According to conceptual role semantics (CRS), the content of a mental representation (or mental state) is determined by the inferential relations among representations and causal relations between representations and extramental events (Block 1986, Loar 1981, Sellars 1963). In this respect CRS is similar to IT. The difference is that, whereas ITs employ holistic principles of interpretations (rationality and charity), CRS attempts to spell out inferential patterns associated with particular concepts. CRS seems plausible for the logical connectives. For example, if a thinker is disposed to infer the representation  $A\#B$  from  $A$  and  $B$  and vice versa, then  $\#$  is the thinker's conjunction concept. Some philosophers (Peacocke 1992) have attempted to formulate conditions that are necessary and/or sufficient for possessing certain predicate concepts. It appears that any such account is committed to a substantial analytic-synthetic distinction, since it will hold that certain inferences involving a concept are necessary to having the concept (Fodor and LePore 1992). Willard Van Orman Quine's arguments (1960) that there are no analytic inferences poses an important problem for CRS.

Another approach is informational semantics (Dretske 1981, Stalnaker 1984). These theories are supposed to provide naturalizations of content; that is, they specify naturalistic properties that are claimed to be sufficient for possessing content. Informational theories claim that the content of a belief is constituted by the information the belief state carries under certain conditions. A state  $S$  carries the information that a property  $P$  is instantiated just in case the occurrence of  $S$  is caused by and nomically implies the instantiation of  $P$ . Informational theories have difficulty accounting for the possibility of error, since if a belief state has the content that  $p$  it carries the information that  $p$ . To solve this problem Fred Dretske proposed that the content of a belief is the information that it carries during what he calls "the learning period." A different suggestion (Stalnaker 1984) is to identify belief content with the information the belief state carries under epistemically optimal conditions. Barry Loewer (1987) has argued that these accounts are not successful as naturalizations, since they appeal to

notions—learning, epistemic optimality—that themselves presuppose semantic notions.

Fodor has developed a sophisticated variant of informational theories that applies to the reference of Mentalese predicates. On this account, asymmetric dependency theory (ADT), a Mentalese predicate  $C$  refers to, for example, the property of being a cow if it is a law that cows cause  $C$ s, and any other causal relation between something other than cows and  $C$ s depends on this law but not vice versa. That is, if the other causal relations were to fail, it would still be a law that cows cause cows, but if the law were to fail, so would the other causal relation.

ADT is an atomistic account of content in that, contrary to CRS and ITs, it implies that the property of possessing a particular reference is metaphysically independent of inferential connections among thoughts and, indeed, independent of the existence of any other items with content. Whether or not one sees this as an advantage will depend on how one views the analytic-synthetic distinction. Obviously, ADT makes heavy use of metaphysical notions that are less than perspicacious, so one may wonder about its naturalistic credentials. It has also been argued (Boghossian 1991) that it is equivalent to an optimal-conditions account and is subject to the objections that show that account not to be a naturalization.

Teleological theories of content ground the contents of mental states in biological functions. The biological functions of a system in an organism are those of its features that increased the organism's fitness. Teleological accounts are quite elaborate, but the basic idea (Millikan 1984, Papineau 1992) is that there are desire-producing and belief-producing biological systems with certain biological functions. The desire-producing system has the function of producing states that tend to bring about certain effects. The effect associated with a particular desire is its content. The belief-producing systems have the function of producing states that tend to be tokened when certain states of affairs obtain. The state of affairs thus associated with a belief is its content.

Teleological accounts are appealing, since they are naturalistic, assign biological significance to contentful states, and seem to supply them with a kind of normativity. But various serious objections have been raised to teleological theories of content (Fodor 1992). The most serious is that it is doubtful that teleological considerations are sufficient to assign determinate contents to mental states. A desire state will typically tend to bring about a number of different advantageous effects. Natural

selection does not select any one of these effects as the content of the desire. Similarly, natural selection will not single out one of the states of affairs a belief state will typically be associated with as its unique content.

Whether or not content properties can be naturalized is an open question. Some consider it a very important question, since they think that if content properties cannot be naturalized then they are unsuitable to appear in scientific theories or, even worse, that they do not exist or are uninstantiated (Stich 1983). The unsuitability of content properties for science would be a blow to the emerging cognitive sciences. But the nonexistence of content properties would be devastating to the way we think about ourselves and others, since these ways are permeated with attributions of contentful states. In fact, it has been argued (Boghossian 1990) that the thesis that there are no content properties is incoherent. Fortunately, no dire consequences strictly follow from the failure of naturalization. It may be that content properties are natural but not naturalizable (McGinn 1991). It is possible that, while content properties are natural, connections between them and properties that occur in the natural sciences are too unsystematic or too complicated for us to discern. But whether or not this is so is also an open question.

Following Gareth Evans's discussion (1982), there has been growing interest in the proposals that there is a distinction between *conceptual* and *nonconceptual* content and that the latter plays a significant role in perception (and perhaps imagination) and in subdoxastic (and so unavailable to consciousness) cognitive processing. Exactly what this distinction amounts to, whether there is nonconceptual content, and what its explanatory and epistemological roles may be are all controversial matters.

Beliefs and other propositional attitudes involve relations to thoughts (or propositions), and concepts are constituents of thoughts. It follows that for someone to have the belief, for example, that the Supreme Court is about to convene, he must have the concepts *supreme court*, *about to convene*, and so on. A widely held necessary condition for concept possession is that one has the concept *C* only if one can think an array of thoughts involving *C*. This is similar to the systematicity that Jerry Fodor (1987/1990) appealed to support his claim that mental representations involved in thought are languagelike. In fact, he and others (who do not necessarily share his views about meaning) think of concepts as words in the mental language deployed in thinking and in propositional attitudes. Evans observed that it is plausible that there are mental states whose contents are not conceptually articulated in this languagelike way. Visual perception

seems to involve such states and processes. When one is looking at, for example, a sunset over a distant mountain range, one's perception seems much richer than what can be expressed in thought. There are particular colors and shapes represented in the perception that one is not able to represent in thought. Further, there do not seem to be components of visual representations that one can combine in the systematic ways in which concepts can be combined. In addition to perceptual states, the mental states of animals and the subdoxastic mental representations of humans posited by cognitive scientists are also said to have nonconceptual contents.

On some accounts of mental content, it is not clear that there can be nonconceptual content. For example, accounts like Donald Davidson's (1984), in which there is an intimate relationship between mental contents and the contents of public-language expressions and in which rationality constraints play a role in content determination, seem to preclude there being contents that cannot be expressed in public language. John McDowell (1994), who advocates such an account, has argued against the existence of nonconceptual content. Specifically, he thinks it is essential to mental states with content that they enter into rational and justifying relations with one another and claims that this requires that their contents be articulated conceptually. Famously, views like these resist attributing contentful mental states to animals and to subdoxastic mental processes, since animals and subdoxastic mental processes cannot harbor concepts.

Philosophers who think of mental content in terms of information (examples are Evans, Fodor, and Fred Dretske) can allow for states with nonconceptual content since non-conceptual representations can possess informational content. Dretske thinks that nonconceptual content is more basic than and prior to conceptual content, and that the latter is in some way derived from the former. Since information makes a division of possible worlds into those in which the information is correct and those in which it is not an informational state can stand in semantic relations of entailment and incompatibility with conceptual representations. On the other hand, it is not obvious how nonconceptualized information states can be involved in inference and reasoning.

There are a number of issues that advocates of nonconceptual content need to address. One is whether the distinction between conceptual and nonconceptual content is really a distinction between *kinds* of content or a distinction between different *ways* of representing content. Of course, this depends on what one takes content to be. As noted, states with nonconceptual content, like

those with conceptual content divide possible worlds into those that are, and those that are not, in conformity with the content. However, conceptual content is often thought of as involving structure that reflects conceptual composition. The question is whether this structure is better understood as a species of content or belongs to the representation that represents the content. Those who think of contents solely in possible-world terms, such as Robert Stalnaker (1998), will see structure as belonging to the representation.

Another issue is that the alleged nonconceptual content of a perception seems to be informationally much more rich than the content of a thought. At the same time, it seems to be finer-grained in that there are distinctions that can be made in perception that we do not and perhaps cannot represent conceptually. It is not clear how these two features fit together. One idea is to think of nonconceptual content as analogous to pictorial or map-like content (Peacocke 2001). If this is correct, it raises the question of whether the pictorial structure belongs to the content or to the representation. Also, as mentioned above, there are issues concerning the epistemological role of nonconceptual content. Can a nonconceptual perceptual state justify a perceptual belief that it causes? Finally, it is not clear whether the contents involved in perception, the mental states of animals, and subdoxastic states and processes are all the same kind of nonconceptual contents. Indeed, theorists who appeal to subdoxastic states and processes often posit sentencelike representations as involved in mental computations. Their contents are nonconceptual only in that they are not available to thought and propositional attitudes.

## CONTEXTUALISM

The term “contextualism” has been used to denote many different philosophical theories. Within epistemology alone, there are two broad categories of theories that have been called “contextualist”: subject contextualism and attributor contextualism.

### SUBJECT CONTEXTUALISM

A few basic concepts are needed to explain subject contextualism. Let *S* be an epistemic subject, a being whose cognitive attitudes are proper targets of epistemic evaluation. Let *C* be a cognitive attitude that *S* has. *C* may be a belief, a judgment, a high degree of confidence, an affirmation or endorsement of some kind—any attitude that is a proper target of epistemic evaluation. *C* has a propositional content *p*. Finally, let *x* be the situation in which *S* *C*s that *p*. We will hereafter specify the target of epistemic evaluation as “*S*’s *C*ing that *p* in *x*.”

According to subject contextualism, whether *S* *C*s that *p* in *x* constitutively depends on features of *x* that are metaphysically independent of *S*’s cognitive attitudes and of the truth-values of the propositional contents of *S*’s cognitive attitudes. As these features of *x* vary, so too does the epistemic status of (the degree of truth attached to) *S*’s *C*ing that *p*, even if *S*’s cognitive attitudes and the truth-values of their propositional contents all remain fixed. One or another version of such a view has been suggested in various passages in the writings of C. S. Peirce, Ludwig Wittgenstein, John Dewey, Karl Popper, W. V. Quine, and J. L. Austin. But only since the mid-1970s has subject contextualism been developed with any precision and generality.

The different versions of subject contextualism differ from each other in at least two ways. First, these different versions specify different features of *x* as relevant to constitutively determining whether *S* *C*s that *p* in *x*. Second, these different versions of subject contextualism specify different ways in which the relevant feature of *x* can determine whether *S* *C*s that *p*. By differences of the first kind, we can distinguish the various theories of subject contextualism that have been propounded into three broad groups.

According to one group of subject contextualist theories (Stine 1976, Goldman 1976, Dretske 1981), the epistemic status of *S* *C*ing that *p* in *x* constitutively depends on the objective probability of *p*’s being true in *x*. Other things being equal, the higher the objective probability of *p*’s being true in *x*, the higher the epistemic status of *S* *C*ing that *p* in *x*.

The most prominent argument in favor of this first variety of subject contextualism proceeds from consideration of case pairs such as the following (from Goldman 1976): Suppose that, in normal daylight, Henry, who has normal visual powers, has an unobstructed view of a barn right in front of him. Henry sees the barn, has a normal visual experience as of a barn, and believes that there is a barn in front of him. If there is nothing unusual about the case, then Henry knows that there is a barn in front of him. But now suppose that Henry’s environment is full of barn facades that look exactly like barns from the angle and distance at which Henry is currently viewing the real barn in front of him. In this second case, just as in the first case, Henry has a true belief that there is a barn in front of him. And in both cases, this belief is based on Henry’s seeing the barn, on his normal visual experience as of a barn. But in the second case, unlike the first, Henry does not know that there is a barn in front of him. What difference in the two cases could account for this difference in whether or not Henry knows? Subject contextualists of the first variety say that the difference in Henry’s extrapsychological environment—in particular, the frequency of barn facades in his environment—is responsible for the difference in whether he knows.

Oponents of this first variety of subject contextualism typically respond to the preceding argument by offering an alternative explanation of why Henry knows, in the first case but not in the second case, that there is a barn in front of him. In each case, they contend, Henry believes that there is a barn in front of him partly because he believes that, in his environment, things that look like barns from his vantage point typically are barns. So his belief that there is a barn in front of him is partly based on the latter epistemic belief. And the epistemic belief is true in the first case and false in the second case. It is the difference in the truth-value of the epistemic belief that explains why Henry knows in the first case but does not know in the second case—or so say the opponents of this first variety of subject contextualism.

According to a second group of subject-contextualist theories (Annis 1978, Williams 1992, Henderson 1994, Klein 1999), whether *S* *C*s that *p* in *x* constitutively depends on the inquiry that takes place in *x*. The inquiry fixes which considerations confer positive epistemic status upon *S*’s *C*ing that *p*. The main argument for this second variety of subject contextualism, propounded in different ways by Annis, Williams, and Klein, has to do with the regress of reasons. According to this argument, neither foundationalism nor coherentism offers a correct account of structure of epistemic reasons, or justifica-

tions. Foundationalism cannot offer a correct account, because it is committed to the unsustainable claim that some cognitive attitudes—the foundational beliefs—are intrinsically justified. And coherentism cannot offer a correct account, because it is committed to claiming either that circular reasoning provides justification or that each belief in a coherent set is a foundational belief. But if there are no foundational beliefs and if circular reasoning does not provide justification, then how can positive epistemic status accrue to *S*'s Cing that *p*? According to this second variety of subject contextualism, this question is best answered as follows: *S*, in a particular context of inquiry, makes certain presuppositions. These presuppositions can provide epistemic reasons, or justifications, for *S*'s other cognitive attitudes in that same inquiry. But when *S* moves into a different context of inquiry, some presuppositions in the earlier inquiry may be put into question in the new inquiry, and other propositions that were in question in the earlier inquiry may simply be presupposed in the new inquiry.

To the preceding argument, Henderson adds that because our cognitive competence is limited, in ways that can be empirically ascertained, we are incapable of forming beliefs about our environment without taking a great deal for granted. What we need to take for granted to form needed beliefs will vary from task to task. Since we are incapable of forming the beliefs that we need to form without taking a great deal for granted, we cannot be epistemically obligated to do otherwise. Our epistemic obligations cannot exceed our cognitive potential. Since our belief-forming processes require us to take more or less for granted, depending on the cognitive task at hand, our epistemic obligations must allow us to take more or less for granted, depending on the task.

Opponents of this second variety of subject contextualism typically respond to the preceding arguments by defending foundationalism or coherentism. While foundationalist and coherentist theories of justification might hold us to normative standards that we do not commonly meet, this is not a problem for those theories if, in the epistemological realm, “ought” does not imply “can.”

According to a third group of subject-contextualist theories (Fantl and McGrath 2002, Hawthorne 2003, Stanley 2004), whether *S* Cs that *p* in *x* constitutively depends on how the truth-value of *p* affects *S*'s interests, or perceived interests, in *x*. Other things being equal, the higher the cost, or perceived cost, of *S*'s being wrong that *p*, the less likely that *S* Cs that *p*. The most prominent argument in favor of this third variety of subject contextualism considers pairs of cases such as the following

(adapted from Fantl and McGrath 2002): Suppose that you are at the train station waiting for the train to New York. You would like to get on the express train so that you can be in New York by dinnertime, but it does not matter all that much to you whether you get there by dinnertime or not. You ask someone else on train platform, “Is the next train an express train, or a local?” and your honest and knowledgeable interlocutor sincerely tells you that it is an express. You believe her, and you have no reason to distrust her. In this situation, it seems that you know, and are justified and warranted in believing, that the next train is an express. But now suppose that the situation is exactly the same except that your life depends on your being in New York by dinnertime. In this case, the testimony of your honest and knowledgeable interlocutor does not justify or warrant—let alone give you knowledge—that the next train is an express. When so much depends on your being right, knowledge, justification, warrant, etc., all require more than they otherwise would require.

Opponents of this third variety of subject contextualism typically respond to the preceding argument by claiming that what depends on a subject's actual or perceived interests is not the epistemic status of the subject's Cing that *p*, but rather the rationality of the subject's acting as if *p* were true. For these opponents, whether *S* Cs that *p* is fixed independently of *S*'s actual or perceived interests.

These are the main varieties of subject contextualism, and the arguments concerning them. Some subject contextualists are also attributor contextualists, and almost all attributor contextualists are also subject contextualists.

### ATTRIBUTOR CONTEXTUALISM

A few more basic concepts are needed to explain what attributor contextualism is. Let *A* be an epistemic attributor, someone who epistemically evaluates *S*'s Cing that *p* in *x*. *A*'s evaluation of *S*'s Cing that *p* in *x* will also be a cognitive attitude of some sort, either expressed (as in the case of an assertion) or not (as in the case of silent thought). *A*'s evaluation may concern whether *S* knows that *p* in *x*, or it may concern whether *S* is justified, reasonable, rational, or warranted in Cing that *p* in *x*, or it may concern whether *S* has adequate grounds, evidence, or reasons to *C* that *p* in *x*. More generally, an epistemic evaluation or appraisal of *S*'s Cing that *p* in *x* is a determination of whether *S* Cs that *p* in *x*. Let *y* be the situation that *A* is in when *A* evaluates whether *S* Cs that *p* in

*x*. We will hereafter specify the act of epistemic evaluation as “*A*’s evaluation, in *y*, of *S*’s Cing that *p* in *x*.”

