belief “of the existence in nature of something real, and independent of human measurement.” He considered “the search for the absolute” to be the highest goal of science. “Our everyday starting point,” he explained, “must necessarily be something relative. The material that goes into our instruments varies according to our geographical source; their construction depends on the skill of the designers and toolmakers; their manipulation is contingent on the special purposes pursued by the experimenter. Our task is to find in all these factors and data, the absolute, the universally valid, the invariant that is hidden in them.”

This point of view was not allowed to remain a philosophical luxury, without influence upon the procedures of physics. One of the main objections that Planck raised against the positivistic creed was its sterility in the promotion of theory. “Positivism lacks the driving force for serving as a leader on the road of research. True, it is

able to eliminate obstacles, but it cannot turn them into productive factors. For ... its glance is directed backwards. But progress, advancement requires new associations of ideas and new queries, not based on the results of measurement alone.”

### SCIENTIFIC DISCOVERIES

Of new ideas Planck himself produced essentially two. He recognized and clearly formulated those properties of heat that separate it from purely mechanical processes, and he introduced and applied to concrete problems the idea of an atomistic structure not only of matter but of radiation also. In his doctoral dissertation he had already separated thermodynamic irreversibility from mechanical processes and had interpreted Rudolf Clausius’s entropy as its measure. Later he showed (independently of Willard Gibbs) that “all the laws of physical and chemical equilibrium follow from a knowledge of entropy.”

His conviction that the principle of the increase of entropy was a genuine and independent physical law and his belief in the universal (or, to use his term, *absolute*) validity of all physical laws led him to apply thermodynamic reasoning in domains that until then had been regarded as inaccessible to it. For example, he determined that the lowering of the freezing point of dilute solutions could be explained only by a dissociation of the substances dissolved, thus extending the science of thermodynamics to electrically charged particles. This tendency to strain laws to the limit rather than to restrict them to the domain of their strongest evidence caused a temporary clash with Boltzmann, who was quite unperturbed by the fact that in his approach the entropy of a system could both increase and decrease. But it also led to Planck’s greatest triumph—his discovery of the quantum of action.

Planck was the only one to correlate the relevant features of radiation with the entropy, rather than the temperature, of the radiant body. “While a host of outstanding physicists worked on the problem of spectral energy distribution, both from the experimental and theoretical aspect, every one of them directed his efforts solely towards exhibiting the dependence of the intensity of radiation on the temperature. On the other hand I suspected that the fundamental connexion lies in the dependence of entropy upon energy. As the significance of the concept of entropy had not yet come to be fully appreciated, nobody paid attention to the method adopted by me, and I could work out my calculations completely at my leisure.” These calculations furnished a formula that agreed with experiment and contained the existing theoretical results (Wien’s formula and the

Raleigh-Jeans law) as limiting cases. In the attempt to find a rationale for this result, Planck used Boltzmann's statistical interpretation of entropy and was thus led to the discovery of the "atomic," or discontinuous, structure of action (energy).

## REALISM, DETERMINISM, AND RELIGION

The discovery of the quantum of action was brought about not only by the specific physical arguments used but also by the philosophical belief in the existence of a real world behaving in accordance with immutable laws. The intellectual climate of the late nineteenth century was opposed to such a belief (Boltzmann was almost the only other figure to uphold it). This climate not only found expression in the philosophical superstructure but influenced physical practice itself. Laws were regarded as summaries of experimental results and were applied only where such results were available. However, it was the "metaphysics" of Planck, Boltzmann, and, later on, Einstein (whom Planck interpreted as a realist from the very beginning) that made possible many of the theories that are now frequently used to attack realism and other "metaphysical" principles.

Planck never accepted the positivistic interpretation of the quantum theory. He distinguished between what he called the "world picture" of physics and the "sensory world," identifying the former with the formalism of the  $\psi$  waves, the latter with experimental results. The fact that the  $\psi$ -function obeys the Schrödinger equation enabled him to say that while the sensory world might show indeterministic features, the world picture, even of the new physics, did not. His belief in the existence of objective laws also provided him with an important steppingstone to religious belief. Planck argued that the laws of nature are not invented in the minds of men; on the contrary, external factors force us to recognize them. Some of these laws, such as the principle of least action, "exhibit a rational world order" and thereby reveal "an omnipotent reason which rules over nature." He concluded that there is no contradiction between religion and natural science; rather, they supplement and condition each other.

## PLANTINGA, ALVIN (1932–)

Born in Ann Arbor, Michigan, Alvin Plantinga is one of the most important and influential philosophers of the twentieth and early twenty-first centuries. His publications range over a wide variety of fields, but his most enduring contributions have been in metaphysics, epistemology, and, especially, the philosophy of religion. He is best known for his work on the metaphysics of necessity and possibility, for his defense of the view that knowledge is to be analyzed partly in terms of proper function, for his development of the "free will defense" against the so-called "logical problem of evil," for his many and vigorous defenses of the rationality of religious belief, and for his much-discussed "evolutionary argument against naturalism."

Plantinga earned his BA in philosophy and psychology from Calvin College in 1953, and he cites his experi-

ence at Calvin as perhaps the single most significant intellectual influence in his life. There he studied with Henry Stob and Harry Jellema, the latter of whom played an especially formative role in his intellectual development. Plantinga received his MA in philosophy from the University of Michigan in 1955, and his PhD from Yale in 1958 under the supervision of Paul Weiss. He was elected to the American Academy of Arts and Sciences in 1975, co-founded the Society of Christian Philosophers in 1978, served as President of the Central Division of the American Philosophical Association in 1981 and 1982, and served as President of the Society of Christian Philosophers from 1983 to 1986. He has given the prestigious Gifford Lectures twice, and in a 1980 article he was heralded by *Time* magazine as “America’s leading orthodox Protestant philosopher of God.”

## METAPHYSICS

Plantinga’s most influential work in metaphysics has focused primarily on the metaphysics of modality. In *The Nature of Necessity* (1974), as well as in various papers, a central theme is the exposition and defense of a *realist* and *actualist* construal of possible worlds and modal properties. On his view, the standard possible worlds semantics for modal logic is to be taken with metaphysical seriousness: it is not a mere heuristic device; possible worlds are not merely useful fictions. Rather, possible worlds exist. They are abstract states of affairs of a certain kind—something like total or complete ways that a world history might have gone. Moreover, individual things have *modal properties*—properties such as *being possibly seven feet tall*, or *being necessarily even*—and, Plantinga thinks, realism about such properties requires one to believe that individual things exist in other worlds. On his view, a thing exists in another possible world only if, had that world been actual, the thing itself, not a mere stand-in or counterpart, would have existed. Thus, if Fred has the property *being possibly seven feet tall*, then there is a possible world such that, had that world been actual, Fred himself would have existed and would have been seven feet tall. Ultimately, this understanding of modal properties, together with his commitment to strong form of actualism, leads Plantinga to endorse the controversial view that objects have *individual essences*—properties that are both essential and essentially unique to them.

## EPISTEMOLOGY

Plantinga’s major works in epistemology are the volumes that comprise his *Warrant* trilogy (1993a, 1993b, 2000). *Warrant*, according to Plantinga, is that property or

quantity that distinguishes knowledge from mere true belief. The main goals of the *Warrant* books are to identify the necessary and sufficient conditions for warrant, and to defend an affirmative answer to the question whether distinctively Christian belief can be warranted.

In the first volume of the trilogy, Plantinga surveys a broad range of post-Gettier analyses of knowledge, arguing that all of them founder on counterexamples involving cognitive malfunction. The basic problem is that, for each candidate analysis of “S knows that *p*,” the conditions listed as necessary and sufficient for knowledge could be satisfied by a person whose cognitive faculties are malfunctioning in such a way that, intuitively, beliefs produced by faculties behaving in that way fail to count as knowledge. He also argues for the striking and controversial conclusion that *justification*, construed at least in part as a matter of epistemic duty-fulfillment, is not necessary for knowledge at all.

In the second volume, Plantinga articulates and defends a new analysis of knowledge, according to which (roughly) S knows that *p* if and only if S believes that *p*, *p* is true, and S’s belief that *p* is the product of faculties that are properly functioning, successfully aimed at truth, and operating in an appropriate environment. The notions of *proper function* and *appropriate environment* are normative notions; but, Plantinga says, the normativity involved is of a sort commonly invoked in the natural sciences. Thus, Plantinga regards his analysis as, strictly speaking, an instance of “epistemology naturalized.” But he also argues that his brand of epistemology naturalized flourishes best in the context of a supernaturalistic metaphysics. Toward establishing this conclusion, he begins by arguing that proper function is an irreducibly normative notion that does not admit of a purely naturalistic analysis. He then attacks naturalism directly, arguing that belief in naturalism and evolutionary theory together is epistemically self-defeating and therefore irrational. This latter argument is the so-called “evolutionary argument against naturalism.”

The third volume of the *Warrant* trilogy applies the account of knowledge defended in the second volume in the service of an argument for the possibility of warranted Christian belief. The central and striking thesis of the book is that if Christian belief is true, then it is warranted. This conclusion is important because it implies, contrary to widespread opinion, that objections against the *rationality* of Christian belief are not independent of objections against the *truth* of Christian belief. In order to defend the conclusion that Christian belief is unwarranted, one must first defend the conclusion that it is

false. In support of his central thesis, Plantinga begins by arguing that the only really philosophically interesting question about the rationality of Christian belief is the question that asks whether Christian belief is or can be warranted. He then notes that, in light of the analysis of knowledge proposed in the second volume, Christian belief can be warranted so long as it is produced by properly functioning faculties that are successfully aimed at truth and functioning in a suitable environment. Much of the rest of the volume, then, is devoted to establishing the conclusion that if Christian belief is true, then these conditions are satisfied.

## PHILOSOPHY OF RELIGION

Plantinga's work in the philosophy of religion has focused on what is sometimes referred to as "negative apologetics": the task of showing that objections to religious belief are unsuccessful. Thus, to take just a few examples, Plantinga has argued that the proposition that God exists is logically consistent with the proposition that evil exists; that the existence of evil does not constitute a defeater for the rationality of Christian belief; that widespread religious pluralism and intractable disagreement on religious matters do not provide reason to doubt that one knows that one's own religious beliefs are true; and that what he takes to be the correct views about human freedom and moral responsibility are not in tension with the traditional belief that God has perfect knowledge of the future.

Plantinga's focus on negative apologetics stems in part from his view that the warrant for Christian belief need not, and, in the ordinary case, does not come from philosophical argument but rather from something like religious experience. This view is a central theme in his work on religious epistemology, especially in the third volume of his *Warrant* trilogy (discussed above), but also in two earlier works: *God and Other Minds* (1967), and "Reason and Belief in God." Nevertheless, he does make occasional forays into the territory of positive apologetics. For example, in *The Nature of Necessity* and *God, Freedom and Evil* (1977), Plantinga argues that a modal version of the ontological argument for God's existence is both valid and plausibly sound. Likewise, Plantinga has devoted considerable energy to rebutting naturalism and its common companion, materialism.

Besides introducing important arguments into the literature on the philosophy of religion, however, Plantinga has also played an important role in shaping the way in which many religious philosophers now approach topics in their own fields of specialization. In his highly influential paper, "Advice to Christian Philosophers,"

(1984) Plantinga urges philosophers who share his Christian worldview to allow the presuppositions of that worldview to inform their work not only on topics in the philosophy of religion but elsewhere as well. He advises them not to become swept up in projects that arise out of and embody presuppositions of rival worldviews (such as naturalism or creative anti-realism), but to pursue a philosophical agenda in which one explores how a person with a Christian perspective ought to think about the various topics central to her discipline. This advice, itself an apt expression of one of the distinctive features of Plantinga's own work, has had a significant impact on the sorts of philosophical projects that have been undertaken in the late twentieth and early twenty-first centuries.

## PLATO

(428/427 BCE–337/336 BCE)

The philosopher Plato was born to an aristocratic Athenian family. His father Ariston was said to be descended from the legendary King Codrus; the family of his mother Perictione was prominent in more historical times.

Dropides, an ancestor of Perictione, was a relative and friend of Solon (as Plato himself reports in the *Timaeus*, 20e). After Plato's father's death, Perictione was remarried to Pyrilampes, a political associate of Pericles and Athenian ambassador to the Persian king. Perictione's brother Charmides and her cousin Critias had a more sinister career, as members (and in Critias's case, ringleader) of the Thirty Tyrants who ruled Athens in a bloody junta, after the defeat by Sparta in 404 BCE.

Plato's family is well represented in the dialogues, perhaps to compensate for his own absence. In the *Charmides*, situated thirty years before the rule of the Thirty, Plato introduces his uncle Charmides as a promising young nobleman, under the influence of his older cousin Critias. The reference here to Charmides' family allows Plato to sing the praises of his own household, as the union of two outstanding families "than which no more noble union can be found in Athens" (*Charmides* 157e). The two families in question are those of Perictione and Pyrilampes, Plato's mother and stepfather. It is Plato's cousin Critias the tyrant (and not, as some scholars have supposed, the tyrant's grandfather) who appears again as introductory speaker in the *Timaeus* and as narrator in the unfinished *Critias*. Plato's older brothers Glaucon and Adeimantus are the chief interlocutors in the *Republic*, his stepbrother Demos is mentioned as a reigning young beauty in the *Gorgias* (481d), and his half brother Antiphon appears in the *Parmenides* as the one who preserves the memory of the philosophical conversation between Socrates, Zeno, and Parmenides. Plato had no occasion to mention his sister Potone, the mother of his nephew Speusippus who succeeded him as head of the Academy.

We are largely dependent on the autobiographical sections of the *Seventh Letter* for information about Plato's life. (The authenticity of this *Letter* is disputed, but even scholars who doubt its authenticity generally assume that the author was well informed.) The author of the *Letter* reports that Plato's relatives in the anti-democratic coup of 404 BCE invited him to join them, and that he, as an upper-class young man of twenty-three with political ambitions, was initially sympathetic; he expected these men to lead the city "from a life of injustice to a just government." But Plato observed that in a short time "they made the previous (democratic) regime look like a Golden Age" (*Epist.* VII, 324d). Thus Plato was repulsed by the behavior of Critias and the oligarchs; on the contrary, he admired the courage of Socrates in refusing to obey the tyrants' command, when they ordered him to lead a death squad against a prominent democrat.

Plato's political ambitions revived in the restored democracy after 403, but after watching the politics of Athens for ten or fifteen years he concluded that the situation was hopeless, and that "the races of mankind would not cease from evils until the class of true philosophers come to political power or the rulers of the cities practice true philosophy" (*Epist.* VII 326b). At the age of about forty, Plato then departed for the Greek cities of southern Italy and Sicily.

Sometime after his return to Athens from Syracuse (c. 387 BCE), Plato began to gather together the group of students and researchers in science, mathematics and philosophy that became known as the school of the Academy. The early fourth century saw the creation in Athens of the first fixed schools of higher education, replacing the wandering Sophists of the fifth century. Antisthenes, the follower of Socrates, and the famous orator Isocrates had both recently established their schools. Unlike these institutions, Plato's community of scholars seems to have had no formally enrolled students and no tuition fees.

We know very little about the functioning of the Academy. The physical basis was a small estate with a garden owned by Plato, in the suburban neighborhood named after a park and gymnasium dedicated to the hero Academos. Formal instruction was probably offered in the gymnasium; the communal meals, or *syssitia*, presumably took place in Plato's villa. We happen to know of one public lecture given by Plato "On the Good." There is no evidence for a curriculum in mathematics and dialectic modeled on the studies of the guardians in *Republic* VII, as some scholars have supposed. There is in fact no evidence for any fixed curriculum. The only contemporary report (other than veiled attacks from Isocrates as head of the rival school) consists of quotations from Attic comedy, which make fun of the haughty manners and elegant dress of intellectuals from the Academy, and of their elaborate pedantry in the botanical classification of a pumpkin.

The intellectual caliber of the school is attested by the quality of its associates: on the one hand, Aristotle, who worked in the Academy for twenty years before Plato's death, and on the other hand Eudoxus, a great mathematician and astronomer, who seems to have maintained close contact with the school over many years, despite philosophical disagreement with Plato on central issues. Clearly, the members of the Academy were as much concerned with ethics and politics as with science and theoretical philosophy; the school is sometimes represented as a training program for statesmen. Plato's personal prestige is reflected in Aristotle's elegy to Friend-

ship, where Plato is called “a man whom the bad do not even have the right to praise, who alone or who first among mortals clearly showed, in his own life as in his teachings, that to become good is also to become happy (*eudaimôn*).”

Plato’s quiet life in the Academy was interrupted in 367 and 361 by two invited voyages to the court of Dionysius II in Syracuse. Plato was persuaded to accept the invitation by his close friend Dion, the uncle of the tyrant, whom Plato had converted to philosophy on his first visit to Syracuse some twenty years earlier. Since the young Dionysius displayed a passion for philosophy, Plato was unwilling to reject this opportunity to influence the politics of the most powerful Greek city of the time. He proved quite ineffective in the intrigues of the Syracusan court, and was barely able to escape safely from his final visit to Dionysius in 360 BCE at the age of sixty-eight. The *Seventh Epistle* presents a detailed account of the Syracusan adventure from Plato’s point of view. It ended in disaster both for Plato and for Sicily. After driving the tyrant out of Syracuse, Dion himself was murdered in 353 BCE. Plato, at seventy-five, responded with an elegy on the death of Dion, ending with the verse “Dion, you who once drove my heart mad with *erôs*.”

## WRITINGS

Of the thirty-six dialogues preserved in the traditional canon (presumably as edited by Thrasyllus in the first century CE), some twenty-six or twenty-seven are generally recognized as the work of Plato. (The authenticity of the *Hippias Major* is contested; some scholars would also defend the *First Alcibiades* and perhaps a few others usually regarded as spurious.) The traditional corpus includes thirteen *Epistles*, most of them now recognized as spurious. Two or three of the *Epistles* have some claim to be authentic; the most important of these, for both philosophical and biographical reasons, is *Epistle VII*.

The only reliable guide to the chronology of the dialogues is the division into three stylistic groups, established by Campbell and Ritter in the late nineteenth century.

Group I: *Apology*, *Charmides*, *Crito*, *Cratylus*, *Euthydemus*, *Euthyphro*, *Gorgias*, [*Hippias Major*], *Hippias Minor*, *Ion*, *Laches*, *Lysis*, *Menexenus*, *Meno*, *Phaedo*, *Protagoras*, *Symposium*

Group II: *Republic*, *Phaedrus*, *Parmenides*, *Theaetetus*

Group III: *Sophist*-*Statesman*, *Philebus*, *Timaeus*-*Critias*, *Laws*

Group III was identified first (as the “late group”) on the basis of several independent studies. These six dialogues are marked by very strong stylistic peculiarities typical of the *Laws*, which we know to have been written towards the end of Plato’s life. Group II includes dialogues stylistically akin to the *Republic*, which show relatively few distinctive features of Plato’s late style. Group I is the default class, the remaining sixteen or seventeen dialogues, from the *Apology* to the *Symposium* and *Phaedo*, in which Plato’s brilliant conversational style bears none of the distinctive marks of the late period.

This chronological division into three groups is only partially in agreement with a conventional division of Plato’s dialogues into early, middle, and late. The dialogues of Group III are all truly “late.” (There was a brief attempt to date the *Timaeus* earlier for philosophical reasons, but that attempt has generally been recognized as a failure. The style of the *Timaeus* was from the beginning recognized as belonging to the latest period.) But the usual classification of “middle” dialogues ignores chronology altogether. It combines two dialogues of Group II (*Republic*, *Phaedrus*) with two from Group I (*Symposium*, *Phaedo*) solely on grounds of philosophical content. Despite their stylistic differences, all four works present the classical version of Plato’s doctrine of Forms. A popular view of Plato’s development locates these dialogues in a “middle period,” divided on the one hand from the more “Socratic” dialogues of an earlier period, and, on the other hand, from the attack on the theory of Forms in the *Parmenides* and hence from the more critical philosophy of the *Theaetetus* and *Sophist*. This tripartite division is not supported by the Campbell-Ritter chronology of the three groups, since stylistically the *Parmenides* and *Theaetetus* are not later than the *Republic*. The notion of a “Socratic” period depends upon a particular interpretation of the role of Socrates in the earlier dialogues.

## SOCRATES

The figure of Socrates appears in every Platonic dialogue except the *Laws*, and he is the chief speaker in all but five. This raises two difficult problems for interpreting Plato’s work. How far does Socrates speak for Plato? And what is the relation between the Socrates of Plato’s dialogues and the historical figure? We deal here with the historical question.

Since Socrates wrote nothing, we are entirely dependent on other writers for knowledge of his thought. The traditional attitude of historians has been to rely on the picture of Socrates presented in Plato’s earlier dia-

logues, supplemented or confirmed by information from Xenophon and Aristotle. The result has been to take dialogues such as the *Laches*, *Euthyphro*, and *Protagoras* as providing a historical account of Socrates, as a moral philosopher who identifies virtue with knowledge, denies the reality of *akrasia* (weakness of will), and systematically pursues definitions of the moral virtues. In these “Socratic” dialogues Plato is thought to be closely following the thought and methodology of his master. On this view, Plato will only gradually develop his own philosophy, first with the doctrine of recollection in the *Meno* and then with the theory of Forms in the *Symposium* and *Phaedo*. This view can be supported by evidence from Aristotle, whose references to Socrates match the picture given in these “early” dialogues.

This account of Socrates has been treated with skepticism in much recent scholarship, because of a realization (pioneered by Gigon but developed by others) that the Socratic literature is a form of fiction rather than of historical biography. This fictional status is particularly clear in the remains of Socratic dialogues by other authors, such as Aeschines or Phaedo, but also in Xenophon’s *Symposium* and in Platonic dialogues such as the *Menexenus*. Plato’s portrait of Socrates is no doubt generally faithful to the moral character of the man as he saw him. But in regard to details of Socratic philosophy and argumentation, Plato would be at least as free as a modern novelist would be in dealing with historical figures. Furthermore, in the view of skeptical critics, Aristotle cannot serve as a reliable witness. He arrived in Athens as a youth more than thirty years after Socrates’ death, and his picture of Socrates can be explained as his own inference from the Platonic dialogues. Judged as a historian of philosophy, Aristotle has serious faults. He generally sees his predecessors through the prism of his own scheme, and his account of the development of Plato’s thought is particularly suspect. Aristotle’s report of Cratylus’s early influence on Plato is scarcely compatible with Plato’s own portrait of Cratylus in the dialogue of that name; and Aristotle’s claim that Plato’s Theory of Forms was derived from the Pythagoreans is not supported by his own account of Pythagorean doctrine. Aristotle never mentions Plato’s much more profound debt to Parmenides’ concept of Being.

For all these reasons, a critical reader may well doubt that we have any reliable information about the philosophy of Socrates. It is perhaps in Plato’s *Apology* that we can best catch a glimpse of the historical Socrates. The *Apology* is a special case among Plato’s writings, since it is not a fictitious dialogue but a courtroom speech, the rep-

resentation of a public event at which Plato claims to have been present. From this and other sources we can form a vivid picture of Socrates’ powerful personality, his strong moral character, and his remarkable skill in elenchus, that is, in arguing his interlocutors into contradiction. But beyond the firm refusal to act unjustly and the conception of virtue (*aretê*) as care of one’s self, or care of one’s soul, our historical knowledge of Socrates’ philosophical views seems to be limited to a handful of moral paradoxes: that no one does wrong voluntarily, that it is better to suffer than to do wrong, that virtue is knowledge, and that no evil can happen to a good man. In order to put philosophical flesh on this skeleton of doctrine, we must turn to the dialogues. But then we can no longer distinguish what derives from Plato’s memory of the historical Socrates from what has its source in Plato’s own artistic and philosophical imagination.

#### THE FIRST DIALOGUES: APOLOGY, CRITO, ION, HIPPIAS MINOR, GORGIAS

Although we do not know the chronological order of the dialogues in Group I, it is natural to begin with the two dialogues directly concerned with Socrates’ trial and death, *Apology* and *Crito*, and with two other very short dialogues, *Ion* and *Hippias Minor*. We connect with this group a much more substantial work, *Gorgias*, which many scholars would put later. These five dialogues serve to illustrate the wide range of Plato’s philosophical concerns, while at the same time revealing no trace of the metaphysics and epistemology that we recognize as distinctly Platonic.

Although it may have been written ten or twelve years after Socrates’ death, the *Gorgias* presents a systematic exposition of Socratic moral doctrine and a strong defense of this view against anti-moralist attack. The *Gorgias* repeatedly recalls Socrates’ trial and matches it with a judgment myth, in which the souls of those who are truly guilty of injustice will be punished. In the *Crito*, Socrates had formulated as his fundamental moral principle that one should never act unjustly, never return a wrong for a wrong. Socrates is prepared to die for this principle, and is unwilling to save his life by an unjust escape from prison. “It is not living that is of chief importance, but living well, and that is living honorably and justly” (*Crito* 48b). *Crito* agrees. Socrates recognizes that, between those who accept and those who reject these principles, “there is no common basis for discussion, no *koinê boulê*, but they must despise one another’s views” (49d). In the *Gorgias* there is no such agreement, and the principle of justice is itself at stake. The Greek conception of justice

(*dikaiousunê*) is broad enough to cover morality generally, understood as respect for the rights of others. (Thus Aristotle defines “justice” as virtue in regard to others.) Socrates in the *Gorgias* has much the same task as later in the *Republic*: to defend the principle of morality against opponents who endorse the ruthless pursuit of wealth and power. The question, “Why be moral?” is posed here in dramatic form, against the background of Socrates’ own fate as a martyr for moral principle.

The Socratic elenchus as practiced in the *Gorgias* is able to show that the anti-moral positions of Polus and Callicles are basically incoherent, but Socrates is less successful in his positive defense of the principle of morality. He relies here on an analogy between virtue or moral integrity, as an internal order of the soul, and the role of order and harmony in other domains: in the health of the body, in the order of the cosmos, and in the successful products of the arts. But an argument from analogy has its limitations. What is lacking here is a positive psychological theory (like the tripartite theory of the *Republic*) as the basis for a constructive argument in support of the conception of virtue as the harmony and health of the soul.

The most important positive doctrine of the *Gorgias* is the claim that all actions are done “for the sake of the good,” that is, for a goal or *telos* that the agent perceives as good (467c–468b). This remains the fundamental axiom in action theory for both Plato and Aristotle; it reappears in the *Republic* as the supreme Form of the Good, “which every soul pursues, and for the sake of which it performs all its actions” (*Rep.* 505d 11). In the argument for this principle in the *Gorgias*, Plato deliberately blurs the distinction between good-for-the-agent and intrinsically or absolutely good. Polus will acknowledge that what people really want is something good, namely good for them or in their interest, but he denies that this is necessarily the honorable or moral thing to do (*to kalon*). Plato’s point will be that moral knowledge consists precisely in the recognition that what is good absolutely (i.e., virtue) is also good for you, so that it is in your interest to be virtuous. This is Plato’s reading of the Socratic paradox that no one is voluntarily unjust.

The *Gorgias* thus expounds, both by paradox and by systematic argument, the principles of Socratic moral philosophy as exemplified in the *Apology* and *Crito*. By contrast, in the *Hippias Minor* we find Socrates arguing for a more perverse paradox, namely, for the blatantly false proposition that anyone who commits unjust and dishonorable actions *voluntarily* is a better person than the one who does such actions unintentionally. The inter-

locutor is unconvinced, and we can only wonder what point Socrates is supposed to be making. This is probably an indirect way of calling attention to the more authentic Socratic claim that in fact no one does such actions voluntarily. But why not? Why does the analogy fail with arithmetic, for example, where the good mathematician makes mistakes on purpose, whereas the bad mathematician does so unintentionally? If moral virtue is a form of knowledge, why is it not to be understood on the model of the arts and sciences? The implicit Platonic answer seems to point to the role of intentions (the verb *boulesthai*, “to want,” is systematically repeated at 366b–367a), and thus to the universal desire (*boulêsis*) for the good recognized in the *Gorgias*. Whatever the implied answer to this paradox may be, the *Hippias Minor* demonstrates Plato’s early preoccupation with the problem of moral knowledge.

Finally, in the *Ion* Plato develops a different Socratic theme concerning knowledge: the refutation of knowledge claims on the part of the poets (*Apology* 22b). Instead of attacking the poets directly, Plato begins with their representative, the *rhapsode* or performer. Socrates’ argument in the *Ion* is a direct refutation only of the claim to knowledge or art (*technê*) on the part of the rhapsode, but the positive theory of poetic inspiration applies to the poet as well. According to this theory, the power of poetry comes from the Muse and is transmitted via the poet to the rhapsode, like the attractive power that is transmitted from the magnet stone via iron rings to other pieces of iron. Hence neither the poet nor the rhapsode needs to understand what is going on. Their divine inspiration is non-cognitive: being possessed by a god, they are out of their mind.

The *Ion* thus presents Plato’s first move in the ancient quarrel between philosophy and poetry, a quarrel that will be dramatically represented in the confrontation between Socrates and the poets in the *Symposium* and will assume canonical form in the criticism of poetry in the *Republic*. The *Ion* is indirectly invoked in the last scene of the *Symposium*, since it provides us with the argument that the narrator has forgotten. In this final episode Socrates is proving to Agathon and Aristophanes, a tragic and a comic poet, that anyone who knows how to compose tragedy by art (*technê*) will know how to compose comedy as well (223d). The needed premise is given by a proposition of the *Ion*, namely, that anyone who possesses the relevant knowledge (*technê*) will be able to deal with poetry as a whole, since it is a single art (532c). With a slight revision, Socrates’ argument against *Ion* will serve as well against Agathon and Aristophanes. In contrast

with the *Republic*, where Plato criticizes poetry first on moral grounds (in Book 3), and then on principles of ontology (in Book 10), in the *Ion* and *Apology* Plato's criticism is more Socratic, rejecting the claims of poetry to be recognized as a kind of knowledge. It is thus aimed directly against the traditional conception of poets as *sophoi* or sages, sources of wisdom. For Plato the quarrel between philosophy and poetry is ultimately a culture war, a competition for the moral leadership of Greek society.

In the course of his attack on poetry in the *Ion*, Plato introduces the important epistemological principle of a one-to-one mapping between a *technê* and its object: "necessarily, the same art will know the same subject matter, and if the art is different, it will know a different subject" (538a). This correlation between a form of cognition and a definite content or subject matter appears frequently in other dialogues (for example *Gorgias* 464b, *Charmides* 171a). In the *Republic* this principle is invoked to show that knowledge and opinion must have different ontological objects (V, 478a); in the *Timaeus* a similar principle is implied as premise in an argument for positing Forms (51d). Problematic in its particular applications, this principle reflects Plato's fundamental realism in epistemology. Truth in cognition reflects reality in the object known: "What *is* completely is completely knowable; what is not in any respect is unknowable in every respect" (*Rep.* 477a 3).

#### DEFINITION AND APORIA: LACHES, CHARMIDES, EUTHYPHRO, PROTAGORAS

On a traditional view, these four dialogues provide something like a philosophical portrait of the historical Socrates: pursuing the topic of moral virtue, seeking definitions of the virtues (courage in *Laches*, temperance in *Charmides*, piety in *Euthyphro*), identifying virtue as a kind of knowledge, and denying the reality of *akrasia*. Most descriptions of the philosophy of Socrates are based upon the evidence of these dialogues, as supported by Aristotle's account. But if Aristotle's account of Socrates is derived from his own reading of these dialogues, his testimony is of no independent historical value. In at least one case Aristotle's report can be seen to be directly dependent on a Platonic dialogue, since for the Socratic denial of *akrasia* he quotes the *Protagoras* verbatim (*N.E.* VII.2, 1145b 24, citing *Prot.* 352c 1).

On the fictional view of the dialogues proposed above, what we have in the *Protagoras* and the dialogues of definition is not documentary evidence for the histor-

ical Socrates but rather Plato pursuing Socratic themes in his own way, and with his own philosophical goals in view. Thus the *Laches* and the *Euthyphro* offer a subtle lesson in the logic of definition, which will be completed in the *Meno*. And in the *Protagoras* we find something entirely new and problematic: a hedonistic anticipation of rational choice theory that is unparalleled in other dialogues.

Whatever Socrates' own concern with definition may have been (and there is no trace of this either in the *Apology* or the *Crito*, nor in the *Ion* and *Hippias Minor*), the treatment of definition in the *Laches-Charmides-Euthyphro-Meno* has a systematic quality and an epistemic orientation that is distinctly Platonic. Unlike the more straightforward search for a definition of rhetoric in the *Gorgias*, which does not raise epistemological issues but leads instead to a formula acceptable to all parties, the attempt to define virtues in these four dialogues of definition is formally aporetic and regularly unsuccessful. Although the search for a definition always fails, in two cases it points incidentally to an account of virtue as the knowledge of good and bad (*Laches* 198c–199e, *Charmides* 174b–e). In the *Protagoras* (as also in *Meno* and *Euthydemus*) virtue is again identified with some kind of knowledge.

The teachability of virtue is a topic debated at length in the *Protagoras* and *Meno*, and raised also in the *Laches* for the special case of courage. The claim of teachability seems to stand or fall with the conception of virtue as knowledge. The *Meno* makes explicit the principle implied at the end of the *Protagoras*: Virtue is teachable if and only if virtue is a kind of knowledge (*Meno* 87b). This assumption reflects the Greek sense that *technê* and teaching go together. But this principle raises the problem posed in the *Hippias Minor*: If virtue is a kind of knowledge, how is it different from other, more professional forms of *technê*? This question is briefly discussed at the beginning of the *Protagoras*: The young Hippocrates wants to study with Protagoras not for professional reasons, in order to become a sophist, but for liberal education, the training appropriate for a free man and citizen (312ab). This leaves open the question of what such training should consist in. We must wait for the *Republic* to get a definite answer to the question of the teachability of virtue. The *Protagoras* and *Meno* present arguments for both sides of the question (see below).

The dialogues of definition direct us to the theory of knowledge by two routes: first, by the suggestion that virtue, the target of definition, is itself a kind of knowledge. And second, by the claim that knowledge as such

depends on knowledge of essences. Thus in the *Laches*, where the two generals Laches and Nicias are being consulted as experts on training in virtue, the request for a definition is proposed as a test of their expertise: “if we know *what virtue is*, we should be able to say *what it is*” (190c). For if we did not know at all what virtue is, how could we advise anyone how to acquire it? (190b). Similarly, if Charmides is temperate, he should have some notion of what temperance is (*Charmides* 159a). In the *Meno* this type of question is justified by the general principle of priority of definition: One cannot know anything whatsoever about *X* unless one knows what *X* is (*Meno* 71b). We will return to this principle below, in discussing the *Meno*.

It is in the *Euthyphro* that the notion of essence or whatness, what *X* is, is most fully articulated as the object to be captured in a definition. To define piety one must specify something quite general, for the pious is “the same as itself in every action... similar to itself and having some one character (*idea*)” (*Euthyphro* 5d). The definiens must be not only coextensive with the definiendum but explanatory of it; necessary and sufficient conditions are not enough for a Platonic definition. Socrates wants to find “the very feature (*auto to eidos*) by which all pious things are pious.” Only then will he be able to “look to this character (*idea*) and use it as a model (*paradeigma*), so that when any action is of this sort I will say that it is pious, and when it is not of this kind I will say that it is not pious” (6e). The definition offered by Euthyphro (“piety is what is loved by the gods”) turns out to fail this test; it is a proprium, an attribute uniquely true of piety, but not an explanatory essence. Socrates complains to Euthyphro: “When you were asked *what the pious is*, you were not willing to reveal to me its essence (*ousia*, literally its being or is-ness), but you gave me instead an attribute (*pathos*), saying that it belongs to the pious to be loved by all the gods” (11a).

The distinction between an essence and an accidental attribute, so fundamental for Aristotle’s philosophy, is here sharply delineated for the first time, but without clear metaphysical implications. In the dialogues of definition, including the *Meno*, essences are presented as logical or epistemological concepts, as items corresponding to a definition, an item true of all the cases, and hence able to serve as a criterion for the use of a term, but without any definite ontological interpretation. Despite the terminology of *eidos* and *idea*, which in later dialogues will serve to designate the Forms of classical Platonic theory, the essences of the *Euthyphro* and *Meno* are not articulated as structures in the nature of things, neither as

immanent nor as transcendent forms. In this situation the reader is free to assume either that the author of these dialogues has not yet decided on an ontological interpretation for his definienda, or that he has chosen to reserve this task for other dialogues, such as the *Symposium* and the *Phaedo*.

### TRANSITIONAL DIALOGUES? *LYSIS*, *EUTHYDEMUS*, AND *MENO*

These three dialogues present or allude to typical Platonic themes in epistemology and metaphysics, but without any definite formulation of what will be the standard theory of the *Phaedo* and *Republic*. Hence they are sometimes described as “transitional.” It is again left to the reader to regard these statements either as deliberately incomplete or as reflecting Plato’s own indecision.

*Lysis* and *Euthydemus* form with *Charmides* a literary group of dialogues with similar introductory episodes, presenting a charming school scene in which Socrates converses with handsome boys or adolescents. (The setting of the *Laches* is comparable, but in that dialogue Socrates converses only with the fathers and not with the boys.) The question of education is implicitly raised by the setting in each case, and discussed at length in the *Euthydemus* and *Meno*. Aside from the literary setting and the general theme of education, in other respects these three “transitional” dialogues are very different from one another.

The *Lysis* is concerned with the topic of friendship and love, a topic discussed below in connection with the *Symposium* and *Phaedrus*. There are a number of parallels between the *Lysis* and *Symposium*), the most striking of which is the concept of a final object of love for the sake of which everything else is loved. In seeking to explain in the *Lysis* why anything is dear or desirable (*philon*), Socrates suggests that one thing is dear for the sake of another, as a doctor is desirable for the sake of health, but that such a regress cannot go on indefinitely: “we must either give up or come to some starting-point (*archê*), which will no longer refer to some other dear, but we will come to “that which is primarily dear” (*prôton philon*), for the sake of which we say that all other things are dear ... This is what is truly dear; the other dear things are like its images” (*Lysis* 219c 5–d5). Since the form of the argument resembles Aristotle’s thesis (in N.E. I.7) that happiness is the supreme good, for the sake of which everything else is good, some scholars have used this parallel to interpret the *Lysis* passage as a reference to happiness. But there is nothing in the text to justify this interpretation. On the contrary, the formula “for the sake

of which” refers to the good in passages cited above from the *Gorgias* and *Republic* (section IV). Furthermore, the context in the *Lysis* identifies the “dear” (*philon*) as the good and the beautiful (216c 6–d2). Above all, the formula “that which is primarily dear” (*ekeino ho esti prōton philon*) is a close approximation to the standard terminology for the Forms in other dialogues, and specifically for the Form of Beauty in the *Symposium* (*auto ho esti kalon* 211d 1). This anticipation of the technical language for Forms, together with the generally quite abstract form of the arguments about friendship, sets the *Lysis* apart from more typical “early Socratic” dialogues such as the *Laches* or the *Euthyphro*.

The *Euthydemus* is equally non-standard for other reasons. Plato presents an entertaining satire on two elderly sophists, the brothers Euthydemus and Dionysodorus, who claim to teach virtue by a shortcut method, and who display their art by confounding the student with a rapid series of fallacious arguments. Their art of unscrupulous refutation, or eristic, is designed to provide the sharpest possible contrast with the genuine Socratic elenchus, represented here not by the usual refutation but by a constructive protreptic in which Socrates argues that wisdom is the only good, ignorance the only evil, and hence that in order to enjoy happiness and a good life (*eu prattein*) one must pursue wisdom and knowledge.

Both Socrates’ protreptic and several of the Sophists’ refutations contain enigmatic allusions to Platonic doctrines presented in other dialogues. In the most surprising of these allusive passages, the young Clinias compares mathematicians to hunters because they must turn over their findings to someone else. Just as hunters turn over their catch to cooks, who know how to make good use of it, mathematicians, if they are wise, will turn over their discoveries about reality (*ta onta*) to dialecticians (*hoi dialektikoi*) to make use of (*Euthydemus* 209c). This subordination of mathematics to dialectic is scarcely intelligible without the epistemology of Books VI and VII of the *Republic*. But this is not the only case where the *Euthydemus* anticipates doctrines to be developed in later dialogues, including an allusion to recollection (296d 1) and a hint that the relativism of Protagoras may be self-refuting. (Compare *Euthydemus* 286c 2–4 with the *peritropē* argument of *Theaetetus* 170a–171c.) There is also a rough version of the principle of non-contradiction (293b 8–d 1), and a kind of caricature of the problem of the presence of “the beautiful itself” in the many beautiful things (300e–301a). The *Euthydemus* is thus one of the most comical and also one of the most puzzling of all the dialogues.

## MENO AND RECOLLECTION

The *Meno* introduces the doctrine of recollection, which plays an important role in two later dialogues, the *Phaedo* and *Phaedrus*. Like the sixteenth-century theory of innate ideas which it inspired, Plato’s doctrine of recollection is an antecedent both for the Kantian notion of a priori knowledge and for contemporary theories of innatism in psychology. The fundamental thesis of the Platonic doctrine is that there is something in the nature of the human mind that predisposes it to grasp the nature of reality: “the truth of beings (*ta onta*) is forever in our psyche” (*Meno* 86b 1). The supernatural form this doctrine takes in Plato is determined by its association with the Pythagorean doctrine of transmigration, which implies a previous existence for the human soul. The *Phaedrus* give a mythical account of prenatal experience, in which human souls travel with the gods outside the heavens, to a vision of ultimate reality described in terms of the Platonic theory of Forms. It is our recollection of this prenatal vision of transcendent Beauty that explains the phenomenon of falling in love.

In the *Phaedo* as well recollection takes as its object the eternal Forms, illustrated in this dialogue by the Equal itself, as distinct from sensible equals. This choice of the Form of Equality in the *Phaedo* connects recollection with mathematics, as in the *Meno*, where recollection is illustrated by the geometry lesson to an uneducated slave boy. (The boy is led by a series of questions to see, first, that he is unable to double a square by numerical additions to the side, and then to recognize the solution when Socrates draws the diagonal.) But it is not only mathematical concepts but conceptual thought generally that is involved in recollection. As the *Phaedrus* insists, a human soul must be able “to understand what is said according to a form (*eidōs*), passing from many sense perceptions to a unity gathered together by rational thought. And this is recollection of what our soul once saw when it traveled together with a god and looked beyond what we now call reality and was able to rise up into the really Real” (*Phaedrus* 249bc). The myth of the *Phaedrus* thus represents Plato’s most brilliant expression of the classical Greek view that reason (*nous*), the cognitive capacity to understand the world, constitutes the immortal, godlike element in the human psyche.

The *Meno* presents a simpler version of the doctrine, without any explicit reference to the theory of Forms. Recollection is introduced in response to Meno’s paradox about learning something new, or seeking for something you do not know. Meno in turn is responding to the principle of “Priority of Definition,” which claims that you

cannot know anything about *X* unless you know “what *X* is.” How then do we ever get started? Recollection answers that what we learn is not new; we only need to be reminded. In the fuller doctrine formulated in the *Phaedo* and *Phaedrus*, it is not Socratic questioning but sense perception that serves to trigger a conceptual understanding (of equality, beauty, and the like) that is provided by the mind from its innate resources.

The “transitional” status of the *Meno* is indicated not only by the fact that it presents the simplest version of recollection, but also by tentative statements of other themes that are more fully developed in the *Phaedo* and *Republic*: the distinction between knowledge and opinion, the method of hypothesis, and two levels of virtue, one dependent on right opinion and the other on knowledge (*Meno* 99a–100a).

### PLATO’S THEORY OF ERÔS

Love is a central topic in three Platonic dialogues (*Lysis*, *Symposium*, *Phaedrus*); it also plays an important role in the moral psychology of the *Phaedo* and *Republic*. The fundamental idea is expressed symbolically in Plato’s etymological reading of *philo-sophia* as love of wisdom or passion for knowledge (*Phaedo* 66e2, 68a). In the psychological theory of the *Republic*, all three parts of the soul are characterized as distinct forms of love: desire for learning (*to philomathes*), desire for honor, desire for pleasure and wealth. Thus for the rational part the object of desire is “to know the truth” (581b). Like the religious mystics, Plato makes use of the language of sexuality to express philosophical passion: the true lover of knowledge will not be relieved of his pangs of *erôs* “until he grasps the nature of each Form with the appropriate part of the soul, and clinging to and mingling with the truly real, he begets truth and understanding (*nous*)” (490b). Plato anticipates the Freudian notion of sublimation in his account of the channeling of desire (485d); the notion of unconscious Oedipal desires is recognized in his description of criminal dreams (571c–d). There is also a superficial analogy between Plato’s tripartite psychology and the Freudian trio of ego, superego, and id, but the second principle is in fact quite different in each case. Plato’s *thumos* or “spirit” is a principle of anger, pride, and self-assertion, in contrast to the guilt-producing and self-punishing aspects of the Freudian superego. What the two psychological theories have in common is the understanding of psychic conflict in terms of deep divisions within the soul.

Plato’s theory of *erôs* has been criticized for devaluing the love for an individual person in favor of love for

an abstract principle like the Forms. Thus in the ladder-of-love passage in the *Symposium*, the lover who follows Diotima’s instructions will leave behind his initial passion for an individual beauty in order to rise to more spiritual beauties and finally to the Beautiful itself. Even in the *Phaedrus*, where the philosophical lovers assist one another in growing the wings of their souls and escape together from the cycle of rebirth, their real love is for the Form of Beauty. But it is misleading to evaluate the Platonic conception of *erôs* as if it were a contribution to the modern theory of love. Plato’s concern with interpersonal love is better illustrated by his treatment of friendship (*philia*), as depicted in the case of the two boys Lysis and Menexenus in the *Lysis*. So it is the *Lysis* that provides Aristotle with the starting point for his own theory of friendship. The philosophical importance of *erôs* for Plato lies not in its role as a relation between persons but rather in its function as the energy driving us to pursue what we take to be good (or good-and-beautiful) and hence, when properly enlightened, to pursue the Good itself. Rightly directed, *erôs* is *philo-sophia*, the passion for wisdom. Only wisdom can recognize the true nature of the Good, “which every soul pursues and for the sake of which it performs all its actions” (*Rep.* VI, 505d11). It is in this sense, as knowledge of the good, that wisdom is equivalent to virtue, since it guarantees that the *erôs* of the wise will be directed to what is objectively good. The emotional drive in question is, however, intrinsically ambivalent; in the absence of wisdom, *erôs* can also become the criminal passion that impels the tyrant to psychological destruction in *Republic* Book IX.

### VIRTUE AND KNOWLEDGE: PLATO’S MORAL PSYCHOLOGY

Many scholars have followed Aristotle in holding that Socrates identified virtue with wisdom and thus ignored the power of irrational emotion to influence action. The conception of virtue as a form of knowledge is represented in a number of dialogues. The neglect or denial of irrational emotion is most extreme in the *Protagoras*, where Socrates interprets *akrasia* as an error in measuring future pleasures and pains. What is generally understood as being overcome by passion is there explained as an intellectual mistake. No other Platonic text explicitly denies the reality of *akrasia*. But several passages in the *Gorgias* and *Meno* have been taken to imply this, by suggesting that everyone desires good things, and hence that virtue consists only in the knowledge of good and bad, that is, in the ability to choose the goal of action correctly.

Nowhere, however, does either Plato or Socrates maintain that *all* desires are desires for the good. On the contrary, the *Gorgias* implicitly distinguishes between *boulesthai* as desire for good things and *epithumia* as desire for pleasure (so explicitly at *Charmides* 167e; this distinction between rational desire or *boulêsis* and non-rational desire or *epithumia* becomes fixed in Aristotelian terminology). The doctrine that virtue is a kind of knowledge can be understood as a paradoxical exaggeration, designed to focus attention on the practical importance of a correct conception of the good, and hence on the value of the Socratic elenchus in leading interlocutors to recognize their own ignorance. But in the face of this exclusive focus on moral knowledge, the existence of *akrasia* (that is, of people acting against their better judgment) is a challenge. The last section of the *Protagoras* was written in response to this challenge. But some readers will doubt that either Plato or Socrates ever held the extreme view presented in this dialogue, namely, that the intellect is all-powerful in the control of human action, so that *akrasia* is simply an error of judgment and vice is always due to ignorance.

What is clear, in any case, is that if Plato ever held such an intellectualist view, he abandoned it in the *Republic*. The exposition of the tripartite psychology includes an unmistakable description of *akrasia* in the story of *Leontius* (who is disgusted at his own weakness in “being overcome by the desire” to gaze at corpses, *Republic* 440a 1). In this tripartite theory, two out of three psychic principles represent emotional drives that can conflict with, and sometimes overcome, the rational judgment of the *logistikon* (the calculating part) as to what is best to do. These two principles are the *thumos*, or “spirit” of anger and pride, and the *epithumêtikon* of animal appetite—hunger, thirst, and sexual desire. The division into three parts rests upon a careful distinction between sheer desire, for example thirst as desire to drink, and the rational desire for something good, as desire for a good drink. The aim of Plato’s tripartite division is precisely to account for the phenomena of psychic conflict, in this case between the desire of a thirsty man to drink and his rational judgment that the water is not good to drink.

On the basis of this division into three parts of the soul, each with its characteristic desire, Plato provides a psychological definition of the virtues in terms of the harmonious working together of all three parts. It is the function of the rational part (*logistikon*) to rule over the others in deciding what is the best thing to do; and wisdom is the excellence of this part in judging well. Courage is the excellence of the spirited part, maintaining its loy-

alty to the commands of reason and law in the face of danger and temptation. The other virtues consist in cooperation, that is, in willing obedience to the commands of the rational part. Hence virtue can be defined as psychic harmony, and vice defined as psychic disorder or *stasis*, civil war between the parts of the soul.

By this assimilation of virtue to psychological health, vice to psychological disorder, Plato formulates his first answer to the challenge to morality (formulated by Thrasymachus in Book I, reformulated by Glaucon and Adeimantus in Book II). But the *Republic* actually represents two different views of psychic disorder. In Book IV the vices are described in terms of disobedience or revolt on the part of the irrational emotions; in this context, there is no distinction to be drawn between vice and *akrasia*, conceived as unruly behavior by the lower parts. (This is also the picture of vice presented by the behavior of the disobedient horse in the *Phaedrus* myth.) In Books VII and IX, on the other hand, the irrational desires are presented not as disobedient subjects but as successful rebels, who have driven reason from the throne and taken its place as rulers in the acropolis of the soul (*Rep.* 553d, 560b–d). The *logistikon* now appears as their subject, carrying out their commands. Thus we have in Books VII–IX a conception of vice represented not as *akrasia*, not as a failure of reason to control the emotions, but rather as moral ignorance, that is, a mistaken conception of the good (as in Aristotle’s distinction between vice and *akrasia*).

This Platonic distinction between two conceptions of vice, only one of which corresponds to *akrasia*, is developed in different ways in several later dialogues. Thus the *Sophist* (228a–229a) distinguishes moral ignorance from *ponêria*, vice as a kind of disease; the former is to be treated by instruction, the latter by punishment. The *Timaeus* 86b–e proposes a similar distinction between moral ignorance and madness due to excessive pleasures and pains; the latter is caused by a disordered condition of the body. The Socratic paradox will be maintained for both kinds of vice, since the loss of self-control from bodily causes can be seen as involuntary (*Tim.* 86e 3). The connection of the non-rational desires with the body rather than with the soul proper, hinted at in the *Phaedo* and in *Republic*, is most systematically developed in the *Timaeus* (42a–e), where the non-rational soul is created by the lesser gods in connection with their creation of the body.

#### POLITICAL CONSTRUCTION: FROM THE REPUBLIC TO THE LAWS

The tripartite psychology of the *Republic* has an exact parallel in the tripartite social structure of the envisaged

polis. Corresponding to reason, spirit and appetite are the three classes of rulers, soldiers, and producers (the latter class consisting of farmers and craftsmen). Scholars have suggested that the psychic tripartition is an artifact of this parallelism, and that Plato's moral psychology would more properly take the form of a bipartition into reason and emotion, as in Aristotle's *Nicomachean Ethics* (I.13) and in modern theories of action based on belief and desire. (Plato actually flirts with such a bipartite psychology in Socrates' first speech in the *Phaedrus* 237d–e). However, Plato remains loyal to the tripartite psychology in non-political settings as well (in Socrates' second speech in the *Phaedrus*, and in the *Timaeus*). There is a theoretical advantage to recognizing more than one type of non-rational emotions, some of which are more amenable than others to rational control.

It is essential to the scheme of the *Republic* that the city is conceived as a great organism, just as the psyche is conceived as a micro-community. Unity and cohesion are fundamental principles of excellence for the city as much as for the individual. Plato's political aim, the greatest good for the city, is for the citizens to share one another's joys and sorrows with a unanimity like that of the parts of a human body, where the whole person suffers if a single part is in pain (V, 462a–e). But this organic unity can be achieved only on the basis of a functional division of labor between the three social classes. Thus the political definition of justice in terms of each group doing its proper job (in Book IV) is prefigured by the initial division of labor through which the city comes into being (in Book II). The first society arises from the mutual need of individuals for one another: one to grow food, one to build houses, one to make clothes. Hence the fundamental principle of specialization: one person, one work.

Instead of a social contract theory, in which civil society is conceived as an artifact designed to bring people out of the state of nature, Plato claims to find a natural basis for social life in reciprocal need and the advantages of cooperation (II, 369–370). He thus sees human beings as by nature friendly and cooperative, in deliberate contrast to the Hobbesian view of human nature presented by Glaucon in the ring of Gyges story earlier in the same book (II, 358e–362c). Since the division of labor is to the advantage of all in the political as well as in the economic sphere, the city of the *Republic* will have a natural cohesion that is absent from the historical cities of Greece, which are (as Socrates observes in a moment of Marxian insight) really two cities, the city of the rich and the city of the poor (IV, 422e–423a). This pathological split will be avoided in Plato's city, because

there the ruling classes will have no private property, no money, and no nuclear family to generate selfish preferences. The needs of the rulers will be provided for by the farmers and craftsmen, who alone will have private belongings and wealth. Thus the ideal city will radically separate economic power from political power; the rulers, who alone possess the latter, will be systematically excluded from the former.

The political structure of the *Republic* is built up in successive stages, beginning with cooperation and division of labor, then the division into three classes, followed by three culminating waves of paradox in Book V. The first wave is the principle of equal education and access to political power for gifted women; the second wave is the community of wives and children, in other words, the abolition of the nuclear family. (This innovation brings with it some extraordinary marriage arrangements requiring a great deal of systematic deception on the part of the rulers. The principle of benevolent deception was established earlier, in presenting the myth of metals as a noble lie in Book III, 414b–415c.) The third wave, and the condition of possibility for the entire scheme, is rule by philosopher-kings. Only philosophers are competent to rule the city, because only philosophers have access to the Form of the Good and the Form of Justice, the knowledge of which is strictly necessary if the rulers are to make the city just and good. The system of education designed to produce these rulers will be discussed below.

Did Plato abandon these ideals in his later work? An answer to this question is provided in two documents, the *Statesman* and the *Laws*. The *Statesman* is a puzzling work. It purports to define the statesman, or *politikos*, and to show how he is different from the philosopher. It then defines *politikê*, the art of statesmanship as a kind of knowledge or understanding that is competent in giving orders, that is, in ruling. But the dialogue never specifies the content of this expertise. It says only that the possession of such knowledge by the ruler (or rulers) is the one indispensable condition of a genuine constitution; all other constitutions can be no better than imitations of this model. Constitutions are ranked by two criteria; the old classification according to rule by one, few or many is now crossed with the new criterion of lawful or lawless. As lawless one-man rule, tyranny is still the worst form of government, but democracy is now the least bad; the best imitation of the model is a constitutional monarchy (302b–303).

How is the ideal model of the *Statesman* essentially different from the constitution of the *Republic*? More precisely, how is this ruler with authoritative knowledge dif-

ferent from a philosopher-king? If we assume that the *Republic* is in the background, we can see Plato as returning here to familiar territory but from a very different point of view. The Forms are not mentioned as objects of the statesman's expertise (although the dialogue does refer to incorporeal and non-sensible realities); nothing whatever is said about the content of the statesman's knowledge or the nature of his training. We are told only that he will act with justice, and so as to make the city and the citizens better (293d8–9, 297b 2). So presumably the perfect statesman must know what is justice and what is good. Whether or not he knows them as transcendent Forms is left for the reader to surmise.

The one point of general theory that is carefully discussed in the *Statesman* is whether or not the true ruler's knowledge should in principle be supreme over and above the law, and the answer of this dialogue is a resounding "yes." The regime of legality is an imitation, a second-best, in the absence of the scientific ruler. But nothing in the human world can be superior to genuine knowledge.

At first sight, the position of the *Laws* is diametrically opposed, for here Plato provides the first philosophical argument in favor of the principle that a city should be ruled by laws rather than by men, and that human rulers should be servants of the law (*Laws* IV, 715c–d). Law, indeed, is said to be "the dispensation of reason (*nous*)" (714a). But on a closer look the two texts are not so far apart, since the omniscient ruler of the *Statesman* is not to be found among us, and according to that dialogue also the best human constitutions must be law-abiding. In the *Laws*, despite the shift in favor of the rule of law, Plato still yearns nostalgically for the unfettered authority of the truly wise ruler. He is now convinced that human nature is too weak to bear such unlimited power and still remain uncorrupted (IV, 713c with IX, 875b, the source of Acton's principle that absolute power corrupts absolutely). But if such a man could be found, he would not need to be controlled by laws. "For neither law nor any order is superior to knowledge; and it is not right for reason (*nous*) to be subordinate to anything" (IX, 875c). This is precisely the thesis of the *Statesman*.

But the author of the *Laws* has given up hope of the messianic politics sketched in the *Republic*. The detailed constitution of the twelve books of the *Laws* presents a complex political system tightly controlled by an extremely precise legal code, with many invasions of individual liberty, and a social structure very different both from that of the *Republic* and also from that of fourth-century Athens. The society of Plato's last city prefigures

that of Aristotle's *Politics*, Book VII. In both constructions one social class possesses all the property and is the only group to bear arms and to have political rights, while the mass of the population—the producer class of the *Republic*—is disenfranchised and reduced to slavery or limited to foreign residents. In the *Laws* the city has become a club of the leisured class, whose members can devote all of their time to the practice of political virtue, to the study of the law code, and to ritual celebrations in song and dance.

The city of the *Laws* is an entirely new project, based upon a different political philosophy in which the rule of law is supreme. The constitution includes several realistic political institutions, representing a compromise with Athenian democracy, which introduce a career of public service into the utopian life style of this privileged class of citizens. But despite all these innovations, one fundamental principle of the *Republic* has been preserved. Although there is no place for a supreme philosopher-king in this law-bound aristocracy, a kind of counterpart is nevertheless preserved in the institution of the Nocturnal Council, introduced at the end of the work. This Council is a group of high officials meeting daily to study the philosophical foundations of legislation, and to revise the laws if need be. To this extent the author of the *Republic* remains loyal to himself. The construction of a good constitution will still require the presence of philosophy in a position of the highest influence.

#### RHETORIC AND DIALECTIC: GORGIAS AND PHAEDRUS

Rhetoric, the art of public speaking, was developed by the Sophists into a powerful instrument of political leadership; and Plato's chief rival as an educator was the orator Isocrates. Corresponding to its important role in Greek society, rhetoric is a frequent topic of the dialogues, notably in the *Gorgias* and the *Phaedrus*, but implicitly also in the *Protagoras*. In the latter dialogue Socrates presents his own art of question-and-answer as an alternative to, and ultimately a victor over, the art of long speeches represented by Protagoras.

The contest between Socrates and Protagoras is thus a contest between two forms of *logos*, two methods for winning an argument. In the *Gorgias* this contrast of methods reflects the deeper contrast between values. The goal of Socrates' rhetorical opponents is wealth and power, and their speeches aim to persuade the majority. Socrates' goal is virtue and knowledge, and his methodology is designed to get only the agreement of his interlocutor (472b). Socrates' characteristic device is the

elenchus: deriving a denial of the interlocutor's thesis from premises that the interlocutor will accept. This is the method that Plato describes retrospectively in the *Sophist*: if someone claims to have knowledge who is in fact ignorant, "since his opinions are confused, it is easy to examine him and to bring these opinions together in discussion and, setting them side by side, to show that they contradict one another" (230b). In the *Gorgias*, Socrates refers to this as the art of conversation (*dialegesthai*) in contrast to the art of speech-making (*rhetorikê*) (448d 10). But Socratic dialectic must also be distinguished from eristic, the pursuit of contradiction for its own sake (illustrated by the notorious behavior of the two sophists in the *Euthydemus*, above in section VI). Unlike this frivolous form of refutation, the Socratic elenchus is designed to free the interlocutor from the false conceit of knowledge, so that the way is opened for him to begin to learn.

In the *Republic* Plato will transform dialectic, as the art of question and answer, into a much more ambitious and constructive method. We look first at his treatment of rhetoric, which is quite different in the *Gorgias* and the *Phaedrus*. In the *Gorgias*, rhetoric is represented by Socrates' opponents, and in particular by Gorgias, the most famous orator of the late fifth century, and teacher of Plato's rival Isocrates. Gorgias stands for the political power of unscrupulous persuasion, and thus for power without moral responsibility or even, in the case of his followers Polus and Calicles, for power without moral restraint. In the *Gorgias*, Socrates argues that the rhetorical practice of public persuasion, without principles of justice and without knowledge, is not an art at all, not a *technê* but a mere empirical knack. To qualify as a *technê* rhetoric would need the theoretical clarity and contact with truth that are characteristic of knowledge. As seen in the *Gorgias*, rhetoric clearly lacks both.

In the *Phaedrus*, by contrast, Plato is concerned with rhetoric not as an instrument of political power but as the form of prose literature, and his sample is not a political speech but a series of epideictic displays on the topic of love. Socrates surprises his interlocutor by not limiting the rhetorical art to speeches in law courts and in public assemblies but generalizing it to cover "the bewitchment of the soul through discourse" (*psychagogia dia logôn*, 261a8). Rhetoric is here conceived as the art of speaking and writing well. Plato makes one of his notable contributions to literary criticism in the discussion of what he calls "literary necessity" (*logographikê anankê*) linking the parts of a composition to one another. Socrates observes that a discourse (*logos*) should have an organic form, like

a living creature, "so as to be neither headless nor footless, with middle parts and extremities that are fitting both to one another and to the whole" (262bc). It turns out that to produce discourse with this quality, the author must be able to gather similar things into unity, and also divide them by kinds. The art of these collections and divisions is called "dialectic" (266c), and it seems that a true art of writing or speaking must include or presuppose dialectic. If rhetoric is to be a *technê*, it will not follow the path of the professional orators (269d). True rhetoric would, for instance, require a philosophic understanding of the psyche and of its natural varieties (271d). Like the *Gorgias*, the *Phaedrus* ends by rejecting the claims of ordinary rhetoric to be regarded as a *technê*. But if Plato's judgment of rhetoric in this dialogue tends to be much more positive than in the *Gorgias*, that is because the art of *logoi* is here conceived constructively as the art of writing, including philosophical writing, and hence as an application of dialectic rather than an alternative to it.

While dialectic was introduced in the *Gorgias* and elsewhere as the Socratic art of conversation (*dialegesthai*) conducted in question-and-answer form, in the *Republic* it becomes the highest method of philosophy, the method by which the intellect ascends to the cognition of transcendent Forms. More specifically, it is the method of passing beyond the assumptions (hypotheses) that function as premises of reasoning in the deductive sciences of mathematics. Dialectic thus presupposes the method of hypothesis developed in the *Meno* and *Phaedo*, a method derived from mathematics, according to which a problem can be solved conditionally on the basis of an explicit assumption. By subjecting these assumptions to critical scrutiny, dialectic is somehow able to rise above them and thus reach the *anhypotheton*, the object of unconditional knowledge, in other words the Forms (VI, 511b). The actual practice of dialectic is not described, but its study follows ten years of training in mathematics. Its connection with the conversational method of question-and-answer is preserved in the requirement that the dialectician must be able to "give an account (*logos*) of the being (*ousia*) of each thing" (VII, 534), that is, to give a systematic answer to the question "What is it?" Giving such an account will necessarily involve a reference to permanent essences or Forms.

Dialectic is described quite differently in the later dialogues, but it remains the highest form of knowledge, the essential method of philosophy. It continues to proceed by question and answer, and to seek the definition of essences in answers to the question "What is X?" According to the *Philebus*, dialectic still takes as its object "true

being which is forever unchanging,” the reality “which neither comes to be nor passes away” (58a2, 61e2),” precisely the kind of Being represented by the Forms in Plato’s classical theory. In the *Sophist* and *Statesman*, however, as in the *Phaedrus*, dialectic is described in more formal terms, as the method of gathering pluralities into unities and dividing them into kinds (*genê*), where the term *eidos*, which designates a transcendent entity in the classical theory of Forms, seems to be used in the more strictly logical sense of “species” or sub-kind. Instead of the relation to mathematics and the method of hypothesis, which is fundamental for the conception of dialectic in the *Republic*, it is the method of Division that is central for dialectic in the later dialogues, from the *Phaedrus* to the *Philebus*. This shift in the description of dialectic corresponds to a different, less metaphysical way of referring to the objects of knowledge (see further below).

#### ESTHETICS AND EDUCATION: PLATO AGAINST THE POETS

Can virtue be taught? That is the question raised dramatically in the school scenes of several early dialogues, and discussed at length in the *Protagoras* and *Meno*. The conclusion of the *Meno* is problematic. Socrates insists that we must first define virtue before we can answer this question. Since we have no definition, we must answer it conditionally. If (and only if) virtue is a kind of knowledge, it is clearly teachable. But such virtue is hard to find. What about virtue based on correct opinion (*doxa*)? It might give the same results as virtue based on knowledge, but would it be teachable? The *Meno* ends without any clear statement on the question of teachability.

If there is a Platonic answer to this question, it must be found in the educational scheme of the *Republic*. There is a different but parallel answer in the scheme of education in the *Laws*. For Plato (as later for Aristotle), an essential function of the city is to make its citizens good, that is, virtuous. Hence education is a central concern in both dialogues. The *Republic* describes two stages of education, one for the wider guardian class (in Books II and III) and one for the select group of future rulers (in Book VII). Corresponding to these stages we have two accounts of virtue, one based on right opinion (in Book IV) and one on philosophic knowledge (Books VI–VII). The limitations of the initial account of the virtues in Book IV are visible only retrospectively, after the distinction between knowledge and opinion is drawn in Book V. Only after this introduction of philosophy can we appreciate the ambiguous status of wisdom, and hence of virtue generally, as defined in Book IV.

In order to become virtuous, the entire guardian class must have the basic system of education described in terms of music and gymnastics. Only a smaller group will enjoy the training in philosophy, consisting of ten years of mathematical science followed by dialectic and culminating in the vision of the Form of the Good. The first stage of education will produce “citizen excellence” (*politikê aretê*); the higher education, accompanied by years of public service, will yield the unqualified virtue of the philosopher-kings. If we take this as Plato’s answer to Meno’s question “Is virtue teachable?” the answer is: yes, but not by the available means of education. Only a fundamental change in the conditions of social life would make it possible to produce in a regular way the kind of excellence that occurs sporadically today, by good luck or (as the *Meno* says) by divine dispensation.

Under the more favorable conditions of Plato’s city, the character of the guardians will be shaped by a carefully controlled cultural environment, that will include a radical change in the literary and musical content of their education. Plato here defines his position in the culture war he describes as the ancient quarrel between philosophy and poetry (*Rep.* X, 607b; see above). All of the arts will play an essential role in the moral education of the young guardians, but it is poetry that is the center of Plato’s attention, because of the fundamental influence of Homer and the tragedians on Greek moral thought. Since Plato regards their influence as essentially malignant, he would eliminate from his educational scheme major themes of Greek poetry (Books II–III). Following Xenophanes and others, he attacks as immoral the Homeric depiction of the gods. His basic theological principle is that the gods are good, and are therefore (by the law of transitive causation) cause only of the good, and they must be represented accordingly (III, 379a–380c). Plato thus avoids the thickets of theodicy; there is no problem of justifying the action of the gods, since they are never responsible for evil. The actions of glorified heroes must also be represented in such a way as to provide a moral paradigm for the young guardians.

Finally, when Plato returns in Book X to the restrictions on poetry, he attacks the imitative arts generally on epistemic grounds, as being at third remove from truth. He also blames the emotional impact of epic and tragedy for relaxing the moral discipline of the soul. Hence the poets are to be banned from Plato’s city, and readmitted only if their influence can be morally justified (697b–e). This is a famous challenge to future aesthetic theory. Aristotle’s *Poetics* and Sir Philip Sydney’s *Defence of Poesie*

count among the more noteworthy responses to Plato's challenge.

At the same time, a properly controlled aesthetic environment is recognized as decisive for the development of virtue in the young. This includes the visual arts, but poetry and music are of particular importance, since rhythm and harmony, more than anything else, penetrate deep into the soul (III, 401d). Because of the close connection between the beautiful and the good, the young should be surrounded by beauty in all its forms, so that later, when moral principles are presented to them in rational teaching (*logos*), they will recognize these as familiar and congenial (402a). The positive use of the arts in education is developed further in the *Laws*, with special attention to dance, since there will be choruses for the citizens at all ages (Books I–II). Literature and lyre-playing will be essential in education, and the Athenian Stranger who speaks for Plato in the *Laws* holds up the Platonic dialogue, and specifically the text of the *Laws*, as a model for the literature to be used in schools (*Laws* VII, 802 ff; 811c–e). In both the *Republic* and the *Laws*, the content of literature and music is interpreted in moral terms: “rhythms and the performing arts as a whole (*pasê mousikê*) are the imitations of the characters of better and worse human beings” (*Laws* VII, 798e).

Plato's positive evaluation of poetry, implicit in his use of literature in these proposed schemes of education, receives a theoretical development in the account of poetic inspiration as divine madness in the *Phaedrus* (245a). In the *Ion* (as in the *Apology*) the notion of divine possession for the poet was employed ironically, in order to emphasize the poet's lack of cognitive competence. In the *Phaedrus*, on the other hand, the madness of artistic inspiration is presented as a positive force, in parallel with the divine madness of love which carries us back in recollection to a prenatal vision of the Forms. Plato never says that artistic experience, like erotic experience, can trigger recollection of the Forms. But it is easy to see how a later Platonist such as Plotinus (and his followers, such as Proclus), less fearful than Plato of the moral and intellectual dangers from poetry, could make use of the *Phaedrus* parallel between poetry and love to develop a powerful conception of art as a privileged mode of access to a higher level of metaphysical reality. This was a theory much in vogue among the Romantics of the nineteenth century, who took over Plato's theory of poetry as divine possession, deprived it of its ironic sting, and transformed it into a theory of creative genius.

## THE CLASSICAL DOCTRINE OF FORMS

The centerpiece of Platonic philosophy is the metaphysical theory of Forms or Ideas, presented in three dialogues (*Symposium*, *Phaedo*, and *Republic*), utilized in two others (*Cratylus* and *Phaedrus*) and criticized in a sixth (*Parmenides*). Whether some version of this theory reappears in dialogues later than the *Parmenides* is a question to be discussed below. The term “idea” is a transliteration of *idea*, one of Plato's terms for the Forms. Since the English word suggests something mental or psychological, “idea” seems misleading as a designation for Platonic Forms, which are clearly intended to be mind-independent realities.

As we have seen above, the dialogues of definition present the object of definition as the being or essence (*ousia*) of the subject under discussion and distinguish it from an ordinary property or attribute (*pathos*). The essence is not only true of all and only instances of the subject, but it is also explanatory of *being the thing in question*. The answer to a question “What is X?” should say what X is, in the sense of explaining what makes something an X. (*Meno* 72c 8.; *Euthyphro* 6d 11). Thus being dear to the gods, although true of all and only pious actions, does not say *what pious is*, because it does not tell us why the gods favor some actions rather than others (*Euthyphro* 11a). These logical properties of essences prepare for, but do not imply, the metaphysical doctrine of the *Phaedo* and *Republic*.

Similarly, the terminology for *definienda* in the dialogues of definition prefigures the later terminology for the Forms, but in a pre-theoretical way: *eidos* and *idea* are ordinary terms for features, structures, or kinds of things. Aristotle says that Socrates was pursuing universal definitions, but that he did not separate the universals as Plato did (*Met.* 1078b 30). Hence some scholars have interpreted the essences of *Meno* and *Euthyphro* as immanent (Aristotelian) rather than transcendent (Platonic) forms. But the texts do not support such a distinction. For example, the idea of piety is described as a model (*paradeigma*) for deciding whether a given action is pious (*Euthyphro* 6e); but the *Euthyphro* does not tell us whether this model would be located in the mind or in the nature of things. The ontology of the *definienda* in these dialogues is left strictly indeterminate.

Plato supplies a metaphysical framework for the objects of definition in the *Symposium* and *Phaedo*, with a further development in the *Republic*. These dialogues introduce the conception of eternal, unchanging Being as location for the objects pursued in dialectic. Plato has taken over from Parmenides this notion of Being or

What-is (*to on*) as an unchanging reality accessible only to thought or rational understanding (*nous*), defined by contrast with the changing realm of Becoming that is accessible to the senses. Plato's conception differs from that of Parmenides in two respects: Platonic Being exists in the plural (*ta onta* or The-things-that-are), corresponding to the plurality of Forms, while for Parmenides, Being is a unique One; and Becoming is allotted a certain measure of reality, whereas its ontological status for Parmenides seems to be that of appearance only.

This metaphysical conception of the Forms, which is assumed throughout the argument of the *Phaedo*, is most succinctly formulated in the final description of the Beautiful in Diotima's lesson on love, as reported by Socrates in the *Symposium* (210e–211b). The Form of Beauty (literally “the Beautiful itself”) is there distinguished from the many beautiful things by (1) being one (unique) rather than many; (2) being a Being rather than a Becoming, that is, being eternally and unchangeably beautiful, rather than becoming beautiful at one time and not beautiful at another; (3) being only and always beautiful, rather than beautiful in one respect or for one observer, but not beautiful in another respect or for another observer. Hence (4) the being of the Form, which is accessible only to thought or understanding, is distinct from its appearance in becoming, which is accessible to opinion (*doxa*) and sense-perception. (5) Anything else that is beautiful is such only because of its dependence on the Beautiful itself. This ontological dependence is described in terms of participating or sharing in the Form, or imitating the Form by being an image of the Form. (6) Reflecting this dependence is the notion of eponymy: everything called an *F* is named after the *F* itself. (7) The converse of the eponymy relation is the principle of one over many: For every plurality of things called *F*, there is the Form *F* itself.

The relation between Forms and their sensible eponyms is the most obscure feature in Plato's theory. In the *Phaedo*, Socrates insists on the derivation of sensible beauty from the Form, but expresses uncertainty as to how this derivation is to be understood: “Nothing else makes it [the sensible thing] beautiful except the presence or communion or whatever connection there may be with the Beautiful itself—I am not sure about this, but [I am sure] that it is by the Beautiful that all the many beautiful become beautiful” (100d). The terminology of participation occurs once in the *Symposium*, repeatedly in the *Phaedo*, and once again in the *Republic*. But this notion of participation as a Form-sensible relation is subjected to a withering critique in the *Parmenides* (131a–e).

In the *Republic* participation is generally replaced by the language of imitation and imaging or copying; and it is this terminology that reappears later in the *Timaeus*.

Difficulties with the classical theory will be discussed in the next section. We consider here the intended scope and motivation of Plato's theory. It is often presented as a solution to the problem of universals. This, however, is not only anachronistic but inaccurate, since the concept of universals (which are not properly *ousiai*, not substances in a strict sense) was introduced by Aristotle precisely as an alternative to Plato's conception of Forms. In the *Republic* the Being of the Forms is introduced on epistemic grounds as the object of knowledge, in contrast to the imperfect reality of the sensible manifold as object of *doxa*. (The deficient reality of the many beautiful things is reflected in the fact that they are beautiful in some respects, not beautiful in other respects. Hence they *are* in some respects, but they *are not* in other respects. The *is* of predication is thus taken to express a reality claim for the subject.) The underlying assumption, often reasserted in later dialogues, is that an object of knowledge must be eternally invariant; otherwise the cognition of it at one time would become false at another time (so explicitly at *Cratylus* 440a). But knowledge must be always true; hence an object of knowledge must be eternally unchangeable.

This is the argument underlying the presentation of Forms as invariant objects of knowledge in *Republic* V. To knowledge strictly understood corresponds Being strictly understood: “what is completely real (*to pantelôs on*) is completely knowable” (*Rep.* 477a 3). Anything less real can be the object only of imperfect cognition and partial truth. Plato hesitates to present this as an argument, however, since it might seem to imply the priority of epistemic considerations. That would be misleading. Epistemology and ontology go hand in hand for Plato, but it is the real that determines what is knowable and not conversely. It is the stability of Being that makes reliable cognition possible.

This Parmenidean insight constitutes the permanent basis for Plato's metaphysical speculation. It is worked out for the first time in the classical theory of Forms, but it persists as well in later dialogues such as the *Philebus* and *Timaeus*. It is in the *Sophist* that we have the most explicit statement that without stability and invariance there can be no knowledge or understanding (*nous*) whatsoever (249b–d). What is distinctive of the classical theory is not the invariance of Being but the one-many and eponymy relations between Forms and sensibles, as expressed at *Rep.* X, 596a: “We are accustomed to posit some one Form concerning each plurality to which we

assign the same name.” Thus there will be one Form of Beauty corresponding to all beautiful things, one Form of Good corresponding to all specific goods, and so on. But the passage just quoted from *Republic X* is destined to cause trouble, for many reasons. For example, it suggests that Forms will be as plentiful as common nouns and adjectives. Plato will have to speak more cautiously about cutting nature at the joints (*Phaedrus* 265e) and thus make clear that not every distinction between words will mark a distinction between Forms or Kinds of things (*Statesman* 262b–263b). The scope of the classical theory is originally undefined, but it does seem to be committed to Forms for artifacts as well as for natural kinds. Thus there is a Form for shuttle at *Cratylus* 389b and a Form for bed at *Rep.* 596b, 597a.

Less obvious than the Parmenidean-epistemic motivation for the doctrine of Forms, but equally important, is the distinctively Platonic conception of philosophy as a form of love or *erôs*, the conception expressed in Plato’s etymological reading of *philo-sophia* as “the love of wisdom” (see above). This notion of the philosopher as lover with the Forms as the beloved object provides the original context for the introduction of the theory in the *Symposium*, where the Beautiful itself appears as the ultimate object of philosophic passion. In the *Phaedo* the philosopher is said to be ready for death because it is only when liberated from the body that he can hope to obtain the object of his desire, namely, full knowledge of the truth (67e–68b). The Form of Good is the ultimate Form, not only because it is the source of being and knowability for the other Forms, but also because it is “what every soul pursues and for the sake of which it performs all of its actions” (*Rep.* 505d 11). The doctrine of Forms is thus designed, from the beginning, to provide not only an epistemology and an ontology but also a philosophy of life, that is to say, a theoretical basis for ethics and politics. It is in virtue of his or her access to the Forms, and above all to the Form of the Good, that a philosopher-king is uniquely qualified to govern, since only such access enables them to know what is a good life for individuals and for the city.

These powerful practical implications of the theory of Forms reflect its origin in the Socratic conception of philosophy as a form of life and in the Socratic concern with defining the virtues as the mark of a good life. No interpretation of Plato’s theory can be adequate unless it takes into account this profoundly practical bent of Plato’s conception of philosophy. The unique character of Plato’s metaphysics lies in this convergence between the Parmenidean demand for eternally unchanging reality

and the Socratic pursuit of what makes a human life worth living. Thus the original focus of the theory is not on the problem of meaning for general words or concepts but specifically on what we may identify as value terms: the noble and beautiful first of all (*to kalon*), the good (*agathon*) and the just (*dikaion*). The first generalization of the theory is to mathematical concepts (the equal, the greater, and the smaller) and then to health and strength and to every term defined in dialectic, that is, to every essence (*ousia*) “on which we put the stamp of what-it-itself-is” (*Phaedo* 65d 12, 75d 1: *auto to ho esti*, the most technical expression for the Forms). How far this generalization of the theory is meant to extend is a question to be raised and partially answered in later dialogues.

### PARMENIDES AND THE CHALLENGE TO THE CLASSICAL THEORY

In the dialogue *Parmenides* Plato brings the two Eleatic philosophers, Parmenides and Zeno, to Athens for an imaginary confrontation with Socrates. This is the first of a series of dialogues in which Socrates is no longer the chief speaker, being replaced here by Parmenides. Since Parmenides was almost certainly dead by 450 BCE (the alleged time of the conversation, when Socrates was about twenty), Plato has ignored chronology in order to introduce Parmenides as a masterful critic of the doctrine of Forms. It is no accident that, in the dialogues generally, Parmenides is the only philosopher who is allowed to win an argument with Socrates. Furthermore, in view of the Eleatic inspiration of Plato’s own conception of Being, Parmenides can be trusted as a sympathetic critic of the theory. He is the first to recognize that to give up the theory completely would mean to abandon philosophy (135b–c).

The dialogue divides into two parts. Part I present a series of objections to the Forms, objections that are never explicitly answered by Plato either in this dialogue or elsewhere. Part II contains eight rigorous deductions from the hypotheses *That the One Is* and *That the One Is Not*. The conclusions come in contradictory pairs. According to Deduction 1, the One has no properties; according to Deduction 2 the One has all properties, including contraries (e.g., it is both at rest and in motion, both greater than itself and smaller than itself). How the deductions of Part II are related to one another and to the objections in Part I are matters of extreme obscurity. Parmenides introduces these arguments simply as an example of how a philosopher should be trained before attempting to formulate a theory of Forms. These deductions are thus presented as a logical “exercise” (*gymnasia*)

preliminary to philosophy proper. They nevertheless represent the only fully developed examples of formal dialectic in the dialogues.

Interpretation of the eight (or on some counts nine) baffling arguments of Part II has been a subject of controversy since antiquity. Skeptics saw these apparently contradictory deductions as purely destructive, whereas Plotinus identified the first three hypotheses with his three principal hypostases: the One, Nous and Soul (*Ennead* V.1.8). Modern views have emphasized the overlap with the mingling of Kinds in the *Sophist* and other topics discussed in the late dialogues, such as whole and part, rest and motion. Several interpreters have found in Part II Plato's answers to the difficulties raised in Part I. Some commentators assume that all the arguments of Part II are intended as valid; others regard some of the deductions as so obviously fallacious that the detection of fallacy must be intended as an essential part of the training.

Part I begins with a brief statement by Socrates of the classical theory of Forms, presented as a response to Zeno's paradoxes about plurality. Zeno is quoted as showing that, if things are many, they must have incompatible properties, for example they must be both similar and dissimilar. Socrates agrees that such contraries will be true of the sensible many but not of the corresponding Form: Similarity itself will never be dissimilar, and the One itself will never be plural. Socrates' brief statement here of the classical theory is peculiar in two respects: the relation between the many and the corresponding Form is consistently described as participation (*metechein*, *metalambanein*), and the Forms are said at one point to be "separate" (*chôris*) from their participants (129d 7). In responding, Parmenides will seize upon this last point: "And do you divide as separate certain Forms themselves, on the one hand, and as separate on the other hand the things which participate in them? And is there in your view some Similarity itself separate from the similarity that we have?" (130b 1–5). Socrates agrees, and thus accepts a fatal replication of the Forms as immanent properties.

Both features—the reliance on the concept of participation and the distinction between Magnitude itself and the magnitude in us—accurately reflect the formulation of the doctrine in the *Phaedo* (e.g. 102d 7). And both will be exploited by Parmenides in his criticism, where the notion of participation is shown to be incoherent, while the separation between Similarity itself and "the similarity that we have" (or the similarity "in us") leads to a two-world ontology in which our world is structured by

immanent forms. In that case the transcendent Forms of Plato's theory become irrelevant and unknowable. This is the conclusion of the last difficulty, which Parmenides describes as the greatest (133b–134e).

As a consequence of Parmenides' criticism, two features of the classical theory as formulated here must be abandoned: namely, participation taken literally as the "sharing" of Forms by sensibles, and the existence of "forms that we have" or "forms in us" separate from the Forms themselves. Among Parmenides' other objections the best known is the so-called Third Man argument, according to which the one-over-many principle of *Republic* X (that for every group of *F*s we posit a Form, the *F*-itself) leads to an infinite regress. The nerve of this argument is the implicit premise that the *F*-itself is *F*; hence if we add the *F*-itself to the first group of *F*s, we get a larger group of *F*s calling for another *F*-itself; and so on indefinitely. Some scholars have claimed that this premise (the so-called self-predication principle, that *F*-itself is *F*) reflects a logical confusion on Plato's part between being a property and having a property. However, the *Sophist* makes clear that Plato remained committed to this principle, and recent interpretations have shown that no fallacy need be entailed. At the same time, the second implicit premiss required for the regress, the so-called Non-identity principle (that for any larger group of *F*s, a new and different *F*-itself is needed), has no deep Platonic motivation, and its role in generating the regress can be blocked in several different ways. More problematic than the Third Man argument is the parallel objection against the conception of Forms as models (*paradeigmata*), where the dependent relation of participation is understood in terms of similarity or being a likeness of the Form (132d–133a). This objection seems to attack the central concept of imaging or imitation, which replaces participation in the doctrine as reformulated in the *Republic* and *Timaeus*. How much of the classical theory of Forms can be thought to survive the critique of the *Parmenides* will depend in part on the interpretation of this model-copy relation as developed in the *Timaeus*.

#### THEAETETUS AND SOPHIST: SURVIVAL OF THE FORMS? THE LATER DIALECTIC

The *Theaetetus* and *Sophist* stand in the shadow of the *Parmenides*: both dialogues refer to the conversation between Socrates and Parmenides as if it were a historical event (*Theaet.* 183e 7; *Soph.* 217c 5). As a consequence, both dialogues distance themselves from the classical theory of Forms. Neither dialogue denies the existence of

Forms, and both refer to concepts or entities that recall Forms. But neither dialogue asserts the metaphysical dualism of the classical theory. The *Sophist* even subjects this theory to a new round of criticism. It is as if Plato in the *Parmenides* had wiped the slate clean, and was prepared to make a fresh start in the later dialogues in addressing the basic issues of epistemology and metaphysics.

The *Theaetetus* is almost the last dialogue in which Socrates appears as the chief speaker (only the *Philebus* is later), and the last one in which his elenctic function is dramatically displayed. In fact the negative character of the elenchus is uniquely underscored here in the comparison of Socrates to a midwife. The official role of Socrates in this dialogue is not to produce theories on his own (as he did in the *Phaedo*, *Republic* and *Phaedrus*, and will again in the *Philebus*) but solely to extract definitions of knowledge from Theaetetus.

Theaetetus's attempts to define knowledge fall into two categories, dividing the dialogue into two unequal parts. The first and longer section corresponds to the initial definition of knowledge as sense perception (*aisthêsis*). This definition is ultimately rejected on the grounds that truth, and therefore knowledge, is not accessible to sense perception as such but only to the rational psychic activity that Theaetetus calls *doxazein*, "having an opinion" (187a). The remainder of the dialogue is then devoted to various accounts of knowledge and error based on this notion of *doxa*, that is, opinion, belief, or judgment. The results of this second section are equally negative, so that the *Theaetetus* has the external form of an aporetic dialogue like the *Laches* or *Meno*—an unsuccessful attempt to define knowledge. The philosophical content of the *Theaetetus* is, however, extremely productive in arguments and insights for epistemology and philosophy of mind. Why then is the outcome so negative?

If we relate this discussion to Plato's theory of knowledge as formulated in the *Republic*, we can see why the enterprise of the *Theaetetus* was doomed to fail. According to the view of *Republic* V–VI (reasserted in the *Timaeus*), sense perception and opinion (*doxa*) take as their object the realm of sensory Becoming, whereas knowledge proper takes as its object only invariant Being. Thus in the Divided Line of *Republic* VI, both sense perception and *doxa* belong to the lower sections of the line, devoted to the visible realm, but knowledge belongs at the top with the Forms as its object. In the *Republic* and *Timaeus* this view of knowledge as metaphysically grounded is presented as a basic assumption, without detailed supporting argument. In the *Theaetetus*, in con-

trast, all attempts to define knowledge avoid any recourse to Parmenidean ontology or to the classical doctrine of Forms. This systematic departure from Plato's classical epistemology can be seen as an application of the method proposed and exemplified by Parmenides in the dialogue named after him: See what follows not only from your own assumption but also from its denial (136a 1). Accordingly, in the *Theaetetus* we pursue an account of knowledge from the opposing, non-Platonic point of view. Let us assume that knowledge can be defined either on the basis of sense perception, or on the basis of *doxa*, and see what follows from either assumption. The *Theaetetus* thus has the form of a double *reductio*. Since neither alternative gives a satisfactory result, we are justified in returning to our original point of view. There is still no explicit argument for the Parmenidean postulate (that knowledge in the full sense takes as its object Being in the full sense). But this assumption is supported indirectly, by the failure of the alternative attempt in the *Theaetetus* to give an account of knowledge that avoids this postulate.

Although the general form of the *Theaetetus* is thus negative, the positive content is extremely rich. The first section develops a subtle theory of subjective perceptual qualities within the framework of Protagorean relativism, on the basis of a neo-Heraclitean doctrine of flux. Commentators disagree on whether this theory of perception should be read as merely hypothetical or whether it in fact represents Plato's own view of the subject. A decision must depend upon whether or not the *Theaetetus* account of perception is compatible both with Plato's own version of cosmic flux in the *Timaeus* and also with his mechanistic account of sense qualities in that dialogue. Of great interest also is the argument known as the *peritropê*, or "overturning," according to which Protagorean relativism is shown to be self-refuting; since it could be true at most for those who believe it, but false for everyone else, therefore even those who believe it must admit its falsity for the others, that is, for most people (*Theaet.* 170a–171c).

The final rejection of sense perception as a candidate for knowledge relies upon a new distinction between sense-perception proper, that is, information derived through the sense organs of the body, and "common thoughts" (*koina*) like "same" and "different," "one" and "many," that apply to more than one sense modality. The argument concludes that the *being* of predication and existence, and hence of truth, is not available to sense perception as such. "But if one fails to grasp the truth of

something, one cannot have knowledge of that thing” (186c 9). Hence sense perception cannot be knowledge.

The “common thoughts” or concepts (*koina*) introduced by this argument include “beautiful” and “ugly,” “good” and “bad,” as well as “same” and “different,” “similar” and “dissimilar” (185a–186a). As non-sensible notions, these *koina* are clearly suggestive of Forms, but nothing whatsoever is said about their ontological status. There is a closer hint of the classical theory in the famous moral digression of the *Theaetetus* (where virtue is defined as *homoiôsis theôi*, “becoming like god” 176b 1): There resemblance at the human level is said to connect us with transcendent models (*paradeigmata*) of justice and injustice “established in reality” (*en tôi ontî hestôta* 176e 3). These two paradigms represent two lives, one of which, as a model of injustice, is “godless and most wretched.” The context of the digression clearly invokes both the judgment myths of *Phaedo* and *Republic* and the moral spirit of the *Gorgias*; but there is no unambiguous reference here to Forms as defined in the classical theory.

In the *Sophist*, Plato returns to questions of ontology with a vengeance. The central theme of the dialogue is the problem of Not-Being, and it is argued that the concept of Being is equally problematic, so that the two concepts must be clarified together. Accordingly, the dialogue surveys a series of metaphysical positions, including both Parmenidean monism and a materialist view that reduces Being to bodily existence. A clearly recognizable version of Plato’s classical theory is discussed as the doctrine of “the friends of the Forms.” As in the *Parmenides*, a sympathetic critique is guaranteed here by the presence of a metaphysically oriented philosopher as protagonist. As a pupil of Parmenides, this “visitor from Elea” can subject both Parmenides’ account of Being and Plato’s own theory to constructive criticism. In particular, the Stranger’s critique of the Friends of Forms shows that the classical theory must expand its ontology to make room for motion and change as a kind of Being. How this is to be done is left for discussion elsewhere, presumably in the *Timaeus*. The *Timaeus* also pursues the most puzzling suggestion of the Stranger’s critique, namely that there must be a place among the Forms for Intelligence (*nous*) and hence for life and soul (*Sophist* 248e–249d).

The doctrine of Forms reappears in the constructive argument of the *Sophist* as a theory of Kinds (*genê*) that are capable of combination or participation with one another; dialectic is accordingly redefined as the science of “dividing according to Kinds,” knowing “which Kinds harmonize with which, and which do not admit one another” (253b–d). Although in this dialogue we set out

to define the Sophist, we seem to have found the philosopher instead, since this dialectical art belongs only “to one who purely and rightly philosophizes” (253e). The description of the philosopher appeals here to the visual imagery of the classical theory: The philosopher is said to be so hard to see because of the brightness of the region “where he is attached always in reasoning to the form (*idea*) of Being; for the eyes of the soul of most people cannot bear for long the sight of what is divine” (254a). The metaphysical discussion is, however, left incomplete. The Eleatic Stranger speaks of participation only between Forms or Kinds; nothing is said of the relation between Forms and their sensible eponyms.

Instead of metaphysics the new theory of participation between Kinds offers something like transcendental logic. “It is through the weaving-together of Forms (*eidê*) with one another that rational discourse (*logos*) has been given to us” (259e). The most elementary weaving-together (*symplokê*) is between noun and verb to form the basic *logos* of a sentence or statement (262c 6). Plato thus introduces the subject-predicate analysis of sentence structure that served as the basis for Aristotle’s own theory of predication. Exactly how this analysis is applied in the detailed account of Not-Being is a matter of dispute, but it is clear that the Form of Not-Being is explained by reference to two other Forms, Being and Otherness. (In effect, negation is analyzed in terms of non-identity.) The *Sophist* thus opens up an entirely new dimension in the theory of Forms: a network of logical and semantic relations between concepts or Kinds, such as whole-part or logical inclusion, combination or extensional overlap, and mutual exclusion.

This conception of dialectic as “dividing according to Kinds” is reflected in the method of Collection and Division that was described in the *Phaedrus* (265d–266c) and is systematically applied here in both dialogues, in successive definitions of the *Sophist* and the *Statesman*. As was noted above, in these definitions the terms *genos* (kind) and *eidos* (form) seem to be used in their logical sense simply as “genus” and “species,” and the ontology of the Forms is apparently left indeterminate. At the same time, the Eleatic Stranger speaks more definitely of “incorporeal beings, the greatest and finest,” which have no images adapted to sense perception but can be clearly indicated only by rational discourse (*logos*); it is for the sake of these beings that the dialectical definitions are pursued (*Statesman* 285e–286a). In such a passage, as in the reference to the divine *idea* of Being at *Sophist* 254a, there is a clear reminder of the classical theory. But nothing is said in either the *Sophist* or *Statesman* to indicate how the dual-

ism of the *Phaedo* and *Republic* is to be altered or preserved.

### PHILEBUS AND THE RETURN OF SOCRATES

In the *Philebus* the problems of ontological dualism and participation are directly confronted for the first time since the *Parmenides*. These issues are presented here within the broader context of relations between the One and the Many. As in the *Parmenides*, the problem of participation is distinguished from superficial or eristic ways of being at the same time one and many (as one subject with many properties, or one whole with many parts). The serious problem arises only when we distinguish unities that do not belong to “what comes to be and perishes” but are truly beings and truly unities, like the one Beautiful and the one Good. (Among the examples of ungenerated and imperishable unities listed at *Philebus* 15a are One Human Being and One Ox, thus providing a partial answer to the Population Problem of *Parmenides* 130c 1. Another partial answer is given in the discussion of Forms of Fire and other elements at *Timaeus* 51b–52a.) The question then is how such unities, “admitting neither generation nor corruption, can remain one and the same while coming to be in many and infinite cases of becoming, either one unity being scattered and becoming many, or (most impossible of all) being separate from itself as a whole” (15a–b, recalling the critique of participation at *Parmenides* 131a–c).

A full discussion of these metaphysical issues is avoided in the *Philebus*, however, because of pressure from the prior question whether pleasure or knowledge is the good and the cause of a good human life. The relation of eternal Forms or Monads to sensible becoming is reformulated here in the light of “an immortal and unaging attribute (*pathos*) of discourse (*logoi*),” an attribute rather cryptically identified as the claim that “the identity of one and many generated by discourse (*logoi*) circulates in every way among everything that is ever said” (15d). As the best way out of this confusion, the dialectical method of collecting unities and distinguishing pluralities is presented as a gift from the gods and the basis for all art or science (*technè*, 16c 2). The discussion thus shifts from the problems of ontological dualism to the dialectical project of discerning unity and plurality in the various kinds of pleasure and knowledge. Instead of metaphysics we are given the method of Division, based on the principle (tossed down from heaven by some Prometheus) that “things that are said to be in every case (or “things said to be forever,” *ta aei legomena einai*) are derived from

one and many, and hence have Limit and Unlimited in their nature” (16c).

These principles of Limit and the Unlimited, introduced here by Plato for the first time, are apparently borrowed from the Pythagorean philosopher Philolaus, who claimed that “Nature in the world-order has been fitted together from unlimited [constituents] and from limiting ones, both the world-order as a whole and everything within it” (fragment 1). In the *Philebus* these two principles provide the basis for a fourfold cosmic scheme that includes several ideas figuring also in the cosmology of the *Timaeus*. “All the beings that are now present in the universe” are analyzed as a blended Mixture of Limit and Unlimited, under the causal influence of Intelligence (*nous*). In this scheme, as in the *Timaeus*, causality is interpreted as the purposeful act of a maker, or *dèmiourgos*. Also common to the *Timaeus* is the introduction of a world soul (*Philebus* 30a–d). But the *Philebus* principles of Limit and Unlimited do not correspond exactly to anything in the *Timaeus*; they figure here as immanent components of Becoming, entering as ingredients into a Mixture that represents both cosmic order and a good human life (23b–27c).

This fourfold scheme of Unlimited, Limit, Mixture, and rational Cause is said to be required in order to decide the contest between pleasure and knowledge for recognition as the good. It has already been settled that neither candidate deserves first place; pleasure and knowledge are each shown to be less choiceworthy alone than the Mixed Life that contains both (20d–22c). The issue for the rest of the dialogue is to assign second place in the competition for the good or, more precisely, to determine the relative position of knowledge and pleasure in accounting for the goodness of the good life. It will turn out that, in the ranking of ingredients in the final Mixture, forms of knowledge occupy third and fourth place, while a selected group of pleasures comes in only fifth. The first two constituents of the good life are principles first of measure (*metron*, *metrion*) and next of beauty and proportion (*kalon*, *symmetron*). The fourfold scheme permits Socrates to identify pleasure as a part or species of the Unlimited, while knowledge and intelligence (*nous*) belong to the genus of the Cause of successful mixtures.

The central section of the *Philebus* is a classification of different kinds of pleasure and knowledge. Socrates proceeds to give a subtle analysis of a number of kinds of pleasure, both mental and physical, in order to distinguish pleasures that are true and pure from various mixed and false pleasures. Only pure pleasures of sense and

intellect will be admitted into the final construction of the good life. Although all forms of knowledge will be admitted, a ranking is nevertheless carried out between different forms of expertise, in a new version of the Knowledge Line of *Republic V*. The lowest division is between various manual crafts, including music; for such arts the level of cognition depends upon the extent and precision of the mathematical component. Mathematics in turn is divided into two, with philosophical mathematics representing a higher standard of precision. (Pure mathematics here recalls, but does not exactly correspond to, the higher form of measurement based upon “due measure” in the *Statesman*. The concept of due measure, to *metrion*, does, however, return to define the first constituent of the Good Life in the final ranking of the *Philebus*.)

Finally, the highest form of knowledge is identified as dialectic, which ranks above natural philosophy and cosmology on ontological grounds familiar from the classical theory. For only dialectic is concerned with what is “really real,” with Being that is eternal and unchanging; whereas the science of the natural world is a study of what has come to be and perishes (*Philebus* 59a, 61e; this is the same ontological contrast that will serve as foundation for the cosmology of the *Timaeus* 28a–b). Dialectic is here described in terms of classical dualism, including the epistemic contrast with *doxai* (at 59a 1). But the reader is inevitably reminded of the quite different account of dialectic given earlier in the *Philebus*, where there is reference not to Being and Becoming but rather to the recognition of unities and pluralities (16b–17a). The old and the new conceptions of dialectic are thus both presented but left uncombined. A similar ambivalence can be seen in the *Philebus* regarding the problems of metaphysical dualism, which are recognized but not resolved. And in another respect we are left with expectations unfulfilled. Much of the dialogue raises the question of the Good as such and the good-making properties of any mixture, but we reach at the end only “the threshold of the good,” in a list of the essential ingredients of a good human life. Any hopes for an account of the Form of the Good are left unsatisfied. It is no wonder that the dialogue ends (67b 11) with the interlocutor reminding Socrates that something has been left out!

We may wonder why Plato brings Socrates back as protagonist in the *Philebus*, after replacing him with an Eleatic Visitor in the *Sophist-Statesman*, and again replacing him with Timaeus and an Athenian Stranger in the other late dialogues. No doubt the role of pleasure in the good life was familiar Socratic terrain. But the presence of

Socrates might equally serve as a reminder of the dualism expounded by the same figure in the *Phaedo* and *Republic*, and also of the unresolved problems raised against Socrates’ presentation of this doctrine in the *Parmenides*. Although the *Philebus* is not formally aporetic like the *Theaetetus*, it certainly concludes on a note of incompleteness. If there is a Platonic response to the metaphysical problem recalled here, one must look for it elsewhere, perhaps in the *Timaeus*.

## TIMAEUS AND THE PLATONIC COSMOS

The *Timaeus* was for many centuries the most influential of all of Plato’s works. After the rise of Christianity, it could be regarded as a philosophical exegesis of the creation story in the Book of Genesis. But the profound influence of the *Timaeus* derives from its mathematical conception of nature, which has also attracted modern admirers from Kepler and Galileo to Whitehead and Heisenberg. For students of Plato the *Timaeus* has the special interest of offering Plato’s only radical reformulation of the classical theory of Forms. The introduction of a spatial Receptacle, on the one hand, and an intelligent Maker of cosmic order, on the other hand, permits Plato for the first time to give a systematic account of the natural world, while deploying new resources to counter the challenges to the classical theory that were formulated in the *Parmenides*.

In addition to the Receptacle and the Demiurge, Plato’s new theory makes use of two other notions developed in the late dialogues: (1) The idea presented in the *Sophist* that the realm of Being must be enlarged to include motion and change is reflected in the theory of mixture in the *Philebus*, where the analysis of phenomenal unities gives rise to the new, paradoxical expressions *genesis eis ousian*, “becoming into being” (26d 8) and *gegenêmenê ousia*, “being that has come to be” (27b 8). Although the *Timaeus* reverts to the classical antithesis between Being and Becoming, the cosmological theory deals in fact almost exclusively with Becoming. (2) Without using the terms “Limit” and “Unlimited” from the *Philebus*, the *Timaeus* presents a comparable analysis of Becoming as the mixed result of an interaction between two principles, represented here allegorically as Reason and Necessity. The victory of the former over the latter is spelled out in the creation narrative as the shaping of the chaotic motions of the Receptacle by the purposeful action of the Demiurge, “structuring [the pre-cosmic elements] with figures (*eidê*) and numbers” (53b 4).

The *Timaeus* thus interprets the cosmic act of the divine Maker in terms of the normative notion of mathematical measure (*to metrion, to symmetron*) expounded in the *Statesman* and *Philebus*. Whereas in the epistemology of the *Republic* mathematics points only upward, to raise the mind towards the Forms, in the cosmology of the *Timaeus* (and, by anticipation, in the *Statesman* and *Philebus* as well) the function of mathematics is also directed downward, to impose order on the mixed products of Becoming, on the good human life as on the order of nature.

By the formal device of Timaeus's monologue, Plato has inserted into this dialogue a prose treatise *peri physeôs* in the Pre-Socratic tradition, applying a revised theory of Forms to produce his own account of the nature of things, that is to say, of the world of perceptible order and natural change. One goal of this account must be to avoid the "greatest aporia" of the *Parmenides* by giving an account of the visible cosmos, including human beings, that does not "separate" the phenomenal world from the Forms. Hence, instead of a sensible realm of immanent forms, Timaeus posits as an entity independent from the Forms only the Receptacle, the place where the Forms are imaged. As joint offspring of Forms and Receptacle, the sensible images are like the Mixtures of the *Philebus*, with no existence independent of their two principles. On the one hand, as modifications of the Receptacle their existence is adjectival rather than substantival. On the other hand, they are no more independent or separable from the Forms than the images in a mirror are independent from the objects mirrored. The *Timaeus* is insistent on this fact of double dependence. "Since in the case of an image even that on which it depends does not belong to it, but it is always carried about as an appearance (*phantasma*) of something else [namely, the Form], it is fitting that it come to be in something else [namely, the Receptacle], on pain of being nothing at all" (52c 2–5). This is Plato's strategy for avoiding the fatal separation between Forms and immanent features of the sensible world, conceived as the "forms that we have" or "forms in us." Properly conceived, images exist only as fleeting determinations of the Receptacle under the influence of one or more Forms.

Of course many questions are left open, including the problem of how Plato can avoid the reciprocity of Similarity which in the *Parmenides* (in a version of the Third Man argument at 132d–133a) threatens to undermine the explanatory role of images and likeness. Images are said to be impressed on the Receptacle "in an amazing way, hard to describe" (50c 6). The promise to return

to this topic is not fulfilled, unless we take the theory of elementary triangles, introduced at 53b, to be the promised account of how images of the Forms are produced in the Receptacle. It is in any case the geometry of these invisibly small triangles that replaces the atomism of Democritus with a more strictly mathematical theory. And it is the same geometric account that provides the mechanism by which the mathematics of Limit and "due measure" imposes order and goodness on the realm of sensory flux. It would seem that the theory of elementary triangles in the *Timaeus* is the physical expression of the notion of normative mathematics developed in the *Statesman* and *Philebus*.

A famous problem, debated already in Plato's school, is whether the creation story is to be taken literally, as positing a chaotic condition of the Receptacle before the Demiurge goes to work, or whether the myth of creation is to be interpreted as an expository device to distinguish different explanatory factors. A non-literal reading of creation would avoid the apparent incompatibility between the *Timaeus* account of pre-cosmic motions before the creation of the world-soul and the account given in the *Phaedrus* and the *Laws*, where the soul as self-mover is the source of all motion and change. A non-literal reading would also dispense with some vexing problems about the ontological status of the Demiurge and his relation to the Forms. (He is described as *noêtos*, "intelligible" like the Forms at 37a 1.) If we do not have to take creation literally, the Maker simply represents the principle of reason as a causal agency among the Forms.

Some problems will nevertheless remain. Why is the eternal and unchanging model for creation presented as a *panteles zôon*, a "complete living thing," containing within itself as parts or species all the intelligible living beings (30c–31b)? On the one hand, this eternal model is described in terms that clearly identify it with the Forms of the classical theory. (Thus at 39e 8 the model is referred to as to *ho estin zôon*, "the what-living-thing-is." This technical expression for the Forms occurs in no other dialogue later than the *Parmenides*.) On the other hand, nothing in the classical theory prepares us for this conception of the Forms as alive. It is as if Plato in the *Timaeus* chose to respond to the criticism of the Eleatic Stranger in the *Sophist*, who complained that the Friends of Forms conceive the highest Being as neither living nor thinking, "but standing immobile like a pious statue, without intelligence" (249a 1). Since it is a fixed doctrine that intelligence (*nous*) requires a mind or *psychê*, and *psychê* entails life (*Sophist* 249a, *Philebus* 30c 9, *Timaeus* 30b), by bringing the Forms to life the *Timaeus* evades

this criticism. But the reader is left without a clue as to how the life and thought of the Forms are to be understood. Does the divine Intelligence of the Forms possess a divine Psyche of its own, before the creation of the World-Soul? And how is this Intelligence among the Forms related to the divine Psyche established as first source of motion by the argument of *Laws X*? These are some of the many questions that the myth of the Demiurge allows Timaeus to avoid.

## Bibliography

### WORKS BY PLATO

#### *Editions and Translations*

The standard edition of the Greek text is by John Burnet, *Platonis Opera*. 5 vols. Oxford: Clarendon Press, 1899–1907. Volume I has appeared in a second edition, edited by E.A. Duke, W. F. Hicken, D. B. Robinson, and J. C. G Strachen, 1995, and a new edition of the *Republic* has appeared as *Platonis Respublica*, edited by S.R. Slings, New York: Oxford University Press, 2003. There are also editions of the Greek text with French translations in the “Les Belles Lettres” series (13 vols. in 25 parts, Paris: Les Belles Lettres, 1920–1956), and with English translations in the Loeb series (12 vols., London and New York: Harvard University Press, 1921–1935). The best English translations are collected in J. M. Cooper, ed., *Plato: Complete Works* (Indianapolis, IN: Hackett, 1997).

#### *Modern Editions and Translations of Individual Dialogues*

- Adam, James. *The Republic of Plato*. 2 vols. Cambridge, U.K.: Cambridge University Press, 1902.

## PLATONISM AND THE PLATONIC TRADITION

The term "Platonism" is so widely used in modern scholarship that it is difficult to determine its meaning precisely as applicable either to a particular group of thinkers or to a specific collection of doctrines. Ancient sources frequently describe "Platonists" as those philosophers who further developed the known or presumed teaching of Plato himself and "Academics" as those who pursued the skeptical methodology believed to have been initiated by the Socrates of Plato's earlier dialogues. However, the substantive "Platonism" seems first to occur in scholarly literature only around the beginning of the eighteenth century when it was used to characterize doctrines that were not only derived from but also combined with Plato's own teaching by later exegetes.

In order to apply this relatively modern usage of the term "Platonism" legitimately to the history of Western philosophy in general, it is useful to distinguish between: (1) Platonism in the sense of a Platonic *tradition*, or a set of ideas that is viewed in a strongly historical sense in connection with Plato or his early exegetes and is sufficiently extensive and coherent to overwhelm any influences from other traditions; and (2) Platonism in the sense of a Platonic *influence*, or a set of ideas that is viewed in a weakly historical sense in connection with Plato or his early exegetes and is not sufficiently extensive or coherent to overwhelm any influences from other traditions. Within the former category, it is useful to distinguish further (a) the *direct* Platonic tradition, that is, various philosophical ideas which we know to form part of the Platonic legacy and which their proponents characterized similarly, and (b) the *indirect* Platonic tradition, that is, those philosophical ideas which we know to form

part of the Platonic legacy but which their advocates characterized differently.

Throughout the ancient period of Western thought, there was a Platonic tradition when Platonic philosophers were either members of Plato's Academy or claimed to revive and continue the "Academy." For this discussion, the medieval period is considered in terms of distinct Byzantine, Arabic, Jewish, and Latin cultural components, and here the distinction between direct and indirect traditions of Platonism becomes important, especially with respect to the Arabic tradition in which a type of indirect Platonism was viewed as "Aristotelianism." During the modern period of Western thought there has been initially a Platonic tradition, when Platonic philosophers again claimed to revive and continue the "Academy," but subsequently only Platonic influence.

Although such a procedure risks oversimplification, it may be useful to introduce the detailed historical analysis with a statement of the "essence of Platonism," that is, the set of philosophical assumptions underlying Plato's own written works or oral teachings in the view of his immediate successors in the Academy. Scholars may perhaps be guided by the ancient summary of Platonism in Apuleius's *On Plato and His Doctrine* (2nd century CE), which can be shown to depend on the early Peripatetics and on the early Academy—both with respect to the individual doctrines attributed to Plato and the pedagogical framework presenting them. According to Apuleius, Plato developed his own philosophical viewpoint after being introduced to the teachings of Heraclitus, studying with Socrates, encountering the Pythagoreans, and absorbing the dialectics of Parmenides and Zeno—the philosophical notions influencing Plato here being obviously those of the world as a continuous flux (Heraclitus), of the pursuit of universal definitions and of the primacy of the moral sphere (Socrates), of number as the underlying reality and of the immortality of the soul (the Pythagoreans), and of the contrast between real being and mere appearance (Parmenides).

Also according to Apuleius, Plato brought philosophy to perfection by combining the physics, ethics, and logic that had been pursued independently by the Pythagoreans, Socrates, and the Eleatics respectively into a single curriculum organized into three parts. On the basis of these historical data, one might therefore summarize the "essence of Platonism" as follows: Platonism is specifically characterized by the establishment of a contrast between the realm of being that is the object of knowledge or reasoning and is not subject to change and the realm of becoming that is the object of opinion or

sensation and is liable to change. The two realms are linked by the soul, which exists indestructibly before, during, and after the temporal period of its combination with the body and for which assimilation either to the realm of being or to the realm of becoming represents the primary ethical choice.

## ANCIENT PLATONISM

Modern scholars customarily divide Platonism in the ancient world into four main periods by using a mixture of ancient and modern terminology.

The "Old Academy" (347–267 BCE) is what Cicero called the original succession of philosophers within the Academy itself. The first of these philosophers was Speusippus (the scholarch, or "head of the school," 347–339 BCE), whose written works do not survive but whose doctrines can be reconstructed somewhat from later reports. Apparently Speusippus was influenced by the Pythagoreans into advocating as the first principles of reality, the One and the Dyad, the former transcending being, goodness, and intellect and the latter coinciding with matter. Speusippus abandoned Plato's own doctrine that the Forms were Ideal Numbers, yet emphasized Plato's teaching regarding the mathematical intermediate between intelligibles and sensibles. He also explained the various levels of being as resulting from the relation between the One and different levels of matter.

Whereas Speusippus's theories were not influential until the time of the Neoplatonists, what became the standard type of Old Academic doctrine seems to have originated with his successor Xenocrates (scholarch, 339–314 BCE). Although the latter's works do not survive, it is possible on the basis of later reports to conclude that he produced the official edition of Plato's works and that he began a process of systematizing Platonic thought. For example, he established the formal tripartite division of philosophy into physics, ethics, and logic and he continued to develop the Pythagorean side of Plato's oral teaching. As first principles of reality, Xenocrates opposed the monad conceived as good to the dyad conceived as evil—the former corresponding to a self-thinking intellect containing the Forms or Ideal Numbers—and derived the entire cosmos from their interaction. The higher and lower worlds were mediated by a soul that was defined as a "self-moving number": in other words, it was self-moving like the soul of the *Phaedrus* and mathematically structured like that of the *Timaeus*.

Xenocrates' successor was Polemo (scholarch, 314–267 BCE), who seems to have differed from his two

predecessors in that he placed somewhat greater emphasis on ethics. According to later testimonies, Polemo advocated the view that the goal of human existence was “life according to nature,” this principle however required neither the rejection of external goods nor the extirpation of passions. Besides the three scholarchs, the Old Academy included other significant thinkers, including Crantor of Soli, the first known author of formal commentaries on the dialogues of Plato.

The New Academy (267–80 BCE) is distinguished by Cicero from the Old Academy on the basis of its shift from a dogmatic to a skeptical mode of philosophizing. Although this radical change of direction seems to have occurred in reaction to the extreme dogmatism of the current Stoic school, it appealed to the aporetic method illustrated by Socrates in the early dialogues of Plato for its historical justification. Arcesilaus (scholarch, 267–241 BCE), who followed the Socratic practice of writing nothing, argued that the degree of cognitive certitude claimed by the Stoic notions of perspicuity and assent was unattainable and that the correct epistemological attitude to the physical world was one of “withholding assent” (*epochē*). In fact, Arcesilaus did not hold to the position that nothing could be known, but more radically to the viewpoint that one cannot be certain whether anything can be known or not.

Later thinkers in the New Academic tradition slightly modified Arcesilaus’s teaching. Carneades (scholarch, c. 160–129 BCE) agreed that it would be possible to reject the Stoic notions of perspicuity and assent while being guided in practical matters by observing three levels of probability. The end of the New Academy seems to have been occasioned by a dispute, the precise details of which are somewhat obscure, between Philo of Larissa (c. 130–69 BCE) and Antiochus of Ascalon (160–80 BCE). According to one reading of the evidence, Philo attempted to reconcile the New Academy and the Old Academy, whereas Antiochus, who was particularly enraged by the interpretation gaining currency that Arcesilaus and Carneades had endorsed the skeptical position publicly while indulging in dogmatic activities in private, preferred to reestablish the Old Academy entirely.

Modern historians call the next phase of ancient Platonism (80 BCE–c. 250 CE) “Middle Platonism.” This terminology has been established in order to characterize Platonism in the period between the revival of dogmatism in the Academy by Antiochus of Ascalon and the innovations of doctrine introduced by Plotinus. Although it is applied to a number of philosophers working at different times and in different places, it is perhaps

possible to identify certain methods and doctrines as typical of this phase of the tradition. From the viewpoint of methods, the Middle Platonists concentrated on the dogmatic aspects of the tradition—although aporetic and dogmatic elements co-exist in the work of Plutarch of Chaeronea (c. 45–125 CE)—and within the dogmatic approach there is a strong tendency toward systematization. The practice becomes fully established of writing commentaries on Plato’s work: Eudorus of Alexandria (fl. c. 25 BCE) is reported to have followed Crantor in commenting on the *Timaeus*—and also of producing handbooks of Platonic teachings—examples of this genre are extant in the form of the *Didaskalikos* of “Alcinous” (fl. c. 130 CE) and *On Plato and his Doctrine* by Apuleius of Madaura (b. c. 125 CE). The tendency toward systematization is accompanied by a tendency toward syncretism. From Aristotelianism, Plutarch can adopt the ethical doctrine of the mean and Alcinous the logical doctrine of the categories. The combination of Pythagoreanism and Platonism implicit in the assumption of monad and dyad as first principles continues with figures like Eudorus, this development being associated with the rise of Platonizing pseudo-Pythagorica around this time (for example, the treatises *On the Soul of the Universe and On Nature* by “Timaeus of Locri” and *On the Nature of the Universe* by Ocellus Lucanus).

From Stoicism, Antiochus of Ascalon can adopt the physical doctrine of active and passive principles and Atticus (fl. c. 170 CE) the ethical doctrine of extirpating passions. From the viewpoint of doctrines, the following physical ideas may be considered as particularly characteristic of Middle Platonism: (1) controversy over the corporeality or the incorporeality of the first principle—here the position of Antiochus should be contrasted very clearly with that of Eudorus and the rest of the tradition; and (2) postulation of a triadic group of first principles consisting of a first God that is One as in Pythagoreanism and Good as in the *Republic* and corresponds to a self-thinking Intellect containing the Forms; a second God having affinities with the Demiurge of the *Timaeus* and the Logos of Stoicism; and a World Soul sharing features with the principle of the same name in the *Timaeus* and the Indefinite Dyad of the Pythagoreans; and (3) tentative emergence of a first principle above Being itself in the work of Numenius of Apamea (fl. c. 150 CE). Among the ethical ideas characteristic of Middle Platonism might be mentioned the debate over the goal of human life. Here, the Antiochean notion of assimilation to nature should be contrasted with the Eudoran ideal of assimilation to God.

The phase in the history of Platonism initiated by the philosophy of Plotinus and in the twenty-first century called “Neoplatonism” may be divided into several “schools,” in the sense of being associated with certain leading thinkers: namely, that of Plotinus and his students Porphyry and Amelius, that of Iamblichus and his followers, and the Athenian school from Plutarch of Athens, through Syrianus and Proclus, to Damascius. This last school claimed to be the successor of the ancient Academy and was closed by the Emperor Justinian in 529 CE.

Plotinus (204–269 CE) studied with Ammonius Saccas in Alexandria and later established his own school in Rome. He set out a metaphysical system, which, with various additions and modifications, became foundational for Platonic philosophy and for the reading of Plato until modern times. Thanks to the complete corpus of Plotinian writings called the *Enneads* and the biography attached by Porphyry to his edition of the latter, historians can understand the methods and doctrines of Plotinus more than they can those of any previous Platonist. The *Enneads* reveal precisely how Plato’s works yielded systematic metaphysical tenets: The *Republic* provided the notion of the Good above Being; the *Parmenides* provided the postulation of the One, the One-Many, and the One-and-Many as the three first principles; the *Symposium* provided the identification of Beauty and Intellect; the *Sophist* provided the five Kinds constituting Intellect; the *Phaedrus* provided the relation between universal and individual Soul; the *Phaedo* provided the individual soul’s attachment and detachment from the body and the notion of virtue as purification; the *Theaetetus* provided the notion of assimilation to the divine; and the *Timaeus* provided the distinction between being and becoming, the notion that the divine has no envy, the treatment of the intelligible living creature as a phase of Intellect, the treatment of the Demiurge as an intellectual phase of Soul, the indivisible and divisible components of Soul, the cosmological reading of the lower gods, and the identification of the Receptacle and Matter.

Plotinus’s philosophical approach was sometimes based on the interpretation of a specific passage, often quite brief, in Plato’s dialogues, sometimes based on the discussion of a particular problem (e.g., that of the relation between Intellect and intelligible objects raised by Porphyry and recorded in *Enneads* V. 5), sometimes based on the critique of some false interpretation of Plato (e.g., that of the evil nature of the visible world maintained by the Gnostics and reported in *Enneads* II. 9) but usually based on a combination of the above. Porphyry’s *Life of*

*Plotinus* describes the role of sources other than Plato in these discussions, Aristotle’s *Metaphysics* being particularly influential (a statement corroborated by Plotinus’s use of the doctrines of potency and act and of the self-thinking intellect), both Platonic and Peripatetic commentators (e.g., Gaius and Alexander respectively) being sources of inspiration, and Stoic doctrines also being utilized (a statement corroborated by Plotinus’s dematerialized reading of the *pneuma* as “procession and reversion”).

The system emerging from this analysis might perhaps be summarized as follows. According to Plotinus, reality—understood dynamically as a descending hierarchy of “procession” (ontological founding and at certain points ethical fall) and as an ascending hierarchy of “reversion” (ontological completing and at certain points ethical perfecting)—consists of three principles or “hypostases”: the One or Good (described less determinately as the Beyond, the Supreme, the First), which is cause or power; Intellect—a macrocosmic unity and microcosmic plurality that timelessly thinks itself is logically distinguishable into the five Platonic Kinds of Being, Sameness, Otherness, Motion, and Rest, and metaphysically contains the Platonic Forms; and Soul—a macrocosmic unity and microcosmic plurality that generates time and receives the Platonic Forms into itself as reason-principles. This hypostasis also contains a higher and a lower aspect: Soul proper and Nature. Below these three principles is the nonprinciple of Matter (in some but not all contexts called Evil), which receives the unfolding of Soul’s lower aspect by projecting the Forms into three-dimensional space. The reversion is the more complex of the two dynamic aspects of reality given that it also comprises the epistemological transition from the discursive and propositional reasoning of Soul to the intuitive and nonpropositional thinking of Intellect to that which is approached in an entirely noncognitive manner.

Iamblichus (c. 245–325 CE) presided over an influential philosophical school at Apamea in Syria. He devoted himself to formal commentary on both Plato and Aristotle, a practice in which he followed his teacher Porphyry, and wrote an extensive study of Pythagorean mathematics. His approach to philosophy initiated certain tendencies especially characteristic of later Neoplatonism: namely, increasing emphasis on systematic and religious elements. In the former case, Iamblichus reinforced both the continuity and the discontinuity between the Plotinian hypostases by introducing numerous mediating terms; in the latter, he postulated a more radical fall of the human soul that could only be reversed by ritual

observances. For Iamblichus, the systematic and religious aims came together since the discernment of more levels of reality provided a metaphysical foundation for traditional polytheism.

Proclus (412–485 CE) was the most influential representative of the Athenian school of Neoplatonism. In a number of extant works that include commentaries on Plato's *Alcibiades*, *Cratylus*, *Parmenides*, *Republic*, and *Timaeus*, a commentary on Euclid's *Elements*, and such independent treatises on Platonic philosophy as *The Platonic Theology* and the *Elements of Theology*, Proclus extended the emphasis on systematic and religious aspects of philosophy already detectable in Iamblichus. The systematization was particularly influential. This can be seen in his *Commentary on the Parmenides*, where he interpreted the famous dialectical discussion starting from the hypothetical proposition "If it is (there is a) one, the one will not be many" by applying the first five hypotheses to the One, the "ones" or gods together with the beings participating in them, nondivinized souls, Forms in Matter, and Matter; by associating three senses of "One" (above Being, with Being, and below Being) with the first three hypotheses; and by showing that all the attributes denied of the One in the first hypothesis are affirmed of the gods in the second.

Systematization can also be seen in the *Elements of Theology* where Proclus applied a method reminiscent of Euclidean geometry in order to "demonstrate" through a series of propositions, proofs, and corollaries and starting from certain initial propositions such as "All that is unified is other than the One itself" what philosophers must believe regarding the One itself (propositions 1–6), regarding the relation between the One and the other hypostases of the expanded post-Iamblichean order of being (propositions 7–112), and regarding the other hypostases themselves (propositions 113–211).

## MEDIEVAL PLATONISM

The medieval Platonic tradition can be divided into the non-Latin and Latin traditions, the former in its turn being divisible into the Byzantine, Arabic, and Jewish traditions. But before turning to these, a few comments are necessary regarding certain transformations of ancient philosophy by patristic writers that formed a basis for later developments.

The most important intermediary between ancient and medieval Platonism in the West was Augustine of Hippo (354–430 CE). In the autobiographical *Confessions*, Augustine reported his encounter with "certain Platonic books translated from Greek into Latin"

(*Confessions* VII. 9)—assumed to be writings of Plotinus and Porphyry by most scholars—and his consequent liberation from the dualistic and materialistic tenets of Manichaeism that had formerly impeded his progress toward Christian truth. What is being described here in narrative terms is the discovery of that synthesis of Platonism (specifically Neoplatonism) and Christianity that becomes a standard feature of Augustine's writing. This synthesis included two versions of a Platonic theory of first principles: (1) the identification of the Neoplatonic One and Being/Intellect with the Trinitarian Father and Word respectively (as in *Confessions* VII. 9); and (2) the identification of the One and Being/Intellect with God and the angels respectively (as in *On the Literal Interpretation of Genesis* II. 15ff.).

These two versions of Platonism are moving in opposite directions, since in the former case the universal aspect of the second principle is intensified while the hierarchical relation between the first and second principles is weakened; in the latter, the universal aspect of the second principle is weakened while the hierarchical relation between the first and second principles is intensified. The most important intermediary between ancient and medieval Platonism in the East was "Dionysius the Areopagite." This otherwise unknown fifth-century Christian achieved a posthumous authority by writing an important group of theological treatises, including *On the Celestial Hierarchy*, *On Divine Names* and *On Mystical Theology*, under the pseudonym of the first-century Dionysius famously converted by St. Paul.

*On Divine Names* in particular provides a skillful Christian adaptation of late pagan Neoplatonism in which the negative and affirmative predicates of hypotheses I and II of Plato's *Parmenides* are applied not to the One and the gods respectively—as in Proclus's commentary—but to a God or "Thearchy"—who is simultaneously transcendent of and immanent in created things. This important transformation in the direction of monotheism has as further philosophical consequences that the distinction between the transcendence and immanence of the deity by being partially mind-dependent introduces an element of idealism into the realist ontology characteristic of traditional Platonism. The Augustinian and Pseudo-Dionysian versions of the Neoplatonic theory of first principles should especially be compared with regard to their handling of the theory of Forms and the doctrine of Soul. With respect to the Forms, both writers understood Forms in the sense of physical paradigms as contained in the divine Intellect but Forms in the sense of moral absolutes as equivalent to

divine attributes. With respect to the Soul, both authors removed the universal Soul from their system but, with suppression of the idea of transmigration between bodies, retained the function of individual souls.

The most important thinker within the Byzantine tradition of medieval Platonism is Michael Psellus (1018–1078). This author's claim to have revived the discipline of philosophy single-handedly is justified to the extent that, in an environment dominated by orthodox Christianity and methodological Aristotelianism, he reestablished the patristic notion of Platonism as a forerunner of Christianity and the later Neoplatonic notion of a relation between Aristotle and Plato in which the former's physics serves as an introduction to the latter's theology. Although Psellus is hardly responsible for metaphysical innovations in works like *On Plato's Psychogony* and *On the Ideas Which Plato Mentions*, the fact that he discussed philosophy by explicitly combining pagan Platonic sources such as Plato, Proclus, and Plotinus with Christian Platonic sources such as Gregory of Nyssa, Pseudo-Dionysius, and Maximus the Confessor represents an innovation in textual practice.

More specifically, this practice might be characterized as selective in that it isolates only certain aspects of traditional Platonism as compatible with Christianity—for example, by removing all theurgic elements (in *On the Activity of Demons*)—as allegorical in interpreting metaphysical principles in pagan texts as symbols of metaphysical principles in Christian scripture, and as combinatory in that it juxtaposes groups of notions drawn from traditional Platonism and Christianity without reducing the conflicting elements—for example, by combining Proclus's metaphysical interpretation of Jupiter's relation to the lower gods with the pseudo-Dionysius's of the Thearchy's relation to the angelic ranks (in *On Homer's Golden Chain*). This highly original textual manipulation of Platonism established an intellectual tradition that endured until the fall of Constantinople. Later representatives include John Italos (c. 1025–after 1082), Eustratios of Nicaea (fl. at the end of the eleventh and early twelfth centuries)—author of a commentary on Aristotle's *Nicomachean Ethics*, which includes material from Proclus and was translated into Latin by Grosseteste, and Nicholas of Methone (mid-twelfth century), author of a “refutation” of Proclus's *Elements of Theology*.

That Arabic writers were able to make a major contribution to the development of medieval Platonism not only in the Islamic but also subsequently in the Christian world resulted from a fortunate circumstance: the avail-

ability of some reasonable translations as sources. Under the Umayyad and 'Abbāsid caliphs, a vast enterprise of translating scientific and philosophical works from Greek into Arabic (sometimes through the intermediary of Syriac) was undertaken by such figures as Hunain b. Ishāq (808–873) and Qustā b. Lūqā (tenth century) with the result that all of Aristotle except the *Politics*, a certain amount of Plato, and many Greek philosophical commentaries, became available. It was in such a milieu that an important group of philosophical *apocrypha* arose.