According to attributor contextualism, the semantic value (the truth) of *A*’s evaluation (of *S*’s Cing that *p* in *x*) constitutively depends on features of *y*. As these features of *y* vary, so too does the semantic value of *A*’s evaluation, even with everything else held fixed. The earliest prominent statements of such a view appear in Lewis (1979) and Dretske (1981). The view gained widespread notice following the publication of Cohen (1988), DeRose (1995), and Lewis (1996).

Different versions of attributor contextualism specify different features of *y* as relevant to constitutively determining the semantic value of *A*’s evaluation of *S*’s Cing that *p* in *x*. And even if two attributor contextualists agree about which features of *y* are relevant to constitutively determining the semantic value of *A*’s evaluation, they might still disagree about precisely *how* those features of *y* are relevant. By differences of the first kind, we can distinguish the various attributor-contextualist theories on offer into several groups. Although there is thus some diversity among attributor-contextualist theories, a single line of argument has generally been used to support attributor contextualism.

The argument in question proceeds from consideration of cases similar to those commonly adduced to support the third variety of subject contextualism. Suppose that Jones and Smith are at the train station trying to catch a train to New York. They want to know whether the next train is an express. They ask a bystander if he knows whether the next train is an express. The bystander looks at a schedule and replies, “Yes, I know. It is an express.” It turns out that Jones and Smith have to be in New York as soon as possible, and cannot afford the mistake of getting on a local train. Jones says, “That schedule could easily have been outdated. That guy does not really know that the next train is an express.” So the bystander claims to know that the next train is an express, but Jones claims that the bystander does not know that the next train is an express. Who is right?

If the bystander is right that he knows, then is Jones making a false assertion when he says that the bystander does not know. Suppose that the bystander’s warrant for thinking that the next train is an express is precisely what Jones takes it to be. If such warrant is strong enough to give the bystander knowledge, then, it seems, it is also strong enough to give Jones and Smith knowledge. But if Jones and Smith have warrant strong enough to give them knowledge that the next train is an express, they have no reason to check further whether the next train is

an express. Since they clearly do have a reason to check further whether or not the next train is an express, their warrant cannot be strong enough to give them knowledge of whether or not it is. But if they do not have enough warrant for knowledge, then it seems that the bystander does not know, since he does not have any more warrant than they do.

Suppose that the bystander is wrong, that he does not know that the next train is an express. In this case, it seems that most of the knowledge attributions that we make in ordinary life are wrong as well, since our warrant for most of what we claim to know is no greater than is the bystander’s warrant for the claim that next train is an express. So if the bystander does not know that the next train is an express, then most of us know very little of what we ordinarily claim to know.

How can we avoid simply granting that Jones and Smith are right to deny that the bystander knows, or that the bystander is right to claim to know? The attributor contextualist avoids granting this by claiming that the truth-values of knowledge attributions are relative to the context in which the attribution is made. Relative to the context in which the bystander claims to know, her claim is true. But relative to the context in which Jones claims that the bystander does not know, his claim is true. So both claims are true, and they do not contradict each other. These assertions only appear to contradict each other because we fail to notice that “knows” requires a higher standard (or signifies a more stringent epistemic relation) in one context of attribution than in the other context of attribution. Analogous arguments may support the conclusion that ascriptions of other epistemic properties, not just ascriptions of knowledge, are semantically sensitive to context.

Opponents of attributor contextualism will typically reply to an argument like the preceding in one or both of the following two ways. First, like Bach (2005), they may claim that, although the bystander knows that the next train is an express, Jones and Smith do not know, and that is because knowledge requires sufficient confidence. Although the bystander is sufficiently confident that the next train is an express, Jones and Smith are not, and so they do not satisfy one of the necessary conditions of knowledge. If, without any further investigation, Jones and Smith claimed to be sufficiently confident of the bystander’s claim, then, given how much is at stake in their being right, their degree of confidence would be irrational.

This suggests a second line of response to the attributor-contextualist argument above: Even if Jones and Smith, prior to doing any further investigation, are sufficiently confident that the next train is an express, their confidence is unreasonable, given how much is at stake. Knowing that  $p$  requires not simply that one be sufficiently confident that  $p$ , but moreover that one's level of confidence be reasonable. Since, without doing any further investigation, Jones and Smith cannot be reasonably confident that the next train is an express, they also cannot know that the next train is an express, even if they are sufficiently confident of it (by the bystander's standards), even if they share all of the bystander's evidence for it, and even if the bystander himself knows. On this second line of response, we resolve the problem set out by the attributor contextualist's argument by appealing to subject contextualism of the third variety distinguished above.

To bolster the argument for attributor contextualism in the face of these objections, attributor contextualists must now attempt to run their thought experiments while controlling for variation in  $S$ 's level of confidence and also in  $S$ 's level of reasonable confidence. To do this, they must focus on a particular epistemic subject  $S$  in a particular context  $x$ , and then find variation in the truth conditions for asserting that  $S$  Cs that  $p$  in  $x$ . To make the case for attributor contextualism, they must make sure that the variation they discover is variation in the truth conditions of an ascription of knowledge, and not simply in the conditions under which we are inclined to make, or are warranted in making, the ascription. DeRose (2004) undertook to do all this.

Three other sorts of argument that have commonly been used to support attributor contextualism. The first is an argument to the effect that attributor contextualism provides the best response to a skeptical argument like the following:

Premise 1: I cannot possibly know that I am not a brain in a vat being electrochemically stimulated to have realistic experiences.

Premise 2: If I knew that I have hands, then I could deduce, and thereby come to know, that I am not a brain in a vat being electrochemically stimulated to have realistic experiences.

Conclusion: I do not know that I have hands.

While some philosophers would simply deny one of the premises, attributor contextualists typically take such denial to be implausible. So how can attributor contextualists avoid accepting the skeptical conclusion of such an

argument? They can do so by claiming that the skeptical conclusion is true *only relative* to contexts of attribution that we enter into by thinking (in some way or other) about premise 1. Relative to other, more commonplace, contexts of attribution, premise 1 is false, as is the skeptical conclusion of the argument. Attributor contextualists typically take this response to the skeptical argument above to be more plausible than any alternative response, and they take this to count as a point in favor of attributor contextualism concerning knowledge attributions. Analogous arguments have been adduced in favor of attributor contextualism concerning attributions of other epistemic properties.

A second style of argument in favor of attributor contextualism proceeds from premises concerning the epistemic properties in question. For instance, Dretske (1981) and Lewis (1996) both claim that knowledge that  $p$  involves having infallible grounds for one's belief that  $p$ . For them, one's grounds are infallible just in case all alternatives to  $p$  are ruled out. But "all," like other quantifiers, involves a contextually restricted domain of quantification. Ruling out "all" alternatives means ruling out all those that fall within the contextually restricted domain of quantification. So on this account, some form of attributor contextualism is true of knowledge attributions. Analogous arguments show that attributor contextualism is true of attributions of other epistemic properties as well.

Finally, a third style of argument in favor of attributor contextualism proceeds from premises concerning the conversational function of epistemic-property attributions and epistemic appraisal. Such arguments (e.g., Neta 2002, Schaffer 2004) claim that for attributions of epistemic properties to serve the function that they are supposed to serve, they must be semantically sensitive to contexts. For instance, if a knowledge attribution of the form "S knows why  $p$ " functions to signal to one's interlocutors that they can trust  $S$  on the topic of why it is that  $p$ , then whether it is appropriate to make such an attribution depends on whether one should signal to one's interlocutors that they can trust  $S$ , and this in turn depends on features of the conversational context. If this appropriateness depends on conversational context because the truth conditions depend on conversational context, then attributor contextualism is true of knowledge-why attributions. Analogous arguments may lead to attributor contextualism for attributions of other epistemic properties as well.

These are some of the main lines of argument that have been adduced in favor of one or another variety of

attributor contextualism. Here is a review of those varieties:

According to one group of attributor-contextualist theories (Cohen 1986, 1988, 1999), what varies with the context of attribution is the threshold of evidential support for  $p$  that must be exceeded for  $S$  to  $C$  that  $p$  (for  $S$  to know, to be justified, to be warranted, etc.). In a particular context  $x$ ,  $S$ 's evidence confers a certain level of epistemic support on the proposition that  $p$ . Does that level of support suffice to warrant asserting that  $S$   $C$ s that  $p$ ? This first kind of attributor contextualism takes the answer to this question to depend on features of the context of attribution  $y$ .

According to a second group of attributor-contextualist theories (Dretske 1981, Lewis 1996, Schaffer 2004), what varies with the context of attribution is the range of relevant alternatives to  $p$  that  $S$ 's evidence must rule out for  $S$  to  $C$  that  $p$ . To say that  $S$ 's evidence must rule out these alternatives to  $p$  is not to say anything about what  $S$  does or does not know, or about what  $S$  does or does not believe. Rather, it is to say that  $S$  has adequate evidence only if these alternatives to  $p$  do not obtain. Epistemologists standardly assume that  $S$ 's evidence cannot rule out all alternatives to  $p$ —in particular, it cannot rule out the alternative that  $p$  is false but  $S$  is being deceived by a deceiving spirit into believing that  $p$ . But  $S$ 's evidence does not need to rule out all alternatives to  $p$  for  $S$  to  $C$  that  $p$ . Rather, for  $S$  to  $C$  that  $p$ ,  $S$ 's evidence must rule out only the relevant alternatives to  $p$ . Which alternatives are relevant? That depends upon the context of attribution  $y$ .

According to a third group of attributor-contextualist theories (DeRose 1992, 1995; Heller 1995, 1999), what varies with the context of attribution is the range of possible situations throughout which, in order for  $S$  to count as knowing that  $p$ ,  $p$  must be true if and only if  $S$   $C$ s that  $p$ . In a particular context  $x$  in which  $S$   $C$ s that  $p$ ,  $S$  has the disposition to  $C$  that  $p$  just in case certain conditions obtain.  $S$   $C$ s that  $p$  if and only if there is an adequate range of conditions under which  $S$  is disposed to  $C$  that  $p$ . But what range of conditions is "adequate"? That is relative to a context of attribution  $y$ .

According to a third group of attributor-contextualist theories (DeRose 1992, 1995; Heller 1995, 1999), what varies with the context of attribution is the range of possible situations in which, for  $S$  to count as knowing that  $p$ , it is required that  $p$  is true if and only if  $S$   $C$ s that  $p$ . In a particular  $x$ ,  $S$   $C$ s that  $p$  just in case certain conditions obtain (such as, for instance,  $S$ 's being an authority). What is the range of conditions throughout which this

biconditional must hold for  $S$  to know that  $p$ ? That is determined by the context of attribution  $y$ .

A view that combines features of the last two varieties of attributor contextualism is defended by Rieber (1998). According to Rieber,  $S$  knows that  $p$  if and only if the fact that  $p$  explains  $S$ 's belief that  $p$ . An explanation answers the question "Why?" "Why" questions are contrastive: To ask "Why is it that  $p$ ?" is always, at least implicitly, to ask "Why is it that  $p$  rather than that  $q$ ?" For Rieber, ascriptions of knowledge inherit the contrasts of explanation statements. Thus, for Rieber, for  $S$  to know that  $p$  is for there to be some contrast proposition  $q$  such that  $S$  knows that  $p$  rather than that  $q$ . And for the latter to hold true, on Rieber's account, the fact that  $p$ , rather than the fact that  $q$ , must explain  $S$ 's belief that  $p$ . On Rieber's view, then,  $S$  knows that  $p$  if and only if the fact that  $p$  (rather than the contrast proposition  $q$ ) explains the fact that  $S$  believes that  $p$ . On Rieber's view, the context of attribution  $y$  determines the contrast proposition.

Finally, according to the most recently espoused version of attributor contextualism (Neta 2002, 2003a, 2004), what varies with the context of attribution is the range of propositions, or of psychological states, that count as part of  $S$ 's evidence set. Relative to some contexts of attribution,  $S$ 's evidence set may include nothing more than  $S$ 's own current states of consciousness. But relative to more ordinary contexts of attribution,  $S$ 's evidence set may include various propositions about, say, widely known results of experiments that took place completely independently of  $S$ . More generally, according to attributor contextualism concerning evidence, whether  $S$   $C$ s that  $p$  depends on  $S$ 's evidence for  $p$  for other epistemic properties  $C$  as well (e.g., knowing, being justified, having warrant).

## THE RECENT CONTROVERSY OVER ATTRIBUTOR CONTEXTUALISM

Since the late 1990s, attributor contextualism has been subject to two sorts of objections. According to the first sort of objection, the problem with attributor contextualism is that it implausibly attributes to native speakers a significant level of semantic self-ignorance. We can see this either by thinking about attributor-contextualist responses to skeptical arguments, as Schiffer (1996) and Rysiew (2001) do, or by thinking about the consequences of attributor contextualism for our practices concerning disquotation of knowledge attributions, as Hawthorne (2003) and LePore and Cappellen (2004) do.

According to attributor-contextualist responses to skeptical arguments, such arguments gain their plausibil-

ity because, when going through these arguments, we confuse the propositions that our epistemic-property attributions express with the propositions that these attributions would express in certain other contexts. But, according to the proponents of this objection, it is implausible to claim that native speakers do indeed suffer from this confusion. Again, according to attributor contextualists, attributor *A* can, in some contexts, truthfully assert something of the following form: “*S* does not know that *p*, even though *S* speaks truthfully when *S* says, ‘I know that *p*,’” or, more generally, “*S* is not justified or warranted in Cing that *p*, even though *S* speaks truthfully when *S* says, ‘I am justified or warranted in Cing that *p*.’” But such assertions appear self-contradictory to native speakers. Thus, the attributor contextualist is committed to claiming that native speakers are wrong to think that such assertions are self-contradictory. Once again, the attributor contextualist is committed to attributing a significant level of semantic self-ignorance to native speakers.

In response to this first line of objection, Neta (2003b) raises the question of whether the level of self-ignorance that attributor contextualism posits is any greater than the level of self-ignorance about their own language that native speakers routinely display at other levels of linguistic analysis (e.g., pragmatics, syntax, phonology). If native speakers generally do not realize that there is a difference between the “t” sound in “butter” and the “t” sound in “putter,” then why should they realize that there is a difference in the meaning of terms of epistemic appraisal, “*C*,” as they occur in different contexts? Of course, naive speakers can be brought to notice the difference between the “t” sound in “butter” and the “t” sound in “putter.” Can the attributor contextualist bring naive speakers (even if not theoretically invested philosophers) to discern a difference in the meaning of terms of epistemic appraisal as they occur in different contexts? This remains an open empirical question.

Stanley (2000, 2004), pursuing the second line of objection, has argued that attributor contextualism is empirically implausible because there is no well-established precedent for the particular kind of semantic context-sensitivity that attributor contextualists posit in our epistemic-property attributions. These empirical arguments have been rebutted most recently by Ludlow (2005) and DeRose (2005), but this issue, like many other empirical issues in semantics, remains unsettled. Indeed, Unger (1984, 1986) has argued that there is no empirically ascertainable fact of the matter as to whether attributor contextualism is true.

## CONTINENTAL PHILOSOPHY

*Continental philosophy* is a term that arose after the Second World War in English-speaking countries as a name for philosophical approaches that take as their point of departure the work of certain nineteenth and twentieth centuries figures from Continental Europe, especially Germany and France, whose themes and methods were different from those of the analytical philosophy common at most leading British and American philosophy departments at that time. As a general term it includes movements such as phenomenology, existentialism, critical theory, hermeneutics, psychoanalytically oriented philosophy, structuralism, deconstruction, and postmodernism as well as feminist theory, race theories, and other critical social theories to the extent that they draw on one or more of these other movements. Its themes can range across all of the traditional philosophical areas—from epistemology, metaphysics, and ethics to aesthetics, philosophy of language, philosophy of religion, philosophy of science, and studies in the history of philosophy, to name just a few.

General comparisons between the intellectual life in Britain and Continental Europe go back at least to the nineteenth century. However, the current opposition between analytical and continental philosophy can be traced back above all to polemical attempts on the part of leading English analytical philosophers, in particular those at Oxford, to justify their own approach to philosophy and distinguish it from the predominant philosophical movements in France and Germany during the 1950s such as phenomenology and existentialism. Gilbert Ryle (1971) and R. M. Hare (1960), for instance, were outspoken in contrasting the way they and their colleagues approached philosophy from philosophy as practiced in the rest of Europe, with a decidedly negative assessment of continental philosophy's Germanic roots. The primary targets at the time were Husserl, Heidegger, Sartre, and Merleau-Ponty, although it is not clear that their attackers had read many of their works closely.

The term became fairly common, however, only during the late 1960s and early 1970s when it was embraced, first in the United States and then later in Great Britain and other English-speaking countries, as a positive term by philosophers who used it as a name for their own work. Continental philosophy was still defined in opposition to analytical philosophy, but without necessarily carrying the negative connotations it had for British and American analytical philosophers. Though discussions about the

differences between analytic versus continental philosophy and the relative merits of each are still common, the term has increasingly become more of a commonly accepted, though still somewhat vague descriptive term used by both proponents and opponents of the different ways of doing philosophy that have been grouped together under the general heading of “continental” (often with a capital “C”) in contrast to “analytical” philosophy.