This group consists of: (1) an Arabic “Plotinian” corpus (possibly the remains of a translation and commentary on *Enneads* IV–VI produced in the circle of al-Kindī [b. late eighth century and d. after 866]) comprising the *Theology of Aristotle*, the *Letter on Divine Science*, and the *Sayings of a Greek Sage*; (2) the adaptation of Proclus's *Elements of Theology*, later known to the Latins as the *Book of Causes* (the Arabic original of which was produced before 992); and (3) an Arabic translation of approximately thirty-five propositions from Proclus's *Elements of Theology* and *Elements of Physics*. These works are connected through their expression of metaphysical teachings that depart from their Plotinian or Proclean originals in identical ways: namely, in describing the first principle as Pure Being—meaning Being without Form—rather than as the One above Being; and as creating, without any preexistent term or materiate substratum—rather than as causing—all subsequent principles. Moreover, that the first principle or Creative Being does not relate indirectly—through the mediation of an order of gods or “ones”—but directly to the second principle or Created Being is the common doctrine of the *apocrypha*.

During the next few generations, various writers developed a uniquely Arabic approach to the reading of the philosophical tradition in which a Neoplatonic doctrinal component drawn from sources of the type mentioned was inserted into an overtly Aristotelian context. Within this tradition al-Fārābī (Latin: *Alfarabius* [d. 950]) outlined a program of harmonizing Aristotelian and Platonic doctrine in his *Reconciliation of the Two Sages*, *Philosophy of Plato*, *Philosophy of Aristotle*, *Attainment of Happiness*, and *Opinions of the Inhabitants of the Virtuous City*. According to his metaphysical system, the Supreme Being or One produces a series of intellects, each of which can think its cause (thereby giving rise to a further intellect) and itself (thereby giving rise to a celestial sphere), this theory being understandable as the transfer of the emanative causal mechanism from the Neoplatonic hypostases to the Aristotelian unmoved movers.

Also within this tradition Ibn Sinā (Latin: *Avicenna* [980–1037]) organized knowledge into logic, physics, and metaphysics along Aristotelian lines in his encyclopedic *Book of Healing* and its abridgement the *Book of Salvation*. He further developed al-Fārābī's metaphysical system in proposing that, when the Supreme Being produces the subsequent terms, the first intellect in a threefold process first thinks the Being necessary in itself (thereby producing by emanation the second intellect), then itself as necessarily existing through its cause (thereby producing the soul of the first heaven), and finally itself as contingently existing through itself (thereby producing the body of the first heaven), this process being repeated until all the intellects, souls, and heavens have been generated. The inevitable reaction came when Ibn Rushd (Latin: *Averroes* [1126–1198]) attempted to liberate the authentic Aristotle from such Neoplatonizing tendencies. Of his two most famous interpretative innovations, the doctrines that the intellects are not connected by emanation and that there is a single agent and material intellect for all humanity, the first but not the second obviously runs counter to Neoplatonism. Ethical and political thought was not neglected by the Arabs and, since both Plato's *Laws* and *Republic* were available in Arabic, in this area they tended to be more Platonic than Aristotelian. Among examples of their work are al-Fārābī's compendium of the former dialogue and Ibn Rushd's commentary on the latter.

The most important thinker within the Jewish tradition of medieval Platonism is Solomon ben Judah ibn Gabirol (Latin: *Avicbron* [c. 1021–1058]). As the author of some excellent poetry in Hebrew, including the famous *Kingly Crown* and one philosophical treatise in Arabic, Ibn Gabirol stands within two cultural traditions. The philosophical work, which survives only in the Latin translation by Iohannes Hispanus and Domenicus Gundissalinus under the title of *Fountain of Life*, continues the speculative approach of the Arabic *apocrypha* but also develops the latter in an original style. Ibn Gabirol argued that the duality of form and matter underlies both the spiritual and the corporeal levels of reality, this combination of the formal and the material being used in subtle ways to explain the relation between unity and plurality. Although form and matter are also two closed doors between the human intellect and its Creator that are difficult to pass through, one can describe the Creator as Wisdom, Unity, and Will inasmuch as he is the cause of form and as Being inasmuch as he is the cause of matter.

Ibn Gabirol's duality of form and matter in created things represents the moments of determination and undetermined within an emanation, as indicated by his

references elsewhere to the dynamic process whereby the inferior comes forth from and strives for union with the superior. Although a Hebrew translation of certain extracts was subsequently made by Ibn Falqera and there may have been some influence on the Jewish mystics of the Gerona circle, the philosophical afterlife of the *Fountain of Life* was mainly in the world of Latin scholasticism.

Because only the *Timaeus* was available in Latin (translated up to 53c with commentary by Calcidius [fourth century CE]) throughout the Middle Ages, the translations of the *Meno* and *Phaedo* (by Aristippus of Catania [d. 1166]) and of the *Parmenides* (included in Proclus's commentary up to 142a translated by William of Moerbeke [c. 1215–1286]) achieving only limited circulation towards the end of the period, one refers to a predominantly indirect transmission of doctrine in speaking of a "Platonic" tradition in the medieval Latin world. However, even this restricted definition of the latter is problematic given that the doctrines concerned are usually combined with Christianity and, during the thirteenth to fifteenth centuries especially, with Aristotelianism. One way of approaching the medieval Latin tradition of Platonism is perhaps to distinguish certain doctrinal clusters; that is, groups of philosophical teachings that exhibit sufficient coherence among themselves and predominate sufficiently in the context where they occur, and then to track the evolution of these clusters through medieval thought. The most important clusters are the following:

- (1) A "Timaeian" cluster. This group of doctrines, which is presented in passages of Augustine's *Against the Academics*, *On the City of God*, and *On Eighty-Three Different Questions* (qu. 46), based on Cicero's works (including his partial translation of the *Timaeus*) and also in Calcidius's *Commentary on the Timaeus* and Macrobius's *Commentary on the Dream of Scipio*, represents a systematic and cosmological Platonism. It emphasizes the metaphysical principles of Soul and Nature, interprets the transcendent Forms as thoughts in the divine mind, and in general has affinities with the Middle Platonic doctrine of Antiochus of Ascalon.
- (2) A psychological and Augustinian cluster. Based on Augustine's *Soliloquies* and *On the Trinity*, this group identifies the relations between the macrocosmic and microcosmic aspects of the Neoplatonic hypostases of the One and Intellect respectively along Porphyrian lines in order to ground human cognition or rather supracognition of the First Principle.

(3) A mathematical cluster. Based on the ancient tradition dating back to Xenocrates, it is transmitted to the Middle Ages by Boethius's *On Arithmetic*, *On Music*, and *On the Consolation of Philosophy*. This group emphasizes the relations between the monadic and dyadic aspects of the hypostases and between monad, dyad, and number series.

(4) A "Proclean" cluster. This group of doctrines, which is presented in different ways by Latin translations of the Pseudo-Dionysian corpus (by John Scotus Eriugena [d. c. 877–879] and several later writers), of the Arabic *Book of Causes* (by Gerard of Cremona between 1160 and 1187), and of Proclus's *Elements of Physics* (by an unknown translator c. 1160), *Elements of Theology*, *Commentary on the Timaeus*, *Commentary on the Parmenides*, and *Minor Theological Tractates* (all by William of Moerbeke between 1268 and 1286), represents a systematic and theological Platonism. It emphasizes the metaphysical principles of the One and Intellect, interprets the transcendent Forms as divine attributes or names, and in general is aligned with the Neoplatonic doctrines of the Athenian School.

(5) A psychological and Avicennian cluster. Based on the Latin translation of the psychological portions of Ibn Sīnā's *Book of Healing* (probably by Ibn Daud [d. c. 1180] and Dominicus Gundissalinus [fl. 1126–1150]), this group equates the relation between the macrocosmic and microcosmic aspects of the Neoplatonic hypostasis of Intellect with the conjunction between the separate agent intellect and the human intellect used by Arabic Aristotelianism to combine the abstraction of universals with the emanation of Forms.

In the medieval Latin world, these clusters occur in the following combinations and sequence. In John Scotus Eriugena's *On Natures*, cluster 4 as it occurs in the pseudo-Dionysian corpus is developed into a comprehensive metaphysical doctrine in which everything that is and is not can be divided on the one hand into the four quasi-species of "creating and not created," "creating and created," "not creating and created," and "not creating and not created" and on the other into a procession and a reversion of the First Cause with respect to its effects and of the effects with respect to their First Cause.

In philosophers of the twelfth century there was a tendency to combine clusters 1 and 3. For example, Adelard of Bath (fl. c. 1110–1125), who also translated the writings of Euclid from Arabic, elaborated within the

context of cluster 1 a view of nature and of reason as theologically quasi-independent and also a theory of universals designed to harmonize the opinions of Plato and Aristotle; see his *On the Same and the Different and Natural Questions*. William of Conches (d. c. 1154), in his *Glosses on Plato's Timaeus*, *Glosses on Macrobius*, and *Philosophy of the World*, wrote extensively on an issue central to a naturalistic cosmology but problematic for Christian theology: namely the status and function of the Platonic world soul. Thierry of Chartres (fl. 1121–1148), who was described by contemporaries as the greatest Platonist of his era, elaborated within the contexts of cluster 1 and cluster 3 a metaphysics in which the interaction between God's unity and Matter produces the multiplicity of Forms equivalent to numbers, the Trinitarian nature of God also being expressible arithmetically as  $1 \times 1 = 1$ ; see his *Commentary on Boethius's On the Trinity* and *On the Works of the Six Days*.

With the appearance of translations from Arabic into Latin and the rise of the medieval university after circa 1200, Platonism had to compete with Aristotelianism: a task that it accomplished most successfully within the sphere of what modern scholars term "Latin Avicennism." In the anonymous *Book of Avicenna on the First and Second Causes and the Emanation of Being*, cluster 2, cluster 4 as it occurs in the Pseudo-Dionysius and in the *Book of Causes*, and cluster 5 are combined to produce a metaphysical system in which the procession and reversion of effects with respect to the First Cause begins with the production of the first created intellect by Pure Being, and in which cognition takes place when the human soul ascends from the looking of reason to the vision of intellect and the tenth created intellect or agent intellect combines with the human intellect. This text represents a kind of standard late medieval Platonism to which all serious thinkers will have to react whether they are predominantly Aristotelian (e.g., Albert the Great [c. 1200–1280]) or predominantly Platonic (e.g., Dietrich of Freiberg [c. 1240–1318/1320], Meister Eckhart [c. 1260–1327]) in tendency.

## MODERN PLATONISM

The modern Platonic tradition can be divided into a phase beginning with the impact of the early-fifteenth-century humanist movement and a phase beginning with Friedrich Daniel Ernst Schleiermacher's German translation of Plato (published 1804–1809). The former phase might also be termed the "early modern" or "Renaissance" phase of Platonism.

Humanism can be defined as an ideal of liberal education based on the study of grammar, rhetoric, poetry, history, and moral philosophy especially through the recovery of authoritative texts in Greek and Latin, the term “humanism” itself corresponding to the *studia humanitatis* advocated by the Roman rhetorician and philosopher Cicero. Although the beginnings of the humanistic movement can be detected in Northern France during the early twelfth century, the main development is usually traced from Francesco Petrarca (in English, “Petrarch,” 1304–1374).

Taking their cue from the latter’s pointed praising of Plato in preference to Aristotle, Italian humanists together with their Byzantine associates produced during the next century and a half a series of Plato translations based on newly imported manuscripts. These included Latin versions of the *Republic* by Manuel Chrysoloras and Uberto Decembrio, by Pier Candido Decembrio, and by Antonio Cassarino, versions of the *Phaedo*, *Gorgias*, several *Letters*, *Phaedrus* (partial), *Crito*, *Apology*, *Symposium* (partial) by Leonardo Bruni, of the *Axiochus* by Cencio de’ Rustici, of the *Ion* by Lorenzo Lippi, of the *Crito*, *Axiochus*, and *Euthyphro* by Rinuccio Aretino, of several *Letters* and the *Euthyphro* by Francesco Filelfo, and of the *Charmides* (partial) by Angelo Poliziano. From this list of titles, one may conclude that the “humanists” interest in Plato was primarily focused on the literary, ethical, and political aspects of Plato’s work.

The first Platonic philosopher affected by humanism was Nicholas of Cusa (originally Niklaus Krebs, 1401–1464), a fact indicated by his commissioning of a Latin translation of the *Parmenides* by the Byzantine émigré George of Trebizond, the manuscript of which exists, together with his own marginal notes (Volaterranus 6201, f. 61r–86v), in the twenty-first century. Although Nicholas was not familiar with the complete *Parmenides* when he wrote his most celebrated philosophical work *On Learned Ignorance* (1440)—and probably not even with the part reproduced in Moerbeke’s Latin translation of Proclus’s commentary—the teaching of the dialogue fitted naturally into the philosophical system already developed for that work on the basis of medieval sources.

In summary, that system involves the threefold distinction of an “absolute maximum” (God), a “contracted maximum” (the Universe), and a simultaneously absolute and contracted maximum (Christ). With respect to the absolute maximum (and also to the relation between the three maxima), one can discern a Pythagorean and Trinitarian metaphysical structure comprising unity, equality, and connection, which is applied to a Dionysian structure

based on the contrast of negative theology (indicating divine transcendence) and affirmative theology (indicating divine immanence) in order to produce an original Cusan metaphysical structure consisting of what surpasses opposites, opposites as such, and the “coincidence of opposites.” Although this system has many affinities with doctrines advocated during the Middle Ages, it is innovative in emphasizing the subjectivity of the negative-affirmative theological antithesis (by transferring the teaching of pseudo-Dionysius’s *On Mystical Theology* to the cosmological sphere), in its frequent recourse to mathematical images: for example, the maximum, infinity, the circles and triangles of geometry, and the concord of music, and in emphasizing the coincidence inherent in opposition (again adapting the teaching of *On Mystical Theology* to a cosmological use), the combination of the first and last points epitomizing the “learned ignorance,” which provided Nicholas with his title.

Marsilio Ficino (1433–1499) is a truly seminal figure who established a pattern of interpreting Platonic philosophy that remained fundamental for the next three centuries. By the late 1450s Ficino had acquired a sufficient reputation as a Platonic thinker and as a Greek scholar to be requested by the Florentine ruler Cosimo de’ Medici in 1462 to translate Plato’s complete works into Latin from a newly acquired manuscript, this translation appearing in a first edition in 1484 and a second edition in 1491. In addition to this commission, Ficino translated the Hermetic corpus (under the title *Pimander*), the *Enneads* of Plotinus (published in 1492), and various treatises by Porphyry, Iamblichus, Proclus, Synesius, and Michael Psellus for the first time, and also made a fresh translation of the pseudo-Dionysian corpus.

Historians rate him highly not only as an exegete of Plato and Platonism (on the basis of his translations and the commentaries published with the latter) but also as a constructive Platonic thinker (on the basis of his substantial independent treatise titled *The Platonic Theology or On the Immortality of the Soul*). Ficino is important as an exegete because he considered for the first time since antiquity the complete writings of Plato and was therefore able to draw material from dialogues unavailable during the Middle Ages and to engage more fully with the argumentative context of Plato’s teaching. Moreover, he proposed a special interpretation of the history of philosophy under the influence of late ancient and Byzantine writers and of Diogenes Laertius’s *Lives of the Philosophers* according to which the Christian revelation beginning from Moses is confirmed by a unified and

harmonious system of pagan theology emerging as a six-fold transmission linking Hermes Trismegistus with Orpheus, Aglaophemus, Pythagoras, Philolaus, and Plato.

Dionysius the Areopagite plays a pivotal role in this theory, which basically unifies disparate ideas through allegorical reading. As a thinker of unique inspiration and apostolic authority, Dionysius disclosed the truths concealed in the ancient system to pagan Platonists like Plotinus, the latter in turn transmitting those truths back to Christian writers such as Augustine. Ficino is important as a constructive thinker because he developed the Neoplatonism not only of Proclus (which had become known toward the end of the medieval period) but also of Plotinus (which was almost totally unknown during the Middle Ages) in directions more consistent with the Christian sense of human dignity and individuality. For example, the hypostatic system is sometimes recast so that Soul, instead of being simply the lowest of the three principles of the One, Intellect, and Soul, becomes the third member of a series of five terms God, Angel, Soul, Quality, and Body. This arrangement not only gives Soul a mediating and therefore sustaining function but supplies a novel argument for Soul's immortality in that if Soul were dissoluble then the entire order could likewise suffer dissolution. The hypostatic system is also sometimes modified in that Soul, instead of ascending or descending by identifying with the adjacent term of the series conceived dynamically in the upward direction, ascends or descends by passing through static regions formed by the adjacent terms on both sides.

One work by Ficino was particularly influential both inside and outside philosophy: namely, *On Love* written in 1469 and published in 1484. In fact, it is largely owing to this free commentary on Plato's *Symposium* that Platonism was to become among all doctrines in the history of philosophy the most influential on literature, the visual arts, and music.

Another Platonic philosopher affected by humanism was Giovanni Pico della Mirandola (1463–1494). In his *Conclusiones*—a set of 900 philosophical theses that he would have defended in a public disputation had the Pope not intervened by declaring some of them heretical—Pico attempted to extend the notion of a universal system underlying philosophy by adding the Jewish Kabbalah to the Egypto-Hellenic tradition described by Ficino. On the basis of the number of theses drawn from different schools of philosophy in the more historical first part of the work, it would seem that Proclus (supplying fifty-five theses) and the Kabbalists (supplying forty-seven theses) are the most important influences, the

organization of the project itself into a set of propositions recalling Proclus's methodology (as in the *Elements of Theology*) and the ascription of numbers to the propositions reflecting the Kabbalistic approach (900 being the numerical value of the cruciform Hebrew letter *tsade*).

Other writings by Pico also respond to Ficinian ideas. The *Oration* (called *Oration on the Dignity of Man* after Pico's death) and the *Heptaplus* elaborate the notion of Soul as central in the order of reality, while *On Being and Unity* (part of a projected work *On the Concord of Plato and Aristotle*) discusses the question whether among first principles Unity is prior to Being or not. In the latter essay, Pico's conclusion that Unity is not prior to Being according to either Plato or Aristotle required him to argue that hypothesis I of the *Parmenides* forms part of a purely dialectical exercise and thereby to sustain the Porphyrian, Arabic, and Latin rather than the Plotinian version of the Neoplatonic theory of first principles. In both these cases his theories deviate from Ficino's normal view.

The question of the impact of Platonism on the generations after Ficino is an extremely complex one. Despite the reading of Plato's dialogues in Greek courses at the traditional universities, the attempt of Francesco Patrizi (1529–1597) to establish courses on Platonic philosophy at the Universities of Ferrara and Rome, and the rise of numerous Platonically inclined literary "academies" in Italy and France, Platonism never displaced Aristotelianism institutionally. In fact, with respect to the sixteenth century it is necessary to speak of Platonic influence rather than of a Platonic tradition. Platonism during this period is partially a continuation of earlier tendencies. This description would apply to various discussions of Soul, for example when the Lateran Council of 1512–1517 proclaimed the immortality of the human soul as official dogma perhaps under the influence of Ficino, and when Giordano Bruno (1548–1600) incorporated the Plotinian theory of the World Soul into his cosmological speculation. Closely connected with the theory of Soul and disseminated by the various "academies" were the Platonic doctrines of spiritual love (derived from Ficino's reading of the *Symposium*) and of divine madness (derived from Ficino's reading of the *Phaedrus* and *Ion*) whose influence can be detected in Bruno's *Eroici Furori* and Patrizi's *Della Poetica* respectively.

Sixteenth-century Platonism is also partially an adaptation to newer ideas. Here, Platonism was rightly seen as having more in common with the rising mathematical sciences and quantitative thought than did Aristotelianism. Of the two main concepts of traditional

mathematical Platonism, the notion of the *a priori* validity of numbers and of the symbolic power of numbers, Johann Kepler (1571–1630) applied both the first and the second and Galileo Galilei (1564–1642) the first but not the second to the astronomical-physical sphere.

With respect to the seventeenth and eighteenth centuries it is even more necessary to speak of Platonic influence rather than of a Platonic tradition. Platonism during this period is partially a continuation of earlier tendencies. This description applies to the philosophy of inner spirituality advocated by the “Cambridge Platonists” Henry More (1614–1687) and Ralph Cudworth (1617–1688), the last European thinkers to explicitly place themselves within the Platonic tradition. Seventeenth- and eighteenth-century Platonism is also partially an adaptation to newer ideas. Here, the notion of the intellectual love of God in Benedictus de Spinoza (1632–1677), the notion of reality as a system of spiritual monads each of which reflects the entire universe from its own viewpoint in Gottfried Wilhelm Leibniz (1646–1716), and the notion of thought reaching the sphere of things-in-themselves in the precritical thought of Immanuel Kant (1724–1804) are particularly important.

Between the sixteenth and eighteenth centuries there is also a remarkable example of a Platonism that might be considered as standing on the borderline between Platonic tradition and Platonic influence. The treatise *Siris* by George Berkeley (1685–1753) is a recommendation of tar-water as a panacea taking the form of a chain of reflections linking the properties of this liquid first with the chemical and physical phenomena of air and fire respectively and secondly with the spiritual world ascending to God. The main philosophical aims of Berkeley’s study, which obviously blends the chain of reflections with the chain of being itself, are to oppose the mechanistic, materialist, and pluralistic view of the universe—well established by his own day—with a spiritual, immaterialist, and unified one, and also to supplement the sensuous immaterialism of his own earlier works—notably the *Treatise concerning the Principles of Human Knowledge*—with a theological idealism. The substantial final section of the treatise achieves its aims by mustering an impressive array of explicitly cited Platonic sources, including Plato’s dialogues *Alcibiades I*, *Phaedo*, *Republic*, *Theaetetus*, *Timaeus*, *Parmenides*, and *Letters*, Plotinus’s *Enneads*, Proclus’s *Platonic Theology*, Bessarion, Ficino (especially his commentary on the *Enneads*), Patrizi, and Cudworth.

On the basis of these authorities, it then argues that the three hypostases of Plotinian Neoplatonism are a reflection of the Christian Trinity. Here, the most important points to emerge are that Unity and Being are mutually convertible, that the placing of the hypostasis of the One before the hypostasis of Intellect or Being does not imply any atheism because there is nevertheless no time at which the One was without Intellect—an argument seemingly unprecedented within the Platonic tradition—and that the purely notional distinction between divine attributes allows the first point to be compatible with the second. The Platonic teachings quoted in *Siris* are clearly not to be taken too literally: Rather, the philosophical maxims of ancient times are proposed, as Berkeley put it, not as principles of logical demonstration but as hints to awaken and exercise the inquiring mind.

Schleiermacher’s German translation of the writings of Plato (1804–1809), in which the necessity of distinguishing Plato’s own doctrine from the teachings of later “Platonists” and the suggestion that the authentic teaching of the dialogues is superior to the pedantic systematizations of their later admirers was stressed, is rightly seen as the watershed in the history of Platonic interpretation. This new approach had already been gaining ground during the seventeenth and eighteenth centuries, as evidenced by various comments in Leibniz and reference books like J. J. Brucker’s *Historia Critica Philosophiae* (1742–1744) and Denis Diderot’s *Encyclopédie* (1751–1765). This approach underlines the change from the perception of a unified Platonic tradition to that of more fragmentary Platonic influences. But these changed circumstances present a new set of problems for any interpreter wishing to apply the term “Platonism” henceforth. In short, to what extent is it reasonable to speak of “Platonism” after 1800? A few comments on the “afterlife” of Platonism are perhaps in order.

One should begin by considering what might be termed *modern historical studies* on the question of “Platonism.” Of relevance to the historical question are the distinctions intended by modern interpreters when employing the terms “Middle Platonism” (occasionally “Pre-Neoplatonism”) and “Neoplatonism” with respect to the ancient tradition (see especially the works of Willy Theiler and Heinrich Dörrie). Although the application of such terminology assumes the principle of distinguishing between Plato’s own doctrine and that of later exegetes, it does not exclude the possibility that a particular teaching originates with Plato himself, something that must be ascertained on a case by case basis. Also of

relevance to the historical question is the notion that certain doctrines central to Plato's thought that were taught orally by the master but not included in his dialogues can be identified using the tools of modern criticism (see especially the works of Hans-Joachim Krämer and Konrad Gaiser). The study of such doctrines can yield clarification regarding both the meaning of certain teachings expressed obscurely in the dialogues and the origination of various doctrines associated with Middle or Neoplatonism.

These points represent historiography rather than philosophy in the wake of "Platonism." In order to identify a trajectory of modern philosophical Platonism, one might consider the following three cases in which influential doctrines have been or could be associated with Platonism:

(1) Georg Wilhelm Friedrich Hegel (1770–1831) in his *Lectures on the History of Philosophy* interpreted the Proclean triad of Being, Life, and Intellect within the intelligible world as corresponding to thought-determinations within the Hegelian Idea. One could tentatively propose this as a case of Platonism in that Hegel was explicitly reading a Platonic text and because his doctrine combines similarities with Platonism (the triadic structure occurs in Neoplatonism) with differences (the Platonic structure is abstractly universal whereas the Hegelian is concretely universal). But Hegel is obviously less a Platonist in either of the aforementioned senses than a creative reader of Platonism.

(2) Gottlob Frege (1848–1925) in his *Foundations of Arithmetic* postulated purely logical objects, which inhabit a logical realm of the objectively nonreal in contrast with the physical realm of the objectively real and the psychical realm of the subjectively real, and which especially include numbers. Scholars frequently describe his thinking as "logical Platonism" in that, although Frege was not explicitly reading a Platonic text, his doctrine combines similarities with Platonism (the establishment of an *a priori* element) with differences (the Platonic element is an essence whereas the Fregean is a proposition). But scholars label Frege a Platonist in an extremely loose sense, given that what is common to Platonism and Frege does not enter into any recognizably systematic structure of Platonism.

(3) Martin Heidegger (1889–1976) in his *The Essence of Truth: On Plato's Cave Allegory and Theaetetus* interpreted the Platonic Forms not as what is real as

opposed to what is apparent but as the interplay of appearance and concealment. One could again tentatively propose this as a case of Platonism in that Heidegger was explicitly reading a Platonic text and because his doctrine combines similarities with Platonism (the dual structure occurs in Neoplatonism) with differences (the Platonic duality is metaphysical in character whereas the Heideggerian is phenomenological in character). But Heidegger is again less a Platonist in either of the senses distinguished previously than a creative reader of Platonism.

These ideas in Hegel, Frege, and Heidegger are undoubtedly among the more powerful philosophical thoughts since the 1800s. They reveal clearly that, although Platonism declined in significance as a tradition between 1600 and 1800, it has continued to provide a stimulus to philosophical activities of all kinds. There is no reason to think that this will not continue to be the case in the twenty-first century and beyond.

## PLEASURE

The concept of “pleasure” has always bulked large in thought about human motivation and human values and standards. It seems clear to most people that pleasure and enjoyment are preeminent among the things worth having and that when someone gets pleasure out of something, he develops a desire for it. Moreover, from the time of Plato much of the discussion of the topics of motivation and value has consisted in arguments for and against the doctrines of psychological hedonism (only pleasure is desired for its own sake) and ethical hedonism (only pleasure is desirable for its own sake). One can make an intelligent judgment on these doctrines only to the extent that he has a well-worked-out view as to the nature of pleasure. Otherwise he will be unable to settle such questions as whether a putative counterexample, for instance, a desire for the welfare of one’s children, is or is not a genuine example of desiring something other than pleasure for its own sake.

### DEMARCATIION OF THE TOPIC

Pleasure and pain have usually been regarded as opposite parts of a single continuum. As pain diminishes, it tends toward a neutral point; by continuing in the same “direction” we move toward increasing intensities of pleasure. Thus Jeremy Bentham regarded amounts of pain as negative quantities to be algebraically summated with amounts of pleasure in computing the total hedonic consequences of an action or a piece of legislation. This was in accordance with the utilitarian principle that an action

is justified to the extent that it tends to produce pleasure and the diminution of pain. Since *pain* is most commonly used as a term for a kind of bodily sensation, it is natural to think of pleasure as having the same status. And indeed there are uses of the term *pleasure* in which it seems to stand for a kind of bodily sensation. Thus we speak of “pleasures of the stomach” and thrills of pleasure. But as hedonists have often insisted, in any sense of the term in which psychological or ethical hedonism is at all plausible, the term *pleasure* must be used so as to embrace more than certain kinds of localized bodily sensations. When someone maintains that pleasure is the only thing which is desirable for its own sake, he certainly means to include states of the following sort:

- (1) Enjoying (taking pleasure in) doing something, such as playing tennis.
- (2) Getting satisfaction out of something, such as seeing an enemy humiliated.
- (3) Having a pleasant evening; hearing pleasant sounds.
- (4) Feeling good, having a sense of well-being.
- (5) Feeling contented being.

It seems clear that phenomena of these sorts do not consist in localized bodily sensations of the same type as headaches, except for being of an opposite quality. When someone has enjoyed playing tennis, it makes no sense to ask where (in his body) he enjoyed it. Nor does it make sense to wonder whether the pleasure he got from the tennis came and went in brief flashes, or whether it was steady and continuous; but these would be sensible questions if getting pleasure from playing tennis were a localized bodily sensation like a headache. This is not to deny that various localized sensations might be involved in his enjoyment of the game, such as a swelling in his chest after making a good shot, or a sinking sensation in his stomach after muffing a shot. The point is that his enjoyment of the game cannot be identified with such sensations, for he could be enjoying the game throughout its duration, even though such sensations cropped up only from time to time.

In fact we are confronted with two distinguishable positive-negative dimensions. There is the pleasure-pain dimension, a dimension of bodily sensations ranging from intense pains to intense localizable pleasures of the sort experienced in sexual orgasm. To specify the other dimension we need a terminological convention. We shall use the term *getting pleasure* as a general designation for an experience like those specified in the above list. Thus, enjoying listening to music and feeling good on arising in

the morning are special forms of “getting pleasure.” Getting pleasure can, then, be thought of as the positive segment of a dimension, the negative segment of which will be termed *getting displeasure* and will include such things as feeling bad, feeling discontented, having a miserable time, being uncomfortable, being displeased by someone’s action, being “pained” or distressed at the sight of something, and so on. We have variations of degree in this “pleasure-displeasure” dimension, as well as in the “pleasure-pain” dimension. One can enjoy oneself more or less and be displeased at something more or less. Moreover, it would seem that there is an intermediate neutral point at which one is neither pleased nor displeased at what is happening, neither enjoying oneself nor feeling miserable, and so on. It is the pleasure-displeasure dimension that philosophers are really trying to understand when they discuss “pleasure and pain.” Hence we shall take the problem of the nature of pleasure to be the problem of understanding what it is to “get pleasure.” For simplicity of exposition we shall largely confine the discussion to the positive segment of the pleasure-displeasure dimension; when dealing with the entire dimension we shall use the term *hedonic tone*.

It is important to realize that in posing the problem in this way philosophers (and psychologists) have assumed that there is something fundamental which is common to enjoying something, getting satisfaction out of something, being pleased at something, feeling good, and so on. It is conceivable that this assumption is mistaken, in which case virtually all the discussions of the problem have been misguided. In this article we shall follow tradition in supposing that there is an important common element to be found.

### PLEASURE AS A NONLOCALIZED SENSATION

Admitting all the above, it still might be supposed that pleasure is a nonlocalized bodily sensation on the order of fatigue or “feeling energetic.” (If pleasure is a sensation, it must be a bodily sensation rather than visual, auditory, tactile, olfactory, or gustatory; for it is evident that pleasure is not simply a function of the stimulation of external sense receptors.) If so, to get pleasure out of playing tennis would be to have the pleasure sensation while playing tennis. This view has been made the target of some acute critical attacks, most notably by the Oxford philosopher Gilbert Ryle. The main criticisms are as follows:

- (1) Any sensation can be either pleasant or unpleasant, depending on further features of the context. A thrill can be either a thrill of pleasure or a thrill

of horror. A masochist even gets pleasure out of painful sensations. Some sensations are generally pleasant (moderate warmth), others generally unpleasant (strong electric shock); but the fact that what one enjoys in a particular case depends on factors other than the kind of sensation involved, shows that we cannot identify taking pleasure in something with having a certain kind of sensation.

- (2) It would seem that any sensation, if it becomes sufficiently acute, will tend to monopolize consciousness and interfere with concentration on anything else. On the view under consideration, the more pleasure we get out of, say, playing the piano, the more intense the sensation of pleasure would become, the more our attention would be taken up with the sensation of pleasure, and the harder it would become to concentrate on the playing. But the reverse is the case. The more pleasure we get out of doing something, the easier it is to concentrate on *it*.
- (3) Any kind of sensation could conceivably occur without its usual conscious accompaniments and could, indeed, occupy the whole of consciousness. Even if sinking sensations in the stomach normally coincide with a perception or thought of something as dangerous, it is quite possible for one to have such sensations without being aware of anything else at the moment. Thus, on the sensation theory one could conceivably have the pleasure of playing tennis all by itself, without having it in conjunction with one’s awareness that one is playing tennis. Pleasures do not seem to be detachable in the way this theory requires them to be. However, to this argument the sensation theorist could reply that we do have cases in which the pleasure sensation occurs all alone, such as feeling good or having a sense of well-being without consciously feeling good *about* anything in particular. Of course we cannot get the enjoyment of playing tennis without playing tennis, but that is just because of the way the complex phrase “enjoying playing tennis” is defined. We would not label the pleasure we get “the pleasure of playing tennis” unless the pleasure sensation occurred in conjunction with the awareness that one is playing tennis. But this verbal point does not disprove the contention that what makes enjoying playing tennis a case of getting pleasure is the presence of the

same sensation which occurs alone in feeling good (about nothing in particular).

- (4) A more serious difficulty is posed by another respect in which the sensation theory represents enjoyment as loosely connected with what is enjoyed. According to the theory, to enjoy something is to have the pleasure sensation in conjunction with that something. But if “in conjunction with” means merely “in consciousness at the same time as,” we are faced with the following difficulty. Let us suppose that while enjoying playing tennis at a given moment I am aware not only of playing tennis but also of oppressive humidity in the atmosphere and of a plane flying overhead. The pleasure sensation occurs in consciousness at the same time as all these cognitions. Therefore the sensation theory implies that I must be enjoying the oppressive humidity and the plane just as much as I am enjoying playing tennis. But this is contrary to the facts. A person knows immediately which of the various things he is aware of at the moment he is taking pleasure in; and the sensation theory can give no account of this discrimination. We must posit some more intimate connection between the pleasure and its object than simply being together in consciousness at the same time. But it seems that so long as we interpret getting pleasure as having a certain kind of sensation, no more intimate bond can be specified.

#### VARIANTS OF THE “CONSCIOUS-QUALITY” THEORY

The heavy emphasis on the bodily sensation theory in recent philosophical discussion has tended to obscure the fact that there are a number of other theories that belong to the same family, some of which have been much more important historically than the sensation theory. The general sort of view, of which the sensation theory is a variant, can be described as the view that pleasure is one of the ultimate immediate qualities (or data) of consciousness (experience). To say that it is a quality of consciousness is to say that it constitutes one of the ways in which one state of consciousness differs from another with respect to its own intrinsic nature rather than its relations to other things. (To say that a state of consciousness is a visual sensation of redness is to say something about its intrinsic nature, while to say that it belongs to Jones is not.) It is an immediate quality of consciousness because one is aware of it immediately, just by

virtue of its presence; nothing further is required to get at it. Analogously, in a visual sensation one is aware of the color just by virtue of having the sensation; the color is not something that could be there without being the object of awareness. It is an ultimate quality of consciousness, because it cannot be analyzed in any way with respect to its intrinsic nature. Again we may use the less problematic sensory qualities to illustrate the point. A felt pressure differs from a felt warmth, or a seen color from a heard sound, in a way that cannot be further analyzed. To know what the difference is, one must have experienced both. Henceforth, we shall use the terms *pleasantness* and *unpleasantness* for the supposed ultimate qualities, the awareness of which is, on this kind of theory, essential for getting pleasure or displeasure.

The thesis that

- (A) Pleasure is a kind of bodily sensation (more exactly stated, a quality that defines a kind of bodily sensation)

is one variant of this view; for qualities that do define kinds of bodily sensation are ultimate immediate qualities of experience—tingling, nausea, dizziness, and so on. However, there are other variants that are deserving of more respect.

- (B) Pleasure is a kind of feeling, or a quality that defines a kind of feeling, where feelings are taken to be elements of consciousness distinguishable from sensations, including bodily sensations.
- (C) Pleasure is a quality that can occur only as one aspect or attribute of some larger conscious complex, as a certain pitch or timbre occurs only as an aspect of a sound that has other aspects. Theories of this sort differ according to the sort of conscious element pleasure is thought to qualify: sensations, complexes of sensations, feelings, and so on. However, once we abandon the project of identifying pleasure with a certain kind of mental element, there is no reason not to take the most liberal alternative and consider the quality of pleasantness attachable to any sort of conscious state. This would have the advantage of not forcing us to explain away the fact that thoughts, realizations, memories, and mental images all seem to be accompanied by pleasure in the same way as sensations. For purposes of further discussion we shall take as our formulation of (C): *Pleasure is a quality that can attach to any state of consciousness.*

Let us consider whether the arguments against (A) cited above have any force against (B) and (C). Both the

first argument (that any sensation can be pleasant or unpleasant) and the second (that any sensation is capable of monopolizing consciousness) depend on specific features of bodily sensations; one could hardly expect them to have any bearing on theories that do not identify getting pleasure with having a certain kind of bodily sensation. With respect to thesis (C), it is not clear that every quality of conscious states is inherently neutral between being pleasant and unpleasant, nor is it clear that every quality of conscious states will monopolize attention in proportion to its degree. With respect to thesis (B), there are, of course, feelings that are, or essentially involve, bodily sensations (feeling nauseated, feeling tired), and the arguments do apply to these. But thesis (B) identifies pleasure with feelings that are distinct from bodily sensations. Apart from this qualification there are feelings, ordinarily so called, which, no matter how “strongly” one has them, do not tend to monopolize attention (feeling calm), and there are feelings that are not, by their nature, neutral between pleasantness and unpleasantness (feeling contented, feeling distressed). Such examples show that the consideration adduced in the first two arguments cannot be used to rule out the possibility that pleasure is some kind of feeling.

The third argument (that any sensation should be capable of occurring without its usual conscious accompaniments), on the other hand, does rule out the possibility of pleasure being a feeling, if a feeling is conceived as a mental element that could occur alone. However, we must remember that thesis (B) is distinguishable from thesis (A) only to the extent that it is restricted to feelings that are not identifiable, in whole or in part, with bodily sensations. And insofar as such feelings exist, it is doubtful that they are capable of occupying the whole of consciousness.

To make this point more concrete, let us look at the way position (B) developed. Its historical roots are to be found in the tripartite division of the mind into faculties of cognition, will, and feeling, a scheme developed in Germany in the eighteenth century by such men as Moses Mendelssohn and Immanuel Kant. Roughly speaking, the faculty of feeling is the faculty of being consciously affected, positively or negatively, by things of which one becomes aware through the faculty of cognition. Already the suggestion appears that a feeling is something that arises only in reaction to one or more cognitions and hence does not have the essential autonomy of a sensation. The introspective psychologists of the nineteenth and early twentieth centuries who tried to work out a doctrine of feeling as a distinctive kind of element of con-

sciousness, most notably Wilhelm Wundt and E. B. Titchener, wound up with a notion of feelings as, in effect, simply hypostatized bearers of the supposed ultimate qualities of pleasantness and unpleasantness. Wundt, indeed, tried to incorporate other qualities into feelings, namely, the dimensions of strain-relaxation, and excitement-quiescence; but other workers in the field tended to regard these as features of associated bodily sensations.

More generally, it seems likely that insofar as two feelings, ordinarily so called, differ in their immediate “feel,” other than with respect to pleasantness and unpleasantness, this difference can be attributed to the bodily sensations involved. Thus, if we contrast feeling homesick and feeling relieved, or feeling distressed and feeling contented, the difference in “feel,” apart from different degrees of pleasantness and unpleasantness, will come down to differences in the kinds of bodily sensations involved. Hence, we are left with pleasantness and unpleasantness as the only qualitative dimension of feelings, construed as elements distinguishable from bodily sensations. Since it was generally held that such feelings could occur only in reaction to “cognitive” mental elements, including sensations, the third argument has no force against the thesis that getting pleasure out of something consists in having a pleasant feeling in conjunction with that something. But immunity from those criticisms is purchased at the price of any significant distinction between theses (B) and (C). Instead of saying that pleasantness and unpleasantness are qualities of special mental elements termed *feelings*, which can occur only in conjunction with other mental elements, we might just as well say that pleasantness and unpleasantness are qualities that can attach to any mental element. For since on the feeling theory nothing can be said about the intrinsic nature of feelings, other than that they “bear” the qualities of pleasantness and unpleasantness, it would be in principle impossible to determine by introspection whether, when I am relieved at discovering that my child is out of danger, the pleasantness I experience attaches to my awareness of the situation or to a feeling that occurs in response to my awareness. There would be a point in adopting the more complex categorization of the experience in terms of special feeling-elements if the postulation of such elements were needed for the construction of a theory as to the causes and/or effects of getting pleasure and displeasure. But the notion of feeling-elements has not so far demonstrated any theoretical fertility. Thus, when probed, thesis (B) reduces to thesis (C).

Thesis (C)—that pleasure is a quality that can attach to any state of consciousness—escapes the third and fourth arguments, as well as the first two. The third argument obviously has no application since, according to this thesis, pleasure can exist only as a quality of some more concrete entity. It escapes the fourth argument (that according to the sensation theory, pleasure would attach to any awareness present in consciousness at the same time) because it is possible that the quality of pleasantness would attach to one apprehension and not another, even if both are in the same consciousness at the same time. Thus, in the example given, pleasantness could attach to my awareness of playing tennis but not to my awareness of the humid atmosphere, even though I am aware of both simultaneously.

Thus thesis (C) emerges as the only serious contender from the ranks of quality-of-consciousness theories, and historically most such theories can be regarded as approximations to it. John Locke treated pleasure and pain as “simple ideas obtained both from sensation and reflection,” and for David Hume pleasure and pain were “impressions of sensation.” Neither Locke nor Hume distinguished in any systematic way between kinds of sensations, qualities of sensations, feelings, and qualities of feelings. If we look at the way they actually used the notions of an “idea of pleasure” or “impression of pleasure,” we can see that in effect they took pleasure to be a qualitative feature that can attach to any state of consciousness. The “sensationist” psychologists, such as David Hartley and James Mill (whose psychology, in the hands of Jeremy Bentham and John Stuart Mill, became the basis of the utilitarian ethics and social philosophy), took pleasure and pain to be ultimate, unanalyzable properties of sensations, copies of sensations (ideas), and combinations of sensations and ideas; pleasure and pain were thought to be transferred, via association, to any mental content. None of these thinkers distinguished between the pleasure-pain and the pleasant-unpleasant dimensions, but once we clear up that confusion their view, as applied to the latter, can be seen to be a form of thesis (C).

### CONSIDERATION OF CONSCIOUS-QUALITY THEORY

The main support for the conscious-quality theory comes from the fact, already noted, that a person knows immediately when he is getting pleasure from something. He knows it in a way no one else could conceivably know it—just by virtue of being the one who is getting the pleasure. He has an epistemologically “privileged access” to the

fact. Since it is natural to take the awareness of sensory qualities, especially visual ones, as a paradigm of immediate knowledge of one’s psychological states, it is natural to construe what one knows when he knows that he is enjoying something as some ultimate quality of consciousness.

Nevertheless, on further probing, the thesis that pleasure is a quality that can attach to any state of consciousness is not very plausible phenomenologically. When we reflect on a wide variety of cases of getting pleasure, as indicated by the list at the beginning of this article, we are unable to isolate a felt quality that they all share, in the way in which we can easily isolate a quality of redness which a number of different visual sensations share, or a quality of painfulness that a number of different bodily sensations share. On the contrary, enjoying playing tennis feels very different from getting satisfaction out of seeing an enemy in distress, and both feel very different from the sense of well-being one has when, in good health, one arises carefree from a good night’s sleep. Nor does it seem possible to find *in* these experiences some respect in which they are qualitatively the same, as two sounds, otherwise very different, can be the same in pitch. Even if we stick to one term in the “pleasure family,” such as *getting satisfaction*, it seems equally implausible to suppose that there is some felt quality common to getting satisfaction out of seeing an enemy in distress and getting satisfaction out of the realization of a job well done. The enjoyment or satisfaction seems to take whatever felt quality it has from what one is enjoying or getting satisfaction from. Thus John Stuart Mill was on sound ground in insisting, against Bentham, that there are qualitative differences between “pleasures.”

These doubts are reinforced by the fact that here we are without external support for the postulation of basic conscious qualities. In the case of sensory qualities, at least those of the external senses, we can tie down the quality to a certain kind of stimulation; people ordinarily get red visual sensations when and only when their optic nerves are stimulated by stimuli of a certain physical description. Moreover, certain kinds of variations in the physical properties of the stimulus can be correlated with judgments of degrees of properties of the sensation, such as hue, saturation, and shade. These correlations support our confidence in purely introspective discriminations between visual qualities. Nothing of the sort is possible with pleasantness. This quality, if such there be, does not vary with variations in physical stimuli in any discernible fashion. Nor can anything much better be found on the response side. It is true that there are gross typical differ-

ences in bearing and manner between a person enjoying himself and a person having a miserable time, between a person satisfied with the way things are going and a person who feels terribly frustrated. On the positive side of these contrasts we are more likely to get relaxation, expansiveness, and smooth coordination; on the negative side tenseness, constriction, and disruption of ongoing activities. But these manifestations differ so much from case to case because of other factors—general personality characteristics and state of health, for example—that they cannot be taken as reliable indications of how much pleasure or displeasure a given person is getting at the moment.

### MOTIVATIONAL THEORIES

No doubt there is something that all the experiences we have classified under “getting pleasure” have in common. If it is not an immediately felt quality, what is it? In searching for an alternative we might well take note of a different tradition in which the notion of pleasure was analyzed motivationally, in terms of the realization of the good, of the object of striving. In many systematic schemes of the “passions of the soul,” the basic notion is appetite, inclination, striving, or tendency of the person toward some object he apprehends as good or desirable. Pleasure, delight, or joy is then defined as the state in which this object is actually present, in which the appetite has reached fruition. Versions of this view are to be found in Thomas Aquinas, Thomas Hobbes, Benedict de Spinoza, and many other philosophers, as well as in some more-recent psychologists, notably William McDougall. The basic presuppositions of this approach to the subject are quite different from those of Locke and Hume. For Locke and Hume, and British empiricists generally, the way to understand any psychological concept is either to find it among the immediate data of introspection or to show how it is to be analyzed into such data. This approach ultimately stems from the Cartesian insistence that one knows one’s own states of consciousness better than anything else, in particular, better than physical objects and events, since it is possible to doubt the existence of all the latter but not of all the former. Hence it is natural for one in this tradition freely to posit immediate qualities of consciousness whenever there is any plausibility to doing so. Thinkers in the other tradition have a more objectively oriented epistemology, according to which conscious experience has no priority over, for instance, overt behavior as an object of investigation and an object of knowledge. This leaves them free to explore the possibility of analyzing the notion of pleasure in

terms of notions like appetite, or tendency, which could not be regarded as immediate objects of introspection.

Their view of the nature of pleasure might be formulated as follows:

- (D) To get pleasure is to be in a state of consciousness which includes the awareness that one has obtained something one wants.

There are serious difficulties with this version of a motivational theory of pleasure. No doubt there are many pleasures that do presuppose a want in the absence of which no such pleasure would be forthcoming. I would not take pleasure in the discomfiture or prosperity of a certain person unless I wanted him to be discomfited or to prosper, as the case may be. But it seems that there are many pleasures which do not presuppose any such preexisting want. Simple sensory pleasures, such as the pleasure of eating a good steak, are the most obvious cases. Having found steak pleasant, we may then develop a desire for a steak; but here the want presupposes the prior experience of pleasure, not vice versa. The view under consideration does not deny that wants can be reinforced or strengthened by the experience of pleasure in their satisfaction. But it does deny that one can get pleasure from anything except by way of that thing satisfying some previously existing want. And this seems contrary to experience. Surely infants take pleasure in many things, such as throwing a ball, when they encounter them for the first time. Prior to this encounter they could not have had a desire for it, for they did not yet know what throwing a ball is. It is noteworthy that proponents of this position maintain it in the face of these difficulties only by generously positing instincts and other nonconscious “tendencies” and “strivings.”

However, there are other versions of a motivational theory that do not presuppose a preexisting desire for each pleasure. The most promising is a view put forward by Henry Sidgwick, among others:

- (E) To get pleasure is to have an experience that, as of the moment, one would rather have than not have, on the basis of its felt quality, apart from any further considerations regarding consequences.

This account makes pleasure a function not of a preexisting desire but of a preference one has at the moment of the experience. To say that one has the preference at the moment is not to say that one expresses the preference even to oneself; it is not to say anything about what is before one’s consciousness at the moment. It is, rather, to say something dispositional—for example, that one would choose to have an experience just like this rather

than not if one were faced with such a choice at this moment and if no considerations other than the quality of the experience were relevant. This, unlike thesis (*D*), allows for the possibility of taking pleasure in something one did not previously have a tendency to seek. On the other hand, it is also clearly distinct from the conscious quality theory. According to thesis (*E*), when one says that he is enjoying something, he is saying something about the quality of his experience; he is saying that the quality of his experience is such that on that basis alone he would prefer to have it rather than not to have it. But he is not saying what the quality of his experience is; he is saying, rather, how it is related to his preferences, likes, or desires. More particularly, he is not saying that there is some particular quality, “pleasantness,” present in the experience. On this view, the felt qualities on the basis of which the experience is valued can be as diverse as the range of human likes. They can involve calm, excitement, warmth, cold, thrills, and sinking feelings.

It might seem that the strongest reason for the conscious-quality view, the fact that pleasure is something to which the subject has privileged access, would pose a difficulty for thesis (*E*), but this is not necessarily so. It is natural to think that the only things an individual can know about immediately, in a way no one else can, are the qualities of his experience; and indeed sensory qualities have this status. But there are many things to which an individual has privileged access that cannot be regarded as immediately felt qualities, such as intentions, attitudes, and beliefs. If I intend to quit my job tomorrow, I know that I have this intention without having to do any investigation to find out; I know just by virtue of having the intention; I know this as immediately as I know that I am now aware of a reddish patch. And it is in principle impossible for anyone else to know in this way that I have that intention. Yet an intention is neither a felt quality nor a complex of felt qualities. Hence the epistemological status of pleasure is not a conclusive reason for construing it as a quality of experience. The epistemological status of pleasure does place a constraint on the range of possible theories; we cannot identify pleasure with something to which the subject does not have privileged access, such as a certain pattern of neuron firings in the brain. However, among the nonsensory quality items to which a person has privileged access are his likes, preferences, and wants. It seems reasonable to suppose that a person’s knowledge that he would choose to have an experience just like his present one on the basis of its felt quality can be just as immediate as his knowledge that he is aware of a red patch.

Motivational theories have the following superiority over conscious-quality theories. It does not seem to be merely a contingent fact that pleasure is desirable, or that the fact that an activity is enjoyable is a reason for doing it. “I get a lot of satisfaction out of teaching, but I see absolutely no reason to do it” sounds like a self-contradiction. This is not to say that the fact that one will get pleasure out of something is a conclusive reason for doing it; there may well be other considerations that outweigh this. I would enjoy playing tennis now, but if an urgent job has to be completed, that is a good reason for not playing tennis. What we are suggesting to be necessarily true is (*P*) the fact that one gets pleasure out of *x* is a reason for doing or seeking *x*. This reason must be put into the balance along with other relevant reasons in making a decision in any particular case. The conscious-quality theory can throw no light on this necessity. If pleasure is an unanalyzable quality of experience, there is nothing about the meanings of the terms involved in (*P*) that would make it necessarily true. Why should it be necessarily true that a certain unanalyzable quality of experience is something to be sought? It would seem that any such quality is something that would or would not be taken as desirable by a given person, or people in general, depending on further factors. A motivational theory, on the other hand, analyzes the concept of pleasure in such a way as to make principles like (*P*) necessary. If to enjoy an experience *is* just to be disposed to choose an experience exactly like it if nothing other than the felt quality is relevant, then it follows trivially that the fact that something involves enjoyment is a reason for choosing it.

Superficially it might appear that opting for a motivational theory would involve a commitment to psychological hedonism, but this would be a mistake. The motivational theory commits us to holding that pleasure is (always) intrinsically desirable, but it carries no implication that pleasure is the only thing intrinsically desirable. One could adopt thesis (*E*) as his theory of the nature of pleasure and still regard other things as intrinsically desirable, such as fulfillment of one’s potentialities and intellectual consistency, independent of any pleasure they might bring. It is an analysis of desire in terms of pleasure that would stack the cards in favor of psychological hedonism. If we hold that to desire something is to think of it as pleasant, it does follow that we do not desire anything except pleasure or what is believed to lead to pleasure.

## THE MEASUREMENT OF PLEASURE

The problem of measuring hedonic tone has occupied both psychologists and philosophers. Psychologists have addressed themselves to such problems as the physiological basis of pleasure, the dependence of pleasantness on various aspects of sensory stimulation (such as contrast), and the effect of pleasure and displeasure on the speed and efficiency of learning. To deal with these problems they have to study the effect of variation of sensory stimulus conditions, for instance, on degree of hedonic tone, or the effect of variations in hedonic tone on something else, such as ease of recall of learned material. To do this, one must be able to specify the degree or amount of hedonic tone present at a given moment. Philosophical concern with the measurement of pleasure has grown out of utilitarianism and other hedonistic ethical theories. According to utilitarianism, an action is justified if and only if it will probably lead to a greater balance of pleasure over displeasure for everyone affected than any possible alternative action. Applying this principle to a particular case would involve estimating the total quantity of pleasure and displeasure that would be produced by each of the possible choices. To do this we would first have to list the ways in which one choice or another would make the situation, patterns of activities, and so on of a given person different from what they would be if that choice had not been made. Second, we would have to obtain information concerning how much pleasure or displeasure that person has derived from the situations and activities in question. Third, we would have to project how much pleasure and displeasure the person would derive from each of these in the future, taking into account any changes in circumstances, age, and so on that could be expected to make a difference. Fourth, we would have to sum up the hedonic consequences for that person. Fifth, having done this for each person likely to be affected, we would have to sum these results, arriving at a figure representing the probable total hedonic consequences of that choice.

Some of the problems relevant to these procedures fall outside the scope of this article. These include the problem of determining just what the objective consequences of a choice are likely to be, the problem of determining what features of a situation are responsible for the pleasure or displeasure felt, and the problem of projecting probable future pleasure from past pleasures. These are all essentially general problems of inductive reasoning. The problems having to do specifically with the measurement of pleasure are (1) How can one determine the degree of pleasure or displeasure experienced by a given

person at a given moment? (2) How can one compare the amount of pleasure felt by one person at a given time with the amount of pleasure felt by another person at a given time?

In everyday discourse we compare pleasures and displeasures. We say things like "I didn't enjoy that party as much as the last one," "I get more pleasure out of gardening now than I used to," and "That interview was not as unpleasant as I had expected it to be." Even granting the reliability of such comparative judgments, the utilitarian needs something more. He needs to be able to specify the hedonic value of particular experiences in numbers that he can meaningfully subject to arithmetical operations, so that if a person gets four positive units (pleasure) from one minute of playing tennis and one negative unit (displeasure) from the next minute of playing tennis, the total hedonic value of the two minutes is greater than that of two minutes spent lying in the sun, from which he derived one positive unit per minute.

An obvious move is to try to refine everyday comparative judgments in such a way as to yield these kinds of results. (In fact, all the methods that have actually been used have been of this sort.) We might ask the subject to consider a large number of his past experiences and to make a comparative judgment on each pair. Possibly after ironing out a few inconsistencies, we would arrange a series such that each experience is more pleasant, or less unpleasant, than any experience lower in the series. We could then have the subject locate a point of hedonic indifference, after which we could assign positive and negative integers to the ranks diverging in either direction from the point of indifference. This would constitute a hedonic scale for that individual. Any other experience would be assigned a number by matching it with an experience on the scale from which it is hedonically indistinguishable. (If it fell between two experiences on the scale, the scale would have to be revised.)

Even assuming that subjects make responses that would enable us to set up an unambiguous scale, one might still doubt that it provides an adequate measuring procedure. First, it relies heavily on the subject's memory of how much pleasure or displeasure he got out of something in the past, and such memories are notoriously fallible. Second, even if we have constructed a scale such that, given two adjoining experiences, the subject is unable to think of an experience which would lie between them, it is still an open question whether the intervals between the items are equal. We have as successive items (a) taking a shower after a game of tennis, (b) being complimented on a performance, and (c) seeing one of one's

children receive a prize. What reason is there to think that (*c*) is just exactly as much more pleasant than (*b*) as (*b*) is than (*a*)? And yet we have to make that assumption if we are going to use the numerical assignments to compare one “sum” of pleasures with another.

A different procedure would be to have the subject rate an experience, when it happens, by an absolute scale, for instance, a nine-point scale ranging from +4 to -4. This would avoid the problem about memory, but it brings fresh difficulties in its stead. Why suppose that the subject is in fact using the same standards every time we get him to make a rating? For that matter, why suppose that ratings which people are forced to make on an artificially constructed scale correspond to any real differences in experience at all? Moreover, there is still the question of whether the intervals on our “absolute scale,” as used by the subject, reflect equal differences in actual degree of hedonic tone. If one of these procedures yielded measurements that entered into well-confirmed hypotheses relating hedonic tone to, for example, various properties of learning, this would bolster our confidence in the procedure. At least it would show that we were measuring something important. But such results have not been obtained to any considerable extent.

Even if all the above problems were surmounted, it would still be very difficult to compare the amount of pleasure or displeasure experienced by two different people. Suppose that I am trying to determine whether the total balance of pleasure over displeasure (or the reverse) is greater for my wife or for myself with respect to a given party. Even if the foregoing problems could be surmounted and we could find a valid way of assigning a hedonic number for each of us, relative to a scale for each, how are we to calibrate the two scales? How are we to determine whether a rating of +3 on my scale represents the same amount of pleasure as a rating of +3 on her scale?

So long as we restrict ourselves to refinements of the method of introspective judgment, the problem of inter-subjective comparison seems insoluble. On the other hand, if there were some intersubjectively measurable variable, or complex of variables, which we had reason to think is intimately related to hedonic tone and which correlated well enough with rough introspective judgments to be taken as a measure of hedonic tone, all problems would be solved. Such a development is still in the future. Attempts to correlate introspective hedonic judgments with gross physiological variables on the order of pulse rate or patterns of respiration have not been fruitful. There has been no end of speculation concerning the

neurological basis of hedonic tone. Pleasantness has been thought to depend on the degree to which assimilation counteracts dissimilation in the activity of any group of central neurones (A. Lehmann), the degree of the capacity of a neural element to react to stimulation (H. R. Marshall), the average rate of change of conductance in the synapses (L. T. Troland), and so on. Thus far, none of these theories has yielded effective physiological measures.

### Bibliography

Plato discusses the nature of pleasure in his dialogues *Philebus* and *Timaeus*. Aristotle's main discussion is in Book X of the *Nicomachean Ethics*. A very illuminating history of the topic is H. M. Gardiner, R. C. Metcalf, and J. G. Beebe-Center, *Feeling and Emotion, A History of Theories* (New York, 1937).

Important discussions by contemporary analytical philosophers include Gilbert Ryle, *The Concept of Mind* (London: Hutchinson, 1949), Ch. 4, and *Dilemmas* (Cambridge, U.K.: Cambridge University Press, 1954), Ch. 4; a symposium, “Pleasure,” between Ryle and W. B. Gallie in *PAS*, Supp. 28 (1954): 135–164; Terence Penelhum, “The Logic of Pleasure,” in *Philosophy and Phenomenological Research* 17 (1957): 488–503; Anthony Kenny, *Action, Emotion, and Will* (London: Routledge and Kegan Paul, 1963), Ch. 6; P. H. Nowell-Smith, *Ethics* (London: Penguin, 1954), Chs. 8–10; and R. B. Brandt, *Ethical Theory* (Englewood Cliffs, NJ: Prentice-Hall, 1959), Ch. 12.

Carl Duncker's article “Pleasure, Emotion and Striving,” in *Philosophy and Phenomenological Research* 1 (1940): 391–430, is a brilliant phenomenological analysis of the varieties of pleasure and their relation to desire. The psychological research on hedonic tone is well summarized in J. G. Beebe-Center, *The Psychology of Pleasantness and Unpleasantness* (New York, 1932). More recent developments are surveyed in Beebe-Center's article “Feeling and Emotion,” in *Theoretical Foundations of Psychology*, edited by Harry Helson (New York: Van Nostrand, 1951).

The measurement of pleasure is discussed in Jeremy Bentham, *Introduction to the Principles of Morals and Legislation* (2nd ed., Oxford, 1907), Ch. 4; Henry Sidgwick, *The Methods of Ethics* (London: Macmillan, 1874), Book II, Chs. 2 and 3 (also good on the nature of pleasure); R. B. Perry, *General Theory of Value* (New York: Longmans Green, 1926), Ch. 21; and Robert McNaughton, “A Metrical Conception of Happiness,” in *Philosophy and Phenomenological Research* 14 (1954): 172–183.

William P. Alston (1967)

## PLEKHANOV, GEORGII VALENTINOVICH

(1856–1918)

Georgii Valentinovich Plekhanov, the Russian Marxist, revolutionary, philosopher, sociologist, and historian of social thought, was the son of a poor nobleman. After graduating from a military academy in Voronezh, he studied at the Mining Institute in St. Petersburg. As a student he joined the revolutionary movement and became one of the leaders of the revolutionary organization of the Narodniki (Populists), called *Zemlia i volia* (Soil and freedom). After *Zemlia i volia* split into the terroristic *Narodnaia volia* (People's freedom) and the Bakuninist-anarchist *Chernyi peredel* (Redistribution of soil) groups, Plekhanov became the leading theoretician of the *Chernyi peredel* group.

In the beginning of 1880, Plekhanov emigrated to France and then settled in Switzerland. Between 1880 and 1882 he turned from Populism to Marxism, and in 1883 he founded in Geneva the first Russian Marxist group, *Osvobozhdenie truda* (The emancipation of labor). In the summer of 1889 he took part in the founding congress of the Second International. In the late 1890s Plekhanov was one of the first to criticize both the international revisionism of Eduard Bernstein and its Russian variant, "economism."

In 1900, Plekhanov's group joined forces with a new group headed by V. I. Lenin. The two groups organized the second congress of the Russian Social-Democratic Labor Party in London in 1902. The congress accepted a party program written mainly by Plekhanov. Disagreements over the nature of the party led to the split of the party into Bolsheviks and Mensheviks. Plekhanov supported Lenin at the congress, but he became neutral soon afterward and even leaned to the Menshevik side.

During the first Russian revolution (1905), Plekhanov severely criticized the tactics of the Bolsheviks, but after the defeat of the revolution he again came closer to Lenin. The onset of World War I led to the final parting of Plekhanov and Lenin. Plekhanov urged socialists to support the Allied governments, but Lenin declared war on the imperialist war.

After the February revolution of 1917 Plekhanov returned to Russia. Believing that Russia was not yet sufficiently mature for socialism, he regarded the October revolution as a fateful mistake. Nevertheless, he refused to engage in active struggle against Soviet authority.

As the founder of the first Russian Marxist group, Plekhanov is rightly called the father of Russian Marxism and of Russian social democracy. He was also an outstanding leader of the Second International. But the workers' movement is indebted to Plekhanov for his theoretical work, especially in philosophy, even more than for his practical organizational activity.

### GENERAL PHILOSOPHICAL VIEWS

Plekhanov regarded himself as an orthodox follower of Karl Marx and Friedrich Engels and severely criticized those who tried to "revise" the basic teachings of Marx or to "supplement" them with the ideas of Immanuel Kant, Ernst Mach, or some other philosopher. But he insisted that the views of Marx and Engels should be developed further.

In his early writings Plekhanov exhibited the tendencies to reduce philosophy to the philosophy of history and to regard philosophy as a preliminary to science. He later stressed the independent tasks and problems of philosophy and defined philosophy in a broader way, as a study of the basic principles of being and knowledge and of their mutual relationships. Whereas Marx and Engels often insisted on the methodological character of their philosophy, Plekhanov stressed its systematic character. Marxist philosophy, according to Plekhanov, is a system, which Plekhanov named dialectical materialism.

Following Engels, Plekhanov maintained that the basic question of every philosophy was "the question about the relationship of subject to object, of consciousness to being," and he regarded materialism and idealism as two basic answers to the question. Dualism was a possible, but weaker, answer. A consistent thinker must choose between an idealistic and a materialistic monism, but vulgar materialism is not the only alternative to idealism. The real solution is dialectical materialism.

As the concept of matter was not clearly defined by Engels, Plekhanov made several attempts to do so. His formulations were more or less modifications of the traditional materialist view that matter is what exists independently of man's consciousness, affects his sense organs, and produces sensations. Plekhanov tried to show that opposing philosophies that maintain the world exists only in the consciousness of one man (solipsism), only in the consciousness of humankind (solohumanism), or only in that of some superindividual objective spirit (objective idealism) all lead to contradictions. The belief in the existence of the external world is, according to Plekhanov, an unavoidable leap in philosophy. Lenin reproached Plekhanov for such Humean terminology,

and Soviet philosophers later exploited this criticism to accuse Plekhanov of Humeanism.

In criticizing idealistic views that *mind*, *spirit*, *consciousness*, or *psyche* (he used these terms more or less interchangeably) is the only reality, Plekhanov at the same time rejected the view of those materialists who regard mind as a part of matter or (as Engels did) as a form of the movement of matter. Nevertheless, he held that mind is one of the properties of substance, or matter. In some earlier writings Plekhanov affirmed that mind is merely a mode of matter, a property characteristic of matter organized in a certain way. Later he modified his view, maintaining that mind is an attribute of matter, a property that, at least to a minimal, nonobservable degree, belongs to all matter. This theory led to his being accused of hylozoism. Plekhanov first thought that mind could be regarded as a consequence of another, more fundamental property of matter, movement. Later he changed this view and asserted that consciousness is an “inner state” of matter in motion, a subjective side of the same process whose objective side is motion.

Accepting the traditional correspondence theory of truth, Plekhanov tried to explain in a more specific way the character of correspondence or agreement holding between thought and reality. Against naive realism he stressed that “correspondence” does not mean “similarity.” He maintained that sensations are “hieroglyphs” because although they can adequately represent things and their properties, they are not “similar” to them. To avoid misinterpretation of his views, Plekhanov later renounced this terminology; nevertheless, he was severely criticized for it by some Soviet philosophers, who held that it was a concession to Kantianism.

Plekhanov often stressed that Marxist philosophy is *dialectical* materialism and that dialectics is the soul of Marxist philosophy. But in explaining his conception of dialectics, he added little to what had already been said by Marx and Engels. He was more original in his view of the relationship between formal logic and dialectics. Starting from Engels, who likened the relationship between the two to that between lower and higher mathematics, Plekhanov maintained that thinking according to the laws of formal logic is a special case of dialectical thinking. By the help of a number of distinctions, like those between motions and things, between changing and relatively stable things, and between simple and compound things, he tried to determine more precisely the limits of fields in which the two logics could be applied. These explanations, although they gave no final clarification of the problem, nevertheless were the most explicit treat-

ment of the problem in classical Marxist literature and served as the starting point for many later discussions.

## PHILOSOPHY OF HISTORY

Plekhanov's views on the philosophy of history have sometimes been misinterpreted. The fault is partly his own. Trying to present Marx and Engels's view on the relations between the economic foundation and the superstructure in a simple schematic way, he produced a formula involving:

1. The state of the forces of production; 2. Economic relations conditioned by these forces; 3. The socio-political regime erected upon a given economic foundation; 4. The psychology of man in society, determined in part directly by economic conditions and in part by the whole socio-political regime erected upon the economic foundation; 5. Various ideologies reflecting this psychology. (*Fundamental Problems of Marxism*, edited by D. Ryazanov, p. 72)

This formula may be regarded as an adequate schematization of economic materialism, the theory according to which the economic factor (the forces of production) is ultimately predominant in history. However, in other places Plekhanov maintained that neither man as man nor society as society can be characterized by a constant relationship between economic and other factors because such relationships are always changing. He even explicitly criticized the view that the economic factor must always be decisive and called it a “libel against mankind.” Plekhanov admitted that so far men have been the “slaves of their own social economy,” but he insisted that “the triumph of human reason over the blind forces of economic necessity is possible” (*Izbrannye filosofskie proizvedeniia* [Selected philosophical works], Vol. II, p. 233).

In his best writings Plekhanov criticized not only the theory of the predominant role of the economic factor but also the theory of factors as such. In polemics against those who attributed the theory to Marx, he maintained that genuine materialists are averse to dragging in the economic factor everywhere and that “even to ask which factor predominates in social life seems to them pointless” (*The Materialist Conception of History*, p. 13). The question is unjustified because, “strictly speaking, there exists only one factor of historical development, namely—social man” (*Izbrannye Filosofskie Proizvedeniya*, Vol. V, p. 363); different branches of the social sciences—ethics, politics, jurisprudence, political economy—investigate one and the same thing, the activity of social man.

## AESTHETICS

Plekhanov was one of the few Marxist thinkers interested in aesthetics and the sociology of art. Criticizing the view that art expresses only feelings, he insisted that it expresses both feeling and thoughts, not abstractly, however, but in lively pictures. He added that the pictorial expression of feelings and thoughts about the world is not an end in itself but is done in order to communicate one's own thoughts and feelings to others. Art is a social phenomenon.

The first task of an art critic, according to Plekhanov, is to translate the idea of a work of art from the language of art into the language of sociology in order to find what could be called the sociological equivalent of a literary phenomenon. After the first act of materialistic criticism, the second act—the appreciation of the aesthetic values of the work in question—must follow.

Investigating the social roots of the theory of art for art's sake and of the utilitarian view of art, Plekhanov came to the conclusion that the inclination toward art for its own sake emerges from a hopeless separation of the artist from the surrounding social milieu, whereas the utilitarian view of art emerges when a mutual understanding between the larger part of society and the artist exists. The utilitarian view of art can thus be combined with both conservative and revolutionary attitudes.

The value of a work of art is primarily dependent on the value of the ideas it conveys, but correct ideas are not enough for a valuable work. A work of art is great only when its form corresponds to its ideas.

## IMPORTANCE AND INFLUENCE

Although Plekhanov is not one of those greatest of philosophers who have opened up new vistas to humankind, he was not a mere popularizer of Marxist philosophy. Starting from Engels's interpretation of Marxist philosophy, he improved it and developed it in many directions. He greatly influenced Lenin's conception of Marxist philosophy, and through both his own works and Lenin's he decisively influenced Soviet philosophy between the two world wars. The leaders of the Soviet "philosophical front" in the 1920s, A. M. Deborin and Deborin's most outstanding opponent, L. I. Aksel'rod, were Plekhanov's immediate disciples.

In 1930 a new period in Soviet philosophy began, a period that included severe criticism of Plekhanov. All kinds of accusations were made against Plekhanov, but the Stalinist criticism abated in the 1940s and 1950s, and Plekhanov's philosophical views survived. Nevertheless,

the publication of previously unpublished writings of Marx in the 1930s and 1940s and new discussions of Marx's philosophy in the 1950s and the 1960s seem to have produced an interpretation of Marxist philosophy that is more profound than that offered by Engels and developed by Plekhanov and Lenin.

## PLESSNER, HELMUT (1892–1985)

Helmut Plessner, was, with Max Scheler, the founder of modern philosophical anthropology. Born in Wiesbaden, Germany, he studied medicine, and then zoology and philosophy, at the universities of Freiburg, Heidelberg, and Berlin. He received a doctorate in philosophy from Erlangen in 1916 and his *Habilitation* in philosophy with Scheler and Hans Driesch at Cologne in 1920. His academic career in Germany was terminated by the National Socialist regime, and in 1934 he went to Groningen, the Netherlands, first as a guest of the Physiological Institute (where he was associated with F. J. J. Buytendijk), then as Rockefeller fellow, and from 1929 to 1942 as professor of sociology. Again dismissed by the Nazis, he was reinstated at Groningen by the Dutch in 1945 and occupied the chair of philosophy from 1946 to 1951. In 1951 he accepted the chair of sociology at the University of Göttingen in Germany. He became professor emeritus in 1962 and lectured as a visiting professor at the New School for Social Research in New York in 1962–1963. He received an honorary doctorate from Groningen in 1964.

Plessner's work—he published twelve books and approximately ninety monographs, essays, and papers—ranges over an extraordinarily wide area, including animal physiology, aesthetics, phenomenology, the history of

ideas, the history of philosophy, sociological theory, sociology of knowledge, sociology of education, and political sociology. Most of these studies are linked to the problems of philosophical anthropology, the discipline to which he devoted his most important publications. His background in zoology and physiology, his phenomenological training under Edmund Husserl, and his sociological orientation led him to redefine the problems and findings of the modern sciences of man.

Plessner agrees with the view that man artificially creates his nature, or more precisely, that what man makes of himself is contingent on history. However, man is bound by the structural principle of his position in the world; in contrast to the centrality of animals, who are, simply, what they are as organisms, in their *Umwelt*, man is "eccentric." Plessner rejects the dualism of spirit and matter present in Scheler's anthropology. He sees man as being a body (with such organically determined traits as upright posture, impoverishment of instincts, and drive surplus) and consequently exposed to his environment, and also as having a body and acting by means of it, as being open, within certain limits, to the world. Man is both "inside" and "outside" himself. Social and historical order is based on the precarious balance of these two dialectical moments. This order enables man to maintain a distance from things, from situations, and from himself, making it possible for him to use language and to plan actions. Man's eccentricity leads him to enter history, "to make himself" in history. However, when man faces ambivalent or insuperable situations, the balance on which order is founded is disrupted; planned action, speech, and all historically determined "orderly" ways of coming to terms with the world are blocked. His indirect, socially mediated relationship with the world momentarily breaks apart. In such marginal situations man responds in a prehistorical, presocial, and yet peculiarly human manner: by laughter or by tears.

## PLETHO, GIORGIUS GEMISTUS

(c. 1355–1452)

Giorgius Gemistus Pletho, the leading Byzantine scholar and philosopher of the fifteenth century, was born in Constantinople, the son of a cleric. Pletho is noted primarily for advocating a restoration of ancient Greek polytheism and, above all, for inspiring the interest of the Italian humanists of the *quattrocento* in the study of Plato. His studies followed the usual pattern of Byzantine education, emphasizing the classical Greek heritage. Influenced by certain of his teachers, Pletho became interested primarily in the philosophy of Plato, whose writings had again been brought into vogue in Byzantium during the eleventh-century renaissance under the influence of the Neoplatonic philosopher-statesman Michael Psellus. In 1380, Pletho went to the Turkish court at Brusa, or Adrianople, where he is reputed to have studied under the Jewish scholar Elisaeus. There Pletho presumably received training in the Muslim commentators on Aristotle, in Zoroastrianism, and in Chaldean astronomy and astrology and was encouraged by Elisaeus to further his study of Greek philosophy. Indeed, Gennadius Scholarius, who later condemned Pletho for his belief in polytheism, credits Elisaeus with leading Pletho to apostasy. About 1390, Elisaeus was burned at the stake by the Turks, probably for heterodoxy, and Pletho returned to Constantinople, from which he moved in 1393 to Mistra in the Peloponnese, near the ancient site of Sparta. It was at this administrative and cultural center of Mistra, which ranked second only to Constantinople and Thessalonica, that he spent the most important years of his life.

In 1438 Pletho appeared as adviser to the Greek delegation at the Council of Ferrara-Florence, convoked in order to effect a union between the Eastern and Western

churches. An antiunionist and in some respects even anti-Christian, he took little interest in the council's proceedings. He preferred to consort with the Italian humanists, themselves fascinated by his knowledge of the works of Plato, which had for centuries been virtually unknown to the West. He left the council before the final ceremony of union to return to Mistra, where he remained until his death.

Pletho's works reveal a deep insight into Platonic philosophy and, remarkably, a devotion to Greece rather than to the crumbling Byzantine Empire. Many of his treatises aim at the revivification and restoration of Greece's ancient glory. In his famous tract "On the Differences between Plato and Aristotle," he asserts the superiority of Platonism to Aristotelianism, and his *Laws*, inspired by Plato's *Laws* and *Republic*, advocates a return to the polytheism of ancient Greece. Two memoirs based on a Platonic reconstruction of the state present a systematic plan of social and economic reform for Greece. Pletho felt that the collapse of the Byzantine Empire was due primarily to Christianity, the adoption of which had caused the alteration of the institutions of ancient Greece. In order to restore Greece to its former greatness it was necessary to foster a return to the ancient religion and to adopt a philosophy based on Platonic principles, which could serve as a guide in the process of governing. Pletho's numerous works include treatises on Zoroastrianism, Chaldean astronomy, music, history, rhetoric, the "philosophic virtues," geography, and various theological subjects. Among his theological writings is a treatise on the procession of the Holy Spirit composed in response to the Latin view presented at the Council of Ferrara-Florence.

Despite some modern opinion to the contrary, Pletho's apostasy from Christianity seems certain. Scholarius, his Aristotelian opponent, condemns him for advocating paganism in his *Laws*, and George of Trebizond quotes Pletho as asserting that a new religion, neither Christian nor Islamic but similar to that of the ancient Greeks, would sweep the world. Why then did Pletho attend the Council of Ferrara-Florence and evidently acquiesce in the act of union? Pletho was taken to the council by the Byzantine emperor John VIII, probably as a learned layman philosopher who could buttress the arguments of the theologians. Pletho's opposition to union was more on nationalistic grounds than dogmatic. As a patriot he feared that the consummation of union would precipitate a fresh Turkish attack on Constantinople. Moreover, he seemed to fear the Latinization of the Greeks, as for example in the possible suppression of

Greek in favor of Latin in the ritual of the church. Finally, as a propagandist for the formation of a “Greek” nation and a restored Hellenism (in contrast to a “Byzantine” or, more correctly, “Roman” state), he was opposed to the international papal control implicit in the union of the two churches. His acceptance of the union can then be explained only as an act of political expediency with the aim of aiding Greece, not as the result of conviction that any particular doctrinal position was correct.

Almost every Greek humanist scholar of the fifteenth century was in some way influenced by Pletho, the most notable being his pupil, Cardinal Bessarion. A great many Italian humanists were also influenced by his writings and presence at the council. Through Pletho, ancient doctrines of the Chaldeans and Pythagoreans were transmitted to the West. More important, he set in motion at Florence the passionate interest in Platonism that was soon to permeate much of western Europe. Marsilio Ficino credits Pletho with inspiring Cosimo de’ Medici to found the famous Platonic Academy. By introducing into Italy (especially through Paolo dal Pozzo Toscanelli) the geographical concepts of Strabo, Pletho may have prepared the ground for the correction of Ptolemy’s geographical errors. Pletho consequently helped to alter the Renaissance conception of the configuration of Earth, thus indirectly influencing Christopher Columbus, for whom Strabo was an important authority. The high esteem in which Pletho was held by the Italian humanists is attested by the transfer of his remains from Mistra to Rimini, where they were interred in the Church of St. Francis.

## PLOTINUS

(c. 205–270)

Plotinus, usually considered the founder of Neoplatonism, was probably born in Lykopolis, Upper Egypt, and he may have been a Hellenized Egyptian rather than a Greek. He turned to the study of philosophy when he was twenty-eight. Disappointed by several teachers in Alexandria, he was directed by a friend to Ammonius Saccas, who made a profound impression on him. Of Ammonius’s teachings we know extremely little, but a promising line of investigation has been opened up in a comparison of Plotinus’s doctrines with those of Origen the Christian, also a student of Ammonius. Of other students of Ammonius, Origen the Pagan and Longinus deserve special mention.

Plotinus was Ammonius’s pupil for eleven years. He left Ammonius to join the expeditionary army of Emperor Gordianus III that was to march against Persia, hoping to acquire firsthand knowledge of Persian and Indian wisdom, in which he had become interested through Ammonius. When Gordianus was slain in Persia in 244, probably at the instigation of his successor, Philip the Arabian, Plotinus had to flee from the army camp—which could mean that he was politically involved in some way. Plotinus reached Antioch in his flight and from there proceeded to Rome, where he arrived in the same year. In Rome he conducted a school of philosophy and after ten years started writing. At about this time he gained influence over, or the confidence of, the new emperor, Gallienus, and it is possible that his philosophy was meant to aid the emperor in some way in his attempted rejuvenation of paganism. In any case, Plotinus asked the emperor to grant him land in order to found some kind of community, the members of which would live according to the laws (or *Laws*) of Plato.

Despite the emperor's favorable attitude, a cabal of courtiers brought the plan to nothing, indicating that they may have seen in it some political implications. However, because the contents of Plotinus's writings and some facts of his life seem to point to a complete absence of political interests, the problem of Plotinus's involvement in affairs of state is controversial. Nevertheless it is strangely coincidental that his literary activity began in the first year of Gallienus's rule. Moreover, when Plotinus died (probably from leprosy, about two years after the assassination of Gallienus), he was not in Rome but on the estate of one of his friends (of Arabic origin), and only one of his pupils, a physician, was present. These circumstances make it difficult to rule out the possibility that Plotinus had left Rome and that his pupils had all dispersed at the death of Gallienus (between March and August of 268) because he and they were afraid they would be affected by the anti-Gallienus reaction; this would again contradict a completely apolitical interpretation of Plotinus.

Plotinus's works, which were all written in the sixteen years after 253, have come down to us only in the edition by his pupil Porphyry. Porphyry arranged the works according to content into six sections called *eneads* because each contains nine treatises; he arbitrarily created some treatises by dissecting or combining the originals. Independent of this arrangement, he indicated when each treatise was written by assigning it to one of three periods in the life of Plotinus: before Porphyry became Plotinus's student, 253–263; while Porphyry was his student, 263–268; after Porphyry left him, 268–270. Whether Porphyry numbered the treatises within each period in strictly chronological order is open to some doubt. The presentation of Plotinus given here follows the three periods of Porphyry with only a few forward or backward references. The standard citation to Plotinus's work designates the number of the *enead* first, by Roman numeral; the treatise second, by Arabic numeral; and the place of the treatise in Porphyry's chronological enumeration third, in brackets. The chapter number and, where relevant, the line number are also given in addition to the standard citation.

Contrary to the frequent attempts to present Plotinus's philosophy as a consistent whole, this presentation will stress all tensions by which the philosophy is permeated and leave it an open question whether Plotinus succeeded in reconciling them.

## INFLUENCES

To understand the philosophy of Plotinus, a knowledge of some of the doctrines of Plato, Aristotle, the Neo-Pythagoreans, and the Stoics is very important.

In his dialogues Plato divided all reality into the realm of ideas (intelligibles) and the realm of sensibles, treating intelligibles alone as that which truly is (*ousia*), which implied that they are eternal and changeless (but see below). One of these ideas, the idea of the Good, he elevated above others, calling it beyond being (*epekeina ousias*). Comparable to the sun, it is the source of being and cognizability of all existents. In a lecture (or a lecture course) he seems to have identified the Good with the One.

Plato discussed the concept of the One in his dialogue *Parmenides*, ostensibly without any conclusion. In one passage he asserts hypothetically that if the One existed, it would be ineffable and unknowable. Whether this assertion was supposed to reveal the self-contradictory and, therefore, unacceptable character of the One, or on the contrary to express Plato's positive assertion as to the character of the One, is controversial. In another dialogue, *The Sophist*, Plato seems to contradict his standard doctrine concerning the unchangeable character of the ideas by ascribing life, change, and knowledge to the realm of ideas.

As to the realm of the sensible, Plato in his *Timaeus* explains the origin of the cosmos in the form of a myth—as the work of a divine artisan (*demiurge*) who uses an ideal cosmos as model and fashions it out of something Plato calls “receptacle” and describes as void of any qualities, after ideas have in some way “entered” this void and by so doing created rudiments of the four elements. In addition to the physical universe the *demiurge* also fashions a cosmic soul and the immortal part of individual souls. The cosmic soul and the individual souls consist of a mixture of the same ingredients, on which mixture the *demiurge* imposes a numerical and a geometrical structure.

The immaterial and substantial character of the individual souls (or at least part of them) guarantees their preexistence and postexistence (immortality). They are all subject to the law of reincarnation.

In the *Second Letter* (the authenticity of which was never doubted in antiquity, though today it finds virtually no defender), Plato, in a brief, and entirely obscure passage, seems to compress his whole philosophy into a formula reading: There are three realms, the first related to

“the king,” the second to the second, the third to the third. Plotinus was convinced that Plato is here describing the three realms of the One, Intelligence, and the Soul (whereas many Christian writers were convinced that Plato must have darkly anticipated the doctrine of the Trinity).

From Aristotle, Plotinus drew an important presentation of Plato’s philosophy, ostensibly different from the one professed by Plato in his dialogues. According to Aristotle, Plato had assumed a realm of mathematical mediating between ideas and sensibles (other sources identified this realm with that of the soul). Aristotle also attributed to Plato the view that two opposite principles, the One and the Indeterminate Dyad, are the supreme principles constitutive of everything, particularly of ideas and mathematical—a doctrine Aristotle related to a similar, equally dualistic doctrine of the Pythagoreans. Aristotle represented Plato as having identified the Indeterminate Dyad with the receptacle and as having seen in it the principle of evil.

Plotinus also adopted Aristotle’s doctrine of Intelligence (*nous*) as superior to the rest of the soul. Aristotle implied that it alone is immortal, the rest being merely the “form” of the body, hence incapable of separate existence. Aristotle designated the supreme deity as Intelligence contemplating (that is, intelligizing) itself; the cognitive activity of the Intelligence differed from sensation in that its objects (immaterial intelligibles) are identical with the acts by which Intelligence grasps them.

Plotinus was also aware of Academic and Neo-Pythagorean attempts to take over and modify the two-opposite-principles doctrine by elevating the One above the Indeterminate Dyad (sometimes above another One, coordinated with the Dyad), which thus changed Plato’s dualism into monism culminating in a transcendent One. Plotinus also knew of the syntheses of Plato’s and Aristotle’s philosophy attempted by some Platonists, especially of the second century CE, most prominently Albinus and Apuleius. Another influence was the strictly materialistic and immanentistic Stoic doctrine of the omnipresence of the divine in the cosmos. Finally, two Neo-Pythagorean teachers are particularly relevant as sources for Plotinus: Moderatus, who seems to have taken his cue from Plato’s *Parmenides*, distinguishing a first One above being from a second and a third; and Numenius, who distinguished the supreme god from the divine artisan, creator of the cosmos.

## PLOTINUS’S PHILOSOPHY FIRST PERIOD, 253–263

Plotinus subdivided Plato’s realm of intelligibles into three: the One, Intelligence, and the Soul (presupposed in IV 8 [6], Ch. 6; V 4 [7], Ch. 1; VI 9 [9], Chs. 1f.; V 1 [10], Ch. 10; V 2 [11]).

**THE ONE.** Following what are at best hints in Plato, Plotinus developed a full-fledged theory of the One as the highest principle, or cause. Precisely because it is the principle of everything that is—and is therefore omnipresent—it is itself above being (absolutely transcendental: VI 9 [9], Ch. 4, ll. 24f., Ch. 7, ll. 28f.; V 4 [7], Ch. 1, ll. 4–8; V 2 [11], Ch. 1). Since it is above being, it is fully indetermined (qualityless), although it may be called the Good as the object of universal desire. Because it is one, it is entirely undifferentiated (without multiplicity: V 4 [7]; VI 9 [9], Ch. 3, ll. 39–45). As every act of cognition, even of self-cognition, presupposes the duality of object and subject, Plotinus repeatedly and strongly states that the One is void of any cognition and is ignorant even of itself (VI 9 [9], Ch. 6, l. 42; III 9 [13], Chs. 7, 9). He tries to mitigate this statement in some places, hesitatingly attributing to the One some kind of self-awareness (V 4 [7], Ch. 2, l. 16) or quasi awareness of its “power” to engender being (V 1 [10], Ch. 7, l. 13). In other places he distinguishes the ordinary kind of ignorance from the ignorance of the One and says that there is nothing of which the One is cognizant but that there is also nothing of which it is ignorant (VI 9 [9], Ch. 6, ll. 46–50).

**INTELLIGENCE.** The realm of the One is “followed” by that of Intelligence (intellect, spirit, mind—all somewhat inadequate translations of the Greek word *nous*). Here, for the first time, multiplicity appears. Roughly, this realm (hypostasis) corresponds to Plato’s realm of ideas and, therefore, to that of true being. But whereas Plato’s ideas are self-sufficient entities outside the Intelligence that contemplates them, Plotinus develops a doctrine of the later Platonists (perhaps originating with Antiochus of Ascalon) that interpreted ideas as thoughts of God and insists that intelligibles do not exist outside the Intelligence (V 9 [5], Chs. 7f.; III 9 [13], Ch. 1). The structure of the second hypostasis also differs from that of Plato’s ideal realm in that Plotinus assumes the existence of ideas of individuals; the resulting difficulty that the infinity of individuals would demand an infinity of ideas Plotinus meets by assuming that the sensible world is, as the Stoa had it, subject to cyclical destruction and regeneration and that in each of these worlds the same indistinguish-

able individuals, for which one idea would suffice, would exist (V 7 [18], Ch. 1).

Another difference between Plato's and Plotinus's realm of ideas is that Plotinus assumed the existence of souls in this realm (IV 8 [6], Ch. 3). This doctrine creates a special problem. The ideal Socrates, unlike the soul of Socrates, must be composed of soul and body. It should follow that the soul of the empirical Socrates should be only a copy of that of the ideal Socrates, a consequence that, however, Plotinus rejects in places (V 9 [5], Ch. 13; VI 4 [22] Ch. 14) and approaches in others (III 9 [13], Ch. 3; V 2 [11], Ch. 1, l.19). Finally, Plotinus's realm of Intelligence contains even archetypal matter.

Despite all this multiplicity Intelligence remains one. In it everything is contained in everything without losing its identity, just as in mathematics every theorem contains all the others and, thus, the totality of mathematics (V 9 [5], Chs. 6, 9; IV 3 [27], Ch. 2).

Plotinus found it necessary to relate his doctrine of the One and Intelligence to the doctrine of the two opposite principles that figures in Aristotle's obscure presentation of Plato's philosophy in the *Metaphysics* (A6, 987a29ff.). In that difficult passage (the text of which may be faulty), Plato is said to have identified ideas with numbers. Plotinus also found it necessary to relate his philosophy to the doctrine identifying the soul with number, the best-known example of which was Xenocrates' definition of the soul as self-changing number. Thus, Plotinus calls the realm of Intelligence the realm of number and calls the soul number (V 1 [10], Ch. 5). But as he conceives number to be derived from the interaction of One with plurality and yet elevates the One above the realm of Intelligence (being), he seems to assign to his One a double role, a doctrine very close to the Neo-Pythagorean assumption of a double One, one superior and transcendental and another inferior, present in the realm of Intelligence, or number (V 1 [10], Ch. 5).

**SOUL.** Below the hypostasis of Intelligence Plotinus locates that of the Soul. Some souls remain unembodied; others "descend" into bodies. These bodies are either celestial or terrestrial. Celestial bodies offer no resistance to the soul's dwelling in them and thus these souls do not suffer from their incarnation (IV 8 [6], Ch. 2); terrestrial bodies, however, do offer resistance, and governing them may involve the soul to such an extent that it becomes alienated from Intelligence, its true home, and thus "sinks." In addition to these souls of individual bodies, Plotinus also assumes the existence of a cosmic soul (IV 8 [6], Ch. 7; III 9 [13], Ch. 3; II 2 [14], Ch. 2; I 2 [19], Ch.

1); thus, the world at large is one living organism. Probably the realm of the Soul does not consist of these individual souls alone; rather, they are all only individualizations of something we could call Soul in general (compare IV 3 [27], Ch. 4). In any case, all souls form only one Soul, and this unity implies that all souls intercommunicate by extrasensory means (IV 9 [8]).

Plotinus sometimes proves, sometimes merely assumes, not only the incorporeality, substantiality, and immortality of all the individual souls of humans, animals, and even plants (IV 7 [2], Chs. 2–8<sup>iii</sup>, 14), but also proves or assumes reincarnation, in the course of which the same soul may pass from the body of a human into that of a beast or a plant (III 4 [15], Ch. 2). Plato's best-known proof of immortality is based on the absolute simplicity and, therefore, indissolubility of the human soul. But Plato also taught that the soul is tripartite, and perhaps in an effort to reconcile these two doctrines, Plotinus assumes that the simple and, therefore, immortal soul on its "way" to the body receives additional, lower parts as accretions. This seems to be similar to a doctrine usually associated with Gnosticism—a downward journey of the soul, during which it passes the several planetary spheres, each of which adds something to it.

**EMANATION.** The explanation of the relation of the three hypostases to one another leads to one of the most characteristic doctrines of Plotinus, but it is a strangely ambiguous one. This relation is described as "emanation," or "effulgration," of Intelligence from the One and of Soul from Intelligence—an emanation that, however, leaves the emanating entity undiminished (VI 9 [9], Ch. 9; V 1 [10], Chs. 3, 5–7; compare III 8 [30], Ch. 8, l. 11). The emanating entity thus remains outside of its product and yet is also present in it (VI 4 [7], Ch. 3; VI 9 [9], Ch. 7), a position sometimes described as dynamic pantheism to distinguish it from immanentist pantheism. This emanation Plotinus describes as entirely involuntary: What is full must overflow, what is mature must beget (V 4 [7], Ch. 1, ll. 26–41; V 1 [10], Ch. 6, l. 37; V 2 [11], Ch. 1, l. 8; compare IV 3 [27], Ch. 13).

Seen in this way, there is no fault, no guilt involved in emanation, nor is any justification of why the One had to become multiple necessary. On the contrary, the process deserves praise; without it the One would have remained mere potentiality, and its hidden riches would not have appeared (IV 8 [6], Ch. 5f.). But sometimes, particularly when discussing the Soul's descent, Plotinus speaks of emanation in an entirely different manner. Even the emanation of Intelligence from the One, let alone that of Soul

from Intelligence, he describes in such terms as *apostasy* and *falling away*. It is recklessness and the desire to belong to nobody but oneself that cause Intelligence to break away from the One (VI 9 [9], Ch. 5, l. 29). The Soul is motivated to break away from Intelligence by the desire to govern, which causes the Soul to become too immersed in bodies; by a craving for that which is worse; by a will to isolation (V 2 [11], Ch. 1; IV 8 [6], Ch. 4, l. 10; V 1 [10], Ch. 1). Matter emanates from Soul as the result of the Soul's wish to belong to itself (III 9 [13], Ch. 3). The "lowest" kind of Soul (the vegetative) is called the most foolhardy (V 2 [11], Ch. 2, l. 6). Thus, instead of an outflow, we should speak, rather, of a fall—with all its implications of will, guilt, necessity of punishment, and so on. These two interpretations—we shall call the former optimistic and the latter pessimistic—are difficult to reconcile.

**INTELLIGENCE AND SOUL.** Let us now consider the constitution of the second and third hypostases in additional detail. On the whole, Plotinus teaches that the One is in no way engaged in producing Intelligence. But sometimes he speaks as if Intelligence were the result of some kind of self-reflection of the One: The One turns to itself; this turning is vision; and this vision is Intelligence (V 1 [10], 7, l. 6—but the text is uncertain). Once more, we see that it is not easy for Plotinus to deprive the One of all self-awareness (consciousness). In any case, Intelligence is already multiple and, thus, less perfect than the One. However, the outflow from the One would not be sufficient to produce Intelligence. Rather, this flow must come to a stop—congeal, as it were. Incipient Intelligence must turn back to its source to contemplate it, and only by this act does Intelligence become fully constituted (V 2 [11], Ch. 1, l. 10). The emanation continues, and Soul emerges, again constituted by its turning toward the source, which is Intelligence (V 1 [10], Ch. 6, l. 47; V 2 [11], Ch. 1, l. 18; III 9 [13], Ch. 5). In Soul, multiplicity prevails over unity, and perfection has therefore decreased.

From Soul emanates matter, the totally indetermined (III 9 [13], Ch. 3; III 4 [15], Ch. 1). Because Plotinus tends to split the Soul into a higher, lower, and lowest kind, it is only the lowest that is the source of matter. Matter, when illuminated by the Soul, becomes the physical world, the model of which is in the realm of Intelligence (Soul thus corresponds to Plato's divine artisan, the demiurge). Thus, Plotinus's system would seem to be entirely monistic. But sometimes Plotinus speaks as if matter existed by and in itself, "waiting" to be ensouled (IV 8 [6], Ch. 6, ll. 18–20; V 2 [11], Ch. 1).

Emanation must be described in temporal terms. But, of course, it is in fact an entirely timeless event (VI [10], Ch. 6, l. 19). Once the sensible world, particularly the human body, has been constituted, the Soul in the acts of incarnation becomes submerged in the realm of the temporal. The clash between a pessimistic and an optimistic evaluation of the emanative process can now be repeated in Plotinus's evaluation of incarnation.

**INCARNATION.** The Platonist cannot easily ignore either the myth of the *Phaedrus*, implying that souls "fall" by some kind of failing, or the otherworldly mood of the *Phaedo*, implying that the soul should try to flee the body and be polluted as little as possible by it. But just as it is difficult for a Platonist to forget that according to the *Timaeus*, the first incarnation of the soul is the work of the divine artisan himself and, thus, a blameless event, so it is equally difficult for him to forget the myth of the *Republic*, according to which embodiment seems to be the result of some universal necessity. As a result, Plotinus had to resolve a contradiction. Sometimes he did so by trying to prove that there is no true contradiction (IV 8 [6], Ch. 5). But recognizing that such an assertion is in the last resort unsatisfactory, even when it is assumed that only part of the Soul descends (IV 7 [2], Ch. 13, l. 12; IV 8 [6], Ch. 7, l. 7), he adopted a theory that he explicitly claims as his innovation (he otherwise presents himself as an orthodox Platonist).

According to this theory, a true fall has never taken place. Actually, even when in a body, the soul still lives its original "celestial" life and remains unseparated from Intelligence. Only we are not aware of this "hidden" life of the soul; in other words, we are partly unconscious of what happens in our minds (IV 8 [6], Ch. 8). What is true of the Soul in relation to Intelligence is even truer of the relation between our embodied selves and Intelligence. Not even when present in us does Intelligence discontinue its activity (V 1 [10], Ch. 12).

Plotinus also makes an optimistic and a pessimistic evaluation of the deterioration that has taken place in the soul as a result of its incarnation. On the whole, he tries to prove that no real deterioration has taken place, but he often feels that he must find reasons why the soul should try to escape the body and return home. One of these reasons is that the body prevents the soul from exercising the activity peculiar to it (IV 8 [6], Ch. 2, l. 43), which means, of course, that some deterioration does take place.

**DUALISM.** There are some dualistic traits in the philosophy of Plotinus, particularly the recognition of the Inde-

terminate Dyad (as opposed to the One), to which he also refers simply as the Indeterminate (II 4 [12], Ch. 11, l. 37). Aristotle presented Plato's philosophy as a dualistic system, identifying the Indeterminate Dyad with Plato's receptacle and also with matter, in his own sense of the word; in other words according to him, Plato's ideas, being the product of the interaction of the two opposite principles, contain matter. Aristotle furthermore asserted that the Indeterminate Dyad is also the principle of evil. Plotinus is willing to recognize the Indeterminate as a second principle and to see in matter the principle of evil, but he refuses to recognize the existence of evil in the realm of Intelligence (ideas). He is thus forced to recognize the existence of two kinds of matter, one in the realm of the sensible and the result of the last emanative step, the other in the realm of Intelligence ("intelligible matter"), which does not have some of the properties usually associated with matter—specifically, it is not evil. He justifies this by the assumption that everything, including matter in the physical world, must have its archetype in the realm of Intelligence (II 4 [12], Chs. 2f., 11, 14). Whether the assumption of intelligible matter can be reconciled with monism appears dubious; its "origin" is never made clear by Plotinus.

As to matter in the realm of the sensible, it is sheer indeterminacy, incorporeal, and, thus, different from the Stoic conception of matter (II 4 [12], Chs. 1, 4, 9, 10). It remains as unaffected by the ideas (or "ratios," *logoi*, by which Stoic term Plotinus often designates ideas as present in the soul qua formative powers) as the mirror is unaffected by what it reflects. Precisely because this matter is indeterminate, it is evil (II 4 [12], Ch. 16, l. 19), which means that evil is not something positive, but sheer privation.

There is a strange parallelism between matter and the One, because both are entirely indeterminate. Therefore, they both elude ordinary concepts, and Plotinus faces the question of what it means to know them. As far as matter is concerned, Plotinus likens it sometimes to darkness, and the mental act by which we grasp it to "unthinking thinking," or the soul's reduction to indefiniteness (II 4 [12], Chs. 6, 11)—concepts reminding us of Plato's pseudo thinking (*nothos logismos*), declared by him to be the appropriate way to think the receptacle.

**KNOWLEDGE OF THE ONE.** But much more important for Plotinus is the problem how the One, in spite of its being ineffable, can be known. In the pseudo(?)-Platonic *Epinomis* (992B), the author insists that in order to know the One (whatever "knowledge" means here), the soul

must itself become one; the Platonic *Letters* also seem to teach some kind of suprarational insight. Perhaps starting from passages such as these and also from passages in Aristotle and Theophrastus in which some kind of infallible knowledge of certain objects is described as a kind of touching (*thinganein*), Plotinus asserts that to "know" the One means to become one with it, which the soul can accomplish only by becoming as simple or as "alone" as the One. In the moment of such a union the soul has become God or, rather, is God; the soul has reascended to its original source (VI 9 [9], Ch. 9f.). Among the terms Plotinus uses to describe this condition are *ecstasy*, *simplicity*, *self-surrender*, *touching*, and *flight of the alone to the alone* (VI 9 [9], Chs. 3, 11). This ecstasy—repeatedly experienced by Plotinus himself—is undoubtedly the climactic moment of man's life. It is not expressible in words (compare Plato, *Epistle VII*, 341D); only he who has experienced it knows what it means to be ravished away and full of God.

For this reascent man prepares himself by the acquisition of all the perfections (virtues, *aretai*). However, each of these perfections acquires different meanings according to the level on which man's spiritual life takes place—thus, there is a social fairness, above it another kind of fairness, and so on. Man also prepares himself by the exercise of dialectics (I 2 [19]; I 3 [20]). The preliminary stages of achievement Plotinus calls "becoming Godlike" (I 6 [1], Ch. 8), a condition often described by Platonists preceding Plotinus as the ultimate goal of Plato's philosophy.

**FREE WILL AND DEMONOLOGY.** Among the other topics treated in this period, Plotinus's defense of the freedom of the will—only "reasonable" souls are free; others are subject to fate, *εἰμαρμένη* (III 1 [3])—and his demonology deserve special mention. In regard to demonology Plotinus tries to steer a middle course between two theories, one identifying demons with the supreme parts of our soul, and the other assuming the existence of demons as extrapsychical beings (III 4 [15]).

## SECOND PERIOD, 263–268

**POLEMICS.** More than two-fifths of Plotinus's total literary output was produced during the brief period between 263 and 268, when Porphyry was studying with Plotinus. Perhaps Porphyry's presence worked as a powerful stimulus. A considerable part of the output of this period is devoted to polemics with other schools, notably on the doctrine of categories and against Gnosticism.

**Categories.** Plotinus rejects both the Aristotelian and the Stoic versions of this doctrine, adhering to the principle that there can be no categories common to the realms of the sensible and the intelligible. In application to the realm of the sensible he corrects and modifies Aristotle's categories; to the realm of Intelligence he tries to apply Plato's five genera—being, identity, diversity, rest, and change (VI 1–3 [42–44]).

**Ideal numbers.** Aristotle presented Plato as professing the existence of ideal numbers (twoness, threeness, and so on, as distinguished from ordinary numbers—two, three, and so on). And he devoted much effort to the criticism of the theory of ideal numbers. Plotinus defends the theory of ideal numbers—which differ from nonideal numbers in that they do not consist of addible unities and are therefore not addible themselves (V 5 [32], Ch. 4)—and, objecting to any nominalist or abstractionist theory of numbers, attributes to them subsistence. Specifically, after having divided the realm of Intelligence into three layers—Being, Intelligence (in a restricted sense of the word), and the original Living Being—he assigns ideal numbers to the uppermost layer and explains that only because of their existence can Being divide itself into beings (VI 6 [34]), Chs. 8, 16). In this context he also introduces a peculiar concept of infinity: The truly infinite is a thing that has no limits imposed on it from without but only from within (VI 6 [34], Chs. 17f., but compare V 5 [32], Ch. 4).

**Polemic against Gnosticism.** Of all the polemics of Plotinus, the most significant is the one against Gnosticism. One could say that when facing Gnostic pessimism point-blank, Plotinus overcompensates for the pessimistic and Gnostic strand present in himself and responds with an almost unlimited optimism. The fundamental mood underlying Gnosticism is alienation from a hostile world, and Gnosticism undertakes to explain this mood and to open the road to escape from the world. The explanation is in the form of a history of the origin of the visible cosmos; according to Gnosticism, this cosmos is the result of the activity of an evil god sometimes identified with the Creator-God of the Old Testament or with Plato's divine artisan. This evil god is only the last in a succession of beings. The manner in which this succession takes place consists in a number of voluntary acts by which divinities of an ever lower order originate. The relation between these deities is often personal, based on such traits as curiosity, oblivion, daring, ambition. Man, as he exists in this evil world, contains in himself a spark of what was his original, divine substance, now imprisoned in his body owing to the scheming of the evil god.

At a certain moment a messenger-savior in some way breaks the power of the evil god and makes it possible for those who hear the whole story (acquire gnosis) to regain their original standing and free themselves from the tyranny of the evil god.

Plotinus treats Gnosticism as a strictly philosophic system. He simply compares its doctrines with his own and with those of Plato; its salvatory aspects are of little interest to him (compare III 2 [47], Ch. 9). In the succession of divine beings he sees only a superfluous multiplication of the three hypostases of his own system (compare V 5 [32], Chs. 1f.). To the cosmic drama that results in the creation of the visible cosmos he opposes his view of a totally undramatic, unconscious emanation, a product of necessity without arbitrariness and, contradicting even Plato's *Timaeus* (40B–45A), without planning (V 8 [31], Ch. 7) and, therefore, entirely blameless. The cosmos, product of the activities of the Soul (or Intelligence or both), he considers to be beautiful. Whereas Gnosticism sees the visible universe filled with spirits inimical to man, most outstanding among them being the rulers of the celestial bodies (planets), Plotinus sees in these spirits powers related to man in brotherly fashion. What is true in Gnosticism can, according to him, be found in Plato. The Gnostic objection that Plato did not penetrate the mysteries of the intelligible world Plotinus considers ridiculously presumptuous (II 9 [33]; compare V 8 [31], Ch. 8).

**PROBLEMS.** In the second period Plotinus was also concerned with the problems inherent in his own system, especially with the relation between the intelligible world and the sensible world and with the structure of the intelligible world.

**The One.** First, Plotinus tries to elucidate the nature of the One still further. He does this particularly in the context of a discussion concerning the nature of human freedom, in which he also asks whether the One should be considered as a necessary being or as a free one (*ens necessarium* or *ens liberum*)—in theistic terms, whether God must exist or has freely chosen to exist. In what is perhaps his most profound theological discussion, Plotinus tries to establish the concept of the One as Lord of itself and thus not having to serve even itself, so that in the One freedom and necessity coincide (VI 8 [39], Chs. 7–21). And without any vacillation he excludes any kind of consciousness from the One (V 6 [24], Chs. 2, 4f.).

**Intelligence and Soul.** As far as Intelligence is concerned, Plotinus reiterates his doctrine that it contains ideas within itself (V 5 [32], Chs. 1f.), and he again tries

to explain how, in spite of being one, it still contains multiplicity (VI 4 [22], Ch. 4; VI 5 [23], Ch. 6). With regard to souls Plotinus tries to explain how they can remain distinct from one another although they all are only one soul (VI 4 [22], Ch. 6; IV 3 [27], Chs. 1–8; compare IV 9 [8], Ch. 5).

Both Intelligence and Soul are supposed to be present in the sensible world and, therefore, present in what is extended, although they themselves are not extended. Starting from the famous discussion in Plato's *Parmenides* (131B), in which the attempt is made to explain how one idea can be present in many particulars, Plotinus tries to show that just because Intelligence and Soul are not extended, they can be omnipresent and ubiquitous in what is extended (VI 4 [22], especially VI 5 [23], Ch. 11). And also in this context he tries to establish the concept of differentiated unity (VI 4 [22], Ch. 4), that is, the non-contradictory character of "one" and "many."

**Intelligence, Soul, change.** Probably the most formidable difficulty facing Plotinus is the result of his theory treating Intelligence and Soul as metaphysical principles on the one hand and as present in man on the other (that is, as both transcendent and immanent) and, therefore, in some way engaged in mental life, particularly in sensing and remembering. As metaphysical principles—that is, members of the realm of the intelligible—Intelligence and Soul should be unchangeable, whereas in man they seem to be involved in change. From this difficulty Plotinus tries to extricate himself in many ways, of which two will be presented.

On the one hand he keeps even the human soul away as much as possible from the processes of sensing, remembering, desiring, experiencing pleasure and pain, and so on (III 6 [26], Ch. 1–5). Sometimes he insists that the soul simply notices all these processes without being affected by what it perceives (IV 6 [41]; IV 4 [28], Ch. 19). Sometimes he insists that it is not the soul itself but only some trace of it which is engaged in these activities (IV 4 [28], Chs. 18f.; compare VI 4 [22], Ch. 15, l. 15), and this ties in with the theory that the soul did not really—or not in its entirety—descend (VI 4 [22], Ch. 16). Sometimes he introduces the concept of a double soul, a higher and a lower, with only the lower being changeable. This doubling of the soul Plotinus carries to such extremes that he assumes two imaginative faculties and two faculties of memory, each belonging to its respective soul and each remembering in a different manner and different events. This is particularly the case after man's death; the higher soul no longer remembers anything it experienced while in the body, whereas the lower soul still remembers (IV 3

[27], Chs. 25–32; IV 4 [28], Ch. 1, l. 5). Sometimes he suggests that all the mental activities involving change happen not to the soul but to the composite of soul and body (IV 4 [28], Ch. 17), leaving undecided how anything can affect a whole without affecting the part that belongs to it.

On the other hand, when it comes to Intelligence and Soul as metaphysical principles (and even to the world soul and astral souls), Plotinus disallows them memory entirely (IV 4 [28], Chs. 6–17). As to sensing, he distinguishes two kinds, one serving such practical purposes as self-preservation, the other purely theoretical; it is only the theoretical kind that he ascribes to metaphysical entities, the implication obviously being that this kind of sensation does not cause any change in the perceiver (IV 4 [28], Ch. 24). Why they should still be called Intelligence and Soul remains somewhat unclear. Perhaps the most striking example of the real effects of the Soul's falling away from Intelligence (despite everything said by Plotinus to minimize these effects) is that the cosmic soul, as it falls away, engenders time because of an inability to contemplate the totality of Intelligence simultaneously (III 7 [45], Ch. 11).

**Ethics.** The difficulties created for the explanation of the cognitive aspects of man's mental life without the assumption of a real change (passibility) of the soul return with even greater significance in the field of ethics. If there is no actual fall of the soul and if no deterioration of its nature has taken place as the result of incarnation (III 6 [26], Ch. 5), why is purifying the soul necessary? Yet the concept of purification plays a central role in the ethics of Plotinus (compare I 6 [1]; I 2 [19]); he even describes the perfections—wisdom, self-control, justice, courage—as purifications. Plotinus tries to help himself by a metaphor: The soul is merely covered with mud, which, however, has never penetrated it. According to another explanation, what the soul has acquired because of its fall is nothingness, and all it has to do, therefore, is to get rid of nothing (VI 5 [23], Ch. 12, ll. 16–23).

**Cosmic sympathy.** The insistence that memory and sensation, in their ordinary senses, are absent from the realm of Intelligence and even from that of the celestial sphere Plotinus explains with his theory that the universe is one animated organism. The sympathy existing among parts of one organism make memory and sensation superfluous, since the mutual affection need not be perceived. This leads to characteristic explanations of the efficacy of magic, prayers, and astrology. All these activities (and prophecies) are made possible by the fact that each part of the universe affects the others and is affected by them, not by mechanical causation nor by influencing

the will of deities—particularly stars—but exclusively by mutual sympathy (IV 3 [27], Ch. 11; IV 4 [28], Chs. 40f.). In this doctrine of sympathy many scholars see the influence of the Stoa, particularly Posidonius, on Plotinus.

*Matter.* As to matter, Plotinus in the writings of this period—with less ambiguity than in other periods—characterizes it as the result of the last step of the emanative process, thus fully preserving the monistic character of his system (II 5 [25], Ch. 5; compare I 8 [51], Ch. 7). Some other problems discussed by Plotinus are distinctly occasional pieces and somewhat peripheral with regard to the system. Thus, we find a theory of vision, explained by sympathy (IV 5 [29]; II 8 [35]); a discussion of the Stoic concept of the complete interpenetration of bodies (II 7 [37]); a cosmology without the assumption of ether (II 1 [40]).

### THIRD PERIOD, 268–270

As is to be expected, some earlier themes recur in the third period. In fact, one of the essays of the third period (V 3 [49]) contains what is perhaps the most comprehensive presentation of the basic tenets of Plotinus's philosophy. Plotinus proves that there must be a One preceding all multiplicity and that this One must be ineffable (V 3 [49], Chs. 12f., 17). To explain its presence in us and the fact that we know about it although we do not know it, he says that those full of and possessed by the divine also feel that something greater than themselves is present in them, although they cannot say what it is (V 3 [49], Ch. 14). Once more facing the problem of how the One, which is absolutely simple, can be the source of multiplicity, Plotinus is on the verge of admitting that the One is at least potentially (though it is a potentiality *sui generis*) many (V 3 [49], Chs. 15f.; compare VI 5 [23], Ch. 9). The same essay contains what is probably the most detailed and the most impressive description of the upward journey of the soul to reach the goal of ecstatic union, described by the formula “through light light” (V 3 [49], Ch. 17, ll. 28–37; compare V 5 [32], Chs. 4–9). As advice on how to achieve this union, Plotinus says “strip yourself of everything” (V 3 [49], 17, l. 38). Furthermore, Plotinus still feels he must prove that ideas are not external to Intelligence (V 3 [49], Chs. 5–13).

On the whole, the writings of Plotinus's last period are dominated by two themes. The first concerns theodicy, the origin and justification of evil, and the second asks what man's true self is.

**THEODICY.** To explain the origin of evil, Plotinus tries to reconcile the view that matter, though void of any

quality and actually only deficiency, is still evil in some sense of the word and is the source of all evil (I 8 [51], Chs. 8, 10). In so doing, he sometimes comes dangerously close to the Gnostic theory that matter imprisons the soul (I 8 [51], Ch. 14, ll. 48–50) and to a completely dualistic system (I 8 [51], Ch. 6, l. 33). Nevertheless, his optimism is particularly strong in this period; he has high praise for the beauty of the visible cosmos (III 2 [47], Ch. 12, l. 4), and rejects the idea of an evil creator of the cosmos (III 2 [47], Ch. 1). His theodicy is a blend of Platonic arguments, drawn especially from Book X of the *Laws*, and Stoic arguments. Perfection of the whole demands imperfection of the parts (III 2 [47], Chs. 11, 17; III 3 [48]) and the existence of evil (I 8 [51], Chs. 8–15). At the same time he minimizes the importance of evil by insisting that it exists only for the wicked one (III 2 [47], Ch. 6). Furthermore, he points out that the cosmic order rewards and punishes everybody according to his merits and assigns each one an appropriate place, thus making for a completely harmonious whole (III 2 [47], Ch. 4). Ultimately, his theodicy is based on convictions characteristic of most theodicies—that to designate a particular as evil is to lose sight of the whole, that everything participates in the good as far as it can, and that evil is only absence of the good (III 2 [47], Chs. 3, 5; I 8 [51], Chs. 1–5).

*Providence.* Closely connected with the problem of theodicy is the problem of providence. Plotinus insists on the all-pervasive character of providence, thus rejecting Aristotle's dichotomy of the universe into a sublunar sphere dominated by necessity and a supralunar world to which providence is restricted. He replaces Aristotle's distinction by the dichotomy of good and wicked men; only the wicked are subject to necessity (III 2 [47], Ch. 9; compare III 1 [3], Chs. 8–10). But this providence is entirely impersonal (compare VI 7 [38], Ch. 1) and actually coincides with the order of the universe.

**TRUE SELF AND HAPPINESS.** The second major theme of Plotinus's last period is that of ascertaining what man's true self is—that is, of ultimately obeying the divine command “Know thyself.” Attendant subproblems are the explanations of wherein man's true happiness consists and of the concept of self-knowledge. It is extremely difficult for Plotinus to give a consistent account of what constitutes man's true self. He cannot simply identify it with Intelligence or Soul (as he did in IV 7 [1], Ch. 1, l. 24 or in I 4 [46], Chs. 8–16, where it is identified with the “higher” soul), precisely because both, in their character of metaphysical entities, remain transcendent; however, he rejects the idea that man is truly the composite of soul and body (I 4 [46], Ch. 14, l. 1) because this would grant

the body too much importance. One of the solutions favored by Plotinus is that Intelligence is man's true self, but only if and when he succeeds in identifying himself with it. On the other hand, no such identification is actually necessary, because Intelligence is always in and with us even though we are not aware of it. (*Mutatis mutandis* this can also be applied to the relation of man and whatever is to be conceived the highest divinity: compare VI 5 [23], Ch. 12). Once more the concept of the unconscious plays a decisive role in the system of Plotinus (I 4 [46], Chs. 9f.; V 3 [49], Chs. 3f.). All this ties in with the idea that self-knowledge occurs only when the subject, the act, and the object of knowledge coincide—which takes place only on the level of Intelligence—whereas neither man as a whole nor Soul can possess full self-knowledge (V 3 [49], Chs. 3, 6). The One is, of course, above any kind of self-knowledge (V 3 [49], Chs. 10–13).

The thesis that only Intelligence is man's true self (if and when he makes full use of it) serves also as a basis for a discussion of the problem of man's happiness. If by "man" we mean the composite of body and soul, man cannot experience happiness, nor can he if he is body alone. However, if by "man" we mean the true self, it is obvious that happiness consists in the exercise of Intelligence—that is, in contemplation. But as the activity of Intelligence is uninterrupted (here in the argument Plotinus switches from Intelligence as immanent to transcendent Intelligence; see I 1 [53], Ch. 13, l. 7) man is actually always happy, although he may remain unconscious of it (I 4 [46], Chs. 4, 9, 13–16). Why this should apply only to the sage remains unclear.

The formidable problem of how the soul, the essence of which is unchangeability, can ever become evil also vexed Plotinus to the end (compare I 8 [51], Ch. 4, 12, 15). In the work of his last period he explains that as the soul at its descent acquires additional parts, evil resides only in them. Thus, the ethical task of man is not so much to separate the soul from the body as it is to separate it from these adventitious parts (I 1 [53], Ch. 12, l. 18). In this context the problem of who is the subject of punishments in afterlife also emerges; Plotinus answers that it is that "composite" soul (I 1 [53], Ch. 12). Why we should call soul an entity that is or can become evil, "suffer" punishment, and so on, after Soul has been presented as belonging to the realm of the unchangeable, remains unanswered; so do virtually all questions resulting from the dual character of Intelligence and Soul as metaphysical (transcendental) entities on the one hand and human (immanent) entities on the other.

There is almost something providential in the fact that the very last of Plotinus's essays, written at a time when death was approaching him, reasserts that all things participate in the One (the Good) and discusses the question of how to reconcile the two theses that life is good and yet death no evil, though it deprives us of something good (I 7 [54], Ch. 3). The battle between the pessimistic and the optimistic strands in Plotinus continued to the very end of his activity. Optimism ultimately won: Life is good—though not for the wicked one; death is good, because it will permit the soul to live an unhampered life.

## Bibliography

### WORKS BY PLOTINUS

The standard edition of the Greek text of the *Enneads* and of Porphyry's *Life of Plotinus* is by Paul Henry and Hans-Rudolf Schwyzer, *Plotini Opera*, in 3 vols. (Oxford: Clarendon Press, 1964–1982) (*editio minor* with concise apparatus). For full critical apparatus and an English translation of the important Arabic tradition see their *editio maior*, in 3 vols. (Paris: Desclée de Brouwer, 1951–1973).

Modern translations (some including ancient text and/or valuable notes) are available in English by A. H. Armstrong, in 7 vols. (Cambridge, MA, and London: Harvard University Press and Heinemann, 1966–1988); in French by É Bréhier, in 6 vols. (Paris: Belles Lettres, 1924–1938); in German by R. Harder, R. Beutler, and W. Theiler, in 5 vols. (Hamburg: F. Meiner, 1956–1962); in Spanish by J. Igal, in 3 vols. (Madrid: Gredos, 1982–1998); and in Italian by M. Casaglia, C. Guidelli, A. Linguiti, and F. Moriani, in 2 vols. (Torino: Unione Tipografico-Editrice, 1997). A new French translation of individual treatises with extensive commentary, under the direction of Pierre Hadot (Paris: Cerf, 1988–), comprises, so far, 8 vols.

### WORKS ON PLOTINUS

A complete lexicon for Plotinus' writings is J. H. Sleeman and Gilbert Pollet, *Lexicon Plotinianum* (Leiden: Brill, 1980). For a comprehensive bibliography, see Richard Dufour, *Plotinus: A Bibliography 1950–2000* (Leiden: Brill [*Phronesis*, vol. 46, No. 3], 2001). This is updated in: <http://rdufour.free.fr/BibPlotin/Anglais/Biblio.html>.

## PLOTINUS [ADDENDUM]

What is it, Plotinus asks (Plotinus 1956), that lures the eye toward a beautiful sight and that draws the ear to a beautiful sound? It is the thrill that the soul feels in sensing its affinity with the noble being that manifests itself in those beautiful sights and sounds. Material things become beautiful by sharing in Form and thus in Unity. This applies to the productions of artists as much as to the beauties of nature. Thus the true objects of artistic imitation are Form and Unity; and so the artist is always entitled to "add where nature is lacking" (Plotinus 1956). Beauty is also found in noble conduct, in excellent laws, and in human virtue. The virtuous soul acquires Beauty and becomes godlike by purifying itself from evil. Thus Beauty in general has a metaphysical significance through its relation to Form, the One, and to the divine. In Plotinus's eyes, Beauty's significance is not only metaphysical but quasi-religious, not only because of its relationship to the divine, but also because Beauty is what draws the soul

onwards in its ascent to the suprasensible world whence it came (Plotinus 1956).

## PLOUCQUET, GOTTFRIED

(1716–1790)

Gottfried Ploucquet, the German philosopher and logician, studied philosophy and theology at Tübingen, experiencing both Wolffian and Pietist influences. After serving as a pastor, he was professor of logic and metaphysics at Tübingen from 1750 to 1782. He was elected to the Berlin Academy in 1748. Ploucquet was one of the few logicians between Gottfried Wilhelm Leibniz and George Boole to study a symbolic calculus. In metaphysics, despite his Wolffian training, he developed a quite personal position inspired by René Descartes and Nicolas Malebranche and aimed at revising Leibnizianism on a theological basis.

Ploucquet regarded the problems of theology, cosmology, and psychology as inextricably intertwined, with theology as the predominant discipline. There were some variations in Ploucquet's doctrines, but typically he held that a monad is a spiritual substance, and that even being is spiritual. Spiritual substances and material things can interact because God represents both and connects them. Human perceptions are an effect of God's "real vision." Spiritual and material things are both real because God represents them; material things are real in a further sense, as *phaenomena substantiata*, insofar as God represents them as real. This divine representation is the cause of the real existence of things; but we perceive only an appearance of this real existence. Ploucquet showed, by an examination of the logical difficulties of the concept of infinity, that space and time cannot exist outside of human representation.

Ploucquet's philosophy was basically a pronounced metaphysical subjectivism and phenomenalism. But in order to escape the consequent idealism of this position,

Ploucquet reintroduced a variety of realism based on God. Ploucquet's was one of the most significant attempts before Immanuel Kant to develop a phenomenalism that asserted the real existence of things but denied (contrary to Leibnizian and Wolffian phenomenalism) that we can know such things on the basis of their appearances.

## PLURALISM

Pragmatism and Continental hermeneutics combined to produce a decided turn toward forms of "pluralism" in twentieth-century philosophy (Geyer 1993, B. Singer 1990). This has led to the rejection of any one favored epistemological method (e.g., the scientific method, scriptural exegesis, introspection) and any one favored basis for the reconstruction of reality (e.g., mind, matter). Neopragmatists propose to replace the notion of truth with notions such as "fitting," "useful," and "warranted." Given that what is "fitting" is relative to the problem being faced and the means at one's disposal, we are left with the possibility of a plurality of ways of conceiving the world and of achieving our aims within it.

Moral pluralism opposes the monistic view that there is any one method of determining what is morally right (e.g., the utilitarian calculus or Kantian universalizability), and it also opposes the relativistic view that all things have value only with respect to a particular cul-

tural context. Pluralists insist that a good life typically involves the desire, not for one, but for many kinds of “goods,” often of incommensurable value; moreover, the realization of certain “goods” may conflict with and even preclude the realization of others. As such, pluralists believe that moral conflicts are inevitable and that there are not one but many alternative ways of resolving such conflicts (Kekes 1993). The trend toward pluralism has also been influenced by our growing awareness of different cultures with nonequivalent conceptions of reality and “the good life.”

The modern nation-state has evolved beyond the belief that it manifests the cultural orientation of a single “race,” usually its majority. The reality is that every nation is composed of numerous groups with different cultural orientations. And the state is considered the primary guarantor that minority views will be presented, respected, and given a voice in determining policy (Guttman 1993). The rejection of the view that a Eurocentric male-dominated culture is the norm to be achieved universally has led to the demand that the cultures of non-Europeans, women, and minorities be recognized and granted equal voice (Taylor 1992). In this way pluralism is considered by many to be an essential part of the liberal democratic state, and this has manifested itself in terms of educational policy as the rejection of monoculturalism and the demand for a multicultural orientation.

One form of multiculturalism has focused on the need of suppressed groups to have their cultures recognized. Such a demand for recognition may motivate certain proposals—for example, to replace a Eurocentric focus with an Afrocentric focus or a male-centered orientation with a feminist-centered orientation. Some argue that because of the past harms inflicted upon such groups, ostensibly because they were different, they are justified in embracing those differences in order to cleanse them of the negative valuations imposed by the hegemonic culture. It is right for such groups to adopt a separatist posture if this is the best means of achieving a redefinition of themselves that is positive and self-affirming (Young 1990). Where members of the hegemonic culture have inflicted unjust harms on members of an oppressed group, some argue that the oppressed group has the right to cultural restitution. The domination of culture A by culture B may not be the result of culture A’s not offering viable options; rather, it may be the result of unjust injuries and harms visited on culture A by culture B. In such cases groups sharing culture A have a right to “moral deference,” affirmative action, and the preserva-

tion of their culture (Mosley 1990, Nickel 1994, Thomas 1992–1993).

Many have been concerned that multiculturalism might degenerate into a bedlam of different groups, each espousing its own brand of cultural authenticity. Critics argue that this would amount to merely replacing one culture’s hegemony with another culture’s hegemony. Multiculturalism in this sense would fail to reflect the pluralist maxim that no orientation is “fitting” for every situation and that for a given end there may be several equally “fitting” means (West 1993, Yates 1992).

An alternative form of multiculturalism, closer to pluralism, emphasizes the importance of diversity and cross-cultural communication. On this view the more cultural orientations there are for consideration, the better the likelihood of finding or constructing a “fitting” adaptation to some current problem (Rorty 1992). For this reason every culture should be allowed the opportunity of articulating itself to the public at large and of thereby influencing the manner in which individuals construct their character.

Pluralism does not end with the insistence on an equal voice for every culture but extends itself to the view that different biological species often have interests that may conflict with the interests of human beings. Some have argued that, just as racism and sexism accord special preference to white males and victimize women and non-Europeans, so speciesism accords special preference to the interests of human beings and unjustly victimizes nonhuman species (P. Singer 1990). The insistence on a plurality of interests and capacities has been extended to include the interests of other animal species, as well as trees, rivers, and ecological systems (Wenz 1990).

## PLURALS AND PLURALITY

Plurality falls under the concept of grammatical number. So, one prefaces the discussion of plurality with a brief overview of grammatical number. Since this entry is written in English, one can consider grammatical number in English.

English nouns are either plural or singular, which is usually signaled by the presence or absence of the inflectional ending *s*. Thus, *book* (singular) contrasts with *books* (plural). However, some nouns have peculiar forms for singular and plural. For example, the plural of *louse* (singular) is *lice* (plural). Some nouns, like *deer*, do not take the suffix *s*, yet behave as both singular and plural. This is shown by the form of its preceding determiner and, should the noun be in the subject position, by the form of the main verb. Thus, in the sentence *That deer is crossing the road*, *deer* behaves like a singular noun, while in the sentence *Those deer are crossing the road*, it behaves like a plural noun. Still other nouns, such as *police*, behave only as grammatically plural.

While every English noun must appear in either a singular or plural form, not every English noun may appear in both forms. On the contrary, English pronouns have both a singular (e.g., *he*, *she*, or *it*) and a plural form (*they*), which, for the most part, share no stem. In addition, as illustrated earlier, many English common nouns, known as count nouns, occur as both singular and plural nouns. By contrast, English proper nouns appear in the singular or plural form, but not both. The singular proper noun *Aristotle* does not occur in the plural (in the same relevant sense), nor does the plural proper noun *the Andes* occur in the singular. Moreover, English common nouns, such as *dust* and *advice*, called mass nouns, occur typically only in the singular. This division between nouns that can occur both in the singular and in the plural and those that do not occur is crosscut by words that cannot be preceded by the full range of English determiners and those that can be. Thus, English nouns can be partitioned into four classes. On the one hand, proper nouns and pronouns cannot be preceded by determiners, while common nouns can be; and on the other, count nouns and pronouns occur in both singular and plural forms, while mass nouns and proper nouns do not.

	Occurs with a determiner	Admits the contrast of singular and plural
Proper name	–	–
Pronoun	–	+
Mass noun	+	–
Count noun	+	+

The contrast between singular and plural forms is signaled by the inflection of the noun, but the distinction applies to the noun phrase containing the noun. This is manifested by the fact that conjoined proper nouns behave as though they are plural. For example, while the sentence *Russell and Whitehead was coauthors* is unacceptable in English, the sentence *Russell and Whitehead were coauthors* is not.

Bearing in mind these facts about English grammatical number, one may ask what contribution grammatical number makes to a noun phrase. The commonsensical view, the one of traditional grammar, maintains that a plural noun phrase, such as *these books*, denotes more than one thing, whereas a singular noun phrase, such as *this book*, denotes precisely one thing. Matters, however, are not so simple. Some singular noun phrases, such as *Pegasus*, and some plural noun phrases, such as *the Furies*, denote nothing at all. Some singular nouns denote more than one thing. The proper noun *Benelux* denotes Belgium, The Netherlands, and Luxemburg; the collective

count noun phrase *the team* denotes the people making up the team; and *this furniture* may denote a roomful of furniture comprising, say, two tables and a sofa, each of which is, of course, a piece of furniture. At the same time, plural count nouns such as *these pants* (compare *this pair of pants*) may denote only a single thing. Finally, what single thing, if any, does the singular noun phrase *the average Roman legionnaire* denote?

Common nouns contrast with pronouns and proper names in that they tolerate being preceded either by almost any determiner or by no determiner. When a common count noun is not preceded by any determiner, it must appear in the plural form. Such noun phrases are known as bare plurals. As Greg Carlson (1977) notes, such noun phrases are liable to different construals. The noun *dogs* in the sentence *dogs are barking* can be paraphrased as *Some dogs are barking*; however, when it occurs in the sentence *dogs bark* it is not paraphrased as *some dogs bark*. Rather, it seems to express a quasi-universal statement, something like *almost all dogs bark*, often known as the generic construal. Carlson notices that a similar contrast applies to mass nouns in the bare usage. *Water is liquid* as opposed to *water is dripping* (see Carlson and Pelletier 1995).

Further questions arise with quantified noun phrases. The singular noun phrase *some boy* might be thought to contrast with the plural noun phrase *some boys* because the former pertains to a single boy, while the latter pertains to more than one boy. This contrast does not appear to obtain for the singular noun phrase *each boy* and the plural noun phrase *all boys*, nor for the singular noun phrase *no woman* and the plural noun phrase *no women*.

An important source of data for the investigation of plural noun phrases is their susceptibility to so-called collective and distributive construals. One useful way to determine what these construals consist in is to use an equivalence between plural noun phrases and conjoined noun phrases, where the conjoined noun phrases contain proper nouns. If *the men* denotes Bertrand Russell and Alfred Whitehead, then (1.0) is paraphrasable by (1.1):

- (1.0) The men wrote a book.  
 (1.1) Whitehead and Russell wrote a book.

It has long been recognized that sentences such as (1.0) and (1.1) have different construals, distinguishable with the help of adverbs:

- (2.0) The men wrote a book.  
 (2.1) The men wrote a book *together*.

- (2.2) The men *each* wrote a book.

These are paraphrasable by the following sentences, respectively:

- (3.0) Whitehead and Russell wrote a book.  
 (3.1) Whitehead and Russell wrote a book *together*.  
 (3.2) Whitehead and Russell *each* wrote a book.

The sentences in (1) are true on the collective construal, since *Principia Mathematica* was written as a collaborative effort of Whitehead and Russell. This construal can be forced by the use of the adverb *together*, as in (2.1) and (3.1). The sentences in (1) are also true on the distributive construal, since Russell wrote at least one book on his own, for example, *An Inquiry into Meaning and Truth*, and Whitehead also wrote a book on his own, for example, *A Treatise on Universal Algebra*. This construal can be enforced by the use of the adverb *each*, as in (2.2) and (3.2).

As shown by the next example, the susceptibility of plural noun phrases to collective and distributive construals is not confined to collaboration:

- (4.0) These two suitcases weigh fifty kilograms.  
 (4.1) These two suitcases *each* weigh fifty kilograms.  
 (4.2) These two suitcases weigh fifty kilograms *together*.

Moreover, collective and distributive construals seem to be the extremes of a range of construals. If *the men* denotes Richard Rodgers, Oscar Hammerstein, and Lorenz Hart, it is true to say that

- (5) The men wrote musicals.

even though none of them wrote a musical on his own and the three never wrote a musical together. What is true is that Rodgers and Hammerstein wrote musicals and Rodgers and Hart wrote musicals (see Gillon 1987).

Next, it should be noted that susceptibility of collective and distributive construals is not confined to plural noun phrases in the subject position. Every argument position containing a plural noun phrase—be it the subject, object, indirect object, or object of a preposition—is liable to these construals, regardless of whether the noun phrase is an argument of a verb or of a noun (see Gillon 1996).

- (6.1) Isabelle gave the girls a cookie.  
 (6.2) Rick drove through the Redwood trees. (Compare *Rick drove through the Redwood tree*.)

(6.3) The two suitcases' weight is fifty kilograms.

(6.4) The writing of *Principia Mathematica* by Russell and Whitehead.

Finally, even singular count nouns give rise to collective and distributive construals. Suppose that someone has two suitcases and says:

(7) This luggage weighs fifty kilograms.

The sentence could be taken to mean that altogether the luggage weighs fifty kilograms or that each piece of luggage weighs fifty kilograms.

Two crucial questions arise for the semantics of plural noun phrases: First, what do plural noun phrases denote? Second, how does one account for the various construals to which they are liable?

One can begin with the first question. According to the earliest researchers to address the question, such as Michael Bennett (1974) and Roland Hausser (1974), plural noun phrases denote sets. This view was roundly criticized by Godehard Link (1983) and Peter Simons (1983), who argued, independently of each other, that plural noun phrases do not denote sets, but what Simons called pluralities. Whereas a set of concrete individuals is an abstract mathematical entity, without spatial or temporal location, a plurality of concrete individuals is a concrete entity, with the spatial and temporal location of its membership. However, for both a set and a plurality, identity is determined by membership.

A plurality, then, is nothing more than the sum of its members. At the same time, a plurality is different from a collective, which may be more than the sum of its members. Thus, while a plurality is identified by its membership, so that if it acquires or loses a member, it becomes a different plurality, a collective is not identified simply by its members, for it can remain the same, even if its membership changes. Thus, an orchestra can remain the same, even though its members change. Inversely, the exact same individuals might constitute two collectives. Indeed, Simons (1982) reports that once the same musicians made up the Chapel Orchestra, the Court Opera Orchestra, and the Vienna Philharmonic. Nonetheless, a plurality can also be seen as the limiting case of a collective: that is, a plurality is a collective without conditions governing its constitution (Simons 1987, chapter 4.4).

The set of pluralities on a finite domain has the structure of a join semilattice. For example, consider three people: Dan, Paul, and Rick. They can form seven pluralities: three improper—Dan, Paul, and Rick; and four improper—Dan + Paul, Dan + Rick, Paul + Rick,

and Dan + Paul + Rick. The algebraic operation symbolized here by +, is a join operation. It is idempotent ( $x + x = x$ ), since there is no difference between Dan and Dan + Dan; it is commutative, since there is no difference between Dan + Paul and Paul + Dan; and it is associative, since Dan + (Paul + Rick) is the same plurality as (Dan + Paul) + Rick. The seven pluralities are all concrete individuals.

The join semilattice just described is isomorphic to the join semilattice obtained by assigning each plurality, proper and improper, a set: An improper plurality is assigned a singleton set. Thus, Dan is assigned  $\{Dan\}$ , a plurality comprised of two people is assigned a doubleton set. Thus, Dan + Rick is assigned  $\{Dan, Rick\}$ . And the plurality comprising three people is assigned a set of three people. The operation on these sets corresponding to + is that of union. Since every join semilattice of pluralities is isomorphic to a join semilattice of sets, a number of semanticists, including Fred Landman (1989a, 1989b), Roger Schwarzschild (1996), and Yoad Winter (2001), are content to treat pluralities as sets.

Link (1983) develops a semantics for a formal notation, designed to simulate singularity and plurality. Like Simons (1983, 1987), Link views the denotations of plural count noun phrases as distinct from the denotations of singular mass noun phrases, the former having their denotation based on individuals, the latter on so-called masses (see the mass noun entry). This distinction in denotation seems implausible, in view of the near synonymy of mass nouns such as *footwear*, *luggage*, *traffic*, and *advice*, with count nouns such as *shoes*, *suitcases*, *vehicles*, and *suggestions*. In light of such facts, Gillon (1992) provides a semantics of common nouns whereby a plural noun phrase such as *shoes* and a singular noun phrase such as *footwear* may have the same denotation; after all, all shoes are footwear, even if some footwear are not shoes. Another semanticist to provide a uniform domain for the interpretation of mass nouns and count nouns is Almerino Ojeda (1993), who takes all nouns to denote, in the first instance, kinds.

One can now turn to the second question: How are the various construals of plural noun phrases to be explained? A few authors such as Gillon (1987, 1992, 1996) and Schwarzschild (1996) think that the collective and distributive construals are extremes of a variety of construals, which, in their view, is pragmatically determined. However, the preponderance of authors recognize only two construals—the collective and distributive construals of traditional grammar—and take them to be the result of an ambiguity arising from the presence or

absence of an unpronounced adverb. For some, like Link (1983), the adverb is essentially a phonetically null version of the English adverb *each*. For others, like Landman (1989a, 1989b), it is a phonetically null collectivizing operator applying to noun phrases. In fact, each of these views require no less than three kinds of phonetically null operators. Since virtually every plural noun phrase, no matter where it occurs in a sentence, is liable to collective and distributive construals, no fewer than three such phonetically null words are required (see Gillon 1996). Finally, several authors (Schein 1993, Lasersohn 1995, Landman 2000) have tried to develop a theory of events and their parts and participants to account for collective and distributive construals.

## PLUTARCH OF CHAERONEA

(c. 46–after 119, before 127 CE)

Plutarch, a Greek biographer and Platonic philosopher, was born in Chaeronea, Boeotia. His teacher was Ammonius, an Egyptian Platonist who resided in Athens and was head of a school that he called the Academy. After his studies (c. 90?) Plutarch established a philosophical school in Chaeronea. Plutarch held important public offices and was a priest at Delphi for twenty years or more. His extant writings include forty-eight biographies and various other works (*Moralia*): dialogues; diatribes; theoretical treatises; essays; collections of anecdotes; moralistic lectures; and polemical, antiquarian, and exegetical works. Several dialogues have Delphi as their setting and are concerned with the oracle and other religious problems. *Socrates' Daemonic Sign* has a historical setting. It portrays Plutarch's circle of friends and students. *Table-Talks* is a long collection of conversations on a wide range of questions.

### INFLUENCES

Plato's dialogues, especially the *Timaeus*, but also Platonic school philosophy, as it could be found in manuals and introductory works, provide the basis of Plutarch's philosophy. In Plutarch's day, Platonism was dominated by Pythagorean tendencies, most importantly the tendency to construct a hierarchy of metaphysical principals based on an ontological derivation from the principals "one" and "dyad." Plutarch himself, however, was just as much influenced by the skepticism of the Hellenistic Academy, though in the mitigated form it took under Philo of Larissa. This influence shows in the limited epistemic sta-

tus he granted to empirical science, his cautious attitude regarding the epistemic claims of popular religion, and his reflections on the unreliability of the senses. This epistemology can be traced back to Plato's *Timaeus*, and Plutarch explicitly did so. He developed a kind of fallibilism that allowed him provisionally to accept various physical doctrines, for example, about the nature of the moon, or the function of specific organs of the body. The Hellenistic Academy provided Plutarch with numerous arguments against Stoics (*Common Notions, Stoic Contradictions*) and Epicureans (*Reply to Colotes* and *That Epicurus Actually Makes a Pleasant Life Impossible*).

### COSMOLOGY AND METAPHYSICS

Plutarch devoted a separate treatise to Plato's description of the composition of the world soul in the *Timaeus* and discussed this issue in several other places. Contrary to the large majority of his fellow Platonists, Plutarch understood Plato's story of the creation of the cosmos by a divine craftsman literally, in that he believed that the cosmos had existed only for a finite time. It came into being when the craftsman, or demiurge, imposed order on a preexisting chaos. Previous to his intervention, there was matter and a precosmic soul, as the principle of motion, both in a disordered state. The Platonic forms too existed, as their existence is eternal, but the world did not yet participate in them. When the demiurge imparted something of himself—namely intelligibility, or mathematically expressible rationality—to this preexisting soul, it became the world soul. The world soul then started to organize matter and create a structured, beautiful world (or cosmos).

Time, in the Platonic sense of succession characterized by cyclic regularities, was born together with the world. Plutarch leaves unspecified the relation between the craftsman and the forms. The forms and the craftsman belong to the same realm, and when the craftsman imparts something of himself to the preexisting soul, the latter, and through it the world, partake of the forms. The world is not perfect, as the original irrational soul, now integrated into the world soul, at times makes its influence felt. Soul itself, that is, soul in abstraction from the order it has received, is thus Plutarch's principle of evil. Plutarch espouses a mitigated metaphysical dualism: The rational and the irrational, order and disorder, good and evil are engaged in an unending struggle, but the good always dominates. The good he attributed to the gods, whereas higher forces responsible for evil can be mere demons, not gods. Plutarch linked his dualist views to an antagonism, at the level of metaphysical principles,

between the One and the indeterminate Dyad. This doctrine was attributed to Plato from as early as Aristotle and was cherished by Pythagorean Platonists. Plutarch equates the demiurge with the highest deity. In his dialogue *The Delphic E*, Plutarch has his master Ammonius define the supreme god as true being, eternity, and absolute unity, and call this god the One. In his treatise on Egyptian religion, *Isis and Osiris*, Plutarch interprets Egyptian myths allegorically and explains how they conform with Plato's cosmology and metaphysics, as he understands them.

### MORAL PSYCHOLOGY AND ETHICS

The human soul, being an image of the world soul, is analogously constituted. It too consists of rational and irrational parts, the latter being more prominent than it is in the world soul, however. The irrational is part of the human soul itself, is the cause of disorder and the passions, but is also the dynamic force of our mental life. Rationality is intellect and the truly divine coming from outside.

In the eschatological myth at the end of *The Face in the Moon*, Plutarch develops a theory of a double death: In "ordinary death," the human soul frees itself from the body and ascends to the moon; after purification a second death ensues wherein the intellect sheds the irrational part. In *Moral Virtue*, Plutarch transposes his cosmological views onto the human soul and on this basis erects a theory of virtue as the mean and the moderation of the passions (*metriopatheia*). Plutarch's virtue ethics stands in a Peripatetic tradition, yet has its theoretical foundations in Platonic traditions as well. Our souls have a rational and an irrational part or force—the passions. The passions have to be made obedient to reason. Reason imposes limit and structure, or even in a sense *is* the limit, establishing the right mean between extremes, moral virtue between opposite vices. When the passions obey reason, the human soul achieves psychic harmony, which is a necessary and perhaps even sufficient condition for happiness in this life (though not necessarily for success in one's undertakings) and leads to felicity in the next. This is also the fundamental lesson of Plutarch's texts on practical ethics. Plutarch was a keen observer of human behavior, virtues, and vices. His *Lives* essentially consists of character studies, and some two dozen of his *Moralia* are on moral themes. Titles include *Advice to Bride and Groom*, *How to Tell a Flatterer from a Friend*, *Inoffensive Self-Praise*, *Exile*, *Compliancy*, *Superstition*, *Control of Anger*, *Tranquillity of Mind*, *Brotherly Love*, *Talkativeness*. Moral considerations dominate his

approach to literature in *How to Study Poetry*. He even wrote on the behavior of animals: *The Cleverness of Animals and Beasts Are Rational*.

## PLATONISM, STOICISM, AND EPICUREANISM

Plutarch incorporated ideas, examples, and terminology from other schools into his texts, but he subordinated them to his overall Platonism. This is especially obvious in his dialogues: He presents and examines various views; this typically leads to a Platonic position in which he combines what is sound in the views of other schools and adds an additional, transcendental, perspective. Plutarch construed his Platonism as occupying a middle position between Stoicism and Epicureanism. Whereas the Epicureans denied providence and the Stoics made the gods responsible for everything, the Platonic god is causally responsible for good things only. Plutarch combated the Stoic monolithic view of the mind and the Stoic ideal of being passionless: The passions constitute an intrinsic, indelible part of our psychic make-up; hence we have to learn to manage and control them.

## PNEUMA

Ancient Greek thought early posited a connection between breath and life. The notion that wind or breath—*pneuma*—accounted for the functions of living things persisted in philosophical and medical accounts of organisms, sometimes alongside the notion of an immaterial soul or *psychē*. The idea that a distinct kind of *pneuma* played a role in the functioning of organisms seems to have developed in early medical theory. Some texts refer to *pneuma* as a kind of nutriment. The idea that there is a specifically "psychic" *pneuma* is found in the doctor Diocles of Carystus (fourth century BCE), who had connections to Aristotle's school.

In Aristotle's biology an innate *pneuma* is mentioned in connection with a number of functions of the organism and is even compared to the *ether*, the fifth element from which the heavenly bodies are composed. In the case of sexual generation *pneuma* is used to explain the ability of the male seed to convey its movements to the female matter without contributing matter to the resulting embryo; in animal movement it helps explain the movement of the limbs. There is room for doubt about how systematically Aristotle used the concept, however, or its relationship to the elements. His second successor, Strato of Lampsacus, seems to have considered *pneuma* to be the material substance of the soul, perhaps in recognition of the discoveries of Hellenistic medicine; a treatise on *pneuma* survives in the Aristotelian corpus.

Praxagoras (fourth century BCE), who distinguished veins from arteries, theorized that the latter contain only *pneuma*; this was eventually rejected by Galen. The Hellenistic doctors Herophilus (c. 335–c. 280 BCE) and Erasistratus (flourished c. 250 BCE) recognized a system of *neura* or nerves originating from the brain, responsible for motor and perceptual functions. Because some nerves were seen to be hollow, they were thought to contain a special kind of *pneuma* suited to their functions. In Galen's physiology the "vital *pneuma*" is distributed through the arteries; the brain refines this into "psychic *pneuma*," which, through the nerves, is the instrument by which the soul performs its functions.

Unlike these medical theories associating *pneuma* with the vascular systems, Epicurus describes the material

soul as like, or partly composed of, *pneuma*. In Stoic philosophy it played a broader role. The Stoics hypothesized that *pneuma*—for them, a kind of hot air—is distributed throughout all other matter in the cosmos. Supposing that all action happens by bodies in contact, yet needing to account for apparent cases of action at a distance, the Stoics held that the pervasiveness of this single material accounted for the “sympathy” between distant bodies, as well as the cohesiveness of the cosmos as a whole and the qualities of individual things. Associated with the divine intelligence pervading the cosmos, the part of the cosmic *pneuma* pervading living things is the soul.

The Greek term *pneuma* was later used in religious contexts and associated with spirit and the divine. The physiological use of *pneuma* to account for functions of living things is echoed in the early modern notion of “animal spirits.”

## POINCARÉ, JULES HENRI (1854–1912)

Jules Henri Poincaré, the French mathematician and philosopher, was born into a distinguished family at Nancy. His cousin Raymond was both prime minister and president of the Third French Republic. At an early age Poincaré showed an interest in natural history and the classics, and at the age of fifteen he developed an interest in mathematics. However, he trained first as a mining engineer, studying mathematics on his own during this training. In 1879 he was appointed to teach courses in mathematical analysis in the Faculty of Science at Caen. In 1881 he moved to the University of Paris, where he was soon given charge of the courses in mathematics and

experimental physics. He lectured on mechanics, mathematical physics, and astronomy. Poincaré wrote an enormous number of papers on mathematics and physics and several important books on the philosophy of science and mathematics, as well as popular essays on science. His most important mathematical contributions were in differential equations, number theory, and algebra. In 1887 he was elected a member of the Académie des Sciences, and in 1899 he was made a knight of the Légion d'Honneur for his work on the three-body problem. In 1906 he became president of the Académie des Sciences, and in 1908 he was elected to the Académie Française.

Poincaré's work in the philosophy of science was in the tradition of Ernst Mach and Heinrich Hertz, and he admitted a debt to Immanuel Kant. His work was clearly influenced by his mathematical approach, and his interest was largely in the formal and systematic character of theories in the physical sciences. He showed less concern with epistemological problems connected with their support and establishment although he did write on the psychology of discovery. Albert Einstein had a profound respect for his work in both mathematics and the philosophy of science. He is often claimed as an ancestor of logical positivism, although the justification is not always easy to see.

### AIMS AND GENERAL CHARACTER OF SCIENCE

Underlying scientific procedures, Poincaré held, is a belief in a general order in the universe that is independent of us and our knowledge. This is what mainly distinguishes the sciences from mathematics, which presupposes, if anything, merely the ability of the human mind to perform certain operations. The aim of the scientist is to discover as much as possible of the order of the universe, a point which must be borne in mind when Poincaré's view is called “conventionalism.”

The method of discovery is basically inductive, proceeding by generalizing from observed facts; its lack of finality is due to its basis in a belief in a general order, since we can never be sure that the discovered order is absolutely general. Modifications in scientific conclusions spring from the constant pursuit of this generality. The discovery of facts depends upon observation and experiment, but these, in turn, depend upon selection because scientists cannot observe and absorb everything at once. There must be some principle of selection, but this principle must not be one of morality or practical utility. The search for an acceptable principle of selection led Poincaré to the idea of simplicity and a somewhat unusual

defense of this idea. The best scientists are motivated by disinterested curiosity about how the world is, and their interest in general truths leads them to select those facts that “have the greatest chance of recurring.” These are simple facts—that is, facts with few constituents. On grounds of probability there is more chance of the recurrence of a few constituents together than of the recurrence of many constituents together. However, familiar facts are more likely to appear simple to us than are unfamiliar facts. This seems to involve an unresolved conflict between two conceptions of simplicity.

What did Poincaré mean by “facts”? This is a question to which he gave less attention than it deserves. He held that science is to some extent objective. He toyed with sensationalism, but as a means of obtaining the necessary objectivity, he asserted that many sensations have external causes. Thus, he cannot strictly be regarded as a sensationalist. Objects are groups of sensation but not merely this; the sensations are “cemented by a constant bond,” and science investigates this bond, or relation. Our sensations reflect whatever it is in the external world between which relations hold; science teaches us not the true nature of things but only the true relations between things. Scientific conclusions may thus be true of the world since they can give us a picture of its structure, though not of its content. We should expect theories of light, for example, to tell us not what light is but only what relations hold between the various occurrences of whatever light is.

The two main aims of scientific investigations are to relate what previously appeared unrelated and to enable us, by using these relations, to predict new phenomena.

## CONVENTIONS

Poincaré constantly compared the physical sciences with pure mathematics and said that their methods of discovery are similar even though their methods of supporting conclusions are different. His view of science emerges most clearly from his comparison of it with geometry, in *Science and Hypothesis*. The space of geometry is not the space of sense experience; we can arrange conditions so that two things that look equal to a third thing do not look equal to each other. The mathematical continuum is invented to remove this disagreement with the law of contradiction; then, in mathematics things equal to the same thing are equal to one another *whatever* our senses tell us. This is one of those axioms of analysis, not geometry, which Poincaré called “analytical a priori intuitions.”

Some geometrical axioms look superficially like this—for example, the Euclidean axiom that through one

point only one line parallel to a given line can be drawn. The development of non-Euclidean geometries has shown that such axioms do not, as was formerly supposed, state fundamental properties of observable space. Coherent systems of geometry can be constructed based on the denial of Euclid’s axioms, and these new geometries, when suitably interpreted, are translatable into Euclidean geometry. Moreover, they have physical applications. The applicability of the various systems is a function of context, or scale. The representation is purely structural.

Poincaré concluded that geometrical axioms are not synthetic a priori truths, for they are not of necessity true, and not experimental truths, for geometry is exact. They are conventions, or disguised definitions. It does not follow, as some critics have supposed, that they are arbitrary, for our choice is controlled by observation, experiment, and the need to avoid contradictions; nevertheless, such axioms cannot be either true or false. They are adopted because in certain contexts they are useful for saying how the world is. For most purposes Euclidean geometry is the most convenient. The application of geometry to the world involves an idealization. “Thus we do not *represent* to ourselves external bodies in geometrical space, but we *reason* about these bodies as if they were situated in geometrical space.” No experimental support for Euclidean or any other geometry is possible, since experiments tell us only about the relations between bodies and nothing about the relations of bodies to space or of one part of space to another.

The physical sciences contain a conventional element as well as experimental, mathematical, and hypothetical elements, a fact which has been missed by most scientists. For example, the principle of inertia, according to which a body under the action of no force can move only at a constant speed in a straight line, is neither a priori nor experimental. It was originally conceived as experimental but has become a definition and so cannot now be falsified by experiment. Scientific conclusions are always conventional to some extent since alternatives to any hypothesis are always possible and, other things being equal, we choose those that are most economical. Because we have no means of knowing that the qualitative features of our hypothesis correspond to the reality, it does not make sense to regard the chosen hypothesis as the one true hypothesis.

In the physical sciences there are two kinds of statement—laws, which are summaries of experimental results and are approximately verified for relatively isolated systems, and principles, which are conventional

postulates, completely general, rigorously true, and beyond the reach of experimental testing because for reasons of convenience we have made them so. Science is not entirely conventional because it does not consist wholly of principles. We begin with a primitive law, or experimental conclusion, but this is broken up into an absolute principle (definition) and a revisable law. Poincaré's example is the empirical statement "The stars obey Newton's law," which is broken up into the definition "Gravitation obeys Newton's law" and the provisional law "Gravitation is the only force acting upon the stars." Gravitation is an invented, ideal concept, but the provisional law is empirical and nonconventional because it predicts verifiable facts. The law of the conservation of energy is an outstanding example of a convention; it defines the concept of energy.

Prediction involves generalization, and generalization involves idealization. We connect a number of points on a graph by a smooth curve which does not pass through every one of them, and so we presuppose that the law we seek is best represented by a smooth curve even if this does not exactly fit the experimental results.

Points chosen midway between the existing points have a much better chance of showing which curve we should draw by eliminating one of them. A hypothesis is most strongly supported when it passes the tests that it was most likely to fail.

### UNITY AND SIMPLICITY

We can obtain new knowledge only through experiment, and the role of mathematics in the physical sciences is to direct our generalizations from experiment. But experiment and generalization depend on presuppositions, most of which we make unconsciously. Among our presuppositions the most important are beliefs in the unity and simplicity of nature. Unity involves the possibility that various parts of the universe act upon one another as do the various parts of the human body, in the limited sense that to understand and describe one phenomenon, we may have to investigate other, superficially unrelated phenomena. The presupposition of simplicity is weaker: We can generalize any fact in an infinite number of ways, and we actually generalize in the simplest way until we have evidence against this way.

Two opposing trends can be discerned in the history of science. There is a movement toward simplicity and unity when we discover new relations between apparently unconnected objects and a movement toward complexity and diversity when, with the help of improved techniques, we discover new phenomena. The progress of sci-

ence depends upon the first tendency, for "the true and only aim is unity." The second tendency is important, but it must ultimately give way to the first. Poincaré argued, referring to the growing unification of the studies of light, magnetism, and electricity, that there are signs of a continued victory for the tendency toward unity. But there are also signs that this does not always go along with simplicity since unity can sometimes be achieved only by revealing the increased complexity in things when shown to be related. However, unity is essential and simplicity merely desirable.

Poincaré's account, like many others, suffers from a lack of clarity concerning precisely what is meant by "simplicity."

### HYPOTHESES

Poincaré distinguished three kinds of hypotheses. The first kind he called "natural and necessary," and they are the very general hypotheses that we use in making judgments of relevance—for instance, when in physics we judge that the effect of very distant bodies is negligible. These form the common basis of theories in mathematical physics and should be the last to be abandoned.

The second kind he called "indifferent," and these are useful artifices for calculation or pictorial aids to understanding. Hypotheses are of this kind when they are alternatives that cannot be distinguished by experiment. Thus, he said, the two hypotheses that matter is continuous and that matter has an atomic structure are indifferent because experiment cannot establish the real existence of atoms. Such hypotheses may be useful, but they may also be seriously misleading if they are not seen for what they are.

The third kind of hypotheses he called "real generalizations." They are direct generalizations from observations and are indefinitely open to further testing. Whether or not they are finally accepted, they are always valuable, if only for their suggestiveness.

### THEORIES AND THE ROLE OF MATHEMATICS

The aim of experiments in physical science is to break up complex phenomena into simple ones with respect to time and space, to connect each moment in the development of phenomena with immediately contiguous moments and each point in space with immediately contiguous points. We also aim to break up complex bodies and events into elementary bodies and events. Because observable phenomena may be analyzed in this way and

be regarded as the result of large numbers of elementary phenomena similar to one another, they are conveniently described by differential equations. This accounts for the ease with which scientific generalization takes a mathematical form. Mathematical physics depends upon the approximate homogeneity of the matter studied, since this enables us to extrapolate.

A physical theory may be superseded by another that uses qualitatively different concepts but the same differential equations; the equations are merely given different interpretations in the two theories. The superseded theory will be just as valuable for prediction because it contains the same relations as the new one, and as long as these stand up to testing, we can say that these are the real relations between things in the world. Both theories are true in the only way in which it makes sense to talk of the truth of a theory. Any advantage that the new theory has over the old will be merely psychological and will lie in its suggestions rather than in its implications. It is relatively unimportant that one theory of light refers to the movement of an ether and another refers to electric currents; what is important is the extent to which their equations agree, and it is on this that their truth must be judged.

Theories do not set out to explain, although they may provide possible explanations. They are devices enabling us to connect and predict phenomena but not to describe reality in all its details. The assertion that, for example, atomic theories explain the behavior of matter implies that we are able to establish the actual existence of atoms as delineated by the theories. But this is a metaphysical and not a scientific assertion because such existence can never be established by scientific means.

## MATHEMATICS AND LOGIC

In mathematics Poincaré was, on the whole, an intuitionist, holding that the integers are indefinable and that underlying all mathematics is the principle of mathematical induction whose validity is intuitively recognized—that is, synthetic a priori.

In his last years Poincaré made a lively attack on the logic of Giuseppe Peano, Bertrand Russell, and others, especially on the logistic attempt to reduce mathematics to logic (*Mathematics and Science: Last Essays*, Chs. 4–5). He thought it important to study not only the consequences of adopting given conventions but also the reasons for adopting these conventions rather than others. He argued that it is impossible to derive all mathematical truths from the accepted logical principles without further appeals to intuition. He pointed, for example, to the difficulty of defining numbers without begging the ques-

tion, and he saw even in the foundations of Russell's logic a reliance, inescapable on any satisfactory account, on synthetic a priori principles. He objected to the idea of an actual infinity, which he claimed was essential to Russell's system, and held that the logical paradoxes could be avoided by excluding nonpredicative definitions—that is, definitions of particular members of a class which refer to all the members of that class (*Science and Method*, Book II, Chs. 4–5). He expressed a general dissatisfaction with the extensional interpretation of logical constants.

## Bibliography

### WORKS BY POINCARÉ

*Oeuvres de Jules Henri Poincaré*. 11 vols. Paris: Gauthier-Villars, 1928–1956. Contains all Poincaré's important scientific papers together with part of his own account of his work, a biography by G. Darboux (Vol. II), and centenary lectures on his life and work (Vol. XI).

*La science et l'hypothèse*. Paris: Flammarion, 1902. Translated by W. J. Greenstreet as *Science and Hypothesis*. London, 1905. Poincaré's most important book on the philosophy of science and mathematics.

*La valeur de science*. Paris: Flammarion, 1905. Translated by G. B. Halsted as *The Value of Science*. New York: Science Press, 1907.

*Science et méthode*. Paris: Flammarion, 1908. Translated by Francis Maitland, with a preface by Bertrand Russell, as *Science and Method*. London: Nelson, 1914.

*Dernières Pensées*. Paris: Flammarion, 1912. Translated by John W. Bolduc as *Mathematics and Science: Last Essays*. New York: Dover, 1963.

"Analyse des travaux scientifiques de Henri Poincaré, faite par lui-même." *Acta Mathematica* 38 (1921): 1–385. Partly reprinted in *Oeuvres*. This is a Poincaré issue of the journal and contains an extensive bibliography and appreciations by J. Hadamard, H. A. Lorenz, P. Painlevé, M. Planck, L. Fuchs, and others.

### WORKS ON POINCARÉ

Carnap, Rudolf. *Logical Syntax of Language*. London: Kegan Paul, 1937.

Einstein, Albert. "Geometry and Experience." In *Sidelights on Relativity*, translated by G. B. Jeffery and W. Perrett. London, 1922.

Frank, Philipp. "Einstein, Mach and Positivism." In *Albert Einstein, Philosopher-Scientist*, edited by P. A. Schilpp. Evanston, IL: Library of Living Philosophers, 1949. Other articles also mention Poincaré.

Frank, Philipp. *Modern Science and Its Philosophy*. Cambridge, MA, 1949. Logical positivism's debt to Poincaré.

Grünbaum, Adolf. "Carnap's Views on the Foundations of Geometry." In *Philosophy of Rudolf Carnap*, edited by P. A. Schilpp. La Salle, IL: Open Court, 1964.

Hadamard, J. S. *The Early Scientific Work of Henri Poincaré*. Rice Institute Pamphlet (Houston, TX) 9 (3) (1922).

- Hadamard, J. S. *The Later Scientific Work of Henri Poincaré*. Rice Institute Pamphlet (Houston, TX) 20 (1) (1933).

Peter Alexander (1967)

## POLITICAL PHILOSOPHY, HISTORY OF

The history of political philosophy is the succession of notions about the actual and proper organization of people into collectivities and the discussion of those notions. It is philosophical in character, because it is concerned with obedience and justice as well as with description; the persistent preoccupation of political philosophers has been the definition of justice and of the attitude and arrangements that should create and perpetuate justice.

A distinctive characteristic of political philosophizing is that it has usually been undertaken in response to some particular political event, or possibility, or threat, or challenge. This has led to a raggedness, even an incoherence, in works devoted to it and to an emphasis on intuitive argument which compares unfavorably with the content of other philosophical literature. Political philosophy has sometimes been supposed to confine itself to a particular entity called "the state," but in fact political philosophers have always concerned themselves with the collectivity as a whole, even when they have drawn a distinction between "state" and "society."

Problems of definition and description might appear to be prior to problems of analysis and prescription in political philosophy. In fact, however, ethical doctrine has always had a powerful effect on the view that a political thinker takes of the collectivity; he has tended to see it in terms of what he thinks it ought to be. Nevertheless, it has become usual to separate the empirical element from the normative. Empirical study has been further divided into sociology and political science. These definitions and

divisions are no more satisfactory than others devised for similar purposes, and although we talk with some confidence of "sociologists," "political scientists" have only very recently emerged as an independent class of thinkers.

It is often useful to look upon political philosophy as in some sense systematic, proceeding from a view of reality and knowledge (ontology and epistemology) to a view of the individual (psychology) and a view of the social bond (sociology), and so to a general ethic, a political ethic, and finally to a set of recommendations about the form of the state and about political conduct. The expression "political philosophy" will be used in this sense here, and it will be considered solely in terms of the Mediterranean-European tradition.

## CRITIQUE OF THE SUBJECT

There are several ways in which the history of political philosophy has been found important. Every thinker who engages in speculating about state and society and in formulating principles concerning them is anxious to know of the performance of his predecessors, to learn from them and to share their minds. Every thinking citizen is in this position too, to some extent, at least in the democracies: The questions raised in political life are frequently philosophical questions. Both thinkers and citizens, moreover, have good reason to believe that the intellectual and cultural life which they share with their contemporaries, together with the institutions which make political and social life possible for them, in some sense embody notions inherited from past political philosophy and philosophies. Certainly neither political attitudes nor political behavior nor political machinery can be understood without knowledge of this kind.

These various requirements have led to differing standards for the study. Insofar as it is the record of thought about state and society, its level of accuracy has to be as high as possible. For academic historical purposes, every word of the text of Aristotle, or Marsilius of Padua, or Jefferson must be correctly registered, his intentions known, the circumstances of the writing and publication of his work discovered and recorded. But neither the conscientious citizen nor the inquiring political theorist need be much affected by the particular version of a given work which he reads, even if it is an indifferent version, clumsily translated and abbreviated perhaps, or a brief and tendentious summary in a general history. The complete book need not be known, nor the attitude of its author. It may even help if little fables are allowed to grow up around such works. The misunderstanding of one political philosopher by another, or the misreading of

authoritative books by citizens and constitution makers, has often been fruitful.

Moreover, historians of thought and of society have not been content with the role of annalists or of mere recorders of what was once written. They have sought to discover why the works were composed at all, to trace interconnections and influences covering whole generations, whole centuries of intellectual development. More recently they have been concerned to study literature in the light of ideology and to see in the writings of political philosophers especially the “reflection” or “expression” of the social structure at the time of writing, with its discontinuities, inconsistencies, and ambivalencies. Classics have come to be regarded not only as determined in this way but also as instruments in the social process, intellectual weapons in the hands of interested men and groups of men.

Although these differing motives can be distinguished in the historiography of political philosophy, individual commentators are seldom moved by one alone and often fail to see them as distinct. To this confusion must be added the unfortunate consequence of confining attention to a particular selection of authorities, a selection perhaps made originally for good philosophical reasons but which persists for reasons of convenience, curriculum, or plain conservatism. This, which is itself an example of a confusion between the interests and outlook of the historian and of the philosopher, has led to the creation of a canon of “classics” which alone go to make up “the history of political philosophy.” Taken together, these circumstances are responsible for a number of persistent weaknesses in the study of this subject, some of which are listed below:

(1) The scripturalist tendency to criticize works as if their authors should have written out the final truth with complete coherence and as if, therefore, their failure to do so, their incoherencies and inconsequences must conceal some inner truth to be unraveled.

(2) The philosophizing tendency to relate the select thinkers to each other and to no others, as if contrasts between them and them alone are significant and as if they can be thought of as addressing each other. The reader’s task becomes that of welding the various works into some philosophic whole.

(3) The tendency to mistake the theoretical interest of a work for its significance in other directions. This tendency is the general form of the failure to distinguish the separable interests and objectives of historians (as annalists and explainers), of philosophers, and of citizens.

(4) The tendency toward what might be called “naive sociology”: The particular circumstances of a thinker are seen as expressed in his thinking in a literal and unconvincing way, and the dominant social conditions of the present are read almost unchanged into apparently analogous conditions of the past.

Each of these tendencies can be disabling enough in itself; when they are present in combination, the results can be strange indeed. The search for Hobbist elements in John Locke, for example (tendency 2), can become an attempt to prove that he was really a Hobbist altogether and that his work on government must be examined for cryptic signs of those elements. More familiar are the exaggerations that come from stressing the relations of influence between the canonical works (tendency 2) and seeing all other intellectual elements as “anticipations” and “derivations” of these to such an extent that the relationships between bodies of thought and past societies are entirely distorted (tendency 3). Worst of all, perhaps, is a commentator who allows his thought to be so dominated by his experiences as a citizen in his own day that he betrays himself into an extreme form of the fourth tendency. When this happens, not only do Plato’s or Rousseau’s politics appear “totalitarian,” but they are also made distantly responsible for the totalitarian proclivities of the twentieth century.

Weaknesses of this kind, however, do not necessarily deprive the commentaries concerned of their interest. In the historiography of political philosophy, as in many other inquiries, the intrusion of obvious but stimulating fallacies helps to maintain the enterprise.

## GREEK POLITICAL PHILOSOPHY

The Greek city-state, or polis, gave us the word *political* and is usually supposed to have been the social organization which provided the necessary conditions for men to take for the first time a rational-critical view of the relation of the individual to the collectivity. The claim might be made that only in completely autonomous, small-scale, urban societies, like those of the Mediterranean area from the tenth century before Christ on, could an attitude of this kind develop. Because of the small size of these political entities, deliberations could take place, and decisions be made, in face-to-face discussion among all citizens, who could also see their collectivity as parallel with numerous other collectivities of the same character. It is certainly the case that the mold in which political philosophy has been set ever since is patently recognizable as Greek, and the assumption of face-to-face discus-

sion and decision persists to this day, with not entirely fortunate results.

**SOCRATES AND PLATO.** The issues of freedom versus tyranny, of the various forms of the state (monarchy, aristocracy, or democracy), and of the nature and operation of law are not certainly known to have been debated until very close to the time of Socrates, who was born about 470 BCE, well into the famous fifth century. The Sophists, or teachers of the art of rhetoric and persuasion for use in the law courts and in Greek public life generally, are usually credited with initiating political discussion properly defined. Although he was unsparing in his criticism of these professionals in the techniques of influence, of *sophistry* in fact, it is hard not to classify Socrates himself as a Sophist.

A determined effort has been made, by Karl Popper and others, to separate the political doctrine of Socrates, the champion of the critical discussion of dogmas and of institutions, from that of Plato, “the enemy of the open society,” and their thinking has been related to the political events of late fifth-century Athens in a way which betrays many of the weaknesses described above. It seems best, however, to take Socrates and Plato as the dual spokesmen in the first known critical inquiry into the nature of the collectivity, with the peculiarity that one of them, Plato, did all the recording. The point at issue was the perennial point of how justice can be secured between men, organized as they have to be for the purposes of making a livelihood, propagating their kind, and cultivating the humane arts and accomplishments.

The answer given in Plato’s *Republic*, probably composed about 365 BCE and the most powerful of his dialogues, is straightforward enough in principle, perhaps even a little banal, but it is argued on the very loftiest plane. Justice is secured only when every member of the polis is doing what he is best suited to do, and those who are best suited to do the ruling are the philosophers themselves—lovers of wisdom, those who really know. “Unless,” says Socrates at the end of Book V, “either philosophers become kings in our states or those whom we now call kings and rulers take to the pursuit of philosophy seriously and adequately, and there is a conjunction of these two things, political power and philosophic intelligence, ... there can be no cessation of troubles for our states, dear Glaucon, nor I fancy for the human race either.”

The steps of the argument before and after this passage are by no means a matter of formal political-theoretical demonstration, and the *Republic* is at one and

the same time many different treatises, a characteristic which it shares with most of its successors as classics of political philosophy. What has probably sunk deepest into the European political imagination is its utopian element, the description of an ideal condition of the collectivity when it is ruled by a select society of guardians.

The famous Platonic guardians were to be brought into the world in accordance with premeditated principles of eugenics and were not to know who their parents were. They were to live in conditions of complete communism and poverty, without privacy and outside the family; both men and women were to spend their whole lives in the service of the polis and to undergo thirty years of education—gymnastics and military training to prepare the body, music and philosophical instruction to prepare the mind. Although it is implied that the guardians would be a small minority of the whole population, and that their undisturbed rulership would ensure justice, their actual relationship with the other two elements in the polis, the soldiery and the consumers (by which term Plato presumably meant the mass of handicraftsmen and peasants, producing and consuming), is never specified. These divisions of the polis are presented as analogues of the divisions of the soul; indeed, the polis is the soul writ large. Insofar as there is a positive political doctrine in this most famous of all works of political philosophy, it seems to be hypothetical—if the polis-soul could be constructed in this way, then all problems would be solved.

Several other Platonic dialogues are concerned with political issues, and the last of them, the *Laws*, can be looked upon as the complete recasting of the Socratic-Platonic political philosophy in the light of a lifetime’s reflection and experience, some of it Plato’s own practical experience in advising a pupil of the Platonic Academy in the administration of the polis at Syracuse, in Sicily. But although Plato’s *Politicus* (otherwise called the *Statesman*) presents an account of political life and political ideals rather different from that of the *Republic*, and although his *Laws* clashes at certain points with the *Politicus*, the ideal state of the *Republic* is that element of the political thought of Socrates and Plato which has interested posterity and influenced its thinking, almost to the exclusion of their other views.

**ARISTOTLE.** Aristotle, Plato’s pupil, was the first of many later philosophers and thinkers who addressed themselves to the Platonic utopia, and he rejected a great deal of it. Aristotle was even more of a synoptic thinker than Plato and was much more interested in the amassing and

classification of knowledge. The gathering of information about politics and political organization was, therefore, only one of the many tasks on which Aristotle spent his extraordinarily industrious life (384–322 BCE), along with his Herculean studies of logic, psychology, biology, literature, economics, physics and other subjects. But there is evidence to show that, like Plato and other Greek thinkers, Aristotle considered politics the most important subject of all.

The Aristotelian treatises on political philosophy, the *Eudemian Ethics* and *Nicomachean Ethics* and the *Politics* itself, appear to have been based on a monumental assemblage of material of a political-scientific character, including a record of no fewer than 158 constitutions of Greek poleis. These writings had even more impressive experience behind them, because Aristotle, a Macedonian by birth, had actually been tutor to Alexander the Great, who in Aristotle's lifetime subjugated Greece and Athens. Nevertheless, Aristotle's political theory was properly philosophical, that is, it proceeded from a general view of the world and of knowledge.

He was no more disposed than any other citizen of the polis to see the individual as a reality apart from the collectivity, but he did provide a critique of the reasons why human life implied compulsory association. Man, he claimed, is a species of animal that possesses intelligence and is found in intelligently collaborative groups; therefore "man is a political animal." The natural unit of the human family forms part of the natural unit of the village, which in turn forms part of the natural unit of the polis; but the polis is not merely the family enlarged, it is an association for leading the good life, which is otherwise incapable of realization—and this means a difference in classificatory, in logical, order. States (poleis—Aristotle significantly dismisses all larger organizations as capable of ordered living only by religious means) must be judged by the extent to which they enable citizens to become virtuous and to live the good life, a life of moderation, the mean. This line of argument led Aristotle to sketch his own ideal state, but it also led him, in the *Politics*, to raise a series of crucial issues which have endured almost unchanged as decisive questions for political science as well as for political philosophy.

Probably the most conspicuous are the claims of fundamental inequality between humans: Slaves and barbarians are by nature inferior to Greeks and to citizens, although Aristotle conceded that inequality in some respects does not mean inequality in all respects. Within every collectivity, however, quite apart from the division between citizens and those incapable of citizenship, there

are three classes: an upper class of aristocrats; a middle class of substantial men, mainly merchants, craftsmen, and farmers; and a lower class of laborers and peasants. The interests of these classes conflict: in sharp contrast with Plato and his anxiety for a harmony, a unity, in the polis-soul, Aristotle recognized politics as a conflict-defining, conflict-resolving activity. The actual distribution of political power among these classes—Aristotle himself insisted on the political virtue of the middle class—together with the web of manmade laws, goes to make up the particular constitution (*politeia*, the same word as the Greek title of Plato's *Republic*) of that polis. In spite of his fundamental inegalitarianism and his Greek inability to conceive of consent or representation as relevant to politics, Aristotle has often been hailed as the initiator of constitutionalism, as "the first Whig."

## JUDAIC AND CHRISTIAN POLITICAL PHILOSOPHY

It is conventional to reckon the death of the polis at the death of Aristotle in 322 BCE and to believe that nothing new of importance to political philosophy appeared until the Roman Stoics evolved the universalistic dogmas of natural law. It is undoubtedly true that no systematic philosophical discussion of political principles can be traced in Judaic thought or in early Christian thought. But it is important to recognize that the symbols and the symbol system of subsequent political thinking derives from Judaic as well as from Greek sources and that its psychological assumptions are deeply tinged with Christian revelationism.

The three social institutions of the ancient Hebrews, whose significance for the history of political thinking has only recently come to be recognized, are patriarchalism, the sense of the people, and kingship. The text of the Old Testament that proclaimed the duty of obedience as the basis not only of political discipline but of all social order, including economic order, was the commandment "Honor thy father and thy mother." Throughout the Christian centuries, therefore, all questions of obedience were seen in a patriarchal context, and the political power of the Hebraic patriarch (Judah, who condemned his daughter to death for playing the harlot, or Abraham, with his fighting army of servants) was the model for the power exercised by kings and ministers. Quite as significant was the Judaic sense of the chosen people, the people led by the hand of God through the wilderness because they had an enduring purpose and being. Whenever Christian political theorists thought of the people as having a voice in the appointment of a king or a regime,

or of the king as having a duty to his people, their model was the peculiar people of Israel. European kingship was also conceived in biblical terms, and the tribal hero-king whose actions committed the people before God and whose power came from God can be seen behind the western European dynastic regimes.

Even more authoritative, of course, were the words of Jesus himself on political matters, and the few texts which could be made to bear at all upon them have been perpetually cited throughout the Christian era. Christ's submission to the Roman authority, his use of an inscription on a Roman penny ("Render unto Caesar the things that are Caesar's"), and his repeated insistence that his kingdom was not of this world made it difficult to find authority in the New Testament for any doctrine of resistance. Saint Paul's sayings pointed in the same quietist direction ("The powers that be are ordained of God"). But more interesting to the twenty-first century are those fragments of evidence from the apostolic era that make it possible to believe that Christ's immediate followers lived a communistic existence.

## ROMAN STOICISM AND NATURAL LAW

The belief that there is a universal and eternal moral ordering which is common to all men and which therefore carries weight on certain issues in every collectivity is a widespread ethical and religious notion, and it need have very little specific content. Its origins have been sought in Plato's immutable Ideas and, further back, in Greek poetry. The source most often favored, however, is the religious-philosophical sect of the Stoics, who took their name from the *stoa*, or porch, before which Zeno, their reputed founder, preached and taught in Athens soon after the time of Aristotle, about 390 BCE. Stoicism was brought to Rome during the classical generations of Roman republicanism, and it continued to be a system widely accepted, although changing in content, from the time of the Scipios (about 100 BCE) until about 200 CE, when even the great Roman political families began to feel the attraction of Christianity.

The orator-statesman Cicero, although eclectic in his intellectual outlook and not usually thought of as a philosopher, wrote probably the most widely read of all works in political philosophy until recent times, *On the Laws* (*De Legibus*, c. 46 BCE) and *On the Duties of the Citizen* (*De Officiis*, a year or two later). The *Laws* was composed in deliberate imitation of Plato and was intended to complement Cicero's *De Re Publica* (his *Republic* of a year or two before), a work that was lost until 1820. *De Re*

*Publica* contains, however, the classic text for the universalistic theory of natural law as it entered into political philosophy:

True law is right reason in agreement with Nature; it is of universal application, unchanging and everlasting ... there will not be different laws at Rome and at Athens, or different laws now and in the future, but one eternal and unchangeable law will be valid for all nations and all times, and there will be one master and one ruler, that is, God, over us all, for He is the author of this law, its promulgator and its enforcing judge. (Book III, Ch. 22, Sec. 33)

The cosmopolitan character of this doctrine—a society of all humanity ruled by one God—is in sharp contrast with the earlier Greek outlook, which assumed that only the small-scale polis could embody political good. The individual is recognizably the unit of this universal society and is the subject of the rights conferred on all citizens, all Roman citizens, by the Roman law. The identification of law with reason must be noticed in this process; reason carries its own claims to the individual's obedience. The final sanction of law and authority is placed here outside the collectivity altogether, in the Deity. Nevertheless, nothing in Stoicism could be taken as an argument against the deification of the later emperors, and one of them, Marcus Aurelius, was himself a Stoic thinker. So also was Epictetus, who began life as a slave. A rough doctrine of original freedom and equality, even the use of the contractarian model for the collectivity, has been read into Stoic texts—"All seats," so the Stoic proverb went, "are free in the theatre, but a man has a right to the one he sits down in"—but it was religious rather than specifically social equality. Much of the intellectual groundwork, in fact, of subsequent political philosophy can be sighted in the intellectual-religious tradition of Stoicism, and it is only the philosophizing tendency of historians which has prevented its attracting more attention than it has done.

## ST. AUGUSTINE

*The City of God* (*De Civitate Dei*), written between 410 and 423 by St. Augustine, bishop of Hippo in north Africa (354–430), traditionally occupies an important place in the canon of great works on political philosophy. This extraordinary treatise raises in an acute form the problem of the historical reputation and effect of a body of thought in contrast with its actual content and the intention of its writer. *The City of God* was undoubtedly read in medieval times and afterward as the authoritative

statement of the superiority of ecclesiastical power over the secular, because it was believed to identify the visible Christian church with the mystical city of God, thought of as the bride of Christ or, even more mystically, as the body itself of the Christian Saviour. But it is very doubtful whether this was St. Augustine's intention or is even implied by his text. What is more, the conscientious political scientist finds it very difficult to decide whether *The City of God* contains any positive political doctrine at all, theoretical or otherwise.

Very recent political philosophy might, therefore, justifiably claim this work as an antipolitical classic, stating in very different terms the position sketched out by Karl Marx and V. I. Lenin as "the withering away of the state." There is the same tendency to identify all arrangements in the collectivity with evil, with the unjustifiable exercise of naked power, and the same confidence that in the fullness of time this monstrous regimentation will disappear. Moreover, Augustine was a historicist: He sought to show how God's plan to fill up the places left in Heaven when Satan and his angels revolted was being fulfilled. The creation of man and the world was intended to reveal candidates for the heavenly choir, and some few men on earth at any one time, the pilgrims (*peregrinati*), were destined at the last trumpet to be among them. They and they only were the living members of the City of God, but no one would know who constituted this select few until the judgment. It seems to have been a matter of almost complete indifference to St. Augustine how those who were to be saved behaved toward society, secular or spiritual, or what was the nature of political arrangements.

The occasion of Augustine's beginning *The City of God* was the sack of Rome by Alaric the Goth in 410, and the fall of the Roman Empire, which this event presaged, could not possibly affect the Christian who held such views about history, state, and society. The complement of the City of God was the city of the devil (*civitas diaboli*), and although it seems unjustifiable to identify the one city with the church, it seems that Augustine did quite often refer to the Roman Empire as the other. Since the heathen Romans could not possibly do justice to God and since kingdoms without justice are but great robberies (*Remota itaque justitia quid sunt regna nisi magna latrocinia?*—Ch. 4, Bk. 4), what could the Roman Empire be but thievery on a colossal scale? If by the Roman Empire Augustine implied all possible forms of the collectivity—and there are passages to confirm this assumption—then he must indeed be supposed to have had a completely negative political philosophy. Justice could

never be found in any of them. In this final work of ancient political theory, then, the overriding concern is with justice, just as it had been with Socrates at the very beginning, but in it justice is viewed from an anarchist, antipolitical outlook.

## MEDIEVAL POLITICAL PHILOSOPHY: POPE AND EMPEROR

Apart from the development of natural law in Christian form, the Middle Ages did not give rise to much speculation about the nature of the collectivity that has affected subsequent attitudes, nor to any great body of specifically political philosophy. Before the time of St. Thomas Aquinas in the thirteenth century, what little critical analysis there was seems to have been dominated by the Church Fathers and especially by Augustine. Although these early medieval thinkers knew of the great Greek philosophers, the actual treatises of Plato, Aristotle, and others had been lost in the West. There seems to have been a certain amount of political awareness among the subjects of the Germanic kingdoms which had come to spread over Europe, and during the nineteenth century a great deal was made of the primitive Germanic sense of community (*Gemeinschaft*), people (*Volk*, folk), and corporation (*Gesellschaft*). But unless jurisprudence is counted a part of political philosophy, neither these arrangements nor the universal social institutions associated with feudalism seem to have been the subjects of much corresponding theorization. It is remarkable how little headway the analysis of political theories in ideological terms has made with the Middle Ages.

ST. THOMAS. John of Salisbury's *Policraticus* (1159) was still Ciceronian and Augustinian in content, in spite of the fact that by his time the text of Aristotle had already reached the Latin West from the Arabs. It was left to St. Thomas to arrange the enormous access of Aristotelian information and principle in a form acceptable to a Christian Europe, which he did in his great *Summa Theologiae*. The frank acceptance of natural man—man as revealed by Aristotelian science; man not incurably maimed by sin and therefore indifferent to social-political arrangement; man whose nature is perfected, not taken away by the grace of God (*gratia non tollit naturam, sed perfecit*)—distinguished the sociology of Thomas from that of his predecessors. But although of enduring importance for politics, indeed still the final authority for the Thomist thinkers of our own day, the *Summa* and its Christian doctrine of natural law contains no developed political philosophy. For this we must turn

to the *De Regimine Principum* (*Of the Rulership of Princes*) and other works, including Thomas's commentaries on Aristotle's *Politics* and *Ethics*.

In these works St. Thomas presented his theory of the relationship between pope and emperor, which had already preoccupied Christian Europe for centuries and would continue to do so until the end of the medieval period. He developed the traditional distinction of *regnum* and *sacerdotum* (secular and spiritual jurisdiction) in Aristotelian terms, in terms of ends, the ends of humanity. "We are confronted," as A. P. d'Entrèves says, "with the doctrine of the distinction and interrelation of two great spheres of human life within one single society—the Christian society, *respublica christiana*." But although Thomas is moderate in his claims for the pope against the emperor, although he never talks of the direct sovereignty of the pope, he is firmly convinced that all kings in Christendom should be subject to the Vicar of Christ as to Christ himself. Yet willing as he was to temper Aristotelian inegalitarianism with Christian grace, anxious as he was to give every Christian his share in the affairs of the collectivity, Thomas was absolutely intolerant of the Jew and the infidel: They remain outcasts in the Christian community.

Authority in St. Thomas's system must be legitimate, otherwise it may be resisted. An evil ruler exceeding his powers and burdening his subjects must be resisted—resisted not by the individual citizen in virtue of his individual rights (Thomas had no room for such rights) but presumably by the church. This is the sense in which Thomas's thinking has been hailed, like that of Aristotle, as the forerunner of constitutionalism.

**DANTE AND MARSILIUS.** The other two medieval thinkers usually accorded a place in the history of political philosophy are Dante Alighieri, the supreme poet of the city of Florence, whose political essay *Monarchia* was composed between 1310 and 1313, and Marsilius of Padua, whose *Defensor Pacis* (*Defender of peace*) was completed in 1324. Both were imperialists, on the opposite side of the pope-emperor controversy from St. Thomas, but both were Aristotelians. Dante's work was an idealization of the position of the medieval European emperor, who was in fact a ruler of Germany to whom the traditional trappings of the Western Roman emperor still attached as the secular ruler of all humanity, whose powers were derived directly from God and not indirectly through the pope. Marsilius approached somewhat closer to realism and had a recognizably empirical sociology: He insisted on the Aristotelian class analysis of political soci-

ety and regarded the clergy as one among the classes, and therefore not in the privileged position which papal theory claimed.

The twenty-first-century observer is far more at home in the Greek polis or in a Roman province than at the papal *curia* or the court of a feudal king. So much was the medieval collectivity a religious whole, embracing not only all the territory occupied by Christians but also the whole of intellectual and cultural life, that it may be doubted whether there existed anything which corresponds to the term *state* as political philosophers ordinarily use it. Apart from the metaphysics of the papal-imperial argument, most "political thought" of the European Middle Ages is recognizable as advice to a ruler, wise reflections on commonplace situations that are entirely traditional in context and object and show no trace of the analytic attitude. Nevertheless, the medieval collectivity and the reflections of medieval theologians upon it can be appreciated under more headings than that of record.

Apart from the paradigm for the metaphysical approach to the final problem of ethics and politics provided by Thomas, the medieval situation provides the extreme example of territorial political relationships, in which the psychological mechanism usually called religious can be seen most clearly at work in providing the consensus on which such collective action as went forward had to rely. Any properly empirical account of how a collectivity in fact works, at any time, has to recognize that this mechanism is still very much in operation and that the mistake of supposing it to be replaced by rational-technical cooperation has still to be properly appreciated.

#### MACHIAVELLI AND REALPOLITIK

Although the polis began to lose its independence of policy as early as the lifetime of Aristotle, the towns of the Roman Empire continued to maintain a collective life that differed very little from the life of the classical polis. The decline of the cities was the outstanding feature of the fall of the empire, but they never entirely disappeared, at least in Italy. By the time of Dante and Marsilius such cities as Florence, Venice, and Milan were again in the formal position which Athens had occupied: They were independent urban communities having diplomatic relationships with each other and with the territorial monarchies. The cities possessed their own hinterlands, too, and colonies. It is not surprising, therefore, that the rational-critical attitude reappeared and that a consuming interest in ancient culture, in Plato and Aristotle, in Rome and

Greece, led to an appreciation of classical political philosophy on something like its own terms.

Nevertheless, Niccolò Machiavelli's *The Prince* (written 1513, first printed 1532), in some ways the most effective and interesting of all works of political philosophy, was in form merely one more piece of advice to a ruler. It was not presented as a philosophical work, and it contained neither abstract argument about politics nor any systematic discussion of the nature of state and society. Its analysis is confined to situations between a prince and his people and between princes (or cities) themselves. Its method is historical, the citing of significant instances. The outcome of discussion is advice, with occasional reflective aphorisms. Some of these aphorisms have become famous, and all of them show an astonishing realism and insight: "Above all a prince should abstain from the property of others; because men sooner forget the death of their father than the loss of their patrimony." "Whoever is responsible for another becoming powerful ruins himself." "Fortune is a woman and if she is to be submissive it is necessary to beat and coerce her." The headings of the twenty-six brief chapters of *The Prince* are even more significant than the sayings; Chapter 17 is titled "Cruelty and Compassion, Whether It Is Better to Be Loved Than to Be Feared."

Machiavelli's well-known answer is that it is far better to be feared than to be loved, if you cannot be both. His cool discussion of the effects of cruelty and unscrupulousness, his detached attitude toward Christianity and the traditional virtues, and his professed admiration for men of his time who are known to have been villainous and contemptible, especially the political gangster Cesare Borgia, have given Machiavelli the reputation of being the theorist of power politics, deliberate immoralism, and irresponsible, tyrannical government. But the contents of his major work on politics, the *Discourses on Livy*, have been cited to show that he was a believer in republican, not monarchical, government, and they have been used with the famous last chapter of *The Prince* itself to demonstrate that he was in fact a virtuous, patriotic Italian, worthy of the reputation he enjoyed among the English Whigs, for example, for political probity and insight. It has even been suggested, not for the first time in our generation, that *The Prince* was a satirical work. But there can be no doubt that from the time of its appearance this book was regarded as a textbook for tyrants and an exposition of the principles of power politics.

## THE REFORMATION AND SECULAR NATURAL LAW

If Machiavelli's writing is looked upon as philosophical in intent, its most remarkable feature is its failure even to mention the doctrine of Christian natural law, which since the time of Thomas had dominated discussion of the nature of the collectivity and of the duties of citizens. The arrival of Protestantism raised the question of political obligation in an acute form for the first time in the history of political philosophy. It challenged a believing Lutheran or Calvinist to decide whether he should go on obeying a Catholic prince, and a Catholic subject to make the same decision about a Protestant prince. This had the effect of emphasizing, crystallizing, and codifying natural-law doctrine, since it was only under a legal or quasi-legal system of natural law that most citizens felt that they could claim a right to disobey and ultimately to resist political authority which commanded actions against their faith. Once this codification was made, systematic reflection on the philosophical problems raised by political allegiance began in earnest, and in the process natural law began to lose its exclusively religious sanction and become secularized.

It took a long time for the breakdown of universal religious consensus to have effects of this kind, even though many other influences going far back into the Middle Ages tended toward the secularization of political life. Martin Luther himself offered no systematic political teaching, certainly no doctrine of the right to resist princes for conscience sake'. In fact, in his treatise *Of Good Works* (1520) Luther wrote out traditional patriarchal rules for submission in a particularly emphatic form. John Calvin preached nonresistance too, but the religious wars in France in the later sixteenth century gave rise to a multitude of theories of the social contract that provided justification for disobedience and even for revolution on the basis of natural law. In England the Calvinists went even further, or so it seemed to the great doctor of the English Reformed church, Richard Hooker, when he sat down to write *The Laws of Ecclesiastical Polity* (written in the 1590s, first four books published in 1594 but not in print complete until 1662). Hooker believed that the claims to inspiration made by the extreme Puritans amounted to a denial of the efficacy of reason itself and to a complete rejection of natural-law principles. His response was a majestic reformulation of Thomas's natural-law philosophy that took account of the changes brought about by the Reformation, particularly of the doctrine of the final sovereignty of each individual state and its ruler, which had come to replace the ultimate

authority of emperor or pope in Christendom. The absolute sovereignty of the secular ruler, from whose decree there was no appeal, a doctrine which might be called that of ethical self-sufficiency of every political system, was given its classical expression in the *Six Books of the Republic*, published by the eminent French lawyer Jean Bodin in 1576.

Along with these developments went another that can be seen very clearly, as early as Machiavelli. This was the recognition that the body politic—the people and their political instruments, such as their parliament or their local institutions—might itself be an object of governmental action, worked on and molded by an enlightened ruler, just as the body politic might in its turn take action against government, rebel against it, replace and change its constitution. Meanwhile, secular natural law was providing a framework within which such processes could go forward and within which—as a code of international law—the various sovereign states could negotiate with one another. By the time that Hugo Grotius came to write that source book of all subsequent international law, *De Jure Belli ac Pacis* (The law of war and of peace; 1625), these relationships had come to include Islamic and Buddhist societies and societies entirely alien to the Christian point of view, even societies with no apparent belief in a deity. Natural law therefore had to become independent of Christian revelation, and Grotius stated that his principles would endure even if God did not exist. The stage was set for the first great classic of modern European, as opposed to classical ancient, political philosophy, the *Leviathan* of Thomas Hobbes (1651).

## HOBBS

Although Hobbes is rightly regarded as above all a philosopher, with his own view of knowledge and of the nature of the physical world, his point of departure was political, as much as Plato's or Aristotle's was. Hobbes's declared object was "to set before men's eyes the mutual relation between protection and obedience, of which the condition of human nature, and the laws divine require an inviolable observation." This relation required the absolute submission of each individual to the dictates of an arbitrary sovereign, of "That great LEVIATHAN, or rather (to speak more reverently) of that *Mortal God*, to which we owe under the Immortal God, our peace and defence" (*Leviathan*, Ch. 17). Political science—though Hobbes did not use the phrase itself, he insisted that the proper name for the knowledge he was examining was in fact "science," on the geometrical model then beginning

to take hold on men's minds—implied absolutism, despotism.

But Hobbesian political doctrine was no doctrine of the divine right of kings, nor even of one-man rule, for in this system democracies, aristocracies, and monarchies should all equally be absolute sovereigns, whose every dictate is law. Monarchy was to be preferred, as might be expected, and democracy, "the government of a few orators," was least desirable. The power of government is a part of the divine providence, but its sanctions are much more tangible. They rest on the unqualified alienation of all the rights of every individual into the hands of the sovereign at the time of the making of the social contract—of compact, as Hobbes called it—and thereafter every attribute of every citizen, even his property, depended on the sovereign's will. So anxious was Hobbes to remove any possible grounds that might be used to justify resistance to authority that he advanced two positions entirely unacceptable to most of his contemporaries. One was the reformulation of natural law in a form that gave no rights to the citizen and the other was to confer on the sovereign the function of pronouncing on the interpretation of Scripture itself.

Perhaps the most famous element in the Hobbesian system was the account of the state of nature, and the best-remembered passage reads:

during the time men live without a common power to keep them all in awe, they are in that condition which is called war; and such a war, as is of every man against every man.... In such condition, there is no place for industry, because the fruit thereof is uncertain: and consequently no culture of the earth, no navigation, nor use of the commodities that may be imported by sea; no commodious building; no instrument of moving, and removing such things as require much force; no knowledge of the face of the earth; no account of time; no arts; no letters; no society; and which is worst of all, continual fear, and danger of violent death; and the life of man, solitary, poor, nasty, brutish and short. (*Leviathan*, Ch. 13)

If this fighting anarchy is in fact the natural state of man, then it does seem to follow that the only possibility of cooperation in the collectivity is by absolute submission, and every human value must depend on the existence and efficacy of "the great Leviathan." The law, or rather the laws, of nature did exist at that repulsive stage of human development but only as rules of prudence, for "Reason suggesteth convenient articles of peace, which otherwise

are called the laws of nature.” Whatever the status of these principles, they could not possibly be used to justify resistance to the sovereign, although Hobbes did provide for the transfer of allegiance to another sovereign when the one established can no longer provide protection. He also allowed to the individual the right to refuse to confess to a crime or to take his own life. The appeal to revelation and to conscience, which Hobbes believed was responsible for the political instability of his own time, and especially for the Puritan rebellion in England, was completely precluded by his interpretation of the claims of his sovereign.

In spite of Hobbes’s confident belief that his elucidation of the true principles of political science would resolve conflict, his work aroused immediate opposition and has given rise to unending controversy. There is first the question of whether his state of nature, succeeded by a covenant, or social contract, was intended to be taken literally as a historical and anthropological claim, or whether it was simply hypothetical. A recent ideological interpretation has claimed that the state of nature was hypothetical but that the aggressive, competitive emphasis arose from Hobbes’s observing the possessive individualism informing the increasingly capitalist society in which he lived. The second question concerns the continuity between his state of nature and his state of society. How could men with the characteristics Hobbes gives them ever form themselves into a collectivity? A third question is whether he ever intended men to be morally obliged to obey the sovereign, or, if this was his intention, whether he succeeded in tying them down ethically. A further question is how far he was indeed abandoning the whole natural-law position and advancing an entirely utilitarian political ethic; men obey always and only because they see it is to their advantage.

## WHIG CONSTITUTIONALISM AND LOCKE

Hobbes was not the first writer to invoke what came to be called the “pleasure-pain principle” in political discussion, and his radical contemporaries, the Levellers of the English Civil War, also made claims which seemed to rest on strictly utilitarian grounds, although in an unphilosophical and unsystematic form. The appearance of writings of this character, which have claims to be the first emanating from the common man, raises an important issue about the career of political philosophy from the seventeenth century on. The Levellers were democrats, and the political rights they claimed were meant to be exercised by a far greater proportion of the population

than ever had been previously contemplated, even by the English Parliamentarians locked in their struggle with the house of Stuart. It has been recently and justifiably questioned whether all individuals were intended to be covered by Leveller declarations, or even all male householders, but from that time on, there is a recognizable class content in the doctrines of the political philosophers. Until the late eighteenth century most thinkers continued to share the universal assumption that “citizen” must be confined to the fully literate, propertied, elite minority, but they showed an increasing awareness that this was a tiny minority and that the right of this minority to stand for the whole might need justification.

Paradoxically enough, this crucial question was raised in an awkward form by one of Hobbes’s exact contemporaries, Sir Robert Filmer, a traditionalist rather than a progressive. Sovereignty is a patriarchal matter, Filmer claimed, a matter of natural subordination, and unless this is recognized, the inequality of distribution of property and the subjection of poor men, men without the vote, servants, and women could never be justified. Much of Filmer’s thinking, and that of the commonsensical Englishmen who came to accept his authority, is present in the writing of Hobbes. Nevertheless, for historical reasons it was against Filmer rather than against Hobbes that in the years 1679 and 1680 Locke wrote out the classic statement of Whig constitutionalism and government by consent, *Two Treatises of Government* (revised and published in 1689).

This modification of the accepted account of the relation of Locke to Hobbes is due to very recent scholarship, and the same evidence goes to show that the work of Benedict de Spinoza, the only immediate follower Hobbes had among philosophers, was more of an intellectual preoccupation for Locke than Hobbes ever was. Spinoza (*Tractatus Theologicopoliticus*, 1670; *Tractatus Politicus*, 1677), if easily the least influential, was in some ways the most engaging of all the political thinkers of the early modern age in Europe. Unfortunately, we cannot dwell here on his modification of the Hobbesian system; his overt insistence that the contract was hypothetical; his specific insistence that all obligations had to be utilitarian, based on self-interest; or his attempt to ensure that the enlightened sovereign must seek the welfare of his people.

Locke’s *Second Treatise*, with its subtitle *Of Civil Government*, seems to have been the first composed of the two, and it begins with the following assertion against Filmer’s claim that all men are born unfree, unequal, and in patriarchal subjection:

To understand political power right, and derive it from its original, we must consider what state all men are naturally in, and that is, a state of perfect freedom to order their actions and dispose of their possessions, and persons, as they think fit, within the bounds of the law of nature, without asking leave, or depending on the will of any other man. A state also of equality, wherein all the power and jurisdiction is reciprocal, no one having more than another. (Sec. 4)

The law of nature, then, was real, and it governed all men in the peaceable condition which preceded the foundation of the collectivity, when order was maintained by what Locke called “the executive power of the law of nature” in the hands of every man. This law of nature gave men tangible rights, even before the contract. It ensured them the right to their religious opinions (not argued for, or even mentioned, in the work on government but in a succession of *Letters on Toleration*, the first published in 1689); it guaranteed them the right to property, whose acquisition was brought about by men “mixing their labour” with the goods of nature; it made it legitimate for every person to take some political responsibility and in due course to act as sovereign himself or as part of the sovereign power, for the vital political right was that of insisting that government rested on the consent of the governed, the consent of the majority expressed constitutionally through representation. The stage of contract came about because the predominantly peaceful state of nature was liable to war and because property was insecure under it. When it arrived, political power was “a right of making laws for the regulating and preserving of property, and of employing the force of the community, in the execution of such laws, and in defence of the commonwealth from foreign injury, and this only for the common good” (*Second Treatise*, Sec. 3).

Contract, to Locke, was an agreement to pool the natural political virtue of individuals and to establish a sovereign power thereby which was in a perpetual trust relationship with the people. If the trust was broken, the people had a right to cashier their governors and put others in their place or, if necessary, to alter the constitution, and all this without the return of the state of nature. In this sense, and in allowing a final appeal to God if the compact itself was dissolved, Locke can be said to have held to a doctrine of the sovereignty of the people and to a perpetual reserved right of revolution. He believed in a form of the separation of powers and in the rule of majorities, but he shows little sympathy with representative democracy.

Recent studies have shown that Locke’s political philosophy, as contrasted with his general philosophy, was much less influential in the eighteenth century than had been supposed. Nevertheless, the Lockean outlook, along with that of his friend and contemporary Sir Isaac Newton, must be counted as the point of departure of the intellectual movement known as the Enlightenment.

## THE ENLIGHTENMENT AND MONTESQUIEU

Locke could not deal adequately with Newtonian mathematics, but in spite of the intellectual barrier between them, the two men shared one passionate curiosity: to know all that could be known about societies, customs, and religions outside Europe. Confidence in the efficacy of mathematico-physical methods to solve all problems, including those of social and political organization, and cultural relativism leading to doubt about religious revelation and the necessary value of any familiar institution underlie much Enlightenment thought. Meanwhile, the steady spread of literacy and the consequent growth of the size of the politically conscious, curious, and ambitious community, especially in France and England, was changing the conditions of political and social speculation.

The result was a proliferation of works of political philosophy which from now on defeats the summary historian. Sir Isaiah Berlin has said that “the conflict of the rival explanations (or models) of social and individual life had by the late eighteenth century become a scandal.” Except as a critical movement, compelling all established dogma to give an account of itself, the Enlightenment cannot be called a uniform current of thought at all. Of the multiple works of Voltaire, Baron de Montesquieu, David Hume, Claude-Adrien Helvétius, Adam Ferguson, Jean-Jacques Rousseau, Gabriel Bonnot de Mably, D’Argenson, Richard Price, Thomas Paine, Thomas Jefferson, Edmund Burke, and their successors, we can comment here on only one or two that find a place in the traditional canon.

MONTESQUIEU. Charles Louis de Secondat, Baron de Montesquieu, may serve as the example of the early sociological attitude, presented with great literary skill and at considerable length in his *Esprit des lois* (in preparation from 1734, published 1748). To Montesquieu, who sought to examine and record social uniformities, natural laws describe necessary human behavior, and because they are necessary, they also oblige men ethically, or, rather, they are the basis of legal systems which men are

morally obliged to obey. At this point it is usual to say that Montesquieu's attitude touches that of Hume in his *Treatise of Human Nature* (1739), containing his famous aphorism about all systems of morality imperceptibly changing from propositions containing "is" and "is not" to propositions containing "ought" and "ought not." But the French author's interest was not in obligation as such; rather, it was in the structure of the collectivities which men find themselves obeying and in the ways in which these structures or their "spirits" (*esprits*) express environment.

**ROUSSEAU AND THE GENERAL WILL.** Montesquieu is scarcely representative of the most characteristic feature of the political philosophy of his age, at least when viewed from the somber century we now inhabit, because he was neither an optimist nor a believer in the perfectibility of man. Rousseau was skeptical of progress too, for in some moods he seems to have believed that human nature had once been perfect but had been corrupted by society. This was the position which he defended in his first *Discourse* (1751). In his second *Discourse*, the *Discourse on Inequality* (1755), not society but property was the evil attacked.

Neither of these works contained Rousseau's specific contribution to political philosophy. In the *Social Contract* (*Du contrat social*, 1762) Rousseau elaborated a doctrine that was both original and potentially revolutionary; the relation of the individual to the collectivity was seen as a matter of will, not of agreement, and the solution of the problem of obligation was the discovery of a general will directed to universal moral ends, which the individual had only to obey in order to secure justice. Rousseau presented the general-will model in individualistic, contractarian terms:

Man was born free, and everywhere he is in chains. What is it that can make this legitimate? ... The moment men leave the state of nature and set up society, that act of association brings into being a moral, collective body in the place of the particular persons of each contracting party, composed of as many members as there are voices in the assembly, which from this same act receives its unity, its common personality (*moi commun*), its life and its will. This passage from the state of nature to the state of society produces a very remarkable change in man, in substituting justice for instinct in his conduct, and giving to his actions the morality which before they lacked. (*Du contrat social*, Book I, Chs. 1 and 6)

In spite of the care that Rousseau took to effect a moral reconciliation of the will of the individual and that of society, the collectivist possibilities of his approach to political obligation are evident. Since he insisted that a collectivity which has no general will is unworthy of the obedience of its citizens, its revolutionary potentialities are also obvious. The most conspicuous element supporting the interpretation that the *Social Contract* is a statement of tyrannical revolutionary nationalism is its final chapter, "The Civil Religion," which can be interpreted as justifying the condemnation to death of anyone who flouts Rousseau's own dogmatic statement about the relation of the individual to the state.

**THE FEDERALIST, BURKE, AND PAINE.** The supposed direct relationship of Rousseau's thinking with the revolutionary movements of the late eighteenth century, particularly with the American and French revolutions—even with the Reign of Terror and the despotism of Napoleon Bonaparte—is a conspicuous example of that interplay between intellectual speculation and political movement in which both citizens and historians seem to want to believe. It is of course doubtful whether any element from the multifarious theorization about politics which went on during the Enlightenment could ever be shown to be causally related to what happened in France after 1789, and it is certain that the rebelling American colonists took little trouble to justify their actions in philosophical terms. Nevertheless, the foundation of the American political attitude is of importance to political philosophy, and *The Federalist* (written jointly by James Madison, Alexander Hamilton, and John Jay in the form of a collection of papers published in the New York press in 1787 and 1788) is an outstanding instance of a book's being taken as a compendium of the theoretical content of a nation's political outlook. Max Beloff has said that the sociology of this work was static; in their day there had been founded in America a society, a prefabricated, premeditated structure that would endure unchanged forever. It had the characteristic common to all ethically justified institutions: "Justice is the end of government. It is the end of civil society. It ever has been and ever will be pursued, until it be obtained, or until liberty be lost in the pursuit." But justice is not the imposition of equality—it is the protection of the weak against the stronger. Government will otherwise be content to hold the ring, and liberty will be ensured by the separation of the powers and by the balance between the state and federal governments.

Edmund Burke was a champion of the Americans against the arbitrary powers of the British crown, and he

must have approved of much of the argument of the *Federalist*, especially that concerning the benefits of unequal distribution of property. The exercise of political power was the greatest challenge to the wisdom and responsibility of an individual and to his capacity to decide weighty issues on behalf of others. Where were such men to be found but among those experienced in the proper administration of great possessions and of the people who went with them?

Each of Burke's voluminous writings on politics, which occupied his whole life, contains a remark or two of importance to the philosophy of politics. But the work that has caught the eye of posterity is the one he wrote in horrified protest against the actions of the French revolutionaries, *Reflections on the Revolution in France* (published in 1790). The famous passage remembered from this book goes as follows:

Society is indeed a contract. Subordinate contracts for objects of mere occasional interest may be dissolved at pleasure—but the state ought not to be considered as nothing better than a partnership in a trade of pepper and coffee, calico or tobacco, or some other such low concern, to be taken up for a little temporary interest, and to be dissolved by the fancy of the parties. It is to be looked upon with other reverence; because it is not a partnership in things subservient only to the gross animal existence of a temporary and perishable nature. It is a partnership in all science; a partnership in all art; a partnership in every virtue, and in all perfection. As the ends of such a partnership cannot be obtained in many generations, it becomes a partnership not only between those who are living, but between those who are living, those who are dead, and those who are to be born. Each contract of each particular state is but a clause in the great primeval contract of eternal society, linking the lower with the higher natures, connecting the visible and invisible world, according to a fixed compact sanctioned by the inviolable oath which holds all physical and moral natures each in their appointed place. (pp. 163–164)

The extravagance of the language and the lamentable vagueness of the statements are typical of Burke, and typical also of the uncritical acceptance of the contractarian model long after it had become unnecessary. Indeed, Burke's account of obligation, insofar as he presented one

at all, was far closer to Rousseau's general-will argument than he would have admitted.

But the phrases that have interested posterity are those that limit the freedom of each generation to act against the expectations of the past and the interests of the future, and those in which he condemns as immoral the action of any society which allows fundamental revolution. It was an offense against all humanity to act as the French revolutionaries were doing. The very language of abstract natural right was excoriated by Burke, and he challenged all subsequent political thinkers with the problem of the status of political principles in relation to political action and practice.

Burke's effusive, skeptical conservatism was too much for Thomas Paine, his acute Anglo American contemporary, whose *The Rights of Man* (Part I, 1791, a direct answer to Burke) is often acclaimed a minor classic of political philosophy. There has been no writer more optimistic about the effects of violent political action, or more indifferent to the existence of established government. "The instant formal government is abolished, society begins to act. A general association takes place and common interest produces common security." But in the second part of *The Rights of Man* (1792) Paine identified himself with the nascent working class, and added to the responsibilities of government policies that were hitherto scarcely contemplated and are hailed in our day as the first discernible sign of welfare legislation, even down to family allowances and maternity benefits. The talk of property, representation, and the will and wants of all, which had increased steadily since the time of Hobbes, had issued at last into something like universalistic claims for participation in political activity, into that "numerical democracy" which has characterized the industrialized world ever since.

## THE UTILITARIAN TRADITION

BENTHAM. "It is the greatest happiness of the greatest number that is the measure of right and wrong." This famous tag appears in the second paragraph of Jeremy Bentham's *Fragment on Government* (1776) and may be looked upon as the original formulation of the utilitarian principle for specifically political purposes, although Bentham had the law in mind. (Utilitarian ethics of course goes back as far as Hobbes, and Bentham's use of it may be directly referred to Hume.) Bentham went on to offer a definition of the collectivity which was followed more or less faithfully by all his successors in the utilitarian tradition: "When a number of persons (whom we may style subjects) are supposed to be in the habit of pay-

ing obedience to a person, or an assemblage of persons, of a known and certain description (whom we may call governors) such persons altogether (subjects and governors) are said to be in a state of political society.”

The unsatisfactory character of crude utilitarian ethics is plain in Bentham’s best-known book, the *Introduction to the Principles of Morals and Legislation* (1789). “It seems to me,” John Plamenatz has said of this work, “that Bentham, without quite knowing what he is doing, is trying to reconcile two couples of irreconcilable doctrines; egoistic hedonism with utilitarianism on the one hand, and a psychological with an objective theory of morals on the other.” But in clarifying legal principles and in giving directions to lawyers and politicians, Bentham was much more effective, perhaps the most effective writer of principle for the purpose of advice. So anxious was he to make it crystal clear what men should do tomorrow that he went so far as to proclaim that the motives from which men act are morally irrelevant; only the consequences matter. Carrying out this advice made Bentham into an advocate of the doctrine that government is a necessary evil, since all that government can do is to coerce, and coercion must be kept to that minimum (Bentham’s coinage) which will prevent even greater pain. In this way, with Paine as well as with Bentham, utilitarianism was used to justify equality between citizens and representative democracy.

J. S. MILL. The logical difficulties of utilitarian ethics and the possible dangers of numerical democracy—leaving every man to make up his mind about his own and the general happiness and giving him an equal right to a part in decisions about them—are also evident in the classic statement of liberalism, John Stuart Mill’s *On Liberty* (written 1854, published 1859). It was followed in 1861 by *Utilitarianism* and *Representative Government*.

Mill’s *On Liberty* shares some of the social unreality that is so evident in Bentham’s definition of the collectivity, but to a very much smaller degree. “Wherever,” says Mill, “there is an ascendant class, a large portion of the morality of the country emanates from its class interests, and its feelings of class superiority.” In his later life Mill might well have described himself as socialist. But the doctrinal legacy of his text is very different:

The object of this Essay is to assert one very simple principle, ... that the sole end for which mankind are warranted, individually or collectively, in interfering with the liberty of action of any of their number, is self-protection, ... to prevent harm to others.... The only part of the

conduct of any one, for which he is amenable to society, is that which concerns others.... The only freedom which deserves the name, is that of pursuing our own good in our own way, so long as we do not attempt to deprive others of theirs. (*On Liberty*, Ch. 1)

This principle of other-regarding actions being distinguished from self-regarding actions, and being alone amenable to control from outside, is one of extreme difficulty in practice but of great convenience in argument. With it goes a deep suspicion of the “tyranny of the majority,” not simply as expressed in governmental action but even more in the form of intolerant conformism of opinion. Mill is at his most persuasive when he argues that “all silencing of discussion is an assumption of infallibility” and when he insists that it is to the universal advantage that the truth should be known. His book may be regarded as the most forceful of all pleas for freedom of thought and expression. He ends it by insisting on three very general reasons against “government interference.” States should not do things better done by individuals, things which it is better for the individuals to do themselves, and things which might unnecessarily add to governmental power.

SIDGWICK. Mill was by no means the last of the utilitarian thinkers, although the positive grounds for freedom and justice put forward by the idealists were already beginning to replace the negative arguments summarized above. Henry Sidgwick’s *Elements of Politics* (1891) may be taken as the final statement of political utilitarianism, although in its later editions it is marked by repeated concessions to socialism, always referred to in quotes. Sidgwick’s definition of the collectivity is still Bentham’s, although he admits that the principles of politics are not absolutely true but are based on psychological propositions approximately true of civilized man. He adopts from the great utilitarian jurist, John Austin, the claim that in every state the legislature must be legally unlimited, but he also qualifies this. He comes down emphatically on the side of individualism, “which takes freedom—the absence of physical and moral coercion—as the ultimate and sole end of governmental interference.”

## GERMAN IDEALISM

KANT. The general-will model associated with Rousseau underwent some development at the hands of the great German philosopher Immanuel Kant in various works written in the 1780s and 1790s. His idea of a “general and

public will” is not a particularly lucid concept, but it does express for political purposes the supreme ethical principles of the Kantian philosophy that each man should treat each other man as if he were an end, never as a means, and that each act should be such that it might become a universal law. V. F. Carritt has also praised him highly for the recognition that obligation is a condition of political societies, not a product of them. More influential for subsequent political philosophy, however, was Kant’s theory of history. In the course of this complex argument he proposes that the attainment of political society which shall enforce justice requires that man have a master to force him to be free and that this master be the will of the community.

HEGEL. Most philosophers have tried to bring to bear on the problems of political philosophy an overall view of the world and of knowledge. No philosopher has been so devoted to system and the whole as Georg Wilhelm Friedrich Hegel. Political philosophy has its appointed and necessary place within the dialectic exposition of reality. Reality is spiritual, the Absolute, and collectivities have their part to play in the teleological “unfolding” of the Absolute. Collectivities—the family, “civil society,” and the state—are manifestations of objective spirit, and the state is the culmination of objective spirit. Collectivities arise when the manifestation of objective spirit in the individual reveals itself as inadequate. The individual can be truly himself only in some society. Formal ethics is bare and empty, and it must be made concrete. Concrete ethics can only be social. Thus the family is a dialectical necessity.

But the family is not a permanent institution; although the members of the family are united in the family and hence are one, the children grow up and leave the family. This “negation” of the family is negated in a new collectivity, civil society. Civil society embraces the economic order and the economic organizations and institutions through which it is expressed, as well as the legal system and the enforcement facilities necessary to it. But the legal system implies something over and above civil society, namely, the state, without which a legal system is impossible. Family and civil society are both embraced within the state; they are at the same time fulfilled by it and manifestations of it. The same is true of the individual. In the state the individual rises above his mere particularity to become a person and truly free.

What the concept of a state fully embraces can be known only through the historical development of actual states. Among the many possible forms of the actual state,

the most rational is a monarchy. A corporative state, in which individuals participate in governmental affairs by virtue of their standing in the corporative bodies of civil society rather than as individuals, is more rational than representative democracy, in which individuals are represented merely as individuals. Nevertheless, the constitution which is best for any particular state is that one which has developed slowly in that state over the course of centuries. A constitution imposed artificially is bound to fail.

It might seem that Hegel’s conceptual scheme would require that the state be embraced in some other form of collectivity, but this is not the case. The state is the highest form of objective spirit, and, at this point of the dialectic, objective spirit is negated by absolute spirit—the realm of art, religion, and philosophy. Thus Hegel rejected the Kantian notion of a federation of states and regarded war as not only natural but the motive force of history.

#### GREEN AND BOSANQUET

The meaning and implications of Hegel’s political philosophy provoked immediate and lasting controversy. The central points of discussion have been the relation of the individual to the collectivity, whether state, society, race, or nation; the meaning of the notion of state; and the application of dialectic to the discovery of a necessary pattern in political history. The first point was the dominant problem of the social thought of the British idealist philosophers of the later nineteenth and early twentieth centuries. In political philosophy the two chief figures, with rather opposed views, were T. H. Green and Bernard Bosanquet. Green undertook the task of updating British liberalism to meet the changing circumstances of a rapidly industrialized society. To do so, he sought to divorce liberalism from the ethical egoism of utilitarianism and the laissez-faire economic doctrines of David Ricardo and to replace them with an idealist theory of society based broadly on Kant and Hegel.

For Green, as for earlier liberals, the effect upon freedom was the criterion by which a piece of legislation was to be judged. Did it tend to enlarge or to restrict freedom? Green held that Benthamite liberals had arbitrarily identified freedom with absence of legal restraint, implying that any piece of legislation must necessarily restrict freedom. Green pointed out that it had become evident that a person could be legally free and still not have the power to act for his own benefit. Where one party to a contract has all the powers of coercion on his side and the other party cannot help but agree to the terms proposed by the

first party, then the state has the right and the obligation to interfere to restore the original freedom. There are other restraints on freedom than those imposed by the state.

Nevertheless, freedom was not, for Green, a natural right, for he held that there are no natural rights in the eighteenth-century sense. No one possesses abstract rights independent of his membership in a society in which the members recognize some common good as their own ideal good. Thus Green, more a Kantian than a Hegelian, held that the basis of all political obligation is the moral obligation to treat the other members of one's own society as ends in themselves, as having wills whose realization should not be interfered with. The state, on Green's view, has the duty to foster the conditions that permit each member so to act, and to lead him to regard and treat the other members as ends. The members in turn obey the state because they recognize it as the embodiment of their common right.

Green's liberalism stressed the positive function of the state in supporting the moral well-being of all its citizens, and it was not far from the Fabian conception of a national minimum of physical well-being below which the state should not allow any of its citizens to fall—for otherwise they could not participate fully as moral and political beings in society. The liberal side of Green's thought has greatly influenced British political philosophy, which has tended to remain idealist or partially idealist long after idealism passed out of fashion in other areas of British philosophy. But it has been certain antiliberal tendencies which have come to be generally thought of as most typical of idealist political thought, especially since the publication of L. T. Hobhouse's *The Metaphysical Theory of the State* (London and New York, 1918). This work was a direct attack on Hegel and on Bosanquet's *Philosophical Theory of the State* (London, 1899).

Bosanquet developed the notion of the relation between individual and society beyond Green's claim that individuals are individuals only insofar as they are social. He claimed that society itself is more real and more of an individual than any of its members can ever be. And within each member of society it is the social self, rather than any purely individual desires or aims, that is most real. The social self is somehow identical with society, and thus social coercion is coercion by the higher, social self of the lower, individual self. In short, social coercion is self-mastery and true freedom.

Hobhouse charged that this revival of Rousseau's (and Locke's) notion that a man can be forced to be free

is in itself dangerous and illiberal. He further charged that this notion, combined with Bosanquet's failure to distinguish properly between society and the state, or indeed to give any clear or unambiguous definition of the state, leads to the doctrine that the state can do no wrong, and hence to the justification of almost any action on the part of the government in power. There is no doubt that idealist claims have in fact so been used; however, Bosanquet held not that individual governments can do no wrong but that they can do wrongs of a kind totally different from those which individuals can commit—a government can confiscate property, but it cannot commit theft. And individual states can be judged by how well or poorly they fulfill the functions of a state.

### MARX AND MARXISM

The Marxian development of Hegelianism is of an entirely different order from the academic philosophies of Green and Bosanquet. The difference is epitomized in Marx's famous eleventh thesis on Ludwig Feuerbach: "The philosophers have only *interpreted* the world, in various ways; the point is to *change* it."

Karl Marx, the great theoretician of socialism, applied the Hegelian dialectic of history to the Hegelian analysis of collectivities. Hegel's family, civil society, and state are not three eternal ideas partially or imperfectly manifested at all periods of history. Rather, they are abstractions from the particular socioeconomic arrangements of the period in which Hegel and Marx lived. Hegel was right in stressing the central role of the economic function in civil society and in holding that, as now constituted, civil society requires a police power and hence a state. But he failed to see that civil society is not necessarily the same as capitalist, bourgeois society (civil society and bourgeois society are designated by the same phrase in German), and he did not see that those who determine the economic arrangements of society are not abstract individuals but are those who exercise control over the economic resources and forces available at the time. Since all others are excluded from having a voice in these economic arrangements, the result is class divisions and the need for the dominant class to defend its economic and political position against the other classes. Thus, as Hegel said, the state is necessary, but it is necessary as an instrument of the oppression of one class by another and not as something inherent in the very notion of social life. If class divisions were done away with, then there would be no one to oppress and the state would disappear. Civil society would be all that there was.

Marx, of course, believed that although in all previous periods (except for an initial period of primitive communism) the state had been necessary, the economic forces of capitalism had so developed that it was not only possible but also necessary for the state to disappear. The complexity of previous class divisions was becoming polarized into two antagonistic classes: the bourgeoisie, who controlled the instruments of production, and the proletariat, who had no choice but to work for the bourgeoisie at subsistence wages. Once the proletariat rises up and takes over the means of production from the bourgeoisie, there will be no more classes to oppress. In the classless society the state, the government of persons, will be “replaced by the administration of things and by the conduct of processes of production” (Friedrich Engels, *Anti-Dühring*, Moscow, 1962, p. 364).

Three intellectual tasks emerge from this view of the historical situation: a study of the laws according to which one era passes into another; a study of the present bourgeois era to discover in it those forces and movements tending toward its breakup and the emergence of the inevitable next era of the classless society; and some sort of preparation and anticipation, however blind, of the period of transition and its aftermath. Thus, economic history and political sociology become pressing practical subjects, and the central problem of politics becomes that of revolution.

The problem of justifying revolution had often been raised before. For Marxists, justification is no longer in question; revolution is inevitable, and only its date is unknown. Marxists must know how to bring about a revolution, whether it must be violent, and whether the revolution can be hastened if the productive forces are not yet ripe. Marx was sure that the bourgeoisie would not yield power without a struggle and that the revolution must be violent. He also held that it could not be hastened: “No social order ever disappears before all the productive forces for which there is room in it have been developed” (*A Contribution to the Critique of Political Economy*, translated by N. I. Stone, Chicago, 1904, preface).

Those later developments of Marxist thought that have been serious and not merely propagandistic justification of a position have generally been attempts at adjusting or revising the theory of revolution to changing historical situations—the growth of mass socialist parties with the apparent possibility of their coming into power by peaceful means; abortive revolutionary governments like those of the Paris Commune of 1870 and the soviets of workers and peasants of the Russian revolution of 1905

(both as interpreted somewhat mythically by Marxist writers); the rapid succession in 1917 of a bourgeois revolution in Russia by a proletarian one before all the possibilities of the bourgeois era could come to flower; the conspiratorial character ascribed to that proletarian revolution; the imposition of socialist regimes in Eastern Europe by Soviet intervention; and the greater or lesser success of Marxist-inspired revolutions in countries, notably China, where modern bourgeois capitalism had only the most tenuous foothold. These revolutions in countries with precapitalist economies were totally inexplicable on classical Marxist grounds, and interpretations of them generally rely on some variant of Lenin’s doctrine that in the latter part of the nineteenth century capitalism developed into a higher, final phase of international imperialism, with a corresponding internationalized proletariat and an interaction between the proletariat of the imperialist states and of the populations of the colonies.

## ANARCHISM

Socialism, both Marxist and non-Marxist, has since the time of Marx generally favored some sort of centralized control at least of economic life, despite the Leninist prominence given to Friedrich Engels’s phrase “the withering away of the state.” Although in general it has been held impossible to predict the exact character of a communist society, it has not been claimed that there would be no central authority. In opposition to this collectivist view were most of those early socialists whom Marx classified as utopian, as well as the anarchists and the later guild socialists, such as G. D. H. Cole.

The anarchists differed enormously in their attitudes toward social and economic arrangements, especially in their attitudes toward the institution of private property, but they were united in their opposition to the state, and hence to any centralized authority and to any participation in governmental functions. Engels expressed the Marxist’s difference with the anarchist ideal succinctly:

In this society there will, above all, be no *authority*, for authority = state = absolute evil. (How these people propose to run a factory, operate a railway, or steer a ship without a will that decides in the last resort, without single management, they of course do not tell us.) The authority of the majority over the minority also ceases. Every individual and every community is autonomous, but as to how a society of even only two people is possible unless each gives up some of his autonomy Michael Bakunin again

maintains silence. (Letter to Theodor Cuno, January 24, 1872)

The anarchists see the primary fault of the present economic order not in the economic arrangements, as do socialists, but in the existence of the state. The state is to be overthrown (although many anarchists, despite the popular identification of anarchism with terrorism, would stop short of violence), and then society will take care of itself. The actual order that will emerge is variously pictured as anything from an extreme individualism to voluntarily cooperating groups of various sizes. Marxists deny this primacy to the state, which, they hold, will collapse when the economic order of which it is the instrument collapses.

Ideas resembling the doctrines of the anarchist thinkers can be found in writings of various periods from Greek times onward, but the first fully articulated anarchist theory is to be found in William Godwin's *Enquiry concerning Political Justice* (1793). Like later anarchists, Godwin was as much an ethical writer as a political theorist. All social organization, and especially all governments, are necessarily corrupting. Society creates prejudices—preconceived ideas. We see people in terms of their social function and status rather than as individuals, and we judge in terms of false ideals—honor in a monarchy and public-spiritedness, a concern for the good of the state rather than of the individual, in a republic. Neither is a substitute for the ideal of benevolence. Godwin's solution is a small, classless community without rules in which individuals cooperate without compulsion, out of friendship, understanding, and benevolence.

Pierre-Joseph Proudhon, a self-educated Besançon printer, was the first theorist to describe himself as an anarchist. Despite his famous definition, "Property is theft," Proudhon was not against property as such but only against its unequal distribution. His ideals were equality and independence. As political science discovers the natural laws according to which society functions, then the arbitrary laws of governments become unnecessary. Proudhon favored individual ownership of the means of production by peasants and artisans. As political science revealed their mutual interests to them, they would freely join together in an ever-widening system of interlocking economic contracts that would make government unnecessary. Only in the case of some large-scale industries and public utilities would workers' syndicates be necessary.

With Bakunin anarchism became associated with the nineteenth-century revolutionary tradition. The son of a Russian nobleman, Bakunin was involved in a number of

revolutionary movements from the 1840s on, took part in abortive revolutions in France, Prague, Dresden, and Bologna, and was imprisoned in Saxony, Austria, and Russia. Bakunin was influenced by Proudhon but also by Hegel, Comte, Arnold Ruge, Charles Darwin, and Marx. Like Proudhon, he held that what is produced should be distributed according to the amount of labor the recipient has provided, but he differed in advocating public ownership of the means of production. He differed from Marx in advocating the early destruction of the state rather than its seizure by the workers.

Another Russian writer, Prince Peter Kropotkin, was also influenced by Proudhon. His chief differences from Proudhon and Bakunin were that he favored the small local community as the unit of social organization and argued that goods should be distributed on the basis of need rather than on the basis of what the recipient had produced. Thus he envisaged warehouses where goods would be distributed freely rather than earlier schemes of distribution based on some measure of the recipient's production. Kropotkin also tended to stress the notion that man is naturally social, which was a factor in earlier anarchist theories, even going so far as to find that cooperation, and not merely competition, is a factor in animal evolution.

Far too complex in his views to be classed merely as an anarchist is the French philosopher Georges Sorel. Sorel is important less for his programmatic views than for his analysis of social systems into consumers' and producers' societies, each with its own system of morality, and of the roles of violence and of political myths in revolutionary movements. In a consumers' society the good is things to be obtained—welfare, prosperity, distributive justice, or the classless society. The consumers' society is based on envy. A producers' society sees the good in the cooperative creative endeavor of self-reliant individuals. But this creative endeavor tends in the end to decay into a consumers' society. Violence is a sign of moral health in a revolutionary movement. It ranges from a violence of principles to, occasionally, physical violence. It is intended as much to discourage the "reasonable" sympathizer who feels the time is not ripe for revolution and the man of good will seeking reconciliation as it is to intimidate the enemy. A myth is the revolutionary morality stated in terms of a hoped-for future. Thus, the notion of the general strike may be self-contradictory, but this is beside the point. It is not scientific prophesy but the expression of the aspirations of the revolutionary masses.

## FASCISM AND NATIONAL SOCIALISM

Marxism and anarchism are representative of a modern tendency to see political arrangements in terms of a program and often of one dominant idea. There have been others, notably racism and the various forms of nationalism, but only two can be mentioned here. Like Marxism, fascism and national socialism were official philosophies, justifications of particular revolutions and of the regimes that ensued from them. Unlike Marxism, they were not coherent doctrines, and their proponents never made more than a pretense of reconciling theory and practice. New situations called out new theoretical pronouncements in diametrical opposition to earlier ones—but the earlier pronouncements were deliberately allowed to remain as part of the doctrine, with no attempt at harmonizing them with the new claims. Complicating any systematic interpretation is their deliberate irrationalism. Benito Mussolini tended to glorify action—any action; Adolf Hitler relied on his own intuition.

Of these two ideologies, fascism had the twin advantages for clarity and consistency, if not for ideological use, of being largely confined to a conception of the right arrangement of politico-economic life and of having an official formulation compiled by a philosopher, Giovanni Gentile (although Gentile's formulation was worked over by Mussolini himself). Both fascism and national socialism pretended to be nationalist and socialist. In Italy this meant the corporative state and the denial of class antagonisms. Political power was supposed to pass upward through organizations embracing all those who worked in an industry, workers and owners alike, but these organizations would naturally merge their own interests in the national interest. In practice, although not as efficiently as in Germany, this meant totalitarian political control. The fascist glorification of the leader and the attempted revival of the glories of the Roman Empire seem peripheral to fascism when compared with the role played by similar claims in national socialist doctrine.

The tenets of national socialism, unlike those of fascism, were purposely left vague and were allowed to shift as circumstances warranted. The actual doctrines could only be what Hitler said they were, yet he deliberately tolerated or encouraged conflicting outlines of national socialism by Alfred Rosenberg and others. Even statements by Hitler himself were authoritative for the doctrine only at the time they were made. What can be said is that national socialism, like anarchism, was an antipolitical doctrine, but at the same time it was paradoxically a doctrine that aimed at total control. It was antipolitical in that this control was centered outside the state even

though it might work through the state. The authority of the governmental workers and even of national socialist party leaders was diffused, indistinct, and broken on the lower levels so that it could be centered at the top. Hitler's own authority was held to derive not so much from his political position as chancellor of the Reich as from his being the *Führer*, or leader, of the people. He somehow embodied, and knew nonrationally, their strivings and desires; his will was theirs.

Of the various doctrines of national socialism, the central one was undoubtedly that of the racial war between Aryans and Jews. In this war the Jews were seen as the aggressors. They were guilty of constant and unceasing conspiratorial attacks on the superior Aryan race, which in self-defense was forced to undertake their extermination. All other violence instigated by Hitler, both against other nations and against the Germans themselves, was an incidental means to the strengthening of the Aryan race in its main battle. Nevertheless, even the race doctrine could have been dropped unceremoniously, or aimed at some other target, if circumstances had seemed to warrant, just as, for expediency, Hitler dropped first the anticapitalist claims of national socialism and then its anti-Bolshevist ones.

## TWENTIETH-CENTURY POLITICAL THOUGHT

With the growing professionalization of political thought into political science and its various branches, and the development of related sociological disciplines, there has been a decline in the Anglo-Saxon countries of political philosophy in the tradition with which Hobbes, Locke, Burke, Mill, and Green are identified. Books of traditional political philosophy have continued to be written, but not generally by those who are writing the most vital works in the more central areas of philosophy, and the new works have not generally been regarded as major contributions to philosophy by those working in the newer analytic modes of philosophy. Perhaps only the subtle and persuasive Burkean traditionalism of Michael Oakeshott has attracted the continuing interest, if not the agreement, of contemporary analytic philosophers.

The dearth of major systematic treatises of the nineteenth-century kind written by contemporary philosophers does not mean that they have completely neglected political philosophy. Despite the recent claim that political philosophy is dead, contemporary philosophers have applied new techniques developed in other fields to the study of the political realm. The apparent death of one tradition of political philosophizing has per-

haps been confused with the death of political philosophy. Two main contemporary trends, which overlap to some extent, can be distinguished.

**METHODOLOGY.** The first trend consists in the application of the insights gained by the logical positivists and other philosophers of science into the logical status of laws, theories, and concepts in the physical sciences to the problems of political philosophy and to the methodology of political science. The most eminent representative of this trend was Karl Popper. Popper's conception of politics depended on his conception of scientific research, and its exposition is closely intertwined with his critique of earlier political philosophies. It is thus difficult to do justice to his view on how politics should be practiced without explaining his scientific methodology and his reasons for holding that the notions of historical development held by Hegel, Marx, Comte, and Mill are mistaken, and that therefore their notions of what the aims and methodology of the social and political sciences should be are fallacious. But in general he took a cautious attitude toward social change. He used the analogy of scientific investigations to advocate what he terms "piecemeal engineering"; small-scale social changes are to be preferred, because our predictions are always fallible, and mistakes on a small scale are more easily rectifiable than large-scale ones. A total change of society, or the prophecy of the results of a total change, is logically impossible; but the broader the change, the more factors which we must predict and which may go wrong or be overlooked. Connected with this viewpoint is his limited utilitarianism: It is better to attempt to alleviate pain by rectifying an existing evil than to try to increase pleasure by initiating some apparently beneficial change.

The writings of Popper and others on the logic and methodology of the social and political sciences has pioneered in a field that was little more than discovered in the nineteenth century by Mill, Comte, and Spencer—a field in which there is much important work to be done. For example, philosophers have begun to study the logic of political decision making, a subject that has heretofore been left largely to the political scientists themselves.

**ANALYTIC POLITICAL PHILOSOPHY.** The other main trend in contemporary political philosophy consists in the manipulation of the methods of philosophical analysis developed in the English-speaking countries in the middle decades of the twentieth century. However, neither the variety of philosophical tasks undertaken nor the results achieved present a unified picture, since the approach analytic philosophers take to political philoso-

phy is no more unified than their approach to other groups of philosophical problems.

The first full-scale analytic treatment of the problems of political philosophy, T. D. Weldon's *The Vocabulary of Politics* (Harmondsworth, U.K., 1953), is popularly supposed to have proclaimed the death knell of political philosophizing. Weldon claimed that the various philosophical theories put forth as foundations for liberal democracy, communism, and authoritarianism cannot do what they are held to do. Either they are logically empty and thus have no consequences, or they are mistaken and harmful empirical generalizations open to refutation. Thus Weldon made short work of the social contract theory. Assume, he said, that the Mayflower Compact was shown to be a forgery and that the laws of Massachusetts are held to be based on it. If the citizens of Massachusetts then claimed that because the compact was a forgery, they had lost faith in their democratic institutions, we would feel that this reason was a cover for some other reason.

But despite his denial of the usefulness or the possibility of providing foundations for a political viewpoint, Weldon's alternative description of the political process is a good example of philosophizing about politics, and he himself claimed that "a great deal needs to be done about the language in which discussions of political institutions are conducted" (p. 172).

Other contemporary philosophers have not taken as negative an attitude toward traditional philosophizing about politics as Weldon's. Rather than rejecting out of hand notions like the social contract or general will, they have sought to give new interpretations of such notions, regarding them, for example, as models of the political process. When so interpreted, new sorts of questions arise, questions appropriate to the relation between a model and reality rather than to the analysis of an empirical description. Many other new analyses of traditional political problems and of earlier answers to them are being given, particularly of such problems as sovereignty and natural law, on the borderline between philosophy of law and political philosophy. But the variety of work being done precludes any overall description.

### **Bibliography**

#### GENERAL HISTORIES

The standard work is still G. H. Sabine, *A History of Political Theory* (New York, 1938, and revisions). More recent inclusive works, such as John Plamenatz, *Man and Society*, 2

vols. (London: Longman, 1963), tend to be much more restricted in range.

#### CRITIQUE OF THE SUBJECT

No reasoned survey has yet appeared, but in such works as Karl Popper, *The Open Society and Its Enemies* (Vol. I, *The Spell of Plato*, Vol. II, *The High Tide of Prophecy, Hegel, Marx and the Aftermath*; London: Routledge, 1945; Princeton, NJ: Princeton University Press, 1950), and C. B. Macpherson, *The Political Theory of Possessive Individualism* (Oxford: Clarendon Press, 1962), examples of contemporary critical attitudes will be found. They are themselves instances of an approach criticized in the first part of the article; for works sharing the view taken there, see the continuing collections titled *Philosophy, Politics and Society*, edited by Peter Laslett, W. G. Runciman, et al. (Oxford: Blackwell, 1957–).

#### ANCIENT POLITICAL PHILOSOPHY

Ernest Barker's books are the most useful for the ancient period: *Greek Political Theory, Plato and His Predecessors*, 3rd ed. (London: Methuen, 1947), *The Politics of Aristotle* (Oxford: Clarendon Press, 1946), and *From Alexander to Constantine* (Oxford: Clarendon Press, 1956). The editions of the ancient classics are innumerable, but the student is recommended to use the Loeb editions if he possibly can, with the original and its English translation on facing pages. All the relevant works (Plato, Aristotle, Cicero, Augustine, etc.) are now in print, although the edition of *The City of God* has yet to be completed.

#### MEDIEVAL POLITICAL PHILOSOPHY

The great works on medieval political philosophy are those of R. W. Carlyle and A. J. Carlyle (*A History of Mediaeval Political Theory in the West*, 6 vols., London: Blackwood, 1903–1936) and of Ernst Troeltsch (*The Social Teaching of the Christian Churches*, translated by Olive Wyon, 2 vols., New York: Macmillan, 1931). The books of Walter Ullmann, beginning with *The Medieval Idea of Law* (London: Methuen, 1946), contain a stimulating if highly individual interpretation. The important texts are available in Thomas Aquinas, *Selected Political Writings*, edited by A. P. d'Entrèves (Oxford: Blackwell, 1948); Marsilius of Padua, *Defensor Pacis*, translated with an introduction by Alan Gewirth as Vol. II of his *Marsilius of Padua, Defender of Peace* (New York: Columbia University Press, 1956); and Dante, *De Monarchia*, translated and annotated by P. H. Wicksteed (1896).

#### MACHIAVELLI AND THE SIXTEENTH CENTURY

*The Prince* was edited in Italian by L. H. Burd (Oxford: Clarendon Press, 1891), but there is a more recent critical edition in English of the *Discourses* (by L. J. Walker, London: Routledge and K. Paul, 1950) which is valuable for Machiavelli generally. A useful if uninspired book is J. W. Allen, *A History of Political Thought in the 16th Century* (reprinted, London, 1957). Jean Bodin's *Republic* has been edited in English by K. D. Macrae (Cambridge, MA: Harvard University Press, 1962). Hooker is still best read in John Keble's Victorian edition of his *Works*, 3 vols. (London, 1836).

#### THE SEVENTEENTH AND EIGHTEENTH CENTURIES

The general authority on the seventeenth and eighteenth centuries is Otto von Guericke, *Natural Law and the Theory of*

*Society*, translated by Ernest Barker (Cambridge, U.K.: Cambridge University Press, 1934). Hobbes's *Leviathan* has been edited by Michael Oakshott (Oxford, 1947); Spinoza's *Political Works* by A. G. Wernham (Oxford: Blackwell, 1958); Locke's *Two Treatises* by Peter Laslett (Cambridge, U.K.: Cambridge University Press, 1960); and Robert Shackleton has written a standard work on Montesquieu: *Montesquieu, a Critical Biography* (Oxford: Oxford University Press, 1961); Montesquieu's *De l'esprit des lois* is available in English, edited by F. Neumann (New York, 1949). Rousseau studies are still dominated by C. E. Vaughan, *The Political Writings* (1915; reprinted, Oxford: Blackwell, 1962); there is also a translation of the *Social Contract* by F. M. Watkins (London, 1953). There are many reprints, but so far no critical editions, of the books of Burke, Paine, Bentham, Mill, and Green quoted in the text.

#### THE ENLIGHTENMENT AND UTILITARIANISM

Ernst Cassirer wrote a definitive work, *The Philosophy of the Enlightenment*, translated by F. C. A. Koelln and J. P. Pettegrove (1932, English ed., Princeton, NJ: Princeton University Press, 1951), and J. L. Talmon one with a more tendentious if stimulating thesis, *The Origins of Totalitarian Democracy* (London: Secker and Warburg, 1952). John Plamenatz prefixed a brilliant essay, "The English Utilitarians," to his reprint of Mill's *Utilitarianism* (Oxford: Blackwell, 1949). Élie Halévy, *The Growth of Philosophic Radicalism*, translated by Mary Morris (London: Faber and Gwyer, 1928), is still important.

#### HEGEL AND GERMAN IDEALISM

Hegel's main work on political philosophy is *Naturrecht und Staatswissenschaft im Grundrisse* (Berlin, 1821), 2nd ed. edited by E. Gans as *Grundlinien der Philosophie des Rechts* (Berlin, 1833), translated by T. M. Knox as *The Philosophy of Right* (Oxford: Clarendon Press, 1942). His *Phänomenologie des Geistes* (Würzburg and Bamberg, 1807), translated by J. B. Baillie as *Phenomenology of Mind* (London: S. Sonnenschein, 1910), and *Vorlesungen über die Philosophie der Geschichte*, edited by E. Gans (Berlin, 1837) and translated by J. Sibree as *Lectures on the Philosophy of History* (London: Bohn, 1857), should also be consulted. See also *Hegel's Political Writings*, translated by T. M. Knox with an introductory essay by Z. A. Pelczynski (Oxford: Clarendon Press, 1964). On Hegel's political thought, see M. B. Foster, *The Political Philosophies of Plato and Hegel* (Oxford: Clarendon Press, 1935); Franz Rosenzweig, *Hegel und die Staat*, 2 vols. (Oldenburg, 1920); Eric Weil, *Hegel et l'état* (Paris: J. Vrin, 1950), and the works by Popper and Plamenatz cited above.

Hermann Lübbe, ed., *Die Hegelsche Rechte* (Stuttgart and Bad Canstatt, 1962), and Karl Löwith, ed., *Die Hegelsche Linke* (Stuttgart and Bad Canstatt, 1962), contain selections from right-wing and left-wing German successors of Hegel, respectively. The second is more directly relevant to political philosophy. From the voluminous writing on this period, see Sidney Hook, *From Hegel to Marx* (New York: Humanities Press, 1950); Georg Lukács, *Die Zerstörung der Vernunft* (Berlin: Aufbau, 1954); and Herbert Marcuse, *Reason and Revolution: Hegel and the Rise of Social Theory*, 2nd ed. (New York: Humanities Press, 1954). Johann Gottlieb Fichte was an idealist contemporary of Hegel whose writings are of considerable political interest. See

especially his *Der geschlossene Handelsstaat* (The closed commercial state; Tübingen, 1800).

#### BRITISH IDEALISM

Green's *Lectures on the Principles of Political Obligation* were first published in *The Works of Thomas Hill Green*, edited by R. L. Nettleship, 3 vols. (London, 1885–1888). See Melvin Richter, *The Politics of Conscience: T. H. Green and His Times* (London: Weidenfeld and Nicolson, 1964). On Bosanquet, besides Hobhouse, see F. Houang, *Le néo-Hégélianisme en Angleterre: La philosophie de Bernard Bosanquet* (Paris, 1954). For a general account of British Neo-Hegelian political and social thought, see A. J. M. Milne, *The Social Philosophy of English Idealism* (London: Allen and Unwin, 1962). *The Philosophy of Loyalty* (New York: Macmillan, 1908) by the American idealist Josiah Royce shows a related development. On Royce, see J. E. Smith, *Royce's Social Infinite* (New York: Liberal Arts Press, 1950). Other works by Hobhouse are *Liberalism* (London: Williams and Nirgate, 1911) and *The Elements of Social Justice* (London: Allen and Unwin, 1922). See J. A. Hobson and Morris Ginsberg, *L. T. Hobhouse, His Life and Work* (London: Allen and Unwin, 1931). Of the many British political writings broadly following in the tradition of Green, the following may be mentioned: Ernest Barker, *Reflections on Government* (London: Oxford University Press, 1942); A. D. Lindsay, *The Modern Democratic State* (London: Oxford University Press, 1943); and J. D. Mabbott, *The State and The Citizen* (London: Hutchinson's University Library, 1948). A curious wartime idealist work with an intent similar to that of Hobhouse's *Metaphysical Theory of the State* is R. G. Collingwood's *The New Leviathan* (Oxford: Clarendon Press, 1942).

#### MARXISM

Almost any writing of Marx or Engels is relevant to their political philosophy. See especially Marx's *Das Kapital*, 3 vols. (Hamburg, 1867–1894), translated by Samuel Moore, Edward Aveling, and Ernest Untermann as *Capital*, 3 vols. (Chicago, 1915); Marx and Engels's *Die deutsche Ideologie*, edited by V. Adoratsky (Vienna, 1932), translated as *The German Ideology*, edited by S. Ryazanskaya (Moscow: Progress, 1964); Marx and Engels's *Manifest der kommunistischen Partei* (London, 1848), translated as *The Communist Manifesto*, edited with an introduction by Harold Laski (London: Allen and Unwin, 1948); and Engels's *Der Ursprung der Familie, des Privateigentums und des Staat* (Zürich, 1884), translated by Ernest Untermann as *The Origin of the Family, Private Property, and the State* (Chicago: Kerr, 1902). Two convenient anthologies are Lewis S. Feuer, ed., *Basic Writings on Politics and Philosophy* (Garden City, NY: Doubleday, 1949), and T. B. Bottomore and Maximilien Rubel, eds., *Selected Writings in Sociology and Social Philosophy* (London: Watts, 1956). Of the writings of Lenin, see especially *Chto Delat? (What Is to Be Done?)*; Stuttgart: Dietz, 1902), *Shag Vperyod, Dva Shaga Nazad (One Step Forward, Two Steps Back)*; Geneva: Partii, 1904), *Imperializm, kak Vysshaya Stadiya Kapitalizma (Imperialism, the Highest Stage of Capitalism)*; Petrograd: Zhizn' i znaniye, 1917), and *Gosudarstvo i Revolyutsiya (State and Revolution)*; Petrograd: Zhizn' i znaniye, 1918). There are various English editions of all of these. Of the many other Marxist writers on political philosophy, one of the most

interesting is Antonio Gramsci. See his *Opere*, 6 vols. (Turin, 1947–1954), and *The Modern Prince and Other Writings*, translated by Louis Marks (London: Lawrence and Wishart, 1957). For other Marxist writings and for writings on Marxism, consult the bibliographies to the entries Dialectical Materialism, Historical Materialism, and Marxist Philosophy.

#### ANARCHISM

Among the chief anarchist works are William Godwin, *An Enquiry concerning Political Justice and Its Influence on General Virtue and Happiness* (London: GGJ and J. Robinson, 1793); the writings of Michael Bakunin, translations of which appear in *The Political Philosophy of Bakunin: Scientific Anarchism* (Glencoe, IL: Free Press, 1953); Prince Peter Kropotkin's *The State, Its Part in History* (London: Freedom office, 1898), *Mutual Aid, a Factor of Evolution* (London, 1902), and *Modern Science and Anarchism* (Philadelphia, 1903); Pierre-Joseph Proudhon's *Qu'est-ce que la Propriété?* (Paris, 1840), translated by Benjamin R. Tucker as *What Is Property; An Inquiry into the Principle of Right and of Government* (New York: Humboldt, 1890); Henry David Thoreau, "Civil Disobedience," in *The Writings of Henry David Thoreau*, Vol. X (Boston and New York, 1863); Benjamin R. Tucker, *Instead of a Book: A Fragmentary Exposition of Philosophical Anarchism* (New York, 1897); and Georges Sorel, *Réflexions sur la violence* (Paris: Librairie de "Pages Libres," 1908), translated by T. E. Hulme and J. Roth as *Reflections on Violence* (New York: Huebsch, 1914). On anarchism, see George Woodcock, *Anarchism: A History of Libertarian Ideas and Movements* (Cleveland, OH: World Publishing, 1962); James Joll, *The Anarchists* (London: Eyre and Spottiswoode, 1964); and Alexander Gray, *The Socialist Tradition* (London: Longmans, 1946).

#### NATIONAL SOCIALISM AND FASCISM

For further pronouncements by national socialists, see Josef Goebbels, *Goebbels Tagebücher*, edited by Louis Lochner (Zürich, 1948); Adolf Hitler, *Mein Kampf*, 2 vols. (Munich, 1925–1927), and *Hitler's Secret Conversations 1941–1944* (New York: Farrar, Straus and Young, 1953). German Philosophy and National Socialism contains an extensive bibliography of relevant works, which may be supplemented by bibliographies in many of the works cited there. On fascism, consult Benito Mussolini, *Scritti i discorsi*, 12 vols. (Milan, 1934–1939) and *The Doctrine of Fascism*, translated in *Social and Economic Doctrines of Contemporary Europe*, edited by Michael Oakeshott, 2nd ed. (New York, 1942); and Giovanni Gentile, *Che cosa è il fascismo* (Florence: Vallecchi, 1925) and *Origini e dottrine del fascismo* (Rome: Libreria del Littorio, 1929).

#### CONTEMPORARY POLITICAL THOUGHT

The best picture of contemporary analytic political philosophy can be gathered from the series of collections titled *Philosophy, Politics and Society*, edited by Peter Laslett, W. G. Runciman et al. (Oxford, 1957–). Popper's main works on political philosophy are *The Open Society and Its Enemies* and *The Poverty of Historicism* (London: Routledge, 1957). Weldon also published *States and Morals* (London: J. Murray, 1946). On Oakeshott, consult his inaugural address in the first volume of *Philosophy, Politics and Society* and his

*Rationalism in Politics* (New York: Basic, 1962). Other examples are H. L. A. Hart, "The Ascription of Responsibility and Rights," *PAS* 49 (1948–1949): 179–194, reprinted in *Essays on Logic and Language*, edited by A. G. N. Flew (Oxford: Blackwell, 1951); Margaret Macdonald, "The Language of Political Theory," in *PAS* 41 (1940–1941), reprinted in Flew, *op. cit.*; J. W. N. Watkins, "Epistemology and Politics," in *PAS* 58 (1957–1958): 79–102; and S. I. Benn and R. S. Peters, *Social Principles and the Democratic State* (London: Allen and Unwin, 1959).

(*Hegel through recent political thought*)

## POLITICAL PHILOSOPHY, HISTORY OF [ADDENDUM]

Political philosophy, theory, and thought all focus on the arguments that have been advanced—by prominent thinkers from around the world and throughout human history—for various conceptions of a just human community. Different schools of such political thinking have developed over time and here some of these schools will be sketched and the major contributors will be listed. The bibliography lists sources for further study of these ideas.

### LIBERTARIANISM AND CAPITALISM

Libertarianism is the political system wherein the highest political good is the protection of the individual citizen's right to life, liberty, and property. Capitalism is the economic system of libertarianism because in libertarian societies the institution of the right to private property, that is, to own anything of value (not, of course, other human beings, who are themselves owners), is fully respected and protected.

Libertarian law rests on the idea that the individual is the most important member of society, with all groups to be formed by the consent of individual members, including the military, corporations, universities, clubs, and the government itself. What is primarily prohibited in a libertarian society is involuntary servitude. What is primarily promoted via the political administration is the liberty of all persons to advance their own objectives provided they do not in this process violate anyone's equal rights. The major contributors to libertarian political thought have been Murray N. Rothbard, Ayn Rand (although she eschewed that term, preferring *radical capitalism* instead), Robert Nozick, Loren Lomasky, Jan

Narveson, Douglas B. Rasmussen, Douglas J. Den Uyl, and Tibor R. Machan.

There is dispute about the label *capitalism* as the proper way to call the economic order under libertarianism, mostly because its definition is often a precondition of having either a favorable or unfavorable view of the system. Some have insisted on the use of *laissez-faire*, in memory of the French entrepreneurs who responded to the king's question as to what the government can do to help the economy by exclaiming: "Laissez-faire, laissez-faire, laissez-faire," or "Leave us to do, leave us to act." Some use F.A. Hayek's term *the spontaneous order* to stress such a system's support of uncoerced behavior. There is also the more popular term *free enterprise*.

Yet capitalism is most widely used, by both critics and supporters of an economic order in which individuals have the right to own property and to use of it on their own terms. By itself capitalism is an economic arrangement of an organized human community or polity. Often, however, entire societies are called capitalist, mainly to stress their thriving commerce and industry. More rigorously understood, however, capitalism presupposes a libertarian legal order governed by the rule of law in which the principle of private property rights plays a central role. Such a system of laws was historically grounded on various classical liberal ideals in political thinking. These ideals can be defended by means of positivism, utilitarianism, natural rights theory and/or individualism, as well as notions about the merits of *laissez-faire* (no government interference in commerce), the invisible hand (as a principle of spontaneous social organization), prudence and industriousness (as significant virtues), the price system as distinct from central planning (for registering supply and demand), and so on.

Put a bit differently, *capitalism* or *economic libertarianism* are the terms used to describe that feature of a human community whereby citizens are understood to have the basic right to make their own (more or less wise or prudent) decisions concerning what they will do with their labor and property, or whether they will engage in trade with one another involving nearly anything they may value. Thus capitalism includes freedom of trade and contract, the free movement of labor, and the protection of property rights against both criminal and official intrusiveness.

The concept of freedom plays a central role in the understanding of both libertarianism and capitalism. There are two prominent ways of understanding the nature of freedom as it pertains to human relationships. The one that fits with capitalism is negative freedom: the

condition of everyone in society not being ruled by others with respect to the use and disposal of themselves and what belongs to them. Citizens are free, in this sense, when no other adult person has authority over them that they have not granted of their own volition. In short, in capitalism one enjoys negative freedom, which amounts to be free from others' intrusiveness. The other meaning of freedom is that citizens have their goals and purposes supported by others or the government so as to prosper. Under this conception of freedom one is free to progress, advance, develop, or flourish only when one is enabled to do so by the efforts of capable others.

In international political discussions the concept of capitalism is used very loosely, so that such very diverse types of societies as Italy, New Zealand, the United States of America, Sweden, and France are all considered capitalist. Clearly, no country today is completely capitalist. None enjoys a condition of economic laissez-faire in which governments stay out of one's commercial transactions except when conflicting claims over various valued items are advanced and the dispute needs to be resolved in line with due process of law. But many Western type societies protect a good deal of free trade, even if they also regulate most of it as well. Still, just as those countries are called democratic if there is substantial suffrage—even though many citizens may be prevented from voting—or if there exists substantial free trade and private ownership of the major means of production (labor, capital, intellectual creations, and so on), the country is usually designated as capitalist.

The most common reason among political economists for supporting capitalism is this system's support of wealth creation. This is not to say that such theorists do not also credit capitalism with other worthwhile traits, such as encouragement of progress, political liberty, innovation, and so on. Those who defend the system for its utilitarian virtues—its propensity to encourage the production of wealth—are distinct from others who champion the system—or the broader framework within which it exists—because they consider it morally just.

The first group of supporters argue that a free market or capitalist economic system is of great public benefit, even though this depends on private or even social vice, such as greed, ambition, and exploitation. As Bernard Mandeville, the author of *The Fable of the Bees*, put it, this system produces "private vice, public benefit." Many moral theorists see nothing virtuous in efforts to improve one's own life. They believe, however, that enhancing the overall wealth of a human community is a worthwhile goal. Those who follow along lines of Man-

deville in the twentieth century, including Ludwig von Mises, Milton Friedman, F. A. Hayek, Gary Becker, and James Buchanan, stress the practical merits of this economic system rather than its moral justification.

Those who stress the moral or normative merits of capitalism, mostly libertarians, say the system rewards prudence, hard work, ingenuity, industry, entrepreneurship, and personal or individual responsibility in all spheres of human life, and this is all to the good. This alone makes the system morally preferable to alternatives. Yet, another reason given why libertarianism or capitalism is not only useful but morally preferable is that it makes possible the exercise of genuine moral choice and agency, something that would be obliterated in noncapitalist, collectivist systems or economic organization. Most of the libertarians (see previous paragraph) advance this type of normative argument for capitalism.