From the outset, even though it suggests a geographical reference, the term “continental philosophy” has referred only to those figures from continental Europe whose approaches were not consistent with those of the project of earlier analytical philosophy. It specifically excluded thinkers such as Frege, Carnap, and Wittgenstein, whose work was viewed in a positive light by the English opponents of continental philosophy, because they were seen rather as precursors to or representatives of analytical philosophy. Moreover, even though the original point of difference goes back primarily to differences in philosophical work being conducted in Britain as opposed to continental European countries after the Second World War, these differences were projected backwards into the history of philosophy. Most observers agree that there were no clearly identifiable differences along geographic lines in philosophy as practiced in England and on the continent before the twentieth century. However, because analytic philosophy as practiced after World War II excluded idealistic philosophy and some other nineteenth-century movements that were originally from Germany or France from its lineage, the term continental philosophy soon came to include not only postwar and earlier twentieth-century philosophical movements from the continent, but also philosophers such as Kant, Hegel, Marx, Kierkegaard, Nietzsche, and others from eighteenth- and nineteenth-century European philosophy whose approaches were not consistent with the historical development of analytical philosophy.

Toward the end of the twentieth century it became common to speak of a “continental tradition” instead of simply referring to “continental philosophy.” One reason for this is that many of the adherents and leading practitioners of these directions in philosophy come from countries all around the world instead of just Europe. Another reason is that, from the outset, the fate of this term has been tied to that of its opposite, namely “analytical philosophy,” and critical developments within the latter movement led many of its adherents to refer to a “postanalytical” phase that is still part of an analytical tradition of philosophy. As philosophers from both tradi-

tions became increasingly familiar with each others’ work and many of the original claims in both traditions have had to be modified, it became increasingly difficult to provide a simple characterization of what continental philosophy is and hence also of how it is and is not different from analytical philosophy. Increasingly, some scholars, especially those outside of English-speaking countries, have begun to draw on ideas and resources from both traditions to address philosophical problems across the differences that had previously divided them, so that it makes good sense to think of both continental and analytical philosophy as competing traditions of philosophy and less as two clearly delineated camps situated in different geographic locations.

## CONTINUITY

In the decades bracketing the turn of the twentieth century, the real number system was dubbed the *arithmetic continuum* because it was held that this number system is completely adequate for the analytic representation of all types of continuous phenomena. In accordance with this view, the *geometric linear continuum* is assumed to be isomorphic with the arithmetic continuum, the axioms of geometry being so selected to ensure this would be the case. In honor of Georg Cantor (1845–1918) and Richard

Dedekind (1831–1916), who first proposed this mathematico-philosophical thesis, the presumed correspondence between the two structures is sometimes called the *Cantor-Dedekind axiom*.

Since their appearance, the late nineteenth-century constructions of the real numbers have undergone set-theoretical and logical refinement, and the systems of rational and integer numbers on which they are based have themselves been given a set-theoretic foundation. During this period the Cantor-Dedekind philosophy of the continuum also emerged as a pillar of standard mathematical philosophy that underlies the standard formulation of analysis, the standard analytic and synthetic theories of the geometrical linear continuum, and the standard axiomatic theories of continuous magnitude more generally.

Since its inception, however, there has never been a time at which the Cantor-Dedekind philosophy has either met with universal acceptance or has been without competitors. The period that has transpired since its emergence as the standard philosophy has been especially fruitful in this regard, having witnessed the rise of a variety of constructivist and predicativist theories of real numbers and corresponding theories of analysis as well as the emergence of a number of alternative theories that make use of infinitesimals. Whereas the constructivist and predicativist theories have their roots in the early twentieth-century debates on the foundations of mathematics and were born from critiques of the Cantor-Dedekind theory, the infinitesimalist theories were intended to either provide intuitively satisfying (and, in some cases, historically rooted) alternatives to the Cantor-Dedekind conception that have the power to meet the needs of analysis or differential geometry, or to situate the Cantor-Dedekind system of real numbers in a grander conception of an arithmetic continuum.

Speculation regarding the nature and structure of continua and of continuous phenomena more generally therefore naturally falls into three periods: the period of the emergence and eventual domination of the Cantor-Dedekind philosophy, and the periods before and after. These three periods are considered in this entry in historical turn.

### THE ARISTOTELIAN CONCEPTION

Before the Cantor-Dedekind philosophy the idea of the continuum stood in direct opposition to the discrete and was generally thought to be grounded in our intuition of extensive magnitude, in particular of spatial or temporal magnitude, and of the motion of bodies through space.

Some of the essential characteristics of what emerged as the standard ancient conception were already described by Anaxagoras of Clazomenae (c. 500–c. 428 BCE) when he observed that “Neither is there a smallest part of what is small, but there is always a smaller (for it is impossible that what is should cease be [no matter how far it is being subdivided])” (Kirk, Raven, and Schofield 1983, p. 360). Thus, not only is the continuum infinitely divisible, but through the process of division it cannot be reduced to discrete indivisible elements that are, as Anaxagoras picturesquely put it, “separated from one another as if cut off with an axe” (ibid. p. 371). However, while ingredients of the standard ancient conception are already found in the writings of some of the pre-Socratics, it was Aristotle (384–322 BCE), inspired by the writings of the geometers of his day, who provided its earliest systematic philosophical treatment.

Central to Aristotle’s analysis is the distinction between discrete and continuous quantity; whereas the former lack, the latter have, a common boundary at which the parts join to form a unity. For Aristotle, number—by which he meant the positive integers greater than or equal to two—is discrete, whereas measurable magnitude—lines, surfaces, bodies, time, and place—are continuous. Lines, in particular, are continuous because “it is possible to find a common boundary at which its parts join together, a point” (*Categories* 6, 5<sup>a</sup>1–2, in Aristotle 1984, p. 8); in the cases of surfaces and bodies, the common boundaries are lines, and lines or surfaces, respectively, and in the case of time they are moments.

Motion for Aristotle is also continuous, its continuity being a reflection of spatial and temporal continuity (*Physics* IV.11, 219<sup>a</sup>10–13, in Aristotle 1984, p. 371). It is this reflection or isomorphism, for Aristotle, that endows continuous motion with its familiar characteristic properties such as the absence of spatial jumps and the absence of temporal pauses.

Aristotle’s characterization of the continuous emerges as the culmination of the following series of definitions he offers in the third chapter of Book V of his *Physics*:

Things are said to be *together* in place when they are in one primary place. ... Things are said to be in *contact* when their extremities are together. ... A thing is in *succession* when it is after the beginning in position or in form or in some other respect in which it is definitely so regarded, and when further there is nothing of the same kind as itself between it and that to which it is in succession. ... A thing that is in succession and touches [i.e., is in contact] is *con-*

*tiguous*. ... The *continuous* is a subdivision of the contiguous: things are called continuous when the touching limits become one and the same ... (*Physics* V.3, 226<sup>b</sup>22–227<sup>a</sup>12, in Aristotle 1984, pp. 383–384)

Aristotle maintains that the previous definition implies that

nothing that is continuous can be composed of indivisibles: e.g. a line cannot be composed of points, the line being continuous and the point indivisible. For the extremities of two points can neither be *one* (since of an indivisible there can be no extremity as distinct from some other part) nor *together* (since that which has no parts can have no extremity, the extremity and the thing of which it is the extremity being distinct). ... Moreover, it is plain that everything continuous is divisible into divisibles that are always divisible; for if it were divisible into indivisibles, we should have an indivisible in contact with an indivisible, since the extremities of things that are continuous with one another are one and in contact. (*Physics* VI.1, 231<sup>a</sup>24–29, 231<sup>b</sup>15–19, in Aristotle 1984, pp. 390–391)

For Aristotle, the infinite divisibility of the continuous—a property, which on occasion, he appears to take to define the continuous—is a *potential* infinite. Indeed, for Aristotle, the infinite, which is a property of a process rather than of a collection or of a substance, is always potential as opposed to *actual* or completed; that is, no matter which finite stage of the process has been completed, in principle another such stage can be completed. Processes may be infinite with respect to addition or division. Moreover, in the case of spatial continua, in particular, it is the very process of division from which points arise. Thus, while a line segment contains an infinite number of points and an infinite number of parts, for Aristotle it does so only potentially. It is the infinite divisibility of the continuum in this sense that Aristotle appeals to in his treatment of the various paradoxes of Zeno of Elea that are intended to challenge the coherence of the continuity of space, time, matter, and motion. It was also this conception of the continuum that was the dominate conception among philosophers, scientists, and mathematicians alike until the time of Cantor and Dedekind.

#### NONSTANDARD ANCIENT CONCEPTIONS

However, while Aristotle's theory was the dominate theory until well into the nineteenth century, it never

achieved hegemony. Among the ancients, in particular, there were a number of alternative conceptions of continua, including a variety of atomistic conceptions (Furley 1967, Sorabji 1983, White 1992) and the nonatomic conception of the *Stoics* (Sambursky 1959, White 1992). While atomic theories tended to apply solely to the physical realm, there appear to have been atomistic conceptions of geometrical continua as well. Democritus, for example, apparently held that a cone was made up of an infinite number of parallel sections, each of the same indivisible thickness; some who sought to square the circle, including Antiphon, also appear to have embraced atomic theories of geometrical objects. The Stoics, on the other hand, while continuing to adhere to the Aristotelian conception in the mathematical realm, and even to infinite divisibility in the physical realm, may well have distanced themselves from the standard conception in an important respect. According to the interpretation introduced by Shmuel Sambursky (1959) and championed by Michael J. White (1992), the Stoics maintained that there are no points, edges, and surfaces serving as sharp boundaries in physical continua, but rather regions of indeterminacy in which the parts of bodies and adjacent bodies blend. Sambursky (1959, p. 98) likens the physical continuum of the Stoics to the fluid intuitionistic conception of L. E. J. Brouwer, and White proposes instead that “[p]erhaps the best place to look for contemporary elucidation of the Stoic idea is the nonstandard mathematics based on L. A. Zadeh's fuzzy-set theory” (1992, p. 288).

Unlike the Stoics, Aristotle maintains that the physical continuum is a reflection of the geometrical continuum. Indeed, according to Aristotle, “geometry investigates natural [ie. physical] lines, but not qua natural” (*Physics* II.2, 194<sup>a</sup>9–10, in Aristotle 1984, p. 331). It was this widely held ancient view that the physical mirrors the geometrical that bequeathed to the geometers and their ideas regarding continua an influence far beyond the mathematical domain.

#### ANCIENT GEOMETRICAL CONCEPTIONS

Aspects of the distinction between discrete number and continuous magnitude are conspicuous in Euclid's *Elements*. Whether Euclid (flourished c. 300 BCE) was directly influenced by the Aristotelian corpus or by earlier geometric practice, however, is the subject of dispute. In any case, reminiscent of Aristotle's characterization, Euclid regards number as a multitude composed of units and believing that one is not itself a number but the unit of number, he appears to identify the numbers with the

positive integers greater than one. Geometrical magnitude, on the contrary, for Euclid, is infinitely divisible. Line segments, in particular, can not only be bisected (Book 1, Proposition 10) *ad infinitum*, they can be divided into  $n$  congruent segments for each positive integer  $n$  (Book 6, Proposition 9).

Other ingredients of the Euclidean synthesis that shed important light on the nature of the classical conception of the geometrical continuum are the theories of proportions and incommensurable magnitudes presented in Books 5 and 10, respectively, and the so-called method of exhaustion that is developed in Book 12.

Though arguably the result of an evolutionary process (Knorr 1975, 1978), the theory of proportions developed in Book 5 is usually attributed in its entirety to Eudoxus (c. 400–c. 350 BCE), who, like his contemporaries Plato and Aristotle, lived about half a century before Euclid's *Elements* were compiled. Central to the theory is the concept of a *ratio*:

A ratio [says Euclid] is a sort of relation in respect of size between two magnitudes of the same kind. ... Magnitudes are said to have a ratio to one another which are capable, when multiplied [by a positive integer], of exceeding one another. ... Magnitudes are said to be in the same ratio, the first to the second and the third to the fourth, when, if any equimultiples whatever be taken of the first and third, and any equimultiples whatever of the second and fourth, the former equimultiples alike exceed, are equal to, or alike fall short of the latter equimultiples respectively taken in corresponding order. (Book 5, Definitions 3–5 in Heath 1956, Volume 2, p. 114)

While Euclid never contends that two magnitudes of the same kind necessarily have a ratio to one another, his geometry (with the one possible exception of his treatment of horn angles [Book 3, Proposition 16]) is limited to systems of magnitudes for which this is the case. Following Otto Stolz (1842–1905), such systems are said to satisfy the axiom of Archimedes (although it is Eudoxus to whom Archimedes (c. 287–212 BCE) attributes the proposition). In contemporary parlance, if  $A$  and  $B$  are members of a given system of magnitudes,  $A$  is said to be *infinitesimal relative to B* if  $A$  and  $B$  do not have a ratio to one another and  $A$  is smaller than  $B$ . Collaterally, if  $A$  is infinitesimal relative to  $B$ ,  $B$  is said to be *infinite relative to A*. Thus, in Euclid's geometry, no line segment is either infinitesimal or infinite relative to another segment, and analogous results hold for planer and solid figures as well.

Moreover, as in the case of line segments, where there is a well-defined means of subtracting the smaller of two magnitudes of the same kind from the larger, the absence of infinitesimal magnitudes of a given kind precludes the existence, more generally, of magnitudes of a given kind that differ by an infinitesimal amount.

Among the virtues of the theory of proportions of Book 5 is that, unlike the older Pythagorean theory that was based on ratios of integers, it is applicable to both *commensurable* and *incommensurable* magnitudes. Following Euclid, “Those magnitudes are said to be *commensurable* which are measured by the same measure, and those *incommensurable* which cannot have any common measure” (Book 10, Definition 1 in Heath 1956, Volume 3, p. 10). The commensurable-incommensurable dichotomy is as close as the ancients came to the modern dichotomy of rational and irrational numbers, a dichotomy that is central to the Cantor-Dedekind conception of the continuum. The discovery of the existence of incommensurable magnitudes, which is usually attributed to the fifth-century Pythagoreans, was significant because it showed that not every pair of magnitudes of the same kind (straight line segments, rectilinear plane figures bounded by such segments, and so on) has a common measure that divides each an exact integral number of times. Thus, for example, since the side and diagonal of a square are incommensurable, it was not possible (given the ancients' conception of measure) to measure all the sides of even so simple a figure as an isosceles right triangle employing a common unit of measure. These and related discoveries, coupled with their conception of number as a multitude of units, convinced the ancients that it was impossible to bridge the gap between the discrete domain of number and the continuous domain of geometry.

Guided by their intuitions about geometrical continua, the Greeks assumed that simple curvilinear planer figures such as circles, ellipses, and segments of parabolas have areas and perimeters of the same kinds as those of polygons, and they made analogous assumptions about the surface areas and volumes of solids such as spheres, cylinders, and cones. The misleadingly term *exhaustion* was introduced by Gregory of St. Vincent (1584–1667) to describe the method devised by Eudoxus, incorporated into the *Elements* by Euclid, and later extended by Archimedes to measure these and other lengths, areas, and volumes in a rigorous fashion without appealing to either the infinitesimal techniques of the Newtonian and Leibnizian calculi or the passage to the limit concept that has been characteristic of the standard approach to calcu-

lus since its arithmetization during the latter part of the nineteenth century.

As early as 430 BCE Hippocrates of Chios established that the area of a lune (that is, a curvilinear area bounded by circular arcs) of a particular kind is equal to the area of a square. Soon thereafter, Antiphon contended it was possible to obtain a rectilinear figure having the same area as a circle by beginning with an inscribed regular polygon, say a square, and constructing successively more inclusive inscribed regular polygons until the area of the circle was exhausted. Surprisingly, however, he held that the area of the circle would be exhausted after a sufficiently large finite number of steps (perhaps believing that the side of the polygon would coincide with a small arc of the circumference of the circle). Bryson (c. 420 BCE) later developed an alternative account where he considered a circle  $C$  sandwiched between a finite series of successively more inclusive inscribed regular polygons, on the one hand, and a finite series of successively less inclusive circumscribed regular polygons, on the other. He maintained that for some positive integer  $n$  there is an  $n$ -sided regular polygon  $P$ , whose area equals the area of  $C$ , that properly contains and is properly contained within the aforementioned inscribed and the circumscribed polygons, respectively. To reach his conclusion he appears to have invoked a continuity principle to the effect that a magnitude passes from a smaller to a greater value solely through values of magnitudes of the same kind. The reliance on this principle, which was criticized by Proclus, John Philoponus, and others, was later obviated by the Eudoxean approach.

Central to the exhaustion approach is an alternative continuity principle—the so-called *bisection principle*—that, following Euclid, may be stated as follows:

Two unequal magnitudes being set out, if from the greater there be subtracted a magnitude greater than or equal to its half, and from that which is left a magnitude greater than or equal to its half, and if this process is repeated continuously, there will be left some magnitude which will be less than the lesser magnitude set out. (Book 10, Proposition 1 in Heath 1956, Volume 3, p. 14)

Using the Archimedean axiom, Euclid proves the bisection principle for the case where the magnitudes subtracted are greater than half the given magnitude, and immediately thereafter observes that “the theorem can be similarly proved even if the parts subtracted be half” (Book 10, Proposition 1 in Heath 1956, Volume 3, p. 15).

The exhaustion method essentially consists of showing that the magnitude (or, more often, ratio of magnitudes)  $M$  in question is equal to another magnitude (or ratio of magnitudes)  $M'$  one already knows how to determine by showing—using a pair of *reductio ad absurdum* arguments, each of which employs the principle of bisection—that neither  $M < M'$  nor  $M' < M$ . To draw the conclusion that  $M' = M$ , a tacit appeal is made the presupposition, alluded to earlier, that either  $M < M'$ ,  $M' < M$ , or  $M' = M$ . In the version developed by Archimedes, by evoking the geometrical properties of the geometrical object whose perimeter, area, or volume is to be determined, two sequences  $I_1, I_2, \dots, I_n$  and  $C_1, C_2, \dots, C_n$ , consisting respectively of inscribed and circumscribed lines, polygons, or polyhedrons are constructed whose corresponding perimeters, areas, or volumes are such that  $I_n < M < C_n$  and  $I_n < M' < C_n$  for all  $n$ . Using the principle of bisection, it is then either shown that, given  $\varepsilon > 0$ ,  $C_n - I_n < \varepsilon$  for  $n$  sufficiently large or that, given  $\alpha > 1$ ,  $C_n/I_n < \alpha$  for  $n$  sufficiently large.

Archimedes’s version of the method of exhaustion resembles and, to some extent, inspired the technique of integration later employed in the calculus. Before the development of the calculus, however, a variety of the concepts and techniques inherited from the ancient geometers would undergo marked change. Of these perhaps none has had a more profound or lasting impact on theories of continua than the rethinking of the number concept and its relation to the geometrical continuum.

## EARLY MODERN THEORY OF REAL NUMBERS

The early modern theory of real numbers began to emerge when mathematicians such as Simon Stevin (1548–1620) argued that not only is 1 also a number but that there is also a complete correspondence between (positive) number and continuous magnitude, as well as a parallelism between certain geometrical constructions and the now familiar arithmetic operations on numbers. In a number of his works, including his influential *L'Arithmétique* (1585), Stevin expresses the matter thus:

I consider the relation between number and magnitude to be such that what can be done by the one can be done by the other. ...

... these two quantities cannot be distinguished by continuity or discontinuity.

To a continuous magnitude corresponds the continuous number to which it is attributed. (Strong 1976, p. 105; Klein 1968, p. 195; Stevin 1585/1958, p. 501)

This viewpoint soon led to, and was implicit in, the analytic geometry of René Descartes (1596–1650), and was made explicit by John Wallis (1616–1703) and Isaac Newton (1643–1727) in their arithmetizations thereof. Influenced by work of Wallis, Isaac Barrow (1630–1677), and others, the (positive) numbers came to be associated with Eudoxian-Euclidean ratios that were assumed to exist between the magnitudes of a given kind and a selected unit magnitude of the same kind (compare Klein 1968, Pycior 1997). In accordance with the Eudoxian-Euclidean framework, no two such magnitudes of the same kind could differ by an infinitesimal amount. In his popular and influential *Arithmetica Universalis* (1707/1728), Newton extends the correspondence between numbers and ratios to include negative numbers and zero, but whereas some of his predecessors had identified the positive numbers with the symbolic representations of the ratios, Newton identifies numbers with the abstracted ratios themselves. Emphasizing his sharp break with the ancient conception of number, says Newton:

By *Number* we understand not so much a Multitude of Unities, as the abstracted Ratio of any Quantity, to another Quantity of the same Kind, which we take for Unity. And this is threefold; integer, fracted, and surd: An *Integer* is what is measured by Unity, a *Fraction*, that which a sub-multiple Part or Unity measures, and a *Surd*, to which Unity is incommensurable. (Newton 1728/1967, p. 2)

That zero could not be a number in accordance with this definition did not preclude Newton from asserting it was, and the careful treatment that late nineteenth-century mathematicians would recognize to be required to handle ratios involving negative quantities is nowhere to be found.

## THE CALCULUS OF NEWTON AND LEIBNIZ

During the sixteenth century the works of Archimedes were widely studied by Western mathematicians and served as the chief source of inspiration for the seventeenth-century development of the infinitesimal calculus, the branch of mathematics erected by Newton and Gottfried Wilhelm Leibniz (1646–1716) for the study of continuously varying magnitudes or quantities. The conception of the continuum embraced by most mathematicians of the period was geometrical or kinematical by nature and grounded in intuition. It was commonplace to consider a curve as a path of a moving point, the curve being continuous insofar as motion itself was pre-

sumed to be continuous. Moreover, perhaps as a result of the medieval speculations on the infinite and the continuum, the mathematicians of the day, unlike their mainstream Greek counterparts, were not adverse to employing infinitesimal techniques and appeals to the actual infinite in these and related works. Some authors, such as Galilei Galileo (1564–1642), following in the footsteps of such fourteenth-century thinkers as Henry of Harclay, Nicholas Bonet, Gerard of Odo, Nicholas of Autrecourt, and John Wyclif (Murdoch 1982), maintained that line segments, surfaces, and solids are made up of an actual infinite number of indivisible or infinitesimal elements. And similar ideas were employed by Johannes Kepler (1571–1630), Bonaventura Cavalieri (1598–1647), and others in their determinations of areas and volumes and by Barrow in his determinations of tangents to curves, determinations that would be the focus of the unifying algorithmic frameworks that would come to be called the calculus.

Following in the footsteps of their just-cited forerunners, infinitesimal techniques were employed by Newton and Leibniz in their treatments of the calculus, but unlike some of their predecessors neither of them attributed ontological status to either the actual infinite or the actual infinitesimal. Both regarded infinitesimals—or incomparables as Leibniz sometimes called them—as varying quantities in a state of approaching zero that serve as useful fictions to abbreviate their mathematical proofs. The abbreviated proofs in turn, they contended, could be replaced by limit-based proofs the latter of which not only constitute the rigorous formulation of calculus but are a direct version of the indirect method of exhaustion due to Archimedes. Newton and Leibniz also agreed that the justification for the limit-based proofs lay in the concept of continuity but they differed on the justification itself. Whereas Newton sought it in terms of one's intuition of continuous flow, Leibniz sought it in terms of his *law of continuity*, a philosophical principle to the effect that “[n]o transition is made through a leap” or that “nothing takes place suddenly.” The natures of their respective attempts at justification, however, only begin to intimate that the limit-based proofs envisioned by Newton and Leibniz, while akin to, are by no means identical with the limit-based proofs that emerged during the nineteenth century.

Unlike the calculus of today, the calculi of Newton and Leibniz were not concerned with functions but with variable quantities, their rates of change, and so on. However, whereas Newton regarded these quantities as varying at finite rates with respect to time, Leibniz envisioned

them as ranging over discrete sequences of values that successively differ by infinitesimal amounts. Underlying this difference was a difference in fundamental concepts: For Newton it was the *fluxion* or finite rate of change of the variable with respect to time, and for Leibniz it was the just-cited infinitely small differences or the differential. As a result, in Leibniz's treatment of the calculus the limit concept was suppressed or at least disguised, whereas it was explicit in Newton's formulation. In the case of differentiation, for example, since for Leibniz it is the distinct differentials  $dx$  and  $dy$  that are fundamental, their ratio  $dy/dx$  is of principal significance, whereas for Newton, especially in his later treatment, it is the derivative itself—as a ratio of fluxions or an ultimate ratio of evanescent quantities—that is of central importance.

That there were foundational difficulties with the science of continuously varying quantities was well known among seventeenth- and eighteenth-century mathematicians including Newton and Leibniz themselves. These difficulties were brought into sharp focus by George Berkeley (1685–1753) in his stinging critique of the logical and ontological foundations of the calculus titled *The Analyst* (1734/1992). According to Berkeley, there is no justification for attributing existence to either limits or infinitesimals: A limit of a ratio is either a limit of finite quantities, and therefore not an ultimate ratio, as Newton contended, or it is a mysterious indeterminate ratio  $0/0$ ; and if the infinitesimal quantities  $dx$  and  $dy$  are not equal to zero, one has the problem of explaining how it is possible that  $x + dx = x$ , and if they are equal to 0, once again one has the problem of explaining the meaning of the indeterminate  $0/0$ . It was with these and related quandaries that mathematicians concerned with the study of continuously varying magnitude grappled well into the nineteenth century. Some eighteenth-century mathematicians, such as Colin Maclaurin (1698–1746) and Jean Le Rond d'Alembert (1717–1783), attempted to address the foundational worries with refinements of the limit approach of Newton, but it was the infinitesimal approach of Leibniz that emerged as the dominant approach of the day. Moreover, the remaining puzzlement over infinitesimals no longer applied solely to the fictional infinitesimals of Leibniz, but to the actual infinitely large and the actual infinitely small numbers and magnitudes employed to great effect throughout the eighteenth and early nineteenth century by a host of distinguished analysts working in the Leibnizian tradition including Jakob Bernoulli (1654–1705), Johann Bernoulli (1667–1748), Daniel Bernoulli (1700–1782), and Leonhard Euler (1707–1783), to name only a few.

## THE ARITHMETIZATION OF ANALYSIS

During the nineteenth century, building on the work begun in 1821 by Augustin-Louis Cauchy (1789–1857) in his *Cours d'analyse*, the calculus was given a rigorous foundation that is still accepted today. By the middle of the century, developments in subject persuaded many mathematicians that the traditional concepts of the calculus were too imprecise, unreliable, and ineffective to provide such a basis. It was held that the traditional relation between real quantities and intuitively given continuous magnitudes such as straight lines was more of a hindrance than an aid in achieving that end as was the then familiar reliance on infinitesimals. In response, the modern *arithmetico-set-theoretic* conception of a real number emerged when a number of mathematicians including Cantor (1872/1939) and Dedekind (1872/1996) introduced systems of real numbers that were designed to dispense with the former and provide a basis for the calculus that made superfluous the latter.

Cantor's system is based on *Cauchy sequences* of rational numbers. A sequence  $\{r_n\}$  of rational numbers (indexed over the natural numbers) is said to be a Cauchy sequence (or *fundamental sequence*, as Cantor called it) if for every rational number  $\varepsilon > 0$  there is a natural number  $k$  such that  $|r_m - r_n| < \varepsilon$  for all  $m, n > k$ . Two such sequences  $\{r_n\}$  and  $\{s_n\}$  are said to be equivalent if for every rational number  $\varepsilon > 0$  there is a natural number  $k$  such that  $|r_n - s_n| < \varepsilon$  for all  $n > k$ . In modern parlance, Cantor's construction amounts to identifying the set  $\mathbb{R}$  of real numbers with the set of all equivalence classes of Cauchy sequences of rational numbers. If an equivalence class contains the Cauchy sequence  $\{r_n\}$  where  $r_n = r$  for all  $n$ , the equivalence class corresponds to the rational number  $r$ , otherwise it corresponds to an irrational number. Each irrational number is associated with the equivalence class containing the Cauchy sequence consisting of the initial segments of its unique nonperiodic decimal representation. For example,  $\sqrt{2}$  is associated with the equivalence class containing the Cauchy sequence

$$r_0 = 1; r_1 = 1.4; r_2 = 1.41; r_3 = 1.414; \dots$$

If  $\alpha$  and  $\beta$  are real numbers represented by the Cauchy sequences  $\{r_n\}$  and  $\{s_n\}$ , then the sum and product of  $\alpha$  and  $\beta$  are represented by the Cauchy sequences  $\{r_n + s_n\}$  and  $\{r_n s_n\}$ , respectively; and it is said that  $\alpha > \beta$  if there is an  $a > 0$  such that  $r_n \geq s_n + a$  for sufficiently large  $n$ .

Dedekind's system, by contrast, is based on *cuts* of the ordered set  $\mathbb{Q}$  of rational numbers. By a cut  $(A_1, A_2)$  of  $\mathbb{Q}$  Dedekind means a partition of  $\mathbb{Q}$  into two non-empty sets  $A_1$  and  $A_2$  in which every member of  $A_1$  pre-

cedes every member of  $A_2$ . Dedekind identifies  $\mathbb{R}$  with the set of all cuts of  $\mathbb{Q}$ ; if  $A_1$  has a greatest member or  $A_2$  has a least member, say,  $r$ , the cut  $(A_1, A_2)$  is associated with the rational number  $r$ ; otherwise it defines an irrational number.  $\sqrt{2}$ , in particular, is defined by the cut

$$(\{a \in \mathbb{Q} : a < 0 \vee a^2 \leq 2\}, \{a \in \mathbb{Q} : a^2 > 2\}).$$

Given two real numbers  $\alpha = (A_1, A_2)$  and  $\beta = (B_1, B_2)$ , Dedekind stipulates that  $\alpha < \beta$  if  $A_1$  is a proper subset of  $A_2$ . He also defines  $\alpha + \beta = (C_1, C_2)$  where  $C_2 = \mathbb{Q} - C_1$  and  $C_1$  is the set of all  $c \in \mathbb{Q}$  such that  $c \leq a_1 + b_1$  for some  $a_1 \in A_1$  and some  $b_1 \in B_1$ , and further observes that the remaining familiar arithmetic operations on real numbers can likewise be defined.

On the basis of Cantor's and Dedekind's systems of real numbers, whose equivalence (modulo the then tacitly emerging underlying set-theoretic assumptions) would soon be established, the classical concepts of the calculus, including Cauchy's and Bernhard Riemann's (1826–1866) modern definitions of the derivative and the integral, were reformulated in a rigorous fashion using the now familiar  $\delta$ ,  $\varepsilon$ -techniques, as were the concepts of convergence, sum of an infinite series, and continuity to name only a few. Central to this development was Karl Weierstrass's (1815–1897) replacement of Cauchy's dynamic conception of the limit concept, together with its Newtonian connotations of continuous motion, with a static purely arithmetical formulation. Instead of setting  $\lim_{x \rightarrow \xi} f(x) = L$  provided that  $f(x)$  approaches  $L$  as  $x$  approaches  $\xi$ , Weierstrass set  $\lim_{x \rightarrow \xi} f(x) = L$  provided that, given a positive real number  $\varepsilon$ , there is a positive real number  $\delta$  such that  $|f(x) - L| < \varepsilon$  if  $0 < |x - \xi| < \delta$ . With the host of limit dependent concepts so reformulated, the calculus assumed the form that one still finds in the standard textbooks of the early twenty-first century.

## CONTINUOUS FUNCTIONS

As was already noted, the calculus of Newton and Leibniz was not a calculus of functions. It was Euler in the middle of the eighteenth century who placed the concept of function and, in particular, the concept of continuous function at the center of analysis, and it was Cauchy in 1821, and independently Bernard Bolzano (1781–1848) in 1817, who gave the concept its now standard meaning. Following these authors, a function  $f(x)$ , defined in a neighborhood of a point  $\xi$ , is said to be *continuous at*  $\xi$  if  $\lim_{x \rightarrow \xi} f(x) = f(\xi)$ ; and  $f(x)$  is said to be *continuous in a closed interval*  $[a, b]$  if it is continuous at each point of the interval, it being understood that the limits corresponding to the endpoints  $a$  and  $b$  are right-sided and left-

sided limits, respectively. Thus, within the Weierstrassian framework,  $f(x)$  is continuous in a closed interval iff for each member  $\xi$  of the interval and for each positive real number  $\varepsilon$  there is a positive real number  $\delta$  such that  $|f(x) - f(\xi)| < \varepsilon$  whenever  $|x - \xi| < \delta$ .

The Cauchy-Bolzano conception of continuity accords nicely with the intuition that the values of a continuous function  $f$  differ slightly when its arguments differ slightly and, hence, with its geometric analog that the graph of  $f$  does not have a *break* or *jump* in the interval in question. Indeed, using the Cauchy-Bolzano definition nineteenth-century mathematicians were able to show that formal replacements of a number of the familiar intuitions about continuous functions and curves could be established as theorems including the following two:

**The Intermediate Value Theorem.** If  $f$  is a continuous function on a closed interval  $[a, b]$  of  $\mathbb{R}$  and  $f(a) < \xi < f(b)$  for some  $\xi$ , then there is a  $c \in (a, b)$  with  $f(c) = \xi$ ;

**Extreme Value Theorem.** If  $f$  is a continuous function on a closed interval  $[a, b]$  of  $\mathbb{R}$ , then  $f$  has a maximum value at some  $c \in [a, b]$  and  $f$  has a minimum value at some  $d \in [a, b]$ .