Capitalist theorists note that most critics of capitalism demean wealth. Indeed, they virtually attack the pursuit of human individual well-being itself and, especially, luxury, anytime there are needy people left anywhere on earth, as well as, more recently, if any portion of nature is overrun by human beings (as if they were not natural creatures). But, the champions of capitalism argue, this stems from utopian thinking and has the consequence of begrudging anyone a measure of welfare because some people will always be poor some of the time and nature will continue to be transformed by people.

Yet the capitalist advocate need not be seen as reckless toward the environment. Indeed, arguably the strict and consistent institution of the principle of private property rights—through, for example, privatization and prohibition of dumping waste into other private as well as public realms—may solve the environmental problems we face better than any central planning champions of the environment tend to propose. Libertarians and capitalists think that the environment suffers worst when the "tragedy of the commons" is permitted, whereby commonly owned values are overused because everyone is deemed to have a right to such use, while no one in particular is left with the responsibility to care for it.

Capitalism rests in large part on the belief that human beings are essentially individuals and a society's laws must value individuals above all else. Most historians of ideas admit that whether the importance of human individuality should have been recognized in earlier times, it certainly was not much heeded until the modern age. Even in our time it is more often that groups—ethnic, religious, racial, sexual, national, and cultural—are taken to have greater significance than individuals. The

latter are constantly asked to make sacrifices for the former. In capitalism, however, the individual (e.g., as the sovereign citizen or the consumer) is king. Undoubtedly a capitalist system does not give prime place to economic equality among people, something that group thinking seems to favor because, in groups, all are deemed to be entitled to a fair share.

### WELFARE STATISM

The welfare state or, from the economic viewpoint, the mixed economy, may be understood as a combination of the principles of capitalism and socialism. Sometimes the emphasis in this system is placed not so much on economic dilemmas as on certain moral considerations. Basically the welfare state consists of a legal system that aims at securing for everyone the negative right to liberty and the positive right to well-being. The main defenders of this system in the later twentieth century are John Rawls, Amartya Sen, Martha Nussbaum, and Jurgen Habermas.

The welfare state, which is to say most Western countries, balances the two values that together seem to its advocates to be the bedrock of a civilized society. No one ought to have his or her sovereignty seriously compromised, nor should anyone be permitted to fall below a certain standard of living. This is difficult to maintain because at different times one or another of these objectives will probably take priority and, in mostly democratic systems, political leaders will vacillate between giving more support to one or the other. The right to strike, for example, which is the negative liberty to quit one's job in an effort to gain respect for one's terms of employment, may conflict with the positive right to be provided with various services (e.g., health care, mail delivery, or education).

It is indeed a prominent feature of the welfare state that both negative and positive rights receive their legal protection. Negative rights involve respect for a person's life, liberty, and property—that is, everyone is by law supposed to abstain from interfering with these. Positive rights, in turn, involve respect for a person's basic needs—that is, everyone who is unable to secure the requirements of survival, and even flourishing, is supposed to have those provided by way of the appropriate public policy (e.g., taxation, mandated services, public education, and national health care).

The moral underpinnings of the welfare state can be utilitarianism, altruism, or certain intuitively held moral precepts. Utilitarianism requires that the general welfare be pursued by all and whatever public policies to facilitate

this were needed would be justified. Although many utilitarians believe that the general welfare is best achieved when government operates in a largely laissez-faire fashion, there is no objection to government intervention in social affairs if without those many in the society may fail to achieve a decent and prosperous form of life. Altruists, in turn, often hold that to make certain that people fulfill their primary obligation to help others, it is necessary to introduce public measures that will secure such help, given that many might wish to breach their duty to do the right thing. Finally, there is the claim that, by our common intuitions, it is evident that both a measure of personal liberty and social welfare must be guaranteed to all, lest the quality of life in society fall below what it should be.

Whereas the welfare state is objected to by people from several other perspectives, it is thought by its supporters to be the most stable modern political order. Although it is characterized by much dispute and controversy, in the long run, its supporters maintain, the system seems to be overall satisfactory and just.

### COMMUNITARIANISM

Communitarianism could be viewed as a sort of halfway house between the collectivist system of socialism and the individualist one of capitalism. The idea is less capable of being sharply defined than these others. Roughly it comes to the view that human beings are necessarily or essentially parts of distinct human groups, communities, with their diverse values, histories, priorities, practices, laws, and cultures. The organizing principles of these different groups will themselves vary. There is no overriding true social and political order, not even any universal ethics. Rather it is the particular character of the communities that establish for its parts or members what is the proper way to live, what laws should be enacted, and what aesthetic and religious values need to be embraced.

Some communities can be Spartan, others Stoic, yet others bohemian and so forth. Each can have its peculiar way of life without implying any objective condemnation of some alternative form. Yet participation in the community's form of life is not a matter of individual consent. Such an idea derives from a mistake: There is a transcendent or general human nature that requires every community to adhere to certain minimal standards of justice. No such transcendent human nature exists, as far as many communitarians see things, so those that, say, grant individuals certain rights are not superior to those that do not—they are simply different. Among those who are prominent communitarians, Charles Taylor, Amitai

Etzioni, Thomas Spragens, Michael Sandel, and Richard Rorty stand out.

Actually there is not much more that can be said about communitarianism because there are simply too many types of community, each with its own framework and priorities. The main point is that the rules, laws, ideals, and so forth are all the result of the often slowly evolving consensus or collective practices of the community's membership. Just as socialism sees humanity as the whole to which individuals belong, communitarianism sees different ethnic, national, racial, gender, cultural, professional, or similar distinguishable groups as the whole to which the individual member belongs. One may imagine, for example, that languages have developed, in part, to meet the requirements, imagination, and circumstances of different linguistic communities, with no language superior or completely translatable to any other.

Communitarians often unite in their criticism of bourgeois society or liberal capitalism because of their emphasis on individuality, privacy, personal freedom, consent, and competition. Communitarians believe that the view of human nature underlying such liberal capitalist views is seriously flawed. They are convinced, also, that the central idea of liberal capitalism is what has come to be known as *homo economicus* or *economic man*. That idea figures heavily in economic analysis and views individuals as autonomous entities who enter the world fully formed, ready to make choices in the market, and self-sufficient. While there are other conceptions of the human individual that might support liberal capitalism, it is this that has occupied the attention of communitarians and it is in contrast to this view that they have advanced their position.

## ISLAMIC POLITICAL THEORY

Muslims are divided into two communities, the Sunni majority and Shii minority, and they adhere to different ideas as to political rule. They are known as the Sunni caliphate and the Shii Imamate.

When Muhammad died, most Muslims, since they thought that Muhammad did not name a successor, relied upon the decision of a group of his cohorts. The caliphate, chosen by way of consultation (called *shura*) and agreement (called *ijma*), an oath of loyalty (called *baya*) that is sworn by those who elect him, and the compact (called *ahd*) with the people to govern by Islamic law (Sharia) developed into what is widely regarded as legitimate government for Sunni Islam.

But the Shii rejected the Sunni caliphs and regarded them as subverting Islamic law. They adhered to the idea that Muhammad had selected Ali, who was reported to be his cousin and son-in-law, to be the ruler (*Imam*) of Muslims. They held that the oldest (male) descendant (*Ahl al-Bait*) must be the divinely anointed, religious, and political chief. Abbasid rule (750–1250) formed Islamic political theory as theocratic, with theologians as the legal authorities who had royal privilege and professed to uphold the divine goal for the Muslim community under Abbasid edicts. In the last analysis, as matters now stand, there is no unified Muslim political theory that enjoys widespread acceptance.

In geopolitical affairs a very influential version of Muslim politics comes from the clerics and adherents of the Wahhabi branch of radical Islam, based mainly in Saudi Arabia and considered to be the most virulently anti-Western in light of the belief that any accommodation of Western values is an intolerable compromise with the words of the Prophet. The main point of contention is that the West legally tolerates freedom of religion and even nonbelief, which undermines the virtuous life demanded of the faithful, leading to their corruption.

## JEWISH POLITICAL THEORY

Jews, as such, do not adhere to a firm political creed, unlike many Muslims, but tend to embrace varieties of democratic, even liberal, institutions, while also encouraging some socialist economic practices and certain mild forms of theocracies, depending on the version of Judaism they embrace. Jewish political ideas derive mainly from the belief that Jews are a separate, unique—chosen—people, not merely adherents to a different religion or a system of moral principles that emerge from such a religion (of course this idea is shared by nearly all traditional and organized religious groups). Jewish political ideas pertain to how the Jews as a unified people have held on to a political community throughout the centuries, without becoming amalgamated into communities wherein they lived as exiles and how they shaped these by giving clear expressions of their own culture and forms of political conduct.

Jews often choose to demonstrate a Jewishness via political means and this for many of them consists of loyalty to modern Israel as well as various Jewish missions, including various communal groups (for example, the *kibbutz*) constituted almost exclusively by Jews. As is common in politics everywhere, Jews will often stress the need for power as they advance the causes of their various

groupings, although this also includes extensive education and proselytizing.

## CONCLUSION

None of the systems we have sketched here are fully exemplified anywhere, although some—for example, Islamic theocracy—are approximated in some parts of the world (e.g., Iran). There are, however, no purely capitalist, socialist, or communist societies and the welfare states are also quite different, with various ways of balancing the values of personal autonomy and social security. Instead, most societies—countries—exhibit mixed systems and often where democratic decision-making takes place, the main topic of debate is which of these values should be stressed more, as well as how much state support should be given to various special interests.

## POMPONAZZI, PIETRO (1462–1525)

Pietro Pomponazzi, the Italian Renaissance Aristotelian, was born in Mantua. He studied philosophy at the University of Padua, where, after obtaining his degree, he became extraordinary professor of philosophy in 1488 and ordinary professor in 1495. When war caused the university to close in 1509, he left Padua. After a short period at Ferrara he became a professor of philosophy at

the University of Bologna, where he taught from 1512 until his death. He married three times and had two children.

Of Pomponazzi's writings only a few were published during his lifetime. Best known is the treatise *De Immortalitate Animae* (On the immortality of the soul, 1516), which immediately provoked a large controversy. It was publicly attacked by several philosophers and theologians and was followed by the author's two treatises in defense—the *Apologia* (1518) and the *Defensorium* (1519)—which were longer than the original work. Probably as a result of this experience Pomponazzi did not publish anything else except for a few short philosophical questions that he added to the 1525 reprint (*Tractatus Acutissimi*) of his three writings on immortality. Equally important are his treatises *De Incantationibus* (On incantations) and *De Fato* (On fate), both written about 1520, which were published posthumously in Basel by a Protestant exile in 1556 and 1567, respectively. A sizable body of other writings has been preserved in manuscript, and the study and publication of this material have barely begun. The most important among these unpublished writings are questions on Aristotelian and other problems, which Pomponazzi probably worded himself and that therefore directly reflect his thought. A much larger group consists of his class lectures on various works of Aristotle. Since they were taken down by students and show a certain amount of oscillation from year to year and from copy to copy, they must be used with caution in any attempt to reconstruct Pomponazzi's thought and philosophical development.

Pomponazzi was a product and in many ways a typical representative of the tradition of scholastic Aristotelianism that flourished at Bologna, Padua, and other Italian universities from the thirteenth to the seventeenth century. This school, often referred to as Paduan Averroism, had no institutional or doctrinal connections with theology, as did its northern counterparts, but rather with medicine, and this accounts for its secular orientation. In the study of Aristotle, whose writings served as the prescribed texts for the teaching of the philosophical disciplines, the emphasis was, as in Paris and elsewhere, on logic and natural philosophy rather than on ethics and metaphysics.

Pomponazzi's main sources were the writings of Aristotle and of his commentators, and his style, far removed from classical or humanistic elegance, is a rather harsh example of scholastic terminology and argument, although he was at times capable of concise formulation and caustic wit. His reasoning shows great subtlety and

acumen, but he is repetitious and sometimes inconsistent. He obviously enjoyed spinning out an argument and following reason wherever it led, and out of intellectual honesty he was prepared to admit his puzzlement before certain dilemmas and to modify his views whenever he felt compelled to do so by some strong argument. Thus, we may well understand the outburst in *De Fato* (III, 7) in which he compares the philosopher with Prometheus. In his efforts to understand the secrets of God the philosopher is eaten up by his continual worries and thoughts; stops eating, drinking, and sleeping; is held up to ridicule by all; is taken as a fool and a faithless person; is persecuted by the Inquisition; and is laughed at by the multitude.

In spite of his general scholastic orientation Pomponazzi was by no means unaffected by other currents. He knew and respected Plato and was clearly influenced by Marsilio Ficino (and Giovanni Pico della Mirandola) in his remarks about the place of man in the universe and perhaps in his preoccupation with the immortality of the soul. Like the humanists he cultivated the monographic treatise in addition to the question and the commentary, occasionally injected personal remarks about himself, and cited such sources as Cicero and Plutarch. His doctrine that virtue is its own reward has Stoic rather than Aristotelian antecedents, and his insistence that the end of man consists in practical virtue rather than in contemplation is at variance with Aristotle and may owe something to Cicero and to such humanists as Leonardi Bruni and Leon Alberti.

One may even link with humanism Pomponazzi's interest in Alexander of Aphrodisias. Alexander was not entirely unknown during the Middle Ages, but his writings acquired a much wider diffusion through new translations around the turn of the sixteenth century. The label of Alexandrism often attached to Pomponazzi is dubious and misleading. We know from a question composed by Pomponazzi in 1504 that his view on the problem of immortality, as adopted in his treatise of 1516, was derived from that of Alexander. We also learn that the writing of his treatise *De Fato* was occasioned by his reading a new Latin translation of Alexander's treatise on the subject (Pomponazzi knew no Greek). However, *De Fato* is actually a defense of the Stoic position against Alexander.

Pomponazzi's *De Incantationibus* is an attempt to offer natural explanations for a number of occurrences popularly ascribed to the agency of demons and spirits. The effects ascribed to the stars by the astrologers form for Pomponazzi a part of the system of natural causes.

This work is the only one by Pomponazzi that was once on the Index of Prohibited Books (it no longer is) because of its implied criticism of miracles. It contains an interesting passage on prayer that shows a certain affinity to some ideas expressed in the treatise on immortality. The value of prayer, he said, consists not in the external effects it may have but in the pious attitude it produces in the person who prays.

The *De Fato*, which is divided into five books, is by far the longest of Pomponazzi's works. He discusses in great detail and with a great number of intricate arguments the problems of fate, free will, and predestination. His conclusions are by no means simple or clear-cut, but it appears from his final remarks that he regarded the Stoic doctrine of fate, on purely natural grounds, as relatively free from contradictions. Yet, because human wisdom is subject to error, Pomponazzi was willing to submit to the teaching of the church and to accept the doctrine that God's providence and predestination are compatible with man's free will. However, he was not satisfied with the way in which this compatibility is customarily explained and tried to propose an explanation that he considered more satisfactory.

*De Fato* has been unduly neglected by students of Pomponazzi, perhaps because of its length and difficulty. It is now available in a critical edition and may be studied within the twofold historical context in which it belongs: first, the philosophical controversy between determinism and indeterminism as it appeared in antiquity in the works of the Stoics and Alexander and again in more modern discussions and, second, the specifically theological problem of reconciling providence and predestination with free will. The second question has occupied Christian theologians of all centuries; it had been discussed before Pomponazzi by Lorenzo Valla in his treatise on free will, and it was to be debated by Martin Luther, Desiderius Erasmus, and many other theologians during and after the Reformation.

#### DE IMMORTALITATE ANIMAE

Pomponazzi's treatise *De Immortalitate Animae* is much better known, and it had far wider repercussions during the sixteenth century and even later. Pomponazzi explains the origin of the treatise as follows: He had stated in a class lecture that Thomas Aquinas's view on immortality, though perhaps true, did not agree with Aristotle's, and he was subsequently asked by a Dominican friar who was his student to express his own opinion on the question, staying strictly within the limits of natural reason. In complying with this request, Pomponazzi begins with the

statement that man is of a manifold and ambiguous nature and occupies an intermediary position between mortal and immortal things (Ch. 1). The question is in what sense such opposite attributes as mortal and immortal may be attributed to the human soul (Ch. 2). Pomponazzi first lists six possible answers, and after having discarded two of them because they had never been defended by anybody, he promises to discuss the remaining four (Chs. 2–3).

The first of the four answers is the view attributed to Averroes and others, according to which there is only one immortal soul common to all human beings and also an individual soul for each person, which, however, is mortal. Pomponazzi rejects this opinion at great length (Ch. 4). The Averroist position maintains that the intellect is capable of acting without a body and can therefore be considered as separable and immortal. Yet in our experience, Pomponazzi argues, the intellect has no action that is entirely independent of the body, and therefore we have no evidence that the intellect is separable. If we wish to understand the relationship of the intellect and the body, we must distinguish between being in the body as having the body for its organ or subject or substratum and depending on the body as having the body, its perceptions, and imaginations for its object. Pomponazzi insists that the intellect does not have the body as its subject as do the souls of animals and the lower faculties of the human soul. Yet the human intellect cannot know anything without the perceptions or imaginations offered to it by the body, and this fact alone proves that the intellect is not separable from the body.

Second, Pomponazzi discusses an opinion he attributes to Plato, according to which each person has two souls, one immortal and the other mortal (Ch. 5). This position is rejected on the ground that the subject of perception and that of intellectual knowledge must be the same and that it is therefore impossible to distinguish two separate natures within the human soul (Ch. 6).

Third, he examines the view, attributed to Thomas Aquinas, which holds that the human soul has but a single nature and that it is absolutely (*simpliciter*) immortal and only in some respects (*secundum quid*) mortal (Ch. 7). Elaborating on some of the arguments he had already advanced against Averroes, Pomponazzi insists that he finds no evidence to prove the absolute immortality of the soul. He has no doubt, he adds, that the doctrine of the absolute immortality of the soul is true, since it is in accordance with Scripture, but he wonders whether it is in agreement with Aristotle and whether it can be estab-

lished within the limits of natural reason without recourse to the evidence of faith and revelation (Ch. 8).

Fourth, Pomponazzi discusses a position according to which the human soul, having only one nature, is absolutely mortal and only in certain respects immortal (Ch. 9). He then proceeds to defend this position, which he had identified elsewhere as that of Alexander of Aphrodisias. Insisting once more on the middle position of humankind, he argues that the human intellect, unlike that of the pure intelligences, always needs the body for its object and has no way of acting without the help of the images of sense or imagination. It must therefore be considered absolutely mortal and only relatively, or improperly speaking, immortal. However, unlike the souls of the animals, the human intellect does not have the body as its subject because it does not use a bodily organ in knowing. If it resided in an organ, the intellect could not reflect on itself or understand universals. The fact that the human intellect is capable of some knowledge of itself and of universals shows that it participates somewhat in immortality and, hence, that it is in some respect immortal. This interpretation of immortality is claimed to be more probable than the others and to be more in accordance with the teachings of Aristotle (Chs. 9–10).

Having reached this conclusion, Pomponazzi continues in good scholastic fashion to formulate several sets of objections to his view (Chs. 11 and 13) and to answer these objections in great detail (Chs. 12 and 14). In addition to repeating and elaborating some of the same arguments presented in the preceding chapters, he introduces, especially in Chapter 14, several new arguments and conclusions that are of great intrinsic interest.

Along with other objections to his view Pomponazzi cites (Ch. 13) the argument that, according to Aristotle's *Ethics*, the ultimate end of man is contemplation and that the satisfactory fulfillment of this end requires immortality. In his reply he states that man has a threefold intellect—speculative, practical, and technical. Only a few persons have a share in the speculative intellect, whereas the technical intellect is shared by some animals. We may thus conclude that the practical intellect, in which all human beings and only all human beings share, is the faculty peculiar to human beings. Every normal person can attain the practical intellect in a perfect way, and a person is called absolutely good or bad with reference to this practical intellect but merely in some respect good or bad with reference to the other two intellects. For a man is called a good man or a bad man with reference to his virtues and vices, yet a good metaphysician with reference to his speculative intellect and a good architect with ref-

erence to his technical intellect. However, a good metaphysician or a good architect is not always a good man. Hence, a man does not mind so much if he is not called a good metaphysician or a good architect, but he minds very much if he is called unjust or intemperate, for it seems to be in our power to be good or wicked, but to be a philosopher or an architect does not depend on us and is not necessary for a man. The ultimate end must thus be defined in terms of the practical intellect, and every man is called upon to be as virtuous as possible.

By contrast, it is neither necessary nor even desirable that all men should be philosophers or architects but only that some of them should be. Moreover, since the perfection of the practical intellect is accessible to almost everybody, a farmer or a craftsman, a poor man or a rich man, may be called happy and is actually called happy and is satisfied with his lot whenever he is virtuous. In other words, Pomponazzi departs in this important respect from Aristotle and identifies the end of human life with moral virtue rather than with contemplation, because this end is attainable by all human beings.

There had been another objection—that God would not be a good governor of all things unless all good deeds found their reward and all bad deeds their punishment in a future life. To this Pomponazzi replies that the essential reward of virtue is virtue itself, and the essential punishment of vice is vice itself. Hence, it makes no difference whether the external or accidental reward or punishment of an action is sometimes omitted, since its essential reward and punishment are always present. Moreover, if one man acts virtuously without the expectation of a reward and another with such an expectation, the act of the latter is not considered to be as virtuous as that of the former. Thus, he who receives no external reward is more fully rewarded in an essential way than he who receives one. In the same way the wicked person who receives no external punishment is punished more than he who does, for the punishment inherent in guilt itself is much worse than any punishment in the form of some harm inflicted upon the guilty person.

Pomponazzi further develops this idea in reply to another objection. It is true that religious teachers have supported the doctrine of immortality, but they have done so in order to induce ordinary people to lead virtuous lives. Yet persons of a higher moral disposition are attracted toward the virtues by the mere excellence of these virtues and are repelled from the vices by the mere ugliness of these vices; hence, they do not need the expectation of rewards or punishments as an incentive. Rejecting the view that without a belief in immortality no

moral standards could be maintained, Pomponazzi repeats that a virtuous action without the expectation of a reward is superior to one that aims at a reward and concludes that those who assert that the soul is mortal seem to preserve the notion of virtue much better than those who assert that it is immortal. In thus stating that moral standards, as defined by the philosopher, do not depend on religious sanctions, he does not deny the validity of religious beliefs but asserts the autonomy of reason and philosophy, drawing upon certain passages in Plato and above all on Stoic doctrine and anticipating to some extent the views of Benedict de Spinoza and Immanuel Kant.

Having presented all arguments against the immortality of the soul, Pomponazzi states in the last chapter that the question is a neutral one, as is that of the eternity of the world. That is, he does not believe there are any natural reasons strong enough to demonstrate the immortality of the soul or to refute its mortality, although he knows that many theologians, notably Thomas Aquinas, have argued otherwise. Since the question is thus doubtful on purely human grounds, it must be resolved by God himself, who clearly proved the immortality of the soul in the Holy Scriptures. This means that the arguments to the contrary must be false and merely apparent. The immortality of the soul is an article of faith, for it is based on faith and revelation. It must thus be asserted on this ground alone and not on the basis of inconclusive or unconvincing rational arguments.

This conclusion and a similar one found in the *De Fato* have given rise to a variety of interpretations on the part of Pomponazzi's contemporaries and of modern historians. The statement made by some that Pomponazzi simply denied the immortality of the soul is patently false. He merely said that the immortality of the soul cannot be demonstrated on purely natural grounds or in accordance with Aristotle but must be accepted as an article of faith. This position is widely and somewhat crudely referred to as the theory of the double truth. The term is inadequate, for neither Pomponazzi nor anybody else ever said that something is true in theology and its opposite true in philosophy. What Pomponazzi did say, and what many respectable thinkers before and after him said, is that one theory—for example, that of the immortality of the soul—is true according to faith but that it cannot be demonstrated on the basis of mere reason and that its opposite would seem to be supported by equally strong or even stronger probable arguments.

This view has been called absurd by many modern historians and, ironically, by some who actually take a similar position themselves, though perhaps on other issues and with different words. Yet the persistent charge made against Pomponazzi and against many other medieval and Renaissance thinkers who took a similar position has been that the so-called theory of the double truth is merely a hypocritical device to disguise their secret disbelief and to avoid trouble with the church authorities. Thus, in saying that immortality cannot be demonstrated and that mortality may be defended by strong rational arguments whereas immortality is to be held as an article of faith, Pomponazzi, according to these historians, merely concealed his opinion that the soul was really mortal and substituted for it a formula that would protect him against ecclesiastic censure or punishment.

This is a serious and delicate problem. We cannot deny that a thinker of the past may have entertained opinions that we do not find expressed in his writings or that he may have put into writing views which he did not hold in his innermost heart. On the other hand, unless we have some text or document in support of this assertion, we are not entitled to claim that a thinker held some specific views that he failed to express in his writings or that are even in contrast with his expressed views. As a theologian of the eighteenth century said on this matter, we must leave it to God to look into Pomponazzi's heart and to see what his real opinion was. The human historian has no basis other than the written document, and the burden of proof, in history as in law, rests with those who want to prove something that is contrary to the overt evidence. Neither innuendo nor the assertions made by unfriendly critics or extremist followers can be accepted as valid evidence in lieu of some original statement or testimony concerning the author's view.

According to this standard, we have no real grounds for maintaining that Pomponazzi was hypocritical. The position he takes in the treatise on the immortality of the soul is fundamentally retained in two lengthy works composed afterward in defense of the first and, with a few dubious exceptions, also in his questions and class lectures. He was attacked by some theologians but defended by others, and his treatise was not condemned by the church authorities. The general position that immortality could not be rationally demonstrated, if not all the specific opinions that Pomponazzi associated with it, was held also by John Duns Scotus and even by the leading Thomist of Pomponazzi's time, Cardinal Cajetan. After the first excitement had passed, Pomponazzi continued to teach at a university located in the papal states, had

among his students many clergymen who apparently found nothing offensive in what he said, and died peacefully as a widely respected scholar. The pupil who took his remains to his hometown and erected a monument for him was Ercole Gonzaga, later a cardinal and president of the Council of Trent. If there is any presumptive evidence, it hardly favors the opinion that Pomponazzi was a secret disbeliever or atheist.

## INFLUENCE

Pomponazzi's influence, although not easily traceable, was considerable. The school of Italian Aristotelianism to which he belonged flourished for a hundred years or more after his death, and within this tradition his name remained famous and his views on such questions as the immortality of the soul and the unity of the intellect continued to be cited and discussed, if not adopted. The posthumous publication of several of his writings later in the century also gives testimony to his continued fame. His lectures and questions were copied in a large number of manuscripts, an indication of his popularity among his students; moreover, a considerable number of manuscripts containing the *De Incantationibus* and the *De Fato* prove that these works circulated widely, although, or perhaps because, they were not published during the author's lifetime. A few anecdotes associated with his name that we find in biographies, short stories, and dialogues of the period suggest that he made some personal impression even on the larger public outside university circles. He obviously was read by students and writers who did not belong to the Aristotelian tradition, and we may cite as an example Giulio Cesare Vanini, who seems to have used him as one of his favorite sources.

During the seventeenth century the Aristotelian school that had dominated the teaching of philosophy for such a long time finally lost its hold, especially in the field of natural philosophy, which was gradually replaced by the new mathematical physics of Galileo Galilei and his successors. Aristotelianism persisted much longer in the fields of logic, biology, and metaphysics. Yet because physics was the center and stronghold of medieval and Renaissance Aristotelianism, especially in Italy, most of Pomponazzi's specific teachings lost their immediate validity when the Aristotelian system within which he had developed his ideas came to be abandoned. Nevertheless, we may say that his view of the relation between natural reason and faith was capable of being reformulated in terms of the new physics and that in certain instances this did happen.

Even more important is another development. The seventeenth century, and still more the eighteenth, witnessed the rise and diffusion of free thought and overt atheism, especially in France. Some of the freethinkers who set out to discard faith and established religion came to consider the Aristotelian rationalists such as Pomponazzi as their forerunners and allies. Pomponazzi's treatise on the immortality of the soul was praised by the free thinkers and condemned by Catholic apologists, although moderate thinkers like Pierre Bayle tried to preserve a proper perspective. Pomponazzi's treatise was even reprinted in a clandestine edition with a false early date.

The use to which the French Enlightenment put Pomponazzi and the other Italian Aristotelians has had a strong influence on modern historians of the school, beginning with Ernest Renan. Again, a distinction is needed. It is one thing to say that Pomponazzi and the Aristotelians held the same views as later freethinkers, and it is another to state that they represent an earlier stage in a development that was to produce the views held by the freethinkers. In the first sense Pomponazzi was a forerunner of the freethinkers; in the second sense the evidence says he was not. Hence, we should not praise or blame him, depending on our own preferences and values, for being a freethinker, since we lack the factual basis for judgment. Yet in a different sense we may praise him. He belongs to the long line of thinkers who have attempted to draw a clear line of distinction between reason and faith, philosophy and theology, and to establish the autonomy of reason and philosophy within their own domains.

## Bibliography

### WORKS BY POMPONAZZI

Pomponazzi's *De Immortalitate Animae* is available in several modern editions—edited by G. Gentile (Messina, 1925), by G. Morra (Bologna, 1954), and by W. H. Hay II in a facsimile of the original edition of 1516 (Haverford, PA, 1938). It is also included, along with the *Apologia*, the *Defensorium*, and several shorter treatises, in the collection titled *Tractatus Acutissimi* (Venice, 1525).

The *De Naturalium Effectuum Causis Sive de Incantationibus* was printed separately in Basel (1556) and with the *De Fato* in the *Opera* (Basel, 1567); the volume contains only these two works. There is also a French translation—*Les causes des merveilles de la nature*, translated by Henri Busson (Paris, 1930).

There is a modern critical edition of the *De Fato* edited by Richard Lemay (Lugano, 1957). Of the *De Immortalitate* there is an English translation by W. H. Hay II, first published with the facsimile edition of the text and then in a revised and annotated version in *The Renaissance Philosophy of Man*, edited by Ernst Cassirer, Paul Oskar Kristeller, and John H. Randall Jr. (Chicago: University of Chicago Press, 1948).

For the unpublished works of Pomponazzi see L. Ferri, "Intorno alle dottrine psicologiche di Pietro Pomponazzi . . .," in *Atti della Reale Accademia dei Lincei, Memorie della classe di scienze morali, storiche e filologiche*, Series 2, Vol. 3 (1875–1876), Part III, 333–548; C. Oliva, "Note sull'insegnamento di Pietro Pomponazzi," in *Giornale critico della filosofia italiana* 7 (1926): 83–103, 179–190, 254–275; Bruno Nardi, "Le opere inedite del Pomponazzi," in *Giornale critico della filosofia italiana*, 29–35 (1950–1956); and Paul Oskar Kristeller, "A New Manuscript Source for Pomponazzi's Theory of the Soul . . .," in *Revue internationale de philosophie* 2 (1951): 144–157, and "Two Unpublished Questions on the Soul of Pietro Pomponazzi," in *Medievalia et Humanistica* 9 (1955): 76–101, and 10 (1956): 151.

## POPE, ALEXANDER

(1688–1744)

Alexander Pope, England's leading poet of the Age of Reason, was born in London, the son of a prosperous Roman Catholic linen draper. His Catholicism barred him from public school and university; and he was educated by private tutors and by extensive reading and study on his own, largely at Binfield in Windsor Forest, where his father had retired. About the age of twelve, a severe illness stunted Pope's growth and deformed his spine, and for the rest of his life he was infirm. His devotion to poetry came early, and his genius was immediately recognized by William Wycherley and William Walsh. Early publications of note include the *Pastorals* (1709), *An Essay on Criticism* (1711), *The Rape of the Lock* (1712, enlarged 1714), and *Windsor Forest* (1714). During frequent visits to London, he became the friend of many prominent literary figures: Jonathan Swift, Joseph Addison, Richard Steele, John Arbuthnot, John Gay, and Lord Bolingbroke. Although not an ardent party man, Pope inclined more to the Tory than to the Whig. In 1718, after the death of his father, he removed to Twickenham, on the Thames near London. Pope's translations of the *Iliad* (1715–1720) and the *Odyssey* (1725–1726) were well received and financially successful. The edition of William Shakespeare appeared in 1725.

Author of the *Essay on Man* (1733–1734), *Moral Essays* (1731–1735), and *Imitations of Horace* (1733–1737), and of the *Dunciad* (1728–1743) and various other satires, Pope was a philosopher-moralist-poet. He was generally so regarded throughout the eighteenth century, both at home and abroad. There is little of the original in Pope's thought, nor did he pretend to any, the very notion of originality being distasteful to the rationalistic mind. In the *Essay on Criticism*, he stated that his aim was to present "What oft was thought, but ne'er so well expressed." His writing in general admirably fulfills this precept, and his memorable formulations of traditional and familiar ideas bear the stamp of literary genius.

Despite frequent allegations to the contrary, Pope was not a deist. Indeed, in the *Dunciad* he specifically attacks Anthony Collins, Bernard Mandeville, Thomas Morgan, Matthew Tindal, John Toland, and Thomas Woolston, the leading deists of the day. He eschewed the role of Christian (Catholic) poet, however, preferring to represent what he considered the best in Western thought, both pagan and Christian. His universality is best seen in the *Essay on Man*, where in Epistle I a rationalistic metaphysics is presented, centering on the "Great

Chain of Being," a concept as old as Plato's *Timaeus* that was a part of the heritage of Western man and was influential until well into the eighteenth century. The rationalistic myth of a "chain of being" extending from the Godhead at the one extreme to the lowliest atom at the other, with man as the middle link between the pure reason of angelic spirits and the pure instinct of lower animals, is presented by Pope as a means of chastising presumptuous man for attempting to be too rational, for attempting to deny the earthbound aspect of his nature. Such generic "pride" on the part of man would necessarily push him into a higher link and thus destroy the entire chain. The moral is clear: "The bliss of Man (could Pride that blessing find)/Is not to act or think beyond mankind." Man must submit to his ordained place in the universe because "Whatever is, is Right."

Pope has been frequently ridiculed for ending Epistle I on this seeming note of "easy optimism," as it has been erroneously labeled. A moment's recollection, however, of the fact that Pope devoted much of his career to satirizing contemporary mores and morality will make it evident that his "optimism" was not ordinary or glandular optimism but strictly metaphysical optimism, which is not necessarily of any comfort to humankind. Granted the "chain of being" as ordained by Deity, that plan and that chain must be right, even though, according to the "principle of plenitude," evil is just as necessary as good. Thus, apart from the totality of cosmic rightness, many circumstances of life may not be good for man himself. Small comfort, therefore, to man to be assured that what seems evil to him personally is actually good from the cosmological point of view: God, but not man, can afford to be optimistic. In fact, the theme of the entire *Essay* is the problem of reconciling the contrary, apparently irreconcilable elements of man's nature with the infinite wisdom of a God of order and harmony. Thus it is that in the opening lines of Epistle II, Pope makes an effort to dismiss the prior metaphysical optimism with the homely precept: "Know then thyself, presume not God to scan;/The proper study of Mankind is Man." The remainder of the *Essay* is concerned with the world of real existence, insofar as this is possible given the background of rationalistic formalism. Epistle II treats of man as an individual; Epistle III treats of man and society; and Epistle IV treats of man and happiness. Here there is little "easy optimism."

Pope teaches that self-love is superior to reason and that the passions are requisite for action. The "dominant passion" (which varies from man to man) rules life in different ways, and virtue and vice are joined in man's mixed

nature. In the second epistle reason is “The God within the mind” that distinguishes between virtue and vice, to which in the third epistle are added instinct and social love. The fourth epistle, after much deliberation, declares that only in virtue is happiness to be found. Pope then ends the *Essay* with the affirmation that he has

Shew'd erring Pride, *Whatever is, is Right*;  
That *Reason, Passion*, answer one great aim;  
That true *Self-Love* and *Social* are the same;  
That *Virtue* only makes our Bliss below;  
And all our Knowledge is, *Ourselves to Know*.

The major sources of Pope's philosophy have been much disputed, with Gottfried Wilhelm Leibniz, the earl of Shaftesbury, Bolingbroke, and William King the most frequently mentioned modern authors. There is no direct evidence that Pope knew Leibniz, and he specifically denied any influence by him. Pope had certainly read parts of Shaftesbury's *Characteristics* and undoubtedly acquired something from the reading. The case for Bolingbroke's *Fragments or Minutes of Essays* was widely accepted until recent investigations adduced evidence that the *Fragments* were composed later than Pope's *Essay*; what Pope may have received from Bolingbroke in the course of conversation, however, remains unknown. Archbishop King's *De Origine Mali* (1702), probably in Edmund Law's translation of 1731, contains much of the metaphysical thinking of the first epistle of the *Essay on Man*; and there is little doubt that Pope found much useful information and many references in Law's elaborate notes. Gleanings from the ancient Platonists, Neoplatonists, and Stoics are to be assumed, as are, of course, some from the Christian tradition.

The *Essay on Man* first appeared anonymously, and Pope did not claim it until 1735. On the Continent it was translated (poorly) into French prose in 1736 and the following year into French verse (even more poorly). It ran through several editions with considerable praise until attacked in 1737 by J. P. de Crousaz in his *Examen de l'essai de M. Pope sur l'homme*. The Swiss theologian, ignorant of English, deliberately used the poem as a means of assailing the Spinozistic and the Leibnizian philosophies, of which Pope was innocent. The attack was taken up by several English pamphleteers until William Warburton (later bishop of Gloucester and editor of Pope's *Works*), that colossus of controversy, came to the defense with a series of articles in the *History of the Works of the Learned*, published as a book in 1739 and revised in 1742. Warburton vindicated Pope against allegations of unorthodoxy, including that of deism.

Another Continental attack came in 1742 from Louis Racine in a poem titled *La religion*. In 1755 Gotthold Lessing and Moses Mendelssohn, in *Pope ein Metaphysiker!*, ridiculed both the Prussian Royal Academy for using a poet as the subject of a prize essay in philosophy and Pope for attempting to be a metaphysician in poetry. To Immanuel Kant, on the contrary, Pope was a favorite poet from whom he quoted frequently and whose thought he took seriously. Arthur O. Lovejoy has ventured the statement that “it would be hardly excessive to say that much of Kant's cosmology is a prose amplification and extension of the ‘philosophy’ of the First Epistle of the *Essay on Man*.” Scorned or admired, at any rate, Pope's venture into verse philosophy was exceedingly popular, as is indicated by its translation into at least fifteen European languages and by scores of editions in English during the eighteenth century. And his century was the last that would have approved of such a venture.

Pope's original plan as poetical philosopher and moralist was ambitious, although somewhat vague. His magnum opus, to be titled “Ethic Epistles,” was to consist of four books: the *Essay on Man*, as we now have it in four epistles; four more epistles dealing with “the extent and limits of human Reason,” arts and sciences both “useful” and “unuseful,” “the different Capacities of Men,” and the “Use of Learning,” science and wit; the “Science of Politics,” to treat “of Civil and Religious Society in their full extent”; and “Private Ethics or Practical Morality.” The plan—but not the philosophy—is curiously reminiscent of that of David Hume as stated in the “Advertisement” to the *Treatise of Human Nature* (1739). (Incidentally, Hume probably took from Pope such terms as “the science of man,” “the science of human nature,” “the soul's calm sunshine,” and “the Feast of Reason.”) In 1741 Hume was to devote an entire essay, “That Politics may be reduced to a Science,” to the refutation of Pope's lines (*Essay on Man*, III, 303–304): “For Forms of Government let fools contest;/Whate'er is best admister'd is best.”

The *Essay on Man* was the only part of the magnum opus completed as planned. However, the *Epistles to Several Persons*, commonly known as the *Moral Essays*, constitute part of the original design and would have been portions of the fourth book, “Private Ethics or Practical Morality.” These four epistles or essays are “To Cobham” (“Of the Knowledge and Character of Men”); “To a Lady” (“Of the Characters of Women”); “To Bathurst” (“Of the Use of Riches”); and “To Burlington” (also “Of the Use of Riches”). Pope was always the philosopher-moralist-poet whose description of his own career (*Epistle to Dr. Arbuthnot*, ll. 340–341) is essentially accurate: “not in

Fancy's Maze he wander'd long,/But stoop'd to Truth, and moraliz'd his song."

## POPPER, KARL RAIMUND (1902–1994)

Karl Raimund Popper, the Austrian philosopher of natural and social science, was born in Vienna and was a student of mathematics, physics, and philosophy at the university there. Although he was not a member of the Vienna circle of logical positivists and was in sharp disagreement with many of its doctrines, he shared most of the group's philosophical interests and was in close touch with several of its members, having a considerable influence on Rudolf Carnap. His first book, *Logik der Forschung*, was published in 1935 in the circle's series *Schriften zur wissenschaftlichen Weltauffassung*. In 1937 Popper went as senior lecturer to Canterbury University College in Christchurch, New Zealand, and remained there until his move in 1945 to a readership at the Lon-

don School of Economics in the University of London. From 1949 to 1969 he was professor of logic and scientific method at the London School of Economics, and then became professor emeritus. He was knighted in 1964.

### REJECTION OF VERIFIABILITY THEORY

The foundation of Popper's wide-ranging but closely integrated philosophical reflections is the bold and original form he first gave in 1933 to the problem of demarcating science from pseudo science in general and from metaphysics in particular. The logical positivists had taken this problem to be one of distinguishing meaningful from meaningless discourse and had proposed to solve it by making empirical verifiability the necessary condition of a sentence's meaningfulness or scientific status—in their eyes one and the same thing. Popper dis-sented both from their formulation of the problem and from their solution. His view had always been that the important task is to distinguish empirical science from other bodies of assertions that might be confused with it: metaphysics, such traditional pseudo sciences as astrology and phrenology, and the more imposing pseudo sciences of the present age, such as the Marxist theory of history and Freudian psychoanalysis. To identify this distinction with that between sense and nonsense is, he held, to make an arbitrary verbal stipulation. It is also an unreasonable stipulation because the line between science and pseudo science is neither precise nor impermeable. Pseudo science, or "myth," as he sometimes called it, can both inspire and develop into science proper: Indeed, the general progress of human knowledge can be considered as a conversion of myth into science by its subjection to critical examination.

### FALSIFIABILITY CRITERION

A crucial difficulty for the verifiability theory of meaning was David Hume's thesis that inductive generalization was logically invalid. Being unrestrictedly general, scientific theories cannot be verified by any possible accumulation of observational evidence. Moritz Schlick sought to interpret scientific theories as rules for the derivation of predictive statements from observational ones and not as statements themselves at all, but this attempt came to grief on the fact that theories can be empirically falsified by negative instances. This logical asymmetry in the relation of general statements to observations underlies Popper's view that falsifiability by observation is the criterion of the empirical and scientific character of a theory. He maintained, first, that scientific theories are not, in fact,

arrived at by any sort of inductive process. The formation of a hypothesis is a creative exercise of the imagination; it is not a passive reaction to observed regularities. There is no such thing as pure observation, for observation is always selective and takes place under the guidance of some anticipatory theory. Second, even if induction were the way in which hypotheses were arrived at, it would still be wholly incapable of justifying them. As Hume showed, no collection of particular observations will verify a general statement; nor, Popper added, is such a statement partially justified or rendered probable by particular confirming instances, since many theories that are known to be false have an indefinitely large number of confirming instances.

For Popper the growth of knowledge begins with the imaginative proposal of hypotheses, a matter of individual and unpredictable insight that cannot be reduced to rule. Such a hypothesis is science rather than myth if it excludes some observable possibilities. To test a hypothesis, we apply ordinary deductive logic in order to derive singular observation statements whose falsehood would refute it. A serious and scientific test consists in a persevering search for negative, falsifying instances. Some hypotheses are more falsifiable than others; they exclude more and thus have a greater chance of being refuted. “All heavenly bodies move in ellipses” is more falsifiable than “All planets move in ellipses,” since everything that refutes the second statement refutes the first but much that refutes the first does not refute the second. The more falsifiable a hypothesis, therefore, the less probable it is, and by excluding more, it says more about the world, has more empirical content. Popper goes on to show that the obscure but important concept of simplicity comes to the same thing as falsifiability and empirical content. The proper method of science is to formulate the most falsifiable hypotheses and, consequently, those that are simplest, have the greatest empirical content, and are logically the least probable. The next step is to search energetically for negative instances, to see if any of the potential falsifiers are actually true.

### CORROBORATION

If a hypothesis survives continuing and serious attempts to falsify it, then it has “proved its mettle” and can be provisionally accepted. But it can never be established conclusively. The survival of attempted refutations corroborates a theory; the corroboration being greater to the degree that the theory is falsifiable. Popper’s critics have fastened on this theory of corroboration as the point at which the inductive procedure he ostensibly rejects

makes an implicit reappearance. Is there any real difference, they ask, between the view that a theory depends for justification on the occurrence of confirming instances and the view that it depends on the failure of falsifying ones to occur?

Furthermore, his critics claim, there is apparently an inductive inference embedded in Popper’s doctrine—the inference from the fact that a theory has thus far escaped refutation to the conclusion that it will continue to do so. Popper could reasonably reply that the formal likeness between confirming and falsifying instances conceals an important difference in approach—that between those who glory in confirmations and those who ardently pursue falsifications. However, a certain disquiet about the inductivist flavor of the positive support that his theory allows a hypothesis to derive from the failure of attempted refutations is expressed in Popper’s leanings toward a rather skeptical view of the status of unrefuted hypotheses: “Science is not a system of certain, or well-established, statements.... Our science is not knowledge (epistēmē): it can never claim to have attained truth, or even a substitute for it, such as probability.... *We do not know: we can only guess.*” (*The Logic of Scientific Discovery*, Ch. 10, Sec. 85, p. 278).

### EMPIRICAL BASIS

To complete his account of the growth of scientific knowledge, Popper had to explain the empirical basis of the falsificatory operation, that is, he had to make clear the formal character of the observation statements that are logically deduced from theories. It follows from the falsifiability criterion that unrestricted existential statements of the form “There is (somewhere at some time) an *X*” are unempirical because however many spatiotemporal positions have been examined for the presence of an *X*, an infinity of further positions remains to be examined. This is not true, however, of circumscribed existential statements reporting the existence of something at a specified place and time. Popper takes the basic observation statements to be of this form, to refer to publicly observable material objects, and to be capable of being straightforwardly affirmed or denied as true or false. Such basic statements are motivated by perceptual experiences, but they do not, as they are held to in the usual empiricist tradition, describe them. They can themselves be empirically tested in the light of the further basic statements that follow from them, together with accepted scientific theories. The infinite regress that this conception involves is not a vicious one: It can be halted by a conventional assignment of truth to basic statements at any point. But

this convention is not dogmatic, since it is only provisional; if the basic statements in question are challenged, they can always be exposed to empirical tests.

### EPISTEMOLOGY

In his later writings Popper drew many further inferences from his initial body of ideas. One is that knowledge has no foundations or infallible sources, either in reason or the senses. He sees the rationalist and empiricist epistemologies of the modern age as united in a determination to replace one sort of authority—a sacred text or an institution—with another—a human mental capacity. Both kinds of intellectual authoritarianism hold the mistaken opinion that truth is manifest and consequently that error is a sin and its propagation the outcome of some kind of conspiracy to deceive. There is no more comprehensive critique of the quest for certainty in the work of any other modern philosopher.

A second conclusion Popper drew is that the traditional empiricist account of concept formation—essentially Hume's idea that concepts are acquired by perceiving the similarity of sets of particular impressions—is mistaken because it embodies the same inductivist error as Francis Bacon's and J. S. Mill's accounts of scientific knowledge. Resemblance is not passively stumbled upon; rather, we classify things together in the light of antecedent preconceptions and expectations. Popper rejects innate ideas strictly so called but believes that we approach the world of experience with innate propensities—in particular, with a general expectation of regularity that is biologically explicable even if not logically justifiable. The influence of Immanuel Kant is especially evident in this side of Popper's thought. In a sense the proposition that nature contains regularities is for him synthetic a priori: It is neither a logical truth nor an empirical truth (since it is unfalsifiable), but it has a kind of psychological necessity as a general feature of the active human intellect.

### THEORETICAL ENTITIES

Popper's dissent from the usual empiricist and positivist view that private, experiential propositions constitute the empirical foundation of knowledge and his insistence on the provisional and incompletable nature of scientific theorizing together determine his attitude to the subject matter or ontological significance of scientific theory. He rejects the essentialism of the rationalist philosophy of science, which conceives the goal of inquiry to be a complete and final knowledge of the essences of things, on the grounds that no scientific theory can be completely justifi-

fied and that the acceptance of a new theory creates as many problems as it solves. He is equally opposed to the instrumentalist or conventionalist doctrine of those who, like Ernst Mach, Henri Poincaré, and Pierre Duhem, take the theoretical entities of science to be logical constructions, mere symbolic conveniences to assist us in the prediction of experience. The entities of scientific theory (such as molecules and genes) are not distinguishable in nature from the medium-sized public observables (such as chairs and trees) referred to in basic statements: Both are possible objects of genuine knowledge.

### PROBABILITY

A difficulty arises for Popper's falsifiability criterion from the presence in normal scientific discourse of statements about probability in the sense of frequency. No finite sequence of *A*'s of which none are *B* decisively refutes the proposition that most *A*'s are *B*. In his first book Popper put forward a modified version of Richard von Mises's view that the probability of the occurrence of a property in an unrestrictedly open class is the limit of the frequencies of its occurrence in finite segments of the open sequence, a version that made probability statements accessible to decisive empirical refutation. Since then he had argued that probability statements, although they may rest on statistical evidence, should not themselves be interpreted statistically but rather as ascribing objective propensities to natural objects.

### DETERMINISM AND VALUE

Popper's conviction that the mind is essentially active in the acquisition of knowledge and that its progress in discovery cannot be subsumed under a law and made the subject of prediction led him far beyond the philosophy of natural science, with which his central doctrines were concerned. Scientific knowledge is a free creation; it follows that the mind is not a causal mechanism. He contended that no causal model of the most elementary acts of the mind in empirical recognition and description can be constructed, since such a model would leave out the intention to name that is essential to any real act of description. Although the pursuit of knowledge is guided by an innate propensity to expect deterministic regularity in the world, the existence of knowledge as developed by a series of unanticipatable novelties is the strongest reason for rejecting general, metaphysical determinism.

Popper's theory of mind and knowledge also has ethical implications. Judgments of value are not empirical statements but decisions or proposals. Our valuations are not determined by our natural preferences but are the

outcome of autonomous acts of mind—a further link with Kant. Popper’s own basic moral proposal was, however, not very Kantian. Popper was a negative utilitarian for whom the primary moral imperative is “diminish suffering.”

## HISTORY AND SOCIETY

In *The Open Society and Its Enemies* (1945) and in *The Poverty of Historicism* (1957), Popper applies his theory of knowledge to humankind and society in the form of an attack on historicism, the doctrine that there are general laws of historical development that render the course of history inevitable and predictable. In *The Open Society* historicism is examined in three influential versions, those of Plato, G. W. F. Hegel, and Karl Marx. In *The Poverty of Historicism*, historicism is formally refuted and attributed to two oppositely mistaken views about the nature of social science. The formal objection is that since the growth of knowledge exercises a powerful influence on the course of history and itself depends on the anomalous initiatives of original scientific genius, neither the growth of knowledge nor its general historical effects can be predicted. Some historicists have been motivated by the mistaken idea that a science of society would have a general evolutionary law as its goal. This is a naturalistic error. The evolutionary process is not a lawlike regularity at all; rather, it is a loosely characterized trend whose phases exemplify the laws of genetics, for example. The historicists who have made this error are right in believing that scientific method applies to society, but they have a false idea of what scientific method is. However, among historicists there are antinaturalists who hold that ordinary scientific method does not apply to society, for which laws of a special historicist form must be found. Popper asserts that scientific method applies both to nature and to society, and in the same way—to particular isolable aspects of the whole. Social science can discover laws that make clear the unintended consequences of human action, but there can be no laws of the whole system. It follows that social reform must proceed by piecemeal social engineering, not by total revolutionary reconstructions of the social order. Popper presents the central problem of politics in a characteristically falsificationist way: The question “Who should rule?” he says, should be replaced by the question “How can institutions be devised that will minimize the risks of bad rulers?”

## PHILOSOPHY AND KNOWLEDGE

Popper did not believe, as do most analytic philosophers, that philosophy is sharply distinguishable from science,

either in its methods—which, like science’s, must be those of trial and error, conjecture and attempted refutation—or in its subject matter—which is not only language but also the world to which language refers. Furthermore, there is no uniquely correct philosophical method. Both the examination of actual language and the construction of ideal languages can contribute to the philosophical understanding of particular problems, but they are not universal keys to truth. Popper believed that if philosophy is to be of any general importance, it must stand in a close relation to the work of other disciplines. When it is isolated, as a special autonomous craft, from the general pursuit of knowledge, it degenerates into scholasticism and triviality.

- Warnock, G. J. Review of *The Logic of Scientific Discovery*. *Mind*, n.s., 69 (1960): 99–101.

*Anthony Quinton (1967)*

## POPPER-LYNKEUS, JOSEF

(1838–1921)

Josef Popper-Lynkeus was an Austrian inventor, social reformer, and philosopher. Now almost completely forgotten, Popper enjoyed great fame in the early years of the twentieth century and on several topics his writings are far from dated.

## LIFE AND WORKS

Popper grew up in the ghetto of the small Bohemian town of Kolin. At the age of sixteen he began his studies in mathematics and physics at the German Polytechnikum in Prague. Four years later he moved to Vienna, where he attended lectures first at the Imperial Polytechnikum and later at the University of Vienna. In spite of his acknowledged brilliance, Popper was not able to secure a teaching position, partly because he was Jewish and partly because of his radical opinions on religious and social questions. For some time he had a minor clerical job with the National Railways in southern Hungary. Returning to Vienna, he earned his living as a private tutor and as the owner of a scientific-technical literary agency. He attended scientific conferences and lectures, taking notes in longhand. These he wrote up, making ten to twelve carbon copies which he sold to the city's newspapers. In his autobiography, Popper recalls that during

those years his income barely equaled that of the lowest-paid unskilled laborer. Popper's extreme poverty came to an end at the age of thirty with his invention of the so-called *Kesseleinlagen*—a device that significantly improved the working capacity of engine boilers. Although this, as well as several other of Popper's inventions, became generally used, he did not acquire wealth and it was not until he was almost sixty that he could retire from active participation in the production and selling of his various appliances in order to devote himself to literary pursuits.

During the last twenty years of his life, when Popper's books on social and philosophical questions had a very wide circulation, he became the center of what amounted almost to a cult. Popper's books give the impression of a man of transparent honesty and uncompromising hostility to every kind of humbug, especially of the kind that infested German public life in the late nineteenth and early twentieth centuries, but they do not, according to those who knew him, convey an adequate idea of his character and personal impact. His friends and admirers included Ernst Mach, Wilhelm Ostwald, Albert Einstein, Sigmund Freud, Arthur Schnitzler, Hermann Bahr, Stefan Zweig, Philipp Frank, and Richard von Mises. Mach referred to him as a "genius of freethinking"; Einstein, who visited Popper when a young man, spoke of him as a "saintly and prophetic person"; and all who met Popper were impressed by his deep serenity, warmth, and unusual and genuine kindness.

Popper was not a scientist of the first rank, but several of his publications dealing with problems in physics are favorably mentioned in standard histories of the subject. He was the first person to suggest the possibility of transmitting electric power, he was a pioneer in aerodynamics, and he was one of the first to see the full implications of the work of Robert Mayer. Popper's treatise "Über die Quelle und den Betrag der durch Luftballons geleisteten Arbeit" (On the sources and the amount of the work done by balloons; *Sitzungsberichte der Kaiserlichen Akademie der Wissenschaften*, 1875) led to correspondence with Robert Mayer, who requested Popper to review the second edition of his *Die Mechanik der Wärme* (*Mechanics of Heat*, 1874). Popper's article, published under the title "Über J. R. Mayer's Mechanik der Wärme" in the periodical *Das Ausland* (1876), did not confine itself to a discussion of Mayer's conservation principle but also contained a statement of a phenomenistic philosophy of physics. In its "sharpness and fresh originality," according to Philipp Frank, "it equals the best that is found in Mach's works." In this essay there are also some

remarkably perceptive criticisms of the common view that the law of entropy implies the “heat-death” of the universe. In his later work, *Physikalische Grundsätze der elektrischen Kraftübertragung* (Physical principles of the transmission of electricity; Vienna, 1884), Popper emphasized the analogies between different forms of energy and suggested that every type of energy be regarded as a product of two factors, one of which can be regarded as a kind of quantity and the other as a “difference of level.” This idea was subsequently employed in the “energetics” of Georg Ferdinand Helm and Ostwald, both of whom made due acknowledgment to Popper.

Popper’s first work dealing with religious and social questions was published in Leipzig on May 30, 1878, the hundredth anniversary of Voltaire’s death. It was titled *Das Recht zu Leben und die Pflicht zu Sterben, sozial-philosophische Betrachtungen, anknüpfend an die Bedeutung Voltaires für die neuere Zeit* (The right to live and the duty to die, social-philosophical reflections in connection with Voltaire’s significance for our times). This work contains most of the ideas that Popper was to develop in later writings—a defense of the value of the individual in opposition to the national policies of all existing states, proposals for various social welfare measures totally at variance with the prevailing laissez-faire philosophy, recommendations for drastic reforms of the criminal law and judicial procedures, and reflections about the baleful influence of religion and metaphysics, accompanied by suggested methods for their elimination from the human scene. Both here and in a later more detailed study, *Voltaire, eine Charakteranalyse* (Voltaire—a character analysis; Vienna, 1905), Popper went out of his way to rebut the charges of German nationalists and romantics about Voltaire’s disruptive (*zersetzende*) influence on morals and society, praising Voltaire for his great honesty, humanity, and courage, which, in Popper’s opinion, were not matched by any of his German detractors.

In 1899 Popper published, under the pseudonym of Lynkeus (Lynkeus was the helmsman of the Argonauts, famous for his keen sight), a two-volume book titled *Phantasien eines Realisten* (Fantasies of a realist), which consisted of eighty sketches in the form of short stories or dialogues, most of them centering on some controversial philosophical or social topic. One story, “Gährende Kraft eines Geheimnisses” (The fermenting power of a secret), is set in fifteenth-century Florence and deals with the incestuous relations between a mother and her adolescent son, both of whom were burned at the stake. The *Phantasien* was banned in Vienna, and clerical members of the Austrian parliament demanded a criminal prosecution of

the author. Since the book was published in Dresden and the German authorities took no action, it remained in circulation and went into no fewer than twenty-one editions. Philosophically of more interest than “Gährende Kraft eines Geheimnisses” are various sketches illustrating the influence of religion on human life, including an imaginary conversation between David Hume, Denis Diderot, Baron d’Holbach, and other outstanding figures of the French Enlightenment. One of the stories, “Träumen wie Wachen” (Dreaming like waking), independently arrived at several of the key doctrines of Freud’s theory about dreams. Like Freud, Popper insisted that there is a continuity between waking thought and dream content and that dreams cannot be dismissed as “nonsense.” Freud did not read Popper’s story until after the first edition of *The Interpretation of Dreams* had been published, but later he repeatedly complimented Popper on his insights.

Of Popper’s other books, three deserve special mention. *Über Religion* (Vienna, 1924), which was written in 1905 but could not be published before the overthrow of the monarchy with its clerical censorship, contains the fullest statement of Popper’s criticism of religion and metaphysics. *Das Individuum und die Bewertung menschlicher Existenzen* (The individual and the evaluation of human lives; Dresden, 1910) is the most complete statement of Popper’s individualistic ethics and his objections to the many theorists from G. W. F. Hegel to Friedrich Nietzsche whose writings bristle with contempt for the common man.

Popper himself regarded *Die allgemeine Nährpflicht* (Vienna, 1912) as his most important work. It develops in detail the system which, in Popper’s words, should replace “our dreadful economic conditions” by such as are “good and moral.” Society, according to Popper, has the duty to secure every individual against want, irrespective of his talents and qualifications. He classifies goods and services into “necessities” and “luxuries,” the former including food, clothing, shelter, medical attention, and basic education. To ensure for every human being a “guaranteed subsistence-minimum,” Popper proposes a term of labor service in the *Nährarmee* (Nourishment army). Utilizing an elaborate analysis of agricultural and industrial conditions in Germany at the beginning of the century, he calculates that twelve years of service by men and seven by women, working a thirty-five-hour week, would be sufficient for this purpose. There is to be a double economy: The provision of necessities is to be regulated by the state, while private enterprise is to handle the production and distribution of luxuries. After a person has completed his

term of service, he is free to work in any occupation he chooses, or not to work at all. In the latter event, he is still fully entitled to receive all “necessities.” As technology advances, the period of service in the Nourishment Army will become progressively shorter.

Popper deliberately used the term *Nährpflicht* (literally “the duty to furnish nourishment”) to express the key concept of his program, since it rhymes with *Wehrpflicht*, the German for compulsory military service, which Popper resolutely opposed. Popper’s idea of a “compulsory civil service” is similar to one proposed by William James in his essay “The Moral Equivalent of War,” but Popper anticipated James by several decades. If Popper’s ideas about the duty of society to secure the individual against economic uncertainty do not sound exciting to the contemporary reader now that the concept of the welfare state is accepted by the majority of the populations of western Europe and the United States, and even the notion of a guaranteed income is advocated by leading economists, it should be remembered that at the time of their first publication, these ideas were extremely radical and were in fact received with violent hostility. In 1878 the great majority of political theorists, economists, and statesmen still adhered to the view that people are poor because of their laziness and ineptitude and that any state intervention in economic matters is a highly dangerous tampering with natural laws.

In spite of his courage and independent spirit, Popper failed to emancipate himself in some important areas of thought from the prejudices of his times. For example, he accepted without any question the view that masturbation “shatters” (*zerrütet*) the nervous system. He also had no doubt about the soundness of the prevailing hereditarian theories, according to which mental disturbances are largely the result of an innately weakened nervous system, and Popper frequently indulged in generalizations about the basically weak or strong nervous system of this or that national group. Although he knew of Freud’s high esteem of his own work, Popper had no appreciation whatsoever of any of the ideas of psychoanalysis. Fritz Wittels, a psychoanalyst who was one of Popper’s most devoted and trusted followers, called his attention to Freud’s books and there was some polite correspondence between Popper and Freud. However, according to Wittels, Popper scarcely did more than look at Freud’s books. In one case, when the subject was society (Freud’s *Group-Psychology and the Analysis of the Ego*), Popper went to the trouble of reading the book. “I enjoyed what he quoted from the Frenchman [Le Bon],” he later told Wittels, but as for Freud’s own theories, Pop-

per added, “I must tell you that I did not understand one word.”

## THE SANCTITY OF HUMAN LIFE

None of Popper’s theories is philosophically more interesting than the ethical individualism on which he bases his program of social reform. On the opening page of *Das Individuum und die Bewertung menschlicher Existenzen* (from now on referred to as *Das Individuum*) Popper announces what he calls his “motto,” and the rest of the book consists of its elaboration and defense as well as of detailed criticism of the anti-individualist positions of various influential writers, including Hegel, Nietzsche, Thomas Carlyle, Herbert Spencer, Heinrich von Treitschke, and Popper’s own friend Wilhelm Ostwald. Popper formulates the motto as follows:

### Basic Principle of a Moral Social Order

When any individual, of however little account, but one who does not deliberately imperil another’s existence, disappears from the world without or even against his will, this is a far more important happening than any political or religious or national occurrence, or the sum total of the scientific and artistic and technical advances made throughout the ages by all the peoples of the world.

Should anybody be inclined to regard this statement as an exaggeration, let him imagine the individual concerned to be himself or his best beloved. Then he will understand and accept it.

To make clear what he means, Popper lists a number of propositions that he terms “the value-arithmetic” of human lives. The valuation of a person’s life by the person himself, he writes, is something indefinite, varying, according to the mental state of the individual, from nothing to infinity. His life means nothing to him in moments of extreme unhappiness or when he is willing to sacrifice it for a cause in which he believes; but in other circumstances he regards it as possessing infinite value. “From an ethical point of view,” Popper writes, “the existence of a stupid peasant-boy is just as infinitely valuable as the existence of a Shakespeare or a Newton” (*Das Individuum*, p. 193). “There is not the remotest equivalence,” he remarks, “between the existence of a human being who wants to go on living and who is not trying to destroy another one, and any other value; the former exceeds the latter infinitely” (p. 189). Let us suppose that the angel of death were to allow William Shakespeare and Isaac Newton, in the most creative periods of their lives, to go on

living only on condition that we surrender to him “two stupid day-laborers or even two incorrigible thieves.” As moral beings we must not so much as consider an exchange of this kind. It would be far better if Shakespeare and Newton were to die. One may call attention, as much as one wishes, to the pleasure produced in countless future ages by Shakespeare’s plays; one may point to the immense progress of science which would be the consequence of the prolongation of Newton’s life—by comparison with the sacrifice of a human being, these are mere “luxury-values.”

However, all of these considerations, Popper repeatedly insists, apply solely to “non-aggressive individuals.” A person whose life is threatened by another may, in self-defense, kill the aggressor without having to feel the slightest remorse or misgivings. In such a case, the person’s own life rightly counts as something infinite, while the life of the aggressor, be he one or many, counts as nothing. It is in fact a person’s *duty*, and not merely his right, to defend himself in such a case with all means at his disposal. In addition to helping himself, he also “exerts a beneficial influence on millions of others if he demonstrates to them by his example what importance and value a non-aggressive human being attaches to his life” (p. 218). In one place Popper goes so far as to assert that it would be better if all the aggressors in the world, even if they numbered millions, were to be destroyed than if a single human being succumbed to them without resistance.

On occasions Popper concedes that his own principles cannot be proved and that the principles of his assorted opponents cannot be disproved, but for the most part he maintains that they can be shown to be “true” by means of an “evident deduction” from premises granted by most civilized men (p. 64). He employs two types of arguments, the first of which consists in calling attention to the way in which civilized persons actually judge and behave in a great many situations, when their vision is not clouded by special bias or prejudice. Suppose, for example, a fire were to break out in the Louvre; in such a situation, Popper maintains, it would not occur to any of the firemen or any of the voluntary helpers to save the paintings in preference to the human beings present. If somebody were to save a painting and let a human being die, his behavior would be generally condemned and he might in fact be subjected to punishment. It is true, Popper admits, that sometimes when people *hear* that in a fire in some distant location a number of human beings perished but that certain valuable manuscripts or collections were saved, they respond with greater satisfaction

than if it had been the other way around; but this only proves that distance from the place of a disaster produces indifference and makes people forget the enormous value of somebody else’s life. “It becomes altogether different,” Popper observes, “if one stands in front of the burning house.” To take another illustration, in all civilized nations a person may not be subjected to vivisection or become the involuntary subject of a medical experiment, regardless of the benefits that might accrue to medical science and, indirectly, to future generations.

Popper also considers at great length another type of case that, in his opinion, shows particularly clearly that civilized people do in fact adhere to his principles. In fortresses or on ships, where the shortage of food may become so acute as to necessitate the sacrifice of some individuals, civilized men would always decide the issue by the casting of lots; in such a situation it would not occur to anybody to refer to the special literary or scientific talents of some member of the group. Shakespeare and Newton would here count no more than anybody else, and nobody would dare to propose that a less talented person be killed so that the great dramatist or the great physicist be kept alive instead. This is very evident in a case of this kind because “once the terror of death is so close, everybody perceives that the naked existence of a human being is something so elevated and infinite that compared with it everything else—be it genius, scholarship, or physical beauty—becomes quite inferior in value and a mere luxury” (*ibid.*, p. 208).

The analysis of these and many other cases makes it clear, Popper contends, that his principles, which seem so strange and unrealistic when first stated in general terms, are quite commonly invoked. It is true that they are widely ignored when it comes to certain questions, such as compulsory military service, the death penalty, and the duty of society to guarantee the basic subsistence of every human being. However, in these cases it can be shown that people are simply inconsistent and have not perceived the implications of their own principles.

Popper’s second type of argument, which is already indicated in his “motto,” is much more interesting and original. It may not unfairly be labeled an *ad hominem* technique. Arguments of this type consist of two steps: (a) If a person, *X*, recommends a policy that involves the killing of one or more nonaggressive human beings, we extract from him the admission that the policy would not be justified if he, *X*, were the individual to be killed; (b) we then extract from him the admission that other human beings have the same right to live and not to be sacrificed to some biological, cultural, or aesthetic goal.

Popper observes that, except in special “periods of hate,” most human beings are ready to make the latter of these admissions, at the very least for other members of their own nation or class. It does not, of course, mean, Popper explains, that a human being should mourn the death of any given person the way he mourns the death of somebody close to him; but human beings should realize that the mourning of somebody else in a similar situation is as justified as one’s own and that to this other person his life or the life of somebody dear to him is more important than anything else in the world.

Popper employed his *ad hominem* strategy with relish in dealing with assorted philosophers and aesthetes who flaunted their readiness to approve the killing or enslavement of millions of ordinary human beings if this were necessary to achieve a biologically superior race or to produce great works of art. Thus, Popper devoted a good deal of attention to Spencer’s conclusions that in giving artificial aid to the weakest members of a society, its physical and moral qualities are undermined and that, furthermore, all acts by the state to protect the weak and the sick are a “sin against the natural laws of life.” After pointing out the dubious analogies on which such conclusions are based and the arbitrary preference for the value of future lives to those now in existence, Popper turns to his “frequently employed method.” Suppose, he writes, Spencer or those taking such a “biological viewpoint” were themselves to become sick or unable to look after themselves. Would they approve of a society that turned to them and said: “Perish miserably! To help you is to make future generations less perfect.” Will Spencer and his followers then be prepared to be treated as damaged goods, as refuse in a human breeding institution? Will they then still hold to the theories which they so calmly advocated while they were in good health and *others* were sick and in need of assistance?

Apparently nobody, not even the “monstrous” Nietzsche, irritated Popper more than the anti-Semitic historian and aesthete Heinrich von Treitschke, who in his essay “Der Sozialismus und seine Gönner” (Socialism and its patrons) had claimed that “the one statue of Phidias more than makes up for all the misery of the millions of slaves in Antiquity.” One may well believe, Popper comments, that Treitschke can look at the statue of Phidias with great delight when *others* were compelled to labor as slaves. “A person holding such a view,” Popper proceeds, “ought to have his own principles applied to himself to determine whether he will adhere to them after he has come to feel in his own person what they mean” (*ibid.*, p. 166). It would have been a good idea to condemn Treitschke to five years of service as a slave and then offer him an apartment in the Berlin Museum, where he could spend all his days admiring antique statues. That would be the time to ask Treitschke how he feels about Phidias and the slaves. Perhaps this is the only method, Popper concludes, to make people like Treitschke have some respect for human life.

It would lead too far afield to attempt a detailed assessment of Popper’s principles here, particularly of his rather curious “value-arithmetic” of human lives. A few words, however, are perhaps in order about his *ad hominem* technique, both because arguments of this kind are in fact very common (although few employ them with Popper’s deliberateness and persistence) and because there may be a tendency to dismiss them too readily. Anybody with a training in logic is apt to regard all such arguments as flagrant instances of the fallacy of *ignoratio elenchi*. If a person makes a moral judgment but violates it in his own behavior, this is surely no argument against the soundness of the moral judgment. We all tend to smile at the familiar stage figure of the preacher of temperance who takes out his whiskey flask as soon as the congregation has departed, but his failure to practice what he preaches does not by itself invalidate his preaching—it does not even prove that he is insincere. A doctor, unable to break his own smoking habit, is not necessarily giving bad advice and also may be perfectly sincere when he advises his patients to stop smoking. Turning to one of Popper’s examples, if Spencer, after becoming ill and helpless, were to abandon his views concerning the social or biological undesirability of aiding the weak, this would not disprove his views; nor, conversely, would it be evidence for Spencer’s position if, upon falling ill, he refused all aid and cheerfully disintegrated in the belief that he was thereby promoting biological progress.

Yet surely this is not the end of the matter. In reading Popper, one cannot help feeling that he is doing a great deal more than expressing his indignation at the defenses of callousness and inhumanity by writers like Spencer, Nietzsche, and Treitschke. Granting that Popper’s *ad hominem* arguments do not disprove the positions he attacks and that they do not prove his own ethical individualism, it might nevertheless be held that his strategy helps to bring out at least two points of some interest. In the first place, Popper may be said to call attention to a double use of “understand” and related expressions which seems of special importance in ethical controversy.

Bernard Shaw once remarked that nobody should be allowed to be a judge unless he had spent at least six months in prison. The average judge, he explained, does

not really know what he is doing when he sends a man to prison. In a sense this is no doubt false, but in another and deeper sense it may well be true. A judge can of course understand the statement “You are hereby sentenced to imprisonment for a period of five years” without having been a prisoner and even without having visited a prison—he obviously knows the difference in meaning between “two years” and “five years,” and he also knows when to apply and when not to apply the word *prison*. At the same time, however, he might not know what he is doing in the sense that he has no clear conception of what it is like to languish for years in prison—what conditions really prevail in most prisons and what such a term of imprisonment frequently does to a man’s character.

It may very plausibly be held that when intellectuals like Nietzsche, Spencer, and Treitschke advocate or condone the destruction or enslavement of millions of men, they do *not*, in this latter sense of the word, understand what they are recommending and that they could properly understand their own recommendations only if they became slaves or if they themselves experienced the prospect of being forcibly done away with. If we are satisfied that a person who recommends a certain policy does not himself understand, in this deeper sense, what he is recommending, this does not indeed show his policy to be mistaken, but it does undermine his standing in the discussion. For it means that he is ignorant of relevant, perhaps crucially relevant, facts, and hence, on almost any normative theory, his recommendation would not be adequately supported.

Second, Popper’s strategy may help to determine the true *status* of the recommendations under discussion. Most people would want to make a distinction between a genuine moral or evaluative judgment and the mere expression of a desire or feeling; and it is the mark of the former but not of the latter—so, at least, a defender of Popper would argue—that it is universalizable: In passing a moral judgment on somebody, one is, in virtue of its being a moral judgment, committed to passing the same judgment about *anybody else* in similar circumstances, including oneself and those one cares for. Now, the writers whom Popper was opposing presumably wished their pronouncements to be treated as genuine evaluative judgments, as the advocacy of certain ideals and not merely as expressions of their desires. However, unless they were willing to maintain that they, too, ought to be enslaved or killed or left without assistance in order to further the goals in question, their original assertions will not qualify as genuine evaluations.

It will be instructive to see how Popper’s challenge, thus interpreted, helps to determine the status of Treitschke’s recommendation. Treitschke, we will assume, has just declared that certain “inferior” human beings ought to be enslaved for the purpose of producing a sublime work of art. Let us also assume that, in the sense under discussion, Treitschke admits that he, as well as his children (whom he loves), is “inferior.” Now, if Treitschke, in this hypothetical situation in which he imagines himself and his children to be inferior, is ready to maintain that he and his children, no less than other inferior human beings, ought to be enslaved, his original declaration has the status of a genuine evaluative judgment. If, however, Treitschke wishes to exempt himself and his children, not merely in the sense that he would resist any attempt to be sold into slavery but in the sense of declaring that he and his children, although inferior beings, ought not to be enslaved, it would follow that his initial statement was not a genuine evaluation—that “ought” was not used there in its moral or evaluative sense. (More accurately: It would follow either that Treitschke was not offering a genuine evaluation or that he was inconsistent in denying a proposition entailed by one asserted previously.) Popper would probably add to this that in actual fact the great majority of those who talk like Treitschke, and very likely Treitschke himself, would insist that they and those they love ought not to be enslaved or otherwise mistreated. While it may be disappointing to realize that the callous positions against which Popper wrote have not been refuted, it is not a mean achievement to have shown that certain pronouncements masquerading as value judgments are in fact nothing more than the expressions of certain desires.

## ELIMINATION OF RELIGION AND METAPHYSICS

Popper’s positivism, like that of Mach, may be regarded as a midway stage between the philosophy of Auguste Comte and the logical positivism of the Vienna circle. Although he knew a great deal about mathematics, Popper did not advance beyond J. S. Mill’s position that mathematical statements are extremely well supported empirical propositions. Metaphysics he dismissed as futile, but he wavered between dismissing metaphysical questions as meaningless and treating them as meaningful but unanswerable.

He never wavered, however, in regarding metaphysics, and more especially the theological varieties associated with Western religions, as exceedingly harmful. No change in economic arrangements, however rational

and beneficial it may be, can bring about a happy world unless all forms of supernaturalism are banished. There can be no peace in the world, Popper insists, as long as there is the slightest vitality in organized religious superstition, which is something “necessarily aggressive.” Some of Popper’s more conservative followers have done their best to play down his antireligious sentiments. It is therefore necessary to insist that he himself regarded the *Ausrottung* (extermination) of religion and metaphysics—and of all “enthusiasm for transcendent ideals”—as an essential part of his philosophical and social program, one that was necessarily implied by his humanitarian individualism. Margit Ornstein, his literary executor, relates how Popper, very shortly before his death, when he was revising the manuscript of *Über Religion*, remarked to her with a smile, “This is my Parthian arrow,” adding, “When the Parthians left the battle scene they turned around once more to aim a final arrow at the enemy” (*Über Religion*, p. 3).

Purely ceremonial or “civil” religions, such as those practiced by the ancient Greeks and Romans or most of the people of China and Japan, are relatively harmless: Unlike the religions that we know in the West, they lack any kind of metaphysical foundation, anything that can be called a theological system, and above all, they do not possess a powerful priestly caste. Religion begins to have an evil influence only when it is given a systematic formulation and when it becomes “an affair of the heart.” Popper’s condemnation is sweeping and is meant to apply to the kind of belief fostered by rationalistic theologians no less than to the pietistic enthusiasm found in many religious groups all over the world. “At first it [religious zeal] is just nonsense, then it becomes obstinacy and spite, and in the end it is wildness and insanity beyond all limits” (*Über Religion*, p. 2). The harmfulness of religion is exactly proportional to the degree of religious fervor. Popper approvingly quotes Pierre Bayle’s saying that “the person who is convinced that he is promoting the Kingdom of God by the extermination of heretics will step on all moral laws,” and he offers numerous examples from the history of the “genuine positive,” as opposed to the merely ceremonial and civil religions, to support his indictment that the former increase bad feeling in the world, that they encourage malicious tendencies which are then covered up and justified in high-sounding language, that they place love of man below the love of religious conceptions, that they multiply situations of strife and conflict by promoting the intervention of priests in even the most intimate details of everyday living, that they weaken and indeed destroy respect for truth and justice, and, finally, that they use, wherever they can, the

power of the state for their purposes, especially in matters of education.

Popper disliked Christianity most of all, and in a section of *Dos Individuum* (A digression on the valuation of human lives in the Christian religion) he undertakes to correct the long-standing and, he claims, erroneous notion that Christianity encourages respect for the individual. Christianity does indeed speak of the value of the individual *soul*, but both in doctrine and in practice this notion has coexisted with contempt for the individual’s body and life here on Earth. Popper does not deny that now and then religious belief has given people hope and consolation and that some of the expressions of religious devotion have been touchingly beautiful. However, such considerations must not be allowed to affect our overall judgment—“the burning of one heretic more than cancels ten thousand beautiful and deep feelings” (*Dos Individuum*, p. 72).

Popper had no doubt that the ideal of a “superstition-free culture,” which, for him, meant a world without religion, was entirely attainable. He repeatedly takes issue with the widespread view that religious belief or religious needs are innate. This, he argues, is clearly disproved by the existence of entire nations without religion and of numerous persons in our own culture who are entirely devoid of religious belief and whose lives are no less happy or responsibly conducted than those of most believers. Moreover, the existing statistics on the prevalence of religious faith are suspect in the sense that, as far as religious issues are concerned, most people are not allowed to develop freely but live under the constant pressure of proreligious propaganda and the threat of social disapproval and economic loss if they avow their disbelief. “The masses of Europe,” he writes, live in effect “in a religious penitentiary” (*Dos Individuum*, p. 59). Once the social and political power of the churches is shattered and education, uninfected by proreligious bias, becomes universal, religious belief is bound to vanish. “A person who has learned about the history and origin of religions, including Christianity, who has absorbed the main results of the sciences and the relations of these to the claims of religion, will not for a moment be afraid of or express gratitude to imaginary entities or persons” (p. 223).

Prior to the elimination of religious influences from the public schools, freethinkers must band together into a powerful “International League for the Liberation from Superstition.” Such a league would publish and obtain the vast circulation of what Popper calls “counter-books”—works written in simple and clear prose, which would refute point by point the fallacies, the lies, and the distortions

tions in the religious and prreligious textbooks used in the schools. This league would also open “counter-schools” and train “wandering counter-preachers,” whose function it would be to bring enlightenment to the peasant population. The counter-preachers would conduct meetings in the villages immediately after the Sunday services. In the beginning the peasants, incited by the priests, would try to chase away the “godless intruders,” but with some courage and persistence it would be possible to receive a hearing, to catch the interest of the peasants, and in the end to make them see the soundness and good sense of the unbeliever’s position. In his first formulation of this program in 1878, Popper estimated that such a “gigantic cleansing operation” would take several hundred years, but writing thirty years later, apparently encouraged by the constant decline in religious belief, he thought that a “few generations” would be quite sufficient.

In some places Popper admits that the teaching of science and of the history of religions and the exhibition of the conflict between scientific conclusions and religious assertions is not enough to banish supernaturalism. We also have to take into account the “metaphysical need” which is commonly found in Europeans, though it is for the most part lacking in the peoples of east Asia. This metaphysical need can be eliminated by “improved epistemological instruction.” The metaphysical need is “nothing other than the longing to find a resting place in the exploration of the universe, to reach a stage at which there will be no urge to ask new questions” (p. 62). It is however, a senseless drive and must be recognized as such if we are to have a healthy mental constitution. Our knowledge of the world consists in the establishment of functional relations between experienced data (Mach’s “elements”). Knowing the world means discovering correlations and subsuming these under ever wider correlations. “We cannot do anything further,” writes Popper, “than to determine ever richer relations between elements already known or to insert new ones as connecting links between them.” The world may be likened to a carpet spread out in front of us, between whose webs we go on weaving ever-new webs without limit. It is a vain effort “to try to see behind the carpet,” as the metaphysicians and mystics do, in the hope of finding there all kinds of wonderful happenings. In discovering causal relations, “we do not descend step by step into the Ground of the World ... rather we crawl like an insect on that colorful carpet which we call the world and which, as a consequence of our explorations, becomes ever more dense” (p. 63). This carpet has no “other side” transcending the one we explore.

### Bibliography

In addition to the works by Popper mentioned in the body of the article, the following deserve to be mentioned. *Fürst Bismarck und der Antisemitismus* (Vienna, 1886) is an examination of the violent anti-Semitic fulminations of Eugen Karl Dühring and Richard Wagner, as well as of the milder anti-Semitic arguments of Eduard von Hartmann. Popper’s *Selbstbiographie* (Leipzig, 1917) reprints the complete text of “Über J. R. Mayer’s Mechanik der Wärme,” as well as the correspondence between Mayer and Popper. *Die Philosophie des Strafrechts* (Vienna: R. Löwit, 1924) presents the details of Popper’s objections to existing penal systems and his own alternative, based on his ethical individualism. Parts of a major epistemological treatise that Popper had planned to write were posthumously published under the title “Über die Grundbegriffe der Philosophie und die Gewissheit unserer Erkenntnisse” in *Erkenntnis* 3 (1932–1933): 301–324.

Very little by Popper is available in English. “Dreaming and Waking,” translated by A. A. Brill, can be found in *Psychoanalytic Review* 34 (1947): 188–197. The story about incest is translated by S. Rosenzweig as Appendix I of his article “The Idiocultural Dimension of Psychotherapy—Pre- and Post-History of the Relations between Sigmund Freud and Popper-Lynkeus,” in *Psychoanalysis and the Social Sciences* 5 (1958): 9–50. Extracts from various of Popper’s writings are translated in H. 1. Wachtel, *Security for All and Free Enterprise; A Summary of the Social Philosophy of Josef Popper-Lynkeus* (New York: Philosophical Library, 1955), which has an introduction by Einstein.

A. Gelber, *Josef Popper-Lynkeus, sein Leben und sein Wirken* (Vienna, 1922), and F. Wittels, *Die Vernichtung der Not* (Vienna, 1922), are full-length studies of Popper’s life and work. The latter is available in English, translated by Eden and Cedar Paul as *An End to Poverty* (London: Allen and Unwin, 1925). There is a shorter but very informative study by Richard von Mises in Vol. VII of the series *Neue Österreichische Biographische* (Vienna, 1931), pp. 206–217. Popper’s scientific work is discussed in P. Frank, “Josef Popper-Lynkeus zu seinem achtzigsten Geburtstag,” in *Physikalische Zeitschrift* 19 (1918): 57–59; and in T. von Karman, “Lynkeus als Ingenieur und Naturwissenschaftler,” in *Die Naturwissenschaften* 6 (1918): 457–463. Popper’s contributions to “energetics” are discussed in G. Helm, *Die Energetik nach ihrer geschichtlichen Entwicklung* (Leipzig: Veit, 1898), Part VII, Ch. 2. A most interesting excerpt from the correspondence between Mach and Popper, containing a remarkable anticipation of the quantum theory, is reprinted

in H. Löwy, "Historisches zur Quantentheorie," in *Die Naturwissenschaften* 21 (1933): 302–303.

Freud's estimate of Popper is found in his article "My Contact with Josef Popper-Lynkeus," which is reprinted in Vol. V of Freud's *Collected Papers* (New York, 1959) and also in his *Character and Culture* (New York, 1963). Popper's remark about Freud quoted in this article will be found in F. Wittels, "Freud's Correlation with Popper-Lynkeus," in *Psychoanalytic Review* 34 (1947): 492–497.

In recent years there has been a good deal of discussion of ad hominem arguments of the kind employed by Popper against writers like Spencer, Nietzsche, and Treitschke. This discussion is in large measure due to the work of the influential British philosopher R. M. Hare, who in his *Freedom and Reason* (Oxford: Clarendon Press, 1963) employed a strategy strikingly similar to that used by Popper. Among discussions of how much (or how little) can be established by means of such arguments, the following are especially noteworthy: A. C. Ewing, "Hare and the Universalization Principle," in *Philosophy* 39 (1964): 71–74; D. H. Munro, "R. M. Hare's *Freedom and Reason*," in *Australasian Journal of Philosophy* 42 (1964): 119–134; G. Madell, "Hare's Prescriptivism," in *Analysis* 26 (1965): 37–41; and G. Ezorsky, "Ad Hominem Morality," in *Journal of Philosophy* 63 (1966): 120–125.

There is a complete bibliography of writings by Popper on philosophical, political, and scientific topics in H. I. Wachtel, *Security for All and Free Enterprise* (see above).

*Paul Edwards (1967)*

## POPULAR ARGUMENTS FOR THE EXISTENCE OF GOD

Argument about the existence of God is rare, for religious beliefs are effectively supported in our society by means that are not principally rational. It is common to answer the question "Why are you a believer?" with "Because I was taught to be," uttered in the tone of voice, or in the context, of one presenting reasons, not mere causes, of belief. It is even more common to speak of faith in God as if this were a specially compelling reason for belief and, moreover, one beyond logical criticism. Faith, however, is merely determination to believe and no kind of reason. Literature giving such justifications is not considered in this entry. Despite this omission of the greater part of the popular writing and what one might call the traditional verbal folklore of religion, a vast quantity of material remains that can be considered argumentative. After omitting further the grossest absurdities among these arguments, it has still been necessary to choose in a rather arbitrary way what should be dealt with, and no claim to completeness is made.

## GENERAL REMARKS

Most of the arguments in popular literature may be seen as variants of the more strictly philosophical arguments, such as the Cosmological and Teleological arguments, or those from morals and common consent. The variants are popular largely because they are posed as probable rather than as valid arguments; that is, they are not offered as arguments whose premises entail their conclusions. Almost all of them fall into a common class of arguments of the form "The universe contains some puzzling feature, *F* (design, an objective morality). God's existence explains *F*, and no other known hypothesis does. Therefore, God exists." That they have this form is a matter of no small importance; it affects the whole question of what kind of objection is likely to succeed against a given popular argument.

It is beside the point to demonstrate the formal invalidity of such arguments, although their invalidity is very easy to show in almost every case. However, it is entirely relevant to require of such an argument that it should make clear just how God's existence explains *F*. (Similarly, the real force of the well-known infinite regress counter to the Cosmological, or First Cause, Argument, is that it demonstrates the failure of this argument to provide the promised explanation. The argument merely postpones the explanation. That God's nature is mysterious does not, of course, fill any explanatory bill.) On this score, popular arguments are universally unsatisfactory, appealing tacitly (for the most part) to the claim on the one hand that all things are possible to God and on the other that, God being a transcendental mystery, it is presumptuous to expect any account of his efficacy to be actually intelligible. As the substance of an explanation, this is thin. Further, it is an entirely relevant question to ask whether any explanation is required of some singled-out feature, and whether alternative explanations are simply not known or whether there appears to be a reason to suppose there are none.

## ARGUMENT FROM COMMON CONSENT

The argument from common consent is an old and constantly recurring popular argument (see J. A. O'Brien, *God: Can We Find Him?*). The argument has a large measure of plausibility, despite the fact that it is formally invalid; for it is very often overwhelming evidence for some view that the majority holds it. For example, if a huge majority of spectators at a football game believes that a certain team won the game, that is exceedingly good evidence that this team indeed won it; and any

minority dissent can be written off in some way, such as irrational partisanship for the beaten team. However, the proportion of majority to minority views is not the only, or by any means the most important, factor in such situations. It is also crucial whether the majority has any competence to judge the issue. On the outcome of football games the majority of spectators is well placed to judge, but on the significance of some scientific experiment the majority is not at all well placed. Obviously, the general run of humankind has always been and still is poorly placed to pronounce on such a question as the existence of a Deity. This requires a competence in logical reasoning on highly abstract matters and an ability to assess complex evidence that the majority does not possess. Their vote carries no weight on this issue.

### ARGUMENT FROM MORALS

An argument widely used, especially by evangelists who aim at the most general audience, is the argument from the intelligibility of morals. (On a more sophisticated level it has been argued by A. E. Taylor in *The Faith of a Moralist*.) Many who urge it seem to have dimly in mind an essentially rather sophisticated argument, encapsulated in naive remarks like “But if God doesn’t exist, why do you not murder or plunder?” and “If God doesn’t exist, then a morality could amount only to doing what you please.” The rather sophisticated argument thus hinted at is as follows: To call an action moral (immoral) is, first, to provide a motive for doing (avoiding) it. Second, the claim that an action is moral can be a subject of rational dispute, which requires that the claim be not simply a disguised subjective remark about the speaker’s tastes. The existence of God explains these two features of normal discourse. Therefore, God exists.

As was pointed out earlier, the first question must be “Does the existence of God explain these features of moral discourse?” If the question whether an action is moral is equivalent to the question whether the action is consistent with God’s commands, then moral questions are not purely subjective. On the other hand, it is doubtful whether the theory accounts for the sort of discussion that actually goes on when moral issues are argued. God’s commands must, according to the hypothesis, be arbitrary. It cannot be that he consults something beyond his own will, since that external thing or principle would then be the source of morality and God its mere interpreter and announcer, not its creator. However, moral reasoning surely requires empirical knowledge of other persons and the world generally—and a very great deal of intelligence if the reasoning is to be satisfactory. It is far

from clear that the hypothesis allows for the relevant play of intelligence and knowledge in arriving at moral conclusions.

Again, it is rarely stated just which motive for behaving morally is provided under the hypothesis of God’s existence. It cannot be suggested that we have a moral duty to obey God’s commands because the whole point of the proposed explanation is that his commands are the source of all moral duties. It could be claimed that terror of punishment and desire for reward are perfectly adequate motives for obeying the commands. However, despite the undoubted efficacy of these motives, they are seldom urged because they do not adequately account for what we feel our motives really are in moral behavior. The most satisfactory suggestion as to the motive provided under the hypothesis seems to be that one obeys the commands out of love of God.

In sum, it is uncertain how the hypothesis clearly explains the required features of moral discourse. Further, it seems quite possible to account for them at least as well without being committed to the theistic view. For if love of God is an adequate motive for moral behavior, why should not love of one’s fellows also be adequate? And if it is, then it further seems an objective empirical question that courses of action promote those almost universally desired ends of continuance of life, adequate food and shelter, and freedom from violence, as well as less fundamental and more subtle ends that promote smooth social intercourse.

### TELEOLOGICAL ARGUMENTS

Versions of the classical Teleological Argument are by far the most popular of all popular arguments. The variety of changes rung upon this old theme in respect of its premises is astonishingly wide, as may be gathered from the following brief examples: The smallness of the human gene has been cited by A. C. Morrison, for no very clear reason, as an instance of God’s designing hand, and so has the immensity of the orbital velocity of an electron. More markedly odd are such suggestions as “This old world has three times as much water as land but with all of its twisting and turning not a drop sloshes off into space” (*Ebony* symposium, November 1962, p. 96) and that the annual progress of Earth round the sun, although it is much more rapid, is also much smoother than the most sophisticated jet airliner yet designed. Although it is difficult to see what relevance these considerations may be thought to have, they perhaps involve a confusion between a good argument to the conditional conclusion that if these things are designed, then the technology of their produc-

tion is well beyond our present reach, and a bad argument to the conclusion that these things have, in fact, been designed.

An ingenious variant, heard in conversation but apparently never published, neatly turns the tables on a standard polemic against belief in a God that stems from Freudian psychology—that such belief is caused by a psychological mechanism arising from various sexual stresses in an infant’s relationship with its father. This mechanism, it is claimed, far from showing that belief in God is pathological and irrational, really demonstrates his loving care for his creatures in providing a psychological mechanism that promotes belief, thus preventing the damnation of his creatures as heretics and infidels. This does not at all answer the point that insofar as belief depends upon the psychological stresses, it is irrational and pathological. (Irrational and pathological beliefs may, of course, be true.)

#### ARGUMENTS FROM THE SCIENCES

Only more recent arguments taken from the biological and the physical sciences will be discussed. First, however, there is a general argument from the very existence of science, or as it is more likely to be put, from the intelligibility of nature (see D. Elton Trueblood, *Philosophy of Religion*, pp. 94–98). It is felt that the universe must be rational if science, using logic and mathematics, is able to comprehend it. But logic and mathematics are concerned with deriving some propositions or formulas from others. It is not the conclusions or the premises of arguments that may properly be called rational, but only the procedure of deriving conclusion from premises. This procedure reflects no rational process in nature. It would be more accurate (although still not very accurate) to call this a linguistic procedure. We can move from “If there is lightning, then there is thunder” and “There is lightning” to the conclusion “There is thunder” by the rational procedure known as *modus ponens*, but it is not even intelligible to suppose that *modus ponens* is a natural physical process by means of which lightning produces thunder. Scientists may discover the important equation that relates the speed of a falling body to the square of the time of its fall. They may differentiate this equation,  $v = t^2$ , to show that the body’s acceleration is constant. Differentiation is a mathematical procedure of derivation, but it is not intelligible to say that the body or the gravitational field in which it falls undergoes any such process of differentiation, or that it undergoes some nonmathematical counterpart of it.

ARGUMENTS FROM BIOLOGY. It has been argued—by Pierre André Lecomte du Noüy and Pierre Teilhard de Chardin, for example—that the pattern of evolution as displayed by modern biology shows clear marks of a designing hand. The direction of evolution, it is claimed, is toward progressively more intelligent life forms, thus showing the desire of the Creator (Omega, as Teilhard de Chardin called him) to bring about beings like himself. The claim is highly dubious. It induces “a certain shuffling of the feet” (to quote P. B. Medawar’s review) in Teilhard, when he discusses the fact that insects and plants do not seem to evolve in this way at all. Lecomte du Noüy solved the difficulty by defining the problematic cases not as evolutions but as adaptations. The direction of adaptation is toward usefulness; that of evolution, toward liberty. Thus he made the claim perfectly, if trivially, safe. Even so, there is a difficulty, for if it is all a plan, why does God not bring about immediately and at a stroke the desired state of affairs now being so laboriously approached with such a plethora of wasteful products? Lecomte du Noüy’s apparent answer is merely that since God is an eternal Being, what seems to us simple mortals as a drear immensity of wasted time is to him but the twinkling of an eye. The irrelevance of this to the original objection is obvious enough. The waste is still waste, and the existence of so many pointless dinosaurs (whose lives played no part in future evolution) can scarcely have escaped the attention of him who takes note of the fall of a sparrow.

One prevalent argument, put forward by Morrison, among others, is based on the allegedly remarkable hospitality of our planet to complex forms of life. Temperatures are neither too high nor too low, and there is an abundance of water and oxygen and an atmospheric blanket against lethal doses of cosmic radiation. But the argument inverts the situation. We now have good reasons (of a Darwinian kind) to believe that the surviving life forms are those that adapt to the environment rather than those for whom the environment has been adapted by a beneficent Overseer. So far as is known, only one of the nine major planets of our particular star is hospitable to complex life forms. It might be surprising if every planet of every star fulfilled the quite detailed set of conditions that favor life as we know it and that prevail over most (not all) of our planet. But that there is one such planet is not so surprising that we need recourse to metaphysical entities to explain it.

Similar arguments from alleged improbabilities also spring from biology. Lecomte du Noüy and others have claimed that life is inconsistent with the Second Law of

Thermodynamics. This law states that entropy increases, which means, roughly, that in any isolated system energy breaks down from various differentiated forms that are usable in doing work to an undifferentiated state of uniform heat. In statistical thermodynamics, increase of entropy is defined roughly as increase of the randomness of systems, that is, their movement toward more probable forms. But, it is said, living organisms decrease in entropy as they grow; they build up differentiated forms of energy and hence are improbable structures.

However, the phenomena of life are quite consistent with the law, for living organisms are not thermodynamically isolated systems. In whatever way life may be improbable, it is certainly not improbable in any sense that makes it inconsistent with statistical thermodynamics.

A second, more plausible, claim of this kind is that even a simple protein molecule is a highly improbable structure, so improbable that it is simply incredible that it should ever have come into existence by pure chance. A calculation cited by V. H. Mottram puts the odds against a chance “manufacture” of a simple protein molecule as  $10^{160}$  to 1, a small chance by any standards. Mottram also claimed that  $10^{243}$  years would be needed for such an event to occur on this planet (a much longer period than that accepted for the cool Earth) and that it would require sextillion sextillion sextillion times more material than is believed to be in the entire universe. Another calculation shows that the probability of such a molecule’s arising by chance manipulation of amino acids (already quite complex structures) is still as low as  $1:10^{48}$  and hence very improbable indeed.

The ways of statistical arguments are notoriously complex. We must always ask “Relative to what assumptions are these probability figures reached?” This was not made clear by Mottram. Presumably we are to assume at least that the atoms are rearranged in various positions by a process of mechanical shuffling of some sort in which all the rearrangements so envisaged are equally probable.

The possibility of such a rearrangement is very dubious. Even elementary chemistry informs us that certain combinations are not possible—for example, five hydrogen atoms may not be linked to one carbon atom. There is no evidence that such groups were excluded from the class of equiprobable arrangements considered in constructing this figure. If one considers the various linkages of more complex groups in which, say, a group of fifty atoms hooks on to another group of fifty, the number of chemically possible combinations is, presumably, very small. But this cannot have been taken into consideration

in constructing the figures, because we do not have sufficient knowledge of the chemical possibilities at this level. The theists appear to have committed at this point the fallacy of assuming equal probabilities in cases where we have no positive knowledge of what the probabilities are.

Consider a liter of hydrogen containing, say,  $10^{22}$  atoms. If we attempt to assign a number to all the conceivable arrangements of those atoms, the number is enormous. Yet we invariably find them divided into hydrogen molecules,  $0.5 \times 10^{22}$  pairs of atoms extremely close together. The improbability of this always coming about as a random arrangement of atoms is immense, and certainly far greater than any of the figures quoted by Mottram, yet this is presumably not evidence of design. Without more information about and justification of the assumption of equiprobability on which Mottram’s calculation is based, plainly no reliance can be placed upon it.

**ARGUMENTS FROM PHYSICS.** Perhaps even more than biology, modern physics has given rise to a group of widely circulated arguments purporting to show that, despite the fact that God nowhere appears in the calculations of physicists, modern physics demands, suggests, or allows for the existence of God.

Although most apologists agree that the views of a scientist have no special authority outside the field of his expertise, this does not prevent their citing a vast mass of material produced by those physicists who spend their less strenuous hours philosophizing on their findings. The view almost universally favored among such writers, and perhaps most forcefully expressed by Sir Arthur Eddington and Sir James Jeans, is that modern physics establishes the subjectivity of all knowledge and that reality is mental, not material. It is often further concluded that physics has shown the world to be a nonrational place about which clear logical argument is out of place.

Relativity theories are alleged to have shown the subjectivity of all knowledge and to have confirmed Protagoras’s doctrine that man is the measure of all things. But the special theory of relativity is concerned with relations between inertial systems (a notion definable wholly within objective dynamics). It is not at all concerned with any observers who may be reading clocks or using measuring rods within these systems. The general theory only extends the results of the special theory to cover relations between systems of a wider class. Neither theory is subjectivist or mentalistic.

A similar example of needless obscurantism concerns the primary place given the concept of energy by the relativistic notion that mass (matter) may be con-

verted into energy, and vice versa. Few of us are sure just what energy is; and, when a scientist such as E. J. Bing informs us that everything is energy, that it may exist in the form of electromagnetic vibration, and that it is a vehicle of universal thought (a gratuitous addition), we are apt to think that, while we do not know what this really means, perhaps everything is, in some obscure way, thought and hence in the mind of God.

Trueblood (op. cit., pp. 102–105) has invoked the science of thermodynamics to yield a theistic conclusion. The Second Law of Thermodynamics shows that the universe is steadily increasing its thermodynamic randomness—it is dissipating its stores of differentiated energy usable in doing work. It also shows that, as we trace the history of the universe in time according to the law, we come to a state of minimum energy, a sort of beginning in time of the universe. But this is far from lending support to the theistic hypothesis. It simply means that the law leads us to a point beyond which it will not take us. It gives no warrant for the conclusion that the minimum entropy state has a supernatural cause.

The greatest number of arguments are derived from the difficult and puzzling field of quantum mechanics. It is possible to give some indication of the relevant state of affairs in physics in terms of two features: (1) The Schrödinger wave equation, which is fundamental to quantum physics, contains the  $\psi$  function. This gives as its square the probability that an electron, for example, is in a certain spatiotemporal region. This feature leads to the result that the exact later states of electrons are unpredictable even from the fullest statement of their earlier states. (2) Beams of radiation or of electrons show some features characteristic of beams of particles but others characteristic of beams of waves, although their being particles is inconsistent with their being waves.

Feature (2) leads directly to such distortions as “If an electron can be two wholly inconsistent things, it is a little narrow to expect so much less of God.” The electron, of course, is not, nor can it be, two inconsistent things—and (2) does not entail this. But the claim, together with the breakdown of the Laplacean view that given the complete mechanical state of the universe at any one time, any future or past state could be rigorously deduced in every detail, is generally hailed by religious apologists. Very few apologists claim that quantum physics actually provides evidence for God’s existence. It is simply that in quantum theory mechanical determinism breaks down and there is no mechanical picture of quantum processes that is an adequate interpretation of the mathematical formalism of the theory. To religious apologists it appears that these

facts allow for occult nonphysical causes and forbid rational understanding. They appear to feel that in the overthrow of reason itself lies their best defense.

More specific in their trend toward the admission of occult or physically transcendent causes are the following characteristic arguments. Arguing from the bad habit some physicists have of speaking about unpredictable electron jumps as the electron “choosing” one rather than another energy state, E. J. Bing wrote, “Let’s call a spade a spade. To say that an electron ‘chooses’ to do anything *is to attribute free will to the electron.*” The theory gives no warrant for taking this obvious metaphor literally. It is quite unclear what real meaning there could be for such terms as *choice* and *free will* if their use is extended from describing living things to describing those that are non-living. Such extension can result only in confusion.

Some physicists (Jeans, for example) have an equally deplorable habit of speaking of the Schrödinger wave equation as “waves of knowledge” in discussing the behavior of subatomic particles. This is presumably because the Schrödinger equation, which describes the behavior, is a wave equation and contains a function whose square is a probability. Apparently they regard probability as purely a matter of knowledge and thus suppose that some occult mental principle is at work in the quantum world. These suggestions won no assent from such authoritative quantum physicists as Niels Bohr and Werner Heisenberg, who most strongly insisted on the indeterminacy of quantum physics. Their notion is not that quantum phenomena have occult causes (acts of free will on the part of electrons) or unknown causes, but that they have no causes at all. Although there have been many distinguished scientists, including Albert Einstein, who believe it is possible that in the future we shall have a fully deterministic theory of the subatomic world, they have all taken for granted that the theory would postulate only physical causes.

## PORPHYRY

(c. 232–c. 304)

Porphyry, one of the principal founders of Neoplatonism, was born of Syrian parents at Tyre. He studied philosophy at Athens. In 263 he went to Rome, joined the group that regarded Plotinus as its master, and, apparently some years after Plotinus's death, took over his school. He died some time in the first six years of the fourth century.

Porphyry can be called a founder of Neoplatonism because, while the philosophy he upheld was in the main that of Plotinus, he made it possible for this philosophy to become, as it did, an institution throughout the Roman Empire. He arranged Plotinus's lectures for publication in their present form; he defended and developed their content in independent works of his own; third, he enabled

some of the much more systematic, not to say more teachable, philosophy of Aristotle to be included even by Platonic professors in a university curriculum.

In the so-called *Sententiae ad Intelligibilia Ducentes* (Aids to the Study of the Intelligibles; a short, difficult summary, incomplete as we have it, of Neoplatonism) he presents methodical proofs of two Plotinian theses which were unacceptable to the more conservative Platonists and to Porphyry himself when he first came to Rome: the independence and priority of the One to Being or Intellect, and the identity of Intellect or Thought with its objects. Plotinus, however, had been ambiguous over the extent to which the lower hypostases, Intellect (embracing the Platonic forms) and Soul (embracing nature and the Aristotelian forms), each existed in its own right. It is the monistic strand that seems to dominate in Porphyry: Everything that is not the One is an appearance of the One and is the result of the inadequacy of our thought about the One. The serious consequence of this doctrine is for the ordinary notion of personality. The individual, embodied soul and intellect, themselves appearances (he also calls them parts) of some universal soul and intellect, will be unreal; Porphyry calls the individual soul “the soul in a relation”—for it is related to a body—which implies its nonsubstantiality according to Aristotle’s doctrine of categories. This consequence was vigorously challenged by Iamblichus. Union with the One can be achieved, according to Porphyry, by the unaided effort of intellect, but we do not have enough evidence to know how he met the philosophical problems of this thesis even if he had a consistent doctrine about it.

Porphyry’s ethics followed Plotinus in stressing the universal equation between pursuit of the good, becoming what one “essentially” is, the self-awareness that accompanies thought, and “reversion” to the “cause” of one’s being. Evil, together with matter, was the result of a “deviation from reality.” In schematizing *Ennead* I 2 [19], Porphyry gave Plotinus’s scale of virtues a nomenclature which became conventional for later Neoplatonists. *A*, the virtues of the soul, are (1) civic, (2) purificatory; *B*, the virtues of the intellect, are (3) contemplative, (4) paradigmatic. Less abstractly and on less philosophical grounds he was attracted like many Neoplatonists by the asceticism and taboos of Pythagoreanism.

Nothing has survived of a book that Porphyry wrote comparing Platonism and Aristotelianism. It undoubtedly maintained that there was no substantial conflict between the two, which was commonplace for Platonists of the empire. His commentaries on Plato have perished too; so have those on Aristotle, except for the introduc-

tion to the *Categories* known as the *Isagoge* and an elementary commentary on the same work. But his views were often quoted; and it is clear that what is distinctive about his treatment of Aristotle is twofold—a facility in expounding him without trying to Platonize him or to score against him, and a remarkable gift of clear exposition that does not depend (as it does in some later commentators) on ignoring the difficult issues. Most of the formulas that aimed at accommodating the metaphysical presuppositions of Aristotle’s logic to Platonism had probably been worked out already. But since it was only the metaphysics that was objectionable, the way was open to the full acceptance of a purely formal logic. This meant not the Aristotelian logic of terms from which the nonexistent, the negative, and the particular were excluded, but something roughly equivalent to the Boolean algebra of classes.

This logic without metaphysics is roughly, too, what we find in Porphyry; and it is what has sometimes been inaptly called Porphyry’s nominalism. With some debt to the Stoics, it enabled logic to develop as an autonomous science. For his *Isagoge* was translated into Arabic and Syriac as well as Latin, and his more advanced work was incorporated in Boethius’s logic. The *Isagoge* is traditionally said to have made species a fifth predicable in place of definition. If it had it would have misrepresented Aristotle by implying that the subject was not a universal term, like those of the other predicables, but a particular. The implication might not have disturbed Porphyry, but in fact the *Isagoge*, or *Quinque Voces*, is not about predicables but what it says it is about, the five words that are essential to the understanding of the *Categories*. It does, however, introduce “inseparable accidents” which are an uneasy intermediate between essential attributes and pure or separable accidents.

Porphyry was a man of wide learning and wide interests. He studied many of the religious beliefs and practices with which he came into contact, and though generally sympathetic to them as various if inferior ways to salvation, he was renowned for centuries as the author of a detailed work against the Christians. But this and ventures of a more or less occultist nature—allegorical interpretations of poetry, descriptions of the soul’s “vehicles,” and the like—have mostly survived only in statements from controversial sources; and while respectable as philosophy in their day they are of small philosophical interest in the modern sense.

## PORTER, NOAH (1811–1892)

Noah Porter was an American Congregationalist clergyman, philosopher, and psychologist, and president of Yale College from 1871 to 1886. As a student in the Yale Divinity School, Porter had become a disciple of Nathaniel W. Taylor's modified version of New England Calvinism. For ten years he preached Taylorism at churches in New Milford, Connecticut (1836–1843), and Springfield, Massachusetts (1843–1846). He was then appointed Clark professor of moral philosophy and metaphysics at Yale, holding this chair throughout his tenure of the presidency of the college. On retiring from the office of president, he resumed a small teaching load until his death.

Porter's thought until 1853 was dominated by the conventional Scottish commonsense realism that pervaded American colleges. Then two years spent in Europe, largely in study at the University of Berlin, increased his familiarity with more recent and more daring philosophical systems. He became particularly interested, through the German philosopher Friedrich Adolf Trendelenburg, in the central epistemological problems of modern philosophy. Porter was convinced that these

problems had to be solved before any advance in ontology could be expected. Moreover, he believed that the epistemological questions themselves required a foundation in scientific psychology.

This conviction and a much keener appreciation of the value of the history of thought than was usual among American philosophers of his time, led Porter to the preparation and publication of his important treatise *The Human Intellect*, the best work on psychology in English before William James. Porter presented and critically examined the leading ideas of both English and European (chiefly German) schools of psychology, as well as summarizing earlier work in the field. Because he regarded psychology as a necessary prelude to epistemology which, in turn, he considered prior to metaphysics, he insisted that psychology had to be an inductive science and roundly criticized G. W. F. Hegel for attempting to ground psychology in his metaphysical system. Although inductive, however, psychology cannot be a material or experimental science. Its subjects are the data of consciousness, which must be discovered introspectively; physiological experiments and investigations must be kept in mind by the psychologist, but these studies are ancillary to the direct study of the data of consciousness.

The influence of this major work and of Porter's many lesser writings was one of the chief forces in liberating academic philosophy in America from domination by naive realism and in introducing the study of German philosophy and psychology.

Among the nonphilosophical activities of Porter, special note should be taken of his editorship, with Chauncey A. Goodrich, of a revised edition of Noah Webster's *An American Dictionary of the English Language* (Springfield, MA, 1864). This work was revised under Porter's sole supervision as *Webster's International Dictionary of the English Language* (1890).

## POSIDONIUS

(135–51? BCE)

Posidonius of Apameia, the Stoic philosopher, was famous in his own time and continued to influence writers into the first and second centuries CE. Soon after, his writings seem to have been lost, and even his name is rarely mentioned. Known to modern historiography mainly from the mention of his views in Cicero, Strabo, Seneca, and Galen, he was considered from the Renaissance to the beginning of the nineteenth century as a minor figure in the development of Stoicism. Then his thought began to be discovered in an ever-increasing number of writers, who were believed to follow him although they do not quote him, and he was established as the mediator between the Orient and the Occident, the reconciler of philosophy with religion and mysticism, the foremost representative of dualism. In the early twentieth century the reconstruction of Posidonius's work through *Quellenforschung* ("source criticism") was replaced by a reconstruction based on the inner form of his thought, and Posidonius was represented as a visual thinker, the defender of monism, the proponent of the doctrines of cosmic sympathy and vitalism, and the last Hellenistic philosopher. Both interpretations pay little attention to the fragments preserved under the name of Posidonius and therefore remain largely conjectural. What will be said here is based exclusively on the attested material.

This material leaves no doubt about the fundamentally dualistic character of Posidonius's system. His ethics, which is the best-known part of his thought, teaches, contrary to the general Stoic dogma, that passions are not

simply false judgments but an irreducible force in human nature. This distinction is also echoed in Posidonius's physics in the again unorthodox definition of matter as endowed with its own form and quality, which is merely reshaped and remodeled by divine reason. His logic establishes reason as a criterion of truth independent of sense perception. On the other hand, the duality of matter and reason is bridged by the realm of mathematical forms; among the Stoics only Posidonius was a mathematical realist. The macrocosm and the microcosm are in the end viewed as gradated, as hierarchies as it were, in which reason governs the subordinate irrational forces. God pervades the world; the passions follow the leadership of rational insight; man is here to contemplate and to act.

The Platonic and Aristotelian elements in this Stoicism were noted even by ancient critics. In Posidonius's opinion the founders of the Stoa, Zeno and Cleanthes themselves, had been Platonizing and Aristotelianizing. The strict monism of the school was due to Chrysippus, whose work Posidonius thought had to be undone. Yet although Posidonius harked back to the older teaching and in this sense remained in the Greek tradition—he was innocent of the later Orientalizing—he undoubtedly made an original contribution to philosophy. His ethics is a greatly refined analysis of the emotions that refutes the rationalistic position by pointing to its inner inconsistency and its inconsistency with observed facts. He stressed the importance of the will. Although only a few details of his physics can be rediscovered, it is clear that he was intent on explaining things; he was famous for his etiologies, and he carefully distinguished the various causes, assigning first place to teleology. Cosmic sympathy is but one of the factors he invoked in his exegesis of nature. His logical investigations furthered the understanding of syllogistic thinking, which seemed to him validated not by linguistic connections but by implied axioms. In short, his system marks a step forward in the history of Greek rationalism, and this is in accord with Posidonius's belief in the gradual development of knowledge and in the idea of progress, which he, like so many earlier Greek rationalists, upheld.

Posidonius's contributions were, however, not restricted to the field of philosophy proper. He wrote a history of his own time and in it, if not separately, dealt copiously with the rise of civilization, which he claimed began with practical inventions made by philosophers. In the historical process itself he detected the dominance of freedom over circumstance. Several of his books were devoted to natural sciences, such as astronomy and mete-

orology; he also investigated problems of mathematics and of military tactics. Perhaps the greatest significance of these works lies in the fact that they do not isolate scholarly and scientific research but put it in a philosophical framework. Events are seen as part of the history of the cosmos. Scientific explanations are hypotheses, the correctness and adequacy of which must be judged through philosophical reflection. It was as a philosopher that Posidonius felt impelled to reject the heliocentric theory in favor of the geocentric theory. Although he erred in this respect, he did enforce the idea of the hypothetical character of all scientific knowledge and did restore the unity of the sciences which Hellenistic thought had destroyed.

The stoa of the empire, initially influenced by Posidonius, tended more and more to follow Chrysippus. Thus, the philosopher Posidonius soon lost importance. His scientific writings kept the Greek heritage alive much longer and carried it, through Seneca's *Naturales Quaestiones*, into the Middle Ages. If one judges his achievement and his influence, one cannot compare him with Plato, Aristotle, or Democritus or with Zeno, Epicurus, or Plotinus. It is fair to say, however, that his personality, which he allowed to intrude into his work, makes him one of the most attractive figures among ancient philosophers. He was a man of dignity and not without a sense of irony and humor. He lived the dogma he preached, studying and teaching as well as participating in the political affairs of Rhodes, his adopted city. The variety of his gifts is amazing—his dialectical skill, traced by Galen to his mathematical erudition; the keenness of his powers of observation of men and things, which is especially marked in his reports on the travels that took him throughout almost the whole of the then-known world; and the strength of his analytical ability, along with his love of literature and art. It was perhaps the universalism of his nature that made it possible for him not only to attempt a new explanation of the universe in all its aspects, doing justice to both man's cognitive and his practical concerns, but also to root human existence—for the last time in antiquity, it seems—in the world of reality without depriving this world of the reign of human reason, which he considered of the same nature as the divine spirit ruling the cosmos.

## Bibliography

The approach of *Quellenforschung* has been criticized, and criticized fairly, by J. F. Dobson, "The Posidonius Myth," in *Classical Quarterly* 12 (1918): 179ff. For Posidonius as a monist see K. Reinhardt, *Poseidonios* (Munich: C.H. Beck, 1921); see also his *Kosmos und Sympathie* (Munich: C.H. Beck, 1926) and A. Pauly and G. Wissowa, *Realencyclopädie der classischen Altertumswissenschaft*, Vol. XXII (Stuttgart, 1953), Part I, Cols. 558–826. I. Heinemann, *Poseidonios' metaphysische Schriften*, 2 vols. (Breslau, 1921–1928), considers Posidonius especially in relation to his predecessor Panaerius.

For a reconstruction of Posidonius's philosophy according to the attested fragments see Ludwig Edelstein, "The Philosophical System of Posidonius," in *American Journal of Philology* 57 (1936): 286ff. For the historical fragments see F. Jacoby, *Die Fragmente der griechischen Historiker*, Vol. II, No. 87 (Berlin: Weidmann, 1926). The collection of fragments by I. Bake, *Rhodi Reliquiae Doctrinae* (Leiden, 1810), is antiquated.

*Ludwig Edelstein (1967)*

## POSIDONIUS [ADDENDUM]

Modern study of Posidonius has been transformed since the mid-1960s by the collection of ancient evidence compiled by Ludwig Edelstein and Ian G. Kidd (1972), and minutely analyzed by Kidd (1988, 1999), which contains only texts that name Posidonius explicitly. The picture presented is undoubtedly too narrow, and an accurate assessment of Posidonius's achievement and influence must await further study of other texts in which his influence may be reliably detected. But even the newly circumscribed picture has made it increasingly clear that Posidonius largely adhered to basic Stoic doctrines and principles and that his main innovations lie in his breathtakingly comprehensive effort to integrate both natural and human sciences into Stoic cosmology, epistemology, and ethics. His range was encyclopedic, and while the bulk of his massive output was in physics (embracing also metaphysics, theology, and the special sciences), there is little he neglected.

In metaphysics Posidonius sought to reconcile Stoic materialism with its quasi-dualist principles of matter and God (which are thoroughly blended together throughout the universe), and to explicate the incorporeal status of time, void, and bodily limits (points, lines, and surfaces). In logic relatively little is securely attested: work on the logic of relations and on axiomatic method in mathematics. He also analyzed the structure of scientific explanation (etiology): Subordinating mathematical

sciences to philosophy, he emphasized material and teleological factors in ways that suggest Aristotelian influence (Rhodes, where he worked most of his life, had a tradition of Aristotelian studies, and Andronicus of Rhodes [first century BCE], a younger contemporary, had a prominent role in reviving study of Aristotle's treatises).

Posidonius's scientific work had substantial impact on many later Stoics (notably Lucius Annaeus Seneca, Cleomedes [fl. c. 100 CE], and Geminus [10 BCE–60 CE]) and on ancient science and philosophy more widely (including Strabo [c. 64 BCE–after 23 CE] and Galen). Spanning astronomy, meteorology, geophysics, and geography, his work shows a concerted effort to extend the scope and empirical basis of Stoic theories. Problems he tackled include the size and distance of the sun and moon, the size and climatic zones of the earth, eclipses, comets, rainbows, clouds, thunder, winds, earthquakes, volcanoes, hydrodynamics, and mineralogy. Especially impressive is his theory of oceanic tides, which he correlated with the daily, weekly, and annual periodic motions of the moon; detailed observation here revealed systematic links between celestial and terrestrial phenomena that exemplify the principle of cosmic interaction (sympathy) underlying Stoic determinism and its providential design.

In ethics Posidonius upheld the central doctrines of Stoic Eudaemonism: virtue is a form of knowledge, only it (and anything possessing it) is genuinely good, and it is entirely sufficient for happiness (eudaimonia). He also brought new rigor to Stoic psychology by subjecting previous accounts of emotion and emotional behavior to precise critical analysis. Tendentious evidence in Galen has convinced many scholars that Posidonius rejected the monistic psychology of Chrysippus in favor of a Platonizing dualism, but recent studies (Cooper, Tieleman) argue that he sought rather to defend Stoic intellectualism by analyzing the structure of human motivation more closely. Similar concerns are evident in his massive *History* (fifty-two books covering 146 to 80s BCE—from a Roman defeat of federated Greece to an invasion of Athens), where ethics and ethnography combine with climatology and geography to explain both customs and historical events.

## POSITIVISM

The term *positivism* was used first by Henri, Comte de Saint-Simon to designate scientific method and its extension to philosophy. Adopted by Auguste Comte, it came to designate a great philosophical movement which, in the second half of the nineteenth century and the first decades of the twentieth, was powerful in all the countries of the Western world.

The characteristic theses of positivism are that science is the only valid knowledge and facts the only possible objects of knowledge; that philosophy does not possess a method different from science; and that the task of philosophy is to find the general principles common to all the sciences and to use these principles as guides to human conduct and as the basis of social organization. Positivism, consequently, denies the existence or intelligibility of forces or substances that go beyond facts and the laws ascertained by science. It opposes any kind of metaphysics and, in general, any procedure of investigation that is not reducible to scientific method.

The principal philosophical sources of positivism are the works of Francis Bacon, the English empiricists, and

the philosophers of the Enlightenment; but the cultural climate that made it possible was that of the eighteenth-century Industrial Revolution and the grand wave of optimism to which the first successes of industrial technology gave rise. Positivism made this climate into a philosophical program—that is, a universal project for human life. It exalted science without concerning itself (as does contemporary positivism) with the conditions and the limits of the validity of science, and it claimed that not only ethics and politics but also religion would become scientific disciplines. In one direction, this led to an attempt to establish a “positive” religion in place of traditional theological religions.

Through its acceptance of the concept of the infinity of nature and of history and, therefore, of necessary and universal progress, positivism had affinities with the other important nineteenth-century philosophical movement, absolute idealism, and belongs with it in the general range of romanticism.

There are two fundamental kinds of positivism: social positivism, with a professedly practicopolitical character, and evolutionary positivism, with a professedly theoretical character. Both share the general idea of progress, but whereas social positivism deduces progress from a consideration of society and history, evolutionary positivism deduces it from the fields of physics and biology. Comte and John Stuart Mill are the principal representatives of social positivism, and Herbert Spencer of evolutionary positivism. A materialistic or spiritualistic metaphysics is often associated with evolutionary positivism. A third, critical type of positivism, also known as empiriocriticism, should be distinguished from both social and evolutionary positivism. Contemporary forms of positivism—logical positivism and neopositivism—are directly connected with critical positivism.

## SOCIAL POSITIVISM

Social positivism arose in France through the work of Saint-Simon and other socialistic writers (Charles Fourier, Pierre Joseph Proudhon) and in England through that of the utilitarians (Jeremy Bentham and James Mill), who, in turn, considered their work closely associated with that of the great economists Thomas Malthus and David Ricardo. Social positivism sought to promote, through the use of the methods and results of science, a more just social organization. According to Saint-Simon, men now lived in a critical epoch because scientific progress, by destroying theological and metaphysical doctrines, had eliminated the foundation of the social organization of the Middle Ages. A new organic

epoch, in which positive philosophy would be the basis of a new system of religion, politics, ethics, and public education, was required. Through this system society would regain its unity and its organization by basing itself on a new spiritual power—that of the scientists—and a new temporal power—that of the industrialists. In his last writing, *The New Christianity* (1825), Saint-Simon considered the new organic epoch to be a return to primitive Christianity.

COMTE. Saint-Simon’s ideas inspired the work of Auguste Comte. The point of departure of Comte’s philosophy is his law of the three stages. According to this law, both the general history of humanity and the development of the individual man, as well as that of every branch of human knowledge, passes through three stages: the *theological*, or fictitious, stage in which man represents natural phenomena as products of the direct action of supernatural agents; the *metaphysical* stage, in which the supernatural agents are replaced by abstract forces believed to be capable of generating the observable phenomena; and, finally, the *positive* stage, in which man, refusing to seek the ultimate causes of phenomena, turns exclusively toward discovering the laws of phenomena by observation and reasoning. The positive stage is that of science, whose fundamental task is to predict phenomena in order to use them.

“Science whence comes prediction; prediction whence comes action” is the formula in which Comte epitomized his theory of science. The formula, as Comte himself recognized, expresses exactly Francis Bacon’s point of view. The law of the three stages permits the classification of the sciences according to the order in which they entered into the positive phases—an order determined by the degree of simplicity and generality of the phenomena which are the objects of each science as it reaches the positive phase. Thus, according to Comte the following hierarchy constitutes “a necessary and invariable subordination”: astronomy, physics, chemistry, biology, and sociology. Mathematics remains outside this order because it is at the basis of all the sciences; psychology, because it is not a science, also remains outside. Psychology should be based on introspective observation. But introspective observation is impossible, because the observed and observing organ would have to be identical. The apex of the hierarchy of sciences is sociology, or social physics, which Comte divided into social statics, or theory of order, and social dynamics, or theory of progress.

Progress is a necessary law of human history: The realization of progress is entrusted not to individuals, who are only the instruments of progress, but to the true subject of history—humanity, conceived as the Great Being in which past, present, and future beings partake. “We always work for our descendants, but under the impulse of our ancestors, from whom derive the elements and procedures of all our operations” (*Politique positive*, Vol. IV, pp. 34–35). Humanity is the continuous and uninterrupted tradition of the human race, and it is the divinity that must replace the God of traditional religions. The wisdom and providence of humanity preside infallibly over the realization of progress. At the end of progress there is sociocracy, a new absolutist social regime based on science and the religion of humanity and directed by a corporation of positivist philosophers. Sociocracy, by limiting liberties, will make impossible any deviation from the fundamental beliefs of the positivistic cult.

In his last work, *Philosophy of Mathematics* (1856), Comte proposed a new kind of religious trinity, the Great Being (humanity), the Great Fetish (Earth), and the Great Way (space). The religious aspect of Comte’s philosophy drew a great number of followers and generated the greatest wave of enthusiasm. Pierre Lafitte and Émile Littré in France, Richard Congreve and G. H. Lewes in England were the most philosophical of Comte’s first disciples. The influence of Comte’s religious thought, however, rapidly exhausted itself, except among small groups of devotees, while his philosophical ideas (the law of the three stages; the conception of science as description and prediction; the theory of progress; and sociology as a positive science) have exercised a lasting influence on science and philosophy.

**BENTHAM AND THE MILLS.** Comte’s English contemporaries, the utilitarians Jeremy Bentham and James Mill, presented with equal force, although more modestly, the fundamental requirement of positivism: that every kind of valid knowledge be included within science. They sought to establish a science of mind based on facts, as is the science of nature, and tried to make ethics itself, as Bentham used to say, an “exact science.” They considered the mind to be an associative mechanism, ruled by precise laws whose constitutive elements are sensations, which were regarded as the ultimate facts of mind. Traditional ethics was substantially a theory of the end of human conduct: It established by a priori means what that end was and deduced from it the rules of conduct. Bentham and Mill intended to substitute for traditional ethics a theory of the motives of conduct—that is, of the specific

causes of conduct. If it were ascertained what are the motives and the rules that human beings obey, Bentham and Mill believed, it would be possible to direct human conduct in the same way that nature can be controlled by knowing its causal laws.

These principles remained fundamental in later developments of positivism, first in the work of John Stuart Mill, who was influenced by both Saint-Simon and Comte. Mill, like Saint-Simon and Comte, spoke of reorganizing society on new foundations. He rejected, however, the doctrinaire political and religious absolutism of Comte and defended instead the freedom and development of the individual, to whom he considered the social organization subordinate. Mill’s classic *Principles of Political Economy* (1848) concluded by determining the limits of governmental intervention in economic affairs—limits required so that there would be in human existence “a sacred fortress safe from the intrusion of any authority.”

Mill’s *System of Logic* (1843), which is perhaps the most important work of nineteenth-century positivism, contains a fundamental correction of Comte’s view of science. Comte had stressed the rational aspect of science and considered its experimental basis, the verification of facts, as merely preparatory to the formulation of laws. He had excluded the notion that once they were formulated, laws could again be subjected to the test of facts and eventually placed in question by “a too detailed investigation,” and he had prescribed for scientific investigation a series of limitations to keep it from being transformed into “a vain and at times a seriously disturbing curiosity.” Mill’s logic, instead, appealed to a radical empiricism and avoided any dogmatizing of scientific results. The very principles of logic, according to Mill, are generalizations of empirical data, and induction is the only method that science has at its disposal. The basis of induction itself, the principle of the uniformity of the laws of nature, is, in turn, an inductive truth, the fruit of many partial generalizations. Prediction is possible in science only on the basis of past experience, which alone furnishes the evidence both for the major premise and for the conclusion of the traditional syllogism. “‘All men are mortal’ is not the proof that Lord Palmerston is mortal; but our past experience of mortality authorizes us to infer *both* the general truth and particular fact with the same degree of certainty for one and the other” (*System of Logic*, Bk. II, Ch. 3).

Like the other utilitarians, John Stuart Mill held that the human mind has the same structure as natural phenomena and is knowable in the same ways. “If we knew the person thoroughly, and knew all the inducements

which are acting upon him, we could foretell his conduct with as much certainty as we can predict any physical event" (*System of Logic*, Bk. VI, Ch. 2, 2). To make such predictions possible, he held that a new science, ethology, was needed to study the laws of the formation of character. Mill placed this science alongside Comtian sociology, to which he attributed the task of discovering the laws of progress that make it possible to predict social events infallibly (*ibid.*, Ch. 10, 3).

Mill held that even religion should be based on experience. Experience, by suggesting that there is a limited and imperfect ideological order in nature, permits belief in a divinity of limited power, a kind of demiurge. Such belief encourages a religion of humanity based upon an altruistic ethics and the "supernatural hopes" of humankind.

**SOCIAL POSITIVISM IN ITALY AND GERMANY.** In Italy social positivism had two defenders, Carlo Cattaneo and Giuseppe Ferrari. Both were influenced by the work of Saint-Simon, and both saw him as a continuer of the work of Giambattista Vico, whom they credited with having founded "a science of man in the very heart of humanity."

The German social positivists Ernst Laas, Friedrich Jodl, and Eugen Dühring appealed to Ludwig Feuerbach rather than to Saint-Simon and Comte. But faith in science, in progress based on science, and in a perfect social form to which this progress must lead was the inspiration of all social positivists.

### EVOLUTIONARY POSITIVISM

Evolutionary positivism shared the faith in progress of social positivism but justified it in a different way. Evolutionary positivism is based not on society or history but on nature, the sphere of physics and biology. Its immediate forerunners were the work of the geologist Charles Lyell and the doctrine of biological evolution. Lyell, in *The Principles of Geology* (1833), demonstrated that the actual state of Earth is the result not of a series of cataclysms (as Georges Cuvier had argued) but rather of the slow, gradual, and imperceptible action of the same causes that are acting before our eyes. The doctrine of evolution triumphed in 1859 with the publication of Charles Darwin's *Origin of Species*, which first presented adequate proofs of biological evolution and formulated the doctrine in a rigorous way. Lyell's and Darwin's doctrines made possible the formulation of the idea of a natural and necessary progress of the whole universe, beginning with a cosmic nebula and, through the unin-

terrupted development of the inorganic and organic world, continuing into the "superorganic" development of the human and historical world. It is superfluous to note that the scientific theories that furnish the occasion for the rise of the idea of evolutionary positivism do not constitute the elements of a sufficient proof of it, since it is so highly generalized a hypothesis that it seems to be of a metaphysical nature. Darwin himself remained "agnostic" (to use the term created by another biological evolutionist, T. H. Huxley) with respect to all problems that concern the universe in its totality.

**SPENCER.** The importance of Herbert Spencer, however, and the lasting influence of his work, depends on his defense of universal progress as a continuous and unilinear evolution from a primitive nebula to the more refined products of human civilization. Spencer used the term *evolution* in preference to progress in an early programmatic article of 1857, and even then he saw universal progress as modeled on biological evolution. His definition of evolution as "the passage from the homogeneous to the heterogeneous" or from the simple to the complex was suggested by the development of vegetable and animal organisms, whose parts are chemically and biologically indistinct at first but which then differentiate to form diverse tissues and organs. Spencer held that this process can be discovered in all fields of reality and that each of these fields has a specific science whose task is to recognize and clarify its characteristics. Philosophy is (as Comte conceived of it) the most generalized knowledge of the process of evolution. The role of philosophy begins with the widest generalizations of the individual sciences; from these generalizations it seeks to realize a "completely unified" knowledge. However, neither philosophy nor science, according to Spencer, can take the place of religion.

The truth of religion is that "the existence of the world with all that it contains and all that it encompasses is a *mystery* that always needs to be interpreted" (*First Principles*, London, 1862, Par. 14). All religions, however, fail in giving this interpretation; therefore, the sole task of authentic religion is to serve as a reminder of the mystery of the ultimate cause. The task of science, on the other hand, is to extend indefinitely the knowledge of phenomena. Like William Hamilton and Henry Mansel, Spencer held that human knowledge is enclosed within the limits of the relative and the conditioned, that is, within the limits of phenomena. Beyond these limits there is the unlimited and unknown force on which all phenomena depend. The unknowability of this force is revealed in the insolubility of certain problems at the limits of philosophy and science, such problems as those concerning the

essence of space, of time, of matter, and of energy, the duration of consciousness (whether finite or infinite), and the subject of thought (whether it is the soul or not).

If Comte's religion of humanity had little success among philosophers and scientists, Spencer's agnosticism found many adherents among them, and for a few decades it was a required attitude for intellectuals generally. Other positivists, however, such as Roberto Ardigò, rejected agnosticism and denied that one could speak of an "unknowable" in an absolute sense. Ardigò, moreover, wanted to redefine the process of evolution by considering it as "a passage from the indistinct to the distinct," referring to psychological experience rather than to biology.

Spencer wrote on many fields of knowledge—biology, sociology, ethics, politics, and education. When he turned his attention to sociology, he attempted to rescue it from the practical and political task that Comte had assigned to it and to consider it as a theoretical discipline whose task is to describe the development of human society to its present state. This change was accepted by such positivist sociologists as John Lubbock, Edward Tylor, Émile Durkheim, and William Graham Sumner, who were strongly influenced by Spencer.

Evolutionary positivism is, in its more rigorous form, as far from materialism as it is from spiritualism. Spencer affirmed (*First Principles*, Par. 194) that the process of evolution can be interpreted both in terms of matter and movement and in terms of spirituality and consciousness: The Absolute that it manifests can be defined neither as matter nor as mind. Positivism embraces both trends that interpret the concept of evolution materialistically and trends which interpret it spiritualistically. The laws of the conservation of matter discovered by Antoine Lavoisier (1789) and the laws of the conservation of energy implicit in Robert Mayer's discovery of the equivalence of heat and work (1842) were taken as proofs of the hypothesis that a single substance, of which matter and energy are inseparable attributes, is the eternal subject of cosmic evolution and necessarily determines all its characteristics.

**HAECKEL AND MONISM.** The German philosopher Ernst Haeckel termed the view that matter and energy are inseparable attributes of one basic substance "monism" and utilized it to combat the dualism that he held was proper to all religious conceptions based on the duality of spirit and matter, of God and the world. Haeckel also found a decisive confirmation of biological evolution and of its necessity in what he termed the "fundamental

biogenetic law" of a parallelism between ontogeny, the development of an individual, and phylogeny, the development of the species to which that individual belongs. Monism was accepted by many chemists, biologists, and psychologists and became popular through the diffusion of Haeckel's writings and of such other works as Ludwig Büchner's *Force and Matter* (1855).

Monism also inspired literary and historical criticism. A passage from the introduction to Hippolyte Taine's *History of English Literature* (1863) has remained famous as an expression of this tendency: "Vice and virtue are products just as vitriol and sugar are, and every complex datum is born from the encounter of other simpler data on which it depends."

**LOMBROSO.** The positive school of penal law, founded by Cesare Lombroso, drew its inspiration from materialistic and especially from deterministic positivism. This school taught that criminal behavior depends on inevitable tendencies which are determined by the organic constitution of the delinquent. The structures of this constitution would be analyzed by a corresponding science—criminal anthropology.

**WUNDT.** Evolutionary positivism was also interpreted spiritualistically, notably by Wilhelm Wundt, who sought to substitute "psychophysical parallelism" for materialistic monism. Wundt's doctrine was that mental events do not depend on organic events but constitute a causal series by themselves and correspond point for point to the series of organic events. He made this doctrine the basis of his psychological investigations (Wundt founded the first laboratory of experimental psychology), and for many decades it remained the working hypothesis of experimental psychology. Wundt cultivated, moreover, a "psychology of peoples" that is descriptive sociology, in Spencer's sense. Like Spencer, Wundt intended it to be the study of the evolutionary process that produces institutions, customs, languages, and all the expressions of human society.

**INFLUENCE OF EVOLUTIONARY POSITIVISM.** Evolutionary positivism has left as a legacy to contemporary philosophy the idea of a universal, unilinear, continuous, necessary, and necessarily progressive evolution—an idea that forms the background and the explicit or implicit presupposition even of many philosophies which do not recognize their debt to positivism and which, in fact, argue against it. The idea of evolution is fundamental to the philosophies of C. S. Peirce, William James, and John Dewey, as well as to those of George Santayana, Samuel

Alexander, and A. N. Whitehead. Some of these philosophers have sought to remove the necessitarian character from the idea of evolution and to include within it an element of chance or freedom (Peirce, James, Dewey) or of novelty and creativity (Henri Bergson, C. Lloyd Morgan). Bergson, who interpreted evolution in terms of consciousness and insisted upon its creative character, explicitly acknowledged his debt to Spencer (*La pensée et le mouvant*, 3rd ed., Paris, 1934, p. 8). It is not without reason that his disciple Édouard Le Roy termed Bergson's doctrine a "new positivism," which means a new spiritualistic interpretation of cosmic evolution.

The vitality and the broad diffusion of the legacy of positivism is no sign of its validity. No scientific discipline is as yet able to adduce any sufficient proof in favor of a unilinear, continuous, and progressive cosmic evolution. In fact, in the very field where the phenomena of evolution have been most closely considered—biology—evolution seems to lack precisely those characteristics that positivism attributes to it.

## CRITICAL POSITIVISM

**EMPIRIOCITICISM.** In the last decade of the nineteenth century, positivism took on a more critical form through the work of Ernst Mach and Richard Avenarius. In Germany and Austria this critical positivism was known as empiriocriticism. Mach and Avenarius both held that facts (which for them, as for the other positivists, constituted the only reality) were relatively stable sets or groups of sensations connected to and dependent on each other. Sensations are the simple elements that figure in the constitution both of physical bodies and of perceptions or consciousness or the self. These elements are neutral, neither physical nor psychical, and every substantial difference between the physical and the psychical disappears. From this point of view, a "thing" is a set of sensations and the thought of the thing is the same set considered as "perceived" or "represented." For Avenarius, however, the process of interiorization, which he called introjection, and by which the thing is considered as a modification of the subject or as a part of consciousness, is a falsification of "pure" (that is, authentic or genuine) experience. For Avenarius and Mach, science, and knowledge in general, is only an instrument that the human organism uses to confront the infinite mass of sensations and to act in the light of those sensations in such a way as to conserve itself. The function of science is, therefore, economic, not contemplative or theoretical. It conforms to the principle of least action, and its end is the progressive adaptation of the organism to the environment.

Theories concerning concepts, scientific laws, and causality very different from those of classical positivism are the chief results of empiriocriticism. According to Mach a concept is the result of a selective abstraction that groups a large number of facts and considers those elements of these facts that are biologically important—that is, those adapted to excite the appropriate reaction in the organism. Since the variety of the biologically important reactions is much smaller than the variety of facts, the first task is to classify and simplify the facts by means of concepts, each of which constitutes the project of an appropriate reaction. And since the interests with which people confront facts are different, there are different concepts which refer to the same order of facts. The laborer, the doctor, the judge, the engineer, and the scientist all have their own concepts, and they define them in those restricted ways which are appropriate for stimulating the reaction or set of reactions in which each is interested.

The concept of law, which classical positivism conceived of as a constant relationship among facts (a relationship which in turn was considered as a fact) underwent a radical transformation in critical positivism. The Englishman Karl Pearson, in *The Grammar of Science* (1892), gave a kind of *summa* of the fundamental principles of the science of the time. Although Pearson's work utilized Machian concepts, it supplied Mach himself with many inspirations. Pearson affirmed that scientific law is a description, not a prescription: It "never explains the routine of our perception, the sense-impressions we project into an 'outside world.'" Instead of description, Mach preferred to speak of a restriction that the law prescribes on our expectation of phenomena. In any case, he added, "Whether we consider it a restriction of action, an invariable guide to what happens in nature, or an indication for our representations and our thought which bring events to completion in advance, a law is always a limitation of possibilities" (*Erkenntnis und Irrtum*, Leipzig, 1905, Ch. 23).

Mach and Pearson sought to free the notion of causality from the notion of force, which they regarded as an anthropomorphic interpolation. Mach held that the mathematical notion of function should be substituted for that of cause. When science succeeds in gathering various elements into one equation, each element becomes a function of the others. The dependence among the elements becomes reciprocal and simultaneous, and the relation between cause and effect becomes reversible (*Die Mechanik in ihrer Entwicklung*, 4th ed., Leipzig, 1901, p. 513). From this point of view, time, with its irreversible order, is real at the level of sensations and as a sensation.

The time of science is, on the other hand, an economic notion which serves for the ordering and prediction of facts.

Along the same lines, a disciple of Mach, Joseph Petzoldt, proposed to substitute for the principle of causality the “law of univocal determination,” which would also be applicable to cases of reciprocal action. According to this law, one can find for every phenomenon means that permit determination of the phenomenon in a way which excludes the concurrent possibility of different determinations. According to Petzoldt this law permits the choosing, from among the infinite conditions that either determine a phenomenon or are interposed between it and its cause, of those conditions which effectively contribute to the determination of the phenomenon itself.

Pearson drew from his descriptive concept of law the consequence that scientific laws have only logical, not physical, necessity: “The theory of planetary motion is in itself as logically necessary as the theory of the circle; but in both cases the logic and necessity arise from the definition and axioms with which we mentally start, and do not exist in the sequence of sense-impressions which we hope that they will, at any rate, approximately describe. The necessity lies in the world of conceptions, and is only unconsciously and illogically transferred to the world of perceptions” (*The Grammar of Science*, 2nd ed., London, 1900, p. 134).

The empiriocritical branch of positivism is the immediate historical antecedent of the Vienna circle and of neopositivism in general. The sense impressions spoken of by Pearson and the sensations spoken of by Mach, Avenarius, and Petzoldt as neutral elements that constitute all the facts of the world, both physical and psychical, correspond exactly to the objects (*Gegenstände*) spoken of by Ludwig Wittgenstein in his *Tractatus Logico-philosophicus* as the constituents of atomic facts and to the elementary experiences (*Elementarerlebnisse*) spoken of by Rudolf Carnap in *Der logische Aufbau der Welt*. The restriction of necessity to the domain of logic, and the consequent reduction of natural laws to empirical propositions, is also a characteristic of the neopositivism of Wittgenstein, Carnap, and Hans Reichenbach. The critique of the principle of causality frequently recurs in neoempiricism reinforced by consideration of quantum mechanics (Philipp Frank, Reichenbach). The emphasis on prediction, important at all levels of science, is also a result of both empiriocriticism and logical positivism, as is the principle of the empirical verifiability of scientific propositions and the need to test and correct them constantly.

What empiriocriticism lacks is the stress on logic and language that is central to contemporary neopositivism. This stress developed out of work done in mathematical logic, especially by Bertrand Russell. Empiriocriticism lacks the concern with logic and the preoccupation with the nature of mathematics and of logical principles that is characteristic of contemporary neopositivism. The view that the proper business of philosophy is the clarification of concepts or the analysis of meanings derives largely from Russell, as does the preoccupation with problems about the status of logical and mathematical principles. The so-called linguistic theory about the nature of logical and mathematical principles, although subsequently endorsed by Russell, was developed by Wittgenstein. The use of the verifiability principle to demarcate meaningful from meaningless sentences and questions derives ultimately from David Hume’s theory of impressions and ideas, but it is not to be found in any systematic form prior to the publications of the Vienna circle.

### **Bibliography**

- There are no complete studies on positivism. For the individual philosophers, see J. Watson, *Comte, Mill and Spencer: An Outline of Philosophy* (New York: Macmillan, 1895); Leslie Stephen, *The English Utilitarians*, 3 vols. (London: Duckworth, 1900); D. G. Charlton, *Positivist Thought in France during the Second Empire, 1852–1870* (Oxford: Clarendon Press, 1959); and W. M. Simon, *European Positivism in the Nineteenth Century* (Ithaca, NY: Cornell University Press, 1963), which is limited to Comte’s positivism and reactions to it.
- The best comprehensive exposition of positivism as a philosophy and general world view is Richard von Mises, *Kleines Lehrbuch des Positivismus: Einführung in die empiristische Wissenschaftsauffassung* (Den Haag: van Stockum, 1939), translated under the author’s supervision as *Positivism: A Study in Human Understanding* (Cambridge, MA: Harvard University Press, 1951). A briefer and more historical account, by another member of the logical positivist movement, is Hans Reichenbach, *The Rise of Scientific Philosophy* (Berkeley, CA: University of California Press, 1951). A less partisan overview (by a non-positivist) of positivist thought as a whole, emphasizing its unity while acknowledging its diverse ramifications and placing each episode in historical context, is Leszek Kolakowski, *The Alienation of Reason: A History of Positivist Thought*, translated by Norbert Guterman (New York, NY: Doubleday, 1968).
- On the Enlightenment forerunners to nineteenth-century positivism, Charles Coulston Gillispie, *Science and Polity in France: The Revolutionary and Napoleonic Years* (Princeton, NJ: Princeton University Press, 2004) provides the political and social background, while the ideas are the focus in Keith Michael Baker’s *Condorcet: From Natural Philosophy to*

*Social Mathematics* (Chicago: University of Chicago Press, 1975).

There are a number of valuable studies of the major nineteenth-century figures. On Comte, Robert C. Scharff, *Comte after Positivism* (Cambridge, U.K.: Cambridge University Press, 1995) and Juliette Grange, *La philosophie d'Auguste Comte: Science, politique, religion* (Paris: Presses Universitaires de France, 1996) both focus primarily on philosophical ideas. On Mill, John Skorupski, *John Stuart Mill* (London: Routledge, 1989) also puts philosophical content in the foreground. On the evolutionary positivists, however, most studies have focused on social, political, and cultural aspects. David Weinstein, *Equal Freedom and Utility: Herbert Spencer's Liberal Utilitarianism* (Cambridge, U.K.: Cambridge University Press, 1998), for instance, focuses entirely on political ideas, and the Monist movement is situated in its social context by Gangolf Hübinger. "Die monistische Bewegung: Sozialingenieure und Kulturprediger," in *Kultur und Kulturwissenschaften um 1900 II: Idealismus und Positivismus*, G. Hübinger, R. von Bruch, and F.W. Graf, eds. (Stuttgart: Steiner, 1997, 246–259). Two of the three major figures of critical positivism have been the subjects of informative life-and-works studies: John T. Blackmore, *Ernst Mach: His Work, Life, and Influence* (Berkeley: University of California Press, 1972), and Theodore M. Porter, *Karl Pearson: The Scientific Life in a Statistical Age* (Princeton, NJ: Princeton University Press, 2004). The importance of Mach in particular for later positivist thought is brought out by Richard von Mises in "Ernst Mach and the Scientific Conception of the World," in *Unified Science: The Vienna Circle Monograph Series Originally Edited by Otto Neurath, Now in an English Edition*, edited by Brian McGuinness, translated by Hans Kaal (Dordrecht: Reidel, 1987: 166–190), and by Philipp Frank in "The Importance for our Times of Ernst Mach's Philosophy of Science," in his *Modern Science and its Philosophy* (Cambridge, MA: Harvard University Press, 1949: 61–78).

A great deal of scholarly effort has been devoted since the 1980s to the excavation and philosophical reconstruction of logical positivism, particularly the Vienna Circle. One important strand in this literature has regarded the neo-Kantian roots of logical positivism as more important than the positivist influence going back to Comte, Mill, and the western Enlightenment; exemplary for this trend is Michael Friedman, *Reconsidering Logical Positivism* (Cambridge, U.K.: Cambridge University Press, 1999). The continuity between the Enlightenment and logical positivism, in contrast, has been stressed by Thomas Uebel, e.g. "Enlightenment and the Vienna Circle's Scientific World-Conception," in *Philosophers on Education; Historical Perspectives*, edited by A. O. Rorty (London: Routledge, 1998, pp. 418–438), and *Vernunftkritik und Wissenschaft: Otto Neurath und der erste Wiener Kreis* (Vienna: Springer, 2000). The occlusion of the political, social, and educational dimensions in logical positivism after its main figures emigrated to North America is discussed by George Reisch, *How the Cold War Transformed Philosophy of Science: To the Icy Slopes of Logic* (Cambridge, U.K.: Cambridge University Press, 2005). A useful handbook with comprehensive bibliographies of the major figures and many peripheral ones is Friedrich Stadler, *The Vienna Circle: Studies in the*

*Origins, Development, and Influence of Logical Empiricism*, translated by Camilla Nielsen et al (Vienna: Springer, 2001).

## POSNER, RICHARD

(1939–)

Richard Allen Posner, legal academic and federal court judge, was born in 1939 in New York. He was educated at Yale and Harvard Law School and has taught at the University of Chicago for many years. He was appointed to the federal appellate bench in 1981 and served as the chief judge of his court from 1993 to 2000. He is a leading advocate of the economic analysis of law and, by his own description, a legal pragmatist.

## ECONOMICS OF LAW

Posner has argued that the various doctrines of the common law can best be explained as wealth maximizing. To say that a transaction or institution is wealth maximizing is to say that it creates more wealth than alternative possible transactions or institutions. Wealth, in this usage, is the value that goods have in the hands of their owners, and the value that a thing will have in the hands of a particular person is, qualifications aside, the amount that that person is willing to pay for it. Thus, the goal of wealth maximization is reached when goods are placed in the hands of those who would be willing to pay the most for them. An example of a wealth-maximizing rule, according to Posner, is the negligence rule in tort law: Under the rule of negligence, properly understood, injurers are liable for the losses they cause only when they could have taken precautions that would have prevented the accidents for less than the expected cost (that is, the cost discounted by the likelihood) of the accidents themselves. If prospective injurers take precautions when and only when it would be cost effective to do so—which the rule of negligence gives them an incentive to do—then

the cost of accidents overall will tend to be minimized and the wealth of society will tend to be maximized.

Similarly, but more controversially, Posner has offered an economic explanation of the criminal law. Its major function, according to Posner, is to prevent people from bypassing the market system of voluntary exchange. When goods are exchanged voluntarily, as in a sale, wealth is increased since parties necessarily value what they have received in an exchange more highly than what they traded for it. When the market is bypassed, as in theft, there is no guarantee that the stolen good is valued more highly by the thief than by its owner. Similarly, Posner has argued (thereby creating a great deal of controversy) that one of the things wrong with rape is that it bypasses the marriage and sex market so that wealth tends to be decreased. For Posner this is one of the virtues of wealth maximization over utilitarianism: Wealth maximization can explain why rape is always a crime whereas he believes that utilitarianism would have to condone rape if the enjoyment of the rapist were greater than the pain and unhappiness caused to the victim.

Even if the common law does promote the maximization of wealth, the question remains whether it *should*. Posner believes that wealth maximization is an ethically attractive guide not only for the common law but for social institutions generally. A system that maximized wealth overall would maximize everyone's chance for a higher income and thus would elicit *nearly* universal consent *ex ante*—though Posner's consenting parties would not have to do so in ignorance of their personal attributes. All persons would know of their own productive capacity—the extent to which they can benefit others—so they would know approximately how they would do under wealth-maximizing laws. It is only the unproductive who would not consent: They would be less well off under a wealth-maximizing system.

## LEGAL PRAGMATISM

Posner believes that philosophical pragmatism is largely irrelevant to the law. By contrast, he believes that what he calls *everyday pragmatism* has a great deal to say. The everyday pragmatist—for example, the pragmatic judge—is an instrumentalist in law as in other things. Pragmatic judges are not bound by some conception of the law as an immutable body of rules but rather use their office to try to achieve reasonable resolutions to legal disputes. They reject moral, legal, and political theory (including constitutional theory) as guides to decision making. They are not bound by precedent, but neither are they bound to ignore it. Wise judges realize the virtues of

following precedent—the value of certainty in law, the importance of the reliance interest, the wisdom that inheres in some of the common law—but they are free to ignore it when they can do more good by ignoring it. When pragmatic judges must look beyond the law to settle legal disputes, as they often must, they will find no help in academic moral theory. They must rely on common sense and economics and other sciences, as well as on values that are widely shared.

Although Posner's pragmatic judges are free to follow precedent or not, as they see fit, Posner counsels restraint in constitutional adjudication, placing himself among those judges and theorists that belong to what he calls the *outrage* school: The problem is that most judges are lacking the factual knowledge and expertise in social science that would justify them in striking down legislation. Hence, judges should only declare legislation unconstitutional when it stirs a strongly negative reaction in them. When in the future judges do in fact have a better grasp of social science and the factual underpinnings of the various areas of law, the need for law itself as we understand it will begin to disappear—the *supersession* thesis. Antitrust law and administrative law are two areas of American law that illustrate the thesis: "It is fair to say that at the beginning of its second century antitrust law has become a branch of applied economics" (Posner 1999, p. 229).

Posner calls himself a moral relativist. He believes that there is no rational road to agreement with those of fundamentally different moral beliefs and—what is now largely uncontroversial—that there is no way to reach certainty in moral matters. It follows, he believes, that we cannot call the actions of someone in another culture immoral unless we add *by our lights*, though he does not explain what the difference is between saying that something is immoral and saying that it is immoral by our lights.

## POSSIBILITY

The subject of possibility is a central topic in philosophy. It was frequently discussed in the history of philosophy, and it is actively debated by contemporary philosophers.

### HISTORICAL DEVELOPMENTS

**ARISTOTLE.** The first comprehensive treatment of possibility occurs in the work of Aristotle. Aristotle's writing on this subject is difficult and confusing, but he seems to have held that the idea of possibility is derivative from that of necessity and negation, "It is possible that P" meaning "It is not necessary that not-P" (see *On Interpretation* 13.22b). Necessity of this basic kind is absolute necessity, and like absolute possibility it is applicable to sentences or propositions (*logoi*). According to his *Posterior Analytics* (4.21), a necessary proposition truly predicates something of a thing's essence; an example would be "A man is a rational being." A possible proposition, one that may be asserted to be such by a proposition containing the words "It is possible that ...," attributes an accident to a thing, an accident being a character that, because it is not excluded by a thing's essence, may or may not belong to it, as being seated may or may not belong to a man or woman. Because Aristotle held that what belongs to a thing's essence is given by a "real" definition, necessary propositions for him are either real definitions or logical consequences of such definitions.

**Formal possibility.** Although Aristotle's explicit remarks on absolute necessity relate to his theory of essences, he also uses a formal notion of necessity and, thus, of possibility, as when he argues that "Necessarily, every S is L" follows from "Necessarily, every M is L" and "Necessarily, every S is M." That the necessity and, correlatively, the possibility involved here is not the same as the real necessity and possibility just discussed is evident from the fact that the necessity of the conclusion "Every S is L" (and the impossibility of "Some S is not L") is justified wholly by the logical connection signified by "Every ... is ..." and by the sub-occurrences of "necessarily" in the modal syllogism. Important as this type of necessity and possibility obviously is to his theory of modal syllogisms, Aristotle does not seem to have reached the point

of formulating its meaning explicitly. (See the discussion of Aristotle's modal syllogisms in *The Development of Logic* [1963] by William Kneale and Martha Kneale.) There can be little doubt, however, that this formal notion of necessity is rooted in the necessity of the first principles of all reasoning, such as the principle of contradiction. These principles cannot be demonstrated, Aristotle said, because all demonstration presupposes them (see *Posterior Analytics* 1.3.72b). They are known immediately and intuitively, and they cannot be consistently questioned.

**Relative possibility.** In the *Prior Analytics* (1.19.23a) Aristotle distinguishes absolute from relative necessity, and he implicitly makes a similar distinction for possibility in various passages of the *Organon* (for instance, in *De Sophisticis Elenchis* 4.166a22–166a30). Just as a proposition that does not state an absolute necessity may be considered necessary relative to certain other propositions (as a contingent statement constituting the conclusion of a valid deductive argument may be considered necessary relative to the truth of the premises), so a proposition like "Jones is walking" may be considered impossible relative to the proposition "Jones is sitting," and "Jones is sitting" may be considered possible relative to "Jones is not running." Although this distinction is intuitively clear, Aristotle does not explicitly say whether relative necessity and relative possibility are to be understood by reference to the sort of real absolute necessity and possibility discussed earlier or whether, as is likely, they are to be understood in relation to the formal notions that he sometimes uses but does not explicitly define.

**Potentiality.** Another sort of possibility discussed by Aristotle is potentiality, for certain possibilities can be said to exist as potentialities of concrete things. The possibility of a person's reading this or that may be understood in relation to a potentiality (we would say an ability) that the person has. For Aristotle a person who can read is a potential reader. Although the notion of potentiality is basic to Aristotle's metaphysics, he thought it could be understood only by analogy: "As a man who is building is to one who knows how to build, as waking is to sleeping, that which sees to that which has sight but has eyes shut, that which is shaped out of matter to its matter, the finished product to the raw material, so in general is actuality to potentiality" (*Metaphysics* 1048b).

**MEGRIANS AND STOICS.** A definition of possibility widely accepted in the Hellenistic period was that of Diodorus Cronus of Megara, who said, "The possible is that which either is or will be true" (Kneale and Kneale

1963, p. 117f). This identification of possibility with, in effect, present and future actuality was challenged by the Stoics (for example, by Chrysippus), who defined real possibility as “that which is not prevented by any thing from happening even if it does not happen” (Kneale and Kneale 1963, p. 123). Because the Stoics tended to be strict determinists, holding that whatever happens is necessitated by something else, they typically argued that our assessment of nonactuals as possibles could be based only on ignorance, for any conceivable occurrence that does not take place at some time or other is presumably prevented from taking place by the course of nature. Thus, their conception of real possibility developed into a conception of what is now known as epistemic possibility, or possibility as consistency with our knowledge.

Because the Stoics were especially interested in formal logic, they had another conception of possibility, however. According to this conception, necessary propositions (that is, necessary sentences) are those that are always true, such as the propositions of logic and mathematics. Possible propositions are those that are sometimes true. Since today’s utterance of “A sea battle will occur tomorrow” is sometimes true according to the Stoics, then even though the course of nature may determine its truth with respect to tomorrow, the fact it states still belongs to the category of the possible (in the sense of sometimes true). It is perhaps worth adding that some commentators—for instance, Jaakko Hintikka (1959)—find this conception of possibility in Aristotle as well.

**NEOPLATONISTS.** The next distinctive conception of possibility, which turned out to be of great importance in medieval and modern philosophy, was worked out by the Neoplatonists—although it can be said to have its roots in Plato. According to this tradition, possibilities are not facts or states of affairs (that is, items properly expressed by sentences or propositions) but beings or essences that belong to *Nous* or Intelligence, the “first emanation of the One.” Aristotle had spoken of potential beings inherent in various matters—for instance, a statue of Hermes existing potentially in a chunk of marble—but the idea of a possible being, which cannot be understood in relation to what substances or matter will become under certain conditions or when operated on in a certain way, is evidently new.

Admittedly, the idea may in a sense be traced back to Plato, for a possible being thus conceived is essentially something thinkable or intelligible, and Plato identified the intelligible with the world of Ideas or Forms. But Plato’s Ideas were always general rather than specific, of

humanity rather than of Socrates, and this means that the only possibilities, in this sense, that Plato could accommodate were kinds or species. Such Neoplatonists as Plotinus admitted Ideas of individual souls, and these, being nongeneral, may be regarded as the prototypes of the possible beings that occur in the theories of later philosophers such as Leibniz.

An extremely important aspect of the Neoplatonist treatment of possibles is that all possible beings were held to be actualized; possibility and actuality were regarded, that is, as precisely coextensive. The basic reason for this was that the infinite perfection or “goodness” of the One, which “overflows” into the emanation constituting the world of diverse actuality, requires that every possible being be brought into existence or actualized. This principle of plenitude among actualities was thought to be necessary according to the nature of things, because it is an essential feature of the One’s perfection “to produce otherness” and “necessarily to do this in the maximum degree” (Lovejoy 1936, p. 66).

The Neoplatonic conception of possibles as Ideas in a divine mind that, owing to the perfection of that mind, are necessarily actualized was a recurrent and problematic theme in medieval philosophy. As A. O. Lovejoy pointed out in *The Great Chain of Being* (1936), medieval writers tended to conceive the love or goodness of the Christian God (in whose mind the Ideas were now said to exist) as an “immeasurable and inexhaustible energy,” a love of which “the only beneficiaries ... were not actual sentient creatures or already existing moral agents, but Platonic ideas, conceived figuratively as aspirants for the grace of actual existence” (p. 68).

**ABELARD.** Abelard, writing in the early twelfth century, was led to maintain that what can be is the same as what can be produced by God and that “it is intrinsically impossible for God to do (or make) or to leave undone (or unmade) anything other than the things that he actually does at some time do or omit to do; or to do anything in any other manner at any other time than that in which it actually is done” (Lovejoy 1936, p. 71).

**AQUINAS.** Because Abelard’s view of possibility and actuality seemed not only to deny God’s divine freedom but also, in implying that the created world was so good that it could not be better, to “make the creation equal to the Creator,” it was regarded as heretical (Lovejoy 1936, p. 73). Accordingly, other Schoolmen, who like Aquinas agreed that “all things preexist in God by their types (*rationes*),” had to maintain that the creation involved a

selection among the ideas. In this view not all possibles are actual, and what is actual is not necessary: There are, that is, possible beings that God could have created but did not create, and he did not have to create the things that he did create. To square this claim with God's goodness, Aquinas found it necessary to invoke the Aristotelian distinction between absolute and relative necessity and possibility. Although it is absolutely possible for God, good as he is, to have created things other than what he did create, it may nevertheless be admitted that, relative to his choice, which was "becoming to" rather than necessary to his goodness, the existence of what is actual is necessary and could not be otherwise. That is, relative to this premise, it is impossible for anything to exist that does not sooner or later actually exist.

Even granting the distinction between absolute and relative possibility, it might be objected that Aquinas is still imposing a limit on God's freedom. If what actually exists is determined by God's selection from a class of possibilities, it would appear that God could not, in an absolute sense, have created anything not belonging to this class. In reply to this Aquinas maintained that what is absolutely impossible is self-contradictory and that what is self-contradictory is contrary to God's nature, repugnant to being, and therefore not an object at all. ("So it is better to say that what involves a contradiction cannot be done rather than God cannot do it," *Summa Theologica* 1.25.3–4.) In making this reply, Aquinas may seem to be introducing a formal notion of absolute possibility of the sort defended in more recent times. Yet, as with Aristotle, the category of possibility in question is grounded not in linguistic or purely logical considerations but wholly in intelligible essences ("intelligible forms"). In other words, the definitions relevant to ascertaining the consistency or intelligibility of a term or idea are "real" rather than nominal or analytical, which means that the possibility in question is the absolute kind espoused by Aristotle, not the formal or conceptual sort allowed by most modern philosophers.

**HOBBS.** In the modern period we find in Hobbes a view that not only contrasts vividly with the typical medieval one but which, confused as it is, is occasionally defended by philosophers of the twenty-first century. Hobbes's view contrasts with the medieval one because he held that conceivable beings are not necessarily possible beings. If a being is conceivable, the only conclusion Hobbes would draw is that words standing for it are not gibberish. To be possible, the necessary conditions for a thing's existence must be satisfied. Hobbes therefore contended that every possible being, event, or state of affairs is actual at some

time or another: "If it shall never be produced, then those things will never concur which are requisite for the production of it" (*Elements of Philosophy* 10.4). Because for Hobbes whatever exists does so by virtue of necessary causes, we can call something possible (or contingent), as opposed to necessary, in his opinion only when we do not know the cause that will produce it. This view plainly goes back to that of the Stoics, for it implies that the only legitimate possibilities that are not also necessities are epistemic possibilities—that is, things or states of affairs whose existence is consistent with our knowledge at a given time.

**DESCARTES.** Descartes's approach to possibility is important mainly because it is essentially psychologistic: what is possible is what is clearly and distinctly conceivable. Descartes admitted that if the idea of a thing involves a contradiction, the thing is impossible, but he held that its impossibility is owing to the fact that contradictory ideas cannot be clearly and distinctly conceived. This latter criterion is basic for Descartes because some impossibilities do not, in his view, involve contradictions. As he saw it, there are *a priori* truths that are necessary and guaranteed to be true by the goodness of God but whose denials, which state impossibilities, are consistent. To know firsthand whether a given idea—for instance, the idea of a circular polygon—does represent a possibility, one must therefore be able to form a clear and distinct idea of it. If one is able to form such an idea, one has God's assurance that it represents a real possibility, the sort of thing that God could actualize if he chose to do so.

**SPINOZA.** According to Spinoza, "A thing is said to be impossible either because the essence of the thing itself or its definition involves a contradiction, or because no external cause exists determinate to the production of such a thing" (Spinoza, *Ethics*, 1, prop. 33, note 1). Because Spinoza in effect adopted the Neoplatonic principle of plenitude, he held that if the idea of a thing does not involve a contradiction, it must be actual, for all self-consistent beings are determined to exist, and necessarily exist, by the very nature of reality, which he calls "God":

[Accordingly, a] thing cannot be called contingent unless with reference to a deficiency of our knowledge. For if [and here Spinoza introduces the notion of epistemic possibility] we do not know that the essence of a thing involves a contradiction, or if we actually know it involves no contradiction, and nevertheless can affirm nothing with certainty about its existence because the order of causes is concealed from us, that thing

can never *appear to us* as necessary or impossible, and therefore we call it either contingent or possible (Spinoza, *Ethics*, 1, prop. 33, note I).

LEIBNIZ. To general readers, Leibniz is best known for his metaphysical optimism, the doctrine that this is the best of all possible worlds. He conceived of a possible world as a maximal collection of absolutely possible beings each of which is “compossible” with the other beings contained in that world; the totality is maximal in the sense that it contains everything compossible with its contents. Two things are compossible, Leibniz said, when it is absolutely possible for them to exist together; and something is absolutely possible, for him, when God’s conception of it is free from contradiction. Because Leibniz held that God’s concept of a thing includes all facts about it, including such apparently accidental facts as that it once crossed a certain river in Peru or that it once was bitten by a dog called “Rover,” he concluded that if a thing is absolutely possible, it is so only relative to its place in a possible world, one including certain possible rivers, perhaps, and certain possible dogs. A possible being is strictly a being, therefore, whose existence is compossible with the members of a possible world. This conception comprehends the less restrictive idea, common in recent metaphysics, that a possible thing or state of affairs is one that “exists at,” or belongs to, some possible world.

Like Aristotle, Leibniz drew a distinction between absolute and relative possibility. (Leibniz used the term “hypothetical” here instead of “relative,” but his distinction was the same as Aristotle’s.) Because God created the best of all possible worlds, any existing thing that is not, like God, an absolutely necessary being depends on God’s creative choice. A thing that is absolutely possible but dependent this way on God’s creative choice is hypothetically necessary: its nonexistence is hypothetically impossible, ruled out by the choice God actually made. Everything that has occurred, will occur, or is now occurring is necessary in this hypothetical sense, according to Leibniz. But hypothetical necessity is not the same as absolute necessity, he insisted; Diodorus Cronus (see above) erred in not recognizing this important fact. All human behavior is hypothetically necessary, but it is not thereby inevitable in an absolute sense. This is why one can rightly maintain that free choice remains possible for human beings. A free action, for Leibniz, is one that results from a “rationally spontaneous” choice; its originating principles lie within the agent. Free actions spring from motives and other causes, but these “incline without necessitating,” he said; absolutely necessary is not imposed upon them (see Mates 1986, p. 119)

HUME. The British empiricists, typically rejecting the claims of conceptualism as defended by most epistemic rationalists, seemed to embrace more fully the idea that possibility is a matter of logical consistency. In remarking that, “The contrary of every matter of fact is still possible, because it can never imply a contradiction,” Hume appears firmly committed to a view of logical possibility. But in adding to the quoted sentence, “And is conceived by the mind with the same facility and distinctness,” Hume discloses his tacit commitment to a psychologistic conception of possibility (what is possible is what is conceivable), which was held by Descartes and is often assumed even today. (See Hume’s *Enquiry concerning Human Understanding*, 4.1.)

KANT. In Kant there is not only a clear identification of *a priori* possibility but an explicit distinction between logical and physical (or nomological) possibility. For philosophers like Spinoza, who identified the logical with the real order, there was plainly no sense in this distinction, and there was little place for it in the philosophies of the Greek and medieval thinkers. It is, however, essential to the contemporary outlook. Kant expresses the distinction a bit clumsily thus:

A concept is always possible [he means “represents a possibility”] if it is not self-contradictory. This is the logical criterion of possibility, and through it objects are distinguished from the *nihil negativum*. But it may nonetheless be an empty concept, unless the objective reality of the synthesis through which the concept is generated has been specifically proved; and such proof ... rests on principles of possible experience, and not on the principle of analysis (the law of contradiction). This is a warning against arguing directly from the logical possibility of concepts to the real possibility of things. (*Critique of Pure Reason*, A597/B625, note)

[Thus, the possibility of such things as] a special fundamental power of our mind to *intuit* the future (not merely, say, to deduce it), or, finally, a faculty of our mind to stand in a community of thoughts with other men (no matter how distant they may be)—these are concepts the possibility of which is entirely groundless, because it cannot be grounded in experience and its known laws, and without this it is an arbitrary combination of thoughts that, although it contains no contradiction, still can make no claim to objective reality, thus to the possibility of the

sort of object that one would here think. (*Critique of Pure Reason* A223/B270)

To ascertain that such things are empirically (as opposed to merely logically) possible, we must ascertain whether the nature of things so described agree with the formal conditions of actual experience.

## CONTEMPORARY DEVELOPMENTS

Not all the conceptions of possibility discussed in the previous section on the history of philosophy are equally acceptable to contemporary philosophers, and new conceptions are topics of current debate. Generally speaking, possibility is now discussed in relation to two principal subjects: basic metaphysics, which takes some kind of absolute possibility as fundamental, and the compatibility of freedom and determinism, which introduces possibilities of other kinds. The conceptions of possibility now considered tenable by most philosophers (there is disagreement on this) can be identified by reference to these two subjects.

**BASIC METAPHYSICS.** Until the 1970s, most analytic philosophers described absolute *a priori* possibilities as “logical possibilities” and identified them, as Leibniz did, by reference to logical consistency: An absolute possibility is something that can be exhaustively described without contradiction. In logic a contradiction has the form of “p and not-p” however; and this syntactical structure is not explicit in many statements that fail to express genuine possibilities: it is not present, for instance, in “Some bachelors are married” or “Mary is both taller and shorter than Sally.” To expose the contradictions implicit in these statements one must make use of definitions and conceptual truths such as “For any x and y, if x is taller than y then x is not shorter than y.” Conceptual truths and statements true by definition were called “analytic” truths, and the full range of absolute possibilities was generally conceded to be identifiable only by reference to them. An absolute possibility was then said to be expressed by a statement that is consistent with all relevant analytic truths. According to this conception, a statement that is not so consistent would fail to express a genuine possibility.

This way of identifying absolute possibilities was undermined by Saul Kripke in lectures given in 1970 and subsequently published under the title *Naming and Necessity* (1980). Kripke’s criticism featured two striking examples. The first involved what most philosophers would call an analytic truth pertinent to the standard meter located in Paris. The truth is that the rod is one meter long. Although this truth is a consequence of an

arbitrarily chosen standard specifying what is to count as a meter in length, and thus would be acknowledged to be analytic by most philosophers, it is not necessary because the rod in question does not of necessity possess its current length: it could have a different one. This latter possibility is genuine, but it is identified by reflection on how the rod might change, what might happen if, say, it were heated—not by the consistency of “The rod is not a standard meter long” with the truth that the length it now has equals one meter. The analytic consistency conception of absolute possibility does not give the right result in this kind of case.

Kripke’s second example concerned the identity of Hesperus and Phosphorus, the morning star and the evening star. The statement that Hesperus = Phosphorus is not an analytic truth; it was discovered to be true by empirical investigation. The two “stars” turned out to be a single planet, Venus, seen in the sky at different times and presumed to be different. The fact that the statement is not an analytic truth does not prove that it is not necessary, however. It is in fact necessary because it concerns a single planet, and that planet, like everything else, is necessarily self-identical. Because the identity of Hesperus and Phosphorus had to be discovered empirically, the necessity of their identity had to be inferred from the fact of their identity. If “a” and “b” are used “rigidly,” as Kripke said, to pick out the same objects in actual as well as counterfactual situations, then the following principle provides a basis for the inference: If  $a = b$  then it is necessary that  $a = b$ . Because the necessity of “a” being “b” is equivalent to the impossibility of  $a$  not being  $b$ , a certain possibility is ruled out by our empirical investigation: We learn that it is not possible for  $a$  to differ from  $b$ . This impossibility is not known *a priori* by the discovery that some statement (or proposition) is self-contradictory or analytically inconsistent.

In developing his metaphysical views, Kripke drew a distinction between *de dicto* and *de re* necessity and possibility. A *de dicto* possibility is in effect the possible truth of some proposition; it is expressed in words by a sentence beginning “It is possible that ...” A *de re* possibility, by contrast, is attached to a particular thing, such as a person or chair. We are concerned with such possibilities, Kripke said, when we wonder whether a certain person might have done this or that in some counterfactual situation. Kripke spoke of “contingent properties” in describing such possibilities. A property is contingent for a thing when the thing may or may not possess it in some situation or other. Such a property contrasts with a necessary or “essential” one, this being a property that a thing pos-

esses in every situation, actual and counterfactual, in which it may exist. *De re* possibilities correspond to Aristotle's potentialities; *de re* necessities correspond to his "actualities," or the components, as he conceived them, of a thing's "form" or essence.

Kripke emphasized that the notions of necessity and possibility he discussed belong to metaphysics, not epistemology, and he sometimes spoke of them as metaphysical necessity and metaphysical possibility (see Kripke 1980, p.19). In commenting on the formal semantics he invented for the logic of statements affirming such necessities and possibilities, Kripke used Leibniz's notion of a possible world. A statement, S, is necessary with respect to the actual world, Kripke said, just when S is true with respect to all possible worlds—more exactly, all worlds that are possible relative to the actual world. S is possible with respect to the actual world (it is, for members of this world, possible that S) just when S is true with respect to some possible world—with some world that is possible relative to the actual world. Kripke spoke of worlds possible "relative to" the actual world because different assumptions may be made about this relativity, and these different assumptions are associated with modal principles that are characteristic of different systems of modal logic (see Kripke 1971).

Although Kripke informally used the notion of a possible world in describing the truth-condition for statements affirming metaphysical possibilities and necessities, he did not believe that such statements were understandable only in relation to possible worlds or that the framework of possible worlds provides a reductive analysis of modal discourse. In fact, to avoid philosophical confusions and anxieties regarding possible worlds, he recommended that "possible state (or history) of the world" or "counterfactual situation" might provide a preferable terminology (see Kripke 1980, pp. 18f). As far as modal knowledge is concerned, he seems to believe that intuitiveness (or perhaps intuitive obviousness) is basic. As he put it in *Naming and Necessity* (1980), "Some philosophers think that something's having intuitive content is very inconclusive evidence in favor of it. I think it is very heavy evidence in favor of anything, myself. I really don't know, in a way, what more conclusive evidence one can have about anything, ultimately speaking" (p. 42). In speaking of intuitive content this way Kripke appears to favor an epistemically rationalist (or Cartesian) view of modal knowledge, but he did not discuss the matter in greater detail, and it remains uncertain what the details of his view actually are.

An influential writer about possibility who appears to regard possible worlds and the possible individuals that compose them as basic realities is David Lewis (1986). Lewis believes that all possible worlds actually exist but that only one world, at least from our perspective, is actual: our world. Like Leibniz, Lewis holds that the possible individuals of other possible worlds do not include the individuals of our world; in fact, he thinks the individuals of different worlds cannot be shared. When we consider a counterfactual possibility involving a person belonging to our world—George W. Bush, say—the possibility is grounded in (or actually involves) a counterpart to that person, a being relevantly similar to him, belonging to another possible world. Lewis accepts this counterpart theory because he thinks a given thing cannot have incompatible features. If a thing belonged to two different worlds, the worlds would overlap in it, and this could happen only if the thing's nonrelational features were exactly the same in both worlds: A thing cannot possibly differ from itself. Lewis ably defends his position against a multitude of objections in *On the Plurality of Worlds* (1986), and he also provides a non-Cartesian account of how he thinks we can have genuine knowledge of worlds that, although existing, are possible rather than actual.

**FREEDOM AND DETERMINISM.** The conceptions of possibility relevant to this topic are brought to mind by the question, "If the world is a deterministic system, is it possible for human beings to do anything that they do not actually do?" Not every responsible philosopher agrees that this question requires an affirmative answer if human beings can reasonably be considered capable of acting of their own free will, but the question is commonly asked and different kinds of possibility are mentioned in answering it (see Austin 1961).

**Possibility as ability.** This kind of possibility corresponds to Aristotle's potentiality. We often have this sort of possibility in mind when we wonder what a person is capable of doing, and what he or she could do in specific circumstances. Can Tom do fifty push-ups? Can he do that many after a big meal? What is relevantly possible here? The basic idea pertinent in answering these questions is that of an ability or capacity. To have an ability or capacity a person must be capable of doing something; and to be thus capable is to be such that if conditions are of the right kind, appropriate behavior will occur. In discussions involving human freedom the abilities under consideration are voluntary: they are abilities that a person can manifest "at will." If Sally has the ability to swim, then she will normally succeed in swimming if she is

immersed in water and attempts to swim. The qualification “normal” is important here because a failure to swim would not be evidence of an inability to swim if one’s legs were encased in concrete. Success is required only in “favorable” conditions.

Sometimes we are concerned with what a person can do in special conditions, which may be far from what are considered favorable. Can Tom swim in a rough sea? Can Betty solve an algebra problem when her roommate’s stereo is pounding in her ears, when she is seething with irritable frustration? The relevant test here is success under the specified conditions. In a particular case the test to be satisfied is specified by a conditional statement in the subjunctive mood: If conditions C were to obtain and the subject attempted to exercise the relevant capacity, the subject would succeed in the attempt.

The most important recent work on the logic of subjunctive conditionals is contained in Davis Lewis’s book *Counterfactuals* (1973). Lewis gives the truth-conditions for these statements by reference to possible worlds. A statement of the form “If it were the case that p, it would be the case that q” is true, according to Lewis, just when q is true at the possible worlds that satisfy p and are otherwise most similar to the actual world. (There may or may not be a single most similar p-world.) Thus, to decide whether Tom could do fifty push-ups after a certain meal, one in effect has to decide, Lewis says, whether a possible world in which he (or his “counterpart”) does fifty push-ups after such a meal would be minimally different from the actual world, or whether it would require him to have undergone a course of training, say, that he did not experience in the actual world. Because the negation, according to Lewis, of the conditional “If A were to happen, B would happen” is “If A were to happen, B might not happen,” one can use his theory to identify another kind of possibility, which might be called a “contingent” possibility. Suppose it is false both that if A were to happen, B would happen and that A does happen. Under these circumstances it could be said that B’s not happening is a contingent possibility.

*Relative or hypothetical possibility.* A conception of possibility ultimately vital to the subject of human freedom is that of what is possible given the laws of nature and the occurrence of remotely prior causal factors. Aristotle and Leibniz both acknowledged this conception, but the idea that it represents a genuine kind of possibility is often questioned by contemporary philosophers. Benson Mates (1986), in his commentary on Leibniz, says that the distinction between absolute and hypothetical necessity (and therefore between absolute and hypothetical possi-

bility) seems to originate in a confusion of “Necessarily, if P then Q” and “If P, then necessarily Q.” There is no doubt that this confusion is often made, but it was certainly not made by Leibniz, who explicitly distinguished statements of these kinds and accused Diodorus Cronos, who denied that any possibility could fail to be a necessity, of confusing hypothetical necessity with absolute necessity (see Mates 1986, pp. 117ff).

Peter van Inwagen (1983, 2000), wishing to avoid the confusion Mates mentioned, introduced a new modal operator in formulating an argument against the compatibility of freedom and determinism. The formula “Np” containing his special operator “N” is to be understood as meaning “p [is true] and no one has or ever had any choice as to whether p.” If “O” is a modal operator representing a kind of necessity, there is no doubt that an argument having “Op” and “O(if p then q)” as premises and “Oq” as a conclusion is valid. Accordingly, van Inwagen formulates a corresponding argument featuring his operator “N” and argues that it is valid. The remotely prior causes C occurred and no one now has or ever had any choice about their occurrence; hence “N(C).” Similarly, the laws of nature hold true and no one has or ever had any choice about this fact. The laws also imply that if C then B, where B is a representative item of behavior in a deterministic world. Because this implication is necessary and something no one has or ever had any choice about, van Inwagen concludes that N(B)—that B occurs and no one has or ever had any choice about it: an alternative to B is out of the question.

Van Inwagen’s argument has been seriously criticized since his book was published in 1983, and he has gone on to sketch a new argument to express his sense of the “sheer inescapability” of determined behavior (see van Inwagen 2000). But it is obvious that the sheer inescapability of B is tantamount to the fact that it is relatively (or hypothetically) necessary in Leibniz’s sense, and van Inwagen’s conclusion “N(B)” amounts to nothing more than an assertion that B is a logical consequence of natural laws and the occurrence of initial conditions (or previous causes) that cannot be altered when B occurs. Van Inwagen’s worry about human freedom depends, in effect, on the relative impossibility of behavior that does not occur. So this sense of possibility is vital to the freedom-determinism issue, at least as philosophers such as van Inwagen understand it.

## POSTCOLONIALISM

Not unlike the Renaissance, the Enlightenment, and post-modernism, postcolonialism refers not only to a temporal marker that signals a shift in mentalities and metaphilosophical questioning but also to a decolonizing movement enabled by new material conditions and to a theoretical and philosophical methodology. As a temporal marker postcolonialism is caught in a series of paradoxes. On the one hand, postcolonialism signals the alleged *end* of colonialism and the beginning of a new historical period. On the other hand, at the center of postcolonialism is the exploration of what postcolonial theorists have called the *postcolonial present*, namely, the enduring legacy of colonialism in contemporary times. Still, one of the most basic goals of postcolonialism is to foreground the movements of decolonization that began as early as the end of World War II, peaked during the 1950s and 1960s, and have lasted into the twenty-first century. For this reason many postcolonial theorists argue that postcolonialism is less an “ism” that describes an already past movement, but is more a series of philosophical issues that emerge from the ongoing process of decolonization in the midst of the global hegemony of Europe and the United States.

Undoubtedly, postcolonialism also refers to all the movements of decolonization that emerged during the 1950s, movements that predominantly took the form of so-called Third World nationalism. These movements of national liberation and anti-European imperialism and decolonization spread throughout the so-called Third World, a noun that conceals the specific Cold War context of many of these anticolonial struggles. *Third World* makes reference to all those recently created nations that were part neither of the developed, capitalist, industrialized, democratic *First World* nor the developing, industrializing, and socialist *Second World*. Critical theorist Robert J. C. Young (1950–) has for this reason argued that instead of referring to Third World postcolonialism, we should make reference to *Tricontinentalism*, by which he means, the deliberate and explicit joining of former colonial societies in Latin America, Africa, and Asia in anti-colonial struggles. What postcolonialism as the collective name for a series of movements seeks to foreground is precisely the engagement with what is called by some postcolonial theorists the postcolonial condition, or post-coloniality. Latin American sociologist and critical theorist Anibal Quijano has called this condition the *postcoloniality of power*, a felicitous expression that expresses what Homi K. Bhabha (1949–) has called the *ongoing colonial present*.

As a theoretical and philosophical methodology, postcolonial theory is no less heterogeneous and at times internally contradictory than the Renaissance and the Enlightenment were. Postcolonial theory finds many of its philosophical sources in the discourse of, to use Paul Ricoeur's apropos phrasing, *the hermeneutics of suspicion*: Marxism, psychoanalysis, deconstruction, semiotics, structuralism, and postmodernism. More concretely, most of postcolonial thinking takes place through demystifying readings of canonical figures in Western philosophy. Such demystification is exemplified in the works of Louis Althusser (1918–1990), Jacques Derrida, Michel Foucault, Sigmund Freud, Jacques Lacan, Karl Marx, Friedrich Nietzsche, Jean-Paul Sartre. As a methodology, postcolonialism submits both the production and effects of all cultural artifacts, whether they be novels, philosophical texts, or sociological treatises, to a type of X-ray that shows the ways in which these texts and their effects are caught in the dialectical tension between colonialism, imposed and internalized, and anticolonialism, both internal to the West, and from without, from the colony, the liberated postcolonial nations, and emergent social movements.

This type of double reading that traces the effects of colonialism on colonial consciousness and culture, and that unearths and names the voice and gaze of the colonial other, has been amply developed by what has been called *postcolonial criticism*. With this term some critics seek to differentiate between the kinds of work that literary criticism performs from that which theory or philosophy produces. Yet, the attempt to differentiate between postcolonial criticism and theory reproduces one of the most contested *disciplinary* divisions that postcolonialism, as a methodology of analysis, continuously aims to challenge. As the works of Bhabha and Gayatri Chakravorty Spivak (1942–) illustrate and explore, literary criticism cannot be separated from and made to dispense with philosophical analysis, and the latter cannot dispense with literature nor be made to speak in a language purified of rhetoric, simile, metaphor, and the thick historicity of its diction. Furthermore, postcolonial theorists can neither negate nor neglect the ways in which disciplinary divides have been utilized to silence and deauthorize other forms of questioning—in what postcolonial theorists call the production of knowledge—precisely because of postcolonial theory's own hybrid and interdisciplinary sources.

Postcolonialism can be said to be a phenomenology of the social world that analyses in tandem the mutually conditioning effects of the objective on the subjective and

vice versa. Social existence conditions the ways in which subjects are able to live and experience their subjectivities, and such subjectivities in turn, whether subjugated or insurrected, transform the social world. Postcolonialism is therefore also simultaneously a type of critical epistemology and historical ontology that studies the sources and effects of modes of representation and the ways in which social being is historically conditioned. As Spivak has put it, appropriating and displacing the phenomenological hermeneutics of Martin Heidegger, colonialism has *worlded*—that is to say, woven a thick web of material relationships that made possible meanings and the subjects that are mediated by them—the worlds of both the colonizer and the colonized. What makes postcolonialism different from other forms of phenomenology, ontology, and epistemology is that it has deliberately sought to disclose the world worlded by colonialism from the standpoint of the subaltern. By the term *subaltern* postcolonial critics mean those agents who have been expropriated, exploited, marginalized, racialized, bestialized, and rendered part of the fauna of continents empty of people and subjects. Every social agent and epistemic subject occupies a location, whether this location be literally geographical or figuratively political, epistemological, racial, or gendered. Edward W. Said (1935–2003) has called the analysis of this localization of all agents the *geographical inquiry into historical existence*.

Postcolonial theorists argue that to analyze the world from the perspective of the colonizer—the sovereign European political subject ensconced on the pedestal of racial privileged—would distort at best and conceal at worst the ways in which the colonized, the subaltern of colonial cultures, have been disempowered, rendered invisible and silent, reduced to a mere tabula rasa for the evangelizing, civilizing, and commercializing mission of Europe. The postcolonial critique of Western domination is simultaneously a critique of the imposition of a global economic system of structural inequality, or what is also called the globalization of capitalism through colonialism and imperialism. For this reason postcolonial theory shares many important insights and methods with standpoint feminist epistemological critique. All social location, as both of these positions argue, is mediated by representations: cultural, gendered, racial, religious. Postcolonial critique, as a form of Marxism, thus also aims to unmask the fetishizing and alienating effects of the systems of cultural representation imposed by European colonialism.

Postcolonialism, therefore, maintains that since no cultural or personal identity exists outside representation,

and all representation is mediated by the history of its production, imposition, or rejection, all identities are thus contaminated by instability, hybridity, or creolization. A postcolonial corollary to the hybridity of all identity is that there is no subjectivity and agency that is not affected by power. All subjectivity and agency, argue postcolonial theorists, are forms of power. The postcolonial analysis, however, maintains that some forms of power are genocidal, subjugating, and narcissistic while others are enabling, benign, and indispensable. Power, in this analysis, is neither a stable substance nor a force that emanates from a center but a configuration of relationships that condition modes of social interaction. For postcolonial theorists, however, the uses and abuses of power are discerned from the standpoint of its effects on the subaltern in history and society.

At the center of postcolonial theory, notwithstanding its variegated sources and heterogeneous forms of articulation, is a series of epistemological innovations. Whether one studies the work of Bhabha, Frantz Fanon (1925–1961), Said, or Spivak, to mention just some of the canonical figures in postcolonial theory, we encounter an in-depth and unmitigated analysis of what has been called variously the space of enunciation, the discursive fields, or the structure of attitude and reference. Postmodern theorists mean by these terms that all epistemic locations, statements, and responses of affect are either allowed or disallowed by certain rules, syntax, or injunctions. To claim epistemic authority, make statements, and submit to feelings is to be interpellated by the syntax of a discursive matrix that already also anticipates their assent, response, or evocation.

Some postcolonial theorists have focused their attention on the structures of attitude and reference that condition how subjects and agents are made to know, speak, and feel *from* a location of privilege and plenipotentiary sovereignty *about* other subjects and agents who are located somewhere else in history and space. Said's classic work *Orientalism: Western Representations of the Orient* (1979) documented and analyzed the ways in which orientalism, the collective name for a group of disciplines that studied the Orient, operated as a power-knowledge apparatus that interpellated European agents to adopt imperial affective, epistemological, and enunciative spaces and comportments. Other postcolonial critics have focused on the knowing, speaking, and feeling *to* of all colonial discourse and the ways in which their reifying, objectivifying, and alienating effects are both unsustainable and contested by the other of their addressee. In Fanon's work, for instance, we discover one of the most

elaborate phenomenologies of oppression and liberation as well as a psychoanalytical analysis of the devastating effects of the powers of torture on both colonizer/torturer, and colonized/tortured. Yet other postcolonial theorists have focused on the *how* and by *what* means the mater-slave relationship between colonizer and *subaltern* have been mediated in such a way that neither the master nor the slave are entirely inured to each other's power of conquest or resistance. Spivak's work is without a doubt the most sophisticated, extensive, and sustained engagement with this dialectic of complicit and resisted knowledge production and insurrected agency.

Not unlike how Immanuel Kant illustrated his transcendental method by way of antinomies, postcolonial critics have developed a type of critical philosophy that proceeds also by way of the disclosure of a series of antinomies at the heart of contemporary Western thinking: universalism versus European exceptionalism; rationalism versus racial supremacy; humanism versus racial genocide; technophilia versus Romantic idolatry of the primitive; historicism versus teleological theodicy. As a critical methodology that inherits the discourse of what has been called a second Enlightenment, namely, the discourse of suspicion (Marx, Freud, Nietzsche), postcolonialism can be said to constitute a third Enlightenment, one that awakens the postcolonial world to the enduring legacies of five centuries of colonialism, imperialism, and now, globalization.

Postcolonialism is neither anti-Western, obdurately rejecting all European thinking, nor Third-Worldist, naively celebrating all that is produced and thought by the subaltern. Postcolonialism is a type of thinking that aims to situate us beyond the epistemological, ontological, and phenomenological Manichaeisms that have informed colonialism and postcolonial nationalism. Postcolonialism urges us to think beyond the either/or, for/against and in the proper space of the hybrid of the neither/nor, and/but, not with/but not without. For postcolonial thinkers, the philosophical inheritance of the West, of Europe, is at stake, not solely because it bears the traces of its complicity with colonialism, but because it is also the archive of resistance to that colonialism.

## POSTMODERNISM

The term “postmodernism” first emerged in the 1950s to describe new architectural and literary movements that opposed commonly accepted canons regarding the unity and coherence of narratives and artistic styles. Sociologists, meanwhile, have used “postmodernism” to indicate discordant trends such as the parallel growth in cosmopolitan globalization and parochial traditionalism. The term has also been appropriated by mainly French and German philosophers to designate a criticism of reason, regarded as a universal and certain foundation for knowledge and morality, and of modern culture, understood as

a progressive unfolding of knowledge and morality. An examination of the works of these philosophers shows that many of the postmodern themes regarding the fragmentation (or deconstruction) of the rational subject and its object can be explained from the standpoint of conceptual tensions implicit within post-Kantian philosophy, which remains the main target of postmodern criticism.

A true son of the Enlightenment, Immanuel Kant defended reason as a universal faculty whose untrammelled exercise irresistibly leads to questioning all dogma and all authority, and from there leads to the complete emancipation of all individuals from the fetters of tradition. Faith in reason as it is deployed in science and morality fuels faith in the interminable progress of humanity. However, as postmodernists like Michel Foucault point out, the very reason that develops modern culture disintegrates under its own self-critical gaze, thereby issuing in oscillating and often discordant trends between absolutism and nihilism, totalitarianism and anarchism, humanism and multiculturalism, and universalism and parochialism. The end of rational idealism in turn spells the end of the subject as an autonomous, self-identifying, and self-determining locus of agency.

Ironically, it was Kant himself who initiated the critique of reason that later inspired postmodern philosophy. Kant observed that reason recognizes no limits in questioning the ultimate metaphysical grounds underlying reality, but that any answer it gives in response to its own questions entails contradiction. Rational inquiry must therefore be limited to phenomena within everyday experience. Kant’s critique of pure, experience-transcending reason already anticipated postmodern skepticism regarding the completeness of our knowledge of things in their totality, while rejecting such skepticism with regard to our knowledge of things in their experiential finitude. Kant’s rejection of this latter form of skepticism, whose main exponent is David Hume, requires that reason be seen as a synthetic power that infuses experience of objects with causal necessity as it imposes rational identity on the experiencing subject. However, to reconcile the causal necessity of the world with the uncaused freedom of the moral subject, Kant had to divide reason into two *opposed* deployments—theoretical and practical—only one of which was a source of knowledge (he later added a third, aesthetic deployment to mediate between the moral and the theoretical). Subsequent postmodernists continued to divide reason into an indefinite number of context-specific applications, thereby undermining any certain belief in a common reason, a common world, and a common humanity.

Also postmodern is Kant's view that reason questions even its own authority as a certain foundation of knowledge. As G. F. W. Hegel astutely noted, this self-referential (or reflexive) use of reason is paradoxical. By limiting the valid deployment of cognitive reason to natural science, critical philosophy undermines its own claim to validity as a *nonscientific* form of reflective knowledge. Conversely, by grounding natural science in a nonnatural form of transcendental subjectivity, it unwittingly shows natural science and its object to be partial and superficial forms of cognition and reality, respectively.

According to postmodernists, Hegel's system marks the last great attempt to resolve the crisis of reason bequeathed by Kantian philosophy. It does so by affirming what Kant had denied: reason's infinite demand to know the infinite totality. As noted above, this demand issues in contradiction. However, Hegel thought that this was true only if philosophical reflection did not completely grasp all possible metaphysical categories in a manner that showed how each implied all the others. Hegel's circular reasoning would show that the apparent contradictions implicit in metaphysical reasoning ultimately establish a closed system of resolved complementarities. In contrast, any attempt to found one kind of belief deductively on another in a noncircular way, as Kant had proposed, must issue in unresolved contradiction.

Postmodernists question whether reason can establish a complete and coherent system of thought. From Hegel's thought they retain his dialectical view that the fundamental reasons that define, categorize, and ground our beliefs about things effectively refer to properties that are thought to be external or opposed to these things. Thus, while logic (analytic reason) seeks to establish categorical distinctions between self and other, nature and society, reason and unreason, philosophical reasoning about logic undermines these distinctions. Postmodernists therefore conclude that nothing is certain and definite, not even our certainty that we as rational subjects exist.

The undermining of categorical distinctions has an important bearing on the meaningfulness of language. Postmodernists point to the futility of trying to ground the meaning of concepts in empirically verifiable objects or in what is immediately given in experience. As Ludwig Wittgenstein noted in his *Tractatus Logico-philosophicus*, the logical and philosophical metalanguage that is supposed to ground the meaningfulness of the object language in immediate experience is not itself an object language referring to immediate experience. Citing simi-

lar self-referential paradoxes made famous by Bertrand Russell, Kurt Gödel, and Werner Heisenberg, Jean François Lyotard has argued that epistemic and logical indeterminacy, incompleteness, and uncertainty necessarily infect any scientific or philosophical metanarrative that claims to be all-encompassing. At the beginning of the twenty-first century, the common acceptance by philosophers of language that meaning is relative to context and usage and yet is underdetermined by them has led philosophers as diverse as Donald Davidson and Jacques Derrida to suggest that meaning is at the very least an indefinite project of textual interpretation, if not, as Lyotard and Foucault argue, an anarchic war of contesting and inventing.

For postmodernists, acknowledging the uncertainty, ambiguity, and loss of identity that comes with the demise of rationalism, humanism, and idealism need not commit us to nihilism. On the contrary, as Friedrich Nietzsche observed, by insisting on impossible norms of certainty, clarity, and identity, we end up devaluing those common unfathomable and uncanny modes of moral and religious experience that open us up to novelty, fantasy, and vulnerability. Worse, by insisting on these impossible norms, we become arrogant and drunk on our own "will to power." It was in the name of pure reason, after all, that "enlightened" Europeans sought to eliminate or assimilate to themselves the "unenlightened" peoples of Africa, Asia, and the Americas. Genuine postmodern responsibility, by contrast, endeavors to promote an active, nondomineering receptivity to the other, no matter how different it may appear.

## POTENTIALITY

See *Possibility*

## POWER

The meanings of *power*, *influence*, *control*, and *domination* are uncertain, shifting, and overlapping. Although two of these words may be interchangeable in one context, in another context one of the words may refer to a genus and another to a species, or one may refer to a cause and another to an effect. To substitute *power* for *influence* would not matter much in the sentence “The United States has very great influence in South American politics,” but to interchange them would radically change the meaning of the sentence “Colonel House’s power derived not from any constitutional authority but from his influence over President Wilson.”

Shifts like this account for much of the intractability of problems associated with power. For instance, power is often said to be a relation (Lasswell 1950, Friedrich 1950, Partridge 1963), yet we talk about the distribution of power, about the power of speech, about seeking power as a means to future enjoyment (Hobbes 1946), or about power as “the production of intended effects” (Russell 1938). If power is a relation, between what kind of terms or things does it hold? Does power over men require a minimum of acquiescence, consent, or cooperation (Hume; Friedrich 1956–1957), or can it be analogous to a physical force acting on an otherwise inert object? Is to exercise power always to succeed in what one intends (Russell 1938, Lasswell 1950), or can a man exercise

power in ignorance of what he is doing (Dahl 1961, Partridge 1963, Oppenheim 1961), like a ruling elite that neither knows nor cares about the effects of its actions on other classes?

Instead of seeking a single analysis of *power*, it is more helpful to think of diverse uses of *power* and of associated words like *influence* as instances of different members of a family of concepts that do not all share any one particular characteristic but have various relations and resemblances by which they are recognizably kin. One might construct a power paradigm combining as many of these family features as possible. Thus, “A, by his power over B, successfully achieved an intended result *r*; he did so by making B do *b*, which B would not have done but for A’s wishing him to do so; moreover, although B was reluctant, A had a way of overcoming this.”

There are five main features of this paradigm: (1) an intention manifest in the exercise of power; (2) the successful achievement of this intention; (3) a relationship between at least two people; (4) the intentional initiation by one of actions by the other; and (5) a conflict of interest or wishes engendering a resistance that the initiator overcomes. Not every feature would be present, of course, in every instance in which we properly speak of power; but we can examine how different instances are related to the paradigm and to one another, and thus throw some light on a few of the questions listed above.

### POWER AND CONFLICT

Some instances of power do not involve overcoming resistance to an initiative. A charismatic leader’s power over his followers consists in being able merely by suggestion to move them to do willingly what he wants, even though their interests might have led them to act differently. The family of power concepts might be arranged along a conflict scale (Partridge 1963): At the end at which conflict is least would lie instances of influence, while at the other end would lie instances of domination, and in between, instances of authority. In the extreme case, exercising influence would not involve overcoming resistance, for to manipulate a man’s actions by shaping what he considers to be his interests is not to impose action upon him *in the face of* his interests. Yet this would still be an instance of power satisfying the first four features of the paradigm.

The limiting case at the end of the scale at which conflict is least would be rational persuasion, for to offer a man good reasons for doing something is not to exercise power over him, although it may influence his decision. One possible difference between influence and

power, then, seems to be that power generally implies a difference of standing between the two parties: The one stimulates, the other reacts. Rational persuasion, on the contrary, to the extent that it criticizes and invites criticism, presupposes at least the possibility of a dialogue between equals. To the extent that persuasion is really rational, the influence is not so much that of the persuader as of his arguments; the same arguments from anyone else would do as well. (By contrast, a threat of violence is more effective coming from a strong man than from a weak man.) Of course, if *A* rationally persuades *B* to help him, *A* may get power—not over *B*, however, but over *C* or *D*, or even simply the power to do something he could not otherwise do.

### POWER, INJURY, AND INTEREST

In the case of the man who punishes another for disobedience, conditions (1), (3), and (5) of the paradigm would be satisfied, but not (2) and (4), for the initiative has been refused. Instead, it suffices for an instance of power if the power-holder successfully and intentionally makes the subject suffer for refusing the initiative. And by yet a further extension of meaning, one can exercise power over someone by deliberately making him suffer, whether or not he has refused an initiative. Just as in the limiting case of rational persuasion one could speak of influence but hardly of power, so at the other end of the scale one can talk of power but not of influence, for influence is manifest in what a man is, does, or believes, not in what is simply made to happen to him by another man.

A stoic would probably resist the extension of the concept of power to cover the mere infliction of suffering. By not caring about physical pain or external conditions, he might say, one can remove oneself from the power of another man. So too Martin Luther believed that a true Christian is free because no outer things can touch him at any significant point. It would seem that what characterizes a power situation of this kind is not just the ability to make someone suffer, which after all a dentist possesses, but rather to do him harm—that is, to attack his interests. Thus, by revising the notion of a man's interests, and therefore the notion of harm, the stoic or the Christian can deny the reality of one man's power over another, since nothing that another man can do to me can affect my real interests; I am always free, if once I see what those interests are. This argument is a little odd, because the concept of power generally implies a restriction on choice; but according to the stoic or Christian view, one can always choose to make the restriction insignificant, and therefore one can choose whether to be in the power

of another. In that case, there could not be a real restriction, and all power would be illusory. But then, what would power be like if it were real?

The stoic argument demonstrates, however, that whether one man has power over another depends not merely on what he can do to the other but also on the importance to be attached to his action and on whether the subject can reasonably be expected to disregard it. One would not say that *X* was in *Y*'s power if one thought that what *Y* could do to *X* was trivial—something that *X* could or should readily ignore.

Again, although threats of real harm are an exercise of power, bribes or promises of reward are not, unless some special feature of character or situation makes them irresistible—that is, unless no one so placed could reasonably be expected to resist them (although some in fact might). This is not to say, of course, that a man cannot exercise power by bribery. However, it need not be power *over* his hirelings but power over others *through* them; or it may be power only in the still more general sense of an ability to bring about an intended result. Thus, we speak of power in situations in which a man could either successfully determine another's actions or do him harm. An ability to do him some good is not in itself power over him, although the threat of withholding a good that he has come to count on may well be.

### PROBLEMS OF POWER AS A RELATION

Power may not be a relation between people but between a person and a thing. There is a nonsocial kind of power that is simply an ability to produce an intended result, like a tenor's power to smash a tumbler with a high *C*. And even in a social context, the financier's power to destroy a government comes very close to this, for in this instance too power is manifest merely in the active achievement of an intended result. Although the financier no doubt works by initiating actions on the part of others, the relation between him and his object (the government) is that which exists between agent and patient. This case can be distinguished both from that in which power is exercised by punishing a subject for noncompliance and from that in which power is used to inflict deliberate injury. For in the present case the object of the exercise may be only to remove an obstacle. The manifestation of power does not consist in the government's being made to suffer, for it would be just as much a manifestation of power if the financier had chosen instead to prop it up or if the government welcomed its downfall as a blessed release from responsibility. Power is manifest simply in that what happens is the result of the financier's intentional action, just

as the tenor's power is manifest in his being able to break a glass whenever he likes.

Power is of course relational in a logical sense in that it requires more than one term for a complete statement; and if more than one of the terms is a person, and the relation presupposes institutions, rules, and so forth, power will certainly be a social relation. But writers who stress that power is a relation usually mean that it is an initiative-response relationship of the kind that C. J. Friedrich had in mind when he wrote, "The power seeker must find human beings who value the things [he controls] sufficiently to obey his orders in return" (*Constitutional Government and Democracy*, p. 12).

Now, Friedrich's point is substantially true in those instances in which power implies a successful initiative and even perhaps in those instances in which power tends to injure its subject. To set about hurting someone, one must know how to get the right kind of response: There is no point in depriving nonsmokers of tobacco. It is not so clear, however, that the financier's power is of this type, for he does not secure a response from the government; he merely makes something happen to it. Although his agents respond to his initiatives, one must distinguish the power he has over them from the power he has over the government. These powers would be of the same kind only if he were able not just to destroy the government, but to use it as he wished. But it is presumably because he cannot do this that he uses his power to destroy it.

This analysis further elucidates the relation between power and consent. We have seen that at one extreme a man may exercise power over another by influencing his desires, or a man may do whatever he is told by another because he believes that he ought to do so, which is an instance of authority. Both cases imply some measure of consent or acquiescence, if not to the particular initiative, then to the right of the initiator to issue it. But in cases in which power depends on threats or on physical coercion, the subject's acquiescence amounts to no more than that he continues to value whatever is being used as a lever against him—an acquiescence that only the stoic, perhaps, would seriously regard as a matter of choice. However, political power cannot be entirely coercive. The few can rule the many because the many believe either that the few are entitled to do so or that they could harm them if they disobeyed. But they would not think that coercion were possible if they did not also believe that most of the people were prepared to obey without coercion. A political power situation, therefore, must almost always contain some elements of acquiescence as well as coercion—*almost* always because it is at least theoretically

possible that a reign of terror might enslave a whole people simply by sowing such mistrust that its opponents could never know their own potential strength.

## POWER AND INTENTION

Still further from the paradigm is the case in which one says quite generally that a person is powerful, or that he seeks power, without specifying the range of possible intended action or the persons subject to the power. Usually it would not be difficult to supply terms to complete either one or both of these blanks. Political theorists commonly insist that comparisons of power, without reference to its "domain" and "scope," are meaningless (Lasswell and Kaplan 1950, Oppenheim 1961). However, some have tried to generalize the concept by disregarding intentionality. R. A. Dahl defines power as "the difference in probability of an event, given certain actions by *A*, and the probability of the event given no such action by *A*" ("The Concept of Power," p. 214). At this level of abstraction, *power* is freed not only from intentionality but also from achievement and conflict; what remains is a relation between a stimulus and a reaction. Elsewhere (*Modern Political Analysis*, p. 40), Dahl defines *influence* as a relation among actors in which one induces others to act in some way in which they would not otherwise act. Dahl would want to purge, if he could, the hint of intentionality in the word *induce*. Like a field of force in mechanics, power is a potential for creating disturbance, like the potential of a stone cast in a pond for creating ripples. But this has some odd results. Instead of suffering a *loss* of power, the crashing financier who brings down thousands with him in his fall would be exercising a power that is perhaps greater than ever before. Admittedly, it is a mark of power if a man's actions cause disturbances, even if he is careless or even ignorant of them. Nevertheless, if powerful men cause incidental and unintended disturbances, they do so in the course of *getting what they want*. (C. Wright Mills's conception of a "power elite" seems to be of this kind.) One would not call someone powerful who, like a careless smoker constantly causing fires, was forever causing disturbances but never achieving anything he intended; nor is it clear that any useful methodological purpose in political science would be served by a definition of power that permitted the production of unintended effects alone to serve as a criterion.

To possess power or to be powerful is, then, to have a generalized potentiality for getting one's own way or for bringing about changes (at least some of which are intended) in other people's actions or conditions. *Influence*, it is true, is used in a more general sense. If a parent

has the unintended influence of stiffening his child's determination to be as different from him as possible, this would not be described as an instance of power: It is more like "the influence of climate on national character." The use of the term *influence* suggests that there is a causal relationship between the behavior of the parent and that of the child (cf. P. H. Partridge, "Some Notes on the Concept of Power," p. 114). "A writer's influence on succeeding generations" stands somewhere between this case and that of influence by rational persuasion. For a writer may have influence only to the extent that other writers recognize his merits and choose to imitate him. Although such influence may not be intended, still it is not a cause, at least in the sense that climate is a possible cause of national character. In any case, none of these is an instance of an influence in the sense that House had influence with Wilson. "To use one's influence" usually implies actively and intentionally working through or on other people, and one who can do this recurrently "has influence." Of course, people who have power (that is, who can do many things they want and induce many other people to accept their initiative) are likely on that account to influence (that is, to have effects on) other aspects of society in ways that neither they nor their social inferiors necessarily understand. Other classes, envying and admiring them, may imitate their tastes and practices, and in this sense they may be influenced by them. But this influence is not a manifestation of power; it is only one of its effects.

## PRACTICAL REASON

Reason can and should guide one in deciding what to believe, at least in large part. But can reason also guide one's actions and the goals that one aims to achieve through them? This question is at the heart of philosophical interest in practical reason. One's thoughts and discourse about practical matters are full of references to reason, and each day brings with it a fresh round of deliberation over such things as the costs and benefits of alternative lines of conduct. Disagreement over how best to understand these phenomena has focused on two distinct questions: First, is reason itself ever a genuine source of considerations for or against conduct, or is our everyday thought and discourse simply a *façon de parler*? Second, to what extent, if at all, can such considerations make a difference to what one does? Under the first question, which is addressed in the first three sections of this entry, the central issues concern whether and the extent to which the deliberative process that culminates in a decision or intention can be dubbed *reasoning*. The second question, with which the article ends, concerns the nature of motivation and action and, in particular, what role (if any) reason plays in the explanation of one's behavior.

### INSTRUMENTAL PRACTICAL REASON

Most agree that if any conduct is contrary to reason, then not acting to achieve one's goals with some level of efficiency and effectiveness is. Once one decides to lose weight, for instance, overeating seems unreasonable. But what precisely is reason's role here? Many, such as those who follow the eighteenth-century Scottish philosopher David Hume, argue that its role is limited to delivering and evaluating beliefs about connections between behaving in certain ways and achieving goals. If one's goal is to lose weight, reason's work is done once it delivers the news that eating less will bring that about. This implies that reason concerns itself only with delivering causal information about how to realize one's goals and hence does work in the realm of action that is no different from the work it does in the realm of belief.

To see precisely how little reason does on such a view, consider the following: Suppose my goal is to have the doorbell to ring and I am told to push the button. However, I perversely insist that it is a trick door and that standing motionless will make it ring. If I stand motionless, I will as a consequence frustrate my goal. Reason seems against my conduct. For the minimalist, however, that means only that the belief on which my conduct was based was false. Suppose, alternatively, that I have no idea how to make a doorbell ring. I stand in puzzled silence, and again reason fails to support my behavior. This time, the problem is not that I have incorrect beliefs about how to achieve my goal; it is that I have no beliefs about this at all. Nevertheless, it is again really just in lacking a belief that I've fallen foul of reason. Conforming to practical reason, on this minimalist view, means simply ensuring that I have the right stock of beliefs about how to achieve my ends. Reason does not pass judgment on what I do per se. It is thus not practical in this more interesting sense. Indeed, when I do what I falsely believe will bring results, my action displays a kind of fit with my belief, even if my belief is itself defective.

Suppose, however, that my actions did not display this kind of fit with my beliefs, even while my beliefs were flawless. Imagine, for instance, I failed to push the button when my goal was that the doorbell ring and I correctly believed that pushing the button would achieve this. Was my conduct *then* contrary to reason insofar as it did not fit with my goal and my true means–ends belief? A minimalist such as Hume would deny that it was. An action itself cannot be contrary to reason because an action cannot be evaluated for its truth or falsity. *A fortiori* reason cannot justify an action either, for justification of something is just support for its truth. Thus, no action seems contrary to reason in the way that a false or unjustified belief is.

Reason will be practical in an interesting sense, it seems, only if one of two things is true: Either there exists some special realm of facts about the *to-be-doneness* of certain actions themselves, information about which reason can deliver, or else reason is more than an information-delivering faculty. Philosophers have tended to avoid views requiring special facts although in the case of ethical reasoning, some have thought the idea worth developing. This case will be returned to below. For many, a more attractive strategy is to argue that reason issues distinctive rules of conduct. The most likely candidate for such a rule would be a rule of instrumental reason, for instance: Do what is necessary to achieve your goals. For an action to be contrary to reason would then be for it to fail to con-

form to such a rule. The key issue, then, is whether practical reason is indeed *normative* in this sense, that is, whether there are any genuine rules of reason.

Arguments that a given rule is a norm of reason can be grouped into two kinds: those appealing to the concept of reasonableness, and those appealing to substantive considerations beyond that concept. The eighteenth-century Prussian philosopher Immanuel Kant, for instance, employed the first style of argument regarding conformity to a *hypothetical imperative*. The concept of *reasonable behavior*, he argued, contains the idea of conformity to the rule *take the means necessary to achieve your goals*. The twentieth-century political philosopher John Rawls is an example of a philosopher who also employed the second style of argument. Rawls argued that reasonableness includes a willingness to propose and abide by fair terms of cooperation if assured that others will likewise do so, on the grounds that, although it is not a conceptual truth, the contention enjoys much intuitive support.

### REASONING ABOUT GOALS

Goals can share many of the above features of actions. Suppose, again, my goal is that the doorbell ring. Typically, I don't just want that. Perhaps I believe that the ring will bring my friend to the door. My goal is really an instrumental goal, a goal that is desirable because its achievement is instrumental to achieving a further distinct goal. Suppose, however, that I am standing in front of the wrong house. Even though I am right to believe that pushing the button will achieve the ring, reason is against my pushing the button because it is against achieving the ring. To this instrumental extent at least, our goals can be contrary to reason.

Minimalists will be led say about goals *mutatis mutandis* what they say about action: The defect, as in the case of action, is in the belief that the ring will bring my friend to the door. It is only because of this false belief that my goal falls foul of reason. Goals are just like actions in the sense that they cannot be evaluated as true or false, and *a fortiori* cannot be justified or unjustified either. So, if reason were practical in any interesting sense, there would either have to be a distinctive realm of facts about the *to-be-pursuedness* of certain goals or else reason would have to issue distinctive norms concerning goals such as *pursue intermediate goals necessary to reach your primary goals*.

This sort of reasoning need not exhaust practical reasoning about ends. For instance, suppose I have not one, but two goals: that the doorbell ring and that those behind the door not be disturbed. Do I conform to reason if I

push, or rather fail to push, the button? Given the bell cannot ring and leave the inhabitants undisturbed, the answer must wait until I resolve this conflict. Having goals that are not *jointly realizable* seems contrary to reason. However, goals are jointly realizable only if some can be dropped in favor of others in cases of conflict. We could do this willy-nilly, of course. But ranking seems more reasonable. We should decide whether having the doorbell ring is more or less important than disturbing those behind the door. Given reason counsels joint realizability, it thus also counsels ranking. Moreover, rankings conform to requirements of consistency. For instance, they are transitive: If ringing is ranked above not disturbing the inhabitants, and not disturbing them above not wearing out the button very slightly, then ringing should be ranked above not wearing out the button. This would explain why we would think it unreasonable for me to worry about wearing out the button given that I'm not worried about the more important fact that it will disturb them.

Presumably, one does not pursue all of one's goals for the sake of other goals, however. Some things one cares about for their own sakes; they are *final* goals. Can reason evaluate such final goals? One way that it might is this (Schmidtz 1995): Suppose I am a philistine, but then decide to become the sort of person for whom art is a final end. Suppose further that I decide this because I believe that becoming that sort of person will enhance my standing in the eyes of others. I aim, in other words, to come to pursue something for its own sake, but my reasoning is clearly instrumental. If I find out that learning to love art for arts sake will not lead others to think better of me, then reason will counsel me not to learn that.

### REASON IN ETHICAL DELIBERATION

When one deliberates about what to do, one often considers whether what one proposes is morally permissible, right, virtuous, and so on. One seems to care about such things for their own sakes, so this seems to constitute a final end. But does reason ever really guide one to moral conclusions?

Those who think that it does can be divided into two camps: those who think that moral reasoning can be explained in terms of reasoning from individual goals, and those who think it involves a special kind of reasoning. The former think that moral reasoning is, in fact, not fundamentally different from the above forms of practical reasoning but in some way facilitates the achievement of one's goals—typically, by being based on principles of social conduct that reasonable individuals would accept and act on. Such, for instance, is found in game-theoretic

explanations of morality. On a standard version, game theorists argue that people seeking to achieve their goals will want ground rules for their interactions with each other. They will thus freely engage in a series of bargains with others in which each person tries to secure practices most favorable to their goals. Bargaining would continue until no viable alternative agreement can be struck under which someone would be better off. Moral practices represent these agreements, and because they do, they are justified in light of their being the upshot of these reasonable goal-oriented bargains. Along these lines, David Gauthier (1986) argues that reasonable agents will be disposed to cooperate with others who likewise cooperate, even when doing so will not be the best way to achieve their own goals (as is often the case in moral matters).

A more controversial idea is that moral reasoning is fundamentally different from nonmoral reasoning. There are two main lines of thought here: The first is that there is a distinct realm of moral facts, as real as any scientific fact but accessible only through the exercise of a special faculty of reason. On this view, practical reason operates quasi-perceptually to deliver putative moral facts such as that lying is wrong. Some (McDowell 1979) have held that this is analogous to sense perception, such as is exercised by informed palates when they perceive differences between wines. Others (Ross 1939) think of it as more akin to intellectual perception, such as is exercised in the perception of mathematical truths. Many, however, find this postulation of a *sui generis* faculty of reason too mysterious to accept.

The second line of thought does not appeal to the exercise of a special faculty and access to special facts but to a special rule distinct from those connected to advancing individual goals. The most famous attempt to defend this line of thinking comes from Kant. Moral reasoning is based, he argued, on a rule he referred to as the *Categorical Imperative*. This rule requires one not to act in ways that one could not want everyone else also to act. Every rational agent is committed to this rule, Kant argued, simply by engaging in practical reasoning. Committing oneself to this rule is a presupposition of taking up the point of view of practical deliberation. Therefore, he concluded, it is a rule of practical reason. Few have found Kant's arguments convincing. Nevertheless, some contemporary philosophers have tried to develop and defend some version of Kant's ideas. Rawls's idea of reasonableness is one attempt. Another is Thomas Scanlon (1998) who argues that reasonableness requires being responsive to the appropriateness of principles of conduct to serve as foundations for mutual recognition and accommodation.

## REASON AND MOTIVATION

Suppose deliberating to conclusions about what to do is genuinely a form of reasoning. These conclusions may still make no difference to what one does. Reason, that is, may not be practical in another sense—in the sense that it cannot motivate one to comply with its conclusions. When one acts contrary to conclusions of practical deliberation, is one unreasonable in the sense of being insufficiently motivated by this deliberation?

*Internalists* about practical reason hold that one can be: The conclusions of practical reasoning must motivate reasonable agents. This is especially the case, they argue, in moral reasoning: It is not possible to believe it to be wrong to lie, for instance, yet remain unmotivated to tell the truth. One reason internalism is attractive is that it explains the magnetism conclusions of practical reasoning exhibit. To be sure, the conclusions of practical reasoning do not always motivate everyone. If one is depressed or weak-willed, for instance, practical conclusions may have no motivational effect on one. So, internalists must stipulate which psychological condition a reasonable agent is in such that that agent must be motivated. This has not proven to be an easy task.

Internalism, however, appears inconsistent with an attractive conception of motivation, often referred to as the Humean view. On this view, motivation requires, in addition to belief, a desire. Michael Smith (1995) has offered an influential defense of this view. Briefly, the leading idea is that the best functional account of belief and desire gives them different directions of fit with the world. A belief is an attitude toward a given proposition  $p$ , such that the perception of not- $p$  disposes the believer to change attitude to not- $p$ . Desire has the reverse direction of fit: an attitude toward  $p$  such that the perception of not- $p$  disposes the desirer to change the world to  $p$ . If these accounts are basically right, then three things seem clear: Motivation requires a desire, beliefs and desires are only contingently related, and no state could have both directions of fit. Smith himself argues that, nonetheless, one's beliefs about what one has reason to do must motivate agents in the right psychological condition. His position is controversial, however, and the prospects for internalism remain unclear.

## PRACTICAL REASON APPROACHES

See *Rationalism in Ethics (Practical Reason Approaches)*

## PRAGMATICISM

See *Peirce, Charles Sanders; Pragmatism*

## PRAGMATICS

"Pragmatics" was defined by Charles W. Morris (1938) as the branch of semiotics that studies the relation of signs to interpreters, in contrast with semantics, which studies the relation of signs to designata. In practice, it has often been treated as a repository for any aspect of utterance meaning beyond the scope of existing semantic machinery, as in the slogan "Pragmatics = meaning minus truth conditions" (Gazdar 1979). There has been some doubt about whether it is a homogeneous domain (Searle, Kiefer, and Bierwisch 1980).

A more positive view emerges from the work of Herbert Paul Grice, whose *William James Lectures* (1967) are fundamental. Grice showed that many aspects of utterance meaning traditionally regarded as conventional, or semantic, could be more explanatorily treated as conversational, or pragmatic. For Gricean pragmatists, the crucial feature of pragmatic interpretation is its inferential nature: the hearer is seen as constructing and evaluating a hypothesis about the communicator's intentions, based, on the one hand, on the meaning of the sentence uttered, and on the other, on contextual information and general communicative principles that speakers are normally expected to observe. (For definition and surveys see Levinson 1983.)

## THE SEMANTICS-PRAGMATICS DISTINCTION

In early work, the semantics-pragmatics distinction was often seen as coextensive with the distinction between truth-conditional and non-truth-conditional meaning

(Gazdar 1979). On this approach, pragmatics would deal with a range of disparate phenomena, including (a) Gricean conversational inference, (b) the inferential recognition of illocutionary-force, and (c) the conventional meanings of illocutionary-force indicators and other non-truth-conditional expressions such as *but*, *please*, *unfortunately* (Recanati 1987). From the cognitive point of view, these phenomena have little in common.

Within the cognitive science literature in particular, the semantics-pragmatics distinction is now more generally seen as coextensive with the distinction between decoding and inference (or conventional and conversational meaning). On this approach, all conventional meaning, both truth-conditional and non-truth-conditional, is left to linguistic semantics, and the aim of pragmatic theory is to explain how the gap between sentence meaning and utterance interpretation is inferentially bridged. A pragmatic theory of this type is developed in D. Sperber and D. Wilson (1986).

## IMPLICATURE

Grice's distinction between saying and implicating cross-cuts the semantics-pragmatics distinction as defined above. For Grice, "what is said" corresponds to the truth-conditional content of an utterance, and "what is implicated" is everything communicated that is not part of what is said. Grice saw the truth-conditional content of an utterance as determined partly by the conventional (semantic) meaning of the sentence uttered, and partly by contextual (pragmatic) factors governing disambiguation and reference assignment. He saw conventional (semantic) implicatures as determined by the meaning of discourse connectives such as *but*, *moreover* and *so*, and analyzed them as signaling the performance of higher-order speech acts such as contrasting, adding and explaining (Grice 1989). An alternative analysis is developed in D. Blakemore (1987).

Among nonconventional (pragmatic) implicatures, the best known are the conversational ones: These are beliefs that have to be attributed to the speaker in order to preserve the assumption that she was obeying the "cooperative principle" (with associated maxims of truthfulness, informativeness, relevance, and clarity), in saying what she said. In Grice's framework, generalized conversational implicatures are "normally" carried by use of a certain expression, and are easily confused with conventional lexical meaning (Grice 1989). In Grice's view, many earlier philosophical analyses were guilty of such confusion.

Grice's account of conversational implicatures has been questioned on several grounds:

- (1) The status and content of the cooperative principle and maxims have been debated, and attempts to reduce the maxims or provide alternative sources for implicatures have been undertaken (Davis 1991, Horn 1984, Levinson 1987, Sperber and Wilson 1986).
- (2) Grice claimed that deliberate, blatant maxim-violation could result in implicatures, in the case of metaphor and irony in particular. This claim has been challenged, and alternative accounts of metaphor and irony developed, in which no maxim-violation takes place (Blakemore 1992, Hugly and Sayward 1979, Sperber and Wilson 1986).
- (3) Pragmatic principles have been found to make a substantial contribution to explicit communication, not only in disambiguation and reference assignment, but in enriching the linguistically encoded meaning in various ways. This raises the question of where the borderline between explicit and implicit communication should be drawn (Sperber and Wilson 1986, 1995). It has even been argued that many of Grice's best-known cases of generalized conversational implicature might be better analyzed as pragmatically determined aspects of what is said (Carston 1988, Recanati 1989).
- (4) The idea that the context for utterance interpretation is determined in advance of the utterance has been questioned, and the identification of an appropriate set of contextual assumptions is now seen as an integral part of the utterance-interpretation process (Blakemore 1992, Sperber and Wilson 1986).

## PROSPECTS

Within the cognitive science literature, several approaches to pragmatics are currently being pursued. There are computational attempts to implement the Gricean program via rules for the recognition of coherence relations among discourse segments (Asher and Lascarides 1995, Hobbs 1985). Relations between the Gricean program and speech-act theory are being reassessed (Tsohatzidis 1994). The cognitive foundations of pragmatics and the relations of pragmatics to neighboring disciplines are still being explored (Sperber and Wilson 1995, Sperber 1994). Despite this diversity of approaches, pragmatics now seems to be established as a relatively homogenous domain.

## PRAGMATICS [ADDENDUM]

A major focus of post-Gricean pragmatics is the role that pragmatic inference plays in determining the explicit content of utterances (as opposed to their conversational implicatures). As well as disambiguation and reference fixing, there are pragmatic processes of propositional completion, as in the examples in (1), and, more controversially, processes of "free" enrichment, as in (2):

- (1) a. It's too late. [for what?]  
       b. Cotton is better. [than what?]
- (2) a. I've had breakfast. [today]  
       b. John's car hit Tom's and Tom stopped illegally. [causal relation]

The pragmatic completions in (1) are mandated by aspects of the linguistic semantics of the sentences, specifically by the lexical items *too* and *better*. However, this does not seem to be the case for the examples in (2), which express complete, truth-evaluable propositions without the bracketed addition. These pragmatic inferences seem to be entirely pragmatically motivated (i.e., "free" from linguistic indication); they are undertaken in order to satisfy standing communicative presumptions concerning the informativeness and relevance of utterances. For instance, (2a) is strictly speaking true provided the speaker has had breakfast sometime in her life, but in most contexts a speaker intends a more specific proposition and relevant implications hinge on the enriched content (e.g., "that she is not hungry at this moment"). Another kind of free pragmatic process is "lexical modulation": the encoded meaning of a word may be narrowed down in context (e.g., *drink* used to mean "alcoholic drink"), broadened (e.g., *square* used to mean "squarish") or metaphorically extended (e.g., *nightmare* used to mean "unpleasant experience").

The view that "free" pragmatic inferences can affect explicit content in these ways is labeled "truth-conditional pragmatics" and is held by pragmatists across different theoretical persuasions. Various accounts of the phenomenon and its relation to conversational implicature are being developed. Stephen Levinson (2000) argues for a system of "default" pragmatic inferences triggered by particular linguistic forms (e.g., *and*, *some*, *drink*), which are distinct from the kind of inferences responsible for more context-specific implicatures. François Recanati (2003) makes a different distinction between two kinds of pragmatic processes: "primary" processes, such as free enrichment, which contribute to truth-conditional con-

tent, are a matter of local associative processing, whereas “secondary” ones, which account for implicatures, are cases of global propositional inference, constrained by Gricean maxims. Relevance theorists, led by Dan Sperber and Deirdre Wilson, argue that all pragmatic inference can be accounted for by a single principle geared to the recovery of an “optimally relevant” interpretation and that pragmatic enrichment of explicit content often occurs in order to ensure an inferentially sound basis for an antecedently derived conversational implicature.

An alternative, more semantically oriented position, represented by Jason Stanley (2000), denies the existence of processes of “free” pragmatic enrichment and claims that all aspects of an utterance’s truth-conditional content are indicated in its linguistic form. So the examples in (2) are to be explained in the same way as the examples in (1): There is a covert indexical element in their linguistic form and it is this that triggers the pragmatic process of finding the relevant contextual value.

Which of these views is correct (if either) remains to be seen.

## PRAGMATISM

“Pragmatism” was the most influential philosophy in America in the first quarter of the twentieth century. Viewed against the widely diversified intellectual currents that have characterized American life, pragmatism stands

out as an energetically evolved philosophical movement. As a movement it is best understood as, in part, a critical rejection of much of traditional academic philosophy and, in part, a concern to establish certain positive aims. It is in these respects, rather than because of any one idea or exclusive doctrine, that pragmatism has been the most distinctive and the major contribution of America to the world of philosophy. Among the Continental thinkers it has influenced and with whose philosophy it has been in harmony are Georg Simmel, Wilhelm Ostwald, Edmund Husserl, Hans Vaihinger, Richard Müller-Freienfels, Hans Hahn, Giovanni Papini (leader of the Pragmatist Club in Florence), Giovanni Vailati, Henri Bergson, and Édouard Le Roy.

### BACKGROUND

The origins of pragmatism are clear in outline, if not in detail. The familiar capsule description is as follows: Pragmatism is a method of philosophizing—often said to be a theory of meaning—first developed by Charles Sanders Peirce in the 1870s; revived and reformulated in 1898 by William James, primarily as a theory of truth; further developed, expanded, and disseminated by John Dewey and Ferdinand Canning Scott Schiller.

This glossing of the facts is useful as a summary or for directing us where to look if we want to find out more about pragmatism. But it can be misleading. A reexamination or rewriting of the history is not to be embarked upon here; but the following cautionary points deserve mention. The specific formative conditions of the early evolution of pragmatism are not entirely clear for several reasons. The historical occasion of the birth of pragmatism is complicated because it was to some extent the product of cooperative deliberation and mutual influences within the “Metaphysical Club,” founded by Peirce, James, and others in the 1870s in Cambridge. This may be one of the very few cases in which a philosophy club produced something notable philosophically (compare John Locke’s account of the “club” in the 1670s that stimulated the writing of his great *Essay*). But the paper (now lost) that Peirce drew up as a memento lest the club dissolve without leaving behind anything substantial, the paper in which pragmatism was first expressed, was not the free creation of one mind, even though the major credit surely goes to Peirce. Years later, undertaking to write on pragmatism, Peirce queried James: “Who originated the term *pragmatism*, I or you? Where did it first appear in print? What do you understand by it?” And James replied with the reminder: “You invented ‘pragmatism’ for which I

gave you full credit in a lecture entitled ‘Philosophical Conceptions and Practical Results.’”

In addition to some uncertainty as to the facts in the evolution of pragmatism, there are—as we shall see—several problems of interpretation. Peirce and James often gave very different accounts of what they understood by “pragmatism.” Usually this is explained by holding James responsible for distorting or even misunderstanding Peirce’s ideas. That there were differences between Peirce and James on this score is clear. Peirce, despairing of what James (and his followers) were making of the idea, rebaptized his own view as “pragmaticism,” a word ugly enough, he commented, to keep it safe from kidnapers. Historians usually side with Peirce, tending to discredit James’s overzealous pronouncements upon pragmatism and applications of it to issues of the moral value and truth of religious belief. But with equal justice it can be maintained that James was developing a substantially different approach to a different type of philosophical problem, related in some ways to Peirce’s thought, but mostly superficially; only his habitual overgenerosity led him to call what he was doing “pragmatism” and to cite Peirce as the “inventor.”

There is, however, a more serious and persistent problem of interpretation entrenched in the history of pragmatism. This is the problem of determining with some precision what “pragmatism” means or stands for as a philosophical doctrine. As already suggested, pragmatism, by virtue of being an evolving philosophical movement, is to be viewed as a group of associated theoretical ideas and attitudes developed over a period of time and exhibiting—under the differing influences of Peirce, James, and Dewey—rather significant shifts in direction and in formulation. We have the advantage of historical perspective and can make use of it to survey and select distinctive themes and phases in the formation of pragmatism, but a single definitive statement of a single thesis is not to be hoped for.

In the heyday of pragmatism its rapidly changing character proved to be a source of embarrassment and confusion to pragmatists and critics alike. Arthur O. Lovejoy, in a welcome effort at clarification, in 1908 distinguished thirteen possible forms of pragmatism. And Schiller, in an almost intoxicating pluralistic spirit, commented that there were as many pragmatisms as there were pragmatists (at the time a considerable company). Additional confusion over pragmatism was caused by the tendency of its spokesmen to find the philosophical past well populated with pragmatists. Thus Socrates, Protagoras, Aristotle, Francis Bacon, Benedict de Spinoza, Locke,

George Berkeley, David Hume, Immanuel Kant, J. S. Mill, and an assorted variety of scientists were included in the fold.

These perplexities, once hotly debated in the journals, are now only of historical interest. They need not concern us in surveying and assessing what are undoubtedly the leading ideas of pragmatism. It suffices to note the irony in the fact that while pragmatism was supposed to have made its appearance in the paper by Peirce titled “How to Make Our Ideas Clear” (1878), pragmatists continued to have so much trouble in doing so.

### CHARLES SANDERS PEIRCE

What has come to be known as Peirce’s pragmatism grew out of his study of the phenomenology of human thought and the uses of language. For Peirce, the investigation of thought and language—and, therefore, the way into specific studies of all kinds of claims, assertions, beliefs, and ideas—depended upon the understanding of “signs.” One of Peirce’s lasting ideals, resolutely pursued but never completely achieved, was to work out a general theory of signs—that is, a classification and analysis of the types of signs and sign relations and significations that, in the broadest sense, make communication possible. A sign is anything that stands for something else. While this ancient way of putting it admits of a trivial construction (signs are signs), for Peirce, the main thing was that signs are socially standardized ways in which something (a thought, word, gesture, object) refers us (a community) to something else (the interpretant—the significant effect or translation of the sign, being itself another sign). Thus, signs presuppose minds in communication with other minds, which in turn presupposes a community (of interpreters) and a system of communication.

**PRAGMATIC METHOD.** Put roughly, Peirce’s pragmatism is a rule of procedure for promoting linguistic and conceptual clarity—successful communication—when men are faced with intellectual problems. Because the emphasis is upon method, Peirce often remarked that pragmatism is not a philosophy, a metaphysic, or a theory of truth; it is not a solution or answer to anything but a technique to help us find solutions to problems of a philosophical or scientific nature.

One of Peirce’s best-known statements of the technique was in “How to Make Our Ideas Clear” (1878): “Consider what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of

our conception of the objects.” In a somewhat clearer account he said that “in order to ascertain the meaning of an intellectual conception one should consider what practical consequences might conceivably result by necessity from the truth of that conception; and the sum of these consequences will constitute the entire meaning of the conception” (*Collected Papers*, Vol. V, paragraph 9).

While Peirce often spoke of pragmatism as a method of clarifying the meaning variously of words, ideas, concepts (sometimes of objects), we can take his intended purpose to be as follows:

- (1) Pragmatism is a method of clarifying and determining the meaning of signs. We must note the comprehensive status Peirce gives to signs in this connection, for example: “All thought whatsoever is a sign, and is mostly of the nature of language.” The pragmatic method, however, does not apply to all the various kinds of signs and modes and purposes of communication. Peirce considered pragmatism “a method of ascertaining the meaning of hard words and abstract concepts” or, again, “a method of ascertaining the meanings, not of all ideas, but ... ‘intellectual concepts,’ that is to say, of those upon the structure of which, arguments concerning objective fact may hinge.”
- (2) The aim of the method is to facilitate communication, and in particular cases, the degree to which this is accomplished determines the relevance and justification of the method. This aim takes two main forms illustrated in Peirce’s writings. The first is of a critical nature: Where disputes or philosophical problems seem to have no discoverable or agreed-upon solution, pragmatism advises that words are being used in different ways or without definite meaning at all. For example, says Peirce, pragmatism will “show that almost every proposition of ontological metaphysics is either meaningless ... or else ... absurd.” And it is in this critical capacity that Peirce remarked: “Pragmatism solves no real problem. It only shows that supposed problems are not real problems.”

But the second role the method performs is much less negative: Where signs (that is, concepts, language) are unclear, the method supplies a procedure for reconstructing or explicating meanings. Here the method is directed to translating (or systematically replacing) unclear concepts with clearer ones. It is in this spirit that Peirce offered his explications of the concepts of “hardness,” “weight,” “force,” “reality.” His procedure consisted

in translating and explicating a sign (a term, such as *hard*, or sentences of signs, such as “*x* is hard”) by providing a conditional statement of a given situation (or class of situations) in which a definite operation will produce a definite result. Thus, to say of some object *O* that it is “hard” is to mean that “if in certain situations the operation of scratch-testing is performed on *O*, then the general result is: *O* will not be scratched by most substances.” The sign (or concept) “hard” in statements asserting that some object is hard is replaceable and clarified pragmatically with a conditional statement of the sort just given. Peirce refers to this method of conditional explication of signs as a “prescription” or “precept.” The conditionals are recipes informing us what we must do if we wish to find out the kind of conditions determining the meaningful use of a sign.

MEANING. For Peirce, two points are of considerable importance in the pragmatic procedure for determining meaning, (a) Where one cannot provide any conditional translation for a sign, its (pragmatic) meaning is empty. This is what Peirce intended by such characteristic statements as that our conception of an object is our conception of its “practical effects” or “sensible effects.” He did not mean (as James sometimes did) that the meaning of a concept is the practical effect it has in particular cases when you use it. All Peirce argued was that a concept must have some conceivable consequences, or “practical bearings,” and that these must be specifiable in the manner just discussed if the concept is to play a significant role in communication, (b) Peirce’s pragmatism thus is offered as a schema for getting at the meaning, or empirical significance, of language. As a schema it is not a theory of meaning in the sense of some general definition of meaning; it is a theoretical device for getting at the empirically significant content of concepts by determining the roles they play in classes of empirically verifiable statements. This procedure, or schema, clearly foreshadowed the later programs of operationalism and the verifiability theory of meaning.

Despite some serious difficulties that jeopardize portions of Peirce’s method, the general aspects of his approach appear to be sound canons of scientific practice. Peirce’s recondite statements of pragmatism have created considerable confusion. But Peirce seemed less concerned with the problem of providing an accurate and complete statement of the “maxim” of pragmatism than with its use and justification. This he attempted to show in much of his later philosophical inquiries of a scientific and metaphysical sort.

Peirce's schema, or prescriptive method, for "determining the meaning of intellectual concepts" has several sources in addition to his familiarity with scientific technique. Suggestions of it are to be found in Berkeley and in Kant. Peirce's view that meanings take a general form expressed in schema or formulas that prescribe kinds of operations and results and conceivable consequences and rules of action was directly linked to Kant. Peirce says he was led to the method of pragmatism by reflecting on Kant's *Critique of Pure Reason* and on the Kantian use of *pragmatisch* for empirical, or experimentally conditioned, laws, "based on and applying to experience."

**INQUIRY AND TRUTH.** It should be noted, finally, that Peirce's pragmatism is part of a more general account of "inquiry," aspects of which he elaborated with some care and most of which was taken up into Dewey's extensive construction of a theory of inquiry. Peirce described the function of thought as a form of behavior initiated by the irritation of doubt and proceeding to some resolution in a state of belief. Belief is a condition of organic stability and intellectual satisfaction, but these latter do not determine the truth of beliefs. Peirce outlined a scientific and pragmatic method of clarifying and justifying belief. It was this aspect of Peirce's analysis of inquiry and belief that suggested a pragmatic theory of truth. On this matter he was unclear and wavering. Sometimes truth and pragmatic meaning overlapped or coalesced in his discussions of them. But Peirce also argued that truth theory and pragmatism are entirely separate considerations. Generally, the idea of truth, for Peirce, is drawn from Kant and is to be understood as a regulative idea, one that functions solely to order, integrate, and promote inquiry. Taken as a "correspondence" or "coherence" theory—or criticized from the point of view of such theories—Peirce's account of truth looks strange, cumbersome, and naive.

### WILLIAM JAMES

It was James who launched pragmatism as a new philosophy in a lecture "Philosophical Conceptions" in 1898; it was under his leadership that pragmatism came to be famous; and it was primarily his exposition that was received and read by the world at large.

Although Peirce and James were lifelong friends and exerted much intellectual influence upon each other, they differed in ways that had important effects upon their respective versions of pragmatism. Peirce was a realist (calling himself a scholastic realist); James was far more of a nominalist. Where Peirce sought meaning in general

concepts and formulas of action, James sought meaning in experienced facts and plans of action. James looked to the concrete, immediate, practical level of experience as the testing ground of our intellectual efforts; for Peirce, the immediate sensory experience is all but destitute of "intellectual purport." Furthermore, while Peirce's pragmatism took a logical and scientific character, James, despite being an eminent man of science, was first and foremost a moralist in his pragmatism.

**VALUE.** Moral interests and moral language appear in almost every important passage of James's writing on pragmatism. In *Pragmatism* James made his moral conception of philosophy unmistakably evident in saying that "the whole function of philosophy ought to be to find out what definite difference it will make to you and me, at definite instants of our life, if this world-formula or that world-formula be the true one." The phrase "what definite difference ... at definite instants of our life" is by and large James's way of critically judging the meaning and truth of ideas. For James, meaning and truth are included in a more fundamental category of value; to determine the meaning or truth of ideas one must evaluate their "practical consequences," "usefulness," "workability." In several famous pronouncements, James spoke of truth as what is good or expedient in our beliefs. In a phrase that permanently shocked some of his readers, James described the meaning and truth of ideas as their "cash value."

Generally, for James, the function of thought is that of assisting us to achieve and sustain "satisfactory relations with our surroundings." The value of ideas, beliefs, and conceptual dealings is to be determined accordingly, on each of numerous occasions, by their effectiveness and efficiency as the means of carrying us propitiously "from any one part of our experience to any other part, linking things satisfactorily, working securely, simplifying, saving labor."

James was thus primarily concerned with issues of belief and conceptual renditions of experience in their role of enabling men to deal with environments and to enrich the fare of daily experience. It is the level of life experience that interested James. Hence, his own statements of pragmatism resemble those of Peirce but emphasize the importance of immediate experience and practical consequences and clues to action. For James, our thoughts of an object pragmatically considered lead us to "what conceivable effects of a practical kind the object may involve—what sensations we are to expect from it, and what reactions we must prepare. Our con-

ception of these effects, whether immediate or remote, is then for us the whole of our conception of the object.” If we compare this statement from *Pragmatism* with those cited earlier from Peirce, it is not difficult to see that in James’s pragmatism the emphasis is upon the way individuals interpret environing conditions for purposes of successful action. The passage also reflects how James’s view differed from Peirce’s Kantian conception; James explained “pragmatism” as coming from the Greek *πράγμα*, meaning “practice,” “action.” Indeed, so fundamental are action, exploration, and life experience in James’s philosophy that some of his critics have taken great pains to demonstrate the value of inaction and the general uselessness of philosophy. In this endeavor, it may be said, they have been on the whole successful.

**BELIEF.** It was James’s conception of truth that became a *cause célèbre* for pragmatism and its critics, until eventually James, tiring of the matter, turned his attention to other philosophical pursuits, leaving to Dewey the defense and development of pragmatism. Aside from truth, the other major critical issue in pragmatism was James’s argument for the justification of moral and religious belief. James’s interest in the meaning and function of belief was that of a skilled and perceptive psychologist and moralist. His general view was this: When, for a given person *P*, a belief *B* answers or satisfies a compelling need (of *P* to see or interpret the world in a certain way), the “vital good” supplied by *B* in the life of *P* (the difference it makes as a beneficial causal condition in the psychological and physiological behavior of *P*) justifies *B*. It must be noted that James argued for this justification procedure only when (a) the choice of *B* or not-*B* is, for a given individual at a given time, “live,” “forced,” and “momentous”; (b) the evidence for or against *B* is equal, or admits of no rational adjudication of one over the other; (c) the effect or consequences of *B* are a “vital benefit.” These three qualifications work against ascribing to James some popular defense or universal apologia for religious belief. He thought he was correct in pointing to a psychological and moral right to belief analogous to the justification of postulates or posits (in Kantian and Fichtean transcendental philosophizing) or of certain theoretical hypotheses in science.

Peirce and Dewey, among others, were highly critical of this defense of the will to believe. James the psychologist and literary artist brilliantly described the working consequences of types of religious belief for characteristic types of persons. But James the philosopher tended to confuse a descriptive analysis of how belief functions and why men believe with questions of the evaluation or ver-

ification of specific cases of belief. (Thus, for example, the fact that *B* answers a need of *P* is not of itself evidence that the content of belief *B* is warranted or that *P* has correctly understood his “need.”)

However, it was this side of James that was enthusiastically received as the moral core of his pragmatism by Schiller in England and Giovanni Papini in Italy. Here also James’s views have affinities with those of Bergson, Vaihinger, and Simmel. James seemed to be a democratic, energetic, and lovable Johann Gottlieb Fichte, an artist and scientist exhorting men to trust their beliefs and, above all, to leave the classroom and cloister and start living and acting in the world.

### JOHN DEWEY

In the article “The Development of American Pragmatism,” Dewey described Peirce’s views as stemming from an “experimental, not a priori, explanation of Kant” and James’s pragmatism as inspired by British empiricism. But he also noted this difference: “Peirce wrote as a logician and James as a humanist.” There was, in fact, a cross-fertilization of these strains; but the characterization is apt and traceable enough in the history of pragmatism and in Dewey, too, to be of expository aid. Dewey began to appreciate James while still under the influence of Hegelian and Kantian idealism; later he recognized the importance of Peirce, whose insights and ideas were in many respects anticipations of those Dewey had started to work out on his own. The Hegelian synthesis of the logical and humanistic sides of pragmatism was achieved by the disenchanting Hegelian Dewey.

**INSTRUMENTALISM.** Through Dewey’s patient, critical, and indefatigable efforts, pragmatism was carefully and thoroughly reformulated into what Dewey called Instrumentalism, “a theory of the general forms of conception and reasoning.” Instrumentalism was a single philosophical theory within which the two evolving aspects of pragmatism found coherent expression. Instrumentalism was both theory of logic and a guiding principle of ethical analysis and criticism. For Dewey, this theory bridged the most persistent and noxious of “dualisms” in modern thought—the separation of science and values, knowledge and morals.

Instrumentalism was Dewey’s theory of the conditions under which reasoning occurs and of the forms, or controlling operations, that are characteristic of thought in establishing future consequences. In the paper cited above, Dewey wrote:

Instrumentalism is an attempt to constitute a precise logical theory of concepts, of judgments and inferences in their various forms, by considering primarily how thought functions in the experimental determinations of future consequences ... it attempts to establish universally recognized distinctions and rules of logic by deriving them from the reconstructive or mediative function ascribed to reason. It aims to constitute a theory of the general forms of conception and reasoning.

A suggestive and vital feature of this theory for Dewey was that while the subject matters of scientific inquiry and moral and social experience differ, the method and forms of thought functioning “in the experimental determinations of future consequences” do not differ in kind. The method of thought and the forms of reflective behavior exhibit a common functional pattern whenever problematic situations become resolved through inquiry yielding “warranted assertion.”

**INQUIRY AND TRUTH.** “Warranted assertion” is the term for Dewey’s version of truth. Inquiry is initiated in conditions of doubt; it terminates in the establishment of conditions in which doubt is no longer needed or felt. It is this settling of conditions of doubt, a settlement produced and warranted by inquiry, which distinguishes the warranted assertion. Whereas Dewey once defined “truth” as the “working” or “satisfactory” or “verified” idea or hypothesis, he was led, later—partly as a result of several critical controversies over truth with Bertrand Russell during the 1930s and 1940s—to restate his view of truth as warranted assertion.

In his *Logic* Dewey gave his general definition of inquiry as “the controlled or directed transformation of an indeterminate situation into one that is so determinate in its constituent distinctions and relations as to convert the elements of the original situation into a unified whole.” The theory of inquiry was developed over many years and in many writings; into it went the products of Dewey’s reflections on the nature of thought, his contributions to psychology and education, the influence of the biological and functional aspects of James’s *Principles of Psychology*, and the influence of Peirce on the nature of scientific inquiry. In his analysis of the biological and cultural conditions of inquiry and in his account of intelligence as a function of these interacting conditions in a particular situation with respect to a problem and its outcome, Dewey was also guided by some of the basic ideas in the philosophical social psychology of G. H. Mead,

once Dewey’s colleague at Michigan and Chicago and one of his closest friends. The definitive statement of the theory is in Dewey’s *Logic: The Theory of Inquiry* (1938).

For Dewey, the theory of inquiry is a generalized description of the organic, cultural, and formal conditions of intelligent action. Such action is provoked by problems of diverse kinds—political, ethical, scientific, and aesthetic. But irrespective of the specific content of human problems or the nature of problem situations, inquiry is a reflective evaluation of existing conditions—of shortcomings and possibilities—with respect to operations intended to actualize certain potentialities of the situation so as to resolve what was doubtful. The purpose of inquiry is to create goods, satisfactions, solutions, and integration in what was initially a wanting, discordant, troubled, and problematic situation. In this respect all intelligence is evaluative, and no separation of moral, scientific, practical, or theoretical experience is to be made. So commanding an achievement was Dewey’s last-mentioned work that “pragmatism” is often identified with the position he expounded there as a naturalistic logic for evaluating and reconstructing human experience.

#### MORE RECENT TENDENCIES

A somewhat different articulation of pragmatism, deriving less from James and Dewey than from Peirce, was set forth by C. I. Lewis in the 1920s as “conceptualistic pragmatism.” Lewis emphasized the role of mind in supplying the a priori principles and categories by which we proceed to organize and interpret sense experience. But he also stressed the plurality of categories and conceptual schemes by which experience can be interpreted and the evolutionary character of our systems. Because a priori principles impose no necessary order on the world or upon sense experience (determining only our ways of organizing experience), Lewis argued for a “pragmatic a priori.” Decisions to accept or reject conceptual principles, indeed the very function of those principles, rest upon socially shared needs and purposes and upon our interest in increased understanding and control over experience. According to Lewis (in *Mind and the World Order*), “The interpretation of experience must always be in terms of categories ... and concepts which the mind itself determines. There may be alternative conceptual systems giving rise to alternative descriptions of experience, which are equally objective and equally valid.... When this is so, choice will be determined, consciously or unconsciously, on pragmatic grounds.”

Lewis’s pragmatism resulted in a theory of conceptual and empirical meaning and in an analysis of empiri-

cal judgments as probable and evaluative modes of acting upon passing and future experience.

In more recent literature, under the influence of Dewey and Lewis as well as Rudolf Carnap, Charles Morris, Ernest Nagel, Willard Van Orman Quine, and others, “pragmatism” connotes one broad philosophical attitude toward our conceptualization of experience: Theorizing over experience is, as a whole and in detail, fundamentally motivated and justified by conditions of efficacy and utility in serving our various aims and needs. The ways in which experience is apprehended, systematized, and anticipated may be many. Here pragmatism counsels tolerance and pluralism. But, aside from aesthetic and intrinsic interests, all theorizing is subject to the critical objective of maximum usefulness in serving our needs: Our critical decisions, in general, will be pragmatic, granted that in particular cases decisions over what is most useful or needed in our rational endeavors are relative to some given point of view and purposes.

An expression of this attitude that is of current interest was advanced by Peirce, James, and Dewey, as well as by F. P. Ramsey, the brilliant English philosopher influenced by Peirce and James. This is an interpretation of the laws and theories of science as “leading principles,” or instrumental procedures, for inferring stated conditions from others. Construed as leading principles, theories function as guides for logical inference, indicating how certain formulations are to be derived from other formulations of events, rather than as descriptively true statements of reality serving as premises from which conclusions are deduced. Pragmatically, theories are inference policies, neither true nor false (except pragmatically) but nonetheless critically assessable as to their utility and clarity and the fruitfulness of the consequences that result from adopting them.

While there continues to be an interest in the philosophies of Peirce, James, Dewey, and Schiller, pragmatism as a movement, in the form outlined in these pages, cannot be said to be alive today. But pragmatism has succeeded in its critical reaction to the nineteenth-century philosophical background from which it emerged; it has helped shape the modern conception of philosophy as a way of investigating problems and clarifying communication rather than as a fixed system of ultimate answers and great truths. And in this alteration of the philosophical scene, some of the positive suggestions of pragmatism have been disseminated into current intellectual life as practices freely adopted and taken for granted to an extent that no longer calls for special notice.

The measure of success pragmatism has achieved in encouraging more successful philosophizing in our time is, by its own standards, its chief justification. To have disappeared as a special thesis by becoming infused in the normal and habitual practices of intelligent inquiry and conduct is surely the pragmatic value of pragmatism.

PRAGMATISM  
[ADDENDUM]

Not unexpectedly, given that “pragmatism” is not a doctrine but a method (as Charles Sanders Peirce put it), the tradition of classical pragmatism is formidably diverse. Even the method—the pragmatic maxim—is differently interpreted by different pragmatists; and this diversity is compounded by the different doctrines and interests of the various pragmatists. But there is a pattern discernible within the diversity: a shift from Peirce’s reformist, scientific philosophy, anchored by his realism about natural kinds and laws and about the objects of perception, through William James’s more nominalist pragmatism, his insistence that “the trail of the human serpent is over everything” (1907, p. 37), through John Dewey’s proposal that the concept of warranted assertibility replace the concept of truth, to the radicalism of Ferdinand Canning Scott Schiller’s avowedly Protagorean relativization of truth to human interests.

Contemporary pragmatisms are no less diverse, but the spectrum has shifted to the left. The more conservative neopragmatists are as akin to James as to Peirce, and the most radical go beyond Schiller’s relativism to an antiphilosophical, sometimes antiscientific, even anti-intellectual, stance—a stance so much at odds with the aspirations of the founders of pragmatism as to put one in mind of Peirce’s complaints about writers who persisted in “twisting [the pragmatists’] purpose and purport all awry” (*Collected Papers*, 5.464).

Nicholas Rescher describes his philosophy as pragmatic idealism: idealism, because it holds that “reality ... as humans deal with it is *our* reality—our thought-world as we conceive and model it” (1994, p. 377); pragmatic, because it holds that, though our picture of reality is a mental construction, it is not a free construction but is objectively constrained by success or failure in practice, in prediction and attainment of purpose.

In some ways—not least in philosophizing unapologetically in the grand systematic manner—Rescher is much like Peirce; indeed, his conception of the interlocking cognitive, evaluative, and practical aspects of rationality takes him further than Peirce into some of the territory of value theory. In other ways Rescher’s pragmatism is more reminiscent of James: *inter alia*, for its stress on practical consequences and on a pluralism of perspectival truth-claims. So, too, is his idealism. *Qua* pragmatist Peirce denies the intelligibility of the in-principle-incognizable: *Qua* “objective idealist” he maintains that “matter is just effete mind” (*Collected Papers*, 6.25).

Rescher's idealism sounds more like the Jamesian serpent—or Deweyan interactionism.

In repudiating metaphysical realism and endorsing internal realism, Hilary Putnam evinced some sympathy with Peircean conceptions of truth and reality. But his conceptual relativism—"Our language cannot be divided into two parts, a part that describes the world 'as it is anyway' and a part that describes our conceptual contribution" (1992, p. 123)—sounded more like James. However, his argument against the irrealism of Nelson Goodman (himself classifiable as a left-wing Jamesian of the boldest nominalist stripe) stressed the distinction between wholly conventional names such as "Sirius" and only partially conventional general terms such as *star*. Putnam thus recalled Peirce's realism of natural kinds, and perhaps divided our language after all. It is not surprising, then, to find that most recently, in his Dewey lectures, he tends to a more realist stance.

Sympathetic in the 1950s and 1960s to the positivists' aspiration to a scientific single theory that explains everything" (Putnam 1992, p. 2), Putnam is since then inclined to a pluralistic, problem-centered approach to philosophy. Here, as in his defense of democracy as a precondition for the application of intelligence to the solution of social problems, he acknowledges Dewey.

A year before the publication of W. V. O. Quine's "Two Dogmas," Morton G. White had invoked Dewey in describing the analytic-synthetic distinction as "an untenable dualism." Rejecting that distinction, adopting a holism of verification, insisting on the underdetermination of theory by data, Quine describes himself as going beyond C. I. Lewis's pragmatic a priori to a "more thorough pragmatism" that emphasizes pragmatic considerations in theory-choice generally. "Pragmatic" here suggests the relatively unconstrained rather than, as in Rescher, a kind of constraint. Quine refers approvingly to Schiller's view of truth as manmade as one of pragmatism's main contributions to empiricism. But he hopes to avoid Schiller's relativism by means of a naturalism that views philosophy as internal to science. This differs significantly from Peirce's and Dewey's aspiration to make philosophy scientific by applying the method of science to philosophical questions.

As another of pragmatism's main contributions Quine mentions Peirce's and Dewey's connecting belief and meaning to behavior. But Quine's behaviorism is more stringent, in part because of the influence of B. F. Skinner, and in part because Quine's extensionalism leaves him uneasy, as Peirce was not, with any irreducibly dispositional talk.

As Putnam's allusions to the existentialist character of James's ethics indicate, some hope a neopragmatism might heal the analytic-Continental rift. One example is Karl-Otto Apel's grafting of pragmatic elements from Peirce and Jürgen Habermas onto Alfred Tarski's semantic conception of truth. Another is Joseph Margolis's attempt, emphasizing both the biological roots and the "deep historicity" of human injury, and proposing a reconciliation of a modest realism with a weak relativism, to marry themes from Peirce with themes from Martin Heidegger.

Richard Rorty describes himself as accommodating themes from Dewey with themes from Heidegger. Maintaining that "revolutionary movements within an intellectual discipline require a revisionist history of that discipline" (1983, p. xvii), Rorty dismisses Peirce as having merely given pragmatism its name. And he urges in the name of pragmatism that the project of a philosophical theory of knowledge should be abandoned; that science is exemplary only as a model of human solidarity; that philosophy is more akin to literature than to science; that it should be in the service of democratic politics; that truth is "not the kind of thing one should expect to have a philosophically interesting theory about" (1983, p. xiv) and that to call a statement true is just to give it "a rhetorical pat on the back" (1983, p. xvii); that pragmatism is antirepresentationalism.