The Cauchy-Bolzano conception of continuity is local by nature, referring to the behavior of the function in the neighborhood of a point. Even the notion of continuity in a closed interval is defined in terms of continuity at every point of the interval. A more global conception of continuity that gradually emerged during the process of rigorization that implies but is not implied by the Cauchy-Bolzano conception is that of *uniform continuity*. Following Heinrich Heine (1821–1881), who carefully separated the two notions that had apparently been conflated by Cauchy, a function  $f$  is said to be uniformly continuous on a set  $A$  of real numbers if, for each positive real number  $\varepsilon$ , there is a positive real number  $\delta$  such that for each pair of members  $\xi$  and  $\xi'$  of  $A$ ,  $|f(\xi) - f(\xi')| < \varepsilon$  whenever  $|\xi - \xi'| < \delta$ . Essentially, this asserts that for a given  $\varepsilon$ , the same  $\delta$  for the continuity condition works for all members of  $A$ . The following result, which is of central importance in both standard analysis and a number of the nonstandard alternatives that will be discussed later on, is also due to Heine:  $f$  is uniformly continuous on a closed interval  $[a, b]$  of  $\mathbb{R}$ , whenever  $f$  is continuous on  $[a, b]$ .

It is important to emphasize that the class of functions that are deemed to be continuous by standard analysts are more inclusive than those envisioned implicitly or explicitly by their seventeenth-, eighteenth-, and even

early nineteenth-century predecessors. Basically, all the curves treated by seventeenth-century analysts were expressed everywhere by one and the same algebraic or transcendental equation and were, accordingly, continuous in the now standard sense. In the mid-eighteenth century so-called discontinuous functions were introduced into analysis by Euler, though they would not be recognized as such today. According to Euler's distinction, which was used up to the time it was replaced by that of Bolzano and Cauchy, a function is continuous if it is characterized by a single analytic expression, and it is discontinuous if it lacks any analytic expression, as in the case of freehand curves, or, if it is defined by different analytic expressions in a finite number of different intervals, the points at which the analytical expressions change being the points of discontinuity.

Euler's points of discontinuity correspond to points of the curve having no well-defined derivative. Accordingly, if one thinks of a continuous curve as the path of a moving point—an intuition that played an important heuristic role in the development of the calculus—Euler's points of discontinuity correspond to points at which the moving point has no well-defined direction. With this in mind it is not difficult to understand why during much of the nineteenth century it was widely believed that functions that are continuous in the Cauchy-Bolzano sense may fail to have derivatives at no more than a finite number of points. In fact, a number of mathematicians including Bolzano himself attempted to prove just this. Mathematicians were therefore surprised when in 1861 Weierstrass provided an example of a continuous function that is nowhere differentiable. A similar such function was constructed by Bolzano in 1834, but like the remainder of his work, it did not become known to the mathematical community till after the work of Weierstrass.

The Cauchy-Bolzano conception of discontinuity, by contrast with Euler's, is closer to that of *discontiguity*, an extreme case being P. G. Lejeune Dirichlet's (1805–1859) so-called monster function—the nowhere continuous function defined on the real line by the condition

$$f(x) = \begin{cases} 0, & \text{if } x \text{ is rational} \\ 1, & \text{if } x \text{ is irrational.} \end{cases}$$

Euler apparently was aware of the existence of discontinuous functions in the modern sense (Youschkevitch 1976, pp. 64–65), but they did not play a fundamental role in the calculus of his time. With the work of Riemann on the convergence of Fourier series during the middle of the

nineteenth century, however, this all changed, and they have come to enjoy widespread application not only in analysis, but also in empirical science from where they came. Indeed, referring to their early nineteenth-century roots in the work of Joseph Fourier, the great philosopher-mathematician Jules Henri Poincaré (1854–1912) musingly observes:

Fourier's series is a precious instrument of which analysis makes continual use, it is by this means that it has been able to represent discontinuous functions; Fourier invented it to solve a problem of physics relative to the propagation of heat. If this problem had not come up naturally, we should never have dared to give discontinuity its rights; we should still long have regarded continuous functions as the only true functions. (Poincaré 1913, p. 286)

## THE CANTOR-DEDEKIND CONTINUUM

Central to Cantor's and Dedekind's constructions of the real number system was the underlying belief that only after providing a precise definition of a continuum based on the science of number would it be possible to lend precision to the idea of the continuity of the Euclidean straight line and of continuous magnitude more generally. For this purpose they turned to properties of  $\mathbb{R}$  whose continuity they assumed as a *mathematico-philosophical thesis*. According to Cantor, the continuity of  $\mathbb{R}$  consists in its being both *connected* and *Cauchy complete*; it is connected because whenever  $a$  and  $a'$  are elements of the system such that  $a < a'$ , then for any positive element  $\varepsilon$  of the system, there is a finite sequence  $a_1, \dots, a_n$  of elements of the system where  $a < a_1 < \dots < a_n < a'$  such that  $a_1 - a, \dots, a' - a_n < \varepsilon$ ; and it is Cauchy complete since every convergent sequence of elements of the system has a limit in the system. Dedekind, by contrast, identified the continuity of  $\mathbb{R}$  with its being a totally ordered system having what is today called the Dedekind continuity property; that is, whenever the system is partitioned into two nonempty subsets  $X$  and  $Y$  such that every member of  $X$  precedes every member of  $Y$ , then either  $X$  has a greatest member or  $Y$  has a least member, but not both.

Connectivity, in Cantor's sense, was soon recognized to be equivalent the Archimedean axiom for a large class of structures including ordered fields, the latter of whose roots lie in analytic geometry. Indeed, since the time that Wallis and Newton incorporated directed segments into Cartesian geometry, it had been loosely understood that given a unit segment  $AB$  of a line  $L$  of a classical Euclid-

ean space, the collection of directed segments of  $L$  emanating from  $A$  including the degenerate segment  $AA$  itself constitutes an Archimedean ordered field with  $AA$  and  $AB$  the additive and multiplicative identities of the field and addition and multiplication of segments suitably defined. These ideas were made precise by Giuseppe Veronese (1854–1917) in his *Fondamenti di geometria* (1891) and by David Hilbert (1862–1943) in his *Grundlagen der Geometrie* (1899), works on the foundations of geometry from which the modern conceptions of Archimedean and non-Archimedean ordered fields emerged. It was also these and related works on the foundations of geometry that gave rise to the following familiar characterizations of the arithmetic continuum whose continuity properties are associated with Cantor, Dedekind, Bolzano, and Hilbert, respectively:

- (1)  $\mathbb{R}$  is (up to isomorphism) the unique Archimedean ordered field that is Cauchy complete
- (2)  $\mathbb{R}$  is (up to isomorphism) the unique Dedekind continuous ordered field
- (3)  $\mathbb{R}$  is (up to isomorphism) the unique ordered field having the least upper bound property (that is, every subset of the system that is bounded above has a least upper bound)
- (4)  $\mathbb{R}$  is (up to isomorphism) the unique Archimedean ordered field that admits no proper extension to an Archimedean ordered field

Each of these characterizations of  $\mathbb{R}$  makes use of metrical conceptions. However, in 1895 Cantor demonstrated that it is possible to provide a categorical characterization of the ordered set of real numbers and, hence, of a Cantor-Dedekind linear continuum, using order-theoretic concepts alone. Another such characterization that emerged soon thereafter is the following one given by Edward V. Huntington (1874–1952) that indicates what besides simple density—the set-theoretic analog of infinite divisibility—is required to characterize the order type of  $\mathbb{R}$  (1917):

- (1)  $\langle K, < \rangle$  is a totally ordered set having neither a first element nor a last element;
- (2)  $\langle K, < \rangle$  is dense, that is, if  $a$  and  $b$  are elements of  $K$  such that  $a < b$  there is an element  $x$  in  $K$  such that  $a < x < b$ ;
- (3)  $\langle K, < \rangle$  is Dedekind complete, that is, if  $K_1$  and  $K_2$  are any two nonempty subsets of  $K$ , such that every element belongs either to  $K_1$  or  $K_2$  and every element of  $K_1$  precedes every element of  $K_2$ , then there is at least one element  $x$  in  $K$  such that any element that

precedes  $x$  belongs to  $K_1$ , and every element that follows  $x$  belongs to  $K_2$ ;

- (4) the class  $K$  contains a denumerable subset  $K'$  in such a way that between any two elements of  $K$  there is an element of  $K'$ .

Reflecting on the then newly developed order-theoretic conception of the mathematical continuum, the great philosopher-mathematician Jules Henri Poincaré perceptively remarks that:

[t]he continuum so conceived is only a collection of individuals ranged in a certain order, infinite in number, it is true, but *exterior* to one another. This is not the ordinary conception, wherein is supposed between the elements of a continuum a sort of intimate bond which makes of them a whole, where the point does not exist before the line, but the line before the point. Of the celebrated formula, “the continuum is unity in multiplicity,” only the multiplicity remains, the unity has disappeared. The analysts are none the less right in defining their continuum as they do, for they always reason on just this as soon as they pique themselves on rigor. But this is enough to apprise us that the veritable mathematical continuum is a very different thing from that of the physicist and that of the metaphysician. (1913, p. 43)

To some extent these views are a reflection of those of Cantor and Dedekind themselves. For example, distancing himself from a long line of metaphysicians, Cantor writes:

The concept of the “continuum” has ... always evoked the greatest differences of opinion and even vehement quarrels. This lies perhaps in the fact that, because the exact and complete definition of the concept has not been bequeathed to the dissentients, the underlying idea has taken on different meanings; but it may also be (and this seems to me the most probable) that the idea of the continuum had not been thought out by the Greeks (who may have been the first to conceive it) with the clarity and completeness which would have been required to exclude the possibility of different opinions among their posterity. Thus we see Leucippus, Democritus, and Aristotle consider the continuum as a composite which consists from parts divisible without end, but Epicurus and Lucretius construct it out of their atoms considered as finite things. Out of this a great quarrel arose among the

philosophers, of whom some followed Aristotle, others Epicurus; still others, in order to remain aloof from this quarrel, declared with Thomas Aquinas that the continuum consisted neither of infinitely many nor of a finite Anzahl [number] of parts, but of *absolutely no* parts. ... Here we see the *medieval-scholastic origin* of a point of view which we still find represented today, in which the continuum is thought to be an unanalysable concept, or as others express themselves, a pure a priori intuition which is scarcely susceptible to a determination through concepts. Every arithmetical attempt at determination of this *mysterium* is looked on as a forbidden encroachment and repulsed with due vigor. Timid natures thereby get the impression that with the “continuum” it is not a matter of a *mathematically logical concept* but rather of religious dogma. (1883/1996, p. 903)

Moreover, as to the necessity of even conceiving space as continuous, Dedekind remarks, “If space has at all a real existence it is not necessary for it to be continuous” (1872/1996, p. 772). Indeed,

If anyone should say that we cannot conceive of space as anything else than continuous, I should venture to doubt it and call attention to the fact that a far advanced, refined scientific training is demanded in order to perceive clearly the essence of continuity and to understand that besides rational quantitative relations, also irrational, and besides algebraic, also transcendental quantitative relations are conceivable. (1888/1996, p. 793)

Bertrand Russell, who played the leading role in introducing the ideas of Cantor and Dedekind to the English-speaking philosophical world, goes even further when he remarks, “Whether the axiom of continuity be true as regards our actual space, is a question I see no means of deciding. For any such question must be empirical, and it would be quite impossible to distinguish empirically what may be called a rational space from what might be called a continuous space” (1903, p. 440).

However, despite these and other such pronouncements made in the years bracketing the turn of the twentieth century, and despite the ongoing speculation about quantized space and time that emerged soon thereafter with the advent of the quantum theory (compare Cepek 1961, pp. 223–243; Sorabji 1983, pp. 381–383, 447) and that was redirected toward overcoming the difficulties of

harmonizing the quantum theory with the relativistic theory of gravity and space-time (compare Markopoulou 2004; Smolin 2001, 2004), it became and remains commonplace among philosophers and physicists to assume not only that space and time are continuous, as most of their modern predecessors had supposed, but also that they are continuous in the sense of Cantor and Dedekind. Whether this assumption should be construed instrumentally or realistically there is a multiplicity of views (compare Earman 1989, chapters 8 and 9; Maddy 1997, chapter 6; Hellman 1998), as are the views regarding the testable status of the thesis itself (compare Forrest 1995, Markopoulou 2004).

### MODERN EUCLIDEAN GEOMETRY AND THE CONTINUUM

At least as far back as the seventeenth century there were thinkers who observed that there are places in the *Elements* where Euclid tacitly employs continuity assumptions that are not warranted by the axioms and common notions he assumes. For example, in his proof that given any segment, there is an equilateral triangle having the given segment as one of its sides (Book 1, Proposition 1), Euclid assumes

*The Circular Continuity Principle:* If a circle  $C$  has one point inside and one point outside another circle  $C'$ , then the two circles intersect in two points.

And in his proof that through a point outside a given line there is a line perpendicular to the given line (Book 1, Proposition 12), he assumes

*The Line-Circle Continuity Principle:* If one endpoint of a segment is inside a circle and the other outside, then the segment intersects the circle at one point.

Among the thinkers who thus criticized Euclid was Leibniz in his *Specimen geometriae luciferae* (c. 1695/1962, p. 284). Such criticisms were significant not only because they drew attention to gaps in Euclid’s reasoning but also because they intimated that, contrary to the ancient and the then still standard view, infinite divisibility is not sufficient for continuity. In fact, in the just-cited paper as Ernst Cassirer (1902, p. 183) importantly observes, Leibniz departed from his usual acceptance of the standard view and explicitly stated just this.

During the late nineteenth century geometers showed that by supplementing the then newly emerging refinements of Euclid’s system of axioms with continuity axioms that ensured the satisfaction of the Cantor-Dedekind axiom, one could establish the circular continuity principle and the line-circle continuity principle

and with these all of Euclid's continuity needs (compare Heath 1956, pp. 1:234–240; Greenberg 1993, pp. 93–101). However, as Cantor and Dedekind were aware, whereas the Cantor-Dedekind axiom suffices for the continuity needs of Euclid, it goes beyond those needs. Cantor makes this point, albeit only implicitly, when (following his proof-sketch that to each point of the Euclidean line there corresponds a real number) he maintains:

In order to complete the connection of numerical quantity with the geometry of the straight line, one must only add an *axiom* which simply says that conversely every numerical quantity also has a determined point on the straight line, whose coordinate is equal to that quantity. ... I call this proposition an *axiom* because by its nature it cannot be generally proved. (Cantor 1872/1932, p. 96)

And Dedekind makes the point more forcefully and explicitly when he revealingly observes:

If we select three non-collinear points  $A$ ,  $B$ , and  $C$  at pleasure, with the single limitation that the ratios of the distances  $AB$ ,  $AC$ ,  $BC$  are algebraic numbers, and regard as existing in space only those points  $M$ , for which the ratios of  $AM$ ,  $BM$ ,  $CM$  to  $AB$  are likewise algebraic numbers, then it is easy to see that the space made up of the points  $M$  is everywhere discontinuous. But in spite of this discontinuity, and despite the existence of gaps in this space, all constructions that occur in Euclid's *Elements*, can, so far as I can see, be just as accurately effected here as in a perfectly continuous space; the discontinuity of this space would thus not be noticed in Euclid's science, would not be felt at all. (1888/1996, p. 793)

The ordered field of real algebraic numbers to which Dedekind is referring is an instance of a *Euclidean ordered field*, that is, an ordered field in which every positive element is the square of some element of the field. Besides being Euclidean, the ordered field of real algebraic numbers is both countable and Archimedean. During the twentieth century it emerged that a model of all the axioms of (a modern refined version of) Euclidean geometry less the Archimedean axiom and the Cantor-Dedekind axiom satisfies the circular continuity principle iff it satisfies the line-circle continuity principle iff a line of the model is modeled by a Euclidean ordered field (compare Tarski 1959/1986; Hartshorne 2000, pp. 104–112, 144–145; Greenberg 1993, pp. 143–144). If, following Euclid, the Archimedean axiom is also assumed, the Euclidean ordered fields must be Archimedean as well. It

is essentially for this reason that Euclidean ordered fields have been so named. For historically important examples of modern refined versions of Euclidean geometry, see David Hilbert (1899/1971) and Alfred Tarski (1959/1986); and for examples of non-Archimedean Euclidean ordered fields and their corresponding non-Archimedean Euclidean geometries, see Philip Ehrlich (1997a).