There is some affinity between Rorty and Schiller. But Peirce, who was a pioneer of the theory of signs, of representation, and who desired "to rescue the good ship Philosophy for the service of Science from the hands of the lawless rovers of the sea of literature" (*Collected Papers*, 5.449), would disagree with Rorty's pragmatism in every particular. So too, except perhaps for his description of the best ethical writing as akin to "novels and dramas of the deeper sort" (1891, p. 316), would James. And so, most to the point, would Dewey, who hoped to renew the philosophical theory of knowledge by making it more scientific, and whose political philosophy is infused by the hope that the application of scientific methods would enable intelligent social reform, and by the conviction that a free society is a prerequisite of a flourishing science.

## PRAGMATIST EPISTEMOLOGY

William James's observation that "when ... we give up the doctrine of objective certitude, we do not thereby give up the quest or hope of truth itself" (1956, p. 17) succinctly expresses one important epistemological theme of traditional pragmatism: accommodation of a thoroughgoing fallibilism with a modest optimism about the possibility of successful truth seeking. Also characteristic of that tradition is its naturalism, its acknowledgment of the biological, and the social as well as the logical elements in the theory of knowledge, and its respect for science as, in Charles Peirce's words, "the epitome of man's intellectual development" (*Collected Papers*, 7.49). Since 1968 these ideas have been variously worked out by some who are fully aware of their roots in pragmatism and have also entered the thinking of many who are not. More surprising, some self-styled neopragmatists defend epistemological positions (or anti-epistemological positions) quite unlike these classically pragmatist themes.

Both fallibilism and naturalism are prominent themes in W. V. O. Quine's epistemology, themes of which he acknowledges the pragmatist ancestry; his fallibilism, furthermore, like Peirce's, extends to mathematics and

logic, and his naturalism, like Peirce's, has an evolutionary character. And he shares the pragmatists' regard for science. However, he seems drawn beyond a view of epistemology as resting in part on empirical assumptions about human cognitive capacities to conceiving of it as internal to the sciences of cognition; and thence, under pressure of the implausibility of supposing that psychology or biology could answer the questions about evidence, justification, and so forth, with which epistemology has traditionally been concerned, he seems drawn to a revolutionary scientism that would abandon the traditional questions in favor of questions the sciences can be expected to answer. Unlike his fallibilism and his modest, reformist naturalism, neither his scientism nor his revolutionary displacement of epistemology falls within the tradition of pragmatism.

Nicholas Rescher's approach, from its insistence that we humans "cannot function, let alone thrive, without knowledge of what goes on around us" (1994, p. 380) to its stress on the provisional, tentative character of all our estimates of truth, is unambivalently within the pragmatist tradition. But Rescher takes issue with Peirce's definition of truth, and therefore conceives of progress in terms of improvement over earlier stages rather than closeness to a supposed final stage.

Focusing on criteria of evidence and justification rather than on guidelines for the conduct of inquiry, Susan Haack adapts from the pragmatist tradition: Her fallibilism, expressed in the thesis that justification comes in degrees; her weak, reformist naturalism, expressed in the thesis that our criteria of evidence have built into them empirical presuppositions about human cognitive capacities; her account of perception; and her strategy for the metajustification of criteria of justification.

In stark contrast to Rescher or Haack, Richard Rorty urges in the name of pragmatism that the philosophical theory of knowledge is misconceived; and, in contrast to Quine, that epistemology should be, not replaced by the psychology of cognition, but simply abandoned. Rorty likens his repudiation of epistemology to John Dewey's critique of the "spectator theory." What Dewey intended, however, was to reform epistemology, to replace the quest for certain knowledge of eternal, unchanging objects with a realistic account of fallible, experimental, empirical inquiry. Rorty's revolutionary attitude derives from his conception of justification as a matter exclusively of our practices of defending and criticizing beliefs, not grounded in any connection of evidence and truth. This "conversationalist" conception of justification is moti-

vated by his rejection of any conception of truth as meaning more than "what you can defend against all comers."

Often accused of relativism, Rorty denies the charge. He escapes it, however, only by shifting from contextualism ("A is justified in believing that *p* iff (if and only if) he can defend *p* by the standards of *his* community") to tribalism ("... iff he can defend *p* by the standards of *our* community" [1979, p. 308]). But tribalism is arbitrary if our practices of criticizing and defending beliefs are, as Rorty holds, not grounded in any connection of evidence and truth.

In not-so-stark contrast to Rorty, Stephen Stich (1990) urges in the name of pragmatism that it is mere epistemic chauvinism to care whether one's beliefs are true, and that justified beliefs are those that conduce to whatever the subject values. True, Stich cheerfully embraces relativism (and rejects tribalism since he thinks our epistemic practices too preoccupied with truth); and he looks to the sciences of cognition to help us "improve" our cognitive processing so as better to achieve what we really value. But, as more overtly in Rorty, the effect is profoundly anti-epistemological and "pragmatist" in quite another sense than the traditional one.

## PRECOGNITION

Etymologically, *precognition* is simply the Latin equivalent of *foreknowledge*. But it has come to have a more specialized meaning as a semitechnical term for one of the phenomena or putative phenomena of parapsychology (psychical research). This entry touches on the wider issues of foreknowledge only insofar as they appear in a rather special form in the narrower context of parapsychology. Again, since the philosophical problems centering on some of the other concepts of parapsychology are examined at length elsewhere, telepathy, clairvoyance, and psychokinesis are mentioned here only when necessary to the main goal of becoming clearer about the logical geography of parapsychological precognition. Nor will there be any discussion of what the facts actually are. We shall be concerned only with theoretical questions of implication and explanation.

*Precognition* is one of a group of terms that also includes *telepathy*, *clairvoyance*, and—more peripherally—*psychokinesis* (PK). Telepathy is thought of, initially at any rate, as consisting in the acquisition of information by one person from another without the use of any of the senses normally indispensable to communication. Clairvoyance, at the same initial stage, is conceived of as being generically identical with telepathy; the specific difference is that in the case of clairvoyance the information is supposed to be obtained not from another person but from an object. Telepathy would be termed “precognitive” if the information so acquired was not going to become available to the other person until later. Clairvoyance would be termed precognitive if the information so acquired was not, until later, even going to become available in things, as opposed to minds.

It is thus possible to consider precognitive telepathy and precognitive clairvoyance as being two species of the genus precognition. Straight telepathy, straight clairvoyance, and both sorts of precognition are all supposed to be both nonsensory and noninferential. It is partly for this reason that all these alleged phenomena are frequently classed together as varieties of extrasensory perception (ESP). It is important to recognize that both these

negative characteristics are in all four cases defining. To show that the information was acquired by the use, whether conscious or unconscious, of sensory cues, clues, or signs is a sufficient reason for disqualifying as genuine telepathy, or what have you, any ostensible case of telepathy or other such phenomenon. Similarly, to show that this acquisition was the result of a feat of inference, however heroic and remarkable in itself, again constitutes a completely sufficient reason for insisting that we are not confronted with a genuine case of precognition. At most we must describe it as a pseudo precognition, “precognition” only in quotation marks.

Suppose someone has an intuition or a dream or a waking vision that is found to correspond to some actual later happening. Suppose that it seems out of the question either (1) to account for the correspondence as the result of successful inference, conscious or unconscious, from materials available to the subject at the time, or (2) to trace it back to some causal ancestor common to both the “anticipation” and the “fulfillment,” or (3) to say that the “fulfillment” was somehow a result of the “anticipation,” or (4) even to refuse to account for the correspondence in any way on the grounds that it was just a coincidence. (The counterargument in this last case would be that some intuitions, dreams, visions, and so forth, are bound to prove veridical and that presumably this was just one of those striking cases that is—as the catch phrase has it—“by the law of averages” bound to occur occasionally.) If such an intuition, or what have you, were to occur we would—provided that all four conditions seemed to be met—have at least a *prima facie* case of precognition. Three theoretical questions must then be considered.

### OPERATIONAL DISTINCTIONS

The first question is whether there are real operational distinctions to be made between all the supposed varieties of ESP or whether any of them can be regarded as alternative descriptions of the same logically possible phenomena. For instance, some ingenuity is required to work out an experimental design that would enable us to distinguish decisively between straight clairvoyance and precognitive telepathy.

To make this clear, consider a stylized ESP experiment. The experimenter equips himself with a pack of cards, perhaps the special Zener type, which consists of five suits of five identical cards. He devises a procedure for randomizing the order in which the cards are to be offered as targets. He recruits a subject whose function is to guess the values of the cards chosen as targets. The

experimenter takes drastic and thorough precautions to ensure that it is quite impossible for the subject to tell by any combinations of inference and sensory perception what is or is going to be the value of any target card. (This is, of course, very much more easily said than done. But here our concern is with theory only.) The subject in due course makes his guesses, and these guesses are recorded. If enough guesses are made—provided always that the experiment has been properly designed and properly executed—we should expect “by the law of averages” that when the guesses are scored against their targets about one-fifth of the total will turn out to have been right and the remaining four-fifths wrong. But if significantly more hits have been scored than this mean-chance expectation, then it seems that *some* ESP factor must have been involved.

Suppose now that the experimenter has taken care to ensure that no one at all, himself included, should know, at the time when the subject makes his guesses, what is the value of each target card. It might seem that his experimental results can be interpreted as evidence only for clairvoyance and not for telepathy. But once we have allowed the possibility of precognition, then these same results can be described equally well in terms of precognitive telepathy. The subject is perhaps precognitively “picking” the brains of whoever later does the scoring.

The problem is further complicated if one is also prepared to allow the possibility of PK. Literally, “psychokinesis” means movement by the mind. The idea is that perhaps some people sometimes may be able, whether consciously or unconsciously, to move or otherwise affect things without pushing or pulling them and, indeed, without in any way touching either the things in question or any other things involved in the process. Perhaps, it is suggested, these people or, indeed, all of us really can in some conditions bring about changes in things by simply “willing,” as a gambler might wish that by simply “willing” and without any detectable cheating he could get dice to fall in the ways he desires.

Once this suggestion is allowed there seems to be room for an alternative description of many experiments that might otherwise have appeared to be unambiguous evidence of the reality of precognition. Such a description will be in terms of psychokinesis, guided perhaps by a measure of straight telepathy or straight clairvoyance. The subject may not, after all, really be precognizing the target. Perhaps he or somebody else is consciously or unconsciously influencing psychokinetically the target-determining mechanism in order to increase the degree of correspondence between the guess series and the target

series. With appropriate alterations the same suggestion can be applied to spontaneous, as opposed to experimental, cases of ostensible precognition. The “fulfillment” or “fulfillments” become partly or wholly the results of the “anticipations,” and, by specification, any such cases are disqualified from being classed as genuinely precognitive. Confronted by this kaleidoscopically changing confusion of alternative descriptions, we need not wonder that PK was once described as the parapsychological equivalent of a universal solvent.

## IMPLICATIONS

The second sort of theoretical question concerns the implications of precognition. Suppose it were to be established that there really is such a phenomenon, which actually does satisfy all the conditions stipulated; what would follow?

**THE FUTURE AS PRESENT.** One consequence that has often been thought to follow from the existence of precognition is that, sensationally, the future must somehow be already here—or at any rate there. This is usually derived from a conception of precognition as a mode of perception, of ESP. Thus, J. W. Dunne, in *An Experiment with Time* (3rd ed., London, 1939, p. 7), claims that in precognition “we habitually observe events before they occur.” By valid inference from this misdescription he concludes that the future must therefore really be present. Upon this absurdity he proceeds to erect his logical extravaganza “the serial theory of time.” Or again, in a useful survey of the field, D. J. West remarks: “precognition—foreseeing arbitrary events in the future that could not by any stretch of the imagination be inferred from the present—that is something which is almost impossible for our minds to grasp. How can anyone see things which do not yet exist?” (*Psychical Research Today*, London, 1954, p. 104).

Now it is necessarily true that if anything is to be seen or otherwise perceived—and not just “seen” or “perceived” (in discrediting quotation marks)—that thing must be presently available. (We ignore for present purposes the peripheral problems presented by very distant stars.) West is therefore more right than perhaps he realizes in suggesting that it is inconceivable that anyone should be able to see things that do not yet exist. Nevertheless, the correct conclusion to draw is not, as some have been inclined to think, that precognition is logically impossible. The correct conclusion is, rather, that if the phenomenon specified was to occur, it could not be conceived of as any sort of perception. The argument reduces

to absurdity not the notion of precognition as such but the assumption that such precognition can be assimilated to perception. (There are indeed further reasons, applying equally to all varieties of ESP, which tend to destroy this analogy and therefore make unfortunate the use of the expression “extrasensory perception.” But the present reason, applying only to precognition, is in this case by itself entirely decisive.)

**PRECOGNITION AS FOREKNOWING.** Suppose one begins by thinking of precognition not as foreseeing but as foreknowing. Suppose then that one happens to be one of those who conceives of cognition on the model of perception. This is, of course, a misconception, but one with a most ancient and distinguished pedigree. One relevant reason for insisting that this model is inapplicable is that whereas it is logically possible for me to know now that certain things happened in the past and that other things will happen in the future, it is not logically possible for me now to perceive anything but what is now available to be perceived. Thus, anyone who thinks of precognition as a form of knowing and of knowing as a sort of perceiving will arrive by a rather longer route at exactly the same conclusions—that the future is present—as the person who begins by thinking of precognition as a type of perception. In either case the treatment indicated is essentially the same.

C. D. Broad comments:

The fact is that most people who have tried to theorize about non-inferential precognition have made needless difficulties for themselves by making two mistakes. In the first place, they have tried to assimilate it to sense-perception, when they ought to have assimilated it to memory. And, secondly, they have tacitly assumed an extremely naive prehensive analysis ... [which] is simply nonsensical when applied to ostensible remembering or ostensible foreseeing. (“The Philosophical Implications of Foreknowledge”)

By “prehensive analysis” Broad means believing, mistakenly, that for an occurrence to be remembered it must somehow be present.

**FATALISM.** The model of memory is, as Broad urged, much less inapt than that of perception. But it, too, has its dangers. It has beguiled some into thinking that precognition must necessarily involve fatalism. The suggestion is that precognition would be an exact analogue and complement of memory, but where memory operates backward, precognition would be remembering forward. (See,

for instance, Lewis Carroll, *Through the Looking Glass*, Ch. 5.) Now, if someone remembers that he himself killed Cock Robin, and provided that he really does remember and that he is not merely claiming, mistakenly or even dishonestly, to remember that he committed this crime, then it follows necessarily that he did kill Cock Robin. But if he has done it, then he has done it, and it must now be too late for anyone to intervene to save the victim. It is, notoriously, a tautology that what is done is done and cannot be undone. The past is unalterable. The temptation is to argue that the same must, in exactly the same sense, apply to the future. If I can truly precognize that I will kill Cock Robin—provided that it really is a precognition and that I am not merely claiming mistakenly, or even dishonestly, to be precognizing—then it follows necessarily that I will kill Cock Robin.

The false step is to go on to urge that by parity of reasoning, since he will do it, then he will do it, and therefore it must now be too late for anyone to save Cock Robin. For the conclusion does not follow. From the proposition that he will kill Cock Robin we are entitled to infer that he will kill Cock Robin and hence that no one will in fact save the bird. But what we are not entitled to infer is that it must now be too late to take any steps to save Cock Robin, that no one could possibly do anything to help. It is one thing to know that some catastrophe will in fact occur; it is quite another to know that there is now nothing that anyone could do to prevent it, even if he so wished. To know that he will in fact do it, it is sufficient to know that he in fact will: tautology. It is not necessary also to know, what may very well not be the case, either that he would not have been able to do otherwise had he been going to want to or that no one else would have been able to stop him had they been going to be so inclined.

This point is, of course, involved in the much wider question of whether foreknowledge in the general sense must carry any such fatalist implications. The wider question is beyond the scope of this article, but the argument offered here is as applicable to the wider context as to this narrower one. The problem remains why it should be thought, as obviously it often is, that to establish the reality of noninferential precognition, even as an extremely weak and rare faculty, ought to raise fatalist anxieties in a much more acute form than does, for instance, the present possibility of inferring the outcome of some not too distantly future election—on the basis of a knowledge of the present preferences, psychological traits, beliefs, and expressed voting intentions of the electors concerned.

*The threat to autonomy.* One possible suggestion is that it may be thought that whereas predictions on the

basis of knowledge of human beings do not constitute any threat to the autonomy and dignity of the persons concerned, a precognitive forecast about someone's future actions, made without reference to his peculiar characteristics, plans, and desires, would tend to show that his decisions to act in those ways will not be as causally necessary as he might like to believe. To show that human wishes, plans, and decisions do not affect what happens would indeed be to demonstrate a fatalist conclusion; for this is precisely what "fatalism" means. But to show that someone can know, without reference to that other person's wishes and plans, what another person is going to do is, surely, not sufficient to show that those wishes and plans will not determine his course of action.

It might be argued that knowledge presupposes grounds and that, insofar as the grounds contain no reference to the wishes and plans of the agent, this shows that he cannot properly be held responsible for what he is going to do. This argument would have more force if knowledge of what is going to occur always had to be grounded on knowledge of the presence of particular causes sufficient to bring about the occurrence. But quite apart from any question of whether it is true that all knowledge must be grounded on something else, the argument must be ineffective as long as we have to allow that some knowledge is quite sufficiently grounded simply on a recognition of reliable signs. Suppose precognition does actually occur, and suppose that it is properly to be classed as a form of knowledge; then it can be only either a variety that is not grounded at all or one which is based upon just such a recognition of signs—the recognition, namely, that some particular class of guesses, intuitions, visions, or whatnot are in fact reliable pointers to the future. For any inference, whether conscious or unconscious, from any knowledge, however acquired, of the causes of what is going to happen to the true conclusion that just that is indeed going to happen must by definition disqualify that conclusion as a genuine noninferential precognition.

*Perceptual model and fatalism.* A second suggestion is that the special anxiety felt in this case of precognition is just one more consequence of thinking in terms of a perceptual model. If in having a precognitive experience you were, as it were, seeing the future, then indeed it would be absurd to insist, once that experience has taken place, that there are any steps that anyone could take that could prevent the fulfillment of the precognition. It would be absurd so to insist because on this assumption of a literal foreseeing, the event precognized would by now have been seen happening. But once an event has

happened there cannot be anything that anyone could possibly do to prevent it from happening.

*Precognitive infallibility.* A third suggestion is adapted to a rather different conception of the problem. It is common enough to find people who (at any rate, in their most self-consciously philosophical moments) would be reluctant to concede that there is any such thing as real knowledge of future events, or at least of future human actions. To such a person precognition might appear to present a special problem precisely because of the analogy to memory. This might, of course, be because he naively assimilated memory to perception. But he might in a rather more complicated way be arguing that since from the occurrence of a genuine memory one is entitled to deduce that the past was as that memory represents it to have been, therefore the occurrence of an authentic precognition would, insofar as precognition is to be conceived on the model of memory, provide a similarly inexpugnable guarantee that the future must necessarily be as it is precognized to be going to be. The idea would be, presumably, that whereas inferences can be invalid and their conclusions false, memory is necessarily infallible. Thus, if precognition is a reality, and if it is a faculty exactly analogous to memory, then it, too, must be similarly infallible. In that case there can be nothing which anyone could do to prevent the fulfillment of any such precognitive anticipations.

Insofar as this claim really represents a different contention from any so far considered, and it is not altogether clear that it does, the crucial error seems to lie in a confusion between remembering and mistakenly or dishonestly claiming to remember. True memory is, if you like, infallible, but only in the weak sense that "I remember doing it" entails "I did it," not in the strong sense that "I claim to remember doing it" entails "I did it." This is because it is always possible that in making such a memory claim I may either be mistaken or be acting dishonestly. Thus, to be exactly analogous to memory, precognition would have to be infallible in this and only this sense. But this sort of infallibility pertains equally to knowledge: for "He knows that the dogmas of his Roman Catholic faith are true" entails "The dogmas of his Roman Catholic faith are true"; whereas "He claims with absolute conviction that he knows that the dogmas of his faith are true" is by itself not even evidence for "The dogmas of his faith are true." And we have already devoted enough space to urging that from the possibility of knowledge as such of future human actions no fatalist conclusions follow necessarily.

*"Forward memory" and fatalism.* Another, and perhaps the most important, consideration encouraging the

idea that parapsychological precognition must constitute a fatalist threat more serious than any arising from ordinary possibilities of foreknowledge is that what we remember is always and necessarily something in which somehow we ourselves were previously involved: We remember, that is, only what we have learned or what happened to us or what we did. Therefore, insofar as precognition is to be thought of as “remembering forward,” its contents must be similarly restricted to what we shall later come to know by other means, to what will happen to us, or to what we will do. But now, as long as I remain the sort of creature that I am, it will clearly not be possible for me to precognize something very unpleasant as going to happen to me without my casting about for ways in which the unpleasantness may be avoided.

Hence, if there is to be precognition, at least one of three further conditions must be satisfied: Either (1) the contents of my precognitions must be restricted to terms that even in an unchanged universe would not provoke me to effective avoiding action, or (2) I as the precognizer must be so changed that I no longer attempt any avoiding action, or (3) the universe around me must be so changed that my attempts are all in fact now ineffective. Obviously both the second and the third of these options would constitute major steps towards a fatalistic universe. Yet neither of these represents a necessary corollary of precognition as such. On the other hand, to take the first option is to accept a limitation that drastically reduces the analogy between precognition and memory. The conclusion is that any fatalist consequences belong to precognition as a faculty fully analogous to memory, not simply to precognition as such.

**CAUSE AND EFFECT.** It has sometimes been suggested that to establish the reality of precognition would be to show that in some cases effects can precede their causes. Surprising and disturbing though the effects reported certainly are, this at least is something that neither these nor any other phenomena could ever establish. The reason is, quite simply, that “a cause must either precede or be simultaneous with its effect” is a necessary truth. It is no more possible to discover an effect preceding its cause than to light upon a bachelor husband—and the impossibility is of the same sort in both cases.

Someone who had appreciated this point might well be inclined to dismiss it as merely verbal and trifling. He might claim that nevertheless we have here some radically new and theoretically highly recalcitrant facts and that to take account of them we must revise some of our old ideas.

Not every verbal point is trifling, however, and not all matters of definition are mere matters of definition. What looks like a piece of obstructive lexicography can be justified at a deeper level. The implicit definitions to which appeal was originally made are grounded on a more fundamental necessity. We cannot simply brush off the objection by prescribing a small revision in usage whereby causes may in future be spoken of as succeeding their effects, and then proceed exactly as before. The crux is that causes are—and in principle can always be used by us as—levers for bringing about their effects. But a cause that succeeded its effect could not be, or be used as, a lever for producing it. Once the “effect” has happened it must be too late for any “cause” to bring it about—and too late also for it to be prevented by preventing the occurrence of this “cause.” To make this suggested change in the usage of the terms *cause* and *effect* would be not to modify but to disrupt the concept of cause. The refusal to accept the claim that in precognition we would be confronted with causes operating backward in time may therefore spring from something less discreditable than complacency. It might even be one manifestation of a conviction that to accommodate such a phenomenon we should need something much more radical and much more ratiocinative than a paradoxical but really not particularly significant set of adjustments in the usage of one or two common terms.

#### POSSIBLE EXPLANATIONS

The third kind of theoretical question about precognition is “What sort of explanation or account could we hope to find, supposing it were to be definitely established that precognition does indeed occur?” Presumably this would have to cover whatever other parapsychological phenomena were also found to be genuine. To provide such a theory would be enormously difficult, if not impossible. In any case, in the present confusing and apparently contradictory state of the evidence in this field, a state that should no doubt be attributed (at least in part) to the lack of any theory adequate to serve as even the most tentative of working hypotheses, it is impossible to say with confidence and precision just what are the phenomena of which we need to take account. Nevertheless there are three suggestions that it may perhaps be useful to consider.

**CAUSAL EXPLANATION.** The first suggestion concerns the possibility of interpreting precognitive correlations in causal terms. To give a causal account of the subsistence of a statistically significant correlation between two series of events *A* and *B* involves showing either (1) that *A*

results from *B*, or (2) that *B* results from *A*, or (3) that both *A* and *B* result from some third cause or set of causes, or (4) that both *A* and *B* are causally independent results of separate chains of causation. Suppose *A* is a series of precognitive guesses or anticipations and *B* a series of fulfillments or verifications. Series *A* cannot result from series *B*, for that would involve the logical impossibility of future occurrences bringing about events in the past. Series *B* cannot result from series *A*, for if it does, then the case is ipso facto disqualified by definition. And *A* and *B* cannot both result from some third cause or set of causes, for if they do, then again the case is by definition disqualified from rating as genuinely precognitive. The only remaining possibility is to say that *A* and *B* are both the causally independent results of separate chains of causation.

But to say this is precisely not to display a causal connection between *A* and *B*; it is, rather, to imply that the statistically significant correlation between the two series is a coincidence. This conclusion may be disturbing, but at least it has the merit of not involving any actual self-contradiction. For to establish a statistically significant correlation between two series of events is not thereby and necessarily to establish that these series are in any way connected causally. In the face of any correlation, however perfect and however extended, it is always significant, although often foolishly misguided, to insist that there is nevertheless no causal connection. Statements of constant conjunction do not entail statements of causal connection. Anyone who insists on a stronger sense of statistical significance, which would entail the subsistence of a causal connection, and who then proceeds to stipulate that a precognitive correlation would have to be statistically significant in this stronger sense, will succeed only in making his concept of precognition self-contradictory from the start.

**COINCIDENCE.** It seems that any explanation or, if that now becomes too strong a word, any account of precognition as such will have to center on the notion of coincidence or of something very like it. The laws, if there are any laws to be discovered, will describe the conditions under which we may expect to find precognitive correlations. One is reminded of C. G. Jung's talk about "synchronicity phenomena." For "synchronicity phenomenon" is in fact only a pretentious neologism for "coincidence," with perhaps a built-in suggestion that such phenomena are both more common and also somehow more significant than might be thought. It is a similarity that might easily be overlooked because of Jung's terminological peculiarities, because he associates the idea with

many of his own more bizarre inventions, and because he exploits it for his own, it seems, often willfully antiscientific and antirational ends. A law of the kind suggested might paradoxically but pointedly be characterized as a law about the regularities in the conditions for the occurrence of a certain sort of coincidence.

**STATISTICAL EXPLANATION.** Theorists seem to have taken far too little notice of the surely remarkable fact that it seems to be impossible either for the subjects or for anyone else to achieve any significant success in identifying, without reference to the targets, the particular guesses that are going to prove to be hits. Another similar and similarly neglected fact is that even after the guesses have been scored against the targets we have no criterion for distinguishing any particular hit as precognitive. In each case the reason for talking of precognition is not that any particular guess can, at some stage, be identified as precognitive but that, after the guesses have been checked against the targets, the proportion of hits in a series of guesses is found to be significantly above mean-chance expectation.

With appropriate alterations the same thing seems to be true of all ostensible parapsychological phenomena. It is usually argued that whereas this perhaps has to be allowed in the case of quantitative experiments in card guessing, dice throwing, and so forth, it does not apply at all to what appear to be spontaneous cases of telepathy and clairvoyance, precognitive or straight. But this is surely wrong. For suppose we find that someone who had no means of inferring that the *Titanic* might meet disaster nevertheless had a dream that is later found to have corresponded in amazing detail with what actually happened on the night when that great ship went down. Still, our only warranty for describing his dream as precognitive lies precisely in that extraordinary degree of correspondence: Any single item of correspondence might be dismissed as something that was bound to happen "by the law of averages," and so no single item can be picked out as unequivocally precognitive.

Of course this situation may conceivably at any time be transformed by the progress of the research. But at the time of writing it remains true that all the putative varieties of ESP, precognition in particular, are and must be defined in essentially statistical terms. This is no reason to ignore or to dismiss the evidence. But it may very well prove to be a significant theoretical pointer.

**Bibliography**

For general discussion consult C. J. Ducasse, "Broad on the Relevance of Psychical Research to Philosophy," pp. 375–410, A. G. N. Flew, "Broad on Supernormal Precognition," pp. 411–436, and C. D. Broad, "A Reply to My Critics," pp. 709–830, in *The Philosophy of C. D. Broad*, edited by P. A. Schilpp (New York: Tudor, 1959); and W. G. Roll, "The Problem of Precognition," in *Journal of the Society for Psychical Research* 41 (1961): 2ff. Roll's article is valuable especially for its bibliography.

There have been many ingenious discussions of ways of making operational distinctions between the various forms of ESP phenomena in the parapsychological journals since about 1930. For an excellent example, see C. W. K. Mundle, "The Experimental Evidence for PK and Precognition," in *Proceedings of the Society for Psychical Research* 49 (1949–1952): 61–78.

For a criticism of Dunne's "Serial Theory of Time," see A. G. N. Flew, *A New Approach to Psychical Research* (London: Watts, 1953), Appendix II: "An Experiment with 'Time.'"

C. D. Broad's "The Philosophical Implications of Foreknowledge" was published in *PAS*, Supp. 16 (1937): 177–209. Broad referred the empirically curious to H. F. Saltmarsh's "Report on Cases of Apparent Precognition," in *Proceedings of the Society for Psychical Research* 42 (1934): 49–103. With Saltmarsh's paper one may compare D. J. West's considerably more skeptical "The Investigation of Spontaneous Cases," in *Proceedings of the Society for Psychical Research* 48 (1948): 264–300. The weight of both evidence and research has now shifted away from ostensible spontaneous cases of ESP toward quantitative experiments in card guessing. The classic series is that reported by S. G. Soal and K. M. Goldney in "Experiments on Precognitive Telepathy," in *Proceedings of the Society for Psychical Research* 47 (1942–1945): 21–150. This work was hailed by Broad in 1944 in "The Experimental Establishment of Telepathic Communication." Soal and Frederick Bateman have since produced a general survey, *Modern Experiments in Telepathy* (New Haven, CT: Yale University Press, 1954).

On the infallibility of precognitive experiences and on cause and effect, see M. A. E. Dummett, "Can an Effect Precede Its Cause?" in *PAS*, Supp. 28 (1954): 27–44, and the reply with the same title by A. G. N. Flew in that volume, on pp. 45–62. See also Flew's *Hume's Philosophy of Belief* (London: Routledge and Paul, 1961), Ch. 6.

For a fuller criticism of Jung's theory of synchronicity phenomena, see A. G. N. Flew's "Coincidence and Synchronicity," in *Journal of the Society for Psychical Research* 37 (1953–1954): 198–201.

**PRE-SOCRATIC PHILOSOPHY**

"Pre-Socratic" is the term commonly used (and the one that will be used here) to cover those Greek thinkers from approximately 600 to 400 BCE who attempted to find universal principles that would explain the whole of nature, from the origin and ultimate constituents of the universe to the place of man within it. Yet 400 was the last year of Socrates' life, and among the Sophists, who are also excluded, Protagoras and Gorgias were older than he and others were his contemporaries. "Pre-Socratic" there-

fore indicates not so much a chronological limit as an outlook and a range of interests. This outlook Protagoras and Socrates deliberately attacked, condemning natural philosophy as worthless compared with the search for a good life, the discussion of social and political questions, and individual morality. Socrates also dismissed its explanations as inadequate because expressed predominantly in terms of origins and internal mechanisms. In his view explanation should be functional, looking to the end rather than the beginning. Thus, for the last sixty or so years of the fifth century, both points of view existed, and a lively controversy went on between them. It was not that the natural philosophers excluded human nature from their investigations but that they saw man and society in a larger framework, as a particular late stage in cosmic development, whereas the others deliberately turned their backs on the external world. The universal and speculative character of pre-Socratic thought was also combated by some of the fifth-century medical writers, and it was in the fields of physiology and hygiene that observational science reached its highest point in this period.

#### NATURE OF THE EVIDENCE

Before attempting to describe the pre-Socratic doctrines, it is necessary to emphasize the peculiar nature of our sources of knowledge. None of the pre-Socratics' works has survived independently. We have a few references in Plato, some more systematic discussion in Aristotle, and information from later compilers and commentators of which the greater part goes back to a history by Aristotle's pupil Theophrastus. Actual quotations occur and are in some cases extensive, as with the prose fragments of Heraclitus and the 450 surviving lines of Empedocles. Yet, from Aristotle onward, the men who passed on this information were not historians in the modern sense but wrote from a particular philosophical viewpoint (most often Peripatetic), searching the past for anticipations of their own ideas and selecting and arranging their material accordingly. The task of reconstruction and interpretation is thus very different from and more precarious than that of interpreting a philosopher whose original writings are still available for study.

#### THE MILESIAN SCHOOL

Pre-Socratic philosophy differs from all other philosophy in that it had no predecessors. Philosophy has been a continuous debate, and even highly original thinkers can be seen developing from or reacting against the thought of a predecessor. Aristotle is unimaginable without Plato; Isaac Newton, without René Descartes, Johannes Kepler,

Galileo Galilei, and many others. But with the Greeks of the sixth century the debate begins. Before them no European had set out to satisfy his curiosity about the world in the faith that its apparent chaos concealed a permanent and intelligible order, and that this natural order could be accounted for by universal causes operating within nature itself and discoverable by human reason. They had predecessors of a sort, of course. It was not accidental that the first pre-Socratics were citizens of Miletus, a prosperous trading center of Ionian Greeks on the Asiatic coast, where Greek and Oriental cultures met and mingled. The Milesian heritage included the myths and religious beliefs of their own peoples and their Eastern neighbors and also the store of Egyptian and Babylonian knowledge—astronomical, mathematical, technological. The influence of this heritage was considerable. Yet the Milesians consciously rejected the mythical and religious tradition of their ancestors, in particular its belief in the agency of anthropomorphic gods, and their debt to the knowledge of the East was not a philosophic one. That knowledge was limited because its aim was practical. Astronomy served religion; mathematics settled questions of land measurement and taxation. For these purposes the careful recording of data and the making of certain limited generalizations sufficed, and the realm of ultimate causes was left to dogmatism. For the Greeks knowledge became an end in itself, and in the uninhibited atmosphere of Miletus they gave free play to the typically Greek talent for generalization, abstraction, and the erection of bold and all-embracing explanatory hypotheses.

Consciously, the revolt of the Milesian philosophers against both the content and the method of mythology was complete. No longer were natural processes to be at the mercy of gods with human passions and unpredictable intentions. In their place was to come a reign of universal and discoverable law. Yet a whole conceptual framework is not so easily changed. Poetic and religious cosmogonies had preceded the schemes of the Milesians, and the basic assumptions of these can be detected beneath the hypotheses of their philosophic successors. Nevertheless, the achievement of abandoning divine agencies for physical causes working from within the world itself can hardly be overestimated.

It was common to the mythologies of Greece and neighboring civilizations (and, indeed, to others) that the world arose from a primitive state of unity and that the cosmogonic process was one of separation or division. This was the first act of the Hebrew Creator. In the Babylonian *Enuma Elish* the original state of the universe was an undefined mass of watery cloud. The Greek theogony

of Hesiod speaks of Heaven and Earth, conceived as anthropomorphic figures, lying locked in an embrace until their son forced them apart as Marduk formed heaven and earth by splitting apart the body of the monster Tiamat. Euripides relates an old tale according to which earth and heaven were once “one form” and after their separation brought to birth the whole variety of living things. In Egypt (like Babylonia, a river culture) everything arose out of the primeval waters.

**THALES.** It is not surprising, therefore, that the first people to seek a universal explanation of the world along rational lines assumed that it was in substance a unity from which its variety had been produced by some process of segregation. The key, they thought, lay in identifying the single substance that must satisfy the condition of being able to produce variety out of itself. Thales (active in 585 BCE), who chose water or moisture, may still have had the myths at the back of his mind. For him the earth floated on water as it did for the Egyptians. Little else certain is known of him, and we can only guess at his reasons. Water can be seen as solid, liquid, and vaporous. Aristotle thought it more probable that Thales was influenced by the essential connection of moisture with life, as seen in such substances as semen, blood, and sap. With the removal of external personal agents, the world must initiate its own changes, and at this early stage of speculation the only possibility seemed to be that life of some kind is everywhere and that the universe is a growing, organic structure. This may be the explanation of the saying attributed to Thales: “Everything is full of gods.”

**ANAXIMANDER.** With Anaximander, Thales’ younger contemporary, there emerges the notion of the four primary opposites that later, when the concepts of substance and attribute had been distinguished, gave rise to the four elements adopted by Aristotle and destined for a long and influential history. Anaximander spoke of only the hot and the dry, which were inevitably in conflict with the cold and the wet. This led him to a momentous idea. The original substance of the universe could not be anything definitely qualified like water, for how could the cold and wet produce their opposites, the hot and dry? Water quenches fire; it cannot engender it. Prior to all perceptible body there must be an indefinite something with none of the incompatible qualities implied by perceptibility. Although still regarding all that exists as corporeal, Anaximander is the first to find ultimate reality in the nonperceptible.

This primary substance he called the *apeiron*, a word of many meanings all related to the absence of limits—everlasting, infinite, indefinite. Because it was imperishable, the origin of all things, and the author of their changes, he called it (says Aristotle) divine. From it all things have been “separated out,” though in what sense they were previously “in” it while the *apeiron* itself remained a unity is a question that probably did not present itself to him. Somewhere in the *apeiron*, Theophrastus asserts, a “germ” or “seed” of hot and cold was separated off, and from the interaction of these two flowed the whole cosmic process. A sphere of flame enclosed a moist mass, more solid at the center where the earth formed, vaporous between. The sphere burst into rings around which the dark vapor closed, leaving holes through which we see what appear as sun, moon, and stars. Wet and dry continue to separate, forming land and sea, and finally life itself is produced by the same action of heat (sun) on the cold and moist portions of the earth. The first animals were born in water and crawled onto dry land. Human infants were originally born and nurtured within the bodies of fishlike creatures, for under primitive conditions unprotected babies could not have survived.

Earth, a flat cylinder, hangs freely in space because of its equal distance from all parts of the spherical universe. The sun is the same size as Earth. Eclipses are caused by the closing of the holes in the vapor tubes of the sun and moon. In this first of all attempts at a rational cosmogony and zoogony, the sudden freedom from mythical modes of thought is almost incredible.

**ANAXIMENES.** Further reflection led Anaximenes, the youngest member of the Milesian school, to a different conclusion about the primary substance: It was air. In its elusiveness and invisibility as atmospheric air, it could almost match the *apeiron*, and, whereas *apeiron*, once differentiated into a universe, could no longer be so called, air could become hotter and colder, rarer and denser, and still remain the same substance. Moreover, this theory allowed Anaximenes to break with the notion of separation, which was, at bottom, mythical, and account for the universe by the extension of a known natural process. This was condensation and rarefaction, the former of which he associated with cold and the latter with heat. Air as it rarefies becomes fire; condensed, it turns first to wind, then to cloud, water, earth, and stones. In other words, it is all a question of how much of it there is in a given space, and for the first time the idea enters science that qualitative differences are reducible to differences of quantity. This is Anaximenes’ main achievement,

although there is no evidence that he applied the principle with any mathematical exactness.

With air as his basic, self-changing substance, Anaximenes could find room for the ancient belief that life was identical with breath. Macrocosm and microcosm were animated by the same principle: “Just as our soul, which is air, integrates us, so breath and air surround the whole cosmos.”

The few details that we have of his cosmology suggest that compared with Anaximander’s, it was reactionary and timid. His contribution lies elsewhere.

### THE PYTHAGOREANS

Pythagoras (c. 570–490 BCE) was also an eastern Greek but migrated from his native Samos to Croton in southern Italy. As a result the western or Italian Greek philosophers, even when not actual members of his school, became known for a characteristic outlook very different from that of the materialistic and purely rational Milesians and stamped with the impress of his remarkable genius. He founded a brotherhood dedicated to *philosophia* (the word was believed to be his invention) as a way of life, with a strong religious, and also a political, element. Philosophically, his importance lies in the shift of interest from matter to form. Inspired, it is said, by the discovery that the musical intervals known to the Greeks as consonant (and marked by four fixed strings on the seven-stringed lyre) were explicable in terms of ratios of the numbers 1 through 4, Pythagoras saw the universe as one glorious *harmonia*, or mathematico-musical structure. Number was the key to nature. This idea had incalculable consequences for science even if it led at the time to some rather fanciful equations of natural objects and moral qualities with particular numbers. In spite of that, by the time of Socrates the school had made real progress in mathematics. Since the cosmic harmony included everything, all life was akin. The soul was immortal and underwent a series of incarnations, both human and animal. Philosophy was the effort to understand the structure of the cosmic harmony, with the ultimate aim of integrating the philosophic soul more closely into that harmony on the principle that knowledge assimilates the knower to its object. This aim also demanded the observance of certain religious precepts of which the most important was abstention from animal food.

### HERACLITUS

Heraclitus (active c. 500 BCE) objected to the Pythagorean emphasis on harmony, maintaining that, on the contrary, strife and opposition were the life of the world.

Life was maintained by a tension of opposites fighting a continuous battle in which neither side could win final victory. Thus, movement and the flux of change were unceasing for individuals, but the structure of the cosmos remained constant. This law of individual flux within a permanent universal framework was guaranteed by the Logos, an intelligent governing principle materially embodied as fire, the most subtle element and identified with soul or life.

Philosophy had thus far meant the search for an essentially simpler reality underlying the bewildering confusion of appearances. The answers fell into two broad categories, matter and form: Reality was a single material substance (the Milesians) or an integral principle of structure that could be expressed in terms of numbers (the Pythagoreans). Heraclitus, with a statement like “You cannot step twice into the same river,” reaches the logical conclusion of the materialistic answer. The water will be different water the second time, and, if we call the river the same, it is because we see its reality in its form. The logical conclusion of form-philosophy is the opposite of flux—namely, a belief in an absolute, unchanging reality of which the world of change and movement is only a quasi-existing phantom, phenomenal, not real. (This conclusion was reached in the idealism of Plato, which was largely of Pythagorean inspiration.)

### ELEATIC SCHOOL: UNITY OF REALITY

At this time the direction of philosophy was changed by the precocious and uncompromising logic of Parmenides of Elea, who was perhaps twenty-five years younger than Heraclitus. For the first time abstract, deductive reasoning is deliberately preferred to the evidence of the senses: “Ply not eye and ear and tongue, but judge by thought.” He concluded that if there is any reality at all (in the language of his time, if “it is”), it must be (1) one only (for if more than one, its units could be separated only by “what is not”); (2) eternal and unchanging (for to speak of change or perishing is to say that reality at some time “is not” what it was, but to say of “what is” “it is not” is contradictory and impossible); (3) immovable (this follows from his statement that “all is full of what is”; since it cannot admit discontinuity or lack of homogeneity and since “what is not is not,” the spatial requirements of locomotion cannot be provided).

In this way he “proved” that, on the premise of his predecessors that reality is one, differentiation of the real can never occur. It remains one—a timeless, changeless, motionless, homogeneous mass, which he compared to a sphere. The multiple, changing world of appearances is

an illusion of our senses. Only as a concession to human weakness, and in recognition of our practical need to come to terms with the show of a natural world, did he append a cosmology of the conventional type, beginning with two principles, heat-light and cold-darkness. Cosmogony from a single origin was no longer possible, yet he explicitly warns his hearers that reality is in truth a unity and that the cosmos is only a deceitful appearance to mortals.

It is disputed whether the One Reality of Parmenides is material. The question can hardly be answered, since we are still in a period before the distinction between material and nonmaterial could be drawn. The important thing is that it was nonsensible and could be reached only by thought. Parmenides was the first philosopher to distinguish explicitly between the sensible and the intelligible and to condemn the former as unreal. Plato himself, though fully aware of the distinction between material and spiritual, usually preferred to call them sensible and intelligible, and it is very doubtful whether the philosophy of Platonic idealism would ever have been possible without Parmenides.

**ZENO AND MELISSUS.** Parmenides had two followers, who, with him, are known as the Eleatic school. Zeno of Elea (born c. 490 BCE) concentrated on a defense of the proposition that reality is one and immovable by the dialectical method of showing up absurdities in the contrary view. His famous paradoxes are aimed at demonstrating the impossibility of plurality and movement. Melissus of Samos (active in 440 BCE) modified Parmenides' ideas to the extent of saying that reality is infinite. He explicitly denied the possibility of empty space (which Parmenides had only hinted at) and said that if there were many things, each would have to have the characteristics of the Parmenidean One. It is therefore probable that the atomists had him especially in mind when they boldly explained the world in terms of space plus tiny entities, each of which had many of the Eleatic qualities—indivisibility, homogeneity, unalterability.

The naïveté of Parmenides' logic and the purely linguistic nature of some of his difficulties seem obvious now, but at the time his questions appeared unanswerable. There were only two ways out: either to abandon monism and admit the ultimate plurality of the real or to admit the unreality of the natural world. The latter solution was Plato's, with his contrast between "what always is and never becomes" and "what is continually becoming (like the flux of Heraclitus) but never truly is." The remainder of pre-Socratic thought is occupied with

attempts to save the phenomena by adopting some form of pluralism.

### THE PLURALISTS: EMPEDOCLES

The first of the pluralistic systems was that of Empedocles (c. 490–430 BCE), a Sicilian poet-philosopher steeped in the Western tradition, with its combination of rationalism and mystical religion so different from the purely scientific outlook of the Ionians. His proposal was the first clear enunciation of the four-element theory. Fire, air, water, and earth are the ultimate roots of all things, themselves ungenerated and indestructible. Everything in nature comes into being and perishes by the mixture and separation of these substances. The first premise is no longer "It is" but "They are." Thus, trees and animals, clouds and rocks, are not mere illusion. However, since they are only temporary combinations of the four "realities" in varying proportions, we can admit that they themselves are not "real." Nor need the forbidden concepts of "becoming" and "perishing" be invoked; mixture and separation will account for all. Locomotion is, of course, necessary, and, although he accepts the Eleatic denial of empty space, Empedocles seems to have thought that this could occur by some reciprocal and simultaneous exchange of place, the whole remaining full.

The four elements are not self-moving (another concept that Parmenides had rendered difficult), and the blend of mystic and rationalist in Empedocles appears especially in his motive causes. These were two, Love and Strife, the former bringing disparate elements together and the latter drawing them apart. They are in endless opposition and prevail in turn, bringing about a double evolutionary cycle. Under Love all four elements are indistinguishably fused in a sphere; under Strife the same sphere contains them in separate layers. During the contest, when neither Love nor Strife is in complete control and when the elements are partly joined and partly separated, a world like our own is formed. Nothing existent is as yet incorporeal, though Love and Strife are of finer and more tenuous substance than the elements. Their names are no metaphors, nor is their action purely mechanical. Under Love the elements are dear to and desired by one another; Strife makes them grim and hostile. Nothing is purely inanimate, and everything has its share of consciousness.

Besides his poem on nature, Empedocles also wrote a religious one, in which the moral character of Love and Strife is emphasized—Love is good, Strife evil. In the present world Strife is gaining, and men have fallen from a previous blessed state by giving themselves to Strife and

sin, above all the sin of killing and eating animals. All life is akin, as it was to the Pythagoreans, and our souls are fallen spirits that must undergo a series of incarnations before they can win back their former state by abjuring Strife and cultivating Love. What the substance of the spirits was is not clearly stated, but most probably in their pure state they were portions of Love that are now contaminated with Strife.

## ANAXAGORAS

Anaxagoras of Clazomenae (c. 500–428 BCE) brings us back to Ionia both geographically and in spirit. His motive is rational curiosity entirely uncomplicated by religious preoccupations. Even Parmenides, a Westerner like Empedocles, had written in verse and represented his deductive arguments as a revelation from a goddess. In his return to prose, as in his purely scientific aims, Anaxagoras is the heir of the Milesians. At Athens, where he lived until exiled for atheism, he was a member of the brilliant and freethinking circle of Pericles. His prosecution seems to have had a political flavor, but the charge is nevertheless significant: He declared the sun to be not a living divinity but a lump of incandescent rock larger than the Peloponnese.

To save the phenomena without admitting the coming into being or destruction of what exists, he adopted an extreme form of pluralism plus a first cause of motion, which he called Mind. It is described as knowing all things and having the greatest power, and, in order to control the material world, it is entirely outside the mixture of which the material world is formed. It is not easy to be sure whether Anaxagoras is at last trying to express the notion of incorporeal being without an adequate vocabulary or whether he still thinks of Mind as an extremely subtle and tenuous form of matter. At any rate, its separateness from the constituents of the cosmos is emphasized at every turn. In spite of the references to its knowledge and power, its action seems to be confined to the earliest stages of cosmogony, except in the case of living creatures. They are an exception to the rule that Mind is in nothing else, and them it still controls.

In the beginning “all things were together,” a stationary mass in which nothing could be distinguished. Mind is the agent that has produced from this an ordered cosmos. It did so by starting a rotatory movement or vortex, which by its own increasing speed brought about the gradual separation of different forms of matter. Anaxagoras’s highly subtle and ingenious theory of matter seems to have been especially prompted by the need to explain nourishment and organic growth: How can flesh and hair

come out of the not-flesh and not-hair of the food we eat? After Parmenides the coming into being of new substances is disallowed. Anaxagoras answered that there is a portion of everything in everything—that is, every distinguishable substance, in however small a quantity, contains minute particles of every other but is characterized by that which predominates. He boldly asserted the existence of the infinitesimal (which Zeno had denied) in the words: “Of the small there is no smallest.”

## THE ATOMISTS

Perhaps around 430 BCE Leucippus promulgated the much simpler theory of atomism, which was further developed by his famous pupil Democritus of Abdera (born c. 460 BCE). Like the other theories, this one arose in direct response to the Eleatic challenge. Its most striking innovation for its time was the assertion of the existence of genuine empty space. Thus far, everyone had believed that “what is” must be some form of body, and, when Parmenides brought into consciousness the implicit consequence that space, not being “what is,” must be “what is not” (that is, nonexistent), his conclusion seemed logically inescapable. Hence, even the atomists had to use the paradoxical expression that it is no more correct to say of “what is” than of “what is not” that it *is*.

At this particular point in the philosophic debate, this was the only way of expressing the conviction that, though not any kind of stuff, space must be assumed if the plain facts are to be explained. Democritus, said Aristotle, is to be commended for refusing to be dazzled by the abstract logic of Parmenides and for relying on the kind of argument more proper to a natural scientist. Reality consists of innumerable microscopic and indivisible (*a-tomos* = uncuttable) bodies in motion in infinite space. They are solid and homogeneous but infinitely variable in size and shape. At different places in the infinite, they have collided and become entangled. Projections hook together, convex fits into concave, and so on. Their continued motion sets up a vortex in which the larger and heavier fall into the center and the smaller and lighter are extruded to the circumference; in this way a cosmos is formed. There are many worlds, and not all are similar to our own. The first atomists appear to have provided no separate cause of motion, perhaps because they deemed it sufficient to free the atoms by setting them loose in infinite space. After all, the chief Eleatic arguments against motion had been the continuity of being and the nonexistence of a void.

Only atoms and the void exist. Sensible qualities other than size and shape are subjective, caused by inter-

action between the atoms of external objects and those in our own bodies. This was worked out in considerable detail. For instance, hard objects have their atoms more closely packed than do soft. Sweet flavors are caused by smooth atoms, bitter and astringent by sharp or hooked. Colors vary according to the positions of surface atoms, which cause them to reflect in different ways the light that falls upon them. Objects are continually throwing off films of atoms, and sight is the reception of these films by the eye. The soul, or life principle, is composed of smooth, round atoms that are even more mobile than the rest and impart to the body the power of motion and cognition, for “soul and mind are the same”—that is, composed of the same kind of atoms. Soul is dispersed throughout the body, alternating with body atoms, but the mind appears to have been a collection of these finest particles that is located probably in the breast. Although the direct objects of sight and hearing, taste and smell, are unreal, they lead the mind to the truth about reality, and Democritus quoted with approval a saying of Anaxagoras: “Phenomena are a glimpse of the unseen.”

Ancient atomism (including its revival by Epicurus a century or more after Democritus) has acquired a partly adventitious reputation through its resemblances to nineteenth-century physical theories, but its hard, solid, unbreakable particles have little in common with the ultimate entities of modern science. Its most striking features are the distinction between primary and secondary qualities (upheld by Descartes, Galileo, and John Locke), the explanation of directly observable objects by hypothetical constituents below the level of perception, and the outspoken championship of discrete quanta as opposed to a continuum. Its inadequacy in allowing no mode of action other than direct contact, collision, and interlocking was evident in some physical problems—for example, in its attempted explanation of magnetism and, most of all, in the effort to include within its purview the phenomena of life and thought. The atomic structure of matter has indeed been a fruitful hypothesis, but the intention of its authors is best understood in the context of their time and as an attempt to escape the Eleatic dilemma, rather than as an anticipation of postmedieval science.

### DIOGENES OF APOLLONIA

The teleological explanation, which one would naturally associate with Anaxagoras’s adoption of Mind as first cause, appears more strongly in the second half of the fifth century in a less gifted thinker, Diogenes of Apollonia. He put Mind back into the mixture by returning to Anaximenes’s idea that the primary substance is air or

breath and by identifying this air in its purest (dry and warm) state with intelligence. The regularity of cosmic events he regarded as evidence of intelligent control, going so far as to say that anyone who reflects will agree that all is arranged in the best possible way. Breath is also the life of humans and animals, so that all owe their soul and mind to the same material principle—“a small portion of the god”—which they share in varying degrees of purity. He probably thought he avoided the Eleatic arguments against a materialistic monism by the admission of void, which, by the time he wrote (after Melissus and Leucippus), would in any case be recognized as necessary for the process of condensation and rarefaction by which air produced the variety of nature.

When we consider the grotesqueness of some of the mythological background from which the pre-Socratic thinkers started, we must be amazed by the intellectual insight and firm grasp of universal principles that at their best they were capable of displaying. But a dispassionate assessment of their contribution to the history of philosophy would probably show that, to use a metaphor, although they manufactured many of the pieces and set them on the board, Plato and Aristotle were the first players who learned the rules and started the game. The pieces are those opposed concepts by means of which philosophical discussion is maintained: being and becoming, sensible and intelligible, analytic and synthetic, appearance and reality, time and eternity, materialism and idealism, mechanism and teleology, and so forth. Once these stand out clearly, a philosopher may champion one or the other, but the pre-Socratics could not yet do this. One cannot speak realistically of a controversy among them between, say, materialists and idealists. The achievement of their intellectual effort and controversy was that by the end of this period a clear notion of what was meant by matter and mind, sensible and intelligible, phenomenal and real, and the rest was at last emerging, so that succeeding generations had the set in their hands and could begin the game in earnest. For the first of all philosophers, this was no mean achievement.

Their interests were, of course, in modern terms, as much scientific as philosophical, and in this sphere also they could claim some remarkable results. For instance, before the end of the period the true cause of both lunar and solar eclipses had been discovered (probably by Anaxagoras), and certain Pythagoreans had abandoned the geocentric cosmology, asserting that Earth, the sun, and the planets all circled round a central fire. But it is probably fair to say that their scientific discoveries

appeared only as by-products of the main controversies and of the few universal principles from which they confidently deduced even the details of the physical world. The true and lasting discoveries were not picked up and developed as they would have been by post-Renaissance scientists because, owing to the different preoccupations of philosophy at their time, they had no firm basis in established fact and did not in any way stand out from other and, to us, more fanciful assumptions.

## PRESUPPOSING

The notions of “presupposing” and of contextual implication, which we shall compare and contrast in what follows, have come to play increasingly prominent roles in the philosophical literature of the English-speaking world since the 1940s. This development is not accidental but arises from the stress the twentieth century put upon analysis as a fundamental mode of philosophical inquiry. The notions of presupposing and of contextual implication play both negative and positive roles within this general orientation. Negatively, they are devices that contemporary thinkers employ in order to minimize the tendency of philosophers and other reflective persons to view the world in terms of oversimplified conceptual models. Positively, they function as instruments in the dissection and ultimate understanding of certain human activities, especially those that involve the efforts of human beings to communicate with one another, as in promising, stating, saying, implying, a task that, some philosophers feel, is hindered or obstructed by the natural disposition of reflective individuals to subsume such activities under excessively simple descriptions. The appeal to the notions of presupposing and of contextual implication has thus served to widen—and at the same time to make more accurate—our conceptions of the cir-

cumstances in which human communication takes place. This entry will describe the history (all of it relatively recent, of course) of the major developments that have taken place with regard to these subjects, and will in this way attempt to bring out their essential features.

### SIMILARITIES AND DIFFERENCES

It is no simple matter to show why presupposing and contextual implication are two separate concepts, since the differences between them are subtle. Most writers have, in fact, not discriminated between them, in part because both notions are slippery but also because they have similar functions. Their similarities may be elucidated as follows. If we distinguish between what a person explicitly states, or asserts, when he utters certain words in certain circumstances and what he (or perhaps his statement) implies, then the concepts of presupposing and of contextual implication belong to the latter category rather than to the former. This crude distinction must be refined further, however, for the sense of “implies” that is being marked out here is not that of logical implication in any of the various senses of that term—for example, the sense involved in saying that “*X* is a husband” implies “*X* is married.” Indeed, both presupposing and contextual implication are to be contrasted with logical implication.

The kinds of implications that fall into this category may be indicated by simple examples. In saying “alas!” in certain circumstances, I am normally taken as implying that I am unhappy. But I am not taken to be asserting that I am unhappy, as I would be if I were to utter the words “I am unhappy.” Or, to vary the example, when a person says, “All my children are now in college,” he is normally taken to be implying that he has children (although not to be asserting that he has), and his auditors are justified in making this assumption. Or again, when one says in such sorts of contexts, “Smith has just gone out,” he implies, or his words imply, that he believes or knows that Smith has gone out, and those to whom he is speaking are justified in assuming that he does. That the sense of “implication” expressed by these examples is not that of logical implication may be illustrated by the observation that there is no formal contradiction in asserting “All my children are in college, but I have no children” or in asserting “Smith has gone out, but I don’t believe he has.” Indeed, in standard systems of mathematical logic, the first statement is true whenever the speaker has no children, and the second is true whenever Smith has gone out but the speaker does not believe he has.

Sentences like “All my children are in college, but I have no children” and “Smith has gone out, but I don’t believe he has” thus satisfy the rules of logical syntax and, indeed, the rules for correct English. Yet they fall upon the ear as decidedly odd. If employed at all in everyday speech, they would occur only in unusual circumstances—“I don’t believe he has” might be whispered as an aside to a confederate, for example. But except for situations like this, they would be perplexing things to say. What, then, is the source of their oddity, given that they do not involve any formal mistake?

It is now generally agreed that the oddity we feel upon hearing such sentences stems from a disparity between the conditions we assume will have been satisfied whenever someone is trying to communicate with another and the utterances we expect will be employed in those circumstances. In effect, this is to say that certain assumptions, or presuppositions, that communicating human beings make in the everyday give-and-take of verbal intercourse, assumptions that thus form the ground of such intercourse, fail to hold or are violated in such circumstances.

Talk about presuppositions and talk about what is contextually implied by a speaker’s words thus have in common a reference to the background conditions normally expected to obtain when an utterance is made. If stating and asserting are conceived of as elements constituting part of the foreground of the situation in which communication takes place (that is, as activities that bring an item of information into the immediate focus of attention), then presupposing and contextual implication may be thought of as elements constituting part of the background of the situation (that is, as factors that remain implicit unless they are otherwise articulated but that nonetheless are essential factors in communication). Part of the task that faces the student of informal logic is to specify what these conditions are, how they contribute to the background that makes communication possible, and what sorts of relations exist between them and the utterances that occupy the foreground during the transmission of information.

Let us then call the concepts referring to such conditions background concepts. Because such concepts play covert roles in daily discourse and because their functions are remarkably similar, it is not surprising that many writers have failed to discriminate between them. But not all writers have blurred the distinction. Isabel C. Hungerland is one notable exception. In her important paper “Contextual Implication” (*Inquiry*, Vol. 4, 1960, pp. 211–258), she writes, “The relation (presupposing)

defined by Strawson is *not* that of contextual implication.... The relation between the two may be indicated as follows: When *S* presupposes *S'*, a speaker in making the statement *S*, contextually implies that he believes that *S''* (p. 239). Following Mrs. Hungerland's suggestion and overlooking the many subtleties a full treatment of the subject would demand, we may say that the key distinctions that mark off the one notion from the other are those of scope: Neither the conditions subsumed under the two notions nor the range of entities to which the notions apply are in all cases the same.

Presupposing is a concept referring to those conditions that must be satisfied before an utterance can count as a statement, or if "statement" is so defined that statements need be neither true nor false (see P. F. Strawson, "Identifying Reference and Truth-Values," in *Theoria* 30 [2] [1964]), then presupposing applies to those conditions that must be satisfied before statements can be either true or false. Contextual implication, on the other hand, is a concept that applies to those conditions that must be satisfied before an utterance can count as "normal" in the circumstances in which it is made—that is, it applies to those beliefs a speaker has when he makes the utterance he does in certain circumstances and which rule out that he is lying or deliberately deceiving someone. The range of entities thus referred to by the concept of presupposing is either the class of statements as such or the class of those statements that are either true or false, whereas the range of entities referred to by the notion of contextual implication is the class of beliefs held by the speaker (and, derivatively, by his auditors).

Examples may be invoked at this point to illuminate the above remarks. Suppose during the course of a conversation I say, "The store on the corner sells such goods," not realizing that there is no longer a store on the corner. My remark in this circumstance is neither true nor false; as R. G. Collingwood puts it, the question of its truth or falsity "does not arise." For it is a presupposition of my using that utterance to make a statement (that is, an utterance that can be either true or false) that there be such a store. We may say in such a case that it is a condition of the truth or falsity of the remark that the store exist. But I may well believe that there is such a store, and in making the remark, I imply that I have this belief at the time of my utterance. One of the conditions for the normality of the remark (that is, that I was not lying) is that I had this belief at the time of saying what I did. We may say therefore that the conditions determining the normality of the background from which my remark issued and the conditions determining the background from

which a statement would have issued are different conditions. It is this sort of difference in the background conditions that determines the difference between the concepts of presupposing and of contextual implication.

## HISTORY OF CONTEXTUAL IMPLICATION

The genesis of the notions of contextual implication and of presupposing differs considerably. As a philosophical subject, contextual implication, under another name, has a longer traceable history in the modern period than does presupposing. The history of contextual implication is mainly connected with developments in moral philosophy, especially with efforts to give a correct analysis of the use of moral language. In G. E. Moore's *Ethics* (London, 1912), for example, we find the following comments:

There is an important distinction, which is not always observed, between what a man *means* by a given assertion and what he *expresses* by it. Whenever we make any assertion whatever (unless we do not mean what we say) we are always *expressing* one or other of two things—namely, either that we *think* the thing in question to be so, or that we *know* it to be so." (p. 125)

In the subsequent history of moral philosophy the distinction referred to by Moore became the key distinction invoked by those authors who espoused the emotive theory of ethics. According to advocates of this doctrine, the sorts of utterances used in moral contexts ("That's good," "Stealing is wrong") are not being used to make assertions and hence are neither true nor false, as both naturalists and nonnaturalists had assumed. The primary use of such utterances is to express the attitude or the feelings of the speaker toward whatever he is talking about and to arouse comparable attitudes in the auditor. The later history of contextual implication is deeply concerned with the import of this distinction, and the main works in which it is discussed, sometimes critically, are *Language, Truth and Logic* by A. J. Ayer (London, 1936); *The Philosophy of G. E. Moore*, edited by P. A. Schilpp (Evanston, IL, 1942), pp. 540–554; *Ethics and Language* by C. L. Stevenson (New Haven, CT, 1944); *Ethics* by P. H. Nowell-Smith (Harmondsworth, U.K., 1954); *The Emotive Theory of Ethics* by Avrum Stroll (Berkeley, CA, 1954); *The Logic of Moral Discourse* by Paul Edwards (Glencoe, IL, 1955); and "Contextual Implication" by Isabel Hungerland (see above). Various formulas are proposed by some of these writers.

Nowell-Smith says, for example, "A statement *p* contextually implies *q* if anyone who knew the normal con-

ventions of the language would be entitled to infer  $q$  from  $p$  in the context in which they occur" (*Ethics*, p. 80). According to Hungerland all such early attempts to characterize the relation that obtains between what a speaker expressly asserts and what he implies suffer either from vagueness or from mistakenly thinking that the relation is a special case of inductive inference. Her own contention is that it is neither vague nor a case of inductive inference, but is, rather, the presumption that in a situation of communication, acts of stating are normal. She thus likens contextual implication to the juridical principle that a man is presumed to be innocent until proved guilty, a principle that is not arrived at inductively, by surveying the evidence, but which serves to place the onus of proof in a legal contest upon the prosecution. As she puts it, "Contextual inference (if we wish to use the word) is a matter, rather, of a communal assumption in the absence of evidence to the contrary, that, in a situation of communication, acts of stating are normal" (p. 233). Her view is that contextual implication depends upon three factors: (1) The presence of a stating context (since the question of a man's believing what he says does not arise in a nonstating context); (2) the presumptions of normality (that is, that within a stating context the implication holds only if the presumptions are principles of communication); and (3) rules for the correct use of an expression (that is, whether belief is implied when a man says  $p$  will be in part determined by rules for the correct use of  $p$ ).

## HISTORY OF PRESUPPOSING

Unlike contextual implication, the notion of presupposing has its genesis in logical theory, especially in those developments involving alternative accounts of Bertrand Russell's theory of descriptions and of the so-called square of opposition. The writer most closely identified with both of these matters is P. F. Strawson of Oxford University. He has dealt with the theory of descriptions in his papers "On Referring" (*Mind*, 1950), "Presupposing" (*Philosophical Review*, 1954) and "Identifying Reference and Truth-Values" (see above) and in his book *Individuals* (London, 1959; Ch. 8 especially). In *Introduction to Logical Theory* (London, 1952) Strawson considers both the theory of descriptions and the square of opposition.

In the works that deal only with the theory of descriptions, Strawson rejects Russell's analysis of sentences containing definite descriptive phrases (that is, phrases of the form "the so and so" used in the singular in English). According to Russell, the analysis of a sentence like "The queen of England is beautiful" contains in part an assertion to the effect that the queen of England exists.

Strawson argues, cogently, that this statement is not an explicit part of what is asserted by "The queen of England is beautiful" but is presupposed by a speaker who would use such a sentence in normal circumstances to make a statement. In *Introduction to Logical Theory*, Strawson goes on to define the statement "S presupposes S'" as follows: "The truth of S' is a necessary condition of the truth or falsity of the statement that S" (p. 175).

This characterization has been objected to by various writers, including David Rynin, who points out that when "necessary condition" and "truth or falsity of the statement that" are interpreted in the ordinary, truth-functional way, the definition has the paradoxical consequence that all presupposed statements are true. Rynin's demonstration is that  $(S \supset S')$  and  $(\neg S \supset S')$ , but  $(S \vee \neg S)$ ; therefore S'. Avrum Stroll has also suggested that Strawson's account suffers from the difficulty that if "The king of France no longer exists" is used to make a true statement, then by Strawson's criterion one who employs it thereby presupposes the existence of the king of France. It is now generally agreed that neither Russell's nor Strawson's analysis does full justice to all uses of sentences in everyday English containing "the" phrases in the singular. But regarded as proposals for the development of explanatory models for subparts of everyday discourse, each has considerable merit. In this interpretation Strawson's doctrine belongs to the logical tradition of analyzing descriptive phrases initiated by Gottlob Frege in "Über Sinn und Bedeutung" (1892) and supported by David Hilbert and Paul Bernays in their *Grundlagen der Arithmetik* (Berlin, 1934; Vol. I, p. 384) and by Rudolf Carnap in *Meaning and Necessity* (Chicago, 1947; pp. 33–42).

Strawson has also argued that if universal statements ("All my children are in college") are interpreted as presupposing the existence of the items mentioned by the subject term, paradoxes stemming from modern symbolic interpretations of the square of opposition can be eliminated without affecting the logical relations that one intuitively feels ought to hold between the elements of the square. This matter is persuasively discussed by S. Peterston in "All John's Children" (in *Philosophical Quarterly*, 1960).

## PRESUPPOSING IN METAPHYSICS

The notion of presupposition plays an important role in various metaphysical constructions, including Collingwood's *An Essay on Metaphysics* (Oxford, 1940) and Michael Polanyi's *Personal Knowledge* (Chicago, 1958). Collingwood distinguishes (Chs. 3–4) between absolute

and relative presuppositions, arguing that the former are neither true nor false and that metaphysics is the science that ascertains what these absolute presuppositions are. His view is that absolute presuppositions form the basis of the civilizations developed at various times in history and the ground of the science developed in such civilizations. When a civilization changes, its presuppositions change and are succeeded by others. According to this view, metaphysics is therefore a branch of the historical sciences.

## PRESUPPOSITION

Consider the following famous example from Bertrand Russell.

- (1) The present king of France is bald.

According to Russell, (1) is false because it asserts the existence of the present king of France. However, following P. F. Strawson (1952), a number of philosophers and linguists have maintained that, if there is no present king of France, an utterance of (1) fails to have a determinate truth-value—in Strawson's words, the question of whether (1) is true or false "does not arise." On this view, (1) therefore does not assert or even entail the existence of the present king of France but rather "presupposes" his existence.

### THE RANGE OF PHENOMENA

Sentences like (1) are argued to presuppose the existence of a particular individual, but there are many other "presupposition" effects. It has been argued, for example, that factive verbs such as *know* and *regret* presuppose the truth of their complement clauses and that "certain aspectuals"—a class of verbs such as *quit* and *continue*—also presuppose certain actions having taken place (this class covers the example "Have you stopped beating your dog?"). It also appears that a number of modifiers introduce presupposition effects, for example *again*, *too*, *even*, and so forth. L. Karttunen (1973) argued that in propositional-attitude environments such as "Fred wants to sell his unicorn" it is presupposed that Fred believes he has a unicorn. A number of additional constructions that invoke presupposition effects have been explored, including those triggered by phonological stress. So, for example, if I say "I didn't go to the baseball game," it arguably presupposes that I went to some other kind of game.

### PRESUPPOSITION VERSUS ENTAILMENT

The philosophical controversy surrounding presupposition comes in at the very beginning—determining whether these are genuine cases of presupposition or are merely cases of entailment. To illustrate, consider (2)–(4):

- (2) Fred stopped washing the dishes.  
 (3) Fred didn't stop washing the dishes.  
 (4) Fred had been washing the dishes.

According to the presupposition thesis, both (2) and (3) presuppose (4). Hence, if (4) is false, then (2) and (3) must lack determinate truth-values. Alternatively, accord-

ing to the entailment analysis, (2) entails (4). Should (4) be false, then according to the entailment analysis (2) will be false and (3) will be true. This dispute has all the makings of a stalemate, since it turns on speakers' intuitions about whether sentences lack genuine truth-values under the relevant conditions or are merely false. Indeed, Strawson (1964) came to doubt whether the matter could in fact be settled by "brisk little formal argument[s]" and offered that each view could be reasonable, depending on one's interests. Others have put more stock in brisk little formal arguments, notably D. Wilson (1975), who offered an extensive critique of the presuppositional analysis.

### THE PROJECTION PROBLEM

One of the most interesting questions to surface is the so-called projection problem for presupposition, first observed by D. T. Langendoen and H. Savin (1971). This problem involves the question of what happens when a construction with a presupposition is embedded in more complex constructions (e.g., in propositional-attitude constructions or in the scope of negation). To illustrate, when (2) is negated, yielding (3), it continues to presuppose (4)—the presupposition is said to be projected. Other constructions, such as "doubts that," do not always project presuppositions, and still others (such as the "wants" case from Karttunen, discussed above) project something weaker than the original presupposition. The question is therefore whether projection presupposition is arbitrary or whether it obeys certain specific rules. Much subsequent work has attempted to articulate those "projection rules" (see Gazdar, 1979, Heim 1991, Karttunen 1973, and Soames 1979, 1982, for important examples).

### SEMANTIC VERSUS PRAGMATIC PRESUPPOSITION

If one accepts that there are genuine instances of presupposition, there remains the question of whether presupposition is a reflex of semantics or pragmatics—that is, whether the presupposition follows from the meaning of the sentence or is merely part of the conversational background. R. Stalnaker (1974) gave several arguments in favor of the pragmatic alternative, including the interesting observation that, in a case like (5),

- (5) If Eagleton hadn't been dropped from the Democratic ticket, Nixon would have won the election

there seems to be a presupposition that Nixon lost, although the effect is weak, and, in the right context or given appropriate information, that presupposition can

be overruled. This graded effect suggests that pragmatic phenomena are in play. Stalnaker also observed that the pragmatic alternative is useful in separating the question of entailment relations from the question of presupposition and in working out solutions to the projection problem. (But see Wilson 1975 for criticism of pragmatic accounts of presupposition.)

## APPLICATIONS

The doctrine of presupposition remains somewhat controversial, but at the same time it has found interesting applications. For example, B. van Fraassen (1968, 1970) argued that presupposition might be employed in the treatment of the “liar paradox” and proposed that liar sentences are neither true nor false owing to a presupposition failure. Presupposition has also played an important role in work on the semantics of propositional attitudes, much of it extending from the work of Karttunen (1973). I. Heim (1992), for example, has updated the initial Karttunen analysis with features of Stalnaker’s presuppositional analysis. Still other research (including unpublished work by Saul Kripke) has investigated the interplay of presupposition and the analysis of discourse anaphora.

## PRICE, RICHARD

(1723–1791)

Richard Price, a Welsh dissenting preacher, moral philosopher, and actuary, was born at Tynon, Llangeinor, Glamorganshire. His father, Rees, was a dissenting minister with extreme Calvinist opinions. Richard Price was educated at a number of different academies, finally entering Coward's Academy in London, where he remained for the years 1740–1744. He was ordained at the age of twenty-one and began his ministerial career as a domestic chaplain. He later served a number of London congregations, notably those at Stoke Newington, where he lived, and at the Gravel-Pit Meeting House in Hackney. Price was buried in the cemetery at Bunhill Fields; his friend Joseph Priestley preached the funeral oration.

In addition to his writings on moral philosophy, Price wrote with considerable influence on financial and political questions. His papers on life expectancy and on calculating the values of reversionary payments were instrumental in reforming the actuarial basis of the insurance and benefit societies of the time. His paper on the public debt is said to have led William Pitt, the prime minister, to reestablish the sinking fund to extinguish England's national debt. In his pamphlet *Observations on*

*the Nature of Civil Liberty, the Principles of Government, and the Justice and Policy of the War with America* (London, February 8, 1776), Price defended the American cause. The widespread circulation and generally favorable acceptance of this work is said to have encouraged the American decision for a declaration of independence. Price had become friendly with Benjamin Franklin during the latter's stay in London, and in 1778 the Continental Congress moved to grant Price American citizenship if he would come to America and serve as an adviser on the management of American finances. He was grateful for the invitation but did not accept it. Price also regarded the French Revolution with approval, which he expressed, along with an appeal for reform in England, in his *Discourse on the Love of Our Country* (1789). Edmund Burke's *Reflections on the Revolution in France* (1790) was written in reply.

Price is also the author of *Four Dissertations*: I. "On Providence"; II. "On Prayer"; III. "On the Reasons for expecting that virtuous Men shall meet after death in a State of Happiness"; IV. "On the Importance of Christianity, the Nature of Historical Evidence, and Miracles" (London, 1767). In the fourth of these dissertations Price criticized David Hume's "Of Miracles." Hume was grateful for the civility with which Price argued, and he wrote

to Price that the light in which he put this controversy was “new and plausible and ingenious, and perhaps solid. But I must have some more time to weigh it, before I can pronounce this judgment with satisfaction to myself.”

## MORAL PHILOSOPHY

Price’s contribution to moral philosophy is *A Review of the Principal Questions in Morals* (London, 1758; corrected editions in 1769 and 1787). Price criticized the moral-sense doctrines of Francis Hutcheson in order to clear them away and make room for an account of immutable right and wrong, derived from Samuel Clarke.

Price says that we may have three different perceptions concerning the actions of moral agents. We may notice whether they are right or wrong, whether they are beautiful or ugly, and whether they are of good or ill desert. By talking of perceptions here, he shows that he has accepted the premise, of Lockean origin, that all knowledge is to be accounted for as some kind of perception by one of our faculties. Thus, Price’s first question, “How do we know right?” is treated as a search for the faculty by means of which we obtain our ideas of right and wrong. He considers Hutcheson’s answer that our moral ideas come to us by the way of a moral sense, and he understands Hutcheson to be claiming that this sense is “a power within us, different from reason; which renders certain actions pleasing and others displeasing to us.”

Price objects to this doctrine because of certain consequences that he believes are implied by it. Our approval and disapproval of actions appear to depend on the way our minds work or, to carry the matter back a step, on the way God has made them to work. Thus, our judgments of right and wrong depend on the mere good pleasure of our Maker, who created us in a certain way. But if he had pleased, he might have made us to be pleased or displeased by quite different actions, even actions contrary to those that now please and displease us. Thus, right and wrong would be only matters of taste, only a certain effect in us, and nothing in actions themselves.

For his part, Price is convinced that morality is equally unchangeable with all truth and that right and wrong are real characteristics of actions and not mere sensations derived from the particular way in which our minds are framed. To show the immutability of right and wrong, Price argues that these ideas are derived not from a special sense but from the understanding. As Price sees it, the only debatable issue in morals is not what actions are right and wrong but what is the faculty by which we discern right and wrong.

Price prefaces his argument for regarding the understanding as our moral faculty with the preliminary claim that the understanding is a source of new ideas. He objects to interpreting John Locke as saying that sensation and reflection are the sources of all our ideas. Price argues that Locke may have meant only that all our ideas are ultimately grounded on ideas derived from sensation and reflection. Thus, Price makes room for certain new ideas that may arise as the understanding compares the objects of thought and judges them. Some of these new ideas are solidity, inertia, substance, accident, duration, space, cause or power, entity, possibility, and actual existence.

Price locates these new ideas in a revised classification of simple ideas. He divides simple ideas into those implying nothing real outside the mind and those that denote real and independent existence distinct from sensation. The first class of simple ideas consists, on the one hand, of tastes, smells, and colors and, on the other, of such notions as order, happiness, and beauty. The second class of simple ideas has three subclasses: the real properties of external objects, such as figure, extension, and motion; the actions and passions of the mind, such as volition, memory, and so on; and those new ideas noted above which arise as the understanding considers the ideas it has been supplied with. It is important to note that Price does not regard the second class of simple ideas as constructions of the mind. The real properties of external objects are in the objects, and such new ideas as cause, duration, and space are of properties in a real world.

Armed with his reclassification of simple ideas, Price is now prepared to locate our ideas of moral right and wrong in the scheme and thus establish that they are perceptions of the understanding. Price first considers the question of whether moral right and wrong are simple ideas. He declares that they must be, for we cannot give definitions of them that are more than synonymous expressions. It is Price’s recognition of this point which has led contemporary students to declare him one of the first to recognize the naturalistic fallacy, although he does not use that term. Having established that our ideas of right and wrong are simple ideas, Price then locates them in his scheme as two of those new ideas which arise in the understanding.

Hutcheson had simply assumed that if right and wrong are immediately perceived, they must be perceptions of an implanted sense. But the question of how we perceive these ideas may be settled by simply considering the nature of our own perceptions.

Let anyone compare the ideas arising from our *powers of sensation*, with those arising from our *intuition of the natures of things*, and enquire which of them his ideas of right and wrong most resemble.... It is scarcely conceivable that anyone can impartially attend to the nature of his perceptions, and determine that when he thinks gratitude or beneficence to be *right*, he perceives nothing *true* of them, and *understands* nothing, but only receives an impression from a sense.

Price notes that some impressions of pleasure or pain, satisfaction or disgust, generally attend our perceptions of moral right and wrong; the proponents of a moral sense may have confused these impressions with our actual perceptions of right and wrong.

But there is an assumption in Price's own system on which much depends and for which he offers insufficient argument. He tells us that "all actions undoubtedly have a *nature*. That is, *some character* certainly belongs to them, and somewhat there is to be *truly* affirmed of them." It is the task of the understanding to perceive these truths. Price regards actions in this way because it enables him to say that their rightness or wrongness is in them, not in the mind of the person judging the actions, but apart from noting the advantage to his own moral philosophy, Price offers no justification for the claim that actions have natures. It is unfortunate that he does not, for he rests his contention that morality is eternal and immutable on this claim.

When Price turns to our ideas of the beauty and deformity of actions, the second kind of perception of actions which he promised to account for, he finds that these perceptions are feelings of delight or detestation which may accompany our perceptions of the rightness or wrongness of actions. These feelings of delight and detestation are the effects on us of the actions we consider, and it is very likely that they arise from an arbitrary structure of our minds, which may be called a sense. Price allows that there is a distinction between noting that an action is right and approving it. We are made, however, in such a way that we cannot perceive an action to be right without approving it, for in humans it is necessary that the rational principle, or the intellectual discernment of right and wrong, should be aided by instinctive determinations. When these feelings of the heart support the perceptions of the understanding, we are provided with the motivation for moral behavior. Here Price agrees with Hutcheson, pointing out that he has never disputed that we owe much to an implanted sense and its determina-

tions. He means to resist only the claim that we owe our knowledge of right and wrong to such a sense.

Our ideas of the good and ill desert, the third sort of perception concerning actions which Price notes, carry the mind to the agent. He finds that we cannot but love a virtuous agent and desire his happiness above that of others. Quite apart from any advantage which we may gain from someone else's virtuous behavior, we have an immediate approbation of making the virtuous happy and of discouraging the vicious.

Price distinguishes between abstract and practical virtue. Abstract virtue denotes "what an action is independently of the sense of an agent; or what, in itself and absolutely, it is right such an agent, in such circumstances, should do." But Price recognizes that the actual practice of virtue depends on the opinion of the agent concerning his actions. Thus, an agent may be mistaken about his circumstances but sincere about what he believes he ought to do. In this respect practical virtue may diverge from abstract virtue but be no less obligatory insofar as the agent acts from a consciousness of rectitude. The ideal state of affairs is a correspondence of practical virtue with abstract virtue. Its achievement depends on the liberty and intelligence of the agent. These constitute the agent's capacity for virtue, and intention gives virtue actual being in a character. Price takes a short way with the question, "Why be moral?" "The knowledge of what is right, without any approbation of it, or concern to practise it, is not conceivable or possible. And this knowledge will certainly be attended with *correspondent, actual practice*, whenever there is nothing to oppose it." Why a person chooses to do what he knows he should do is a question "which need not and should not be answered."

Benevolence is not the sole virtue. We also have duties to God and to ourselves, and there is room for many other sorts of good behavior, such as veracity, sincerity, and gratitude. As a measure of virtue Price offers the rule that "the virtue of an agent is always less in proportion to the degree in which natural temper and propensities fall in with his actions, instinctive principles operate, and rational reflexion on what is right to be done, is wanting."

Price discusses at length the relation of morality to the divine nature. Just as moral right and wrong are independent of man's mind, they are also absolutes for God. Were this not so, there would be no sense in which God's will could be good.

## FREEDOM OF THE WILL

Price and Priestley published a set of letters as *A Free Discussion of the Doctrines of Materialism and Philosophical Necessity* (London, 1778). The correspondence had its origin in Price's criticism of Priestley's *Disquisitions Relating to Matter and Spirit*. The letters cover the nature of matter, the human mind, the mortality of the soul, the essence of the deity, and the doctrine of necessity. The last topic is the one that is treated in the most interesting way. Priestley contended that there can be no human liberty because "liberty" must mean someone's willing without a motive, which he regards as impossible. Price enlarges on the account of liberty that he offered in *A Review of the Principal Questions in Morals*. He argues that human agents are not physical objects but unique entities capable of self-determination. Consider the difference between a man who is dragged by a superior force and a man who follows a guide for a reward. Both of these examples may be certainties, but having different foundations, they are of totally different natures. "In both cases the man might in common speech be said to *follow*; but his following in the one case, however certain in event, would be *his own* agency: In the other case, it would be the agency of another. ... In the one case, superior power moves him: In the other he moves himself."

**Bibliography**

Price's *Works* were published in 10 volumes (London, 1816), with a memoir of his life by W. Morgan. *A Review of the Principal Questions in Morals* has been published with a critical introduction by D. D. Raphael (Oxford, 1948). This is a reprint of the third edition (1787) with an appendix and "A Dissertation on the Being and Attributes of the Deity."

For biography, see Carl B. Cone, *Torchbearer of Freedom, the Influence of Richard Price on Eighteenth Century Thought* (Lexington: University of Kentucky Press, 1952). Other works on Price include Joseph Priestley, *A Discourse on the Occasion of the Death of Dr. Price* (London, 1791); Leslie Stephen, *History of English Thought in the Eighteenth Century* (London, 1876; 2nd ed., London, 1902); and Roland Thomas, *Richard Price* (London: Oxford University Press, 1924).

## PRIESTLEY, JOSEPH

(1733–1804)

Joseph Priestley, the English scientist, nonconformist minister, educator, and philosopher, was born at Birstall, Yorkshire, the son of a cloth dresser. His mother died in 1740, and in 1742 Priestley was adopted by a childless well-to-do aunt, Mrs. Keighley, a convinced but unbigoated Calvinist. A sensitive child, Priestley suffered greatly because he could not convince himself that he had experienced the "new birth" essential, on the Calvinist scheme, for his salvation. As a result of these childhood miseries Priestley was left, he tells us, with "a peculiar sense of the value of rational principles of religion" as opposed to the "ignorance and darkness" of Calvinism.

Until the age of sixteen Priestley was educated at a conventional grammar school. For the next three years, his health being too poor for regular studies, he in large part educated himself, reading his way into mathematics, physics, and philosophy and undertaking the study of European and Middle Eastern languages. In 1752 his health improved and he entered Daventry Academy, a university-type institution set up by nonconformists because Oxford and Cambridge would not admit nonconformists to a degree.

At Daventry the emphasis was on free discussion, and the curriculum was considerably broader than at Oxford or Cambridge. Priestley was introduced to David Hartley's *Observations on Man* (1749) and was at once—and permanently—converted to Hartley's general outlook. The simplicity and generality of Hartley's associationist psychology appealed to Priestley's maturing scientific instincts; it provided a theoretical foundation for his belief in perfectibility through education; and it offered a psychological alternative to the doctrine of free will, which Priestley's reading of Anthony Collins's *Philosophical Inquiry concerning Human Liberty and Necessity* (1714) had already caused him to reject.

In 1755 Priestley entered the ministry, taking over a decaying congregation at Needham Market, Suffolk. Stammering and unorthodox, he was not a success as a minister. He moved in 1758 to a more sympathetic but equally impoverished congregation at Nantwich in Cheshire. In an attempt to increase his income he set up a school where, perhaps the first to do so, he taught experimental science with the help of an "electrical machine" and an air pump.

Appointed in 1761 as "tutor of the languages" at Warrington Academy in Lancashire, Priestley taught oratory, literary criticism, grammar, history, and law, as well

as languages. Characteristically, on all these latter topics Priestley developed ideas that he sooner or later published. *The Rudiments of English Grammar* (1761), many times reprinted, is typical of his innovating boldness, insofar as he tried to simplify English syntax by removing from it the complications introduced by classically trained grammarians. His *A Chart of Biography* (1765) and *A New Chart of History* (1769) were even more enthusiastically received; they won for him not only his sole academic distinction, the doctorate of laws of the University of Edinburgh, but also his fellowship of the Royal Society.

Priestley's days of relative isolation were now over. In 1762 he married an ironmaster's daughter, Mary Wilkinson, an intelligent woman with a sense of humor and considerable force of character—qualities she was to need in the years to come. His duties at Warrington left him free to visit London for a month each year, where he came into contact with an active group of scientists, philosophers, and political thinkers, including Benjamin Franklin and Richard Price. Franklin encouraged Priestley's project of writing a history of electrical experiments. The work that resulted, *The History and Present State of Electricity, with original Experiments* (1767), is a notable contribution to the history of science. Describing a number of important original experiments, it is also in some respects the most theoretically adventurous of Priestley's scientific works. It contains as well Priestley's reflections on the use of hypotheses in scientific procedures as a guide to experimentation.

## EDUCATION AND GOVERNMENT

Like many of his fellow dissenters, Priestley was greatly interested in educational reform. Education had, he thought, thus far concentrated unduly on the needs of the clergy. His *An Essay on a Course of Liberal Education for Civil and Active Life* (1765) is a plea for a curriculum that should be suitable for men of affairs, emphasizing history and public administration rather than the classical languages. Priestley did much to encourage the teaching of history in the nonconformist academies. A set of lectures that he delivered at Warrington (published in 1788 as *Lectures on History and General Policy*) provided not only the academies but also the new American colleges with a text suitable for their needs; it was, indeed, recommended even at Cambridge. It is a summary account of the main historical sources, with an emphasis on commerce, law, and administration, rather than a historical textbook of the ordinary kind.

Priestley's political theory was closely related to his interest in education and his experience as a member of a minority group. In an appendix to his *Essay on a Course of Liberal Education* he developed an argument against the introduction of a state system of education, which would inevitably, he thought, favor the *status quo* and produce a quite undesirable uniformity of conduct and opinion. Like John Stuart Mill after him, Priestley gloried in diversity; uniformity, he said, is "the characteristic of the brute creation."

These reflections were more fully worked out in *An Essay on the First Principles of Government* (1768), which bears the subtitle *On the Nature of Political, Civil and Religious Liberty*. For Priestley, the preservation of civil liberty was the crucial political issue. Deciding who should participate in government—who, that is, should possess political, as distinct from civil, liberty—was, he thought, a practical matter, to be settled by considering what groups in the community are most likely, if they possess political power, to act for the greatest happiness of the greatest number. Such groups remain entitled to power only as long as they continue so to act. Legislation, on Priestley's view, should be kept to the minimum. What that minimum is cannot be determined a priori but only as a result of political experiment. But we can see at once, Priestley thought, that legislation that restricts civil and religious liberty is bound to be against the interests of the community. Unlike most nonconformist upholders of toleration and unlike his master John Locke, Priestley was uncompromising on this point; he upheld unbounded liberty of expression even to atheists and Roman Catholics.

In Priestley's eyes, the noblest of occupations was that of the clergyman, not the lecturer, and in 1767 he accepted a call to Mill Hill, Leeds, a congregation to whom his religious views were exceptionally congenial. The years Priestley spent at Mill Hill were extremely important in his development; his salary, although small, sufficed for his needs, and his duties left him considerable leisure.

## UNITARIANISM

Priestley had long before abandoned both the doctrine of the atonement, on which he wrote critically in *The Scripture Doctrine of Remission* (1761), and orthodox Trinitarianism. Now he took what was to be the final step in his transition from Calvinism to Unitarianism. Christ, he argued, although the Messiah, was a man, and not even a perfect man. Priestley's subsequent theological writings were in large part an attempt to prove—most maturely in

his *History of Early Opinions concerning Jesus Christ* (1786)—that Unitarianism was the doctrine of the early church. He defended his unorthodoxies both against clerical attack, as in his *Letters to Dr. Horsley* (1783–1786), and, as in his *Letters to a Philosophical Unbeliever* (Pt. I, 1780; Pt. II, 1787), against those who, like Edward Gibbon, could not understand why Priestley did not make a complete break with Christianity. Priestley valued his theological writings above all his other work. A firm belief in Providence is everywhere evidenced in his writings. Few men have committed themselves so often and so absolutely to the doctrine that “all is for the best in the best of all possible worlds,” although he also believed that the future world could—and therefore would—be better.

### SCIENTIFIC ACHIEVEMENT

It was as a scientist that Priestley won his international reputation. He published in 1772 what was intended to be the second section of a general history of science, *The History of the Present State of the Discoveries relating to Vision, Light and Colours*; but this work, invaluable though it still is to historians of science, did not arouse a great deal of interest. Priestley therefore abandoned his large-scale historical project and concentrated instead on chemistry. His first chemical publication, in 1772, was of an unusually practical character: It described a method of producing “mephitic julep,” or soda water. But it was the paper “On Different Kinds of Air,” which he read in that same year to the Royal Society, that at once established his reputation as a chemist. In 1774 he prepared the first edition of *Experiments and Observations on Different Kinds of Air*; this he republished in a series of editions, with important changes in contents, in method of organization, and even in title, until 1790.

By the end of that period Priestley, following up the work of Joseph Black and Henry Cavendish, had considerably enlarged our knowledge of the chemical properties of gases. He differentiated between nine gases, of which only three had previously been known to science, and described a method of collecting them. Of particular importance was his preparation of “dephlogisticated air” (oxygen), which he produced on August 1, 1774, by heating red mercuric oxide. It then became clear that air was not an element. Priestley went on to examine the properties of oxygen; in a series of chemicobiological experiments he brought out its importance for animal life.

As a resourceful experimenter, using simple and economical methods, Priestley has had few equals. But it was left to others, to Cavendish and Antoine Lavoisier, to appreciate the theoretical significance of his work. Priest-

ley had isolated oxygen and had observed its importance in combustion; he had passed a spark through a mixture of hydrogen and oxygen and had noticed that dew was formed. Yet his last scientific work (1800) bore the title *The Doctrine of Phlogiston established and that of the Composition of Water refuted*. Although he had himself carried out important quantitative experiments, he did not appreciate the significance of the quantitative considerations by which Lavoisier overthrew the phlogiston theory.

### PHILOSOPHY

Much of Priestley’s most important scientific work was carried out at Shelburne, where from 1772 until 1780 he acted as “librarian and literary companion” to the Earl of Shelburne. During these same years Priestley embarked upon his most substantial metaphysical works. He began in 1774 with *An Examination of Dr. Reid’s Inquiry into the Human Mind on the Principles of Commonsense, Dr. Beattie’s Essay on the Nature and Immutability of Truth, and Dr. Oswald’s Appeal to Commonsense on Behalf of Religion*, commonly referred to as *An Examination of the Scotch Philosophers*. This is a vigorous polemic, which sets out to demonstrate the superiority of Hartley’s psychology to the philosophy of the Scottish commonsense school, a philosophy that Priestley thought obviously reactionary insofar as it substituted for the simple Locke-Hartley theory of mind “such a number of independent, arbitrary, instinctive principles that the very enumeration of them is really tiresome.” All the so-called instinctive beliefs of common sense can, Priestley set out to show, be derived from the operations of associative principles working on the materials provided by sensation. He came to regret in later life the tone of this publication but never its doctrines.

**MATERIALISM.** Hoping to make Hartley’s views better known, Priestley published an abridged version of Hartley’s *Observations on Man* in 1775 as *Hartley’s Theory of the Human Mind on the Principle of the Association of Ideas*. In his preface, Priestley somewhat tentatively suggested that all the powers of the mind might derive from the structure of the brain. Even as a suggestion this created a considerable uproar, but Priestley was not to be intimidated by clerical clamor. Convinced that materialism was the natural metaphysical concomitant of Hartley’s associative psychology, he set out, therefore, in his *Disquisitions Relating to Matter and Spirit* (1777) to demonstrate that materialism was theologically, scientifically, and metaphysically superior to orthodox dualism.

On the theological side, materialism had commonly been objected to on the ground that it is incompatible with immortality. Man, Priestley replied, is not “naturally” immortal; he is immortal only because, as we know from revelation, God chooses to resurrect him; this resurrection is of the body and therefore also of the body’s mental powers. As for the commonplace metaphysical objections to materialism, these are based, according to Priestley, upon an untenable conception of matter as being by nature inert and therefore incapable of exerting mental activity. To such a concept of matter Priestley opposed the physical theories of his friend and fellow scientist John Michell and the Jesuit mathematician Roger Boscovich. Material objects, on their view, are centers of force; if this is the nature of matter, Priestley argued, there is no good reason for denying that mental operations are part of the activity of a material object. On the other hand, there are very good reasons for objecting to the traditional dualism, which is quite incapable of explaining how mind and body can enter into any sort of relationship.

**DETERMINISM.** Priestley had been a determinist long before he became a materialist, but not until 1777, in *The Doctrine of Philosophical Necessity Illustrated*, did he fully present his case against free will; indeed, even then he thought of himself as supplementing Thomas Hobbes, Collins, David Hume, and Hartley with illustrations rather than as working out an entirely independent position. The doctrine of free will, he argued, is theologically objectionable because it cannot be reconciled with the existence of an all-seeing Providence; from a metaphysical standpoint, it makes human actions quite unintelligible, and ethics has no need of it. As a basis for our everyday moral judgments, the distinction between acting voluntarily and acting under compulsion is certainly important, but this distinction does not, according to Priestley, rest upon a metaphysical conception of free will.

Priestley’s metaphysical unorthodoxies considerably disturbed his old friends, provoking a candid but good-tempered correspondence with Richard Price, published in 1778 as *A Free Discussion of the Doctrines of Materialism and Philosophical Necessity Illustrated*. Developing his views on the relation between moral judgments and determinism, Priestley admitted that the determinist will prefer to avoid describing people as blameworthy or praiseworthy. He will say of them, rather, that they have acted, or have not acted, from good principles—from principles, that is, that are conducive to the general happiness. But the determinist’s different method of describ-

ing moral conduct has, Priestley thought, no practical consequences, and if determinism is in some respects inconsistent with everyday usage, this is even more true of libertarianism.

## LATER YEARS

There was a real risk, however, that Priestley’s reputation for materialism might endanger the earl of Shelburne’s political ambitions. Perhaps for this reason Priestley and Shelburne parted amicably in 1780, when Priestley, refusing Shelburne’s offer of a post in Ireland, took up residence in Birmingham. There he had a circle of congenial friends who were prepared to offer him financial as well as intellectual support. He became a member of the Lunar Society, with which were associated men of the caliber of Erasmus Darwin and James Watt, and he enjoyed the friendship and help of the scientifically minded potter Josiah Wedgwood, who supplied him with apparatus specifically designed for his chemical experiments. Much of Priestley’s scientific work in this period, under Alessandro Volta’s influence, conjoined his two main scientific interests: electricity and gases. He examined the effect of passing electrical sparks through a variety of gases and studied their thermal conductivity.

He was by no means unsympathetic to the laissez-faire sociopolitical attitude of Birmingham industrialists. In *Some Considerations on the State of the Poor in General* (1787) he strongly criticized the poor laws and elsewhere opposed apprenticeship laws and laws for regulating interest rates. On his view, any sort of social welfare legislation “debased the very nature of man” by treating him as someone who had to be provided for. Although Priestley warmly supported schemes for cooperative insurance against hardship, he was opposed to any legislation that might diminish independence or increase the power of the state over individuals.

**POLITICAL RADICALISM.** In general terms, Priestley’s life at Birmingham was a continuation and development of his earlier activities; theological controversy continued to be his main interest. But one event transformed his life and modified his political attitudes: the French Revolution. Reacting to that revolution, the British government became steadily more intolerant and conservative, and Priestley came to think that extensive political innovations were a necessary condition for the preservation of civil liberty. He moved toward political radicalism of the nineteenth-century kind in his *Letters to Edmund Burke occasioned by his Reflections on the Revolution in France* (1791) and in the anonymously published *A Political Dia-*

*logue on the General Principles of Government* (1791). He had formerly been accustomed to describe himself as “a Unitarian in religion but a Trinitarian in politics” because he had accepted the view that liberty rested on the balance between king, Commons, and House of Lords. He now came to feel that there should be but one source of political power, the will of the people as it would be represented in a reformed House of Commons.

On July 14, 1791, the Friends of the Revolution organized a dinner at Birmingham (Priestley was not present) in order to commemorate the fall of the Bastille. This was the last straw. With the encouragement, it would seem, of the authorities, an angry mob attacked the non-conformist chapels, then turned their attention to Priestley’s house, destroying his books and furniture. Priestley was persuaded by his friends to leave Birmingham for London where he was, however, shunned by his scientific colleagues.

**LIFE IN AMERICA.** For some years, Priestley had been contemplating migration to the United States, where his three sons had already gone. In 1794 he left for New York and finally settled in Northumberland, Pennsylvania. There, still supported by his old friends, he continued to experiment and to write, mainly on theological questions.

He was disappointed, however, by the orthodoxy of the American clergy and alarmed by the growth of intolerance in the United States. Although he took no part in politics, he wrote an uncompromising exposition of his political and religious views in *Letters to the Inhabitants of Northumberland* (1799). There was talk of his being deported under the Aliens Act, but John Adams would not permit the application of the act to “poor Priestley.” With the election of Thomas Jefferson to the presidency, Priestley was not only secure but also at last on good terms with authority. Jefferson consulted him on educational questions, and Priestley’s *Socrates and Jesus Compared* (1803) precipitated Jefferson’s “Syllabus” of his religious beliefs. Another of Priestley’s works, *The Doctrines of Heathen Religion Compared with those of Revelation* (1804), awoke in Adams an enthusiasm for comparative religion. Priestley’s last years, from 1801 until his death, were marred by ill health and bereavements, but his diversified intellectual interests remained with him until the end.

### **Bibliography**

Priestley’s scientific writings have never been collected. The standard edition of his philosophical, theological, and miscellaneous writings is *The Theological and Miscellaneous Works of Joseph Priestley*, edited by John Towill Rutt, 25 vols. in 26 (London: G. Smallfield, 1817–1832). John Arthur Passmore, *Joseph Priestley* (New York, 1965) includes a short list of Priestley’s writings, an introductory essay, and selections from his major works.

See also Thomas Henry Huxley, “Joseph Priestley,” in *Science and Culture* (London, 1881); Thomas Edward Thorpe, *Joseph Priestley* (New York: Dutton, 1906); Edgar Fahs Smith, *Priestley in America, 1794–1804* (Philadelphia: P. Blakiston’s Son, 1920); Wallace Ruddell Aykroyd, *Three Philosophers: Lavoisier, Priestley and Cavendish* (London: Heinemann, 1935); Arthur Handley Lincoln, *Some Political and Social Ideas of English Dissent, 1763–1800* (Cambridge, U.K., 1938); Francis Edward Mineka, *The Dissidence of Dissent* (Chapel Hill: University of North Carolina Press, 1944); Stephen Edelston Toulmin, “Crucial Experiments: Priestley and Lavoisier,” in *Journal of the History of Ideas* 18 (2) (1957): 205–220; and the detailed bibliographies in the *Dictionary of National Biography* and the *Dictionary of American Biography*.

*John Passmore (1967)*

## PRIMARY AND SECONDARY QUALITIES

The distinction between “primary and secondary qualities,” first stated and thus named by Robert Boyle, received its classical formulation in John Locke’s *Essay*. There Locke states that apart from ordinary causal properties or “powers,” material objects possess five primary qualities—extension (size), figure (shape), motion or rest, number, and solidity (impenetrability)—and many secondary qualities, such as color, taste, smell, sound, and warmth or cold. This distinction was made in the context of representative realism; that is, it was presupposed that the qualities of objects are quite distinct from, and are in fact causes of, “ideas” (representations or *sensa*), which are the only immediate objects of sensory awareness. The basis of the distinction was twofold. First, perceived size, shape, motion, number, and solidity are ideas caused by and exactly resembling the corresponding primary qualities of objects; perceived color, taste, smell, sound, and so on are caused by, but do not resemble, the corresponding secondary qualities. Second, the primary qualities are inseparable from matter and are found in every part of it;

the secondary qualities are not true qualities of matter but are merely powers in the objects to produce sensory effects in us by means of the primary qualities in their minute parts. Thus, red as experienced (*idea* or *sensum*) is the effect of the secondary quality red, which is merely the power possessed by a special texture or surface structure of the object to reflect certain light frequencies and to absorb others.

This formulation is rather clumsy, and since George Berkeley the custom has been to apply the first part of the distinction to the qualities of the ideas or *sensa*. The primary or spatiotemporal qualities of these data may then be said to characterize the object as well, for instance, the *sensum* is square and so is the object; but the secondary qualities are said not to characterize the object at all except in a derivative way, for instance, the *sensa* may be red and fragrant, but the object itself is intrinsically neither colored nor scented; it is red and fragrant only in the secondary sense that it causes the appropriate data of color and smell in the percipient. The doctrine is thus essentially the same as Locke's, but the language is slightly different. This second formulation will be used here.

Though Boyle and Locke invented and popularized the distinction and the terminology of primary and secondary qualities, the distinction dates back in principle to Democritus, who said that sweet and bitter, warm and cold, and color exist only by convention (*νόμος*), and in truth there exist only the atoms and the void (Fr. 9, Diels and Kranz). The distinction was revived by Galileo Galilei and accepted by René Descartes, Isaac Newton, and others.

## ARGUMENTS FOR THE DISTINCTION

**RELATIVITY AND MEASUREMENT.** The relativity argument is the most important one: Secondary qualities are affected by the condition of our sense organs and nervous system, by our distance from the object or its motion relative to us, by the lighting or by such intervening media as fog. Since secondary qualities thus vary according to, and depend for their nature on, factors quite external to the physical object, they cannot be intrinsic properties of it. This point was elaborated by Locke in various examples, two of which follow: (a) If one takes three bowls of water, one judged hot, one judged cold, and one judged medium, and places one hand in the hot water and the other hand in the cold, and then transfers both hands to the middle bowl, the water in that bowl will feel hot to the hand that has been in the cold water and cold to the hand that has been in the hot water. But since it cannot be both hot and cold, hot and cold are therefore not intrinsic

properties of the water. (b) Marble is not colored in the dark; its color appears only in the light. But presence or absence of light cannot alter its real properties, so that the perceived color cannot be included among them.

If we grant the position of representative realism that hot, cold, and color, as experienced, are qualities of ideas or representations, then it is plausible to suppose on these grounds that they do not also characterize objects or resemble properties of objects. (Locke does not always make it clear that representative realism is to be presupposed). But this claim is apparently open to the insuperable objection, stated by Berkeley, that the primary qualities also vary: The object's apparent shape or size varies just as much as its color or sound. This would mean that shape and size as perceived do not characterize objects or resemble the actual properties of the object, thus subverting the whole basis of the distinction. That Locke did not see this may have been partly because he felt that he had to argue against the commonsense assumption that all sensible qualities characterize objects, and partly because the belief that primary qualities characterize all matter was apparently guaranteed by the physics of his day.

Although this objection is valid against Locke's position, it does not destroy the distinction between the primary and secondary qualities, which it is natural to recast and support by a revised relativity argument. This new point is that, in contrast with the secondary qualities, the main primary qualities—shape, size, and motion—can all be measured (solidity cannot, but it is dubious anyhow, in that most physical objects, even atoms, are far from solid or impenetrable; number, whether there is one object or two, seems scarcely a quality at all; strictly also in the case of shape, what is measured are various dimensions—diameters, angles, and so on—of the object, and supporters of the distinction must maintain that these are the *differentiae* of the shape). A plate may look elliptical, but by measuring its diameters and seeing that they are equal, we can establish that it is round; one man may look taller than another, but their relative heights may be settled by measurement, as can the speed of objects relative to the earth. The measured size and shape of a plate may thus be held to characterize it, and the sensible size and shape may agree with and resemble them, so that one can say that size and shape (and motion) are primary. Nevertheless, only in favorable circumstances does a given primary sensible quality also characterize the object (for instance, both object and *sensum* are round); otherwise, there is only a projective relationship, as between elliptical *sensum* and round object.

Measurement is objective and does not vary significantly because it is an operation that depends on the coordination of a number of separate perceptions and that may be performed by a number of different persons. Consequently, variations due to the measurer on any particular occasion are compensated for and do not affect the final result, and the various actions confirm that one is not simply establishing the qualities of representations. Measurement also leads to conclusions regarding the dimensions and positions of objects in physical space that can be verified by further activities or operations, such as fitting the objects together, moving one's hand between them, rolling an object to confirm that it is round, and so on. By contrast, the variation found in the sensory qualities seems to be caused by their being simply the content of one single act of perception limited to one person at one time.

If all this is so, the list of primary qualities must be somewhat amended. Shape, size, and motion remain, but one should substitute mass for solidity. Temperature is more difficult: Since it can be measured, it seems at first primary. But what is measured is the property of causing expansion in fluid or metal; this property in no way resembles felt warmth, and in physical theory it is a form of energy. Hence, temperature should not be regarded as a separate primary quality. Material objects do, of course, possess many other properties—causal and dispositional ones, for example—as Locke realized by his doctrine of “powers,” but part of the distinction is that only the primary ones are intrinsic (that is, possessed without reference to other objects) and that all such powers are ultimately due to patterns of primary qualities. Even so, the distinction would have difficulty in coping with some intrinsic “scientific” properties, such as energy or electric charge.

Apart from this, various objections have been made to the distinction in terms of measurement. First, measured motion and size must be stated in terms of some standard, such as a yard or meter; hence, they are purely relational and are not intrinsic properties of the object. But one can reply that it is only the description or labeling of the measurement that is thus relational; the motion or extension labeled, which is actually measured, seems intrinsic to the object.

Second, since colors and sounds may be measured, are they not also primary? But this objection seems based on a misunderstanding of the processes of measurement, for one way of “measuring” color might be to compare a given shade with a standard on a shade card; but that would be like comparing the sensible size of two objects, not meas-

uring them. Proper measurement goes beyond this kind of sensory experience, and even if one gives the shade a number, one cannot calculate with the results as one can with the dimensions of objects. Normally, however, measurement of colors or sounds is either the measurement of the amplitudes or lengths of light waves or sound waves, or a mixture of wave measurement and the comparison of experiences. If one brings up a decibel meter and says that the sound to be measured is 80 decibels, it is the amplitude of the sound waves that is ultimately responsible for the movement of the pointer to 80. It should be noted, however, that the logarithmic scale is used because of a characteristic of human ears—that experienced loudness is related logarithmically to wave amplitude.

Third, measurement is a perceptual process—at least it relies on and largely uses perception—so it may be only producing various correlations of *sensa* and never getting through to the supposed properties of material objects at all. This objection is made from the point of view of phenomenalism, however, while the whole primary-secondary quality distinction presupposes representative realism. Supporters of the latter would say that the best explanation of the correlation is that the sense experiences arise in the measurement of actual physical objects.

**ARGUMENTS FROM SCIENCE.** Science can adequately explain and describe the nature of the physical world solely in terms of primary qualities; hence, while primary qualities must characterize objects, there is no need to suppose that secondary qualities must also. The latter would be otiose, and on the principle of economy, or Ockham's razor (that entities should not be multiplied more than is necessary), it would be unscientific to suppose that they exist as intrinsic properties of objects. The objection to this argument is partly that the science of one's day is not final (thus, Locke was persuaded by seventeenth-century science to include solidity in the list of primary qualities), and mainly that scientific theory and description are not the whole truth—they describe only one aspect of the world, being limited by their quantitative approach and their instruments. Secondary qualities may thus be real properties of matter with biological or aesthetic functions; Ockham's razor oversimplifies the facts pertaining to living things.

Investigation of the causal processes on which perception depends shows that the only variables capable of transmitting information about the properties of external objects are spatiotemporal ones, which are associated with primary qualities. Thus, light waves (energy distributed in space and time) pass from the object to the per-

ipient, but nothing resembling experienced color and sound is transmitted. But the main force of this argument, since it applies to all the senses, is neurological. The nerves from the different sense organs to the brain are all similar, and therefore the only variables are the frequencies of the impulses (which convey the intensity of the stimulus), their different neural pathways, and their different destinations in the brain. Indeed, it seems to be the different destinations that primarily govern the type and quality of the sensation. And although one can conceive of primary qualities being transmitted by spatiotemporal variables, it is difficult to conceive of color, warmth, taste, or smell being so transmitted. (It may be objected that radio and television can transmit color and sound by converting them into electrical impulses for transmission and then reconverting them. But, strictly speaking, what is converted is not color or sound but light waves or sound waves; moreover, the radio or television station must use microphones and cameras to effect the conversion, and there is no evidence of such conversion devices at the objects we see or hear.)

### BERKELEY'S CRITICISMS

Berkeley's formidable criticisms of the distinction between primary and secondary qualities have convinced many people. We have mentioned his objection concerning relativity, which, though valid against Locke, can be avoided by restating the distinction on the basis of measurement. He also has nothing to say on the scientific considerations, which were not explicit in Locke. But he did have some further well-known criticisms. First, he stated, "An idea can be like nothing but an idea." In other words, our *sensa*, being private, mental, and directly perceivable, cannot resemble properties of material objects that are public, physical, and not objects of direct awareness. But resemblance is claimed only for primary qualities; and though *sensa* cannot be extended in physical space, it seems reasonable to claim a structural resemblance, a similarity in form, between the spatial relations that they sensibly possess and those attributed to objects by measurement; thus, it can be confirmed by measurement that various relations between the sides of a square *sensum* hold in the object. A similar resemblance seems plausible in the case of motion. There are, however, some underlying difficulties here. In the older representative realism, *sensa* were mental; and since the mind was held to be unextended, they could hardly have spatial relations. But newer versions would allow some sensible or subjective space different from physical space; certainly *sensa* seem spatial, and there seems to be no reason why what is

directly perceivable and what is not should be unable to have a similar form or character.

Second, matter consisting only of primary qualities—for instance, possessing extension but no color, taste, sound or smell—is inconceivable. This objection is beside the point: Admittedly one cannot conceive, in the sense of "imagine" or "picture to oneself" (Berkeley's sense of the word), any such thing, for what we can imagine is limited by past experience and perception. But the range of possible existents need not be confined to this, and there is much in science, particularly in modern physics, that cannot be imagined or pictured.

### Bibliography

#### CLASSICAL WORKS

Anticipations of the distinction are to be found in Democritus, Fragments 9 and 125, in H. Diels and W. Kranz, *Fragmente der Vorsokratiker*; Galileo, *Il saggiaiore* (The Assayer; 1623), in his *Opere*, edited by F. Flora (Milan, 1952), pp. 311–314; René Descartes, *Principles of Philosophy*, Part IV, Nos. 188–203, and *The World or Essay on Light*, Chs. 1–2. Robert Boyle adumbrated the distinction in his *The Origin of Forms and Qualities* (London, 1666), especially the section titled "An Excursion about the Relative Nature of Physical Qualities"; John Locke stated it in his *Essay concerning Human Understanding* (London, 1690), Book II, Ch. 8; Newton's view is best stated in his *Opticks*, Book I, Part II (paperback, New York, 1952, p. 124), but that was not published until 1704. Berkeley's criticisms are in his *Principles of Human Knowledge*, Secs. 9–20. Edwin A. Burtt, *The Metaphysical Foundations of Modern Physical Science* (London: K. Paul, Trench, Trubner, 1925), contains useful discussion of the early versions.

#### MODERN WORKS

No book is devoted to the distinction, and substantial treatments are rare, but helpful contributions may be found in the following:

A more recent scientific comment on the distinction is Russell Brain, *Mind, Perception and Science* (Oxford: Blackwell, 1951). L. Susan Stebbing, *Philosophy and the Physicists* (London: Methuen, 1937), attacks scientific versions of it, especially those of Newton and of Arthur S. Eddington (see his *The Nature of the Physical World*, Cambridge, U.K.: Cambridge University Press, 1928).

Among the general works available are Charlie Dunbar Broad, *Scientific Thought* (London: Kegan Paul, 1923) and *The Mind and Its Place in Nature* (London: Kegan Paul, 1925); William Pepperell Montague, *The Ways of Knowing* (London: Allen and Unwin, 1925); Roderick Chisholm, *Perceiving: A Philosophical Study* (Ithaca, NY: Cornell University Press, 1957); and more fully, R. J. Hirst, *The*

*Problems of Perception* (London: Allen and Unwin, 1959). D. M. Armstrong, *Perception and the Physical World* (New York: Humanities Press, 1961), Chs. 14 and 15, discusses the subject from a direct realist position, and Gilbert Ryle's criticisms of the distinction in his *Dilemmas* (Cambridge, U.K.: Cambridge University Press, 1954) are well known.

Among articles on the distinction are Reginald Jackson, "Locke's Distinction between Primary and Secondary Qualities," in *Mind* 38 (149) (1929): 56–76; J. J. C. Smart, "Colours," in *Philosophy* 36 (137) (1961): 128–142 (reprinted with additions in his *Philosophy and Scientific Realism*, New York: Humanities Press, 1963); Colin Strang, "The Perception of Heat," in *PAS* 61 (1960–1961): 239–252; and for a more general treatment, W. C. Kneale, "Sensation and the Physical World," in *Philosophical Quarterly* 1 (2) (1951): 109–126.

## PRINGLE-PATTISON, ANDREW SETH (1856–1931)

Andrew Seth Pringle-Pattison, the Scottish personal idealist, was born Andrew Seth, in Edinburgh. (He adopted the surname Pringle-Pattison at the age of forty-two as a

condition of inheriting a family estate in Scotland.) He studied philosophy at Edinburgh University under Campbell Fraser. Two years of study in Germany convinced him that it was the worst place for the study of German idealism but resulted in his completing, at twenty-four, his Hibbert essay, *The Development from Kant to Hegel*. From 1880 to 1883 he served as Fraser's assistant at Edinburgh and then took the foundation chair of philosophy in the University College of South Wales at Cardiff. He left Cardiff in 1889 for the chair of logic and metaphysics at the University of St. Andrews. This he relinquished in 1891, when he succeeded Fraser at Edinburgh. In 1919 he resigned, after thirty-nine influential years as a university teacher.

Philosophy for Pringle-Pattison was a serious enterprise of the human spirit, which he did not distinguish strictly from a statement of his own findings in religion and morality. His writing is clear and eloquent but not very original. He sought to advance his subject through critical interpretation of the great philosophers, especially Immanuel Kant and G. W. F. Hegel. He was skeptical about the value of philosophical systems, holding that we cannot know the universe as we can know its individual parts; only God can do this. Rather, "the ultimate harmony may justifiably be spoken of as an object of faith—something which I am constrained to believe, even though I do not fully see it."

Pringle-Pattison was a Scottish Hegelian with a difference. Rebellious against the absolutism of Hegel and of such Hegelians as Francis Herbert Bradley and Bernard Bosanquet, for whom the individual is merged in the universal, he insisted on the uniqueness of the individual person. It is only as knower that the self is a unifying principle. As a real being it is separate and distinct, impervious to other selves, even to God. "I have a centre of my own—a will of my own—a centre which I maintain even in my dealings with God Himself." We feel this to be so; it neither needs to nor can be established by argument. But God too is a Person; we cannot deny him self-consciousness, because this is the highest source of worth in ourselves. Hegel and the Hegelians were at fault here also.

Philosophy, Pringle-Pattison held, cannot do justice to "the individual within the individual—those memories, thoughts, and feelings which make each of us a separate soul" (*Hegelianism and Personality*, p. 217). Religion and poetry go further and deeper than philosophy, and this, as he said, is why he drew so frequently on the poets.

Our knowledge of the Absolute starts from experience—our experience "of the concrete worlds of morality, of beauty, of love or of the passion of the intellectual life."

It is, however, a postulate of reason that the world is a cosmos, not a chaos, which we can gradually explore but never grasp in its entirety. Pringle-Pattison described his philosophy as “a larger idealism” that reconciles the dictates of morality and religion with the findings of science, purpose being the supreme category.

He was cautious in his claims about immortality. The nature of the soul is such that it is reasonable to entertain the hypothesis of its survival, and since human spirits must be “values for God” they were surely not made to be constantly destroyed and replaced by others. Yet if there is personal immortality, it is not the inherent possession of every human soul but must be won by the continuous effort needed to develop a coherent self. Morality does not depend on personal immortality, nor need immortality be the central article of philosophy or religion. In the apprehension of Truth, Beauty, and Goodness—eternal realities—man has already tasted eternal life and so should not be much concerned about personal survival.

## PRIOR, ARTHUR NORMAN (1914–1969)

Arthur Norman Prior was born on December 4 at Masterton, near Wellington, New Zealand. He acknowledged an early philosophical debt to John Findlay. But his first academic post was at Canterbury University College, where he succeeded Karl Popper. He was the visiting John Locke Lecturer at Oxford in 1956, and in 1958 he was appointed a professor of philosophy at the University of

Manchester. After short periods as a visiting professor at the University of Chicago and at the University of California at Los Angeles, he moved in 1966 to a tutorial fellowship at Balliol College, Oxford, and Oxford University appointed him to a concurrent readership.

Prior's early intellectual interests were very much religious in character. He was influenced for several years by the theologian Arthur Miller, who combined a strict adherence to Presbyterian doctrine with an equally strong support for socialism and opposition to nationalism. But Prior's pacifism weakened, and he served from 1942 to 1945 in the New Zealand air force. And the central focus of his interests gradually shifted—helped by an occasional bout of atheism—from theology to ethics and logic. He exchanged ideas with a wide circle of friends and acquaintances, and his hospitality to students was legendary.

Prior's first book, *Logic and the Basis of Ethics* (1949) traced seventeenth-, eighteenth-, and nineteenth-century anticipations of G. E. Moore's criticism of the so-called naturalistic fallacy. But his main claim to fame lies in his pioneering work on the formal logic of temporal relationships. His most important investigations in this field were published in *Time and Modality* (1957), *Past, Present, and Future* (1967), and *Papers on Time and Tense* (1968). But he also wrote on several logical topics in this encyclopedia; he published a substantial survey of the current state of logical inquiry under the title of *Formal Logic* (1955; 2nd ed., 1962); and a posthumous volume of papers, *Objects of Thought* (1971), was edited by P. T. Geach and A. J. P. Kenny.

Prior almost always used the Polish style of notation in the discussion of logical proofs and principles and was a convinced, though largely unsuccessful, champion of its virtues. The major inadequacy in his tense logic, however, was a failure to discuss or accommodate aspectual differences—roughly, differences between the meanings expressed by verbs in a perfect tense and those expressed by verbs in an imperfect tense (see Galton, 1984). Other criticisms may be found in L. J. Cohen's (1958) review of *Time and Modality* and in his subsequent controversy with Prior (*Philosophy* 34 [1959]). In his *Formal Logic* Prior displayed an impressively wide acquaintance with logical systems outside the field of tense logic, and this book remains a useful text for anyone interested in comparisons between different axiomatizations of the propositional calculus, between different kinds of logical quantification, between different modal logics, or between different three-valued or institutionist logics. But the treatment of metalogical issues in the book is

occasionally rather selective: for example, in its discussion of completeness proofs for the predicate calculus as against its treatment of completeness proofs for the propositional calculus.

Outside the brilliant originality of his work on tense logic, perhaps Prior's most striking idea was expressed in "The Runabout Inference-Ticket" (1960), where he argued that, if the meaning of a logical connective consisted just in the logical uses to which it can be put (as many seemed to hold), then it would be easy to invent a connective with a meaning that would enable one to infer any conclusion from any premises.

## PRIVATE LANGUAGE PROBLEM

The private language problem is essentially the question of whether or not a language as a system of symbols that

are means of thinking is, of necessity, a language as a system of symbols that are means of communication. Defining "private language" as language (in the sense of means of thinking) which in principle the speaker alone can understand (so that it cannot serve as a means of communication), our question is roughly equivalent to: "Is a private language possible?" Many philosophers, following Ludwig Wittgenstein, have made the claim (here called the private language thesis, abbreviated PLT) that private languages are impossible. Armed with it, they have argued against solipsism, phenomenism, the analogical or empirical view of one's knowledge of other minds, and against mind-body dualism. Some of them have gone on to argue for certain versions of philosophical behaviorism as well as for the view that the meaning of a word consists of its use or employment in a social practice and not in its referring to something or its designating a kind of entity.

Thus, the PLT has been a central principle in the cluster of Wittgensteinian doctrines. It is not clear, however, that exactly the same thesis figures in all the arguments in question, since the idea of a private language varies in different contexts. There is, therefore, a multiple problem: First, to differentiate the several propositions which pass as the PLT by clarifying the sense of "private language" being used; second, to determine which ones are true; and third, to explain why they are supposed to be intimately related. These problems differ from the question, debated around 1930, of whether or not it is possible to start with a private language about one's sensations or "raw" feelings and arrive at the intersubjective and communicable language of science. (On this question, see Rudolf Carnap, "Psychology in Physical Language," and J. R. Weinberg, *An Examination of Logical Positivism*.)

### THE SENSE OF "IMPOSSIBLE"

In all the interpretations of the PLT, the word *impossible* is understood in a strong sense that is not easy to characterize precisely. Some philosophers speak of "logical impossibility," but they do not necessarily mean that private languages are impossible in the sense that unbounded triangular figures are impossible. The expression "unbounded triangular figure" reduces to the formal self-contradiction "*unbounded figures bounded by three lines*" by means of a substitution allowed by the definition of "triangle." But few philosophers would suggest that there is a similarly ready definition of "language" by means of which we can produce a formal self-contradiction "private so-and-so which is not private." The impossibility at issue is like (1) the impossibility of unextended red things (that is, the impossibility that something be red and yet lack

width or length), or (2) the impossibility of a cube with fewer than eight edges. These do not lead straightforwardly to formal contradictions, since there are no definitions for all the terms involved; they depend on implication relations that constitute the concepts involved in their statement. In the last analysis, the persistent rejection of (1) and (2) evidences the failure to understand the meanings of all the words involved, that is, the lack of some of the relevant concepts. But (1) is unprovable and obvious, and (2) only needs a trivial argument, while the PLT (if true) requires careful reasoning. We shall speak of *conceptual impossibility* to refer to any formal self-contradiction, to any impossibility which entails a formal self-contradiction, and to any a priori impossibility such as that found in the above examples (1) and (2).

### THE PRIVATE LANGUAGE THESIS

The most important propositions often discussed as the PLT, each embodying a different idea of private language, are the following:

PLT\*: It is impossible for a man to use a word with a meaning that nobody else could, even in principle, understand.

PLT-1: It is impossible for a man to use words that refer to private objects, that is, objects that nobody else could—even in principle—know. (For subtheses arising out of the ambiguities of “know,” see H.-N. Castañeda, “The Private-Language Argument.”)

PLT-2: It is impossible for a man who has always lived in isolation to possess a language, even if his sounds are understandable by another person.

Here the expressions “could not in principle” and “impossible” are meant to express conceptual impossibility. PLT\* allows that a man may use words with meanings that nobody else in fact understands, provided that they are understandable to other people in the appropriate circumstances. PLT-1 allows that a man may refer to objects that, in fact, he alone knows, but again others must be capable of knowing them in the appropriate circumstances. PLT-2 allows that a man, like Robinson Crusoe, keeps possession of a language he learned previously while living in a community of speakers.

Many philosophers assume that it is conceptually impossible for two persons to share one and the same immediate sensation. Many also hold that, in a strict sense of “know,” others do not really know whether one has a certain immediate sensation or not, precisely because they cannot share it. On these assumptions, a language about one’s own immediate sensations would be

a language of the sort that PLT-1 claims to be impossible. Indeed, such a language is customarily regarded as the would-be prototype of private language.

In general, on the assumption that (direct) knowledge of the referent of a word is required for understanding the meaning of the word in question, PLT\* entails PLT-1. On this assumption, a language about one’s own immediate sensations is also private in the way that PLT\* claims to be impossible.

PLT-1 does not entail PLT\*. A word might have a meaning understandable to only one person because the word itself is a private object in the sense of PLT-1, even though everybody may be acquainted with the physical objects it refers to. For example, the words of a person’s language might all be mental images of German written words, so that all his thinking would be a sort of mental reading of German. In this case, the referents of the words would be public, but the words themselves would be private and hence unintelligible to others.

PLT-2 neither entails nor is entailed by PLT-1. If PLT-2 is true, then if on the previous assumptions about sensations, one’s language about one’s own sensations is private in the sense of PLT-1, then one could still, in principle, invent such a language. Conversely, the truth of PLT-1 does not by itself make it impossible for an isolated person to invent a language about physical objects. Similarly, PLT-2 neither entails nor is entailed by PLT\*.

APPLICATIONS OF PRIVATE LANGUAGE THESES. The important claims made with the help of the PLT do require other assumptions, which in their turn play roles, as we shall see, in the defense of the PLT itself. The most natural and pervasive of these assumptions is the following:

(A) In the sense of “thinking” in which one can both have a false (or true) thought and draw inferences from what one thinks, it is conceptually impossible to think without possessing a language that is a means of thinking.

From this assumption and PLT-2, one can conclude that the fact that one thinks, guarantees the existence of other persons, namely, one’s fellow speakers of the same language. Thus, the solipsist who merely asserted that it is possible that he alone exists at the time he is thinking would be contradicting himself (an argument of this sort can be constructed with premises suggested by Rush Rhees in “Can There Be a Private Language?”). Of course, many philosophers have serious objections to (A).

The existence of hallucinations, illusions, and visual perspective leads many philosophers to characterize every

case of perception in terms of our apprehension of sense data or immediate impressions. Some have proceeded to espouse a phenomenalist program of “logical reconstruction” of physical objects and minds as systems of sense data; others, however, have subscribed to some form of realism, that is, the complete irreducibility of physical objects and minds to sense data. But all of them have recently been criticized on the ground that the language of sense data is private in either the sense of PLT\* or the sense of PLT-1. Here, in addition to (A), the critics need the following assumption:

(B) If it is conceptually impossible that there be a language about entities of a sort *T*, then there are no entities of sort *T*.

Again, some philosophers would claim against (B) that if PLT\* or PLT-1 is true, then sense data or the given in experience are simply ineffable.

Many philosophers have subscribed to some form or other of a principle of verification, for example:

(C) It is conceptually impossible to understand a sentence without knowing what state of affairs would verify the statement made with it.

Assumption (C) leads to the view that language about states of consciousness is private, if we add to it and (A) and (B) the following principle:

(P) Only the person himself can verify conclusively and directly that he has certain experiences.

On this view, for instance, when someone else speaking about me says, “He is in pain,” he cannot understand or mean exactly the same thing that I understand and mean when, of myself, I say, “I am in pain.” But if PLT\* is accepted, one is involved in a contradiction. Here many philosophers have given up (P), and in order to guarantee that everybody else can know what somebody is feeling or thinking, some philosophers have espoused some form of behaviorism, that is, a view according to which every description of a person’s experiences or mental states is really shorthand for (synonymous with) a description of his bodily movements, his relations to other bodies, and his abilities to perform further movement. This is often supplemented with the supposition that first-person utterances like “I have a headache” do not make statements of direct knowledge but are, rather, learned responses, analogous to the natural responses of moaning, crying, and so on, which are said to constitute the person’s ache. As is to be expected, other philosophers have preferred to keep (P) and reject one or more of the other premises, in particular (C) or PLT\*. (See Castañeda,

op. cit., Part B, for a discussion of the privacy of experiences.)

THE MAIN ARGUMENTS FOR THE PLT. There are many arguments seeking to prove that being private makes it impossible for a language to have a property required for the existence of a language. Most of the arguments depend on the following assumption:

(D) A language is a system of rules, and to speak or write a language is to follow rules.

On this assumption, it suffices to establish the PLT to show that a man (say, Privatus) cannot be following rules when he is using a private language (to be called Privatish). This is, in fact, what a series of arguments suggested by Wittgenstein purports to do. The gist of the argument is as follows: A rule is, by its very nature, the sort of thing that can be misapplied (or disobeyed), but Privatus cannot misapply the rules of Privatish; hence, when speaking Privatish, Privatus is not following rules. The specific arguments are meant to support the crucial premise:

(1) Privatus cannot misapply the rules of Privatish.

A fair objection to (1) is that Privatus can certainly make slips; he may call something of kind *A* “*B*,” whatever “*A*” and “*B*” may mean in Privatish. Slips of the tongue are precisely ways in which one violates the rules (if there are such) of natural languages. For instance, if there are rules of English governing the application of color words to physical objects; whenever one commits a slip of the tongue and calls a red object “blue,” then one misapplies either a rule governing the use of “red” or one governing the use of “blue.”

This reply to (1) is often met by several rejoinders. The first claims both that a slip counts as a misapplication of a linguistic rule only if there is a way in which the speaker can in principle detect and correct his slip and that Privatus cannot detect or correct his slips. This rejoinder, however, changes the issue, since premise (1) says nothing about verifying the existence of a misapplication of a rule. Nevertheless, the rejoinder has a point, for if to use words is to apply rules, then one must at least sometimes be able both to know of one’s misapplications of the rules for the use of one’s words and to know how to make the appropriate corrections. The question of whether or not Privatish allows this is discussed below under premise (2).

The second rejoinder is that to obey a rule is a *custom* (use, institution), but Privatus’s actions cannot constitute a custom (see Ludwig Wittgenstein, *Philosophical Investi-*

gations, Sec. 199). This rejoinder would establish PLT-2 but not PLT\* or PLT-1. For it may be a custom in a tribe that people use words which they alone understand in the ways required by PLT\* or PLT-1. But as an argument for PLT-2 the rejoinder is by itself question-begging. It must be supported by an argument which shows that obeying a rule is indeed a custom.

The third rejoinder is that Privatus's slips do not count as violations of the rules of Privatish because we cannot be corrected or taught by others what is the correct thing to say (see Wittgenstein, *op. cit.*, Sec. 378, and Norman Malcolm, "Discussion of Wittgenstein's *Philosophical Investigations*," pp. 536f.). If the "cannot" here is taken to mean conceptual impossibility, the rejoinder does not apply to PLT-2. If it is taken in a weaker sense, that is, a sense in which a person may be in the position of being in fact corrected by other persons, then the rejoinder supports PLT-2, but it would not allow that there be just one language-user in the universe. Besides, it is not clear that it would allow that Antonia Udina, for example, used language when, as we normally say, he spoke Dalmatian as the last speaker of Dalmatian. Although a person who uses words must be capable of self-correction, it is not immediately obvious that a person's sounds cannot count as utterances of words if nobody else can (in some sense) correct him. The need for others' possible corrections has to be established by an argument. Thus, we are again thrown back to the other lines of reasoning.

The fourth rejoinder is that Privatus's slips do not count because another person, by noting Privatus's behavior and circumstances, cannot discover that his use of the word is correct or incorrect (adopting Malcolm, *op. cit.*, p. 537). This rejoinder also leaves PLT-2 unsupported if "cannot" is understood as expressing conceptual impossibility. While it must be conceptually possible for Privatus to know whether his uses of language are correct or incorrect, it is not at all clear that it must be possible for others to know this fact. The principle that it must be possible for others to know whether his uses of language are correct or incorrect requires an independent argument to support it. However, the present rejoinder has a point. It reminds us that if there is no way at all of telling, for any word of Privatish, whether or not Privatus used it correctly (however coherent the concept of a private language is), it would be a completely gratuitous hypothesis that Privatus spoke a private language. Although our topic here is only the conceptual possibility of private language, we should note that the claim that somebody's entire language is of the type described in PLT\* is cer-

tainly gratuitous. Yet the claim that someone has a mixed language, part of which is private in the sense of PLT\*, does not seem gratuitous.

The fifth rejoinder dismisses mere slips on the ground that they show at most a breakdown of a linguistic habit. The rejoinder asks us to consider the case of Privatus trying deliberately to apply a rule of Privatish and failing to comply with it. The rejoinder claims that, for Privatish, "thinking one was obeying a rule would be the same thing as obeying it," but "to *think* one is obeying a rule is not to obey a rule. Hence it is not possible to obey a rule 'privately'" (Wittgenstein, *op. cit.*, Sec. 202). This rejoinder does not require that every utterance of a word be a case of deliberately attempting to obey the corresponding linguistic rule(s). Conjoined with assumption (A), this view would lead to a vicious infinite regress. For then, in order to say something, one would have to be aware of the rules governing the words one intends to utter, and these rules in their turn would be formulated in some words the rules governing which one would have to be aware of through some other words, and so on ad infinitum. Therefore, to use language is, of necessity, to use most of the words from habit, not in intended obedience of the linguistic rules. The rejoinder cannot even demand that Privatus sometimes be aware of the rules of Privatish: A being might speak a language without ever rising to the level of formulating any of his rules. But if, by assumption (D), languages are made up of rules, then if it were conceptually impossible for Privatus to be at least sometimes aware of the rules of Privatish, Privatish would be a very defective language indeed, incapable of discharging the philosophical duties that private languages are alleged to discharge. Thus, the rejoinder is right in urging that

(a) For every rule  $R$  of a language  $L$  and every speaker  $S$  of  $L$ , it is conceptually possible that sometimes  $R$  applies to  $S$ 's situation while  $S$  thinks that he is obeying  $R$  without  $S$ 's actually obeying  $R$ .

Presumably, a rule of language is here of the form "If  $x$  is  $\phi$ , you may (must) call it '...,'" but the meaning of "call" is difficult. In one normal sense of "call," slips of the tongue are, again, ways in which (a) is true. Clearly, a person may think that he is calling a thing "red" in deliberate compliance with the English rule for "red," without realizing that he actually called it "blue" because he is deaf or because he simply did not hear what he said. In the same sense of "call," (a) can be true because the speaker deliberately calls a red thing "blue," if he thinks that the rule in question allows (or prescribes) his calling it "blue." In particular, suppose that the rule  $R$  allowing (or prescrib-

ing) that one call a thing “red” is the rule Gaskon typed yesterday and that today, confusedly, Gaskon thinks that the rule he typed yesterday allows (or prescribes) that a certain thing be called “blue,” and he calls the thing in question “blue,” thinking that he is complying with the rule. Here, in spite of his deliberately calling a certain thing “blue,” Gaskon’s use of “blue” and the rule he thinks he is complying with both satisfy (a). Both ways of satisfying (a) are open to Privatus. It might be argued that Privatus’s deliberately calling one of his private objects “A” instead of “B” has no point or “function” (see Wittgenstein, *op. cit.*, Sec. 260), since he is not talking to others. This is, however, false. Privatus may very well play word games involving miscallings of things. But more importantly, whether or not there is a point in Privatus’s flouting of the rules of Privatish has nothing to do with the issue about the possibility of private language.

The rejoinder often uses a stronger sense of “call.” In this sense, by a natural development of assumption (A), to *think* that something is, for example, red is to call it “red.” This stronger sense appears in an argument given in support of PLT-1. As said above, language about one’s own immediate sensations is often regarded as the paradigm of private language in the sense of PLT-1. Now, one knows incorrigibly that one’s sensations have immediately sensible qualities. That is to say, if one believes that one has a pain (itch, tickling, feeling of discomfort), then one knows that one has a pain (itch, tickling, feeling of discomfort). So it is impossible to have no pain while one thinks that one has a pain. Thus, if one thinks that one is obeying the rule of the form “If  $x$  is a pain, you may (must) call it ‘pain,’” one surely thinks that one is in pain and the rule cannot fail to apply. Similarly, since one also has incorrigible knowledge of the absence of one’s immediate sensations, if the objects that Privatus can think about in Privatish are only his immediate sensations, then when he thinks that a rule of Privatish does not apply, the rule does not, in fact, apply. But if “call” is taken in its normal sense, neither of these two features of the rules of Privatish implies that Privatus cannot think that he is obeying a rule (which then applies) without actually obeying it, since slips and deliberate miscallings are still available as violations of the rule. However, if “call” is taken in the strong sense (in which thinking can be calling), then if Privatus thinks that he is obeying a rule of the form “If  $x$  is  $A$ , you may (must) call it ‘A,’” he surely thinks that the rule applies, that is, he thinks that the object  $x$  is  $A$ ; if  $A$  is a sensible property of Privatus’s immediate sensation  $x$ , then  $x$  is  $A$ , and Privatus is both calling  $x$  “A” and unavoidably obeying the rule. Thus, if Privatish is a private language about Privatus’s immediate

sensations and their sensible properties, then (a) above and (b) below are both false:

(b) For every rule  $R$  of a language  $L$  and every speaker  $S$  of  $L$ , it is possible that sometimes  $S$  thinks that he is obeying  $R$  while he is not.

Since (a) is true, Privatish is not a private language.

This argument does not by itself support PLT-2; it may or may not support PLT\*, depending on how one interprets the phrase “knowing the meaning of a word.”

There is, however, a difficulty with the above argument. Consider the rule of English: “If  $x$  is a cat, you may (must) call  $x$  ‘cat’; that is, you may (must) think that  $x$  is a cat.” This rule differs from the above rule for the Privatish word “A” in that thinking that one is obeying the rule for “cat” does not imply that the rule for “cat” applies to the situation in question. For to think that one is obeying the latter rule implies that one thinks that it applies, and this implies that one thinks that some object  $x$  is a cat. But surely one can be mistaken about  $x$ ’s being a cat. Yet the rule for “cat” also fails to satisfy condition (a). Suppose that the rule applies; then the object  $x$  in question is a cat. And suppose that one thinks that one is obeying the rule; then it is true that one thinks that if  $x$  is a cat one may (must) think that  $x$  is a cat, and that one thinks that  $x$  is cat. Thus, one is in fact obeying the rule! Therefore, the strong sense of “call” included in the concept of language rule  $R$  makes (a) an impossible condition.

Now, in the case in which a rule  $R$  does not apply to a man’s situation, we are often reluctant to say that when such a man thinks that he is obeying  $R$ , he is not obeying  $R$ . But we could say this with no great distortion, and if we did, we could say that the above rule for the English word “cat” satisfies condition (b). For in a situation in which an object  $x$  is not a cat and the rule does not apply, we may very well both misperceive or otherwise think that  $x$  is a cat and think that, in accordance with the rule, we may (must) think that  $x$  is a cat. Thus, if we raise (b) as the crucial condition that linguistic rules must satisfy, then we can claim that PLT-1 is established in the sense that a pure language of sensations is impossible. But this answer is inconclusive. Besides the small amount of distortion involved, there is the fact that (b) is not a general condition of rules. This is shown by the following rule which a man might give to his son: “If you think that you need to delay your action, think that  $1 + 2 + 3 + \dots + 24 = 300$ .” Since to think that one thinks that  $p$  entails that one thinks that  $p$ , if the boy thinks that the rule applies, he thinks he needs to delay his action, and the rule applies. If he thinks that he is obeying the rule, he thinks

both that it applies and that  $1 + 2 + 3 + \dots + 24 = 300$ ; hence he thinks that  $1 + 2 + \dots + 24 = 300$ ; hence, the rule applies and he obeys it. Thus, to defend PLT-1 by means of (b) requires an independent argument showing that rules of language must, in any case, comply with (b), distorted as suggested.

Let us turn now to a subtler line of argument. Some defenders of the PLT do not argue for (1) but for

(2) Privatus cannot distinguish his correct uses of Privatish words from his incorrect uses.

Suppose, then, that Privatus is debating whether something is *A* or not. Suppose that Privatish is private in the sense of PLT-1. Here the defenders of the PLT adduce (a) that Privatus lacks a *criterion* of correctness, that is, “something *independent* of his impression” that he is correctly using the Privatish rule governing the use of “*A*” by means of which he can “prove his impression correct” (Malcolm, *op. cit.*, p. 532), and (b) that his impression that he remembers what objects of kind *A* appeared like before is of no help, since memory “is not the highest court of appeal” (Wittgenstein, Sec. 56) and the “process [of checking memories] has got to produce a memory which is actually *correct*” (Sec. 265). Now, these points exaggerate Privatus’s predicament. Privatus’s private objects may be related among themselves by entailment, by coexistence, by similarities, by causal relationships, and so on. Privatus can resort to any of these to test whether he is, on the present occasion, using the term “*A*” correctly. For instance, in Privatish, “being *A*” may be logically equivalent to “being *B* and becoming *C* in the presence of another *C*.” Indeed, Privatus may even employ paradigms. The very first object he calls “*A*” may very well be enduring, so that he can compare the next objects of kind *A* with it. The same applies to languages of the type mentioned in PLT-2. Furthermore, memory is the highest court of appeal when it comes to our knowledge of the past. True, we have records and other historical evidence, but all of this only provides inductive evidence, not a proof, and our inductions involve the acceptance of unchallenged memories.

Nevertheless, Privatus is not only in no position to question the correctness of all of his uses of words, but he also cannot *prove* that the uses he questions are correct unless he is allowed the ability to identify certain properties of objects without criteria and without challenging his memory. But exactly the same happens with the speakers of *any* language. In the case of terms like “red” and “straight,” for instance, there is nothing at all to which an English speaker *E* can resort in order to “prove” that he has correctly called an object red or straight. His

fellow speakers may all utter in unison, “Not red but blue.” Yet this choral utterance is not a proof; the speakers may be lying, may all be victims of a hallucination, or may just be rehearsing a new song—or the whole proceedings may be just *E*’s hallucination. In any case, for *E* to accept the correction, he must correctly identify the words expressing it without the use of criteria and remember correctly the meanings of these words. A vicious infinite regress would ensue if *E* were required to have a proof that he both remembers this correctly and identifies the objects the words apply to.

Moreover, there is nothing to prove each corrector’s use of words correct. Suppose, for example, that one corrector learned the meaning of “blue” with the help of object *O* and that he continuously stares at *O* during the preceding two minutes before correcting Privatus. He still must *remember* correctly that *O* has the same color it had two minutes before, that the color of *O* is called “blue,” that the name of the color sounds “b–l–u–e,” that the noise “red” uttered by *E* has the same meaning that makes red and blue incompatible, and so on. Thus, either somebody *just* identifies some words or objects correctly and remembers some qualities of objects and the meanings of some words correctly, or else nobody can be corrected by another speaker. In sum, demands (a) and (b) cannot be adduced against the possibility of a private language.

**LOGICAL WORDS.** Often it is claimed that a private language cannot have logical words or syntactical rules, both of which are necessary for the existence of logical relationships. Clearly, if a private language is allowed no implications or entailments, it would certainly be no language. But if “private language” is meant in the sense of PLT\* or PLT-1 or PLT-2, this contention appears to be false. Often this contention is defended on the ground that a really private language does not have words with meanings in common with the words of another language (Wittgenstein Sec. 261; Malcolm p. 537). Now, private language in this sense is impossible. A language is a system of words of which some refer to objects, some signify properties or relations, and some express logical connections; the words expressing logical connections must be capable of being understood by anybody else and must, therefore, be common to all languages. This is an important result. But it is not the same as PLT\*, which requires that every single word of a language must be understood by persons other than the speaker. Likewise, the impossibility of languages without logical words does not imply that a language cannot have some nonlogical words which refer to private objects, that is, it does not imply that PLT-1 is true. Again, that a language must have

logical words implies nothing about the possibility of a single man developing a language for and by himself, that is, does not imply that PLT-2 is true.

“THE SAME.” Apparently Wittgenstein knew that there are no criteria (in the sense of something independent) which prove that words have been used incorrectly. He also knew that the correctness of an application of a word is not determined by a rule whose formulation serves as a recipe or canon. His fundamental opposition to private language derives from his profound investigations into the nature of concepts and his strong inclination toward an extreme nominalism. This opposition is never crystallized in a definite argument, but its gist is, in crude form, as follows. Postulate:

(E) The similarities and samenesses we find in things do not exist *in rerum natura*, that is, do not exist in things as we find them, independently of our finding them or of our referring to them in the way we do; they “come from the language” (Rhees p. 80) and at bottom consist of the fact that we “call” the things in question the same (Wittgenstein Secs. 146, 149, 185–190, 208–223, 348–352).

On a rigorous interpretation of (E), we find a rationale for assumptions (A), (B), and (C), as well as for the fact that the PLT has a chameleon-like and pervasive character. If we take (E) literally, then to find a property in several things is to find that we “call” the things in question “the same” or refer to them with the same word. Thus, it is impossible to think that something is such-and-such without a language in which there is an expression (even if a very long phrase) which “constitutes” the such-and-such in question. This is assumption (A). Also, (B), without an expression “constituting” a type *T*, there is no type *T* for things to belong to. Similarly, to understand an expression is not to apprehend an independently existing (or subsisting) property but simply to know how and to what to apply it, and this includes knowing how to call certain utterances “true” in which the expression is correctly applied. This is, in fact, a generalization of assumption (C).

We cannot say that a man in doubt about whether or not he used a word correctly must simply identify certain features of things without criteria and, armed with these identifications, test his uses of words. For on the extreme interpretation of assumptions (A) through (E) to identify a feature is to “call” a thing something. So, when the use of a word is at issue, the identification and nature of the thing is precisely what is at issue. The referents of one’s previous uses of the word, as well as the uses themselves, are irrelevant. If one “calls” something “A,” then it is A

and *a fortiori* similar to the previous A’s; if one withholds the name “A” from it, then it is not an A, and a fortiori it is dissimilar to all A’s with respect to being an A. Clearly, it does not matter whether one’s language is about private or about public objects; one’s uses of words simply fail to be capable of being incorrect. They would seize reality so well that each “would have to be at once a statement and a definition” (Rhees p. 82).

Thus, the following question arises. If, on assumption (D), language is a matter of rules and rules are the sort of thing that can be misapplied or not, how, then, is language possible after all? At this stage, obviously, we are not interested in proving anything but are anxious to find an explanation. Wittgenstein seems to suggest one: A man’s uses of words can be incorrect only if they are compared with those of his fellow speakers. His “calling” something “A” is correct if his cospeakers now also call it “A.” Then it is A and a fortiori similar to the things he and his cospeakers previously called “A.” That is why obeying a rule of language is a practice (Wittgenstein, op. cit., Sec. 202). It is not necessary that the speakers of the language should call the thing in question “A” or that they call it “A” afterward. Nor is it necessary that they call it “A” or anything at all, or that they call it the same thing. It is just a contingent fact that they coincide in calling it “A.” But this coincidence (or agreement) is an empirical fact that is necessary for the existence of language.

Such is the underlying argument of Wittgenstein’s remarks (Secs. 146, 149, 185–190, 208–223; for a discussion of the role of Wittgenstein’s extreme nominalism in his views about necessary truth, see Michael Dummett’s “Wittgenstein’s Philosophy of Mathematics”). He builds a Heraclitean picture of language as something living only in our actual use of it and changing according to our needs. But is this a true picture of the connection between language and reality?

Here we cannot discuss the whole issue of nominalism, but to this writer it seems indefensible. We could doubtless have classified objects in entirely different ways from the ways we in fact do. For instance, we might have had no color words, no terms for species of plants or animals, and instead have used, say, “sha” for some elephants and white roses and reddish sand, and “sho” for female elephants, eggs, and rivers. But even so, we should have had to *find* features of similarity in the things so classified, and these features would have provided tests for the correct application of our words. At any rate, the view that things are the same because we “call” them “the same” or because we refer to them with the same words can get off the ground only by postulating our recogni-

tion of the samenesses of words, that is, the similarities of noises whose application to things constitutes the similarities of the latter. A serious infinite regress would ensue if we also hold that our words are similar only because we “call” them so.

The several propositions that are often debated as the claim that private languages are impossible can be linked to each other only under the assumption of extreme nominalism. None of the arguments given for the claim appear to be successful. There may be no conclusive way of either proving or refuting this claim. Perhaps the only course is to build detailed and rigorous philosophical views on each alternative and assess the adequacy of such views by their consequences. This topic continues to be widely discussed in the literature, and many philosophers adopt a position different from that advocated in the present article.

## Bibliography

### THE PROBLEM BEFORE WITTGENSTEIN

Carnap, Rudolf. “Psychology in Physical Language.” In *Logical Positivism*, edited by A. J. Ayer. Glencoe, IL: Free Press, 1959. Ch. 8. Translated by Frederic (there called George) Schick from the German version, which appeared in *Erkenntnis* 3 (1932–1933).

Weinberg, J. R. *An Examination of Logical Positivism*. New York and London, 1936. Ch. 11.

### WITTGENSTEIN’S VIEWS

Albritton, Rogers. “On Wittgenstein’s Use of the Term ‘Criterion.’” *Journal of Philosophy* 56 (1959): 845–857. An excellent collation and exegesis of the passages in which Wittgenstein discusses criteria; brings out certain internal tensions in Wittgenstein’s conception.

Dummett, Michael. “Wittgenstein’s Philosophy of Mathematics.” *Philosophical Review* 68 (1959): 324–348.

Malcolm, Norman. “Wittgenstein’s *Philosophical Investigations*.” *Philosophical Review* 63 (1954): 530–559. An extended review and discussion that presents Wittgenstein’s arguments against the PLT, with emphasis on the private language speaker’s lack of a criterion of correctness.

Rhees, Rush. “Can There Be a Private Language?” *PAS*, Supp., 28 (1954): 77–94. A symposium with A. J. Ayer containing an exposition of Wittgenstein’s views on private language understood mainly as PLT-2; conveys Wittgenstein’s nominalistic rationale very well, without discussing it as such.

Wittgenstein, Ludwig. *Philosophical Investigations*. German with facing translation by G. E. M. Anscombe. Oxford: Blackwell, 1953.

### THE PROBLEM AFTER WITTGENSTEIN

Ayer, A. J. “Can There Be a Private Language?” *PAS*, Supp., 28 (1954): 63–76. A symposium with Rush Rhees in which Ayer criticizes the PLT and emphasizes the need for criterionless identification at some point.

Carney, James. “Private Language.” *Mind* 64 (1960): 560–565. Favors the PLT.

Castañeda, Héctor-Neri. “Criteria, Analogy, and Knowledge of Other Minds.” *Journal of Philosophy* 59 (1962): 533–546. Discusses some problems of Malcolm’s views on criteria.

Castañeda, Héctor-Neri. “The Private-Language Argument.” In *Knowledge and Experience*, edited by C. D. Rollins. 1962 Oberlin Philosophy Colloquium. Pittsburgh: University of Pittsburgh Press, 1963. A symposium with V. C. Chappell and J. F. Thomson; surveys critically the arguments for the PLT and also replies to the other symposiasts.

Chappell, V. C. “Comments.” In *Knowledge and Experience*, edited by C. D. Rollins. Vigorously defends the PLT from criticisms raised by Castañeda’s discussion.

Garver, Newton. “Wittgenstein on Private Language.” *Philosophy and Phenomenological Research* 20 (1960): 389–396. Favors the PLT.

Hardin, Clyde L. “Wittgenstein on Private Language.” *Journal of Philosophy* 56 (1959): 517–528. Attacks the PLT.

Hervey, Helen. “The Private Language Problem.” *Philosophical Quarterly* 7 (1957): 63–79. Accepts PLT\* but claims that the real problem is whether or not one can recognize and classify one’s sensations apart from their outward expression.

Tanburn, N. P. “Private Languages Again.” *Mind* 72 (1963): 88–102. Attacks PLT-2 and the thesis that all entities referred to in conversation must be publicly available.

Thomson, J. F. “Comments.” In *Knowledge and Experience*, edited by C. D. Rollins. In his part of the symposium with Castañeda and Chappell, Thomson contends that the PLT is too unclear for decision.

Todd, W. “Private Languages.” *Philosophical Quarterly* 12 (1962): 206–217. Argues that “a private language, in the sense of a personal sensation language, is logically possible,” refutes certain arguments of Malcolm, and attempts to show that a private language need not lack criteria of correctness.

Wellman, Carl. “Wittgenstein and the Egocentric Predicament.” *Mind* 68 (1959): 223–233. Discusses critically some of Wittgenstein’s arguments for the PLT in connection with the view that all knowledge is based on private experiences.

Héctor-Neri Castañeda (1967)

## PRIVATE LANGUAGE PROBLEM [ADDENDUM]

Although the proper formulation and assessment of Ludwig Wittgenstein’s argument (or arguments) against the possibility of a private language continues to be disputed, the issue has lost none of its urgency. At stake is a broadly

Cartesian conception of experiences that is found today in much philosophy of mind.

### WHAT IS A PRIVATE LANGUAGE?

In §243 of *Philosophical Investigations* (1967; see also §256) Wittgenstein introduces the idea of a language in which “a person could write down or give vocal expression to his inner experiences—his feelings, moods, and the rest—for his private use. ... The individual words of this language are to refer to what can only be known to the person speaking; to his immediate private sensations. So another person cannot understand the language.” In subsequent sections (according to some commentators, up to as far as §315) Wittgenstein criticizes the possibility of such a “private language,” and this is where “the private language argument” is usually supposed to be located.

Following the main essay, suppose that Privatus speaks Privatish, a private language. §243 suggests that Privatish has two features:

- (1) Privatish contains a referring expression *n* that refers to one of Privatus’s “immediate private sensations” *s*.
- (2) *s* “can only be known to” Privatus.

According to Wittgenstein Privatish has a third feature, which he apparently thinks follows from (1) and (2):

- (3) *n* can only be understood by Privatus (and, hence, Privatish can only be completely understood by Privatus).

At this point three questions arise. First, what does (2) mean? Second, what sort of referring expression is *n*? Third, why is (3) supposed to follow from (1) and (2)?

By (2) Wittgenstein seems to mean that only Privatus can know whether he is having *s*. “The essential thing about private experience is ... that nobody knows whether other people also have *this* or something else” (§272, see also §246). Of course, this conception of sensations is held by Wittgenstein’s opponent (a defender of the possibility of a private language), not Wittgenstein himself.

As to the referring expression *n*, it is a name, not a description (e.g., “the private sensation caused by pin-pricks”) (see §§256–257). Not even Wittgenstein’s opponent would accept that to understand a description that in fact refers to sensation *s* one has to know that it refers to *s*.

Is *n* a proper name of a token sensation, or is it a common noun referring to a type of sensation? If *n* refers

to a token sensation, something occurring only in the mind of Privatus, then Wittgenstein’s opponent looks exactly like Bertrand Russell in “The Philosophy of Logical Atomism” (1918/1956; see also Candlish 2004). According to Russell, “[i]n order to understand a proposition in which the name of a particular occurs, you must already be acquainted with that particular” (1918/1956, p. 204; see also Russell 1912, chapter 5). Since, on Russell’s view, the only particular things with which one is acquainted are private items he calls *sense-data* (and, in addition, perhaps one’s self), no two people can be acquainted with the same particular, and so no two people can understand a genuine name (as Russell puts it, a name in the “logical sense”). Hence, Russell thinks, if Privatus’s name *n* refers to a token sensation, no one else can understand it.

However, it is clear that Wittgenstein takes the sensations in question to be types, not tokens (see, in particular, §258); accordingly, the name *n* is a common noun. But then Russell’s views about acquaintance and understanding play no role in the justification of (3), for Russell holds that two people can be acquainted with the same property (or type), including properties of private objects. Thus, if Privatus is acquainted with a certain type of sensation *s*, that is no barrier, on Russell’s view, to others also being acquainted with *s*.

So why does Wittgenstein think that (3) follows from (1) and (2)? His argument may be this: one cannot know that Privatus’s name *n* refers to *s*, so one cannot know what *n* means, and hence one cannot understand it. But it is not obvious that knowledge that *n* refers to *s* is necessary for understanding *n*, or for successful communication using it: perhaps all that is required is that one believes that Privatus’s name *n* refers to *s*. The upshot is that Wittgenstein’s double characterization of a private language as one “which describes my inner experiences and which only I myself can understand” (§256) is contentious. (This point is due to Edward Craig [1982]; for further discussion see Craig [1997].)

Given that the two characterizations of a private language should be separated, it is probably better to use the first, leaving the second as a disputed consequence. Thus, a private language may be explained as one containing names for types of inner experiences, with the further stipulation that, if there are any inner experiences, no one knows whether others have the same types of inner experiences as him- or herself.

§258

§258 contains the famous example of keeping “a diary about the recurrence of a certain sensation,” and most commentators identify it as the core of the private language argument. The key move in this section is to cast doubt on whether the diary keeper can “impress on [himself] the connexion between the sign [“S”] and the sensation,” and so “remember the connexion *right* in the future.” Anthony Kenny points out, against some commentators, that “remembering the connexion right” does not mean that one correctly applies “S” to one’s sensation, but that one remembers the meaning of S (1973, pp. 191–193).

Supposedly, there is no fact about the meaning of “S” for the diarist to remember because there is “no criterion of correctness.” Here, there is little consensus on what the missing criterion amounts to, or whether its absence does indeed show that the diarist fails to attach a meaning to “S.” For some representative examples of exegesis, see Malcolm Budd (1989, chapter 3), Stewart Candlish (1980, 2003), John V. Canfield (1991, 2001), Robert J. Fogelin (1987, chapter 12), P. M. S. Hacker (1986, chapter 9; 1990, 61–67); Colin McGinn (1997, chapter 4), David Pears (1988, chapters 13, 14, 15), Scott Soames (2003, chapter 2), and Crispin Wright (1986).

### KRIPKE’S WITTGENSTEIN

In *Wittgenstein on Rules and Private Language* (1982), Saul A. Kripke suggests (without unreservedly endorsing) a novel and exciting interpretation of the private language argument (see also Fogelin 1987, p. 241, n. 10). On this interpretation the main argument appears in the earlier long discussion of following a rule starting around §138. As Kripke observes, the conclusion of the private language argument is stated in §202, well before the argument’s traditional location, “Hence it is not possible to obey a rule ‘privately’: otherwise thinking one was obeying a rule would be the same thing as obeying it.” Kripke takes the sections following §243 to be a discussion of a purported counterexample—namely, sensation language—to the conclusion argued for earlier.

The argument Kripke extracts from Wittgenstein is in two parts. The first part purports to establish that there are no facts that make it the case that an individual (Jones, say) means something by a word (addition by “+,” say). This conclusion is reached by canvassing all the plausible candidates for such meaning-constituting facts and finding them all wanting. A *skeptical paradox* (“our paradox” of §201) looms, “no facts, no truth conditions, correspond to such statements such as “Jones means

addition by ‘+’” (1982, p. 77). The second part offers a skeptical solution: “skeptical” because the paradoxical conclusion is embraced; a “solution” because sentences such as “Jones means addition by ‘+’” remain assertible, despite the lack of any “corresponding fact.” And the account of why such sentences are assertible essentially involves a linguistic community, so that if Jones is “considered in isolation,” he cannot be said to mean anything by his words. This is the most general sense in which a “private language” is impossible: An individual considered in isolation from other speakers cannot be said to speak a language (see Kripke 1982, pp. 109–110).

Most commentators have not endorsed Kripke’s interpretation (in particular, see Baker and Hacker 1984, chapter 1; McGinn 1984, chapter 2). However, Kripke’s Wittgenstein has become a philosopher of considerable interest in his own right.

### THE COMMUNITY VIEW

Kripke’s book revived interest in the issue of whether the private language argument and related material on rule following is supposed to exclude a Robinson Crusoe isolated from birth from speaking a language (discussion of this topic goes back to Alfred J. Ayer [1954] and Rush Rhees [1954]; see also Kripke [1982, p. 110, n. 84]). While the characterization of a private language in §243 seems to leave room for such a Crusoe, other sections, notably §198, suggest the opposite. Norman Malcolm (1986, 1989) offers a defense of the “community view,” and is countered by G. P. Baker and Hacker (1990). The community view is rejected by most commentators; for further discussion and references, see Canfield (1996).

## PROBABILITY AND CHANCE

The weather report says that the chance of a hurricane arriving later today is 90 percent. Forewarned is forearmed: Expecting a hurricane, before leaving home I pack my hurricane lantern.

Probability enters into this scenario twice, first in the form of a physical probability, sometimes called a chance, quantifying certain aspects of the local weather that make a hurricane very likely, and second in the form of an epistemic probability capturing a certain attitude to the proposition that a hurricane will strike, in this case one of considerable confidence.

It is not immediately obvious that these two probabilities are two different kinds of thing, but a *prima facie* case can be made for their distinctness by observing that they can vary independently of one another: For example, if the meteorologists are mistaken, the chance of a hurricane may be very low though both they and I am confident that one is on its way.

Most philosophers now believe that the apparent distinctness is real. They are therefore also inclined to say that my belief that the physical probability of a hurricane is very high is distinct from my high epistemic probability for a hurricane. There must be some principle of inference that takes me from one to the other, a principle that dictates the epistemic impact of the physical probabilities—or at least, of my beliefs about the physical probabilities—telling me, in the usual cases, to expect what is physically probable and not what is physically improbable. One can call such a principle, mediating as it does between two different kinds of probability, a probability coordination principle.

The three principal topics of this entry will be, in the order considered, epistemic probability, physical probability, and probability coordination. Two preliminary sections will discuss the common mathematical basis of epistemic and physical probability and the classical notion of probability.

### THE MATHEMATICAL BASIS

What all probabilities, epistemic and physical, have in common is a certain mathematical structure. The most important elements of this structure are contained in the axioms of probability, which may be paraphrased as follows:

- (1) All probabilities are real numbers between zero and one inclusive (for any proposition  $a$ ,  $0 \leq P(a) \leq 1$ ).
- (2) The probability of an inconsistent proposition is zero; the probability of a logical truth, or tautology, is one.
- (3) The probability that either one or the other of two mutually exclusive propositions is true is equal to the sum of the probabilities of the individual propositions. (Two propositions are mutually exclusive if they cannot both be true; the *cannot* is interpreted as a matter of logical consistency, so that the axiom says that for any two propositions  $a$  and  $b$  such that  $a \vdash \neg b$ ,  $P(a \vee b) = P(a) + P(b)$ .)

The axioms as stated here assume that probabilities are attached to propositions, such as the proposition that “A hurricane will strike New York at some time on the afternoon of January 20, 2005.” The axioms may also be stated in a way that assumes that probabilities attach to events. It is more natural to attach epistemic probabilities to propositions and physical probabilities to events, but when the two kinds of probability are discussed side by side it is less confusing, and quite tolerable, to take propositions as the primary bearers of both kinds of probability. Nothing important is thought to turn on the choice.

The three axioms of probability, though simple, may be used to prove a wide range of interesting and strong mathematical theorems. Because all probabilities conform to the axioms, all probabilities conform to the theorems. It is possible, then, to do significant work on probability without presupposing either epistemic or physical probability as the subject matter, let alone some particular construal of either variety. Such work is for the most part the province of mathematicians.

Philosophical work on probability may also be mathematical, but is most often directed to one or the other variety of probability, usually attempting a philosophical analysis of probability statements made in a certain vein, for example, of probability claims made in quantum mechanics or evolutionary biology (both apparently claims about physical probability) or of probability claims made in statistical testing or decision theory (both apparently claims about epistemic probability).

Two important notions encountered in statements of the mathematical behavior of probability are conditional probability and probabilistic independence. Both are introduced into the mathematics of probability by way of definitions, not additional axioms, so neither adds anything to the content of the mathematics.

**CONDITIONAL PROBABILITY.** The probability of a proposition  $a$  conditional on another proposition  $b$ , written  $P(a|b)$ , is defined to be  $P(ab)/P(b)$ , where  $ab$  is the conjunction of  $a$  and  $b$ . (The conditional probability is undefined when the probability of  $b$  is zero.) For example, the probability of obtaining three heads on three successive tosses of a coin, conditional on the first toss yielding heads, is the probability of obtaining three heads in a row, namely one-eighth, divided by the probability of obtaining heads on the first coin, namely one-half—in other words, one-quarter.

Some writers suggest taking conditional probability as the basis for all of probability mathematics, a move that allows, among other things, the possibility of conditional probabilities that are well defined even when the probabilities of the propositions conditionalized on are zero (Hájek 2003). On this view, the mathematical posit stated above linking conditional and unconditional probabilities is reinterpreted as an additional axiom.

The act of conditionalization may be used to create an entirely new probability distribution. Given an old probability distribution  $P(\dot{s})$  and a proposition  $b$ , the function  $P(\dot{s}|b)$  is provably also, mathematically speaking, a probability distribution. If  $k$  is a proposition stating all of one’s background knowledge, for example, then a new probability distribution  $P(\dot{s}|k)$  can be formed by conditionalizing on this background knowledge, a distribution that gives, intuitively, the probabilities for everything once one’s background knowledge is taken into account. This fact is especially important in the context of epistemic probability.

**PROBABILISTIC INDEPENDENCE.** Two propositions  $a$  and  $b$  are probabilistically independent just in case  $P(ab) = P(a)P(b)$ . When the probability of  $b$  is nonzero, this is equivalent to  $P(a|b) = P(a)$ , or in intuitive terms, the claim that the truth or otherwise of  $b$  has no impact on the probability of  $a$ .

Several of the most important and powerful theorems in probability mathematics make independence assumptions. The theorem of most use to philosophers is the law of large numbers. The theorem says, very roughly, when a large, finite set of propositions are independent, but have the same probability  $p$ , then the proportion of propositions that turn out to be true will, with high probability, be approximately equal to  $p$ . (The generalization to countably infinite sets of propositions is easy if the propositions are ordered; substitute *limiting frequency* for *proportion*.)

For example, the propositions might all be of the form “Coin toss  $x$  will produce heads,” where the  $x$  stands for any one of a number of different tosses of the same coin. If the probability of each of the propositions is one-half, then the law of large numbers says, in effect, that provided the tosses are independent, it is very likely that about one-half will yield heads.

It is natural to interpret the probabilities in this example as physical probabilities, but the law of large numbers applies equally to any kind of probability, provided that independence holds. There are, in fact, many variants of the law of large numbers, but the details are beyond the scope of this entry.

### CLASSICAL PROBABILITY

The development of the mathematics, and then the philosophy, of probability was spurred to a perhaps surprising degree by an interest, both practical and theoretical, in the properties of simple gambling devices such as rolled dice, tossed coins, and shuffled cards. Though there was from the beginning a great enthusiasm for extending the dominion of the “empire of chance” to the ends of the earth, gambling devices were—and to some extent are still—the paradigmatic chance setups.

A striking feature of gambling devices is their probabilistic transparency: The discerning eye can “read off” their outcomes’ physical probabilities from various physical symmetries of the device itself, seeing in the bilateral symmetry of the tossed coin a probability of one-half each for heads and tails, or in the six-way symmetry of the die a probability of one-sixth that any particular face is uppermost at the end of a roll (Strevens 1998).

The classical definition of probability, paramount from the time of Gottfried Wilhelm Leibniz to the time of Pierre Simon de Laplace (the late seventeenth century to the early nineteenth century) takes its inspiration from the alignment of probability with symmetry. The best-known formulation of the classical account is due to Laplace:

The theory of chance consists in reducing all the events of the same kind to a certain number of cases equally possible, that is to say, to such as we may be equally undecided about in regard to their existence, and in determining the number of cases favorable to the event whose probability is sought. The ratio of this number to that of all the cases possible is the measure of this probability, which is thus simply a fraction whose numerator is the number of favorable cases and

whose denominator is the number of all the cases possible. (1902, pp. 6–7)

As many commentators note, this formulation, typical of the classical probabilists, appears to involve two parallel definitions, the first based on the notion of equal possibility and the second on the notion of equal undecidedness. Laplace’s relation of equal possibility between two cases probably ought to be understood as picking out a certain physical symmetry in virtue of which the cases have equal physical probabilities. All classical probabilities, on the equal possibility definition, have their basis in such physical symmetries, and so would seem to be physical probabilities. The relation of equal undecidedness between two cases refers to some sort of epistemic symmetry, though perhaps one founded in the physical facts. A probability with its basis in undecidedness would seem to be, by its very nature, an epistemic probability. Classical probability, then, is at the same time a kind of physical probability and a kind of epistemic probability.

This dual nature, historians argue, is intentional (Hacking 1975, Daston 1988). In its epistemic guise classical probability can be called on to do work not normally thought to lie within the province of an objective notion of probability, such as measuring the reliability of testimony, the strength of evidence for a scientific hypothesis, or participating in decision-theoretic arguments such as Blaise Pascal’s famous wager on the existence of God. In its physical guise classical probability is able to cloak itself in the aura of unrevisability and reality that attaches to the gambling probabilities such as the one-half probability of heads.

The classical definition could not last. Gradually, it came to be acknowledged that although the epistemic probabilities may, or at least ought to, shadow the physical probabilities wherever the latter are found, they play a number of roles in which there is no physical probability, nor anything with the same objective status as a physical probability to mimic. The classical definition was split into its two natural parts, and distinct notions of physical and epistemic probability were allowed to find their separate ways in the world.

At first, in the middle and late nineteenth century, physical probability commanded attention almost to the exclusion of its epistemic counterpart. Developments in social science, due to Adolphe Quetelet (1796–1874), in statistical physics, due to James Clerk Maxwell and Ludwig Boltzmann, and eventually (around 1930) in the synthesis of evolutionary biology and genetics, due to Ronald Aylmer Fisher and many others, turned on the successful deployment of physical probability distributions. Begin-

ning in the early twentieth century, however, epistemic probability came into its own, freeing itself over the decades from what came to be seen as the classical probabilists' futile attempt to provide strict guidelines dictating unique rational epistemic probabilities in every situation.

Modern philosophy remade itself in the twentieth century, imposing a historical horizon at around 1900. The story of the interpretation of probability is often told beginning near that year, with the result that the development of epistemic probability, and logical probability in particular, comes first—a convention that will be followed here.

### EPISTEMIC PROBABILITY

Epistemic probability takes two forms. In its first form, it is a measure of a person's degree of confidence in a proposition, increasing from zero to one as his or her attitude goes from almost total disbelief to near certainty. This kind of epistemic probability is called credence, degree of belief, or subjective probability. The propositional attitude one gets when one attaches a subjective probability to a proposition is sometimes called a partial belief.

In its second form, associated most often with the term *logical probability*, epistemic probability measures the impact of a piece or pieces of evidence on a proposition. Its elemental form may not be that of a probability distribution, in the usual sense, but it is related to a probability distribution in some straightforward way, and as will be seen shortly, is quite capable of providing a basis for a complete system of epistemic probability.

There is a foundational dispute between the proponents of the two forms of epistemic probability. It is not a fight for existence but for primacy: The question is which of the two kinds of epistemic probability is the more epistemologically basic.

**LOGICAL PROBABILITY.** The second form of epistemic probability has, since 1900, most often taken the guise of logical probability. A logical probability is attached not to a proposition but to a complete inductive inference. It is a measure of the degree to which the evidence contained in the premises of an inductive inference, considered in isolation, probabilifies the conclusion. The idea of probabilistic inference was an important part of classical probability theory, but from the post-1900 perspective it is associated first with John Maynard Keynes (1921)—who was more famous, of course, as an economist.

In explaining the nature of logical probability, and in particular the tag *logical* itself, Keynes draws a close analogy with deductive inference: Whereas in a deductive inference the premises entail the conclusion, in an inductive inference they partially entail the conclusion, the degree of entailment being represented by a number between zero and one, namely, a logical probability. (Note that a degree zero entailment of a proposition is equivalent to full entailment of the proposition's negation.) Just as the first form of epistemic probability generalizes from belief to partial belief, then, the second form generalizes, in Keynes's hands, from entailment to partial entailment.

For example: Take as a conclusion the proposition that the next observed raven will be black. A proposition stating that a single raven has been observed to be black might entail this conclusion only to a relatively small degree, this logical probability representing the slightness of a single raven's color as evidence for the color of any other raven. A proposition stating that many hundreds of ravens have been observed to be black will entail the conclusion to some much greater degree.

It is an objective matter of fact whether one proposition deductively entails another; so, Keynes conjectured, it is in many cases a matter of objective fact to what degree one proposition partially entails another. These facts themselves comprise inductive logic; the logical probabilities are at base, then, logical entities, just as the name suggests.

Although exact logical probabilities are for Keynes the ideal, he allows that in many cases logic will fix only an approximate degree of entailment for an inductive inference. The presentation in this entry will for simplicity's sake focus on the ideal case.

Keynes's logical probability is not only compatible with subjective probability, the other form of epistemic probability; it also mandates certain values for a person's subjective probabilities. If the premises in an inductive inference are known for certain, and they exhaust the available evidence, then their inductive impact on the conclusion—the degree of entailment, or logical probability attached to the inference, from the premises to the conclusion—is itself the degree of belief, that is, the subjective probability, that a rational person ought to attach to the conclusion, reflecting as it does all and only the evidence for the conclusion.

Keynes uses this argument as a basis for taking as a formal representation of logical probabilities the probability calculus itself: The degree to which proposition *b* entails proposition *a* is written as a conditional probabil-

ity  $P(a|b)$ . Note that these probabilities do not change as the evidence comes in, any more than facts about deductive entailment can change as the evidence comes in. The logical probability  $P(a|b)$  must be interpreted as a quantification of the inductive bearing of  $b$  alone on  $a$ , not of  $b$  together with some body of accepted knowledge.

The unconditional probability  $P(a)$ , then, is the inductive bearing on  $a$  of an empty set of evidence—the degree to which  $a$  is entailed, in Keynes's sense, by the set of logical truths, or tautologies, alone. One might think that the degree of entailment is zero. But this cannot be right: If one has no evidence at all, one must set one's subjective probabilities for both  $a$  and its negation equal to their respective degrees of entailment by the tautologies. But one cannot set both subjective probabilities to zero—it cannot be that one is certain that neither  $a$  nor its negation is true, since one of the two must be true. One's complete lack of evidence would be better represented by setting both subjective probabilities to intermediate values, say one-half. The logical probabilist, in endorsing this assignment, implicitly asserts that the empty set of evidence, or the set of tautologies, entails both  $a$  and its negation to degree one-half.

Although its subject matter is the bearing of evidence on hypotheses, then, logical probability theory finds itself having to take a position on what one should believe when one has no evidence (under the guise of the question of the tautologies' partial entailments). To answer this question, it has turned to the principle of indifference, which recommends—when there is no evidence favoring one of several mutually exclusive possibilities over the others—that the available probability be equally distributed among them. This is, of course, the same principle that comprises one strand of the classical definition of probability: Laplace suggested assigning equal probabilities to cases “such as we may be equally undecided about in regard to their existence” (Laplace 1902, p. 6). It has also played an important role in the development of the theory of subjective probability, and so is discussed in a separate section later in this entry.

As the role of indifference shows, logical probability is close in spirit to the epistemic strand of classical probability. It posits, at least as an ideal, a single system of right reasoning, allowing no inductive latitude whatsoever, to which all rational beings ought to conform. Insofar as rational beings ever disagree on questions of evidential impact, it must be because they differ on the nature of the evidence itself.

Many philosophers find this ideal of inductive logic hard to swallow; even those sympathetic to the idea of

strong objective constraints on inductive reasoning are often skeptical that the constraints take the form of logical truths, or something analogous to logical truths. This skepticism has two sources.

First is the perception that inductive practices vary widely. Whereas there exists a widespread consensus as to which propositions deductively entail which other propositions, there is no such consensus on degrees of evidential support. That is not to say, of course, that there is disagreement about every aspect of inductive reasoning, but there is far less agreement than would be necessary to build, in the same way that deductive logic was constructed, a useful inductive logic.

Second, there are compelling (though not irresistible) reasons to believe that it is impossible to formulate a principle of indifference that is both consistent and strong enough to do the work asked of it by logical probabilists. These reasons are sketched in the discussion of the principle later on.

Rudolf Carnap (1950) attempted to revive the idea of a system of induction founded on logic alone in the mid-century. His innovation—drawing on his general philosophy of logic—was to allow that there are many systems of inductive logic that are, from a purely logical viewpoint, on a par. One may freely choose from these a logic, that is, a set of logical probabilities, that suits one's particular nonlogical ends.

Carnap relativized induction in two ways. First, his version of the principle of indifference was indexed to a choice of language; how one distributes probability among rival possibilities concerning which one knows nothing depends on one's canonical system for representing the possibilities. Second, even when a canonical language is chosen, Carnap's rule for determining inductive support—that this, degrees of entailment or logical probabilities—contains a parameter whose value may be chosen freely. The parameter determines, roughly, how quickly one learns from the evidence. Choose one extreme, and from the observation of a single black raven one will infer with certainty that the next raven will also be black (straight induction). Choose the other extreme, and no number of black ravens is great enough to count as any evidence at all for the blackness of the next raven. A sensible choice would seem to lie somewhere in the middle, but on Carnap's view, logic alone determined no preference ranking whatsoever among the different choices, rating all values apart from the extremes as equally good.

Carnap did give extralogical arguments for preferring a particular value for the parameter, arriving at an inductive rule equivalent to Laplace's rule of succession. Given that, say,  $i$  out of  $n$  observed ravens have been black, both Carnap and Laplace assign a probability of  $(i + 1)/(n + 2)$  to the proposition that the next raven will be black.

One awkward feature of Carnap's system is that, no matter what value is chosen for the inductive parameter, universal generalizations cannot be learned: The inductive bearing of any number of black ravens on the hypothesis "All ravens are black" is zero.

Carnap's system is of great intrinsic interest, but from the time of its presentation, its principal constituency—philosophers of science—was beginning to move in an entirely different direction. Such considerations as Nelson Goodman's new riddle of induction and arguments by Bayesians and others that background knowledge played a part in determining degrees of inductive support, though not beyond the reach of Carnap's approach, strongly suggested that the nature of inductive support could not be purely logical.

Today, the logical approach to inductive inference has been supplanted to a great extent by (though not only by) the Bayesian approach. Still, in Bayesianism itself some have seen the seeds of a new inductive logic.

**SUBJECTIVE PROBABILITY.** Whereas logical probability is a logical entity—a quantification of the supposed logical facts about partial entailment—the other kind of epistemic probability, subjective probability, is a psychological entity, reflecting an actual cognitive fact about a particular person or (if they are sufficiently agreed) a group of people. The rationality of a person's subjective probabilities may be a matter of logic, then, but the probabilities themselves are a matter of psychology.

That for a number of propositions one tends to have a degree of confidence intermediate between the extremes associated with total disbelief and total belief, no one will deny. The advocates of subjective probability as a key epistemological notion—who call themselves Bayesians or simply subjectivists—go much further than this. They characteristically hold that humans have, or ought to have, well-defined subjective probabilities for every proposition and that these subjective probabilities play a central role in epistemology, both in inductive inference, by way of Thomas Bayes's (1702–1761) conditionalization rule, and in practical deliberation, by way of the usual mechanisms of decision theory.

The subjectivist's first challenge is to give a substantial characterization of subjective probability and to argue that subjective probabilities are instrumental in human cognition, while at the same time finding a foothold in the descriptive, psychological scheme for the normative concerns of epistemology. Much of this groundwork was laid in Frank Plumpton Ramsey's influential paper "Truth and Probability" (1931).

Ramsey does not define subjective probability as such, and even goes so far as to acknowledge that the ideal of a definite subjective probability for every proposition is just that—an ideal that goes a long way toward capturing actual human epistemology without being accurate in every respect. What he posits instead is a connection—whether conceptual or empirical he does not say—between the value of a person's subjective probability for a proposition and his or her betting behavior.

If one has a subjective probability  $p$  for a proposition  $a$ , Ramsey claims, one will be prepared to accept odds of up to  $p$ :  $(1 - p)$  on the truth of  $a$ . That is, given a game in which one stands to win  $\$n$  if  $a$  is true, one will pay up to  $\$pn$  to play the game; equivalently, if one will pay up to  $\$m$  to play a game in which one stands to win  $\$n$  if  $a$  is true, one's subjective probability for  $a$  must be  $m/n$ . (Decision theorists, note, talk about utility, not dollars.)

Importantly, all human choice under uncertainty is interpreted as a kind of betting. For example, suppose I have to decide whether to wear a seat belt on a long drive. I am in effect betting on whether I will be involved in an auto accident along the way. If the cost of wearing a belt, in discomfort, inconvenience, and forsaken cool, is equivalent to losing  $\$m$ , and the cost of being beltless in an accident, in pain, suffering, and higher insurance premiums, is  $\$n$ , then I will accept the risk of going beltless just in case my subjective probability for there being an accident is less than or equal to  $m/n$ . (Here, the "prize" is negative. The cost of playing is also negative, so just by agreeing to play the game, I gain something: the increase in comfort, cool, and so on. My aim is to play while avoiding a win.) The central doctrine of decision theory is, then, built into the characterization of subjective probability.

Ramsey (1931) uses this fact to argue that, provided a person's behavior is coherent enough to be described, at least approximately, by the machinery of decision theory, his or her subjective probabilities for any proposition may be inferred from his or her choices. In effect, the person's subjective probabilities are inferred from the nature of the bets, in the broadest sense, he or she is prepared to accept. Because one's overt behavior can be systematized,

approximately, using a decision-theoretic framework, one must have subjective probabilities for every proposition, and these probabilities must play a central role in one's decision theory.

What is the force of the *must* in the preceding sentence? That depends on the nature of the posit that one having a certain subjective probability for a proposition means that one is prepared to accept certain odds on the proposition's being true. Some writers, especially in the midcentury heyday of conceptual analysis and psychological behaviorism, interpret the posit as a definition of subjective probability; on this view, one having certain subjective probabilities just is one having a certain betting behavior. Others, like Ramsey (1931), opt for a looser connection. On any approach, there is a certain amount of latitude in the phrase "prepared to accept." If I am prepared to accept certain odds, *must* I play a game in which I am offered those odds? Or only if I am in a betting mood? The former answer vastly simplifies the subjectivist enterprise, but at a cost in psychological plausibility: It is surely true that people frequently gamble in the broad sense that they take measured risks, but it is not nearly so obvious that they are compulsive gamblers intent on taking on every favorable risk they can find. Work on the psychology of decision making also suggests that it is a mistake to found the subjectivist enterprise on too strong a conception of the connection between subjective probability and betting behavior.

Subjective probabilities are supposed to conform, as the name suggests, to the axioms of probability theory. In a theory such as Ramsey's (1931), a certain amount of probability mathematics is built into the technique for extracting the subjective probabilities; that humans not only have subjective probabilities, but arrange them in accord with the axioms, is a condition for the success of Ramsey's (1931) project.

Insofar as subjective probability is not simply defined as whatever comes out of the Ramsey project, however, there is a question whether subjective probabilities obey the axioms. If they do not, there is little that they are good for, so the question is an important one for subjectivists, who tend to follow Ramsey in giving a normative rather than a descriptive answer: It is rational to arrange one's subjective probabilities in accordance with the axioms. (It is not unreasonable, of course, to see this normative claim, if true, as evidence for the corresponding descriptive claim, since humans are in certain respects reliably rational.)

The vehicle of Ramsey's argument is what is called the Dutch book theorem: It can be shown that, if one's

subjective probabilities violate the axioms, then one will be prepared to accept certain sets of bets (which bets depends on the nature of the violation) that will cause one a sure loss, in the sense that one will lose whether the propositions that are the subjects of the bets turn out to be true or false.

The details of the argument are beyond the scope of this entry (for a more advanced introduction, see Howson and Urbach 1993), but an example will illustrate the strategy. The axioms of the probability calculus require that the probability of a proposition and that of its negation sum to one. Suppose one violates this axiom by assigning a probability of 0.8 both to a certain proposition  $a$  and to its negation. Then one is prepared to accept odds of 4:1 on both  $a$  and  $\neg a$ , which means a commitment to playing, at the same time, two games, in one of which one pays \$8 and wins \$10 (i.e., one's original \$8 plus a \$2 profit) if  $a$  is true, and in one of which one pays \$8 and wins \$10 if  $a$  is false. Whether  $a$  is true or false, one pays \$16 but wins only \$10—a certain loss. To play such a game is irrational; thus, one should conform one's subjective probabilities to the probability calculus. Needless to say, the Dutch book argument works best on the dubious interpretation of "prepared to accept" as equivalent to "compelled to accept"; there have been many attempts to reform or replace the argument with something that makes weaker, or even no, assumptions about betting behavior.

Subjectivism has been developed in several important directions. First are various weakenings or generalizations of the subjectivist machinery. The question of the connection between subjective probability and betting behavior is, as noted, one locus of activity. Another attempts to generalize the notion of a subjective probability to a subjective probability interval, the idea being that where one does not have an exact subjective probability for a proposition, one may have an approximate level of confidence that can be captured by a mathematical interval, the equivalent of saying that one's subjective probability is indeterminately somewhere between two determinate values.

Second, and closely related, is all the work that has been put into developing decision theory over the last 100 years (e.g., see Jeffrey 1983). Finally, subjectivism provides the foundation for the Bayesian theory of inference. At the root of the Bayesian system is a thought much like the logical probabilist's doctrine that, if  $k$  is one's background knowledge, then one's subjective probability for a hypothesis  $a$  ought to be  $P(a|k)$ . Whereas for a logical probabilist a conditional probability  $P(a|b)$  is a timeless

logical constant, for a subjectivist it is something that constantly changes as further evidence comes in (even holding  $a$  and  $b$  fixed). For this reason, the subjectivist theory of inference must be an inherently dynamic theory; what is perhaps its best-known weakness, the “problem of old evidence,” arises from this fact.

Subjectivism had almost entirely eclipsed logical probabilism by the late twentieth century; as the celestial metaphor unwittingly implies, however, there is a cyclic aspect to philosophical history: An interest in the central notion of logical probability theory, evidential weight, is on the rise.

There are three strands to this new movement. First is the perception among philosophers of science that scientific discourse about evidence is almost never about the subjective probability scientists should have for a hypothesis, and almost always about the degree of support that the evidence lends to the hypothesis. Second is the development of new and safer (though limited) versions of the principle of indifference. Third is technical progress on the project of extracting from the principles of Bayesian inductive inference a measure of weight. Note that this third project conceives of inductive weight as something derived from the more basic Bayesian principles governing the dynamics of subjective probability, a view opposed to the logical probabilists’ derivation of rational subjective probabilities from the (by their lights) more basic logical principles governing the nature of inductive support.

**INDIFFERENCE.** The principle of indifference distributes probability among various alternatives—in the usual case, mutually exclusive and exhaustive propositions—concerning which little or nothing is known. The principle’s rationale is that certain probability distributions reflect ignorance better than others. If I know nothing that distinguishes two mutually exclusive possibilities, picked out by propositions  $a$  and  $b$ , then I have no reason to expect one more than the other: I should assign the propositions equal probabilities. Any asymmetric assignment, say assigning twice the probability to  $a$  that I assign to  $b$ , would reflect some access on my part to facts supporting  $a$  at the expense of  $b$ . Thus, ignorance and probabilistic symmetry ought to go hand in hand—or so the principle of indifference would have it.

The principle is an essential part of logical probability theory, for the reasons given earlier, but there have always been subjectivists who appeal to the principle as well. It is most useful within the Bayesian approach to inductive inference.

The epistemic strand of classical probability theory also invokes the principle, of course, blending it with the discernment of “equally possible cases” in the paradigmatic gambling setups. This conflation has confused the discussion of the principle ever since, with proponents of the principle continuing to take aid and comfort in the principle’s apparent virtuoso handling of cases such as the one-half probability of heads. One’s reasoning about the gambling probabilities, however, as the classical probabilists for the most part themselves dimly saw, is a matter of inferring physical probabilities from physical symmetries, not of setting epistemic probabilities to reflect symmetric degrees of ignorance (Strevens 1998).

The most famous arguments against the principle of indifference were developed in the nineteenth century, which was a time of hegemony for physical over epistemic probability. They take their name from Joseph Bertrand (1822–1900), who pointed to the difficulty of finding a unique symmetry in certain indifference-style problems.

Consider, for example, two leading theories of dark matter in the universe: the MACHO and the WIMP theories. Each posits a certain generic form for dark matter objects, respectively large and small. If one has no evidence to distinguish them, it seems that the principle of indifference directs one to assign each a probability of one-half (assuming for the sake of the argument that there are no other possibilities). But suppose that there are four distinct schools of thought among the MACHO theorists, corresponding to four distinct ways that MACHOs might be physically realized, and eight such schools of thought among WIMP theorists. Now there are twelve possibilities, and once probability is distributed equally among them, the generic MACHO theory will have a probability of one-third and the WIMP theory a probability of two-thirds. Cases such as this make the principle seem capricious, if not simply inconsistent (as it would be if it failed to pick out a privileged symmetry).

Matters become far worse, as Bertrand noted, when there are uncountably many alternatives to choose among, as is the case in science when the value of a physical parameter, such as the cosmological constant, is unknown. Even in the simplest of such cases, the principle equivocates (Van Fraassen 1989, chapter 12). As noted earlier, some progress has been made in solving these problems, with Edwin T. Jaynes (1983) being a ringleader. Most philosophers, though, doubt that there will ever be a workable principle of indifference suited to the needs of general inductive inference.

## PHYSICAL PROBABILITY

The paradigms of physical probability are the probabilities attached to gambling setups; there are, however, many more interesting examples: the probabilities of quantum mechanics and kinetic theory in physics, the probabilities of population genetics in evolutionary theory, actuarial probabilities such as the chance of dying before reaching a certain age, and the probabilities in many social science models. It is by no means clear that there is a single phenomenon to be explained here; the physical probabilities ascribed to phenomena by the best scientific theories may differ in their makeup from theory to theory. There is a commonality in the phenomena themselves, however: Whenever the notion of physical probability is put to scientific work, it is to predict or explain what might be called probabilistic patterns of outcomes. These patterns are characterized by a certain kind of long-run order, discernible only over a number of different outcomes, and a certain kind of short-term disorder, the details of the order and disorder depending on the variety of probability distribution.

The simplest and best-known of the patterns is the Bernoulli pattern, which takes its name from the corresponding probability distribution. This is the pattern typical of the outcomes produced by gambling devices, such as the pattern of heads and tails obtained by tossing a coin. The long-term order takes the form of a stable frequency equal to the corresponding probability. In the case of the tossed coin, this is of course the one-half frequency with which heads and tails occur (almost always) in the long run. The short-term disorder, though an objective property of the pattern itself, is perhaps best gotten at epistemically: Once one knows that the long-run frequency of heads is one-half, the outcome of one toss provides no useful information about the outcome of the next. The law of large numbers implies that a chance setup will produce its characteristic probabilistic patterns in the long run with very a high (physical) probability. When discussing physical probability, it is more natural to talk of probabilities attaching to events than to propositions; what follows will be formulated accordingly.

**THE FREQUENCY THEORY** The frequentist theory of physical probability has its roots in the empiricist interpretation of law statements according to which they assert only the existence of certain regularities in nature (on the regularity theory, see Armstrong 1983). What is usually called the actual frequency theory of probability understands physical probability statements, such as the claim that the probability of a coin toss's yielding heads is

one-half, as asserting in a like spirit the existence of the appropriate probabilistic patterns—in the case of the coin toss, for example, a pattern of heads and tails in the actual outcomes of coin tosses exemplifying both the order and the disorder characteristic of the Bernoulli patterns.

The characteristic order in a Bernoulli pattern is a long-run frequency approximately equal to the relevant probability; in the case of the coin, then, it is a long-run frequency for heads of one-half. It is from this aspect of the pattern that frequentism takes its name. (One complication: A distinction must be made between the case in which the set of events exemplifying the pattern is finite and the case in which it is countably infinite. In a finite case, what matters is the proportion or relative frequency, whereas in the infinite case, it is instead the limiting frequency, that is, the value of the relative frequency in the limit, if it exists, as it must for the Bernoulli pattern to exist.)

Although their account is named for frequencies, most frequentists insist also on the presence of appropriate short-term disorder in the patterns. It is less easy to characterize this disorder in the purely extensional terms implicit in a commitment to regularity metaphysics. Suffice it to say that there is a broad range of characterizations, some strict, some rather lax. Among frequentists, Richard von Mises (1957) tends to a strict and Hans Reichenbach (1949) to a lax requirement (though Reichenbach holds, characteristically, that there is no uniquely correct level of strictness; for a discussion of the technical problems in constructing such a requirement, see Fine [1973]).

The probability that a particular coin toss lands heads is one-half, according to frequentism, because the outcome of the toss belongs to a series that exemplifies the Bernoulli pattern with a frequency of one-half. The truth-maker for the probability claim is a fact, then, about a class of outcomes, not just about the particular outcome to which the probability is nominally attached. But which class? If one is tossing an American quarter, does the class include all American quarters? All American and Canadian quarters? All fair coins? Or—ominously—all coin tosses producing heads? To give an answer to this question is to solve what has become known as the problem of the reference class.

The standard frequentist solution to the problem is to understand probability claims as including a (perhaps implicit) specification of the class. All physical probability claims are, in other words, made relative to a reference class. This doctrine reveals that the frequency theory is

best seen as an account, in the first instance, of statements of statistical laws. A claim about the one-half probability of heads, for example, is on the frequency interpretation in essence a statement of a probabilistic law concerning a class of coin tosses, not a claim about a property of a particular toss.

The kinship between the regularity account of deterministic laws and the frequency account of probability is, then, even closer than it first appears. Note that the regularity account has its own analog of singular probability claims, namely, singular claims about deterministic tendencies, such as a particular brick's tendency to fall to earth when released. Regularity theorists interpret a tendency claim not as picking out an intrinsic property of the object possessing the tendency, but as a veiled law statement.

The case of probability introduces a complication, however, that is not present in the case of exceptionless regularities: A particular coin toss will belong to many reference classes, some with different frequencies for heads. There may be, then, no determinate fact of the matter about an individual coin toss's probabilistic tendency to produce heads, or equivalently, about what are often called single case probabilities. Frequentists have made their peace with this consequence of their view.

Opponents of the frequency view argue that single-case probabilities are metaphysically, inductively, and explanatorily indispensable. Are they right? Here is the case for metaphysical indispensability: Some writers, especially propensity theorists, hold that there is clearly a fact of the matter about the value of the probability that some particular coin toss lands heads, independent of any choice of reference class. Frequentists may simply deny the intuition or may try explain away the appearance of a single-case fact (for related versions of the explanation, see Reichenbach 1949, §68; Strevens 2003, pp. 61–62).

And here is the case for predictive indispensability: To settle, for predictive and decision-theoretic purposes, on a rational subjective probability for an event using the probability coordination principle, a corresponding physical probability must be found (see the discussion of probability coordination later on). The corresponding probability is often understood to be the physical probability of that very event, hence, a single-case probability. Frequentists must find an alternative understanding. Reichenbach proposes using the frequentist probability relative to the narrowest reference class “for which reliable statistics can be compiled” (1949, p. 374).

The case for explanatory indispensability rests principally on the intuition that the probabilistic explanation of a single outcome requires a single-case probability. The philosophy of scientific explanation, much of it developed by regularity theorists and other metaphysical empiricists, offers a number of alternative ways of thinking about explanation, for example, as a matter of showing that the outcome to be explained was to be expected, or as a matter of subsuming the outcome to be explained under a general pattern of outcomes (both ideas proposed by Carl Gustav Hempel). The fate of frequentism, and more generally of the regularity approach to laws of nature, depends to some extent, then, on the adequacy of these conceptions of explanation.

Why be a frequentist? The view has two principal advantages. First is its light metaphysical touch, shared with the regularity account of laws. Second is the basis it gives for the mathematics of probability: Frequencies, as mathematical objects, conform to almost all the axioms of probability. Only almost all because they violate the axiom of countable additivity, an extension to the countably infinite case of the third axiom described earlier. Countable additivity plays an important role in the derivation of some of probability mathematics' more striking results, but whether it is necessary to provide a foundation for the scientific role of physical probability claims is unclear.

There is more than one way to be a frequentist. A naive actual frequentist holds that there is a probability wherever there is a frequency, so that, in a universe where only three coin tosses have ever occurred, two coming up heads, there is a probability for heads of two-thirds. This view has been widely criticized, though never held. Compare with the naive regularity theory of laws (Armstrong 1983, §2.1).

What might be called ideal actual frequentism is the theory developed by Reichenbach (1949) and von Mises (1957). On this view, probability statements are construed as ideally concerning only infinite classes of events. In practice, however, they may be applied to large finite classes that in some sense come close to having the properties of infinite classes. Thus, Reichenbach distinguishes the logical meaning of a probability statement, which asserts the probabilistic patterning of an infinite class of outcomes, and the finitist meaning that is given to probability claims in physical applications, that is, in the scientific attribution of a physical probability (Reichenbach 1949). On the finitist interpretation, then, a physical probability claim concerns the probabilistic patterning of some actual, finite class of events—albeit a class large

enough to have what Reichenbach calls a practical limiting frequency. (Reichenbach's wariness about logical meaning owes as much, incidentally, to his desire to have his theory of probability conform to the verifiability theory of meaning as to a concern with, say, the validity of probability claims in a finite universe.)

David Lewis (1994), reviving Ramsey's account of laws of nature, proposes that the fundamental laws are nothing but the axioms of the theory that best systematizes, or unifies, the phenomena. A systematization is good to the degree that it is simple, that it makes claims about a large proportion of the phenomena (ideally all the phenomena, of course), and that its claims are accurate. Lewis (1994) extends the definition of accuracy, or as he calls it, fit, to accommodate axioms attributing physical probabilities: A set of phenomena are a good fit to a physical probability statement if the phenomena exemplify the probabilistic patterns appropriate to the probability ascribed. A system of probabilistic axioms will be a good systematization, then, only if the physical probabilities it assigns to the phenomena are reflected, for the most part, in corresponding probabilistic patterns.

In this respect, Lewis's view is a form of frequentism. Although there is not some particular set of outcomes whose probabilistic patterning is necessary and sufficient for the truth of a given probabilistic law statement, it is nevertheless the world's probabilistic patterns, taken as a whole, that provide the basis for all true statements of probabilistic law.

Some writers suggest that a claim such as "The probability of obtaining heads on a toss of this coin is one-half" is equivalent to the claim that, if the coin were tossed infinitely many times, it would yield heads with a limiting frequency of one-half. The truth-makers for physical probability claims, then, are modal facts (except in the case where there actually are an infinite number of tosses). This view is known as hypothetical frequentism.

Though much discussed in the literature, hypothetical frequentism is seldom advocated. Reichenbach (1949) and von Mises (1957) are sometimes labeled hypothetical frequentists, but the textual evidence is thin, perhaps even nonexistent. Colin Howson and Peter Urbach (1993) advocate a hypothetical frequency view. Bas C. van Fraassen's (1980) frequencies are also hypothetical, but because he holds that the literal meaning of theoretical claims is irrelevant to the scientific enterprise, the spirit of his account of probability is, in its empiricism, closer to Reichenbach's ideal actual frequentism.

The weaknesses of frequentism are in large part the weaknesses of the regularity theory of laws. An interesting objection with no parallel in the regularity account is as follows: In the case of reference classes containing countably infinite numbers of events, the value (indeed, the existence) of the limiting frequency will vary depending on how the outcomes are ordered. There appear to be no objective facts, then, about limiting frequencies. Or rather, if there are to be objective facts, there must be some canonical ordering of outcomes, either specified along with the reference class or fixed as a part of the scientific background. How serious an impediment this is to the frequentist is unclear.

**THE PROPENSITY THEORY.** If frequentism is the regularity theorist's natural interpretation of physical probability claims, then the propensity account is the interpretation for realists about laws, that is, for philosophers who believe that law statements assert the existence of relations of nomic necessity and causal tendencies (Armstrong 1983). For the propensity theorist, probabilities are propensities, and propensities are a certain kind of distinctly probabilistic causal tendency or disposition.

The propensity theorist's home territory is single-case probability, the kind of probability attached to a particular physical process or outcome independently of the specification of a reference class or ordering of outcomes. Because propensities are supposed to be intrinsic properties of token processes, on the propensity view every probability is a single-case probability. Given some particular outcome that one wishes to predict or explain, then, there is an absolute fact of the matter as to the physical probability of the outcome that one may—and presumably, must—use in one's prediction or explanation.

Of course, knowledge of this fact, if it is to be obtained by observing the statistics of repeated experiments, will require the choice of a reference class, the aim being to find a class containing processes that are sufficiently similar that their statistics reveal the nature of each of the underlying propensities in the class. Furthermore, by analogy with the case of deterministic causal tendencies, propensities may owe their existence to probabilistic laws governing classes of processes. Thus, something not unlike the frequentist's reference classes may turn up in both the epistemology and the metaphysics of propensities, but this does not detract from the fact that on the propensity view, there are real, observer-independent single-case probabilities.

To identify probabilities with propensities is revealing because one thinks that one has a good intuitive sense

of the nature of propensities in the deterministic case; one is reasonably clear on what it is to be fragile, aggressive, or paramagnetic. Though the metaphysics of dispositions is still a matter of dispute, it seems that one comes to deterministic propensities, at least at first, by grasping what they are propensities for: for example, breaking, violent behavior, and magnetic attraction. To adopt a propensity theory of probability, then, with the sense of familiarity the word *propensity* brings, is to make an implicit commitment to elucidating what probabilistic propensities are propensities for.

A straightforward answer to this question was given by Karl R. Popper (1959) in one of the earliest modern presentations of the propensity theory: A probabilistic propensity is a disposition to produce probabilistically patterned outcomes. A particular coin's probability for heads of one-half, then, is a disposition to produce a sequence of heads and tails that is disordered in the short term, but in the long term contains heads with a frequency of one-half. (Popper in fact omits the disorder requirement and allows that the sequence may be long and finite or infinite.) On Popper's view, then, a probabilistic propensity differs from a deterministic propensity not in the means of production, but only in what is produced: a probabilistic pattern over a long series of trials, rather than a single discrete episode of, say, shattering or magnetic attraction.

Popperian propensity theory is committed to the claim that, if the probability of a tossed coin's landing heads is one-half (and remains so), then continued tossing of the coin will eventually yield a set of outcomes of which about one-half are heads. But this sits badly with the intuitive conception of the workings of probability: If the probability of heads is one-half, then it is possible, though unlikely, that it will produce all heads for as long as one likes, even forever.

This intuition has an analog in probability mathematics. The law of large numbers prescribes a very high probability that the long-run frequency with which an outcome occurs will match its probability; by the same token, however, there is a nonzero probability that any (finite) long run will fail to produce a probability-matching frequency. There is some physical probability, then, that a probabilistic propensity will fail to produce what, according to the Popperian propensity view, it must produce. If this physical probability is itself a Popperian propensity—and surely it is just another manifestation of the original one-half propensity for heads—then it must produce, by Popper's definition, a matching frequency, which is to say that it must

occasionally produce the supposedly impossible series of heads. If it is to be consistent, Popper's definition must be carefully circumscribed. (There is a lesson here for frequentists, too.)

Most propensity theorists accept that probabilistic setups will occasionally fail to produce probability-matching frequencies. Thus, they repudiate Popper's version of the propensity theory. What, then, can they say about the nature of the propensity? Typically, they hold that the probability of, say, heads is a propensity to produce the appropriate probabilistic patterns with a high physical probability (Fetzer 1971, Giere 1973)—thus, such a probabilistic propensity is probabilistic not only in its characteristic effect, which is, as on Popper's definition, a probabilistic pattern, but also in its relation to the effect. (D. H. Mellor [1971] offers an interesting variant on this view.)

Whereas the Popperian definition comes close to inconsistency, this new definition is manifestly circular. Its proponents accept the circularity, so committing themselves to the ineffability of probabilistic propensities.

The ineffability of propensities, it is asserted, is not a problem provided that their values can be inferred; the usual apparatus of statistical inference is tendered for this purpose. Critics of the post-Popperian propensity interpretation naturally fasten on the question of whether it succeeds in saying anything substantive about probability at all—anything, for example, that illuminates the question of why physical probabilities conform to the axioms of the probability calculus or explain the outcomes that they produce. It does seem that modern propensity theorists are not so far from what is sometimes called the semantic interpretation of probability, on which probabilities are considered to be model-theoretic constructs that ought not to be interpreted at all, but simply accepted as formal waypoints between evidence and prediction in probabilistic reasoning (Braithwaite 1953). Compare Carnap's (1950) notion of partial interpretation and Patrick Suppes (1973).

A characteristic doctrine of the propensity theory is that probabilistic propensities, hence probabilities, are metaphysically irreducible: They are in some sense fundamental building blocks of the universe. The corollary to this doctrine is that the physical probabilities science assigns to outcomes that are deterministically produced—including, according to many philosophers, the probabilities of statistical mechanics, evolutionary biology, and so on—are, because they are not irreducible, they are not propensities, and because they are not

propensities, they are irreducible. Ronald N. Giere (1973) writes that they must be given an “as if” interpretation, but propensity theorists offer no account of “as if” probability’s scientific role.

On a broader understanding of the nature of a propensity, however, at least some of the physical probabilities assigned by science to the outcomes of deterministic processes might count as probabilistic propensities. As explained in the entry on chaos, certain subclasses of chaotic systems have dynamic properties in virtue of which they tend to generate probabilistic patterns of outcomes (Strevens 2003). These dynamic properties may be understood, then, as endowing the systems with a propensity to produce probabilistic patterns, and the propensity itself may be identified with the physical probabilities that science ascribes to the outcomes.

There is one, not inconsiderable, complication: The systems in question will generate the probabilistic patterns only given appropriate initial conditions. Almost all, but not all, initial conditions will do. This raises two important questions that need to be answered if chaos is to provide a part of the foundation for the metaphysics of physical probability. First, ought the necessary properties of the initial conditions to be considered a part of the propensity? If so, the propensity seems not to be an intrinsic causal property of the process. Second, the initial conditions are, in this context, most naturally described using a probability distribution. Thus, the basis of the probabilistic propensity is a further probabilistic element itself in need of analysis.

**THE SUBJECTIVIST THEORY.** It is something of a mystery why the mathematics of the probability calculus should be useful both for capturing elements of belief and inductive inference and for describing the processes that give rise to probabilistic patterns, or in other words, why two such different things as epistemic and physical probability should share the same formal structure.

According to the subjectivist theory of physical probability, there is no mystery at all: Physical probabilities are nothing but a certain kind of subjective probability. The intuition that, say, the probability of heads is a quantification of some physical property of the tossed coin is, on the subjectivist approach, an illusion: There are frequencies and mechanical properties out in the world, but physical probabilities exist entirely in the descriptive apparatus of people’s theories, or in their minds.

For the principal architect of subjectivism, Bruno de Finetti, the appeal of the theory is not only its neoclassical reunification of epistemic and physical probability but

also its empiricism: Subjectivism is most at home in what is now called a Humean world. Of course, frequentism is also a theory of physical probability that the metaphysical empiricist can embrace; the main advantage of subjectivism over frequentism is its provision—if such is truly necessary—of single-case probabilities (de Finetti 1964).

Subjectivism asserts the identity of the subjective probability for heads and the physical probability for heads. But it does not claim that, say, one’s subjective probability for the MACHO theory of dark matter is also a physical probability for the theory. Rightly so, because one does not acknowledge the existence of physical probabilities wherever there are subjective probabilities. A plausible subjectivism must have the consequence that one projects only a small subset of one’s subjective probabilities onto the world as physical probabilities.

At the heart of the subjectivist theory, then, must be a criterion that picks out just those subjective probabilities that are experienced as physical and that accounts for their particular, peculiar phenomenology. The key notion in the criterion is one of resilience: Unlike most subjective probabilities, which change as more evidence comes in, the subjective probabilities one calls physical have attained a certain kind of stability under the impact of additional information. This stability gives them the appearance of objectivity, hence of reality, hence of physicality, or so the subjectivist story goes. Brian Skyrms (1980) employs this same notion of resilience to give a projectivist account of causal tendencies and lawhood in the deterministic as well as the probabilistic case; subjectivism, then, like frequentism and the propensity theory, can be seen as a part of a larger project embracing all causal and nomological metaphysics.

There is an obvious difficulty with the subjectivist position as elaborated so far: My subjective probability for an outcome such as a coin’s landing heads may very well change as the evidence comes in. I may begin by believing that a certain coin is fair, and so that the physical probability of its yielding heads when tossed is one-half. As I continue to toss it, however, I may come to the realization that it is biased, settling eventually on the hypothesis that the physical probability of heads is three-quarters. Throughout the process of experimentation, I project (according to the subjectivist) a physical probability distribution onto the coin, yet throughout the process, because the projected physical probability for heads is changing, increasing from one-half to three-quarters, my subjective probability for heads is also changing. Where is the resilience?

De Finetti's (1964) achievement is to find a kind of resilience, or constancy, in my subjective probabilities even as my subjective probability for heads is changing. This resilience is captured by the property de Finetti calls exchangeability. Consider my subjective probability distribution over, say, the outcomes of the next four tosses of my coin. Every possible sequence of four outcomes will be assigned some subjective probability. The probability assignment—the subjective probability distribution—is said to be exchangeable if any two sequences having the same number of heads and tails are assigned equal probabilities. For example, exchangeability implies that HTHT and HHTT, each having two heads and two tails, are assigned the same probability, but allows this probability to differ from that assigned to, say, HHHT. In an exchangeable distribution, then, the probability assigned to a sequence of heads and tails depends only on the relative frequency with which heads and tails occur in the sequence (in the case of infinite sequences, which de Finetti uses in his mathematical construction, substitute *limiting frequency*).

If my subjective probability distribution over heads and tails is exchangeable, then the order in which the heads and tails come in as I experiment with my coin will not in itself affect my subjective probability for heads. The frequency with which heads and tails come in will, by contrast, most definitely affect my subjective probability. Thus, exchangeability is a kind of partial resilience; it is resilience to information about order, but not frequency.

De Finetti (1964) claims, uncontroversially, that one's subjective probability distributions over future sequences of heads and tails (and the outcomes of other Bernoulli setups) are exchangeable. He goes on to prove a theorem—his celebrated representation theorem—that shows that the following two reasoners will be outwardly indistinguishable: First, a reasoner who has various hypotheses about the physical probability of heads and updates the subjective probabilities for these hypotheses in the usual way as evidence comes in, and second, a reasoner who has no beliefs about physical probabilities, but simply has an exchangeable subjective probability distribution over future sequences of outcomes. The only difference between the two reasoners, then, will be that the first will claim, presumably as a result of introspection, to be learning about the values of physical probabilities in the world.

The subjectivist's sly suggestion is that people are all in fact reasoners of the second kind, falsely believing that they are reasoners of the first kind. Or, in a more revisionist mood the subjectivist may argue that, though they are reasoners of the first kind, they will give up nothing

but dubious metaphysical commitments by becoming reasoners of the second kind.

Critics of subjectivism question the aptness of exchangeability as a psychological foundation for probabilistic reasoning. The sole reason that people assign exchangeable subjective probability distributions to certain classes of sequences, according to these writers, is that they believe the sequences to be produced by physical probabilities (Bernoulli distributions, to be exact) and they know that an exchangeable subjective probability distribution is appropriate for outcomes so produced. Note that this argument has both a descriptive and normative dimension: Against a descriptive subjectivist, who holds that beliefs about physical probability play no role in people's probabilistic reasoning, the critic proposes that such beliefs cause them to assign exchangeable distributions. Against a normative subjectivist, who holds that beliefs about physical probability should not play a role in people's probabilistic reasoning, the critic proposes that such beliefs are required to justify their assigning exchangeable distributions.

A different line of criticism targets subjectivism's metaphysics: Why not identify physical probability with whatever produces the probabilistic patterns? Why not say that the probability of heads is a quantification of, at least in part, the physical symmetry of the coin? Such a position has its problems, of course, but they are not obviously insurmountable. More generally, given the rich array of options available for understanding the nature of physical probability, the subjectivist's flight from any attempt to give a metaphysics seems to many, as yet, insufficiently motivated.

## PROBABILITY COORDINATION

It is generally accepted that it is rational, in normal circumstances, to set one's subjective probability for an event equal to the physical probability ascribed by science to that event or to that type of event. Returning to the first paragraph of this entry, if the physical probability of a hurricane is high, I should expect—I should assign a high subjective probability to—a hurricane strike. This is the principle of probability coordination.

Because the equation of physical and epistemic probability is made explicit in the classical definition of probability, classicists are probability coordinators par excellence. Leibniz, for example, articulates what appears to be an early formulation of the probability coordination principle when he writes “quod facile est in re, id probabile est in mente” (Hacking, 1975, p. 128); Ian Hacking glosses this as “our judgment of probability ‘in the mind’

is proportional to (what we believe to be) the facility or propensity of things” (the parenthesized phrase is not in the Latin; 1975, p. 128). But strictly speaking, of course, classicists cannot conceive of this as a coordination of different kinds of probability, since they allow only one kind of probability.

In the twentieth century, probability coordination was introduced as a topic in its own right by David Miller, who argued, as a part of a Popperian case against inductive inference, that a probability coordination principle would have to be inconsistent. Commentators soon pointed out that there are consistent versions of the principle, and some years later David Lewis wrote what is still the most influential paper about the proper form of a principle of coordination and its role in scientific inference, conjecturing that such a principle “capture[s] all we know about [physical probability]” (1980, p.266).

Modern attempts at a formulation of a probability coordination principle contain two elements not present in Leibniz’s maxim. First is the modification interpolated by Hacking: The principle commands that one sets one’s subjective probabilities equal not to the corresponding physical probabilities, but to what one believes the values of those probabilities to be, or more generally, to the mean of the different possible values, weighted by one’s subjective probability that each value is the correct one. Such a principle might be loosely interpreted as saying that one should do one’s best to set one’s subjective probabilities equal to the physical probabilities.

Second is a restriction of the range of the principle: When one possesses certain kinds of information, probability coordination is not necessarily rational. Suppose, for example, that I know for some science-fictional reason that the coin I am about to toss will land heads. Then I should set my subjective probability for heads equal to one, not equal to the physical probability of one-half. The information that the coin will land heads is what Lewis (1980) calls inadmissible information; in the presence of inadmissible information, the principle of probability coordination does not apply. Note that what is admissible is relative to the outcome in question; knowing how the coin lands is admissible when I am setting my subjective probability for the outcome of a different toss.

An attempt at a probability coordination principle might, then, have the following form: one’s subjective probability for an event  $e$ , conditional both on the proposition that the physical probability of  $e$  is  $p$  and on any admissible information  $k$ , should be set equal to  $p$ . (One’s unconditional subjective probability for  $e$ , then, will be the weighted sum of the physical probabilities, as men-

tioned earlier.) In symbols: If one’s background knowledge is admissible, then set

$$C(e|tk) = P_t(e),$$

where  $C(\cdot)$  is one’s subjective probability distribution,  $t$  is the proposition that the correct physical probability distribution for  $e$  is  $P_t(\cdot)$ , and  $k$  is any other admissible information.

Note that propositions such as  $t$  are normally consequences of two kinds of fact: probabilistic laws of nature and some properties of  $e$  in virtue of which it falls under the laws. For example, if  $e$  is the event of a particular coin toss’s landing heads, then the law might be “All tosses of a fair coin land heads with physical probability one-half” and the additional fact the fairness of the coin in question. In what follows it is assumed that the latter facts are part of the background knowledge, and that  $t$  simply asserts some probabilistic law of nature, as suggested by the previous notation.

The most puzzling aspect of the probability coordination principle is the nature of admissibility. Lewis proposes a working definition of admissibility (he says that it is a “sufficient or almost sufficient” condition for admissibility) on which information is admissible either if it is historical—if it concerns only facts about the past up to the point where the principle is invoked—or if it is purely probabilistic, that is, if it is information about physical probabilities themselves.

The definition is problematic for two reasons. One difficulty is explicitly identified by Lewis (1980) and for many years prevented him from advancing the frequency-based theory of physical probability that he wished to give. As noted earlier, when coordinating probabilities for a given outcome, information about the future occurrence or otherwise of that outcome ought to be counted inadmissible. It turns out that frequency-based probabilities provide information of this sort. Lewis, then, has three choices. The first is to revise the working definition of admissibility so as to rule out such information, in which case information about physical probabilities will be inadmissible and the resulting probability coordination principle will be useless. The second is to stay with the working definition of admissibility, allowing the information provided by frequency-based probabilities to count as admissible by fiat. It can be shown, however, that the resulting principle—that is, Lewis’s original principle—clearly sets the wrong subjective probabilities in certain circumstances: There are certain complex facts about the future that a frequency-based probability distribution entails cannot

obtain, yet assigns a nonzero probability. If such a probability distribution is known to be the correct one, then the right subjective probability for the facts is zero, but probability coordination results in a nonzero subjective probability. The third option is to abandon probability coordination as such. Lewis takes the third way out, proposing a new kind of probability coordination principle that has the form (using the notation from earlier)  $C(e|tk) = P_i(e|t)$ . Michael Strevens (1995) points out that both Lewis's new principle and his original principle are consequences of a more general probability coordination principle according to which conditional subjective probabilities should be set equal to conditional physical probabilities. This principle yields Lewis's original principle when information about physical probability distributions is admissible and Lewis's new principle when it is not.

A different problem with Lewis's working definition of admissibility is that it makes no sense of probability coordination in deterministic systems. If one conditionalizes on the exact initial conditions of a coin toss, one ought not to set one's subjective probability for heads to the physical probability of heads, one-half, but either to zero or to one depending on whether those particular initial conditions cause the coin to land heads or tails. If a probability coordination principle is to be applied to the probability of heads, exact information about initial conditions must therefore be ruled inadmissible. Lewis's (1980) working definition of admissibility counts initial conditions, like all historical facts, as admissible.

Lewis (1980) does not regard this as a problem, since he agrees with the propensity theorists that in deterministic systems there could be only ersatz physical probabilities. Even if this is correct as a metaphysical doctrine, however, it remains a matter of fact that one coordinates one's subjective probabilities with such ersatz probabilities all the time, as when one forms expectations about the outcomes of a tossed coin. Whatever one calls it, then, there is a coordination principle for systems such as gambling devices that apparently has the same form as the genuine probability coordination principle (for a reconciliation of Lewis's account of physical probability and probability coordination in deterministic systems, see Loewer 2001).

There is clearly more work to be done elucidating the form of the probability coordination process, and in understanding admissibility in particular. A different project attempts to justify the practice of probability coordination, by giving an a priori argument that subjective probabilities should track physical probabilities, or

beliefs about such. Lewis himself says no more than that he can "see dimly" why probability coordination is rational. Howson and Urbach (1993) attempt a full-blown justification. Strevens (1999) argues that Howson and Urbach's argument appeals implicitly to a principle of indifference and goes on to make a case that there is a strong parallel between providing an a priori justification for probability coordination and providing an a priori justification for inductive inference, that is, solving the problem of induction.

A final question about the relation between epistemic and physical probability was adumbrated earlier: Why should the same formal structure be central to one's understanding of two such different things as the production of the probabilistic patterns and the nature of inductive reasoning?

## PROCLUS

(412–485)

Proclus was born in Constantinople into a Lycean family that was still faithful to the old Hellenic religion in a society already dominated by Christianity. The talented young man forsook a career as a lawyer and decided to devote his life entirely to philosophy. After studies in Alexandria, he arrived in 431 in Athens where he joined the Platonic school of Syrianus. After the death of his venerated master, he became the leader of this school and remained in that position for almost fifty years until his death in 485. As we know from his biographer Marinus, his whole life was devoted to teaching and writing. Proclus was also a deeply devout person. In the community of the school he continued to practice with his disciples the rituals of the old Hellenic religion as well as the theurgical rituals of the Chaldeans. For Proclus, Plato was more than a philosopher intent upon the search for the truth; he was also a divinely inspired prophet showing the soul a way of salvation. Reading Plato had become more than just a scholarly exercise—it was a religious activity of paramount importance.

Proclus was convinced that the truth had been revealed by the gods in many different ways, in obscure oracles, myths and symbols. He saw himself as the interpreter whose task it was to explain the hidden significance of those religious traditions in a civilization where they were doomed to disappear. It was his ambition to prove the harmony between Plato and the other sources of divinely inspired wisdom, in particular the Chaldean Oracles and the Orphic poems. In his view, only a philosophical approach could offer the framework and rational arguments needed for this interpretation. For that reason Plato remained for him the ultimate authority in all matters, divine and human. Aristotle, on the contrary, was given only a subsidiary role, as he never developed a proper theology. His significance was restricted to matters of logic and physics.

Proclus wrote commentaries on the dialogues of Plato that were part of the curriculum of the Neoplatonic school. The course started with the reading of the *Alcibiades I* about self-knowledge, which was regarded as an introduction to philosophy, and culminated in the explanation of the two major dialogues of the Platonic corpus: the *Timaeus* about the generation of the physical world and the *Parmenides*, which was thought to offer Plato's doctrine on the first principles. Proclus also wrote a series of interpretative essays on the *Republic*. The commentaries of Proclus are masterpieces of their genre: They not only

offer a systematic interpretation of the text, but also introduce his own philosophical views and provide us with a wealth of information about the discussions within the Platonic tradition. That is particularly the case with the commentary on the *Timaeus*: Proclus defends Plato's explanation of the physical world as superior to that in Aristotle's *Physics* because only Plato discovered the ultimate (i.e., divine) causes of the physical phenomena.

Besides his work on Plato, Proclus composed a remarkable commentary on Euclid's *Elements*, the prologues of which offer a philosophical introduction to the study of the mathematical sciences. The *Hypotyposis*, or *Outline of the Astronomical Hypotheses*, is another indication of his interest in science and cosmology. Proclus also wrote short treatises on diverse subjects, such as the treatise *On the Existence of Evils*, in which he attempts to explain the existence of evil in a world proceeding from an absolutely good principle. If all agents act for some good and yet, evil occurs, it is unintended and uncaused. Evil cannot exist in its own right and no proper cause explains it. Its existence is parasitic (*para-hypostasis*), supervening upon substances and acts. This doctrine, which was adopted by a Christian author writing under the pseudonym of Pseudo-Dionysus in his celebrated treatise *On the Divine Names*, became for centuries the dominant view in philosophical and theological debates on evil.

Besides his commentaries, Proclus owes his reputation to his two great syntheses of Platonic philosophy, the *Elements of Theology* and the *Platonic Theology*. Theology is for Proclus a rational investigation into the first causes and principles of all things. The first philosophers only admitted corporeal entities, such as fire or water, as first causes. Later philosophers recognized souls as principles of life and movement and thus discovered noncorporeal being. Aristotle posited unmoved intellects above the self-moving souls and considered the first intellect to be the ultimate divine cause. Only Plato, however, recognized a cause beyond intellect, beyond being, beyond knowledge and discourse, namely the One, from which all things including matter derive their existence (*Platonic Theology* I,1). Therefore, Plato's theology is for Proclus (and for the entire Neoplatonic school since Plotinus) the accomplishment of all preceding theological speculation, since it reveals the "three principal hypostases": the One, the Intellect, the Soul.

## ELEMENTS OF THEOLOGY

In this work, the metaphysical counterpart of Euclid's *Elements*, Proclus demonstrates "in a geometrical manner" the

most fundamental theorems of the theological or metaphysical science as he understands it. The work contains 211 propositions, each of them followed by a demonstration. The first part (props. 1–112) examines the fundamental principles that govern the structure of all reality, such as the relation between the One and the many, the cause and the effect, the whole and the parts, transcendence and participation, procession and reversion, continuity and discontinuity, Being, Life and Intellect, limit and limitedness, self-movement and self-constitution, act and potency, eternity and time.

In the second part (props. 113–211) Proclus gives a survey of all degrees of reality, applying to them the general metaphysical principles he had demonstrated before. He discusses successively the gods (or "henads"), the intellects and the souls. The physical realm falls outside the scope of this theological metaphysics. The *Elements of Theology* is without doubt the most original work of Proclus, not so much because of its content (which offers the standard doctrine of the Athenian school), but because of its extraordinary attempt to develop the entire Neoplatonic metaphysics from a set of axioms. It also had a tremendous influence, in particular through the Arabic adaptation that was made in the ninth century in the circle of Al-Kindī. In the middle of the twelfth century this Arabic treatise was translated into Latin. The *Liber de Causis*, as it was named, circulated as the work of Aristotle and thus obtained a great authority in medieval Scholasticism. The systematic character of the *Elements* and its rigorous method make it for the student the best introduction to the complicated thought of Proclus.

**ONE AND MULTIPLICITY.** The *Elements* begin with the proposition that "every manifold in some way participates in unity." Without some form of unity a multitude would fall apart into an infinity of infinite things. A multitude cannot, however, be itself the unity it participates in. It is not the One, but a unified manifold, having unity as an attribute, and is therefore posterior to the One itself upon which it depends. All things, then, derive their being ultimately from the One from which they proceed.

This One must be identified with the Good, since it is the proper function of the One to hold together all things and maintain them in existence, which is also the function of the Good. For to hold a thing together and make it one is to give it its perfection and well-being, whereas dispersion is the cause of its destruction and evil. Since the Good is what unifies things and the One is what gives them perfection, the One and the Good are names

designating the absolute principle from which and toward which all things eternally proceed and return.

Having demonstrated the necessity of the One as the first principle, Proclus explains how all things in all their specificity proceed from this One. It is impossible to admit that the utmost multiplicity of the material world with its particularized bodies would proceed immediately from the first principle. Plotinus had already argued that from the One comes first the Intellect and from the Intellect proceeds the Soul, which stands itself at the beginning of time, division, and movement. For Proclus, this Plotinian understanding of the procession is unsatisfactory, in particular with regard to the second level, the Intellect, which is identical with true Being and Life. If we respect the “law of continuity,” which governs the procession of all things along the “chain of being,” we cannot admit that the Intellect (which contains already the Forms of all things) comes into existence immediately after the absolute One. There must be “mean terms” connecting the extremities. From the One comes forth Being, from Being Life, from Life the Intellect. Whereas Being is the ultimate intelligible object (*noēton*), the Intellect, which contains in its thought the paradigmatic Forms, is the properly intellectual level (*noeron*). The intermediate realm of Life is the intelligible-intellectual. In this triad of hypostases, the superior level has the most comprehensive and farthest reaching causality: for all things participate in being, but not all are living or capable of thinking. The causality of the One reaches even further than that of Being, since matter, the indeterminate substrate of the physical realm, does depend on the One, though it does not really “exist.”

**THE TRIADIC DYNAMIC STRUCTURE OF REALITY.** Many propositions in the *Elements* concern causality (hence the Latin-Arabic adaptation is appropriately called *De causis*): they are not about the physical causes, which are for Proclus only auxiliary causes, but about the “true causes,” which always transcend their effect. Whatever produces something must be superior to the effect, which owes its existence to it. If this effect has itself the power to produce, it will produce again something inferior to it, until the procession comes down to what is altogether unproductive, that is, matter. Although the effect is inferior to its cause, it is also somehow similar to that which has produced it. The effect is in a secondary manner what its cause is primarily. Insofar as the effect is similar to its cause and shares its character, it is said to “remain” in its cause without yet having its proper existence. On the superior level, it exits “causally” or “potentially” (if “potency” is understood as a productive power).

A being only acquires its proper existence (*hyparxis*) when it proceeds from its cause and becomes distinguished from it. Through the procession it becomes somehow dissimilar to the cause. Yet the procession from the cause cannot go on infinitely: the effect must also revert upon the cause from which it proceeds. Through this “return” (*epistrophē*) the effect strives to be connected again with its cause and becomes similar to it. If things have their being through procession, they attain their well-being or perfection through reversion. For the cause of their well-being can only come from the origin of their being. The final cause is thus identical with the efficient, since all things desire as ultimate end that which is the principle of their procession. As Proclus formulates it: “All that is produced by a cause both remains in it and proceeds from it” (*Elements of Theology*, § 30). “All that proceeds from something reverts upon that from which it proceeds” (§ 31). Therefore, “all that proceeds from a principle and reverts upon it has a cyclical activity” (§ 33). All beings remain in their causes, proceed from them, and return to them, in an eternal circularity, since the end is identical with the origin. Proclus finds this triadic dynamic structure on all levels of reality.

**PARTICIPATION AND NONPARTICIPATION.** When attempting to understand the relation between the Forms and the many things that are similar to them, Plato introduced the metaphor of “participation.” Participation, however, raises as many problems as it solves, as Plato shows in the aporetic discussion of the *Parmenides* (which offered ammunition for Aristotle’s subsequent criticism). The term seems to suggest that the many things sharing in the same Form take “parts” of it. How can one reconcile the transcendence of the Forms with their presence in the many things? If participation is real, the Forms must be immanent in the things sharing them and hence will be divided. But how, then, can the transcendence of the Forms be preserved? If, on the other hand, we stress the unity and the indivisibility of the Forms, we end up making participation impossible.

Proclus’s solution to this problem is the distinction between the participated and unparticipated mode of a *hypostasis*. What is participated in by the particular things cannot be the ideal Form itself, but must be a form that comes forth from it and is present in them. These immanent forms are somehow comparable to the Aristotelian Forms in matter. However, whereas Aristotle rejects the transcendent Forms as an unnecessary duplication of reality, Proclus argues that the unparticipated Forms are necessary to guarantee the universal character of the forms in matter. The participated form belongs entirely

to the particular thing sharing it. Since what inheres in one thing cannot be present in another, there is no explanation of the fact that the many things, though obtaining a proper form, have this form in common. By postulating an unparticipated Form, which exists prior to all participated forms proceeding from it, the Platonists can explain how the *eidos* is common to all that can share in it and nevertheless the same in all. As is said in proposition 23: “all that is unparticipated brings forth from itself the participated; and all the participated hypostases extend back to the unparticipated.”

The distinction between the participated and the unparticipated not only applies to the Forms, but to all levels of reality: Soul, Intellect, and even the One. Within each realm a distinction must be made between the first unparticipated term (the “monad”) and the “series” or multiplicity of beings of a similar nature coordinated with it. Thus, besides the many souls that are participated in on various levels by different bodies—the particular souls by which each human being exists as a particular animal, the souls of demons, the planetary divine souls—we must postulate the existence of the unparticipated Soul, from which a multiplicity of souls proceeds according to diverse modes of participation.

Similarly, besides the many particular intellects participated in by different divine and human souls, there must also exist an absolute unparticipated Intellect, which comprises the totality of all Forms. The many intellects proceed from this absolute Intellect and form together with it a coordinate series of a similar intellectual nature. Following the same line of reasoning, we must also posit after the One, which is absolutely transcendent and can in no way be participated by the inferior levels, a manifold series of “ones,” “units,” or “henads” consequent upon the primal One, which are participated in by the different classes of being. Those henads are not the modalities of unity acquired by beings, but self-subsisting units which remain transcendent above the beings that depend upon them. Though they are in themselves beyond being and beyond knowledge, as is the primal One, in which they remain co-united, their distinctive properties can be inferred indirectly from the different classes of beings dependent upon them. “For differences within an order of participants are determined by the distinctive properties of the principles participated in” (*Elements of Theology* § 123).

In view of the different classes of beings depending upon them, we can distinguish, for example, intelligible, intellectual, hypercosmic, or encosmic henads. Yet, insofar as they are all self-subsisting units, they remain uni-

fied in the One itself. If the One stands for the first divine cause, the different henads constitute the different classes of the gods. “For every god except the One is participable” (§ 116). With this doctrine of the henads, Proclus can defend—against Christian monotheism—both the unity and multiplicity of the divine. In his view, it is the main task of a Platonic philosopher to explain in a rational system the procession and the distinctive properties of all the classes of the gods we know through the diverse religious traditions. That is the purpose of Proclus’s last magnum opus.

## THE PLATONIC THEOLOGY

Proclus distinguishes four types of theological discourse. Divinely inspired poets use dramatic stories (talking about sexual relations, births, fights, cuttings of organs) to symbolically indicate the processions of the divine principles and their mutual relations. This mythological discourse is characteristic of the ancient Hellenic theology, as known through the Orphic poems and the works of Homer and Hesiod. In oracular discourse (in particular the *Chaldean Oracles*) prophets reveal the names and properties of the gods without resorting to the dramatic scenery of mythology. The Pythagoreans resort to mathematical analogies and similitudes (numbers, circles, spheres) to disclose the divine orders. Finally, there is scientific or dialectical theology, which investigates the divine classes and their properties using strictly rational arguments and an abstract philosophical vocabulary: one and many, being, whole and part, identity and otherness, similarity and dissimilarity.

This scientific theology has been brought to perfection by Plato in his dialogue *Parmenides*. In Proclus’s interpretation, this dialogue displays the fundamental axioms and basic concepts needed for the development of a scientific theology. In the second part of this dialogue, Parmenides examines in a dialectical exercise the hypothesis of Unity, considering the consequences following from the position of the One and from its denial, both for the One and for what is other than the One. If we start from the hypothesis of the One, only negative conclusions seem to follow: the One has no parts and is not a whole; it is not in something nor in itself; it is neither similar nor dissimilar. One cannot even say that it “is” or “is one.” In short, no names, no discourse, no knowledge of it is possible. Parmenides therefore has to restate his original hypothesis, now emphasizing the existence of the One. All attributes that were denied in the first hypothesis can be predicated of this One-that-is.

The interpretation of the different hypotheses of the *Parmenides* (of which we mention only the first two) led to a lively debate in the Neoplatonic school, as we know from Proclus's commentary. Proclus defends a theological interpretation of this dialectical discussion about the One and the Many. If the "One" stands for the first principle, the successive hypotheses of the *Parmenides* must refer to the different principles of the whole of reality. The One of the first hypothesis, of which no discourse is possible, is the absolute, unparticipated One or primal god. In the second hypothesis, Parmenides deduces, through the subsequent conclusions following from the position of the One-that-is, the different modes of unity ("henads") that are participated in by the different degrees of being. Whereas the first hypothesis leads to a negative theology, the deductions from the second hypothesis give the articulations of a positive theology. "In this dialogue proceed all the divine classes in good order from the first cause and demonstrate their mutual connection" (*Platonic Theology*, I, ch. 7).

When interpreted in this way, the *Parmenides* provides a framework in which the other discourses about the gods can be integrated and decoded: the mythological stories about Zeus and Kronos from the Hellenic and Orphic traditions, the strange divine names revealed in the *Chaldean Oracles*, the mathematical *theologumena* of the Pythagoreans, the various scattered remarks about the gods in the other dialogues of Plato. In the Renaissance, Marsilio Ficino adapted the model of Proclus's theology in an original way to integrate the revealed truth of Christianity.

## CONCLUSION

It is difficult to evaluate the originality of a thinker who, in most of his works, claims to be nothing but a faithful follower of his master Syrianus. It is Proclus, however, who put his mark on the development of the later tradition of Neoplatonism in Byzantine, Arabic, and Latin medieval thought. His huge influence—much greater than that of Plotinus—is to be explained mainly by two important indirect channels: the Christian reception of his theology by Pseudo-Dionysus and the Arabic adaptation of the *Elements* in the *Liber de Causis*. And yet it is no historical accident that Proclus gained this fame. The *diadochos* (or successor) of Plato, as he was named, has been the authoritative commentator of Plato and the great systematizer of Neoplatonic metaphysics.

## PRODICUS OF CEOS

Prodicus of Ceos, the Greek Sophist, was probably born before 460 BCE and was still alive at the time of the death of Socrates in 399 BCE. He traveled widely as an ambassador for Ceos and also earned a great deal of money lecturing in various Greek cities, especially in Athens. His writings are known to have dealt with physical doctrines,

with religious and moral themes, and above all with distinctions between the meanings of words usually treated as synonyms. Socrates attended a lecture by him on the last of these topics and regularly claimed to be a pupil of Prodicus in the art of synonymy (*Protagoras* 341A, *Meno* 96D).

In physics he appears to have treated the four elements of Empedocles as divine, and no doubt they formed the basis of the cosmology of Prodicus, to which Aristophanes refers in the *Birds* (1.692), although the fanciful cosmology that follows is probably not based on that of Prodicus. Prodicus further held that those natural objects and powers that are useful to human life were made the objects of cult and treated as gods by men. Inevitably, he was later classed as an atheist, but it is more likely that he offered an account of the origin of the gods that was not intended to deny their existence.

In a work titled the *Horae* (Hours) he included the since famous story “Heracles Where the Road Divides,” of which we have a fairly full summary in Book II of Xenophon’s *Memorabilia*. Vice and Virtue appear to Heracles personified as women and invite him to choose between them. Each describes what she has to offer, and Heracles chooses the arduous tasks of Virtue rather than the pleasures of Vice.

Of greater philosophic interest is the ethical relativism attributed to Prodicus in the pseudo-Platonic dialogue the *Eryxias*. There he is apparently quoted as arguing that what is good for one man is not good for another man, so that we cannot speak of anything as good *simpliciter*. On the other hand, the goodness of a thing does not depend on the goodness of the user (although some scholars have interpreted him this way). Rather, the value of a thing inheres in the thing itself in such a way that it will be good in relation to one person and not good in relation to another, according to the person and the way in which it is used.

The discussion of synonyms and the right use of words clearly involved fine distinctions of meaning between words. Many examples quoted are ethical, and a term of narrower application is commonly distinguished from one of wider application that includes in its range of meaning the meaning of the first term. The value of such distinctions is clear in rhetorical argument. But Prodicus was also eager to reject the kind of view found in Democritus, according to which there can be different names for the same thing since names are attached to things by convention only. Prodicus maintained, it would seem, that no two words have the same meaning, and in this he at least prepared the way for the search for precisely stated meanings that later fascinated Socrates and Plato.

## PROGRESS, THE IDEA OF

In broad terms a popular belief in “progress” means the rejection of an attitude that has characterized most human communities throughout history. Normally, people have believed that the future would repeat the past. When they have expected that human life was going to change, they have usually supposed that this change was going to take place suddenly and radically, by supernatural intervention. And if they have permitted themselves to hope for the improvement of the human condition, the hope has commonly been directed toward salvation from the world rather than reform of the world. By and large, historical change, when people have been aware of it at all, has been viewed as a sign of mortality and the proof of a lapse from ideal standards. Indeed, in many societies there has been a popular conviction that humankind’s condition has changed in the course of history but for the worse. Characteristically, when people have believed in a golden age, they have put that age in the past rather than the future.

In contrast, in modern Western societies change and innovation have a different place in the popular imagination. Not everyone assumes that all change is necessarily for the better, but it is widely assumed, even by conservatives, that only a society that has a general capacity to change is capable of surviving. And despite wars and depressions a large proportion of the members of Western societies have tended to expect that, short of a cataclysm, their children would live happier and better lives

than they. They have supposed that this improvement would be cumulative and continuing and that although temporary setbacks, accidents, and disasters might take place, human knowledge, power, and happiness would increase over the long run.

The emergence of this idea is the product of a variety of circumstances, such as the accumulation of an economic surplus, the increase of social mobility, and the occurrence of major inventions that have dramatically increased human power over nature. Over and above these, however, the idea of progress is peculiarly a response to the emergence of the unique social institution of organized scientific inquiry.

### HISTORY OF THE IDEA

Seeds of the faith in progress can be found in the works of the two great spokesmen for the new science, Francis Bacon and René Descartes. The fundamental elements of the idea itself were developed in the course of the so-called quarrel of the ancients and the moderns, which occupied writers and critics in the last part of the seventeenth century. At the heart of this controversy was a dispute over the authority that should be attributed to the opinions and examples left by the ancient writers. Was it the task of scholars to stand as sentinels at the gate, guarding against innovation and protecting established styles and beliefs? The controversy implicitly raised not only literary questions but the larger question of what attitude toward the past should govern the intellectual life.

In developing their position, the moderns argued that the partisans of the ancients were misled by a false analogy. They looked upon the ancients as their forefathers and therefore thought of the ancients as older and, in consequence, wiser than themselves. But just as the individual grows older and presumably wiser as time goes by, so does humanity. The so-called ancients were really the young men of humanity, and those alive today were the true ancients. They stood on the shoulders of their predecessors and could see farther; their wisdom and authority was greater than the wisdom and authority of their predecessors. This argument was developed with particular force by Bernard de Fontenelle in his *Digression sur les anciens et les modernes* (published in 1683).

The analogy between the history of humankind and the life of an individual had already been developed, however, by a number of writers. Blaise Pascal, for example, used it in drawing a belief in intellectual progress from an examination of the nature of scientific inquiry. In 1647, Pascal had published a study, *Nouvelles expériences*

*touchant le vide*, which encountered immediate objections from many scientists and philosophers, including Descartes, on the ground that it denied the time-honored truth that nature abhorred a vacuum. Pascal replied to one of his critics, Father Noel, that an appeal to inherited authority had no force where the study of physics was concerned. And in a longer essay, *Fragment d'un traité du vide*, he went on to give general reasons for moderating the respect for received authority. "The experiments which give us an understanding of nature multiply continually," he pointed out, "from whence it follows ... that not only each man advances in the sciences day by day, but that all men together make continual progress in them as the universe grows older." Pascal believed, however, that such progress took place only where the experimental methods of the sciences were relevant. In theology received authority set the final limits to inquiry, for there the object was not to add to the knowledge provided by ancient authority but only to understand as fully as possible what that authority revealed.

During the eighteenth century, however, and particularly in France an increasing number of intellectuals came to believe that the methods and spirit of science should be applied to all fields. In consequence, the idea of progress came to include a concept of social and moral progress. The cumulative improvement in human knowledge and power that had been brought about in the physical sciences could also be brought about in the organization of human society and the character of human conduct, it was asserted, if only the barriers that existed against the employment of rational methods in morals, religion, and politics could be removed. The Encyclopedists, chief among whom were Denis Diderot and Jean d'Alembert, led in the dissemination of this point of view. The most complete and moving expression of this faith in progress was the Marquis de Condorcet's *Esquisse d'un tableau historique des progrès de l'esprit humain*, written in 1793.

In the nineteenth century a new kind of historicist philosophy emerged that rejected the eighteenth-century conception of reason and the sharp dichotomy between the present and the past that had been made by believers in progress. This philosophy, best represented by G. W. F. Hegel, substituted the view that history followed its own inherent course of development and that this course of development embodied rational principles higher than those of merely human reason. Since this form of historicist philosophy identifies all conceivable changes as elements in an unfolding rational purpose, it deprives the idea of progress of definite meaning.

The more definite and combative eighteenth-century conception of progress, however, also continued to be a central theme in the thought of the nineteenth century. In one form or another, major figures of the century, such as Karl Marx, Auguste Comte, and John Stuart Mill, all propounded the doctrine. Although Marx, Comte, and Mill were influenced, each in his own way, by historicist ideas, each retained the characteristic eighteenth-century emphasis on the struggle between reason and superstition, on the movement of humankind away from theological and metaphysical modes of thought to positive or empirical habits of mind, and on the importance of extending the standards and methods of the sciences to all domains.

In the twentieth century the idea of progress continued to have adherents, particularly among American pragmatists, Marxists, and logical empiricists. For obvious historical reasons, however, advocates of the belief in progress have become steadily more modest in their claims since World War I, and since the turn of the twentieth century the idea of progress has been seized on by an increasing number of philosophers, theologians, and social critics as the prime fallacy of the tradition of liberalism and rationalism.

#### ANALYSIS OF THE IDEA

In tracing the history of the idea of progress, it is useful to distinguish between two motifs. Generally speaking, the belief in progress has been supported by an appeal to the progress of the sciences. In many cases, however, this appeal has consisted in showing that the sciences—usually some particular science—had uncovered fundamental truths that had been previously unknown and that progress would now take place if only these truths were accepted as guides to practice. Thus, progress has been said to be guaranteed if people lived by the fundamental principles disclosed by the science of economics, if they accepted the laws of historical development revealed by a scientific approach to history, or if they extended to the government of human society the Darwinian doctrine of evolution by natural selection. Progress has also been thought to be guaranteed if people could only come to recognize certain rational moral principles, such as universal natural rights. Such universal principles, though antecedent to any particular science, were nevertheless closely identified with science, for it was assumed that their validity would be apparent to anyone who could disencumber himself from the superstitions and prejudices of the past and that this process of disengagement was immensely accelerated by the advent of science. This con-

ception of the nature and conditions of progress lends itself to Utopian and Messianic interpretations of progress when understood as an ideal but to the reduction of the idea, in G. M. Young's phrase, "from an aspiration to a schedule" when associated with rigid, a priori approaches to the problem of improving the human condition.

A second motif in the theory of progress, however, has associated progress not with any particular discoveries of science or reason but with the unique, self-corrective methods of science. From this point of view the essential conditions for progress are the rejection of absolutes and fidelity to the principles of free, fallibilistic, experimental inquiry in all domains of thought and action. Even if we assume that it is valid to assert that the methods of science are universally applicable, this approach obviously imposes practical conditions for progress that are immensely difficult and perhaps impossible to realize. Accordingly, those who adopt this approach to the idea of progress can be taken to be saying only that there is a possibility of progress or, at best, a slow and uneven historical tendency that is characteristic only of societies possessing an appropriate ethic and social order and whose continuation is by no means ensured. In the past many proponents of the idea of progress undoubtedly underestimated the difficulties of domesticating within society at large the attitudes and habits of mind exemplified in scientific investigation. Nevertheless, insofar as their concept of progress depended simply on an appeal to the character of scientific procedure, they cannot be said merely to have offered a secularized version of older religious beliefs in a heavenly city, and criticisms of them for having done so, which are standard in much of the literature related to the history of the idea of progress, are a source of considerable confusion.

To be sure, the theories of progress that were developed in the eighteenth and nineteenth centuries are often based on a combination of these two motifs. In Condorcet's thought, for example, there can be found Utopian as well as realistic formulations of the idea of progress. Nevertheless, it is a mistake, on the whole, to associate the idea—particularly as it arose in eighteenth-century France—with the naive hope that human beings and human society could be made perfect. If we study the specific predictions that Condorcet made with regard to the future of humanity, for example, we find that he pointed ahead, with extraordinary prescience, to what are now such commonplace facts as the lengthening of life expectancy, social insurance, and the guarantee of equal

legal rights to all citizens. Although none of these has brought the happiness and general reasonableness that Condorcet assumed they would, it was historical realism on his part, not juvenile innocence, to make such predictions. An inability to imagine the wretchedness of the past, not a cold, unillusioned understanding of the present, lies behind the failure to appreciate why reasonable men in the eighteenth and nineteenth centuries should have been rhapsodic about the possibility of changes in the human condition that, in the light of contemporary heightened expectations, may tend to appear fairly modest.

**SCIENTIFIC PROGRESS.** What can be said with regard to the validity of the idea of progress? We must first ask what meaning can be assigned to the notion of scientific progress.

One frequent argument against the validity of the belief in scientific progress is that it contains a self-contradiction. The belief that there is scientific progress is usually attached to the argument that science is continually self-corrective. But if science never does anything but correct itself, is there any sense in speaking of scientific progress? Does not the concept of progress presuppose a fixed end or standard, and does not science, at any rate as interpreted by those who emphasize its fallibilism, deny that there can be fixed ends or standards? *Progress*, in short, appears to be a term without meaning, according to this view, unless it can be attached to metaphysical standards, such as absolute truth, whose status is antecedent to science.

This view fails, however, once it is recognized that progress can also refer to the solution of particular problems, not only to the movement toward a general and abstract goal. For example, meaning can obviously be assigned to the statement that science has made progress in determining the causes of malaria or in describing the characteristics of the other side of the moon. Such statements mean that there are now answers to questions to which there were no answers before and that these answers are in accord with the procedures of inquiry in force among competent scientific investigators. Once scientific progress is defined in terms of the solutions to particular problems, sense can also be given to the notion of cumulative scientific progress, for the general scientific capacity to solve problems has also tended to grow.

Some doubt has been thrown on these conclusions, however, by recent philosophers of science. Karl Popper, for example, argued that scientific theories and hypotheses are never genuinely confirmed but at best succeed

only in resisting successive efforts to falsify them. Since the capacity of a scientific conclusion to survive a series of such efforts does not prove that it will always be able to do so, it would seem to make no sense to speak of successful or true solutions of scientific problems. Popper's view, however, seems to involve an unnecessarily paradoxical way of stating the truism that all scientific conclusions are subject to correction in the future. The survival of a scientific conclusion despite successive efforts to overthrow it adds to the degree of reliability that may reasonably be ascribed to it. It is just as possible to describe the critical position of scientists toward accepted conclusions as efforts to extend the range and reliability of these conclusions as it is to describe it as the expression of a compulsion to destroy what has been inherited. The accumulation of increasingly well-tested and continuously powerful ideas by the sciences is an obvious fact of their history, but as seen by Popper, it seems almost an accidental by-product.

Doubt has also been thrown on the belief in scientific progress by the view that the history of science is the record of revolutions in scientific theory so radical in character that it is impossible to establish the continuity between the ideas of one generation and the ideas of a later one. If this were true, it would be impossible a fortiori to establish a concept of progress, since such a concept presupposes a measure of continuity in the sequence of events under examination. Underlying this view is the thesis that the confirmation by experiment of particular hypotheses always entails the use of a specific theoretical framework. When this theoretical framework changes, observations are simply run through a different set of conceptual categories. Accordingly, it makes little sense, it is argued, to say that the sciences have improved or extended their knowledge, for all that has happened is that one body of beliefs has been substituted for another. This point of view raises epistemological and methodological questions of great complexity, and there is no room to discuss them sufficiently here. It appears to leave out of account, however, the consideration that, for example, fundamental principles of Newtonian physics can, with appropriate modifications, be absorbed into modern physical theories. It also appears to underestimate the implications of the fact that these principles, without substantial modification, continue to provide reliable instruments for the explanation and prediction of events in large sectors of macrophysics.

**SOCIAL AND MORAL PROGRESS.** Assuming that both meaning and truth can be assigned to the idea of progress in science, what is the status of the belief in social and

moral progress? Obviously, the answer to this question depends in part on the standards employed as the touchstones of progress. However, some of the difficulties involved in stating and defending such standards can be circumvented if in this sphere we also define progress in terms of the successful solution of specific problems. Thus, there has been striking progress in the control of disease, in methods of farming, in material productivity, in the reduction of backbreaking labor, in the techniques of rapid mass communication, in the spread of literacy, and probably in the reduction of the amount of violence in everyday life.

Of course, it is theoretically possible to hold a moral code from whose standpoint one or more of these historical trends would be regarded as retrogressive rather than progressive. In fact, however, even though members of different contemporary cultures (and members of the same culture) hold widely disparate moral outlooks, there are few informed and disinterested observers, whatever their moral outlooks, who regard any of these trends, considered in themselves, as movements in the wrong direction. And most would also look upon many other historical trends that have characterized the modern world—for example, the development of more humane attitudes in penology, the abolition of slavery and serfdom, the spread of the doctrine of basic human rights—in a similarly favorable light. To this extent it is possible to speak with a measure of precision and truth of social and moral progress.

But this answer, of course, goes only part of the way. On at least two scores it is incomplete. First, it is reasonable to ask whether the gains that have been mentioned have not been bought at a cost that more than cancels them out; second, it is possible to ask how we are to vindicate the moral principles in terms of which we assess these gains as gains.

*The cost of progress.* It is not possible, of course, to give a wholly unequivocal answer to the question of the cost of progress. The notion that large-scale historical trends can be neatly categorized as good or bad belongs to eschatology, not to mature historical analysis. If the reduction of civil violence, considered in itself, is a progressive trend, contemporary mass warfare and genocide must be considered retrogressive; if rapid mass communication is a benefit to humankind, the use of the facilities of communication for totalitarian thought control is a calamity. Moreover, the successful solution of many problems often creates new and more difficult ones. The control of disease, for example, has created a serious threat of overpopulation. And by what calculus can one

measure the gains brought about, for example, by industrial innovations against the losses brought about by mass warfare or cyclical unemployment? A moral accounting system for judging even much simpler matters than these does not exist.

Nevertheless, if the span of time we measure is sufficiently long, it remains true that on the whole the physical lot of most ordinary people has considerably improved in modern societies and that this has largely been due to the application of rational techniques to the economy. The cost has been grievous, and many of the sacrifices this progress has entailed could probably have been avoided if people had employed reasonable forethought and had shown reasonable respect for the equities. Admittedly, too, it is difficult to say whether this physical progress has made individuals “happier”; indeed, it is doubly difficult to say this, for “happiness” is in part a function of what people expect, and physical progress has meant an enormous expansion of their expectations. Nevertheless, it is doubtful that most of those who put forward the view that the costs of material progress outweigh the benefits would willingly exchange places with any but the most privileged members of past societies if they actually had the chance.

Nor must we confine ourselves to a belief in purely physical or material progress. The role of fantasy, ignorance, superstition, and fanaticism in determining the world’s affairs continues to be enormous. It is doubtful, however, whether so many members of human societies, from housewives to statesmen, have ever before thought it reasonable to make decisions on the basis of carefully acquired and sifted information, and never before have societies possessed as much knowledge about themselves and their workings as they do now, shaky and scattered though that knowledge is. Only if one thinks it morally dangerous to seek reliable information before making decisions or thinks it mistaken to try to employ rational methods in the study of human affairs can he declare such long-range social trends to be anything but progressive. Indeed, the very reason that the members of an educated modern society bear a particularly heavy burden of responsibility for the emergence of doctrines such as Nazism is that they have opportunities to be informed and judicious which members of other societies did not have. In sum, although it is not possible to say in wholesale terms that there has been moral progress, it is possible to assert that the context of human behavior has changed and that the collective capacity to achieve human purposes, whether good or ill, has enormously increased. The expectations that it is reasonable to

impose on modern social arrangements are therefore justifiably higher than those that may have been reasonable in the past. In this modified but important sense it is fair to speak of moral progress.

**Justification of moral standards.** All the preceding reflections, however, obviously presuppose the validity of a secular, liberal, and rationalistic moral code. In the end, as must be obvious, objections to the idea of progress usually turn on fundamental differences in values. Whether the validity of one fundamental moral outlook as against another can be demonstratively proved is an issue that falls beyond the scope of the present article. If we assume, however, that we cannot resolve these differences in a way that will satisfy traditional standards of demonstrative certainty, there is no so-called ultimate answer to the question of whether modern society has been the scene of genuine progress.

It is possible, however, to show that a relativistic moral philosophy is perfectly compatible with a belief in progress, for it is not true that a relativistic philosophy cannot make any meaningful statements about progress because it has to grant that there are different moral standards and that all are equally valid. First, even if there is no way of proving the absolute validity of a moral outlook, there is still a way of intelligently and objectively assessing its credentials. The moral ideals that underlie the indictment of modern civilization for its excessive individualism and egalitarianism made by T. S. Eliot, for example, would require, if they were to be seriously employed as positive programs for action, the dismantling of large segments of industrial society. Since we may assume that those who put forward such criticisms would wish medical science to continue its work, for example, and would accept a world population at something like its present size, we must conclude that their announced preferences are both unrealistic and incoherent because they are incompatible with other values that they also hold. An examination of available resources, of the costs of maintaining or instituting alternative systems of values, and of the utility of these systems as guides to the resolution of definite historical problems provides a way of choosing among competing moral outlooks and makes the choice something more than a matter of personal whim or social convention.

Second, although the philosophical relativist may believe that apart from the specification of definite problems in determinate historical contexts, there is no way of showing that a moral code is valid, this does not mean that he does not himself hold any moral standards or that he is any less attached to them than an absolutist would

be. A twenty-first-century American looking at slavery in ancient Rome, for example, will regard it as a change for the better that slavery is now illegal in Western society, and he will do so whether or not he is a relativist. And to say that he might feel different if he were a Roman is irrelevant, for he is a twenty-first-century American, not a Roman, and it would be a different person with a different identity, not he, who felt different in the hypothetical circumstances. Similarly, if the standards of people in the future change, they may well disagree with us in regard to what has been progressive in history. But if these future judgments reverse present judgments, that does not bind a relativist living here and now to accept them. Nothing in his position requires him to say that progress is any historical trend that comes to be thought desirable.

**Progress as a moral standard.** As a final consideration, it is important to recognize that the idea of progress in its most important aspect is itself a regulative moral ideal, not simply a belief about history. It represents a directing principle of intellectual and social action, instructing human beings to regard all social arrangements with a critical eye and to reject any claim that any human problem has been finally solved or must be left finally unsolved. To the extent that this idea of progress is embodied in moral codes and social systems, these codes and systems will contain deliberate provision for self-reform. The idea of progress thus represents the social application of the principle that inquiry should be kept open and that no bounds can legitimately be set to the authority of such free inquiry. As such, it would appear to be an indispensable belief for a fully liberal civilization.

## PROJECTIVISM

"Projectivism" has its roots in David Hume's remark in the *Treatise* about the mind's "propensity to spread itself

over external objects." We sometimes speak of properties of objects where in fact the features we notice are "projections" of our internal sentiments (or other qualities of our experience). The family of metaethical views claiming that value is a projection of our conative and affective physiological states is called projectivism by Simon Blackburn (1984), and the name has stuck. Blackburn proposes that "we say that [we] *project* an attitude or habit or other commitment which is not descriptive onto the world, when we speak and think as though there were a property of things which our sayings describe, which we can reason about, know about, be wrong about, and so on" (1984, pp. 170–171). In ethics projectivism is popular because it provides an explanation of how it is that moral judgment can have the logical role that it seems to have in deciding what to do. Believing that something has some property typically provides me with a reason to act only in conjunction with the desire to promote (or oppose) the realization of that property. But believing that something is good is (or has been taken historically to be) sufficient by itself to provide a person with a reason to act. Nor is this a coincidence; it is not that we humans happen to like good things, as we happen to like to eat sugary things. Rather, it is part of the logic of judgments of goodness that they provide reasons. How can this be? Projectivists explain: the judgment that something is good is the projection of our affinity toward it, our "appetite," as Thomas Hobbes puts it.

There are three varieties of projectivism to distinguish. The most straightforward is the error theory, advanced by J. L. Mackie (1977, see also Robinson 1948), according to which our projection of value into the world is an illusion. Ordinary moral judgments presuppose an objectivity or independence of moral properties that is simply not to be had, and so they are in error. Mackie sees moral thought and language much as an atheist sees religious talk and language. The believers are not conceptually confused, but they are ontologically mistaken. The second sort of projectivism regards moral properties as Lockean "secondary qualities," not illusions, but real properties that consist in dispositions to affect human perceivers in certain ways. According to John MacDowell (1987), a leading exponent, just as we do not understand what the blueness of an object is except as the disposition to look blue to us, so we do not understand what goodness is except as the disposition to seem good to us. The projection involved in attribution of secondary qualities, including values, involves no error at all.