## SET THEORY AND THE CONTINUUM

The Cantor-Dedekind theory of the continuum was originally formulated in a *naïve* set-theoretic framework, grounded in intuitions about sets that included the then radical assumption that infinitely many entities could be collected together in a set. Within this framework Cantor established the existence of an exhaustive hierarchy  $\aleph_0$ ,  $\aleph_1$ ,  $\aleph_2$ , ... of increasingly large infinite cardinals, proved that the cardinality of the set of rational numbers is  $\aleph_0$ , that the cardinality of  $\mathbb{R}$  is  $2^{\aleph_0}$ , and that  $2^{\aleph_0}$  is greater than  $\aleph_0$ . In the early decades of the twentieth century Cantorian set theory was placed on an axiomatic basis that sidestepped a medley of paradoxes that had befallen the naïve theory. In honor of two of its principal architects, Ernst Zermelo (1871–1953) and Abraham A. Fraenkel (1891–1965), the theory has come to be designated ZFC, where ZF indicates the body of axioms outside the axiom of choice. Of the open problems inherited from the naïve theory none was regarded more important than that of deciding the veracity of the *continuum hypothesis* (CH)—Cantor's conjecture that the cardinality of the continuum is  $\aleph_1$ . However, in 1938 Kurt Gödel showed that ZFC + CH is consistent if ZFC is, and twenty-five years later Paul Cohen demonstrated if ZFC is consistent so is ZFC +  $\neg$ CH, thereby establishing the independence of CH from standard set theory. Since the work of Cohen there has been a good deal of speculation on the part of philosophers and logicians whether or not the axioms of ZFC should be supplemented with one or more additional axioms that would settle the matter one way or another (Kanamori 2003). Gödel (1947/1983), who held a platonist view of sets, maintained that CH is either objectively true or objectively false and, accordingly, promoted the search for additional axioms to settle the matter. Many set theorists, including Cohen (1990), however, believe that there is nothing in the intuitive concept of set that would recommend the adoption of an additional axiom that would conclusively settle CH one way or another. The views of Gödel and Cohen, however, only begin to indicate the range of opinion on the matter as is evident from the debate between Solomon Feferman et al. (2000), the writings of Donald Martin and H. G. Dales (Dales and

Oliveri 1998), and the intriguing though controversial views of W. Hugh Woodin (2001, 2002, 2004). Both models of ZFC + CH and ZFC +  $\neg$ CH are being explored by set theorists with perhaps a bit more attention being devoted to the latter. Mathematicians who are not set theorists, however, tend to use CH freely for the purpose of theorem proving, their reliance on CH being indicated in the statement of the theorem.

## NONSTANDARD THEORIES OF CONTINUA

Although the Cantor-Dedekind theory of real numbers and philosophy of the continuum have occupied privileged positions in standard mathematical philosophy since the decades following the turn of the twentieth century, it has never enjoyed the complete allegiance of either philosophers or mathematicians. Early opponents such as Hermann Hankel (1839–1873) and Paul du Bois-Reymond (1831–1889) were critical of the attempts by Cantor, Dedekind, and others to treat irrational numbers formally and without the concept of continuous magnitude, and others such as Leopold Kronecker (1823–1891) complained, on the contrary, that the arithmetization had not gone far enough. Still others, including Emil Borel (1871–1956) and a young L. E. J. Brouwer (1881–1966), continued to regard the continuum as a primitive concept given to one directly by geometric intuition that was not amenable to analysis (compare Troelstra 1982); and others, including Hermann Weyl (1885–1955) (1918) as well as a more mature Brouwer (compare 1918, 1924, 1952), while embracing an analytical approach questioned one or another aspect of the logico-set-theoretic underpinnings of the Cantor-Dedekind theory. Another complaint that was, and to some extent still is, a stumbling block to the acceptance of the Cantor-Dedekind theory is the contention that the Cantor-Dedekind philosophy of the continuum is committed to the reduction of the continuous to the discrete, a program whose philosophical cogency, and even logical consistency, had been called into question over the centuries. Inspired by arguments originating with Aristotle, and reiterated and further developed by Immanuel Kant (1724–1804), Franz Brentano (1838–1917), Edmund Husserl (1859–1938), and others, a string of late nineteenth- and twentieth-century mathematicians and philosophers beginning with du Bois-Reymond (1882) maintained that unlike the unextended points that, by their lights, compose the Cantor-Dedekind continuum, the elements of a genuine continuum must themselves have extension if the continuum itself is to have extension. This view led Charles Sanders

Peirce (1939–1914) to sketch a nonarithmetic theory of the continuum based on infinitesimals (1898/1992, 1900), and it played important contributing roles in the development of Brouwer's and Weyl's aforementioned intuitionist and predicativist alternatives to the standard conception as well.

Veronese (1889, 1891, 1894), however, while agreeing that the parts of a continuum must be intervals as opposed to points, held that for the sake of geometry the geometer may treat the line as an ordered collection of unextended points; moreover, holding that one's intuitive conception of the continuum is independent of the Archimedean axiom, he developed a general axiomatic theory of continua that was not only satisfied by the standard arithmetic continuum but by certain structures with infinitesimals as well, and he illustrated the latter by means of a synthetic construction of a non-Archimedean ordered field that is continuous in his sense. Veronese's non-Archimedean continuum was placed on a logically sound arithmetic foundation by Tullio Levi-Civita (1873–1941), who therewith provided the first analytic constructions of non-Archimedean ordered fields (1892–1993/1954, 1898/1954).

Building on the work of Levi-Civita, Hans Hahn (1879–1934) constructed non-Archimedean number systems (1907) having properties that generalize the aforementioned continuity properties of Dedekind and Hilbert, and he demonstrated that his number systems collectively provide a panorama of the finite, infinite, and infinitesimal numbers that can enter into a non-Archimedean theory of continua based on the concept of an ordered field (compare Ehrlich 1995, 1997, 1997a). Throughout the remaining first half of the twentieth century there continued to be important contributions to the theory of the continuum including the algebraic (Artin and Schreier 1926/1965) and logical (Tarski 1939/1986, 1948/1986) versions of the theory of elementary continuity. During the 1950s, under the influence of A. A. Markov (1856–1922), a Russian school of constructive analysis was developed based on a continuum consisting of real numbers with a *recursive* Cauchy sequence (compare Kushner 1984), and during the 1960s Errett Bishop (1928–1983) introduced an alternative constructive approach to analysis (1967) based on a model of the continuum whose theorems, unlike those of Brouwer and the Russian school, are all provable in classical mathematics.

Also during roughly the same period, interest in Weyl's predicative theory was rekindled by Feferman (1998), who developed his own predicative approach to analysis. In addition, since the late 1950s a number of

nonstandard theories of continua have appeared that make use of infinitesimals including those arising from Abraham Robinson's (1918–1974) nonstandard approach to analysis (1961/1969, 1966/1974), those arising from F. W. Lawvere (1979, 1980) and Anders Kock's (1981) ideas on smooth infinitesimal analysis and synthetic differential geometry, the partially ordered continuum of Curt Schmieden and Detlef Laugwitz (1958), and Ehrlich's so-called absolute arithmetic continuum (1987, 1989, 1992) based on J. H. Conway's (1976) theory of *surreal numbers*. Still another theory that arose during this period is the theory of fuzzy real numbers based on Lofti Asker Zadeh's (1987) theory of fuzzy sets.

Of the nonstandard theories mentioned earlier, the intuitionist, Bishop-style constructivist, predicativist, and the Robinsonian and post-Robinsonian infinitesimalist theories have been given the most attention by philosophers. In the subsequent three sections these will be considered in turn with some attention paid to the Russian constructivist theory as well.

## CONSTRUCTIVIST THEORIES

*Constructivism* is a rubric that has come to designate a family of approaches to the foundations of mathematics that are loosely united by their opposition to certain forms of mathematical reasoning employed in the mainstream mathematical community. However, as the term loosely suggests, there are significant differences between the various schools and substantial differences in attitude can be found even among the representatives of a given school or a single representative over time. However, whether the result of their rejection of actual infinities or the universal applicability of certain principles of classical logic, or their insistence on the use of algorithmic constructions of one form or another, constructivists have always found themselves at odds with the Cantor-Dedekind theory of the continuum and have sought to provide alternatives that are constructively sanctioned by their own particular lights. To distinguish the resulting intuitionist, Russian constructivist, and Bishop-style constructivist arithmetic continua from  $\mathbb{R}$ , from now on they will be denoted as  $\mathbb{R}_I$ ,  $\mathbb{R}_R$ , and  $\mathbb{R}_C$ , respectively.

Before the late 1960s the constructivist theory of the continuum that attracted the greatest attention is the intuitionistic theory of Brouwer. Until 1914, Brouwer, like Borel before him, embraced a holistic view in which the continuum is regarded as a primitive notion given directly by intuition that cannot be understood as the totality of its individually definable elements. Thereafter, while still clinging to certain aspects of the irreducible

conception, Brouwer adopted a more analytic view in which the continuum, while not a completed non-deumerable totality, can be more and more completely specified in a never-ending fashion with one's increasing knowledge as a medium of free development.

The basis of Brouwer's conception of the continuum is the concept of a *choice sequence*, a concept not acceptable to classical mathematics. According to Brouwer, the construction of such a potentially infinite sequence is always incomplete in the sense that at any given instant of its construction the sequence is limited to a finite number of terms. A choice sequence  $\alpha$  is given by a fixed initial segment  $\alpha_1, \alpha_2, \dots, \alpha_n$  of mathematical objects along with a corresponding set of restrictions  $R_1, R_2, \dots, R_n$ , where  $R_n$  restricts the range of possible choices for  $\alpha_{n+1}$ . In particular, real numbers are introduced by Brouwer as choice sequences that are Cauchy sequences of rational numbers. Of course, being a choice sequence, the notion of a Cauchy sequence of rational numbers must be appropriately understood. More specifically, according to the intuitionist one can assert that a potentially infinite sequence  $r_1, r_2, \dots$  of rational numbers is a Cauchy sequence only if one knows there is a procedure that, given any positive integer  $k$ , effectively produces a natural number  $N$  along with a proof that  $N$  has the specified Cauchy property, for example,  $|r_m - r_n| < 1/k$  for all  $m, n < N$ .

For Brouwer, such a choice sequence is not a technique for approximating some preexisting real number—it is the choice sequence itself, growing in time, that is the real number. Some such real numbers are introduced by letting the choices be prescribed by a fixed algorithm. These so-called *lawlike* sequences lead to the existence of real numbers such as  $e$ ,  $\pi$ , and  $\sqrt{2}$ . Other real numbers arise from forbidding any restriction on the rational numbers one chooses outside of assuring that the choice sequence is Cauchy. Between these two extremes, however, there is a wide range of possibilities for introducing real numbers. Until 1927 Brouwer did not place any restrictions on choice sequences—having regarded them as sufficiently explained by the freedom of a supposed ideal mathematician generating them—but thereafter he became more specific and continued to revise his conception of permissible choice sequences until the early 1950s (compare Troelstra 1982, pp. 472–474).

The adoption of choice sequences forces a nonclassical logic on intuitionists that rejects the universal validity of the *law of excluded middle*. For example, given the incomplete nature of choice sequences the intuitionist has no right to assume for an arbitrary pair of choice sequences  $\alpha$  and  $\beta$  having identical initial segments that  $\alpha$

$= \beta \vee \alpha \neq \beta$ . The logic that has come to be embraced by intuitionists is a subtheory of classical logic called *intuitionistic logic* (compare Heyting 1971, chapter 7). For the intuitionist, logic does not provide a foundation for mathematics but emerges from one's mathematical practice. The adoption of intuitionistic logic leads intuitionists to a theory of real numbers and corresponding theory of continuity that differs markedly from their classical counterparts. For example, besides the just-cited deviation, it is not possible for intuitionists to prove precise analogs of the following classical results for their own system  $\mathbb{R}_1$  of real numbers:  $\forall x, y \in \mathbb{R}(xy = 0 \rightarrow (x = 0 \vee y = 0))$ ;  $\forall x, y \in \mathbb{R}(x \leq y \vee x \geq y)$ ;  $\forall x, y \in \mathbb{R}(x > y \vee x = y \vee x < y)$ ; every subset of  $\mathbb{R}$  that is bounded above has a least upper bound;  $\forall x \in \mathbb{R}(x \text{ is rational} \vee x \text{ is irrational})$ . Nor can they prove the intermediate value theorem or the extreme value theorem. From Brouwer's perspective, this inability is not a limitation since each of the previous assertions implies an instance of the law of excluded middle that is not intuitionistically sanctioned (compare Bridges and Reeves 1999, pp. 72–73). This attitude, and the embrace of intuitionistic logic more generally (with the aforementioned implications for their own theories of real numbers and corresponding theories of continuity) is a common thread that binds constructive mathematicians. From the constructivist point of view, accepting the law of excluded middle as a universal principle would mean the existence of a universal procedure for generating for each proposition  $P$ , either a proof of  $P$  or a proof of  $\neg P$ , where a procedure for generating a proof of  $\neg P$  is understood to be a method for generating a contradiction from a hypothetical proof of  $P$ . However, such a procedure is not available; if it were one could decide a proposition  $P$ —such as Goldbach's conjecture—the truth of which has not been decided.

Brouwer's concept of a choice sequence that is Cauchy corresponds, as Heyting notes, "to the intuitive concept of the continuum as a possibility of a gradual determination of points" (1971, p. 34). To develop an adequate theory of continuity and of analysis more generally, however, the mathematician must be able to talk about classes of such real numbers and functions. From the standpoint of the intuitionist, however, one cannot collect them together into a Cantorian set—there are simply too many of them. Rather, for the intuitionist, they are held together in a *spread*—roughly speaking, a growing tree, whose emerging paths through the tree correspond to the various ways an initial segment of a choice sequence can be continued (compare Heyting 1971, chapter 3).

Moreover, to obtain the central continuity theorems concerning such classes of real numbers and functions, Brouwer introduced two fundamental ideas governing the mathematical treatment of choice sequences: the *weak continuity principle for numbers* (compare Veldman 2001, Atten and Dalen 2002, Troelstra and Dalen 1988, chapter 5) and the *principle of bar induction* (compare Kushner 2001). The continuity principle makes choice sequences serviceable by contending that a total function from choice sequences to natural numbers never requires more input than an initial segment (of a choice sequence) to generate its output; and the induction principle ensures, among other things, that the entire intuitionistic continuum can be treated in a constructively manageable fashion (compare Atten 2004, chapters 3–4).

The adoption of the continuity principle and the induction principle gives the intuitionistic theory of continuity its own distinctive constructivist flavor and leads to even more striking deviations from the classical theory than those listed earlier. For example, in virtue of the continuity principle, the analogs of the aforementioned classical results that cannot be established as a result of the adoption of intuitionistic logic are now provably false (compare Bridges and Richman 1987, pp. 4–5; Troelstra and Dalen 1988, pp. 257–258). What is perhaps the most notorious such deviation, however, is that all functions from  $\mathbb{R}_1$  to  $\mathbb{R}_1$  are continuous, and uniformly continuous at that. This apparent absurdity arises in part from the fact that the contention " $f$  is a function defined on all of  $\mathbb{R}_1$ " is substantially stronger construed intuitionistically than is the contention " $f$  is a function defined on all of  $\mathbb{R}$ " construed classically. Consider, for example, the classical discontinuous function  $f$  defined by

$$f(x) = \begin{cases} 0, & \text{if } x < 0 \\ 1, & \text{if } x \geq 0. \end{cases}$$

From Brouwer's perspective,  $f$  is not a function at all since one cannot prove  $\forall x \exists y (f(x) = y)$  by intuitionistically sanctioned means. In particular, one cannot prove  $\forall x (x < 0 \vee x \geq 0)$  insofar as the definition of  $f$  does not tell one how to compute  $f(x)$  if  $x$  is a number for which one cannot assert either  $x < 0$  or  $x \geq 0$ . Closely related to this is still another striking deviation, the so-called *unsplittability* of the intuitionistic continuum; that is, unlike the Cantor-Dedekind arithmetic continuum, there do not exist two disjoint nonempty subsets of an interval of the intuitionistic continuum whose union is the given interval, nor are there such partitions of the intuitionistic continuum whose union is the continuum itself. Accordingly,

for the intuitionist, as for Anaxagoras and Aristotle before them, it is not possible to separate out a point from their continuum or from an interval thereof.

While Brouwer's theory has attracted a good deal of attention from philosophers and logicians, it has received comparatively little attention from standard mathematicians. Whether this is because of the philosophical precepts underlying it, the highly nonclassical nature of the mathematical arguments it employs, the belief that the resulting mathematics is too impoverished, or simply the absence of a perceived need for it, is difficult to say. In 1967, however, Brouwer's theory was given an especially stinging critique, not by standard mathematicians, but by Bishop, whose treatise *Foundations of Constructive Analysis* is widely credited with having breathed new life into constructive mathematics. In the treatise's polemical opening chapter Bishop describes the construction and motivation underlying Brouwer's theory of the continuum in the following biting terms:

Brouwer became involved in metaphysical speculation by his desire to improve the theory of the continuum. A bugaboo of both Brouwer and the logicians has been compulsive speculation about the nature of the continuum. In the case of the logicians this leads to contortions in which various formal systems, all detached from reality, are interpreted within one another in the hope that the nature of the continuum will somehow emerge. In Brouwer's case there seems to have been a nagging suspicion that unless he personally intervened to prevent it, the continuum would turn out to be discrete. He therefore introduced the method of free-choice sequences for constructing the continuum, a consequence of which the continuum cannot be discrete because it is not well enough defined. This makes mathematics so bizarre it becomes unpalatable to mathematicians, and foredooms the whole of Brouwer's program. This is a pity, because Brouwer had a remarkable insight into the defects of classical mathematics, and he made a heroic effort to set things right. (1967, p. 6)

Bishop sought to place analysis on a constructivist foundation that is free of the perceived difficulties mentioned earlier, a project that has been extended by a number of other mathematicians including Douglas Bridges and Fred Richman. In Bishop's arithmetic continuum  $\mathbb{R}_C$  a real number is simply defined as a sequence  $\{x_n\}$  of rational numbers that satisfies the condition  $|x_m - x_n| \leq$

$m^{-1} + n^{-1}$  (for all integers  $m, n \geq 1$ ); though some authors, following Troelstra and Dirk van Dalen (1988, pp. 253–254), prefer to use equivalence classes of certain sequences of rational numbers in their place. Thus, for Bishop, as for Markov, every real number is a lawlike Cauchy sequence. Using a system of axioms for constructive ordered fields with a formulation of the Archimedean axiom and a constructive formulation of the least upper-bound principle, Bridges (1999) shows that  $\mathbb{R}_C$  can be characterized in a manner that closely resembles one of the aforementioned standard axiomatizations of  $\mathbb{R}$ . Working independently, Alberto Ciaffaglione and Pietro Di Gianantonio (2002) and Herman Geuvers and Milad Niqui (2002) provide equivalent axiomatizations of  $\mathbb{R}_C$  that employ constructive versions of Cauchy completeness in place of Bridges's least upper-bound condition. Assuming the axiom of countable choice (compare Troelstra and Dalen 1988, pp. 189–190)—an axiom that is frequently adopted by constructive mathematicians—Geuvers and Niqui (2002) further establish the categoricity of the axiomatizations. Absent the choice axiom (or some equivalent thereof), there are models of the axioms that are not isomorphic to  $\mathbb{R}_C$ —in particular, Troelstra and Dalen's version of the constructive continuum based on Dedekind cuts (1988, pp. 270–274).