A third sort of projectivism is noncognitivism, or as it is more commonly called in discussions of projec-

tivism, expressivism. The expressivist holds that moral judgments do not state propositions at all but rather serve to express some noncognitive mental state of the judge. Like secondary-quality theorists, expressivists deny that there is any mistake involved in moral judgment; true, there are no moral properties, and we speak as though there are, but this “speaking as though” is just a misleading feature of the surface grammar. In fact, according to expressivists, moral judgments do not serve the same semantic function as most declarative sentences, even though they look the same.

Blackburn’s projectivist position (the most influential one of the 1980s) develops an expressivist analysis of moral language with enough logical richness and complexity to model real moral deliberation and argument. His idea is easier to make out against the background of common criticisms of expressivism. Richard Brandt (1959), among others, noted that people’s ordinary thinking about moral judgments runs contrary to expressivism. We have generally believed that normative judgments are used to state facts, that they are true or false, and when we change our moral views we come to regard our earlier views as mistaken, not merely as different. (By contrast, when one’s taste in dessert changes, one generally regards the old preference as merely different or, at worst, childish.) Brandt complained that expressivists had given no explanation of why we are so confused. Blackburn’s theory is designed to meet such objections. While maintaining an underlying expressivist semantics, he tries to show why we speak and think as though moral judgments state facts, can be true or false, and so on.

Imagine that people initially spoke about ethics in a language like English but having a quite explicitly expressivist structure. Rather than saying, “Voting for this health-care bill is morally wrong,” they said, “Boo, voting for this health-care bill!” Now imagine that these speakers valued a kind of consistency of sentiment, so that it was regarded as a confusion if someone said, “Boo, eating mammals, and hooray, eating cows!” And suppose they also believed that some moral sensibilities could never survive reflection by a rational person, so that expressing one of those sensibilities would be conclusive evidence that the speaker simply had not thought carefully about the subject. The expressivist community might “invent a predicate answering to that attitude, and treat commitments as if they were judgments, and then use all the natural devices for debating truth” (Blackburn 1984, p. 195). Since Blackburn’s theory seeks to defend realist-style reasoning without realist metaphysics, he calls it “quasi-realism.”

An important objection to Blackburn’s quasi-realism is made by Crispin Wright (1988) and Bob Hale (1990). Our moral language has a realist surface structure, and quasi-realism seeks to vindicate this structure without giving in to realist metaphysics. But if quasi-realism is successful—if every realist-sounding thing we say can be endorsed in good faith by the quasi-realist—then how will a quasi-realist be distinguishable from a full-blooded realist? As Wright puts it, Blackburn’s program confronts a dilemma: Either it does not account for all the realist logical features of moral language, in which case it fails, or it succeeds in accounting for all of them, “in which case it makes good all the things which the projectivist started out wanting to deny: that the discourse in question is genuinely assertoric, aimed at truth, and so on” (1988, p. 35).

Despite these difficulties, projectivism deserves to be taken seriously, not just in the metaphysics of value, but in other metaphysical domains as well. For example, there have been projectivists about mental states (Dennett 1987—judging that someone has intentional states is taking “the intentional stance” toward the person), causes (saying that one event caused another is projecting one’s psychological propensity to associate events of the first kind with events of the second in temporal sequence), probability (Finetti 1972—judgments of probability project one’s degree of credence into the world), and logical impossibility (Blackburn 1984—projecting a certain kind of inconceivability). With the exception of the first, all of these sorts of projectivism are plausibly attributed to Hume, who should be regarded as the prototype projectivist.

## PROMISES

Promising is a device for obligating oneself. In a culture in which promising is available, people have a normative power that they would lack in the absence of this institution. By exercising this power—standardly through the utterance of a linguistic formula—one can bring about changes in the expectations of others in ways that enhance one's ability to pursue their goals and that foster relations of familiarity and trust.

The existence of a normative power of this kind seems philosophically puzzling: How can the utterance of a linguistic formula cause a change in the normative relations that obtain in the world? In response to this question, it might help to situate promising within the general theory of speech acts, noting that it is one of a range of illocutionary acts that may be performed with words (to be set aside such acts as asserting or commanding). In addition, one might point to the conventional aspect of promising, observing that it is a contingent social practice, sustained by interlocking sets of human dispositions, expectations, and sanctions, which enables people to coordinate their behavior in ways that promote the common good. An analogy might be to the institution of contract in the law.

But there is a normative complexity to promises that these remarks fail to capture. Agents who make a promise incur a distinctively moral obligation, opening themselves to corresponding moral complaint if they should

fail to do what they have promised. Moreover this moral dimension seems crucial to the ordinary operation of promises. Promises serve to assure the promisee that something the promisee values will in fact take place—this is one way in which they differ from threats. But they achieve this effect through the promiser's implicit acknowledgement of the moral obligation that is brought into existence by the act of promising itself. Promisers give promisees to understand that they have a distinctively moral reason to do what has been promised, a reason that is strong enough to lead to performance even in the absence of independent reasons for so acting. This in turn grounds the promisee's assurance that the promised performance will take place. What accounts for the moral obligation that thus figures at the center of promissory interactions?

One answer to this question stresses the value to the agent of the normative power involved in promising. The ability to obligate oneself is a great advantage when it comes to pursuing one's projects and developing interpersonal relationships of depth and commitment. One would potentially deprive oneself of this advantageous capacity if one failed to do what one had promised, insofar as people would be less inclined to take one's promissory acts seriously. It may be doubted, however, whether this approach provides a complete account of the moral obligations brought into existence through promising. One issue is the directionality of promissory obligations. The normative powers approach focuses on the moral importance to the promiser of the ability to obligate oneself in this way. But when one fails to do what they have promised, the moral objection to their conduct turns primarily on the effects of their behavior on others.

This dimension of promissory obligations is central to a second approach, the practice view. On this view, the moral wrong involved in promise-breaking derives from the nature of promising as a valuable convention. This basic idea might be developed in a variety of ways, depending on the more general moral theory one favors. Thus, utilitarians invoke the duty to promote the impartial good, arguing that it is a violation of that duty to act in ways that undermine a highly beneficial social practice such as promising. Other theorists appeal to the idea of fairness, contending that it would be unfair to fail to do one's part to sustain a beneficial practice that one has profited from oneself. The moral duty that promising brings into existence is thus traced to fundamental social duties, in accordance with moral principles of utility or fairness.

There are two potential problems with this approach, however. First, it still does not capture the specific directionality of the moral duty involved in promissory acts. On the practice view, everyone who potentially benefits from the useful convention of promising could equally be said to be wronged when a person breaks a promise. Intuitively, however, it appears that the promisee, in particular, has a privileged ground for moral complaint. Second, it would seem possible to wrong another person in precisely the same way without exploiting a social practice such as promising. Thus, even in the absence of a promise A might deliberately lead B to believe that A will do X, where X is something A knows B wants A to do. Under these circumstances, A's failure to do X would appear to wrong B in just the same way a broken promise would have done. Yet this wrong cannot be explained by appeal to more general duties to sustain beneficial practices.

A third approach, the fidelity view, holds that promissory obligations derive from more general duties not to disappoint the expectations one has deliberately raised in others. This approach accounts well for the specific directionality of promissory obligations, and it does so in a way that explains the similarities between breaking a promise and other cases of dashed expectations. But the fidelity view encounters a different problem. It holds that the moral duty to keep one's promise is in place only when the promisee has come to expect that the promiser will perform. But as was seen above, in the promising case this kind of expectation is supposed to derive from the promiser's acknowledgement of the moral obligation to perform. There is thus a potential circularity in the interpretation of promissory interactions that is suggested by the fidelity view.

Much of the philosophical interest of promises derives from their normative complexity. An account that is adequate to this complexity might need to draw on several of the strategies sketched above, in a kind of hybrid approach. For instance, the practice view might explain how the act of promising brings into existence an initial moral obligation that is independent of the promisee's expectations. Perhaps it is the promiser's acknowledgement of this practice-based obligation that generates a corresponding expectation in the promisee. Once such an expectation is in place, the fidelity view could explain why promisers incur a further and specifically directional obligation to perform. Finally, the normative powers approach illuminates the value of the social practice of promising, highlighting the advantages gained from having the ability to obligate oneself through promissory acts.

## PROOF THEORY

The background to the development of "proof theory" since 1960 is contained in the entry "Mathematics, Foundations of." Briefly, Hilbert's program (HP), inaugurated in the 1920s, aimed to secure the foundations of mathematics by giving finitary consistency proofs of formal systems such as for number theory, analysis, and set theory, in which informal mathematics can be represented directly. These systems are based on classical logic and implicitly or explicitly depend on the assumption of "completed infinite" totalities. Consistency of a system S (containing a modicum of elementary number theory) is sufficient to ensure that any finitarily meaningful statement about the natural numbers that is provable in S is correct under the intended interpretation. Thus, in David Hilbert's view, consistency of S would serve to eliminate the "completed infinite" in favor of the "potential infinite" and thus secure the body of mathematics represented in S. Hilbert established the subject of proof theory as a technical part of mathematical logic by means of which his program was to be carried out; its methods are described below.

In 1931 Kurt Gödel's second incompleteness theorem raised a *prima facie* obstacle to HP for the system Z of elementary number theory (also called Peano arithmetic—PA) since all previously recognized forms of finitary reasoning could be formalized within it. In any case Hilbert's program could not possibly succeed for any system such as set theory in which *all* finitary notions and reasoning could unquestionably be formalized. These obstacles led workers in proof theory to modify HP in two ways. The first was to seek reductions of various formal systems S to more constructive systems S'. The second was to shift the aims from foundational ones to more mathematical ones. Examples of the first modification are the reductions of PA to intuitionistic arithmetic HA and Gentzen's consistency proof of PA by finitary reasoning coupled with quantifier-free transfinite induction up to the ordinal  $\epsilon_0$ ,  $TI(\epsilon_0)$ , both obtained in the 1930s. The second modification of proof theory was promoted especially by Georg Kreisel starting in the early 1950s; he showed how constructive mathematical information could be extracted from nonconstructive proofs in number theory. The pursuit of proof theory along the first of these lines has come to be called relativized Hilbert program or reductive proof theory, while that along the second line is sometimes called the program of unwinding proofs or, perhaps better, extractive proof theory. In recent years there have been a number of applications of the latter both in mathematics and in theoretical computer science. Keeping the philosophical relevance and limitations of space in mind, the following account is devoted entirely to developments in reductive proof theory, though the two sides of the subject often go hand in hand.

## METHODS OF FINITARY PROOF THEORY

Hilbert introduced a special formalism called the epsilon calculus to carry out his program (the nomenclature is related neither to the ordinal  $\epsilon_0$  nor to the membership symbol in set theory), and he proposed a particular substitution method for that calculus. Following Hilbert's suggestions, Wilhelm Ackermann and John von Neumann obtained the first significant results in finitary proof theory in the 1920s. Then, in 1930, another result of the same character for more usual logical formalisms was obtained by Jacques Herbrand, but there were troublesome aspects of his work. In 1934 Gerhard Gentzen introduced new systems, the so-called sequent calculi, to provide a very clear and technically manageable vehicle for proof theory, and reobtained Herbrand's fundamen-

tal theorem via his cut-elimination theorem. Roughly speaking, the latter tells us that every proof of a statement in quantificational logic can be normalized to a direct proof in which there are no detours ("cuts") at any stage via formulas of a complexity higher than what appears at later stages. Sequents have the form  $\Gamma \rightarrow \Delta$ , where  $\Gamma$  and  $\Delta$  are finite sequences of formulas (possibly empty).  $\Gamma \rightarrow \Delta$  is derivable in Gentzen's calculus LK just in case the formula  $A \supset B$  is derivable in one of the usual calculi for classical predicate logic, where A is the conjunction of formulas in  $\Gamma$  and B is the disjunction of those in  $\Delta$ .

## INTRODUCTION OF INFINITARY METHODS TO PROOF THEORY

Gentzen's theorem as it stood could not be used to establish the consistency of PA, where the scheme of induction resists a purely logical treatment, and for this reason he was forced to employ a partial cut-elimination argument whose termination was guaranteed by the principle  $TI(\epsilon_0)$ . Beginning in the 1950s, Paul Lorenzen and then, much more extensively, Kurt Schütte began to employ certain infinitary extensions of Gentzen's calculi (cf. Schütte, 1960, 1977). This was done first of all for elementary number theory by replacing the usual rule of universal generalization by the so-called  $\omega$ -rule, in the form: from  $\Gamma \rightarrow \Delta, A(n)$  for each  $n = 0, 1, 2, \dots$ , infer  $\Gamma \rightarrow \Delta, (x)A(x)$ . Now derivations are well-founded trees (whose tips are the axioms  $A \rightarrow A$ ), and each such is assigned an ordinal as length in a natural way. For this calculus  $LK_\omega$ , one has a full cut-elimination theorem, and every derivation of a statement in PA can be transformed into a cut-free derivation of the same in  $LK_\omega$  whose length is less than  $\epsilon_0$ . Though infinite, the derivation trees involved are recursive and can be described finitarily, to yield another consistency proof of PA by  $TI(\epsilon_0)$ . Schütte extended these methods to systems  $RA_\alpha$  of ramified analysis ( $\alpha$  an ordinal) in which existence of sets is posited at finite and transfinite levels up to  $\alpha$ , referring at each stage only to sets introduced at lower levels. Using a suitable extension of  $LK_\omega$  to  $RA_\omega$ , Schütte obtained cut-elimination theorems giving natural ordinal bounds for cut-free derivations in terms of the so-called Veblen hierarchy of ordinal functions. In 1963 he and Solomon Feferman independently used this to characterize (in that hierarchy) the ordinal of predicative analysis, defined as the first  $\alpha$  for which  $TI(\alpha)$  cannot be justified in a system  $RA_\beta$  for  $\beta < \alpha$ . William Tait (1968) obtained a uniform treatment of arithmetic, ramified analysis, and related unramified systems by means of the cut-elimination theorem for LK extended to a language with formulas built

by countably infinite conjunctions (with the other connectives as usual). Here the appropriate new rule of inference is: from  $\Gamma \rightarrow \Delta, A_n$ , for each  $n = 0, 1, 2, \dots$ , infer  $\Gamma \rightarrow \Delta, A$ , where  $A$  is the conjunction of all the  $A_n$ 's.

Brief mention should also be made of the extensions of the other methods of proof theory mentioned above, concentrating on elimination of quantifiers rather than cut elimination. In the 1960s Burton Dreben and his students corrected and extended the Herbrand approach (cf. Dreben and Denton, 1970). Tait (1965) made useful conceptual reformulations of Hilbert's substitution method; a number of applications of this method to subsystems of analysis have been obtained in the 1990s by Grigori Mints (1994). Another approach stems from Gödel's functional interpretation, first presented in a lecture in 1941 but not published until 1958 in the journal *Dialectica*; besides the advances with this made by Clifford Spector in 1962, more recently there have been a number of further applications both to subsystems of arithmetic and to subsystems of analysis (cf. Feferman 1993). Finally, mention should be made of the work of Dag Prawitz (1965) on systems of natural deduction, which had also been introduced by Gentzen in 1934 but not further pursued by him; for these a process of normalization takes the place of cut elimination. While each of these other methods has its distinctive merits and advantages, it is the methods of sequent calculi in various finitary and infinitary forms that have received the most widespread use.

## PROOF THEORY OF IMPREDICATIVE SYSTEMS

The proof theory of impredicative systems of analysis was initiated by Gaisi Takeuti in the 1960s. He used partial cut-elimination results and established termination by reference to certain well-founded systems of ordinal diagrams (cf. Takeuti 1987). In 1972 William Howard determined the ordinal of a system  $ID_1$  of one arithmetical inductive definition, in the so-called Bachmann hierarchy of ordinal functions; the novel aspect of this was that it makes use of a name for the first uncountable ordinal in order to produce the countable (and in fact recursive) ordinal of  $ID_1$ . In a series of contributions by Harvey Friedman, Tait, Feferman, Wolfram Pohlers, Wilfried Buchholz, and Wilfried Sieg stretching from 1967 into the 1980s, the proof theory of systems of iterated inductive definitions  $ID_\alpha$  and related impredicative subsystems of analysis was advanced substantially. The proof-theoretic ordinals of the  $ID_\alpha$  were established by Pohlers in terms of higher Bachmann ordinal function systems (cf. Buchholz et al. 1981). The methods here use cut-elimination

arguments for extensions of LK involving formulas built by countably and uncountably long conjunctions. In addition, novel "collapsing" arguments are employed to show how to collapse suitable uncountably long derivations to countable ones in order to obtain the countable (again recursive) ordinal bounds for these systems. An alternative functorial approach to the treatment of iterated inductive definitions was pioneered by Jean-Yves Girard (1985).

In 1982 Gerhard Jäger initiated the use of the so-called admissible fragments of Zermelo-Fraenkel set theory as an illuminating tool in the proof theory of predicatively reducible systems (cf. Jäger 1986). This was extended by Jäger and Pohlers (1982) to yield the proof-theoretical ordinal of a strong impredicative system of analysis; that makes *prima facie* use of the name of the first (recursively) inaccessible ordinal. Michael Rathjen (1994) has gone beyond this to measure the ordinals of much stronger systems of analysis and set theory in terms of systems of recursive ordinal notations involving the names of very large (recursively) inaccessible ordinals, analogous to the so-called large cardinals in set theory.

## SIGNIFICANCE OF THE WORK FOR HP AND REDUCTIVE PROOF THEORY

Ironically for the starting point with Hilbert's aims to eliminate the "completed infinite" from the foundations of mathematics, these developments have required the use of highly infinitary concepts and objects to explain the proof-theoretical transformations involved in an understandable way. It is true that in the end these can be explained away in terms of transfinite induction applied to suitable recursive ordinal notation systems. Even so, one finds few who believe that one's confidence in the consistency of the systems of analysis and set theory that have been dealt with so far has been increased as a result of this body of work. However, while the intrinsic significance of the determination of the proof-theoretic ordinals of such systems has not been established, that work can still serve behind the scenes as a tool in reductive proof theory. It is argued in Feferman (1988) that one has obtained thereby foundationally significant reductions, for example of various (*prima facie*) infinitary systems to finitary ones, impredicative to predicative ones, and nonconstructive to constructive ones. With a field that is still evolving at the time of writing, it is premature to try to arrive at more lasting judgments of its permanent value.

## PROPER NAMES AND DESCRIPTIONS

A *singular term* is an expression whose semantic function, when used in a particular context, is to *refer to* (denote, designate)—that is, to stand for—a single thing. A *definite description* is a singular noun phrase beginning with the definite article "the" or with a possessive noun or pronoun, as "the author of *Waverley*" and "my brilliant career." Proper names, such as "Shakespeare" and "London," are generally classified along with definite descriptions, individual variables, pronouns, and some other indexicals as singular terms. A French speaker who utters the words "*Londres est jolie*" asserts the same thing as an English speaker uttering "London is pretty." The thing asserted is a *proposition*, that London is pretty. The fundamental semantic role of a declarative sentence is to *express* (or to *contain*) a proposition (*q.v.*), which is the *semantic content* of the sentence. The proposition that Sir Walter Scott is ingenious has some component in common with the proposition that Scott is ingenuous, because both of these are directly about Scott, and some other component again in common with the proposition that Shakespeare is ingenious. These two proposition components are separately correlated with the proper name "Scott" and the predicate "is ingenious." The proposition component semantically correlated with an expression is the expression's *semantic content*. The principal philosophical controversy regarding proper names (and other singular terms) concerns the question: What are their semantic contents? The theories of John Stuart Mill (1806–1873), Bertrand Russell (1872–1970), and Gottlob Frege (1848–1925) provide rival answers.

## 1. THE NAIVE THEORY AND THE MILLIAN THEORY

One natural theory of semantic content is the naive theory, whose main theses are: (i) the semantic content of any singular term, as used in particular context, is its referent (bearer; the individual referred to); (ii) any semantically contentful expression refers to its semantic content; and (iii) the proposition semantically contained in a sentence is a complex, structured entity whose constituents are the semantic contents of expressions making up the sentence, typically the simple (noncompound) component expressions. (The theory may allow particular sorts of exceptions, as for example those generated by the use of quotation marks.) On the naive theory the proposition contained in “Shakespeare is ingenious” is a *singular proposition*—composed partly of things such as properties, relations, and concepts, and partly of the very individual(s) the proposition is about. By contrast, a (*purely*) *general proposition* is made up exclusively in a certain way of the former sorts of entities. On the naive theory, semantic content and reference collapse into one.

Definite descriptions pose a difficulty for the naive theory because they contain proper parts with semantic content. In *A System of Logic* (1893), Mill proffered a variant of the naive theory on which the proposition contained in “The author of *Waverley* is ingenious” is composed of something involving the attribute of authorship of *Waverley* in place of Scott himself. Mill distinguished between *denotation* (referent) and *connotation*. A general term (“concrete general name”) was said by Mill to “denote” the class of individuals to which the term applies. Mill used the term “connotation” for a semantic content consisting of attributes or properties. General terms were held to have both denotation and connotation. According to Mill, definite descriptions also have both connotation and (typically) denotation, whereas proper names have only denotation. Mill’s theory strongly suggests a systematic modification of the naive theory. The central theses of the Millian theory are: (i) the semantic content of any *simple* (noncompound) singular term is its referent; (ii) any expression refers to its extension; and (iii) the semantic content of a typical contentful compound expression (e.g., a definite description) is a composite entity whose constituents are the semantic contents of expressions making up the compound expression, typically the simple component expressions. (Mill’s actual theory was somewhat more complex, but also somewhat less plausible.)

## 2. THE PUZZLES

The naive and the Millian theories give rise to philosophical puzzles concerning substitution and nonreferring names. Frege’s puzzle arises from certain sentences, especially identity sentences. The sentence “Hesperus is Phosphorus” (or “The Evening Star is The Morning Star”), by contrast with “Hesperus is Hesperus,” is informative. Its semantic content apparently extends knowledge. It is also a posteriori and synthetic. Yet according to both the naive theory and the Millian theory, the semantic contents of both sentences are composed of the same components, evidently in precisely the same way. Those theories thus ascribe the same semantic content to both sentences. In his early work, *Begriffsschrift* (1972 [1879], §8), Frege proposed solving this puzzle by reading the predicate for numerical identity as covertly metalinguistic: It was held that “Hesperus is Phosphorus” contains a substantive proposition concerning the names “Hesperus” and “Phosphorus,” to the effect that they are co-referential. There are serious difficulties with this account, however, and Frege came to reject it. Most significantly, the account fails to solve the general problem of which “Hesperus is Phosphorus” is a special case. Unless the theory is part of a more sweeping proposal concerning all expressions and not just that of identity predicates, there is no explanation for the analogous difference in epistemic and semantic status between “Hesperus is a planet if Phosphorus is” (synthetic *a posteriori*) and “Hesperus is a planet if Hesperus is” (analytic *a priori*).

A second puzzle is the apparent failure of substitution in special contexts, especially those of propositional attitude. Jones may sincerely and reflectively assent to “Hesperus appears in the evening sky” and sincerely and reflectively dissent from “Phosphorus appears in the evening sky,” even while fully grasping their semantic content. This appears to violate the classical logical rule of Leibniz’s law, or the substitutivity of equality. Both the naive theory and the Millian theory treat “Jones believes that Hesperus appears in the evening” and its substitution instance “Jones believes that Phosphorus appears in the evening” as having the same content, and therefore also the same truth-value.

A further nest of problems concerns sentences involving nonreferring proper names. The sentence “Sherlock Holmes is addicted to cocaine” clearly has content. Yet on both the naive theory and the Millian theory, the semantic content of any sentence will lack a necessary component if any contained name lacks a referent. It is evident, moreover, that this sentence (taken as a statement of real fact, rather than as a statement made from

within the fiction) cannot be counted literally true. But, it seems, neither can its negation—“Sherlock Holmes is not addicted to cocaine”—be truly uttered. This seems to violate the classical law of excluded middle. These puzzles are especially pressing with regard to negative existentials, such as “Sherlock Holmes does not exist.” This sentence is true if and only if “Sherlock Holmes exists” is false, and therefore, it would seem, if and only if the referent of “Sherlock Holmes” lacks existence. Yet the negative existential itself implies that the name does not so much as have a referent. How, then, can it be true? Indeed, how can it have any content at all?

### 3. RUSSELL’S THEORY OF DESCRIPTIONS

Russell’s semantic theory (post-1904) is a supplement to the naive theory. Russell employed *propositional functions* in lieu of attributes. A propositional function assigns to any objects in its domain a singular proposition concerning those objects. Russell’s general theory of descriptions, or of what he called “denoting phrases,” consisting of a noun phrase preceded by a determiner such as “all” or “some,” assigns a content to sentences in which they figure while denying that the determiner phrases themselves are meaningful units. The theory analyzes sentences of both the Aristotelian *A* form, “ $\Pi(\text{all } S)$ ” (e.g., “All millionaires are wealthy”), and the *I* form, “ $\Pi(\text{some } S)$ ,” where  $\Pi$  is a monadic predicate. (More generally,  $\Pi$  may be the result of filling all but one of the argument positions of an  $n$ -adic predicate,  $n \geq 1$ .) The *A* form is analyzed as “For everything  $x$ , if  $x$  is a  $S$ , then  $\Pi(x)$ ”—more colloquially as, “Everything is such that: if it is a  $S$ , then  $\Pi(\text{it})$ ” (“Everything is, if a millionaire, then wealthy”). The complex predicate “is such that: if it is a  $S$ , then  $\Pi(\text{it})$ ” stands for a certain propositional function, whereas the quantifier “everything” stands for a higher-level propositional function, which assigns to any first-level propositional function,  $F$ , the proposition that  $F$  is “always true”—that is, the proposition that  $F$  yields a true proposition for each and every argument.

Russell analyzed “ $\Pi(\text{some } S)$ ” as “Something is such that: it is a  $S$  and  $\Pi(\text{it})$ ”—wherein the complex predicate “is such that: it is a  $S$  and  $\Pi(\text{it})$ ” stands for a certain propositional function said to be “sometimes true”—that is, to yield a true proposition for at least one argument. An English phrase of the form “all  $S$ ” thus corresponds to the incomplete string, “everything is such that: if it is a  $S$ , then it ...,” and a phrase of the form “some  $S$ ” corresponds to the incomplete string, “something is such that: it is a  $S$  and it....” Russell called phrases of either form

*incomplete symbols*. The sentences in which such phrases figure have content, though the phrase, in and of itself, does not contribute a proposition-component to the proposition expressed. As Russell put it in “On Denoting,” “denoting phrases have no meaning in isolation.”

The introduction of a quantifier (“everything,” “something”) into the analysis gives rise to ambiguities analogous to that of “every boy kissed a girl” when the simple Aristotelian sentential form occurs within the scope of a governing operator, such as “not,” “necessarily,” or “Jones believes.” Thus, on Russell’s general theory of descriptions, a sentence of the form “not  $\Pi(\text{all } S)$ ” (e.g., “All millionaires are not wealthy”) may be analyzed by giving the indefinite description “all  $S$ ” *primary occurrence* (over “not”), yielding: “Everything is such that: if it is a  $S$ , then not- $\Pi(\text{it})$ .” This reading is equivalent to the Aristotelian *E* form, “ $\Pi(\text{no } S)$ .” Alternatively, and nonequivalently, “not  $\Pi(\text{all } S)$ ” may be analyzed by giving the phrase “all  $S$ ” *secondary occurrence*, yielding the reading, “Not everything is such that: if it is a  $S$ , then  $\Pi(\text{it})$ .” (The latter analysis—equivalent to the Aristotelian *E* form—is obtained by letting the negation in “not  $\Pi(\text{all } S)$ ” govern the entire *A* form, not just its predicate  $\Pi$ .) Similarly, “Jones believes  $\Pi(\text{some } S)$ ” may be analyzed as “Something is such that: it is  $S$  and Jones believes that  $\Pi(\text{it})$ ” (primary occurrence), or alternatively, and nonequivalently, as “Jones believes: that  $\Pi(\text{some } S)$ ” (secondary).

In most cases, only one of the two readings is plausibly intended (as with “Jones believes some husbands are bachelors”). If the simple Aristotelian *A* or *I* form occurs with two or more governing operators, the number of readings is compounded. For example, “Jones believes some millionaires are not wealthy” may be analyzed alternatively, and nonequivalently, as: (i) “Someone is a millionaire and Jones believes he/she is not wealthy” (*wide scope*); (ii) “Jones believes: that someone is both a millionaire and not wealthy” (*intermediate scope*); or (iii) “Jones believes: that no one is both a millionaire and wealthy” (*narrow scope*).

The central tenet of Russell’s theory of definite descriptions is that a description such as “the author of *Waverley*” (used in the sense of “the sole author of *Waverley*”) is semantically equivalent to the corresponding uniqueness-restricted existential quantifier “some unique author of *Waverley*,” in the sense of “something such that it, and nothing else, wrote *Waverley*.” The restricted quantifier falls under the purview of Russell’s general theory of descriptions. On Russell’s theory, then, “the author of *Waverley*” corresponds to the string “Someone is such that: he or she uniquely wrote *Waverley* and he or

she ... ,” making definite descriptions also “incomplete symbols” which have “no meaning in isolation.” The words “The author of *Waverley* is ingenious” are not directly about Walter Scott, but about the complex propositional function, *being a unique author of Waverley who is also ingenious*, expressing that this function yields a true proposition for at least one individual. There is nothing that the phrase “the author of *Waverley*” contributes on its own to this proposition.

As with “some S,” sentences that position a definite description within governing operators yield multiple readings. For example, “Jones believes the author of *Waverley* is not ingenious” may be analyzed alternatively, and nonequivalently, as: (i) “Someone uniquely wrote *Waverley* and Jones believes he is not ingenious”—that is, Jones believes of *Waverley*’s sole author that *he* is not ingenious (*wide scope*); (ii) “Jones believes: that someone both uniquely wrote *Waverley* and is not ingenious”—that is, Jones believes that whoever wrote *Waverley* single-handedly is not ingenious (*intermediate scope*); or (iii) “Jones believes: that no one both uniquely wrote *Waverley* and is ingenious” (*narrow scope*). The wide-scope reading is consistent with Jones’s belief not involving a conception of Scott as sole author of *Waverley*. The narrow-scope reading attributes a belief that is consistent with *Waverley* not having a sole author.

A definite description is said to be *proper* when there is someone or something that uniquely answers to the description, and is *improper* otherwise. Russell artificially, and misleadingly, extended Mill’s term “denotation” to the semantic relation that obtains between a proper definite description and the individual uniquely described, even though a definite description is supposed not to be a singular term. He might instead have called this relation “simulated denotation.” Russell retained the term “meaning” for semantic content.

Both the Millian theory and Russell’s theory deny that the individual that uniquely answers to a definite description is itself a component of the content of sentences involving the description. Those theories are able to solve the puzzles in the special case where the terms involved are definite descriptions rather than proper names, by reading sentences involving definite descriptions as containing propositions involving corresponding attributes or propositional functions. In particular, Russell’s claim that definite descriptions are not singular terms, but quantificational constructions, blocks substitutivity of equality, which is applicable only to singular terms, from licensing the substitution of “the first Postmaster General” for “the inventor of bifocals” in the

secondary-occurrence reading of “Jones believes that the inventor of bifocals was clever.” (By contrast, the envisioned substitution is indeed licensed by logical principles, including substitutivity as applied to variables, when the sentence takes on its primary-occurrence reading.)

Russell handled the same difficulties in the case of proper names (and such devices as demonstratives) through his thesis that names are ordinarily not used as “genuine names” (singular terms). Instead they were held to be “disguised” or “abbreviated” definite descriptions. The proposition expressed by a sentence involving a typical name is to be analyzed in accordance with Russell’s theory of descriptions. This blocks substitution in sentences such as “Jones believes that Hesperus appears in the evening.” Russell acknowledged the possibility of “names in the strict, logical sense” (logically proper names), which function in accordance with the naive theory. The class of admissible semantic contents for usable genuine names was severely limited by Russell’s principle of acquaintance, that every proposition one can grasp must be composed entirely of constituents with respect to which one has a special sort of intimate and direct epistemic access, (*direct acquaintance*). This restriction seems sufficient to prevent the puzzles from arising with logically proper names. (Russell did not countenance genuine names lacking a referent. Curiously, he claimed that singular existential and negative existential statements involving genuine names are without meaning. It would have been better to say that such sentences are always trivially true and trivially false, respectively.)

#### 4. FREGE’S THEORY OF SINN AND BEDEUTUNG

In his classic paper, “*Über Sinn und Bedeutung*” (1892), Frege abandoned the naive theory in favor of a richly elegant philosophy of semantics, which extends the Millian theory’s two-tiered semantics for definite descriptions and predicates to include all meaningful expressions. (Like Mill, and unlike Russell, Frege counted definite descriptions as singular terms.) Frege distinguished between the referent (*Bedeutung*) of an expression and its sense (*Sinn*). The sense of an expression contains a purely conceptual manner of presenting the name’s referent. Individuals that are not themselves senses—such as persons and even their sensations—cannot be constituents of a genuine Fregean sense. Furthermore, the sense of a singular term secures the term’s referent. An expression’s sense is a conception of something, and the expression’s referent, if there is one, is whatever uniquely fits the concept. The reference relation is thus the relative product of

a purely semantic relation (that between an expression and its sense) and a nonlinguistic relation (that between a sense and the object that fits it). Third, the sense of an expression is the semantic content. Expressions having the same sense must have the same referent, but importantly, expressions having the same referent may differ in sense. Frege illustrated his notion of sense by means of three lines that intersect in a single point. Then the phrases “the point of intersection of *a* and *b*,” “the point of intersection of *a* and *c*,” and “the point of intersection of *b* and *c*” converge in reference but diverge in sense.

The observation that proper names have a sense, as distinct from the referent, is tailor-made to solve both Frege’s Puzzle and the problem of how sentences involving nonreferring names can have content. Frege’s solution to the substitution problem is more complex. Crucial to Frege’s theory are the principles of extensionality and compositionality. They hold that the referent or sense, respectively, of a complex expression is a function of the referents or senses, respectively, of the component expressions. In the latter case Frege spoke metaphorically of the sense of a constituent expression as a *part* of the sense of the complex expression, so that the sense of the whole is composed of the senses of the parts.

Thus, if a constituent expression is replaced by one having the same sense, the sense of the whole is preserved, whereas if a constituent expression is replaced by one having the same referent but a different sense, the referent of the whole is preserved even though the sense is not. In particular, Frege held as a special case of extensionality that a compound expression having a nonreferring part must be nonreferring (“Sherlock Holmes’s older brother”). Frege argued, using extensionality, that the *cognitive value* (*Erkenntniswerte*) of a sentence is not the referent of the sentence, but is fixed by its sense, and that the referent of a sentence is one of two truth values, truth and falsity (“the true” and “the false”). Because a sentence refers to its truth-value, and a sentence involving a nonreferring name itself refers to nothing, such a sentence as “Sherlock Holmes is addicted to cocaine” is neither true nor false. (Frege held that the sentence *presupposes*, without asserting, that Sherlock Holmes exists.)

Frege argued that certain expressions create a special context in which subordinate expressions do not refer to their customary referent. When occurring within quotation marks (for example, in “direct discourse” reporting the words used by a speaker) an expression refers to itself. Analogously, expressions occurring subordinate to operators such as “Jones believes that” and “Jones said that” (the latter occurring in “indirect discourse” reporting the

content of a speaker’s utterance) refer to their *ungerade* (indirect, oblique) referent, which is the customary sense. Extensionality is to be understood as requiring the validity of substituting for a name in a sentence any expression having the same referent *in that same position*. (Scattered remarks suggest that Frege might have applied his doctrine of semantic shifting also to the problem of negative existentials.)

## 5. THE THEORY OF DIRECT REFERENCE

Despite a fundamental disagreement over the matter of singular propositions, there is common ground between Russell and Frege in regard to ordinary proper names. Both held a strong version of the theory that names are *descriptional*. On their view, if “St. Anne” is analyzable as “the mother of Mary,” it must be analyzable even further, because “Mary” is also supposed to be *descriptional*. But even “the mother of the mother of Jesus” must be in this sense further analyzable. If “ $\alpha$ ” is a nondescriptional singular term referring to Mary, then it may be said that the description “the mother of  $\alpha$ ” is *descriptional relative to Mary*. A *thoroughly descriptional* term is one that is *descriptional* but not *descriptional relative to anything*. The orthodox theory, shared by Russell and Frege, is the theory that proper names and similar devices are either *thoroughly descriptional* or *descriptional relative only to items of direct acquaintance*. Frege held the stronger thesis (which is retained by contemporary variants of Frege’s theory, such as that of John Searle) that proper names are *thoroughly descriptional*. Any departure from the stronger thesis would constitute a rejection of fundamental Fregean theory.

In recent philosophy the orthodox theory has been forcefully challenged, most notably by Keith Donnellan (1972), David Kaplan, Saul Kripke (1972, 1979), Ruth Barcan Marcus, and Hilary Putnam. These philosophers favor the theory of direct reference, which holds that proper names (and similar devices) are *nondescriptional*. Importantly, this theory does not deny that particular names may exhibit any or all of the three aspects of a Fregean sense mentioned in the previous section. What is denied is that the conceptual representation carried by a name secures the referent. But the direct-reference theory is significantly stronger than a simple denial of Russell’s doctrine that ordinary names are abbreviated definite descriptions. The theory holds that names are not even similar to definite descriptions. An immediate consequence is that a great many definite descriptions fail to be *thoroughly descriptional* or *descriptional relative only to*

items of direct acquaintance, because many contain names of ordinary individuals.

Three main kinds of arguments have been advanced in favor of the direct-reference theory. The modal and epistemological arguments are due chiefly to Kripke. Suppose for simplicity that the name “Shakespeare” simply means “the English playwright who wrote *Hamlet*, *Macbeth*, and *Romeo and Juliet*.” If the orthodox theory of names is correct, then the sentence, “Someone is Shakespeare iff he is an English playwright who is sole author of *Hamlet*, *Macbeth*, and *Romeo and Juliet*,” should express a necessary, a priori truth. On the contrary, however, it might have come to pass that Shakespeare elected to enter a profession in law instead of becoming a writer. Furthermore, it is possible, and is not ruled out solely by semantic reflection, that Francis Bacon should go on to write these plays. These intuitions are supported by a complementary intuition: that “Shakespeare” continues to refer to the same person even with respect to nonactual possible worlds in which Shakespeare lacks the distinguishing characteristics that people actually use to identify him—that is, even in discourse about such a counterfactual scenario. One important consequence of the direct-reference theory is that any proper name is a *rigid designator* (Kripke)—that is, it designates the same thing with respect to every possible world in which that thing exists and does not designate anything else with respect to other possible worlds.

One example of the semantic arguments for the direct-reference theory comes from Donnellan: According to the orthodox theory, the semantic content of the name “Thales” is determined by a description such as “the Greek philosopher who held that all is water.” But suppose that the man referred to by writers from whom the use of the name “Thales” derives never genuinely believed that all is water but was thought to, owing to some error or hoax, and that, by coincidence, there was a Greek hermit who did hold this bizarre view, though he bears no historical connection to anyone. Contrary to the orthodox theory, the name “Thales” would nevertheless refer to the first of the two. This argument seems to reveal also that the surrounding settings in which speakers find themselves, and not merely the concepts evoked in them, are crucial to determining the referents of the names they use. In a word, the securing of a referent for a name is a *contextual* phenomenon. Donnellan and Kripke have provided partial accounts of the securing of a referent for a name by means of historical chains of communication. Putnam has given a similar account of certain terms designating something by means of a “division of linguistic

labor.” Because of these accounts the direct-reference theory is sometimes called the causal theory of reference.

## 6. THE MILLIAN THEORY RECONSIDERED

What, then, is the semantic content of a name? It is tempting to answer that it is, or at least includes, a descriptive or conceptual “mode of presentation.” Although this proposal does not require that the associated mode of presentation secure the referent, it faces some of the same difficulties as the orthodox theory. A more general difficulty arises because the variations of the argument from Frege’s Puzzle against the naive theory and the Millian theory can be mounted against a wide variety of theories of semantic content, including Frege’s. The general strategy involved in that argument, however, seems to involve an error. This might be demonstrated through an application to a situation involving expressions for which it is uncontroversial that semantic content is exactly the same.

Suppose that foreign-born Sasha learns the words “ketchup” and “catsup” by actually consuming the condiment and reading the labels on the bottles. Suppose further that, because of his idiosyncratic experience, Sasha comes to believe that the substances so named are different condiments sharing a similar taste, color, and consistency. Whereas “Ketchup is ketchup” is uninformative for Sasha, “Catsup is ketchup” is informative. It would be a mistake, however, to conclude that “catsup” and “ketchup” differ in semantic content for Sasha. The terms are perfectly synonymous in English; indeed, they are arguably the same English word. Most English speakers learned one in a sort of ostensive definition, and the other as a strict synonym (or as an alternative spelling) of the first. If either may be learned by ostensive definition, then both may be—witness Sasha. This discredits the original argument from Frege’s puzzle.

One important consideration favoring the Millian theory over the orthodox theory comes by consideration of individual variables. Consider the following propositional-attitude attribution:

- (1) The planet Venus is an individual  $x$  such that Jones believes that  $x$  is a star.

It is characteristic of this *de re* (as opposed to *de dicto*) locution that it does not specify how Jones is supposed to conceive of Venus in believing it to be a star. The Orthodox Theorist contends that this is a result of the allegedly descriptive name “Venus” positioned outside of the scope of the nonextensional operator “Jones believes

that,” where it is open to substitution and to existential generalization. What is more significant, however, is that a nondescriptive singular term is positioned within the scope of the nonextensional context: the last occurrence of the variable “*x*” in (1). It follows by the principles of conventional semantics that (1) is true if and only if its component open sentence:

(2) Jones believes that *x* is a star

is true under the assignment of Venus as value for the variable. In turn, (2) is true under this assignment if and only if Jones believes the semantic content of the complete open sentence:

(3) *x* is a star

under the same assignment. But the fundamental characteristic of a variable with an assigned referent is that its semantic content is just its referent. This is precisely the point of using a variable rather than a definite description (such as “the first heavenly body visible at dusk”) within the scope of an attitude verb in a *de re* attribution. If a variable with an assigned value had, in addition to its value, a Fregean sense, then (3) would contain a specific general proposition, under the relevant assignment. If (1) is to fail to specify how Jones conceives of Venus, the content of (3) under the assignment of Venus to “*x*” can only be the singular proposition about Venus that it is a star. If the open sentence (3), under the assignment of Venus as the value of “*x*,” contains the singular proposition about Venus that it is a star, then so does the closed sentence “*a* is a star,” where “*a*” is an individual constant that refers to Venus. It is not the variability of a variable, but its structural simplicity, that gives it the feature that the variable’s semantic content, under an assignment of a referent, is just the assigned referent. (An exactly parallel argument proceeds using pronouns in place of variables, using “The planet Venus is such that Jones believes that *it* is a star.”)

It is important to note also that at least some aspects of the remaining puzzles would arise even in a language for which it was stipulated that the Millian theory is correct. Suppose, for example, that an authoritative linguistic committee that legislates the grammar and semantics of the language, and to which all speakers of the language give their cooperation and consent, decreed that proper names are to function exactly like the mathematician’s variables, “*x*,” “*y*,” and “*z*,” except that they are to remain constant. Ordinary speakers would presumably continue to regard co-referential names as not always interchangeable in propositional-attitude attributions. English speakers who use “ketchup” and “catsup” as exact synonyms may be inclined to assent to “Sasha believes that

ketchup is a sandwich condiment, but he does not believe that catsup is.” On philosophical reflection, however, it emerges that this expresses a logical impossibility. Similarly, speakers who agree to abide by the legislative committee’s decree about proper names might for independent pragmatic reasons be led to utter or to assent to such sentences as “Jones believes that Hesperus appears in the evening, but he does not believe that Phosphorus does.” Insofar as the same phenomena that give rise to the puzzles would arise even in the case of a language for which the Millian theory was true by fiat and unanimous consent (and do in fact arise with respect to such straightforward synonyms as “ketchup” and “catsup”), the puzzles cannot be taken as evidence against the Millian theory. A deeper understanding is needed of the puzzles, and a reexamination of the Millian theory in light of this deeper understanding.

## PROPERTIES

Our every assertion or thought involves "properties" or relations. Most simply, we predicate some property of some thing: Earth is round. Sometimes we refer to properties by name or by description: Red is the color of blood. Sometimes our quantifiers range over properties: Galaxies come in many shapes and sizes.

This familiarity with properties, however, does not reveal what properties are. Indeed, the question is equivocal, both in ordinary and in philosophical discourse. There are different conceptions of properties, equally legitimate, corresponding to the different roles that properties have been called upon to play (Bealer 1982; Lewis 1983, 1986). And for each conception there are different theories as to what sort of entity, if any, is best suited to play the role. The most fundamental division is between abundant and sparse conceptions of properties. On an abundant conception every meaningful predicate expresses some property or relation, including "is blue or round," "is on top of a turtle," "is identical with the planet Mars"; a property's instances need not resemble one another in any intrinsic respect. Abundant properties are needed to serve as "meanings," or components of "meanings," in a compositional semantics for language. On a sparse conception of properties a predicate expresses a property only if the objects satisfying the predicate resemble one another in some specific intrinsic respect; perhaps "has unit positive charge" and "is ten kilograms

in mass" are examples. Sparse properties are needed to provide an objective basis for the scientist's project of discovering the fundamental classifications of things and the laws that govern them. Properties, whether abundantly or sparsely conceived, are neither language- nor mind-dependent: They existed before there were beings to talk and think about them; they would have existed even had there never been such beings.

In this entry only conceptions of properties are explicitly distinguished and discussed, although much of what is said applies also to relations and to propositions. Other philosophers' terms for *property* in the abundant sense include *attribute* (Quine 1970), *propositional function* (Russell 1919), and *concept* (Bealer 1982, Frege 1884); *universal* and *quality* have for the most part been interpreted sparsely. Ordinary language allows abundant or sparse readings of *characteristic*, *feature*, *trait*, and more.

## ABUNDANT CONCEPTIONS OF PROPERTIES

How abundant are the properties on the abundant conception? Whenever there are some things, no matter how scattered or dissimilar from one another, there is the abundant property of being one of those things. Thus, for any class of things, there is at least one abundant property had by all and only the members of that class. It follows that there are at least as many abundant properties as classes of things and that the abundant properties outrun the predicates of any ordinary language. (There are non-denumerably many classes of things—assuming an infinity of things—but at most denumerably many predicates in any ordinary language.) Abundant properties, owing to their very abundance, must be transcendent, rather than immanent: They are not present in their instances as constituents or parts. It is not plausible to suppose that an object has a distinct constituent for each and every class to which it belongs.

If we say that whenever there are some things, there is exactly one property had by all and only those things, then a property may be identified with the class of its instances. For example, the property of being human may be identified with the class of human beings. But there is a well-known objection to this identification (Quine 1970). Consider the property expressed by "is a creature with a heart" and the property expressed by "is a creature with kidneys." If properties are "meanings," or semantic values, of predicates, then the properties expressed by these two predicates are distinct. Yet, these predicates, we may suppose, are coextensive: As a matter of fact, any creature with a heart has kidneys, and vice versa; the class

of creatures with a heart is identical with the class of creatures with kidneys. Thus, distinct properties correspond to the same class and cannot be identified with that class.

Different responses to the objection invoke different criteria of individuation for properties, that is, different criteria for deciding when properties, introduced, say, via predicates that express them, are one and the same. One response simply denies that “is a creature with a heart” and “is a creature with kidneys” express distinct properties. More generally, properties expressed by coextensive predicates are identical. Call this an extensional conception of properties. A property so conceived may be identified with the class of its instances. Extensional conceptions of properties are adequate to the semantic analysis of mathematical language and extensional languages generally (Tarski 1946).

A second response holds that “is a creature with a heart” and “is a creature with kidneys” express distinct properties, because it is logically possible for something to satisfy one predicate without satisfying the other. On this response properties expressed by necessarily coextensive predicates are identical; properties expressed by accidentally coextensive predicates are distinct. Call this an intensional conception of properties. If one accepts the standard analyses of logical possibility and necessity in terms of *possibilia*, then a property, on the intensional conception, may be identified with the function that assigns to each possible world the set of possible objects that has the property at the world. If one holds that each object exists at, and has properties at, only one world, then a property may more simply be identified with the class of (actual and) possible objects that has the property (Lewis 1986). Properties, on the intensional conception, are appropriate semantic values for predicates of (standard) modal languages and intensional languages generally (Carnap 1947, Kripke 1963).

A third response holds that the properties expressed by “is a creature with a heart” and “is a creature with kidneys” are distinct because they are structured entities with different constituents: The property expressed by “is a creature with a heart” has the property expressed by “is a heart” as a constituent; the property expressed by “is a creature with kidneys” does not. On this response properties have a quasi-syntactic structure that parallels the structure of predicates that express them. Call two predicates isomorphic if they have the same syntactic structure and corresponding syntactic components are assigned the same semantic values. On a structured conception of properties, properties expressed by isomorphic predicates are identical; properties expressed by nonisomorphic

predicates are distinct. (Structured conceptions are sometimes called hyperintensional because they allow necessarily coextensive predicates to express distinct properties.) Structured conceptions subdivide according to whether the unstructured semantic values are intensional or extensional and according to whether the relevant structure is surface grammatical structure, or some hypothetical deep structure, or structure after analysis in terms of some chosen primitive vocabulary. Structured properties may be identified with sequences of unstructured properties and other unstructured semantic values. Structured properties, on one version or another, have a role to play in the semantic analysis of propositional attitudes and of hyperintensional languages generally (Carnap 1947, Cresswell 1985).

Thus far, this entry has assumed that predicates of ordinary language are satisfied by objects once and for all. In fact, most ordinary language predicates are tensed; they may be satisfied by objects at some times but not at others. For example, “is sitting” is true of me now, but was false of me ten minutes ago. On a tensed conception of properties, whether or not a property holds of an object may also be relative to times. Most simply, tensed properties may be identified with functions from times to untensed properties. Tensed properties may be taken as semantic values for tensed predicates.

We have, then, a plurality of abundant conceptions of properties. Which is correct? One need not and should not choose. A plurality of conceptions is needed to account for the multiple ambiguity in our ordinary talk of properties. And it seems that both structured and intensional conceptions are needed for compositional semantics: Structured properties are needed to provide distinct semantic values for predicates, such as “is a polygon with three sides” and “is a polygon with three angles,” that are necessarily coextensive without being synonymous; intensional properties are needed to provide distinct semantic values for unstructured predicates that are accidentally coextensive. To accept a plurality of conceptions, it suffices to find, for each conception, entities that satisfy that conception’s criteria of individuation.

Realists with respect to some conception of properties hold that entities satisfying the individuation criteria for the conception exist. Realists divide into reductionists and antireductionists. Reductionists identify properties, under the various conceptions, with various set-theoretic constructions (in ways already noted): class, functions, or sequences of actual or possible objects (Lewis 1986). Antireductionists reject some or all of these identifications. For some antireductionists, classes are suspect or

esoteric entities; classes are to be explained, if at all, in terms of properties, not vice versa (Bealer 1982, Russell 1919). For other antireductionists the problem is not with classes, but with the possibilia that comprise them (on intensional conceptions). Possible but nonactual entities are to be explained, if at all, in terms of uninstantiated properties, not vice versa (Plantinga 1976). According to the antireductionist, properties are basic or primitive; it is merely posited that there are entities satisfying the appropriate individuation criteria. Some entities, after all, must be taken as basic; according to the antireductionist, properties are an acceptable choice.

Eliminativists hold that, strictly speaking, there are no properties. They take aim, typically, at intensional conceptions, at conceptions with modal criteria of individuation. They claim that modal notions, such as logical possibility and necessity (whether taken as primitive or analyzed in terms of possibilia), incorrigibly lack the clarity and precision required of a rigorous scientific semantics or philosophy (Quine 1970). Eliminativists have the burden of showing how ordinary and philosophical discourse ostensibly referring to properties can be paraphrased so as to avoid such reference; or, failing that, of showing that such discourse is dispensable, merely a *façon de parler*.

### SPARSE CONCEPTIONS OF PROPERTIES

On an abundant conception any two objects share infinitely many properties and fail to share infinitely many others, whether the objects are utterly dissimilar or exact duplicates. On a sparse conception the sharing of properties always makes for genuine similarity; exact duplicates have all of their properties in common. Whatever the sparse properties turn out to be, there must be enough of them (together with sparse relations) to provide the basis for a complete qualitative description of the world, including its laws and causal features. The sparse properties correspond one-to-one with a select minority of the abundant properties, on some intensional conception. (“Intensional,” because distinct sparse properties may accidentally be instantiated by the same objects.) Those abundant properties that correspond to sparse properties are called natural (or perfectly natural, since naturalness presumably comes in degrees; Lewis 1983, 1986). The naturalness of properties is determined not by our psychological makeup, or our conventions, but by nature itself.

How sparse are the properties, on a sparse conception? First, there is the question of uninstantiated properties. If sparse properties are transcendent, there is no

difficulty making room for uninstantiated sparse properties; perhaps uninstantiated sparse properties are needed to ground laws that come into play only if certain contingent conditions are satisfied (Tooley 1987). If, on the other hand, sparse properties are immanent, are present in their instances, then uninstantiated sparse properties must be rejected, because they have nowhere to be (Armstrong 1978, 1989). Of course, uninstantiated sparse properties may nonetheless possibly exist, where this is understood according to one’s favored interpretation of modality.

Second, there is the question of the compounding of sparse properties (and relations). Disjunctions and negations of natural properties are not themselves natural: Their instances need not resemble one another in any intrinsic respect. For example, instances of the property having-unit-positive-charge-or-being-ten-kilograms-in-mass need not resemble one another in either their charge or their mass. It follows that there are no disjunctive or negative sparse properties (Armstrong 1978).

The case of conjunctive sparse properties is less clear. There are two views. According to the first, since instances of a conjunction of natural properties, such as having-unit-positive-charge-and-being-ten-kilograms-in-mass, resemble one another in some—indeed, at least two—intrinsic respects, there exists a sparse property corresponding to the conjunction. According to the second view, the sparse properties must be nonredundant; they must be not only sufficient for describing the world but minimally sufficient. On this view conjunctive sparse properties are excluded on grounds of redundancy: A putative conjunctive sparse property would hold of an object just in case both conjuncts hold.

Similarly, structural sparse properties, such as being-a-molecule-of-H<sub>2</sub>O, may be admitted on the grounds that they make for similarity among their instances. Or they may be excluded on grounds of redundancy: A putative structural sparse property would hold of an object just in case certain other sparse properties and relations hold among the object and its parts. But the exclusion of structural (and conjunctive) sparse properties faces a problem. It rules out a priori the possibility that some properties are irresolvably infinitely complex: They are structures of structures of structures, and so on, without ever reaching simple, fundamental properties or relations (Armstrong 1978). A sparse conception that allowed for this possibility would have to allow some redundancy; and if some redundancy, why not more? This suggests that conjunctive and structural sparse properties should generally be admitted. (An alternative treatment makes use of degrees

of naturalness and has it that conjunctive and structural properties are natural to some lesser degree than the properties in terms of which they are defined; a world with endless structure has no perfectly natural properties.)

If structural sparse properties are admitted, the sparse properties will not be confined to fundamental physical properties; there will be sparse properties of macroscopic, as well as microscopic, objects. For example, the sparse properties will include specific shape-and-size properties, such as being-a-sphere-ten-meters-in-diameter (which are arguably structural properties definable in terms of sparse distance relations). However, the vast majority of ordinary-language predicates—“is red,” “is human,” “is a chair,” to name a few—fail to express natural properties to which sparse properties correspond; rather, these predicates express properties that, when analyzed in fundamental physical terms, are disjunctive (perhaps infinitely so) and probably extrinsic. (This judgment could be overturned, however, if there are irreducible natural properties applying to macroscopic objects—most notably, irreducible phenomenological properties of color, sound, and such.)

What are the properties on a sparse conception? There are three principal theories (or clusters of theories, since they each subdivide). According to the first, the properties sparsely conceived are just some of the properties abundantly conceived: The properties that are perfectly natural. What makes some properties natural and others unnatural? One version of the theory simply takes naturalness to be a primitive, unanalyzable distinction among abundant properties (Quinton 1957; see also Armstrong 1989, Lewis 1986). But since a property is natural in virtue of the resemblances among its instances, it might seem more appropriate to take instead some relation of partial resemblance as primitive and to define naturalness in terms of resemblance. The resulting version, called resemblance nominalism, can be worked out in different ways with different primitive resemblance relation (Price 1953; see also Armstrong 1989, Goodman 1951; Lewis 1983). The chief objection to the view is that partial resemblance between ordinary objects, no less than naturalness of properties, cries out for analysis. When two objects partially resemble one another, the objection goes, they must have constituents that exactly resemble one another, perhaps constituents that are literally identical. More generally, it is argued, properties must be constituents of objects if properties are to play a role in the explanation of the natures and causal powers of objects; one cannot explain an object’s nature or causal powers by

invoking a class to which it belongs. Sparse properties, then, must be immanent, not transcendent, entities.

What are these constituents of ordinary things? Not ordinary spatial or temporal constituents—or, at least, not always. For even an object with no spatial or temporal extension might have a complex nature and stand in relations of partial resemblance. If sparse properties are immanent, then they must be nonspatiotemporal constituents of things. There are two prominent theories as to the nature of these constituents. The first theory takes them to be universals (Armstrong 1978, 1989.) They are repeatable: Each of them is, or could be, multiply instantiated. And they are wholly present in their instances: An immanent universal is located—all of it—wherever each of its instances is located. When objects resemble one another by having a sparse property in common, there is something literally identical between the objects. It follows that universals fail to obey commonsense principles of location, such as that nothing can be (wholly) in two places at the same time. But that is no objection. Such principles were framed with particulars in mind; it would beg the question against universals to require them to meet standards set for particulars.

On the other theory of sparse properties as immanent, the nonspatiotemporal constituents of ordinary particulars are themselves particulars, called tropes (Armstrong 1989, Lewis 1986, Williams 1966) or abstract particulars (Campbell 1981). When ordinary particulars partially resemble one another by having some sparse property—say, their mass—in common, then there are distinct, exactly resembling, mass tropes as constituents of each. On a trope theory sparse properties can be identified with maximal classes of exactly resembling tropes (perhaps including merely possible tropes). Exact resemblance between tropes is taken as primitive by trope theory; but it is a simple and natural primitive compared to the partial resemblance relation taken as primitive by an adequate resemblance nominalism.

A possible disadvantage of a universals theory is that it requires two fundamentally distinct kinds of entities: universal and particulars. An ordinary particular cannot simply be identified with a bundle of coinstantiated universals, lest numerically distinct but qualitatively identical particulars be identified with one another. On a universals theory there must be some nonqualitative, nonrepeatable constituent of ordinary particulars to ground their numerical identity. A trope theory, on the other hand, needs only tropes to make a world. Ordinary particulars can be identified with bundles of coinstantiated tropes; numerically distinct but qualitatively identical

particulars are then bundles of numerically distinct but exactly resembling tropes.

The great advantage of a universals theory is that it promises to analyze all resemblance in terms of identity: Exact resemblance is identity of all qualitative constituents; partial resemblance is partial identity, identity of at least one qualitative constituent. But it is unclear whether the promise can be kept. Objects instantiating different determinates of a determinable—such as unit-positive and unit-negative charge—seem to partially resemble one another by both being charged without there being any analysis of this resemblance in terms of the identity of constituent universals or, for that matter, the exact resemblance of constituent tropes. A universals theory and a trope theory would then have to fall back upon primitive partial resemblance between universals, or tropes. Some of the advantages of these theories over resemblance nominalism would be forfeited.

Of the three basic theories of sparse properties—resemblance nominalism, a theory of immanent universals, and a theory of tropes—only one can be true; the theories posit incompatible constituent structure to the world. However, assuming each theory is internally coherent, and adequate to the needs of science, the question arises, What sort of evidence could decide between them? It seems that a choice between the theories will have to be made, if at all, on the basis of pragmatic criteria such as simplicity, economy, and explanatory power. There is as yet no philosophical consensus as to what that choice should be.

## PROPERTY

The institution of property has interested social philosophers in part, at least, because it raises issues of justice. Like government, it is practically universal but varies enough in its particular arrangements to suggest the question What criteria are relevant in assessing the relative merits of various arrangements? Again, because it discriminates between rights and fortune, it invites moral criticism and the demand for justification.

Many of the classical accounts of the origin and function of private property have taken for granted that in nature all things were held "in common." This phrase, however, is ambiguous, for it often meant not a system regulating the use of goods by general agreement but a condition where, there being no rules, everything was *res nullius* (a thing belonging to no one) and the concept "property" was consequently irrelevant. How, then, it was asked, would humans come to appropriate the land and its fruits? How could such appropriation be justified? What would be rational grounds for claiming exclusive possession? And could there be any limit on people's right to do what they would with their own?

## THEORIES OF PROPERTY

According to the Church Fathers, property was both the consequence and the social remedy for the sin of covetousness that came with the Fall. But since owners have appropriated what at one time belonged to all, they have a duty to administer it for the benefit of all. “Our property,” said Gregory the Great, “is ours to distribute, but not ours to keep.” The concept of the owner as steward is the core of the traditional Christian view of property.

**NATURAL LAW AND CONVENTIONALISM.** By the seventeenth century, property rights came to be grounded in the needs and accomplishments of the individual owner, and ownership implied a natural right to enjoy and dispose of its objects, limited only by the duty to respect the rather narrowly defined interests of others. In John Locke’s account, property as an institution is explained by human needs. Although God gave the earth and all its fruits to all people to preserve their lives, still this meant one’s making the fruits of the earth exclusively his own, if only by eating them. However, what in nature entitled one to call something one’s own was that one made the effort to make it so. To add one’s labor to a *res nullius* was to create a title to the whole product. Locke limited this title to whatever one could use before it spoiled; appropriation for waste would be illegitimate.

To appropriate an object implied for Locke not merely a right to enjoy it but also to alienate it at will, so that although the appropriation of *res nullius* could legitimately be effected only by labor, the title, once established, could be freely transferred. It is questionable, however, whether Locke was justified in assuming that because we may appropriate what we need from the common stock, we may therefore transfer what we acquire, but do not need, to whomsoever we choose. Locke needed this right, however, if his theory was not to suggest, as did certain later writers on economic justice, that the laborer was entitled to the entire fruits of his master’s fields, if not to the fields themselves. For where all land had long been appropriated, the titles of present owners would depend entirely on the legitimacy of such transfers in the past. So, since the land was no longer *res nullius*, all the laborer could claim was the value of his labor in wages. Moreover, in a market economy and with the introduction of money, wealth might be accumulated and stored indefinitely without spoiling; furthermore, since money had only a conventional value, hoarding it deprived no one of anything of natural value, and its distribution must be taken to be by common consent. Having accounted, then, for the existence of property, and for

existing titles, with a theory of natural right, Locke overlaid the theory with a conventionalist theory that neutralized the limitations on appropriation that the original theory prescribed.

Nature and convention are to be found similarly blended, if in varying proportions, in Hugo Grotius, Samuel von Pufendorf, and William Blackstone. In Immanuel Kant, too, there is a blend. Kant deduced the principle of first occupier from the autonomy of the will but conceded that only a universal legislative will—the civil state—could give binding force to the intention to appropriate.

**UTILITARIAN POSITIONS.** According to David Hume, a man’s creation ought to be secured to him in order to encourage “useful habits and accomplishments.” Inheritance and the right to alienate were alike valuable as incentives to or conditions for useful industry and commerce. Property rested on convention in the sense of rules upheld by common interests commonly perceived. It was a law of nature, too, but in the sense that men were sufficiently alike the world over for the same general arrangements to be equally to the public advantage. Hume’s argument, then, also blends natural law doctrine with conventionalism but reduces both to utilitarianism.

Jeremy Bentham did little more than elaborate Hume’s arguments. However, by introducing considerations of utility, Hume and Bentham pointed the way for criticism of the distribution of private property and, indeed, of the institution itself. Already in 1793 William Godwin was arguing that in a consistent application of the principle of utility “every man has a right to that, the exclusive possession of which being awarded to him, a greater sum of benefit or pleasure will result, than could have arisen from its being otherwise appropriated” (*Political Justice*, Book 8). J. S. Mill, though broadly committed to a belief in private property, held that, in the case of land at any rate, private ownership must be conditional on its expediency; the rights associated with it, especially the right to exclusive access and enjoyment, ought to be limited to whatever was required to exploit it efficiently. Mill recognized that the rights of property were not an inseparable bundle, to be justified en bloc; each constituent right had to be independently justified on grounds of utility.

However, Mill’s belief that the institution of property would be justified provided that it guaranteed to individuals the fruits of their labor and abstinence is open to question. In a complex industrial society, “the fruits of one’s labor” can mean only the value of a given worker’s

contribution to the finished product. But value derives from the relations of supply and demand, both for the commodity and for labor of the various kinds needed to produce it. “The fruits of one’s labor,” understood as one’s share in a social dividend, will depend not only on one’s efforts but also on the number of other people available to do the same job and on how badly consumers want it done. If for the time being a particular skill is in short supply, is it self-evident that this increases the value of its fruits or that those who have it should be the better off for it?

**MARXIST AND HEGELIAN CRITIQUES.** Again, the exclusive claims of labor take no account of what men owe to others and to the social interest. Émile Durkheim, for instance, objected that “it is not enough to invoke the rights that man has over himself: these rights are not absolute but limited by the claims of the moral aims, in which a man has to cooperate.” Karl Marx was equally critical of the German Social Democrats’ Gotha program of 1875, which claimed that labor should receive its produce “unabridged and in equal right.” He charged that this formula ignored the need for capital replacement and development, social services, and the support of the incapable. In any case, he said, distribution proportional to contribution would still be only partial justice, bearing in mind differences in natural capacity on the one hand and need on the other. In the truly cooperative society, based on common ownership of the means of production, individual labor would be impossible to separate out, and distribution would be according to need alone. This would be possible, however, only because labor would have ceased to be a burden and would have become “life’s principal end.”

This last condition suggests why, in a period when hedonistic premises underlay a great deal of psychology, ethics, and economics, the necessary relation between labor and property should have been so generally accepted. On the assumption that work was painful, the only conceivable reason for working was a greater pleasure expected from its fruits. Marx argued that this account of labor was neither an explanation nor a justification, but a consequence, of the system of private property. The worker was alienated from his work, which appeared to him not as a fulfillment but as a burden; he was alienated, too, from the product of his work, which, passing to his employer in surplus value, confronted him as capital—that is, as an instrument of his own bondage.

Despite the stress on labor as the source of value that Marx shared with the English utilitarians and econo-

mists, his account of property derives at least as much from G. W. F. Hegel as from the English school. Like Kant, Hegel regarded property as necessary not because it helped to satisfy human needs but because “a person must translate his freedom into an external sphere in order that he may achieve his ideal existence” (*Philosophy of Right*, Sec. 41); because “property is the first embodiment of freedom and so is in itself a substantive end” (Sec. 45). Plato erred, in Hegel’s view, in denying private property to the guardians, for he was denying them the conditions necessary for giving concrete realization to their personalities and wills.

Marx and Hegel are alike in seeing the human will objectifying itself in its acquisitions and creations. If for Marx the process is not rationalizing and liberating but alienating and enslaving, it is because the property created is not and cannot be the worker’s own. The laborer can transcend this alienation only in the communist society, in which, like Plato’s guardians or the members of a monastic community, he gets caught up in a common enterprise where “mine” and “thine” are of no account because life is more than the satisfaction of material needs. In a world in which “sharing in” counted for more than “sharing out,” property—like justice—would present no problems.

**ECONOMIC AND SOCIAL SIGNIFICANCE.** In the course of the past century, legal and social philosophers (Léon Duguit and Karl Renner, for example) have come to think of property increasingly as an institution with social functions and not, like Locke, as simply a guarantee of individual interest. Moreover, because property entails inequalities in power, in claims on the social product, in social status, and in prestige, it must be justified, and not merely in terms of the interests or natural rights of its immediate beneficiaries.

It is difficult, however, to see how any one theory could apply generally to all forms of private property and include all rights of ownership. Individual control of productive resources raises very different issues from the exclusive right to enjoy consumer goods such as clothes and furniture. The right to control the use of mines and factories is not really an instance of the right of a Kantian rational and autonomous being to manipulate mere things for his own needs; it is also an exercise of power over other people. According to A. A. Berle, the United States is gradually extending to such property the limitations traditionally applied to state action in order to protect individual freedom.

Again, could one justify one's title to dividends on the ground that instead of enjoying the fruits of one's labor one had invested them? And would the same justification extend to a corporate title to the yield on investments financed out of undistributed profits? Such claims have certainly flourished under the umbrella of natural rights; but it is difficult to see how any but a utilitarian argument could seriously be proposed in defense of such arrangements.

## ANALYSIS OF OWNERSHIP

Talk of property often seems to be talk about things. Things constitute property, however, only inasmuch as they can be assigned to owners; to own something is to have, in respect to it, certain rights and liabilities vis-à-vis other persons or the public at large. Ownership, therefore, is a normative relation or a complex of such relations between owner, object, and third parties, and to refer to something as "property" is to locate it as a term in such a relationship. Some jurists, indeed, insist that *property* refers not to things at all but, rather, to a bundle of rights. And this is obviously true of income titles, such as securities and annuities, and of rights of control over "intellectual property," such as patent rights and copyrights; these are "things" only in a very abstract sense, as characteristic complexes of normative relations.

As the objects of property are diverse, so also are the rights constituting it. Landowners' rights are necessarily different from copyright owners', and the owner of a gun does not have the same unrestricted use and control of it as the owner of a table has of the table. Jurists have nevertheless tried to identify some right necessary to ownership. The rights of exclusive use, possession, or alienation seem to be likely candidates, but each can conceivably be detached (for example, by a lease or an easement, under the terms of a trust, or, in former times, by entail) without the owners' losing property in the object. Accordingly, Sir Frederick Pollock suggested that "we must look for the person having the residue of all such powers when we have accounted for every detached and limited portion of it." But this residue, as held, say, by a ground landlord with a thousand-year tenant, may be very slender indeed, and the owner to whom all the detached rights will revert when the encumbrances reach the end of their term will certainly not be the present owner.

A. M. Honoré suggests a way out of these difficulties by concentrating not on the difficult exceptions but on the standard instance. He defines ownership as "those legal rights, duties and other incidents which apply, in the ordinary case, to the person who has the greatest interest

in a thing admitted by a mature legal system." Among the characteristic features are the right to possess and to be secure in possession, to use and to manage the property, to enjoy income arising from it and to alienate, consume, waste, or destroy the capital, and to transmit ownership to one's successors indefinitely; the absence of a fixed date on which the owners' interests terminate; the prohibition of harmful use; the liability of the property to execution for debt or insolvency; and the reversion to the owner on the termination of whatever lesser interests (leases, usufructs) encumber the property. Now, to say that *A* is the owner of *x* is not necessarily to say that he is the present subject of all these incidents; however, provided the kind of property in question can intelligibly be said to be the object of them and in the absence of special conditions or reservations, it is reasonable to infer that he is.

The Scandinavian legal realists—Karl Olivecrona and Alf Ross, for example—have been more radical in their analyses. According to Ross, ownership is "solely ... a tool in presentation." Theoretically, one could enunciate a mass of directives to judges, each consisting of a conditioning fact or facts (*F*) and a legal consequence (*C*), such as (1) if a person has lawfully purchased a thing ( $F_1$ ), judgment for recovery of possession should be given in his favor ( $C_1$ ); (2) if a person by prescription has acquired a thing and raised a loan that is unpaid ( $F_2$ ), the creditor should be given judgment for satisfaction out of the thing ( $C_2$ ); and so on. Now, to introduce "ownership" is not, according to Ross, to add something that *accounts* for the connections between the *F*'s and the *C*'s but merely to indicate the systematic connection between them such that  $F_1, F_2, F_3, \dots, F_p$  severally and collectively entail the totality of legal consequences  $C_1, C_2, C_3, \dots, C_n$ . The word *ownership* in Ross's view is "without any semantic reference whatever"; it serves only to reduce the complexity of particular rules to a systematic order. There is nothing beyond or in addition to the rules.

Now, it is certainly true that only confusion can result from trying to identify some special kind of a thing, or some special quality of things, which is called "property." Nevertheless, "ownership" does not always imply the same bundle of rights. The possible conditioning facts and the legal consequences are not the same for every case in which one may say that *X* is the owner of *P*. And, therefore, since the relevant rules do not have the rigorous relation to one another that Ross suggests, one can identify them as the rules of property (as distinct from, say, personal rights) only by recognizing some sort of family resemblances between them. Indeed, the terms Ross uses in exemplifying his conditioning facts—"purchase,"

“occupation of *res nullius*,” “acquisition by prescription”—are obviously already impregnated with ownership; to purchase something, for example, is to give money for it—that is, on the understanding that one acquires not merely possession, but also owners’ rights, over it.

Deciding who is the owner of a piece of property is, of course, to decide on the basis of certain facts where certain powers and liabilities lie. But to reduce a legal concept like property to a finite set of directives to judges ignores the fact that judges are constantly having to reshape the rules in the very process of applying them. If the rules of ownership are treated as a more or less arbitrary agglomeration, it is difficult to see how judges could make rational decisions at all.

Ross’s bundle of conditioning facts and legal consequences is significant, however, because it suggests how one goes about constructing a paradigm case of ownership, or, rather, a family of paradigms related by the fact that different conditioning facts entail broadly similar legal consequences. Deciding ownership in an atypical case would then involve deciding whether it can be assimilated to any of the available paradigms even though some characteristic ownership features are absent or other features that are out of character are present. A judge may have all kinds of reasons for making or refusing such an assimilation; but it is difficult to see how the problem could be presented to him at all without presupposing the standard cases of ownership as agreed starting points for discussion.

## PROPERTY [ADDENDUM]

What is property? It is some valued item that belongs to someone. Its existence in society may be collective or individual, although even if collective, it usually emerges from instances of (pooled or expropriated) individual

ownership. And that presupposes the right to *private* property.

### PROPERTY IS PRIVATE

The institution of the right to private property is the single most important condition for a society in which freedom in the classical liberal tradition—which means negative liberty, including free trade, freedom of the press, and freedom of religion—is to flourish. Under communism, in contrast, no such right is recognized. Privacy has a negligible role in a system which holds, as Karl Marx (1818–1883) proclaimed, that “the human essence is the true collectivity of man” (1970, p. 126). Even within noncommunist, nonsocialist systems the exact status of property is in dispute—some hold it is a convention established by implicit consensus and maintained by government or law. Some hold it is a natural normative relationship that comes about by means of the creative and productive initiative of persons and the law of property exists to recognize and not to create it.

### WHAT IS THE RIGHT TO PRIVATE PROPERTY?

Karl Marx understood the right to private property, although it was John Locke (1632–1704) who tried to justify this right. Marx wrote, in “On the Jewish Question,” that “the right of man to property is the right to enjoy his possessions and dispose of the same arbitrarily without regard for other men, independently, from society, the right of selfishness” (1970, p. 53). This, though correct, is not the full story. The right to private property, be it applied to obtaining and holding a toothbrush or, as was Marx’s concern (and what Marx found objectionable), an entire factory, does spell out a person’s authority to use what he or she owns without regard for other persons. This use may be reckless, prudent, or generous. Its exercise may not, however, violate others’ rights. Defenders do not assume that it would be insidious.

The natural right to private property was only discussed in direct terms starting in the eleventh and twelfth centuries. William of Ockham (1285–1347) proposed that “Natural right is nothing other than a power to conform to right reason, without an agreement or pact” (2001, p. 48) or, as Heinrich A. Rommen paraphrased him, “the right to private property is a dictate of right reason” (1954, p. 419), the power to make one’s moral choices on one’s own, free of others’ intrusion. Because such choices are made by persons in the natural world, one of our natural rights is the right to private property.

### ONE ROLE OF PRIVATE PROPERTY IN SOCIETY

Property rights weren’t explicitly identified in ancient times but the Old Testament ban on stealing implies what was spelled out by Locke and other classical liberals. Moreover, there have been strong philosophical intimations of it in, for example, Aristotle’s *Politics* (384–322 BCE). Whereas Plato, his teacher, held that, at least within the ruling class of a political community, there may not be any private property and indeed privacy, at all, Aristotle objected as follows:

That all persons call the same thing mine in the sense in which each does so may be a fine thing, but it is impracticable; or if the words are taken in the other sense, such a unity in no way conduces to harmony. And there is another objection to the proposal. For that which is common to the greatest number has the least care bestowed upon it. Every one thinks chiefly of his own, hardly at all of the common interest; and only when he is himself concerned as an individual. For besides other considerations, everybody is more inclined to neglect the duty which he expects another to fulfill; as in families many attendants are often less useful than a few. (*Politics*, 1261b34)

Earlier Thucydides (c. 471–c. 400 BCE) said,

They devote a small fraction of the time to the consideration of any public object, most of it to the prosecution of their own objects. Meanwhile, each fancies that no harm will come to his neglect, that it is the business of somebody else to look after this or that for him; and so, by the same notion being entertained by all separately, the common cause imperceptibly decays. (*The History of the Peloponnesian War*, bk. 1, sec. 141)

So, communal ownership leads to reduction of responsibility and a corresponding lack of attentive involvement with whatever is owned. This does not mean that people are evil. At their homes, this is likely to be different—if one is late and rushes off, the trash will be disposed of upon one’s return. At a public place the attitude seems to be, “It will get cleaned up somehow, by someone, at some time.” So, it is a systemic problem: people are unable to incorporate the significance of managing the public property within the scale of their values. Each of us knows, directly, how important or not it is for oneself to keep one’s backyard clean. So one will take care of it commensurate with that knowledge. It is not possible, however, for an individual to know how important it is for the

community, society, or humanity at large that one keep the air or river or lake clean, and to what degree.

A more recent defense of the right to private property is closer to that which we get from John Locke; namely, that we require this right so as to have a sphere of moral authority—as Robert Nozick (1938–2002) called it, “moral space,” or as Ayn Rand (1905–1982) noted,

Bear in mind that the right to property is a right to an action, like all others: it is not the right to an object, but to the action and the consequences of producing or causing that object. It is not a guarantee that a man will earn any property, but only a guarantee that he will own it if he earns it. It is the right to gain, to keep, to use and to dispose of material values. (1967, p. 322)

Basically, then, the main normative reason given for why one has a right to private property is that it is the means by which one’s liberty to act free of others’ imposition is secured within a social context. It is also a precondition for individuals to act prudently and productively in human communities without the legal permission for others to take from them what they have earned. Economists tend, in contrast, to defend it as a feature of the infrastructure by which productivity and prosperity is best encouraged in a society. Another support given to the idea is that it makes it possible for individuals to remain sovereign and to distribute resources as they see fit rather than others would demand.

There are innumerable objections to the right to private property, most recently the idea that property is held by the public at large and government merely permits individuals to make use of it to the extent government deems this in the public interest. For why this is a troublesome view the general theory of natural rights would need to be explored and scrutinized.

## PROPOSITIONAL ATTITUDES: ISSUES IN SEMANTICS

Propositional attitudes like knowledge, belief, and assertion play an important foundational role for semantic theory, the goal of which is to specify the meanings of sentences and their semantic contents relative to contexts of utterance. Meanings are plausibly regarded as functions from such contexts to semantic contents, which in turn are closely related to the assertions made, and the beliefs expressed, by utterances. For example, the semantic content of *I live in New Jersey* in a context *C* with *x* as agent and *t* as time is standardly taken to be the proposition that *x* lives in New Jersey at *t*. To understand the meaning of this sentence is, to a first approximation, to know that a competent speaker *x* who sincerely and assertively utters it in *C* asserts, and expresses a belief in, this proposition. Roughly put, if *p* is the semantic content of *S* in *C*, then an assertive utterance of *S* in *C* is an assertion of *p*, and is standardly taken as indicating the speaker’s belief in *p*. Whether the semantic content of a sentence is always among the propositions asserted by an utterance of the sentence, and whether, in those cases in which it is, the assertion of any other proposition by the utterance is always parasitic on the assertion of the semantic content, are matters of detail. Though important, they do not affect the foundational point. A semantic theory for a language is part of a larger theory that interprets the assertions and beliefs of its speakers. This, more than any other fact, allows one to subject semantic theories to empirical test. Competent speakers of a language are relatively good at identifying the propositions

asserted and beliefs expressed by utterances. To the extent to which assignments of semantic content issued by a semantic theory lead to verifiably correct characterizations of speakers' assertions and beliefs, the semantic theory is confirmed; to the extent to which these assignments lead to verifiably incorrect characterizations, it is disconfirmed.

### ATTITUDE ASCRIPTIONS

This point is closely related to the use of attitude ascriptions

(1a) N asserted that S

(1b) N believed that S

to test different semantic analyses of S. It is convenient to express this in terms of the relational nature of the attitudes. Consider assertion. In each case of assertion there is someone, the agent, who does the asserting, and something, the object of assertion, that is asserted. The term *proposition* is used to designate things that are objects of assertion (and other propositional attitudes) and bearers of truth value. Assertion is a mediated relation holding between agents and propositions. An agent asserts a proposition *p* by doing something or employing some content-bearing representation associated with *p*. The most familiar cases are those in which the agent asserts a proposition by assertively uttering a sentence.

Ascriptions like those in (2) report the assertions of agents:

(2a) Edward asserted the proposition that Martha denied.

(2b) Edward asserted the proposition that the Earth is round.

(2c) Edward asserted that the Earth is round.

That in (2a) *asserted* is flanked by two noun phrases suggests that it is a two-place predicate and that a sentence 'NP assert NP' is true if and only if the first (subject) noun phrase designates an agent who bears the assertion relation to the entity designated by the second (direct object) noun phrase. This analysis also applies to (2b), which is true if and only if Edward asserted the proposition designated by *the proposition that the Earth is round*. On the assumption that this proposition is also designated by *that the Earth is round*, this analysis can be extended to (2c), which is equivalent to (2b). Similar remarks hold for other propositional attitude verbs, including *believe*, *deny*, *refute*, and *prove*.

With this in mind, one can return to the ascriptions in (1). If, as many theorists believe, (i) 'that S' in (1) designates the semantic content of S (in the context), (ii) these ascriptions report relations between agents and those contents, and (iii) sometimes substitution of sentences with necessarily equivalent semantic contents fails to preserve the truth values of such ascriptions, then semantic contents must be more fine-grained than the sets of possible world-states in which they are true. On these assumptions substitution in such ascriptions can be used to discriminate different but intensionally equivalent semantic analyses of S.

### PROPOSITIONS, POSSIBLE WORLD-STATES, AND TRUTH SUPPORTING CIRCUMSTANCES

This has significance for possible world semantics. In this framework a semantic theory is a formal specification of truth with respect to a possible context of utterance and circumstance of evaluation. The semantic content of S in C is the set of possible circumstances E such that S is true with respect to C and E. Circumstances of evaluation are traditionally identified with possible world-states—thought of as maximally complete properties that the world genuinely could have had. As a result, the semantic contents of all necessarily equivalent sentences are taken to be identical. This, plus the standard treatment of attitude ascriptions as reporting relations between agents and the semantic contents of their complement clauses, leads to the counterintuitive prediction that substitution of necessarily equivalent sentences in such ascriptions never changes truth value. If one adds the apparently obvious fact that (3a) entails (3b),

(3a) A asserts/believes that P&Q

(3b) A asserts/believes that P&A asserts/believes that Q

one gets the further counterintuitive results (i) that anyone who asserts or believes a proposition *p* asserts or believes all necessary consequences of *p*, and (ii) that no one ever asserts or believes anything necessarily false, since to do so would involve simultaneously asserting or believing every proposition.

In 1983 Jon Barwise and John Perry attempted to evade these results by constructing a semantic theory in which metaphysically possible world-states were replaced by abstract situations—thought of as properties that need be neither maximally complete, nor genuinely capable of being instantiated by any parts of the world. This strategy was shown to be unsuccessful by Scott Soames (1987),

where it was demonstrated that variants of the problems posed by attitude ascriptions for standard possible worlds semantics can be re-created for any choice of truth-supporting circumstances used in formal characterizations of truth with respect to a context and a circumstance. Robert C. Stalnaker explored a different approach in 1984. After providing a naturalistic argument that semantic contents must be sets of metaphysically possible world-states, he suggested that counterexamples could be avoided by (i) allowing for exceptional cases in which attitude ascriptions report relations to propositions other than those expressed by their complement clauses, and (ii) resisting the claim that the agent believes the conjunction of  $p$  and  $q$  in many cases in which the agent believes both conjuncts. These suggestions are rebutted in later work by Mark Richard (1990) and Jeffrey Speaks (forthcoming).

### STRUCTURED PROPOSITIONS, MILLIANISM, AND DESCRIPTIVISM

The problems posed by attitude ascriptions for possible worlds semantics have led many theorists to characterize the semantic content of a sentence  $S$  as a structured complex the constituents of which are the semantic contents of the semantically significant constituents of  $S$ . In essence this was also the classical position of Gottlob Frege (1892/1948) and Bertrand Russell (1905, 1910). A variant of this position, growing out of the possible worlds framework, was championed by Rudolf Carnap (1947). For Carnap, two formulas are intensionally isomorphic if and only if they are constructed in syntactically the same way from constituents with the same intensions (functions from world-states to extensions). In effect, semantic contents of syntactically simple expressions are identified with intensions, while semantic contents of syntactically complex expressions are structured complexes the constituents of which are the semantic contents of their grammatically significant parts. This view was criticized by Alonzo Church (1954), who argued that semantically complex, but syntactically simple, expressions require a stronger notion of synonymy than sameness of intension. Church's modification of Carnap—which relies on rules of sense to induce a notion of synonymous isomorphism—is a variant of the classical Fregean position.

In the late 1980s the assignment of structured semantic contents to sentences was given a neo-Russellian twist by David Kaplan (1986, 1989), Nathan Salmon (1986), and Soames (1987). On the Russellian picture structured propositions are recursively assigned to formulas, relative

to contexts and assignments of values to variables. The semantic content of a variable  $v$  relative to an assignment  $f$  is just  $f(v)$ , and the semantic content of a closed (directly referential) term relative to a context  $C$  is its referent relative to  $C$ . Semantic contents of  $n$ -place predicates are  $n$ -place properties and relations. The contents of truth-functional operators may be taken to be truth functions, while the semantic content of a formula  $\ulcorner \lambda x [Fx] \urcorner$  is identified with a propositional function  $g$  that assigns to any object  $o$  the structured proposition expressed by  $\ulcorner Fx \urcorner$  relative to an assignment of  $o$  to " $x$ ."  $\ulcorner \exists x [Fx] \urcorner$  expresses the structured proposition in which the property of assigning a true proposition to at least one object is predicated of  $g$ . In this framework the attitude ascriptions (1a and 1b) express structured semantic contents in which the relation of asserting or believing is predicated of a pair consisting of an agent and the structured proposition semantically expressed by  $S$ . The semantic theory is completed by specifying the intensions determined by structured semantic contents, including the truth conditions of structured propositions in all possible world-states.

The signature commitment of this approach is to the possibility of asserting and believing singular propositions—which include as constituents the very objects they are about. On this approach to believe *de re* of an object that it is  $F$  is to believe the singular proposition about that object, which says that it is  $F$ . Sentences like (4), involving quantifying-in, are quintessential examples of *de re* belief ascriptions.

- (4) There is a planet  $x$  such that when the ancients saw  $x$  in the morning they believed that  $x$  was visible only in the morning and when they saw  $x$  in the evening they believed that  $x$  was visible only in the evening.

**MILLIANISM.** If, as Kaplan (1989) contends, the semantic contents of sentences containing indexicals are also singular propositions, then belief ascriptions containing indexicals in their complement clauses are also *de re* and hence share the basic semantic properties of ascriptions like (4). Salmon (1986) and Soames (2002) take this a step further, arguing for the Millian view that the semantic content of an ordinary proper name is simply its referent. One potentially problematic consequence of this view is that since *Ruth Barcan* and *Ruth Marcus* are coreferential, (5a) is characterized as semantically expressing the same proposition as (5b) and hence as having the same semantically determined truth value, even though it seems evident to many that it is possible to believe that

Ruth Barcan was a modal logician without believing the Ruth Marcus was:

(5a) John believes that Ruth Barcan was a modal logician.

(5b) John believes that Ruth Marcus was a modal logician.

Different Millians respond to this problem in different ways. Salmon (1986) and David Braun (2002) argue that the intuitions that (5a) and (5b) can differ in truth value are mistaken because speakers tend to confuse the identical beliefs ascribed to John by these ascriptions with the different manners of holding these beliefs associated with their different sentential complements. Soames (2002, 2005a) argues that even though the semantic contents of these sentences are the same, assertive utterances of them may indeed result in assertions of propositions with different truth values. In “A Puzzle about Belief” (1979) Saul Kripke takes a different tack. While neither advocating nor denying the Millian view, he argues that substitutivity problems of the sort illustrated here are independent of Millianism and indicate a breakdown of the basic principles underlying our belief-reporting practices.

**DESCRIPTIVISM.** By contrast, descriptivists, following in Frege’s footsteps, have wanted to assign different semantic contents to the two names and hence to the complement clauses in (5a and 5b). The problem has been to find a way of doing this that does not run afoul of Kripke’s refutation of descriptivism in *Naming and Necessity* (1972). One of Kripke’s arguments holds that since names are rigid designators, their semantic contents cannot be given by any nonrigid descriptions. This argument is not easily avoided by rigidifying candidate descriptions. As shown by Soames (2002), an analysis that takes the semantic content of *Aristotle* to be given by ‘the actual F’ will, all other things being equal, identify the semantic content of *Aristotle was a philosopher* with the singular proposition (about the actual world-state @) that the unique individual who “was F” in @ was also a philosopher. Assuming that the analysis also includes the standard relational treatment of belief ascriptions, one then gets the result that for any possible agent *a* and world-state *w*, ‘*x* believes that Aristotle was a philosopher’ will be true of *a* with respect to *w* only if in *w* *a* believes that the unique individual who “was F” in @ [not *w*] was also a philosopher. Since this is obviously incorrect, names can neither be nonrigid descriptions, nor descriptions rigidified using the actuality operator.

What about descriptions rigidified using Kaplan’s *dthat* operator? Even if, contra Kripke, a correct reference-fixing description ‘the *x*: *Dx*’ could be found for each name, the semantic content of ‘*dthat* [the *x*: *Dx*]’ would simply be its referent, in which case the descriptivist would be saddled with precisely the Millian predictions about attitude ascriptions that the theory was designed to avoid. One possible response, suggested by David Chalmers (2002), is, in effect, to take a belief ascription ‘*a* believes that *S*’ to report that the belief relation holds between the agent and pair consisting of the semantic content of *S* (in the context) and the meaning (function from contexts to such contents) of *S*. However, now a different problem arises. To avoid Kripke’s non-modal arguments against familiar candidates for reference-fixing descriptions, post-Kripkean descriptivists have had to resort to egocentric, metalinguistic descriptions of the sort *the individual I have heard of under the name “n.”* Although this move assigns different objects of belief to the complement clauses of (5a) and (5b), it does not solve the problem. The point, after all, is not simply to assign different belief objects in these cases, but to explain the different information one gathers about John from utterances of (5a) and (5b). As Soames (2005b) argues in *Reference and Description: The Case against Two-Dimensionalism* (2005), it is hard to see how these egocentric, metalinguistic descriptions could, realistically, contribute to this.

## DAVIDSON’S LINGUISTIC VIEW

A different approach to problems involving substitutivity is to take ascriptions ‘*x* says/asserts/believes that *S*’ as reporting relations either to *S* itself, or to a complex in which *S* is paired with its semantic content. Either way, since substitution of one expression for another in *S* always produces a new complement *S*’, attitude ascriptions that differ in this way always report relations to different objects, whether or not the semantic contents of *S* and *S*’ are the same. This encourages the thought that such ascriptions can always differ in truth value.

An early and influential version of this approach was developed by Donald Davidson (1968–1969), who argued that (6a) should be understood on the model of (6b), in which *that* is treated as a demonstrative, utterances of which refer to utterances of the independent sentence that follows it:

(6a) Galileo said that the Earth moves.

(6b) Galileo said that. The Earth moves.

On this analysis what is said by an assertive utterance *u* of (6a) is that one of Galileo's utterances stands in, as Davidson puts it, the samesaying relation to the subutterance *u\** of *the Earth moves*. Although this analysis promised a simple way of capturing the logic of attitude ascriptions, it foundered on certain recalcitrant facts, including the fact that some ascriptions, like *Every mother said that her son was lovable*, cannot be broken up into separate and independent sentences in the manner of (6b) and the fact that the assertion made by an utterance of (6a) could have been true even if the subutterance *u\** had never existed, indicating that the Davidsonian truth conditions are incorrect.

### LATER LINGUISTIC AND REPRESENTATIONALIST VIEWS

Beginning in the 1990s improvements of Davidson's idea, including, most notably, that of Richard Larson and Peter Ludlow (1993), avoid these difficulties by dispensing with utterances and by treating attitude ascriptions as reporting relations between agents and the interpreted logical forms of their sentential complements. These are abstract, syntax-encoding structures that contain both the expressions occurring in sentences and their referential contents. Abstracting, one has here a version of the structured propositions approach in which linguistic expressions are included in the propositions sentences express. Although this version has potential virtues, it shares a crucial problem with Davidson's original analysis. Just as Davidson's silence about the intension of the samesaying relation prevented his theory from making any predictions about when (if ever) substitution of coreferential names or indexicals in a *says that* ascription changes truth value, so Larson and Ludlow's silence about the intension of the belief relation, alleged to hold between agents and interpreted logical forms, prevents their theory from making any predications about similar substitution in belief ascriptions (see Soames 2002). Since some such substitution clearly does preserve truth value, the problem is a daunting one.

Arguably, the most sophisticated approach of this general type is Richard's (1990), which combines context-sensitivity with linguistically augmented, structured Russellian propositions. For Richard, a belief ascription 'x believes that S', used in a context C, is true of an agent *a* if *a* accepts some sentence S' with the same Russellian content in *a*'s context as S has in C, while being similar enough to S to satisfy the belief-reporting standards in C. As indicated by Soames (2002), the evaluation of this view crucially depends on identifying similarity stan-

dards present in contexts and assessing their impact. Although there are certain evident problems here, opinions of their import vary. Finally, a different sort of context-sensitive view, advocated by Mark Crimmins and John Perry (1989), takes belief ascriptions to report that an agent believes a structured, Russellian proposition by virtue of having ideas of a certain sort—where these are mental particulars in the mind of the agent that are either implicitly demonstrated, or implicitly characterized as being of a certain type, by the one uttering the ascription. This view is usefully criticized by Jennifer Saul (1993).

### EXTENSION: INTENSIONAL "TRANSITIVE" VERBS

Example (2a), in which *assert* occurs as an ordinary transitive verb operating on the extensions of its noun-phrase arguments, shows that not all attitude ascriptions contain sentential clauses. The examples in (7) show that there are also verbs, the grammatical objects of which are not overtly clausal, which are intensional in nature:

- (7a) John wants a perpetual motion machine.
- (7b) John is looking for the fountain of youth.
- (7c) John imagined a room full of unicorns.
- (7d) John worships many gods.

The relationship between these examples and ordinary propositional attitude ascriptions is a matter of ongoing investigation. How is it that (7a to 7d) can be true even though there are apparently no real entities described by their postverbal arguments? Are some or all these sentences covertly clausal? For example, are (7a) and (7b) to be assimilated to (8a) and (8b)?

- (8a) John wants it to be the case that he has a perpetual motion machine.
- (8b) John is trying to bring it about that he finds the fountain of youth.

These and related questions have been discussed by philosophical logicians and linguistic semanticists including Richard Montague (1974), Graeme Forbes (2000), Richard (1998), and Marcel den Dikken, Larson, and Ludlow (1997).

## PROPOSITIONAL ATTITUDES: ISSUES IN THE PHILOSOPHY OF MIND AND PSYCHOLOGY

This entry aims to characterize the philosophical issues surrounding the propositional attitudes. Particular attention is paid to the arguments philosophers have brought to bear when discussing the existence and nature of the attitudes.

### SUBJECT MATTER AND PHILOSOPHICAL METHODOLOGY

Discussions of the nature of mind typically distinguish between two fundamental kinds of mental states or properties. One kind of mental state or property involves states that are qualitative in nature: Examples include raw feels, sensations, tickles, and pains. The other kind of mental state or property involves states that are contentful in nature, "pointing to" or "representing" things beyond themselves: Examples include thoughts, desires, fears, and intentions. This distinction is not unproblematic, since it is not clear whether these two categories exhaust the domain of the mental, nor is it clear whether they are mutually exclusive. However, most philosophers of mind accept that there is some important distinction in this region. Propositional attitudes are often cited as the paradigmatic example of the latter kind of mental state.

As their name indicates, the propositional attitudes are *attitudes*—cognitive relations such as belief, desire, fear, hope—that a subject bears to what are typically (though not uncontroversially) taken to be *propositions*. The attitudinal component of a propositional attitude is

a matter of how a particular proposition is being taken: Thus Sally can *believe* that it will rain, *hope* that it will rain, *fear* that it will rain, and so forth. In each case the proposition that is the content of her attitude, *that it will rain*, is the same; what differs is how this proposition is being taken by Sally (believed in, hoped for, or feared). Of course, one and the same attitude can be taken towards different propositions: Thus Sam can believe that the Yankees are a great baseball team, believe that Atlanta is hot and muggy, believe that the office of the U.S. presidency has been demeaned, and so forth. In each case Sam's attitude is the same (belief), what differs is the propositions he believes.

A good deal of the attention philosophers have given to the propositional attitudes is devoted to analyzing the sentences used to ascribe the attitudes. Examples of such *attitude-ascribing sentences* include "Jones believes that it's raining," "Smith worries that State University's soccer team will lose," and "McSorley wants State University's soccer team to lose." Indeed, the very idea that propositional attitudes are cognitive relations that subjects bear to propositions (a variant of which is defended in Jerry Fodor's 1978 article, "Propositional Attitudes") is advanced on the basis of the surface grammar of the sentences used to ascribe the attitudes. Thus "Jones believes that it's raining" is naturally read as saying, of Jones (the reference of "Jones"), that he bears the belief-relation (= the reference of "believes") to the proposition *that it's raining* (= the reference of "that it's raining"). Even sentences such as "McSorley wants State University's soccer team to lose," which do not appear to refer to a proposition at all, can be translated (admittedly with some awkwardness) into equivalent sentences that do, or at least appear to, make such a reference: "McSorley wants it to be the case that State University's soccer team loses." Admittedly, though, such a propositionalist formulation may not be possible in all cases of attitude-ascribing sentences. Consider "Williams fears bats" or "Simon loves ice cream."

Whatever their ultimate nature (more on which below), the propositional attitudes themselves have been thought to be extremely important for the study of human behavior. This is seen when we consider how we go about explaining our own and others' behavior in those cases in which the behavior is taken to be intentional (falling in the domain of human action). In such cases, we explain the behavior as the effect of the subject's propositional attitudes. Thus it seems natural to explain why McSorley walked to the refrigerator in terms of her desire for cold water and her belief that cold water is to be

found there; or to explain why Jackson ran away by citing his belief that a dangerous lion was coming his way and his desire not to get attacked. Explanations of this belief-desire sort are used by ordinary folk as we go about trying to predict and explain the actions of our fellows in everyday circumstances.

One philosophical question that arises in this connection concerns the status of such explanations. Suppose, as many philosophers do, that these explanations are sometimes true. What sort of explanation do they offer? Perhaps everyone can agree that they are *rationalizing* explanations, depicting the action in question as rational in light of the subject's corpus of beliefs and desires. But some philosophers hold that, in addition to rationalizing the behavior in question, they also provide a *causal* explanation of it (see Davidson 1963). If so, then the sort of psychology that appeals to the ordinary "folk" explanations of action—what has been termed *folk psychology*—can take its place beside other sciences that seek to characterize the world's causal nexus.

It is noteworthy that the causal-explanatory perspective provides an alternative approach to the nature of the attitudes, one that differs from the approach involving the analysis of attitude-ascribing sentences. Where the sententialist approach (as we might call it) assumes that we can understand the attitudes by making sense of *our talk* about them, the causal-explanatory approach begins by assuming that, whatever their ultimate nature, the propositional attitudes are the causal springs of human action. Taking the latter approach leads one to conceive of the attitudes as whatever plays the relevant causal role in the production of action. Of course, the two approaches might well be complementary: What one learns about the attitudes from analyzing attitude-ascribing sentences might be compatible with (and supplement) what one learns about the attitudes by thinking about them as the causal basis of action. (Indeed, the desire to secure the compatibility of the sententialist approach and the causal-explanatory approach appears to be a core motivation behind Fodor's 1975 hypothesis in *Language of Thought*, according to which propositional attitudes are tokenings of language-like mental symbols in the brain.) But it is also possible that the sententialist and causal-explanatory approaches will turn out to be in tension, with each one yielding some conclusions not sanctioned by, or perhaps even in conflict with, the other. Settling such a matter is perhaps the main burden of philosophical reflection on the nature of the propositional attitudes.

## THE NATURE OF THE CONTENTS OF THE ATTITUDES

Common to both the sententialist and the causal-explanatory approaches to the propositional attitudes is the idea that the attitudes are *contentful* mental states. As mental states they are *about* things, typically objects and properties from the nonmental environment. Take Sanchez's belief that his grandmother smothers him with kisses. This belief is about his grandmother, him, and the property of smothering with kisses. This aspect of the propositional attitudes—their being *about* worldly states of affairs—raises a number of interesting and related philosophical issues. How does something (such as a mental state like Sanchez's belief) come to be about another thing (such as Sanchez's grandmother) in the first place? What *determines* what a mental state is about? How does the “aboutness” of mental states relate to other forms of “aboutness”? And finally, what can be said about cases in which a mental state is “about” something that does not really exist—unicorns, for example?

Philosophers have introduced the term “intentionality” to designate the domain of aboutness itself. In speaking of mental states as about the world, we are speaking of their *intentional* properties, just as in speaking of, for example, the sentence “Morty Morris has a big red wart on his nose” as about Morty Morris's big red nose wart, we are speaking of the sentence's intentional properties. Such properties are also called *semantic* properties: Both mental states and sentences—and arguably pictures, maps, models, and perhaps other things as well—have such properties. When something, such as a mental state or a sentence, has intentional or semantic properties, and so is about something, we can speak of what the state is about as *the content* of that state. Talk of the content of a mental state is to be understood in terms of what the mental state *represents* as the case. So Sanchez's belief has a content, which is what that belief represents to be the case: namely, that his grandmother smothers him with kisses.

It is noteworthy that a belief can represent something that is not the case. Suppose that Sanchez's grandmother does *not*, in fact, smother him with kisses (it's all “in his head,” so to speak). Then, supposing there is an inventory of all of the facts that make up our world, we would not find in this inventory any fact to the effect that Sanchez's grandmother smothers him with kisses. In short, there is no fact that is represented by his belief. But then what is this shadowy thing we are calling the content of his belief, that which his belief represents to be the case? Above we called this content a “proposition,” and we can now see

the attraction of the view that the content of an attitude is a proposition. For although it is hard to say exactly what propositions are, we can say at least this much: The existence of a given proposition does not depend on the existence of the corresponding fact that would make the proposition true. That is, there can be *false* propositions. Given that Sanchez's grandmother is not as Sanchez's belief depicts her, the proposition that is the content of Sanchez's belief is itself a false proposition.

The postulation of the proposition as the content of the attitudes raises a bundle of related metaphysical questions. What is the nature of propositions? (Is it essentially a linguistic entity? an abstract one? a mental one?) Do propositions have parts, and if so, what is the nature of those parts? Here we focus on a question bearing more directly on the philosophy of mind: How do propositional attitudes come to have the propositional content they have? More concretely, what makes Sanchez's belief a belief about his grandmother, and not, say, about ice cream sundaes or pink elephants or any of an infinite number of other things? Let us address this by asking which facts *fix* the content of his belief: Which facts are such that, if you fix them, then, no matter what else is going on in the universe, you have fixed the content of his belief that his grandmother smothers him with kisses? A natural first guess would be that the facts in question are facts regarding the mental image(s) in Sanchez's mind at the time that he calls this belief to mind. On such a view, once we fix the mental image(s) “in” his mind, we have fixed what his belief is about.

But this cannot be quite right. First, mental images do not appear to have the right sort of specificity to fix the content of the propositional attitudes. To see this, imagine a scenario in which Sanchez's grandmother has an identical twin, from whom the grandmother herself is indistinguishable, but whom Sanchez has never met or otherwise heard of. Then the image in Sanchez's mind “fits” his grandmother's twin as much as it “fits” his grandmother. But it seems implausible to think that his belief is about the twin, for he has never met or heard of her. Second, in addition to not having the right sort of specificity, mental images are too unstable and subjective to fix the contents of one's attitudes. This is clearest in cases in which the subject matter of the attitude is an abstract one. Precisely what image goes before your mind when you call forth your belief that  $1+1=2$ ? And what image is before your mind when you believe that space is (or is not) infinite? Will it be true that any two people who believe e.g. that  $1+1=2$  will have the same type of image before their minds? Presumably not. But then how

does the image fix the content of their belief? It seems that what they have in common, in virtue of which they both count as believing that  $1+1=2$ , is something other than a particular type of image.

And the same point can be made even in cases in which the subject matter of the attitude is not abstract. Take Roger's belief that Morty Morris has a big red wart on his nose. Since Morty Morris is Roger's best friend, Roger has a vivid mental image of Morty (wart and all). But Mathilde, who (having been told by Roger) also believes that Morty Morris has a big red wart on his nose, has never met Morty, and therefore has no such image. Again it seems that what Roger and Mathilde have in common, in virtue of which they both count as believing that Morty Morris has a big red wart on his nose, is something other than a particular type of mental image in mind.

These arguments (and the examples on which they are based) raise a host of issues regarding how propositional attitudes come to have the propositional content they have. Consider first the relation between such contents and the environment in which one lives and interacts. One plausible account of why Sanchez's belief is about his grandmother, rather than her identical twin, is that his belief was caused and sustained by activities involving one woman and not the other. So it can seem that interaction with one's environment is relevant to the determination of the contents of one's attitudes. Next consider the relationship between language and the content of the attitudes. Recalling that mental images are too unstable and subjective to fix the contents of attitudes, we might ask: Precisely what do Roger and Mathilde have in common, in virtue of which they both count as believing that Morty Morris has a big red wart on his nose? At least part (but only part!) of the answer is that they are both disposed to accept and assert a sentence that *means* that Morty Morris has a big red wart on his nose. Perhaps, then, among the facts that fix the content of one's attitudes we must include facts regarding the meanings of one's words.

These conclusions highlight one of the bigger controversies in the theory of content. In particular, we have seen at least three types of fact that might be regarded as relevant to fixing the content of one's attitudes. We started off with the suggestion that facts regarding the subject's mental images fix the content of her attitudes, but we moved quickly to include facts regarding causal history and then on to facts regarding the meanings of one's words. These correspond roughly to three distinct

theoretical options available with respect to the sort of facts needed to fix the content of one's attitudes.

*Content internalism* is the view that the only facts needed to fix the content of a subject's attitudes are facts that do not presuppose the existence of anything beyond the subject herself. The view with which we started, according to which the facts regarding the subject's mental images fix the contents of her attitudes, is one version of content internalism. But the content internalist can allow other sorts of facts, so long as these do not presuppose the existence of anything beyond the subject herself; and the most plausible versions of content internalism (for which see Searle 1983) include facts about the individual's use of language, where the meanings of her words are not thought to depend on the existence of anything beyond the subject herself. Of the various arguments for content internalism, one of the most influential is what we might call the argument from "intentional inexistence." Consider, to begin, that one can form a belief which is "about" something that does not exist—as with Ponce de Leon's belief that the Fountain of Youth is in Florida, or Roger's belief that the largest natural number is even. What is more, it would seem possible (though of course highly unlikely) that none of our beliefs succeed in being about any existing thing: Perhaps you are suffering an eternal and systematic hallucination in a world containing nothing but your own mind! But in that case, although your beliefs remain the same (or so it might seem), there are no worldly objects for them to be "about." This suggests that the "aboutness" properties of beliefs should be understood in such a way as not to presuppose the existence of anything beyond the thinking subject.

Many philosophers, unconvinced by this sort of argument, have thought that the internalist view is too restrictive in the set of facts it regards as relevant to fixing the content of the attitudes. A second view, *content individualism*, expands the set of content-fixing facts to include not just the facts allowed by the content internalist, but also any facts regarding the thinker's own causal history. (See Davidson 1984 and 2001 for an example of a view that combines *content externalism*, which is the denial of content internalism, with content individualism.) Although the cost of moving from internalism to individualism is that of having to rebut the argument from intentional inexistence—something that forces the individualist to come up with an account of beliefs "about" non-existent "objects"—the payoff of making this move can be made clear in connection with the following development of Sanchez's case. Sanchez

has an identical twin, Twin-Sanchez, separated from Sanchez from birth. Twin-Sanchez has interacted only with twin-granny, the identical twin of Sanchez's grandmother. Further, the course of experience Sanchez has with his grandmother is internally indistinguishable from the course of experience Twin-Sanchez has with twin-granny. So, for example, at the very moment Sanchez sees his grandmother wearing a lovely purple vest and making waving motions as she smiles, Twin-Sanchez sees twin-granny wearing an indistinguishable lovely purple vest making waving motions as *she* smiles; at the very moment Sanchez hears his grandmother singing a lovely melody, Twin-Sanchez hears twin-granny singing an indistinguishable lovely melody; and so forth through time. At one point each of the Sanchez twins, admiring the grandmother in his presence, forms a belief he would express with, "She has a wonderful voice." The natural view is that the contents of their beliefs differ: Sanchez's belief represents *his* grandmother (not twin-granny) as having a wonderful voice, whereas twin-Sanchez's belief represents twin-granny (not granny) as having a wonderful voice.

The content individualist can easily accommodate this natural view, as the difference in content can be fixed by the facts regarding each twins' causal history (with distinct grannies). The content internalist, by contrast, will have trouble accepting the natural view: Since the twins' course of experiences are internalistically indistinguishable, there will be some pressure on the content internalist to treat the twins as having beliefs *with the very same content*. (See Searle 1983 for an attempt by an internalist to avoid this conclusion.)

But if the content individualist has this virtue over the internalist, some philosophers have felt that individualism does not go far enough. A third position, which we might designate as *content anti-individualism*, is still more liberal in the range of facts it regards as relevant to fixing the content of a subject's attitudes. As its name suggests, content anti-individualism is the denial of content individualism. But it is helpful to see why a theorist might deny that "individualistic" facts suffice to fix the content of a subject's attitudes. The controversy has to do with the role of language in fixing the content of the attitudes. In one sense, it is uncontroversial that the meaning of one's words determines the contents of the attitudes one expresses with those words. The controversial matter regards what determines the meaning of one's words. The individualist maintains that no facts beyond those regarding the individual speaker herself—the conditions under which she uses her words, how she herself expli-

cates their meanings—are needed to fix the meaning of her words; whereas the anti-individualist maintains that these "individualistic" facts do not suffice to fix the meanings of her words. The insight (or alleged insight) behind anti-individualism is that individual language users typically defer to, and take themselves to be answerable to, public standards of correct usage. Such standards are not typically fixed by the individual's *own* word usage or meaning-explications, but instead are fixed by the usage of other speakers (Kripke 1972) and the meaning-explicating practices of the relevant experts in her linguistic community (Putnam 1975 and Burge 1979).

Interestingly, the sententialist and causal-explanatory approaches to the attitudes bear on the debate regarding the nature of mental content. For example, among the reasons offered in defense of anti-individualism, Burge notes in "Individualism and the Mental" (1979) that variations in public standards for the correct use of a word lead to differences in *the belief-attributing sentences* that would be used to report a subject's beliefs. And among the reasons offered in defense of content internalism are considerations pertaining to the internal basis of mental causes (for which see Fodor 1980). Although neither argument is decisive, each suggests the core motivations for and potential liabilities of the various positions on mental content.

### THE METAPHYSICS OF THE ATTITUDES: VERSIONS OF MATERIALISM

The question regarding the nature of mental content cannot be addressed in isolation from what we might call the metaphysics of the attitudes. What is the nature of the states and properties dubbed "the propositional attitudes"? How do such states and properties relate to the thinker's bodily states and properties? These questions, of course, force us to confront a particular version of the notorious mind-body problem.

The positions that can be taken on the relation between a subject's propositional attitudes and her bodily states and properties correspond to positions familiar from the general mind-body problem. *Attitude dualism* holds that propositional attitudes are *immaterial* states or properties of thinking subjects. But as with dualism generally, attitude dualism runs into trouble in connection with the causal role that the attitudes are thought to play: How do immaterial states or properties affect a subject's body? Most contemporary philosophers take some version of this problem to be decisive against dualism. And of these most go on to endorse *materialism*, according to

which all of the objects and properties of our world are material in nature. So we will restrict our discussion accordingly.

Among materialist views we can begin with the view known as *philosophical behaviorism*, according to which the so-called propositional attitudes really are nothing other than complex behavioral dispositions. Philosophical behaviorism itself (unlike psychological behaviorism) was originally motivated by the verification theory of meaning, according to which the meaning of a sentence consists in the conditions whose obtaining would *verify* the sentence (establish its truth). Since sentences such as “John believes that it’s raining” are typically regarded as true or false in virtue of observable behavior (e.g., John’s uttering “It’s raining!,” carrying an umbrella with him, putting on galoshes, and so forth), the result of applying the verification theory of meaning to attitude-ascribing sentences is that each such sentence is to be regarded as equivalent in meaning to a “behavioral translation,” a much longer sentence describing all of the behaviors and behavioral dispositions whose presence would verify the original sentence (see e.g. Ryle 1949). However, this view faces two obvious and devastating difficulties.

First, as noted in Putnam “Brains and Behavior” (1965), the view is either false or unacceptably circular. It is false if the translation of the target sentence (“John believes that it’s raining”) fails to capture all of the conditions whose presence would be taken as evidence for the truth of that sentence. But in order to avoid falsity on this score, the translation will need to make reference to other attitudes the subject has: For example, John’s uttering “It’s raining!” counts for the truth of “John believes that it is raining” only if he is speaking sincerely and believes that “It’s raining” means that it’s raining; John’s taking an umbrella with him (or putting galoshes on) counts for the truth of “John believes that it’s raining” only if he desires not to get wet and believes that the umbrella (galoshes) will prevent him from getting wet; and so forth. In fact, it would appear that the connection between attitudes and behavior invariably involves other attitudes in this way. But in that case, any attempt to translate a target attitude-ascribing sentence will yield a translation which itself contains mention of other attitudes. On pain of circularity, these latter attitude-ascribing components in the translation must also be translated. But then the problem begins again, and the whole approach appears doomed to an unacceptable sort of circularity.

Nor is this philosophical behaviorism’s only problem. A second objection is that philosophical behaviorism

surrenders the idea of propositional attitudes as *the causes* of behavior. Consider: that a sugar cube dissolves in water is the basis for regarding it as water-soluble; so it would be an empty explanation to regard its solubility in water as *the cause* of its dissolving on a particular occasion. (Compare the doctor spoofed in Molière’s play *La malade imaginaire*: He explained the sleep-producing character of a particular drug to its having a “dormative virtue.”) Similarly, if beliefs and desires are dispositions to act, then it would be an empty explanation indeed to regard beliefs and desires as *the causes* of action.

Given the failure of philosophical behaviorism, the desire to preserve the causal profile of the propositional attitudes within a materialist framework provided the main motivation behind *identity theory*. Recognizing the role of the attitudes as the causes of intelligent behavior, early identity theorists used the fact (or what they regarded as the fact) that the causes of intelligent behavior are to be found in the states and processes of the central nervous system, to conclude that the propositional attitudes are *identical* to those states and processes of the central nervous system. (For an early formulation of identity theory, albeit in connection with sensory rather than contentful states, see Smart 1962.) The proposed identity was between property-*types*: An “attitudinal” property-type (such as the property of *believing that it is raining*) was held to be identical to a property-type instantiated by the central nervous system (such as the property of *having such-and-such a pattern of neural activation in this-or-that region of the brain*). But this gave rise to an objection from the so-called multiple-realizability of mental states (Putnam 1967): On the assumption that creatures whose underlying neurophysiology is very different from our own might nevertheless be regarded as being the subjects of attitudes, such type-identity claims were much too strong.

Such an objection to type-identity theory acquired additional force in light of the development of sophisticated forms of artificial intelligence. Alan Turing’s famous “Turing Test” (1950) taught that a system was to be regarded as “intelligent” so long as it behaved in a way that would lead those with whom it interacted to regard it as intelligent. The implicit idea was that any system with the right sort of *functional complexity*—as seen in its capacity to acquire and process information from its environment and to use this information to guide its subsequent actions—was to be regarded as intelligent (and hence, given some plausible assumptions, as a subject of the propositional attitudes). The result was what is perhaps the most widely accepted view of the metaphysics of

the attitudes: *functionalism*. According to the functionalist, propositional attitudes are best characterized by their functional or causal profile. So just as it would be a mistake to identify the property of *being a carburetor* with the property of *being made of metal and shaped in such-and-such a way*—surely being a carburetor is more a matter of function rather than material—so too it would be a mistake to identify the property of *believing that it is raining* with some particular property of the body. Rather, a subject has this property, and so counts as believing that it is raining, when the subject is in a state with a certain functional or causal profile—one that is caused in certain characteristic sorts of ways (e.g., seeing rain) and interacts with other functionally defined states to bring about certain effects (e.g., producing utterances of “It’s raining!,” movements to retrieve the umbrella when leaving, and so forth).

According to the functionalist, the first task in connection with the metaphysics of the attitudes is to specify the functional role corresponding to each distinct attitude. Once that task is completed, the functionalist philosopher can then pass on to empirical investigation the task of identifying what particular physical property *realizes* that functional role in a given system. (Compare: Once the functional role of a carburetor has been specified, we can go on and ask which feature of a particular car realizes that role.) Such a view is often advanced as part of a “computational” theory of the attitudes, according to which the functional role of particular mental states is best understood in information-processing terms. So formulated, functionalism, as shown by A. Newell (1980) and David Marr (1982), has been popular not only in the philosophy of mind but also in traditional cognitive science.

Of course, having specified what we take to be the functional role of a particular attitude-type (say, the belief that it is raining), there is no guarantee that there will *be* any state or property of the body or the central nervous system playing that role. Perhaps the very idea that there is a state playing that role is itself part of a mistaken theory of the mind, one whose fundamental postulates (beliefs, desires, and so forth) are as misguided as was the postulation of witches and other spiritual entities by misguided theorists of earlier ages. A number of philosophers, such as P. Churchland (1981), have begun to express such misgivings, arguing that the account of mind which postulates propositional attitudes is part of a “worm-eaten myth” that will be replaced as brain science progresses. Such a view, known as *eliminative materialism*, is perhaps the starkest version of materialism there

is, as it combines a general commitment to materialism with the view that there is nothing in the material world that answers to what we take the propositional attitudes to be. Though clearly radical, such a view has challenged mainstream theorists to further clarify what is at issue in the debate over the propositional attitudes.

## PROPOSITIONAL KNOWLEDGE, DEFINITION OF

The traditional "definition of propositional knowledge," emerging from Plato's *Meno* and *Theaetetus*, proposes that such knowledge—knowledge that something is the case—has three essential components. These components are identified by the view that knowledge is justified true belief. Knowledge, according to the traditional definition, is belief of a special kind, belief that satisfies two necessary conditions: (1) the truth of what is believed and (2) the justification of what is believed. While offering various accounts of the belief condition, the truth condition, and the justification condition for knowledge, many philosophers have held that those three conditions are individually necessary and jointly sufficient for propositional knowledge.

The belief condition requires that one accept, in some manner, any proposition one genuinely knows. This condition thus relates one psychologically to what one knows. It precludes that one knows a proposition while failing to accept that proposition. Some contemporary philosophers reject the belief condition for knowledge, contending that it requires a kind of mentalistic representation absent from many cases of genuine knowledge. Some other contemporary philosophers endorse the belief condition but deny that it requires actual assent to a proposition. They propose that, given the belief condition, a knower need only be disposed to assent to a proposition. Still other philosophers hold that the kind of belief essential to propositional knowledge requires assent to a known proposition, even if the assent need not be current or ongoing. The traditional belief condition is neutral on the exact conditions for belief and for the objects of belief.

The truth condition requires that genuine propositional knowledge be factual, that it represent what is actually the case. This condition precludes, for example, that astronomers before Nicolas Copernicus knew that Earth is flat. Those astronomers may have believed—even justifiably believed—that Earth is flat, as neither belief nor

justifiable belief requires truth. Given the truth condition, however, propositional knowledge without truth is impossible. Some contemporary philosophers reject the truth condition for knowledge, but they are a small minority. Proponents of the truth condition fail to agree on the exact conditions for the kind of truth essential to knowledge. Competing approaches to truth include correspondence, coherence, semantic, and redundancy theories, where the latter theories individually admit of variations. The truth condition for knowledge, generally formulated, does not aim to offer an exact account of truth.

The justification condition for propositional knowledge guarantees that such knowledge is not simply true belief. A true belief may stem just from lucky guesswork; in that case it will not qualify as knowledge. Propositional knowledge requires that the satisfaction of its belief condition be suitably related to the satisfaction of its truth condition. In other words, a knower must have adequate indication that a belief qualifying as knowledge is actually true. This adequate indication, on a traditional view of justification suggested by Plato and Immanuel Kant, is suitable evidence indicating that a proposition is true. True beliefs qualifying as knowledge, on this traditional view, must be based on justifying evidence.

Contemporary philosophers acknowledge that justified contingent beliefs can be false; this is fallibilism about epistemic justification, the kind of justification appropriate to propositional knowledge. Given fallibilism, the truth condition for knowledge is not supplied by the justification condition; justification does not entail truth. Similarly, truth does not entail justification; one can lack evidence for a proposition that is true.

Proponents of the justification condition for knowledge do not share an account of the exact conditions for epistemic justification. Competing accounts include epistemic coherentism, which implies that the justification of any belief depends on that belief's coherence relations to other beliefs, and epistemic foundationalism, which implies that some beliefs are justified independently of any other beliefs. Recently, some philosophers have proposed that knowledge requires not evidence but reliable (or truth-conducive) belief formation and belief sustenance. This is reliabilism about the justification condition for knowledge. Whatever the exact conditions for epistemic justification are, proponents of the justification condition maintain that knowledge is not merely true belief.

Although philosophers have not agreed widely on what specifically the defining components of proposi-

tional knowledge are, there has been considerable agreement that knowledge requires, in general, justified true belief. Traditionally, many philosophers have assumed that justified true belief is sufficient as well as necessary for knowledge. This is a minority position now, owing mainly to Gettier counterexamples to this view. In 1963 Edmund Gettier challenged the view that if one has a justified true belief that  $p$ , then one knows that  $p$ . Gettier's counterexamples are:

- (I) Smith and Jones have applied for the same job. Smith is justified in believing that (i) Jones will get the job, and that (ii) Jones has ten coins in his pocket. On the basis of (i) and (ii), Smith infers, and thus is justified in believing, that (iii) the person who will get the job has ten coins in his pocket. As it turns out, Smith himself will actually get the job, and he also happens to have ten coins in his pocket. So, although Smith is justified in believing the true proposition (iii), Smith does not know (iii).
- (II) Smith is justified in believing the false proposition that (i) Jones owns a Ford. On the basis of (i), Smith infers, and thus is justified in believing, that (ii) either Jones owns a Ford or Brown is in Barcelona. As it turns out, Brown is in Barcelona, and so (ii) is true. So although Smith is justified in believing the true proposition (ii), Smith does not know (ii).

Gettier counterexamples are cases where one has a justified true belief that  $p$  but lacks knowledge that  $p$ . The Gettier problem is the difficulty of finding a modification of, or an alternative to, the traditional justified-true-belief analysis that avoids difficulties from Gettier counterexamples.

Contemporary philosophers have not reached a widely accepted solution to the Gettier problem. Many philosophers take the main lesson of Gettier counterexamples to be that propositional knowledge requires a fourth condition, beyond the justification, belief, and truth conditions. Some philosophers have claimed, in opposition, that Gettier counterexamples are defective because they rely on the false principle that false evidence can justify one's beliefs. There are, however, examples similar to Gettier's that do not rely on any such principle. Here is one such example inspired by Keith Lehrer and Richard Feldman:

- (III) Suppose that Smith knows the following proposition,  $m$ : Jones, whom Smith has always found to be reliable and whom Smith has no reason to dis-

trust now, has told Smith, his officemate, that  $p$ : He, Jones, owns a Ford. Suppose also that Jones has told Smith that  $p$  only because of a state of hypnosis Jones is in and that  $p$  is true only because, unknown to himself, Jones has won a Ford in a lottery since entering the state of hypnosis. Suppose further that Smith deduces from  $m$  its existential generalization,  $o$ : There is someone, whom Smith has always found to be reliable and whom Smith has no reason to distrust now, who has told Smith, his officemate, that he owns a Ford. Smith, then, knows that  $o$ , since he has correctly deduced  $o$  from  $m$ , which he also knows. Suppose, however, that on the basis of his knowledge that  $o$ , Smith believes that  $r$ : Someone in the office owns a Ford. Under these conditions, Smith has justified true belief that  $r$ , knows his evidence for  $r$ , but does not know that  $r$ .

Gettier counterexamples of this sort are especially difficult for attempts to analyze the concept of propositional knowledge.

One noteworthy fourth condition consists of a "defeasibility condition" requiring that the justification appropriate to knowledge be "undefeated" in that an appropriate subjunctive conditional concerning defeaters of justification be true of that justification. A simple defeasibility condition requires of our knowing that  $p$  that there be no true proposition,  $o$ , such that if  $q$  became justified for us,  $p$  would no longer be justified for us. If Smith genuinely knows that Laura removed books from the office, then Smith's coming to believe with justification that Laura's identical twin removed books from the office would not defeat the justification for Smith's belief regarding Laura herself. A different approach claims that propositional knowledge requires justified true belief sustained by the collective totality of actual truths. This approach requires a precise, rather complex account of when justification is defeated and restored.

The importance of the Gettier problem arises from the importance of a precise understanding of the nature, or the essential components, of propositional knowledge. A precise understanding of the nature of propositional knowledge, according to many philosophers, requires a Gettier-resistant account of knowledge.

## PROPOSITIONS

On one use of the term, "propositions" are objects of assertion, what successful uses of declarative sentences say. As such, they determine truth-values and truth conditions. On a second, they are the objects of certain psychological states (such as belief and wonder) ascribed with verbs that take sentential complements (such as *believe* and *wonder*). On a third use, they are what are (or could be) named by the complements of such verbs. Many assume that propositions in one sense are propositions in the others.

After some decades of skepticism about the worth of positing propositions, the last quarter of the twentieth century saw renewed interest in and vigorous debate over their nature. This can be traced in good part to three fac-

tors: the development in intensional logic of formal models of propositions; (not altogether unrelated) attacks on broadly Fregean accounts of propositions; and a spate of work on the nature of belief and its ascription.

"Possible-worlds semantics" is a collection of methods for describing the semantical and logical properties of expressions such as *necessarily*; these methods developed out of work done by Saul Kripke, Richard Montague, and others in the 1960s. It illuminated the logic and semantics of modal terms such as *necessarily*, of conditionals and tenses, and other constructions as well. In such semantics one assigns a sentence a rule that determines a truth-value relative to various "circumstances of evaluation" (possible worlds, times, whatever); a sentence such as "it is necessary that S" has its truth-value determined by the rule so associated with S. The success of such accounts made it natural to hypothesize that propositions, qua what is named by expressions of the form "that S," could be identified with such rules—equivalently, with sets of circumstances such rules pick out.

Such a conception of proposition provides too crude an account of objects of belief or assertion: It implausibly makes all logically equivalent sentences express the same belief and say the same thing. A partial solution to this problem supposes that propositional identity is partially reflected in sentential structure, taking propositions themselves to be structured. Given the working hypothesis that a proposition's structure is that of sentences expressing it, critical to determining the proposition a sentence (use) expresses are the contributions made by sentence parts (on that use).

Gottlob Frege (1952) suggested that associated with names and other meaningful expressions are "ways of thinking" or *senses* of what the expressions pick out; one might suppose that sense and sentence structure jointly determine proposition expressed. Sense, in the case of names and other singular terms, has standardly been taken to be given by describing how one thinks of the referent. For example, the sense of "Aristotle" for me might be given by "the author of the *Metaphysics*"; if so, my uses of "Aristotle taught Alexander" and "the author of the *Metaphysics* taught Alexander" would, on a Fregean view, express the same proposition.

During the 1970s Kripke, David Kaplan, and others argued convincingly that this view is untenable: It is obvious, on reflection, that the truth conditions of the assertion or belief that Aristotle was *F* depend on Aristotle in a way in which the truth conditions of the assertion or belief that the author of the *Metaphysics* was *F* do not. So either ways of thinking are somehow tied to the objects

they present (so that the way I think of Aristotle could not present anything but Aristotle), or the contributions of expressions to propositions must be something other than senses.

The success of accounts of intensional language that ignored sense in favor of constructions from references, along with the apparent failure of Fregean accounts, led in the 1980s to debate over the merits of what is variously called direct-reference theory, Millianism, and (neo-)Russellianism, espoused at various times by a wide variety of theorists including Kaplan (1989), Mark Richard (1990), Nathan Salmon, and Scott Soames (1988). On such views sense is irrelevant to individuating a proposition; indeed, it is irrelevant to semantics. In particular, what a name contributes to a proposition is its referent: The proposition that Twain is dead is the same singular proposition as the proposition that Clemens is.