Bishop tended to distinguish his theory of analysis from the classical theory by emphasizing the former's demand for algorithmic constructions. Following in the footsteps of Brouwer, Bishop took the concept of an algorithm as a primitive, undefined notion and was led to reject the universal validity of the law of excluded middle by interpreting mathematical existence strictly in terms of computability or constructivity. Bridges and, especially, Richman speculate that the theory of analysis that emerges from Bishop's approach may be regarded as the subtheory of the classical theory that is obtainable employing intuitionistic logic as opposed to classical logic as the underlying logic (Bridges and Richman 1987; Richman 1990, 1996; Bridges 1999). Since (in accordance with Heyting's axiomatization of intuitionistic logic [1971]) one passes from intuitionistic logic to classical logic by embracing the universal validity of the law of excluded middle, on their view Bishop's theory may be regarded as the subtheory of the classical theory that can be obtained without appealing to the instances of this classical law that are not intuitionistically sanctioned (Bridges and Richman 1987, p. 120).

Besides being a subtheory of the classical theory, Bishop's theory may be regarded as a subtheory of the intuitionist and Russian constructivist theories as well

(Bridges and Richman 1987, chapter 6). Whereas, in accordance with Bridges and Richman's view, one moves from Bishop's theory to the classical theory by embracing the universal validity of the law of excluded middle, to move from Bishop's theory to the intuitionistic theory one introduces Brouwer's weak continuity principle along with a seminal consequence of Brouwer's principle of bar induction called the *fan theorem*, and to pass from Bishop's theory to the Russian constructivist theory one adds a consequence of Church's thesis that all computable sequences of natural numbers are recursive (Bridges and Richman 1987, chapter 5). Talk of such passages, however, applies solely to theories in the logician's narrow sense of the term; it ignores the divergent philosophical motivations and mathematical trappings of the four theories. With respect to the Russian constructivist theory, for example, it ignores that every real number is a recursive real number, that algorithms are Markov algorithms, that functions are Gödel numbers of algorithms that compute them, and so on.

The differences between the classical, Russian constructivist, and intuitionist theories, however, go beyond their respective philosophical motivations and mathematical trappings; they have different theories of continuity, as is evident from the following theorems of the three respective theories:

(Classical): Some functions  $f:[0, 1] \rightarrow \mathbb{R}$  are not continuous and, hence, not uniformly continuous

(Russian Constructivist): Whereas all functions  $f:[0, 1] \rightarrow \mathbb{R}_r$  are continuous, some are not uniformly continuous

(Intuitionist): All functions  $f:[0, 1] \rightarrow \mathbb{R}_i$  are not only continuous, they are uniformly continuous

Despite these differences, Bishop's theory manages to lie comfortably within the common core of the three theories in part because in Bishop's theory attention is restricted from the outset to functions that are assumed to be uniformly continuous on each closed interval of  $\mathbb{R}_C$ .

Restricting attention to the just-said functions, Bishop managed to obtain a surprisingly robust theory of analysis that includes among a wide range of other theorems constructive analogs of the intermediate value theorem and the extreme value theorem. Like many of the theorems of constructive analysis, the latter two theorems differ from their classical counterparts by having weakened conclusions or strengthened hypotheses. One constructive version of the intermediate value theorem asserts that a uniformly continuous function  $f:[a, b] \rightarrow \mathbb{R}_C$  takes on a value as close to the given intermediate value as

one pleases, and the constructive version of the extreme value theorem asserts that a uniformly continuous function  $f:[a, b] \rightarrow \mathbb{R}_C$  does have a maximum (minimum), though the maximum (minimum) is not necessarily assumed. There is also a constructive version of the intermediate value theorem that asserts that in a particular class of cases (which includes all real-analytic functions), the intermediate value in question is in fact realized (compare Bishop and Bridges 1985, pp. 40–41; Troelstra and Dalen 1988, pp. 292–295).

However, despite the strength of Bishop's analysis and its compatibility with classical mathematics, Bishop's theory, like its intuitionist and Russian constructivist forerunner's, has not attracted the kind of attention from classical mathematicians its practitioners had hoped for (compare Bridges and Reeves 1999, p. 67). Moreover, while praising the significance of Bishop's accomplishment, some devotees of Brouwer's theory have questioned the adequacy of the analysis of the continuum that emerges from Bishop's approach. In particular, they are concerned that in Bishop's theory, like Markov's before it, the continuum of real numbers is restricted to those real numbers introduced by lawlike Cauchy sequences. For example, in his monograph devoted to Brouwer's theory, Mark van Atten remarks:

One may, like Markov and Bishop, settle for just the lawlike sequences ... but while practical, that also amounts to ducking the issue of how to model the full continuum. Brouwer's achievement is to have found a way to analyze the continuum that does not let it fall apart into discrete elements ... and it is constructive to boot. (2004, p. 33)

## PREDICATIVE THEORIES

Between classical mathematics, in which arbitrary sets are embraced, and Bishop's constructive mathematics, in which only algorithmically constructed objects are permissible, there is an intermediate approach called *predicativism*, in which only definable sets are considered, and in which quantifiers over sets are interpreted as ranging only over sets that have previously been defined. Although having its roots in Russell's and Poincaré's attempts to lay the blame for the paradoxes of set theory on definitions that define entities in terms of classes to which they belong—so-called *impredicative* definitions—it was Weyl, in his monograph *Das Kontinuum* (1918/1994), who first undertook the development of a theory of the arithmetic continuum and of analysis on it in a predicatively acceptable fashion.

Central to Weyl's critique of the classical theory is its dependence on the proposition that every nonempty set of real numbers that is bounded above has a least upper bound, the definition of the least upper bound of a set being inextricably impredicative. Weyl proposed overcoming this by employing the predicatively sanctioned proposition: Every nonempty sequence of reals having an upper bound has a least upper bound. Using this idea, Weyl constructed a restricted set of real numbers containing all reals that are expressible as Dedekind cuts definable in his system. Although the set of standard real numbers not definable in Weyl's system is everywhere dense, Weyl showed that on the basis of his continuum most, if not all, of the nineteenth-century analysis of piece-wise continuous functions can be carried out predicatively. On the other hand, as Weyl conceded, substantial and significant portions of modern analysis are not obtainable in his system including "the more far-reaching integration- and measure theories of Riemann, Darboux, Cantor, Jordan, Lebesgue and Carathéodory" (Weyl 1918/1994, p. 86).

In the years following the publication of *Das Kontinuum* Weyl abandoned his own approach in favor of Brouwer's intuitionistic framework. Soon thereafter, however, he returned to the standard mathematical fold and distanced himself from Brouwer's school and from foundations work more generally. In the ensuing years, Weyl's predicative theory lay largely dormant until the 1960s, when a number of authors including, most prominently, Feferman undertook a formalization and systematic analysis of Weyl's system as well as the development of a variety of predicative extensions thereof (compare Feferman 1964, 1988/1998, 1993/1998). Unlike Weyl, who worried about the purported *vicious circles* associated with impredicative definitions, Feferman was motivated in part by the concern that the unbridled use of such definitions presupposed a strong form of platonic realism regarding sets, a view he found philosophically objectionable; he was also interested in providing an analysis of predicativity itself, as well as with the purely logical question of the extent to which analysis can be carried out by predicative means. One of Feferman's extensions, called *W* in honor of Weyl, has been proven to be sufficiently strong to permit the reconstruction of almost all of classical analysis as well as important portions of modern analysis that are not obtainable in Weyl's original system. Feferman maintains that:

While there are clearly parts of theoretical analysis that cannot be carried out in *W* because they make essential use of the l.u.b. axiom applied to

sets rather than sequences, or because they make essential use of transfinite ordinals or cardinals, or because they deal with nonseparable spaces, *the working hypothesis that all of scientifically applicable analysis can be developed in W has been verified in its core parts*. What remains to be done is to examine results closer to the margin to see whether this hypothesis indeed holds in full generality. (1993/1998, p. 294)

## INFINITESIMALIST APPROACHES

Following Emil Artin (1898–1962) and Otto Schreier (1901–1929), an ordered field  $K$  may be said to be *real-closed* if it admits no extension to a more inclusive ordered field that results from supplementing  $K$  with solutions to polynomial equations with coefficients in  $K$  (1926/1965). Intuitively speaking, real-closed ordered fields are precisely those ordered fields having no holes that can be filled by algebraic means alone. Tarski demonstrated that real-closed ordered fields are precisely the ordered fields that are first-order indistinguishable from  $\mathbb{R}$  or, to put this another way, they are precisely the ordered fields that satisfy the elementary (i.e., first-order) content of the Dedekind continuity axiom (1939/1986, 1948/1986). For this reason they are called *elementary continua*. While  $\mathbb{R}$  is the best-known elementary continuum, it is hardly the only one.

Some elementary continua, like  $\mathbb{R}$ , are Archimedean, though most are non-Archimedean; and among the latter many are extensions of  $\mathbb{R}$ . In the early 1960s Robinson (1961, 1966) made the momentous discovery that among the real-closed extensions of the reals there are number systems that can provide the basis for a consistent and entirely satisfactory nonstandard approach to analysis based on infinitesimals. Robinson motivated his work with the following words:

It is our main purpose to show that these models [i.e. number systems] provide a natural approach to the age old problem of producing a calculus involving infinitesimal (infinitely small) and infinitely large quantities. As is well known, the use of infinitesimals, strongly advocated by Leibnitz and unhesitatingly accepted by Euler fell into disrepute after the advent of Cauchy's methods which put Mathematical Analysis on a firm foundation. Accepting Cauchy's standards of rigor, later figures in the domain of nonarchimedean quantities concerned themselves only with small fragments of the edifice of Mathematical Analysis. We men-

tion only du Bois-Reymond's Calculus of Infinites [1875] and Hahn's work on nonarchimedean fields [1907] which in turn were followed by the theories of Artin-Schreier [1926] and, returning to analysis, of Hewitt [1948] and Erdős, Gillman and Henriksen [1955]. Finally, a recent and rather successful effort at developing a calculus of infinitesimals is due to Schmieden and Laugwitz [1958] whose number system consists of infinite sequences of rational numbers. The drawback of this system is that it includes zero-divisors and that it is only partially ordered. In consequence, many classical results of the Differential and Integral calculus have to be modified to meet the changed circumstance. (1961/1979, p. 4)

Being elementary continua, Robinson's number systems do not have the just-cited drawbacks of the number system of Schmieden and Laugwitz. By analogy with Thoralf Skolem's (1934) *nonstandard model of arithmetic*, a number system from which Robinson drew inspiration, Robinson called his totally ordered number systems *nonstandard models of analysis*. These number systems, which are often called *hyperreal number systems* (Keisler 1976, 1994), may be characterized as follows: Let  $\langle \mathbb{R}, S: S \in \mathfrak{F} \rangle$  be a relational structure where  $\mathfrak{F}$  is the set of all finitary relations defined on  $\mathbb{R}$  (including all functions). Furthermore, let  ${}^*\mathbb{R}$  be a proper extension of  $\mathbb{R}$  and for each  $n$ -ary relation  $S \in \mathfrak{F}$  let  ${}^*S$  be an  $n$ -ary relation on  ${}^*\mathbb{R}$  that is an extension of  $S$ . The structure  $\langle {}^*\mathbb{R}, \mathbb{R}, {}^*S: S \in \mathfrak{F} \rangle$  is said to be a hyperreal number system if it satisfies the *Transfer Principle*: Every  $n$ -tuple of real numbers satisfies the same first-order formulas in  $\langle \mathbb{R}, S: S \in \mathfrak{F} \rangle$  as it satisfies in  $\langle {}^*\mathbb{R}, \mathbb{R}, {}^*S: S \in \mathfrak{F} \rangle$ .

The existence of hyperreal number systems is a consequence of the compactness theorem of first-order logic and there are a number of algebraic techniques that can be employed to construct such a system. One commonly used technique is the *ultrapower* construction (Keisler 1976, pp. 48–57; Goldblatt 1998, chapter 3), though not all hyperreal number systems can be obtained this way. By results of H. Jerome Keisler (1963; 1976, pp. 58–59), however, every hyperreal number system must be (isomorphic to) a *limit ultrapower*.

Using the transfer principle, one can develop satisfactory nonstandard conceptions and treatments of all of the basic concepts and theorems of the calculus including those from the theories of integration, differentiation, and continuity to name only a few (compare Keisler 1986, Goldblatt 1998, Loeb 2000). For example, it follows from

the transfer principle that a real-valued function  $f$  is continuous at  $a \in \mathbb{R}$  iff  ${}^*f(x)$  is infinitesimally close to  ${}^*f(a)$  whenever  $x$  is infinitesimally close to  $a$ , for all  $x \in {}^*\mathbb{R}$ . On the basis of this result one may prove various classical properties governing the continuity of real-valued functions including the intermediate and extreme value theorems (Goldblatt 1998, pp. 79–80). It should be emphasized, however, that Robinson's discoveries do not provide vindication of the Leibnizian formalism or of the seventeenth- and eighteenth-century preanalytic formalisms more generally. For example, whereas Leibniz conceived of differentiation and integration in terms of ratios of and infinite sums of infinitesimals, respectively, for Robinson they are real numbers that are infinitesimally close to such ratios and sums. On the other hand, nonstandard analysis not only demonstrates that the branch of mathematics erected for the study of continuously varying magnitude can be fully developed using infinitely large and infinitely small numbers as Leibniz and his followers had envisioned but it also provides one with an intuitively satisfying alternative to the standard picture of a continuum and of continuous phenomena more generally that is mathematically adequate and logically sound relative to classical mathematics.

Modern analysis, however, goes far beyond the traditional province of the calculus, dealing with arbitrary sets of reals, sets of sets of reals, sets of functions from sets of reals to sets of reals, and the like. Importantly, nonstandard analysis is entirely applicable to this expanded arena as well. However, the methods of superstructures (Robinson 1966) and internal set theory (Nelson 1977) that are most usually employed for this purpose are of little relevance here (compare Chang and Keisler 1990, §4.4; Robert 1988).

Unlike  $\mathbb{R}$ , the structures that may play the role of  ${}^*\mathbb{R}$  in a hyperreal number system are far from being unique up to isomorphism. From a purely mathematical point of view this causes no difficulty and from the standpoint of varying applications can even be advantageous (compare Keisler 1994, p. 229). On the other hand, if one takes  ${}^*\mathbb{R}$  to be a model of *the* continuous straight line of geometry—something practitioners of nonstandard analysis tend not to do—the absence of uniqueness is a bit disconcerting. Still, as several nonstandard analysts including Tom Lindstrøm (1988, p. 82) and Keisler (1994, p. 229) emphasize, even  $\mathbb{R}$  is not as unique as one would like to think since its uniqueness up to isomorphism is in fact relative to the underlying set theory. In particular, by retaining the construction of  $\mathbb{R}$  and supplementing the set theory with additional axioms, one can change the

second-order theory of the real line. This leads Keisler (1994) to suggest that not only is ZFC not the appropriate underlying set theory for the hyperreal number system but also that set theory might have developed differently had it been developed with the hyperreal numbers rather than the real numbers in mind. According to Keisler, an appropriate set theory “should have the power set operation to insure the unique existence of the real number system, and another operation which insures the unique existence of the pair consisting of the real and hyperreal number systems” (p. 230).

Consistent with the previous observation, one type of axiom that is used to secure categoricity is a saturation axiom (Keisler 1976, pp. 57–60). As the name suggests, saturation axioms ensure that the line is extremely rich. A hyperreal number system  $\langle {}^*\mathbb{R}, \mathbb{R}, *S: S \in \mathfrak{S} \rangle$  is said to be  $\kappa$ -saturated if any set of formulas with constants from  ${}^*\mathbb{R}$  of power less than  $\kappa$  is satisfiable whenever it is finitely satisfiable. If  $\kappa$  is the power of  ${}^*\mathbb{R}$ , the hyperreal number system is said to be saturated. Although there is a wide range of hyperreal number systems in ZFC that are saturated to varying degrees of power less than the power of  ${}^*\mathbb{R}$ , saturated hyperreal number systems do not exist in ZFC. In virtue of classical results from the theory of saturated models, however, there is (up to isomorphism) a unique saturated hyperreal number system of power  $\kappa$  whenever  $\kappa > 2^{\aleph_0}$  and either  $\kappa$  is (strongly) inaccessible or the generalized continuum hypothesis (GCH) holds at  $\kappa$  (i.e.,  $\kappa = \aleph_{\alpha+1} = 2^{\aleph_\alpha}$  for some  $\alpha$ ). So, for example, by supplementing ZFC with the assumption of the existence of an uncountable inaccessible cardinal, one can obtain uniqueness (up to isomorphism) by limiting attention to saturated hyperreal lines having the least such power (Keisler 1976, p. 60).

However, as Ehrlich (2002, 2004) emphasizes, perhaps the most remarkable of all elementary continua that may play the role of  ${}^*\mathbb{R}$  in a hyperreal number system (and bring categoricity to the hyperreal line to boot) is Conway’s ordered field of *surreal numbers* (1976/2001), a system that was not created with nonstandard analysis in mind. This would correspond (to within isomorphism) of adopting a hyperreal number system that is the union of an elementary chain of  $\omega_\alpha$ -saturated hyperreal number systems where  $\alpha$  ranges over the class *On* of all ordinals. Though such models do not exist in ZFC, they can be suitably characterized and shown to exist (up to isomorphism) in von Neumann–Bernays–Gödel (NBG) set theory with the axiom of global choice (Ehrlich 1989). Since NBG is a conservative extension of ZFC, its sets have the same properties as those of standard set theory (compare

Fraenkel, Bar-Hillel, and Levy 1973). The idea of employing such a hyperreal number system to establish the categoricity of the hyperreal line appears to be due (at least implicitly) to Keisler (1976, p. 59; 1994, p. 233; theorem 3 of addendum to Ehrlich 1989), but guided by reasons of simplicity and convenience he chooses the least uncountable inaccessible cardinal approach instead.

The ordered field of surreal numbers, which Conway calls *No*, is so remarkably inclusive that, subject to the proviso that numbers—construed here as members of ordered (number) fields—be individually definable in terms of sets of NBG, it may be said to contain “All Numbers Great and Small.” In this respect, *No* bears much the same relation to ordered fields as the system of real numbers bears to Archimedean ordered fields. Ehrlich (1987, 1989a, 1992, 2002) suggests that whereas the real number system may be regarded as an *arithmetic continuum modulo the Archimedean axiom*, the system of surreal numbers may be regarded as a sort of *absolute arithmetic continuum modulo NBG*. To lend credence to this thesis, Ehrlich provides a variety of categorical axiomatizations of  $\mathbb{R}$  making use of novel continuity axioms (that are equivalent to any of the familiar continuity axioms) with axioms for Archimedean ordered fields (or Archimedean real-closed ordered fields) and shows that by simply deleting the Archimedean axiom one obtains categorical axiomatizations of *No* (Ehrlich 1992, theorems 1, 4, and 6). Ehrlich also introduces a natural generalization of Dedekind’s conception of a gap, called a *set-gap*, and provides further evidence for the thesis by showing that whereas  $\mathbb{R}$  is (up to isomorphism) the unique elementary continuum having no set-gaps that satisfies the Archimedean condition, *No* is (up to isomorphism) the unique elementary continuum having no set-gaps that satisfies the *On*-Archimedean condition, the latter being a natural generalization of the Archimedean condition that is appropriate for *No* (Ehrlich 1992, Lemma 1, Theorem 7; 2001, pp. 1255–1256). Critical to the proof of the latter result is Ehrlich’s (1988, 1989, 2001) further characterization of *No* (up to isomorphism) as the unique elementary continuum such that for all subsets  $X$  and  $Y$  of the field where every member of  $X$  precedes every member of  $Y$  there is a member of the field lying strictly between those of  $X$  and those of  $Y$ . Intuitively, this characterizes *No* (up to isomorphism) as the unique ordered field having neither algebraic limitations nor order-theoretic limitations that are definable in terms of sets of standard set theory.

Besides its distinguished structure as an ordered field, *No* has a rich hierarchical structure that emerges from the recursive clauses in terms of which it is defined. This algebraico-tree-theoretic structure, or *simplicity hierarchy*, as Ehrlich (1994, 2001) calls it, depends on *No*'s structure as a lexicographically ordered binary tree and arises from the fact that the sums and products of any two members of the tree are the simplest possible elements of the tree consistent with *No*'s structure as an ordered group and an ordered field, respectively, it being understood that  $x$  is *simpler than*  $y$  just in case  $x$  is a predecessor of  $y$  in the tree. Among the remarkable consequences of this algebraico-tree-theoretic structure is that much as the surreal numbers emerge from the empty set of surreal numbers by a transfinite recursion that yields chains of increasingly less and less simpler numbers, the recursive process of defining *No*'s arithmetic in turn gives rise to chains of increasingly richer and richer numbers systems with the result that an isomorphic copy of every elementary continuum emerges in *No* as the union of a chain of elementary continua each of which is an initial subtree of *No* (Ehrlich 2001).

Conway (1976/2001) shows that besides the reals *No* contains a natural isomorphic copy of Cantor's ordinals, and hence, by virtue of the axiom of choice, the cardinals as well (Ehrlich 2001, pp. 1253–1256). Ehrlich (1988, 2001, 2002, 2004) notes that *No* also provides a natural setting for the non-Cantorian theories of the infinite (and infinitesimal) pioneered by Veronese, Levi-Civita, Hilbert, and Hahn in connection with their work on non-Archimedean-ordered algebraic and geometric systems and by du Bois-Reymond, Stolz, G. H. Hardy (1877–1947), and Felix Hausdorff (1868–1942) in connection with their work on the rate of growth of real functions (compare Ehrlich 1994, 1995, 2005; Fisher 1981). This, together with the observation about the relationship between *No* and hyperreal number systems, leads Ehrlich (2002, 2004) to observe that over and above providing a panorama of the entire set-theoretic spectrum of numbers great and small (modulo NBG), the purported absolute arithmetic continuum provides a unifying framework for many of the most important totally ordered systems of finite, infinite, and infinitesimal numbers that have played and continue to play prominent roles in mathematics since the days of Cantor and Dedekind.

Within a decade of the development of nonstandard analysis, Lawvere proposed a profound and novel approach to differential geometry based on infinitesimals. Unlike Robinson, who was stimulated by Leibniz's idea that the properties of infinitesimals should reflect

the properties of the reals, Lawvere's ideas more closely mirror the heuristic ideas of geometers who envisioned a vector tangent to a surface at a point as a tiny arc of a curve having the vector tangent to it. Building on Lawvere's ideas, Kock (1981) presents a systematic treatment of the theory under the rubric *synthetic differential geometry* (SDG).

Unlike the nonzero infinitesimals employed in non-standard analysis, the nonzero infinitesimal elements of SDG are *nilpotent*, that is, each such infinitesimal  $d$  satisfies the condition  $d^2 = 0$ . Nilpotent infinitesimals are not *invertible* (in the sense that they have no multiplicative inverses) and as such a line in SDG is not modeled by a field or a portion thereof. Rather, in SDG a line is modeled by a ring  $\mathfrak{R}$  containing a subset  $D = \{d \in \mathfrak{R} : d^2 = 0\}$  which satisfies the

Kock-Lawvere axiom: For every mapping  $f: D \rightarrow \mathfrak{R}$ , there is precisely one  $b \in \mathfrak{R}$ , such that for all  $d \in D$ ,  $f(d) = f(0) + d \cdot b$ .

Geometrically speaking, the Kock-Lawvere axiom asserts that the graph of every function  $f: D \rightarrow \mathfrak{R}$  is a piece of the unique straight line through  $(0, f(0))$  with slope  $b$ . It is a consequence of this assumption that in SDG a tangent vector to a curve  $C$  at a point  $p$  is a nondegenerate infinitesimal line segment around  $p$  coincident with  $C$ .

Another consequence of the Kock-Lawvere axiom is that in SDG, unlike in Euclidean geometry, there are pairs of points in the plane that are connected by more than one straight line. In this regard, SDG resembles Johannes Hjelmslev's (1873–1950) *natural geometry* (compare Kock 2003), a geometry that was designed to mirror real (as opposed to ideal) sense experience and that also employs nilpotent infinitesimals. However, unlike in natural geometry, in SDG there are pairs of points in a plane that are not connected by any line at all. This arises in part from the fact that whereas the nilpotent infinitesimals in natural geometry have "a quantitative (linear ordered) character," those employed in SDG do not (Kock 2003, pp. 226–228). For an axiomatization of "Euclidean Geometry with Infinitesimals" inspired by SDG, see Succi Cruciani (1989).

A space  $X$  in SDG is said to be *indecomposable* if no proper nonempty part  $U$  of  $X$  is *detachable* in the sense that there is a part  $V$  such that  $U \cup V = X$  where  $U \cap V = \emptyset$ . There are models of SDG in which a classical space  $\mathbb{R}^n$  has a counterpart  $X$  that is indecomposable if  $X$  is *connected*. John Bell takes this to imply that "the connected continua of SDG are *true* continua in something like the Anaxagoran sense" (1995, p. 56). In this respect, they are

also reminiscent of the unsplitable continuum of Brouwer; however, the similarity is not perfect and varies depending on the axioms adopted for SDG (Bell 2001).

Another respect in which SDG is similar to Brouwer's theory is the failure of the intermediate value theorem in its underlying theory of analysis. In fact, in SDG, unlike in Brouwer's system, the theorem even fails for some polynomials (Moerdijk and Reyes 1991, pp. 317–318), a failure that runs contrary to the thinking of Leibniz and Euler let alone Bolzano, Cauchy, and Weierstrass. Accordingly, while SDG may provide a viable alternative for differential geometry, its underlying analysis may not be as well suited to provide a natural alternative for classical analysis, at least not if it hopes to mirror the latter's most central ideas regarding continuity.

Unlike nonstandard analysis, which is developed in a set-theoretic setting, SDG is developed in a category-theoretic framework. Moreover, whereas the underlying logic employed in nonstandard analysis is classical logic, in SDG the underlying logic is intuitionistic logic. In SDG every function  $f: \mathfrak{X} \rightarrow \mathfrak{Y}$  is differentiable and, hence, infinitely differentiable (i.e. *smooth*) as well as continuous in the sense that it sends neighboring points to neighboring points. It is sometimes maintained (compare Bell 1995, p. 56) that it is the ubiquitous nature of continuity within SDG that forces the change from classical to intuitionistic logic. This, however, is apt to be misleading since it is possible to develop a theory of continua in which the continuity of functions from the continuum to the continuum is likewise ubiquitous though the underlying logic is classical (compare the so-called Cauchy continuum due to Schmieden and Laugwitz [1958; Laugwitz 2001, p. 134]). Rather, it is the Kock-Lawvere axiom that underlies the incompatibility of SDG with classical logic (compare Lavendhomme 1996, pp. 2–5). It is therefore interesting to note that Paolo Giordano (2001), by suitably modifying the axiom, presents a variation of SDG based on nilpotent infinitesimals in which the underlying logic is entirely classical, and he observes that the nilpotent infinitesimals could be supplemented with invertible infinitesimals as well. Earlier, Ieke Moerdijk and Gonzalo E. Reyes (1991), while retaining the underlying intuitionistic logic, also introduced an alternative approach in which invertible as well as nilpotent infinitesimals are employed. The work of Moerdijk, Reyes, and Giordano, much like the pioneering work of Lawvere and Kock, provides still other models of mathematical continua.

## CONCLUDING REMARKS

“Bridging the gap between the domains of discreteness and of continuity, or between arithmetic and geometry, is a central, presumably even *the* central, problem of the foundations of mathematics.” So write Fraenkel, Yehoshua Bar-Hillel, and Azriel Levy in their mathematico-philosophical classic *Foundations of Set Theory* (1973, p. 212). Cantor and Dedekind of course believed they had bridged the gap with the creation of their arithmetico-set theoretic continuum of real numbers, and it remains a well-entrenched tenet of standard mathematical philosophy that indeed they had. At the same time, Cantor was overly sanguine when in 1883 he seemed to suggest, or at least implied, that his theory of the continuum, unlike that of the ancients, had “been thought out ... with the clarity and completeness ... required to exclude the possibility of different opinions among [its] posterity” (Cantor 1883/1996, p. 903). Indeed, while Cantor and Dedekind had succeeded in replacing the vague ancient conception with a clear and complete arithmetico-set-theoretic conception, a conception that was adequate for the needs of analysis, differential geometry, and the empirical sciences, they did not, nor could not, free their theory of its logical, theoretical, and philosophical presuppositions, nor could they preclude the possibility that other adequate conceptual schemes, each self-consistent, could be devised offering alternative visions of the continuum.

However, it was critiques of the former that gave rise to some of its competitors and the realization of the logical possibility of the latter that gave rise to others. To some extent, the architects of each of its competitors were motivated by the belief, or at least the hope, that their respective theories are or with time would be adequate for the needs of analysis (or differential geometry), though in the cases of the constructivist and predicativist architects *analysis* was equated with *legitimate analysis* constructively and predicatively construed. Outside of the overarching question of the historical needs of analysis, the question of whether legitimate analysis thus understood is adequate for the needs of the empirical sciences and the physical sciences, in particular, is the subject of dispute (compare Fletcher 2002; Hellman 1993, 1993a, 1997, 1998; Bridges 1995; Billinge 2000; Bridges and Ishihara 2001; Feferman 1988/1998, postscript). Nonstandard analysis has bypassed all of these questions since from the standpoint of the standard domain it is as strong as or even stronger than standard analysis depending on what one assumes (Henson and Keisler 1986). Moreover, like their late nineteenth- and early twentieth-century non-Archimedean geometric forerunners, non-

standard analysis and the infinitesimalist approaches more generally have drawn attention to the possibility of physical continua whose logical cogency let alone physical possibility had long been in doubt. Whether empirical science will require such a theory, as some already contend (compare Fenstad 1987, 1988) and others, following Veronese (compare 1909/1994, p. 180), will not rule out, only time will tell. Nevertheless, while showing little sign of displacing the standard theory, the constructivist, predicativist, and infinitesimalist alternatives have performed, and continue to perform, important logical and philosophical service. Nonstandard analysis has also had real success in shedding important light on and establishing significant new results in various areas of analysis, theoretical physics, and economics (compare Albeverio, Luxemburg, and Wolff 1995; Arkeryd, Cutland, and Henson 1997; Loeb and Wolff 2000). However, whether nonstandard analysis or any of the other nonstandard theories canvassed earlier, together with its corresponding theory of the continuum, will eventually assume the status of the standard theory (or even stand alongside the standard theory as a co-standard theory) remains to be seen.

## CONTINUUM PROBLEM

See *Set Theory*

## CONTRACTUALISM

Contractualism, as a distinctive account of moral reasoning, was originally advanced by T. M. Scanlon in his widely admired paper "Contractualism and Utilitarianism" (1982) and was later elaborated on in detail in his book *What We Owe to Each Other* (1998). Drawing on an understanding of the significance of the social-contract metaphor that has its roots in Jean-Jacques Rousseau, rather than Thomas Hobbes, contractualism offers distinctive and interrelated answers to two central questions of philosophical theorizing about moral reasoning. First, what explains the importance of morality for people motivated to comply with the requirements of morality? Second, what kinds of reasons support judgments that particular acts or types of acts are right or wrong? Consequentialism provides what is undoubtedly the most familiar answer to this question. Contractualism seeks to provide a plausible alternative.

The contractualist account of why those who seek to comply with the requirements of morality care about being so guided presupposes a general approach to understanding the nature of value. The central idea of the presupposition is that to take something to be of value is to have reasons to regard it positively and reasons to act in certain ways with regard to it, some of which are required by the value of the thing in question. For instance, one's appreciation of the value of *The Last Supper* might take the form of planning trips to go and admire it, watching documentaries about it, reading scholarly works that deepen one's appreciation of it, worrying about its deterioration due to age, and debating the merits of various proposals to restore it with others who share one's passion.

Recognition of this value need not express itself in one's attitudes in these ways, though they are certainly rationally appropriate ways of responding to the value. But not all ways of engaging with something of value are optional. Some reasons for engaging with something of value in particular ways are reasons that all persons capable of making evaluative judgments are required to take account of in their practical deliberations. A person's indifference to *The Last Supper* does not alter the fact that he has reason not to ridicule or disparage it (even in his thoughts), not to urinate on it, not to attack it with a can of spray paint. These reasons, which are demanded by

respect for the value of the *The Last Supper*, apply to all individuals irrespective of their particular tastes and inclinations. Such reasons can be usefully characterized as *categorical reasons*.

Just as there are categorical reasons that flow from the value of the *The Last Supper*, so there are categorical reasons that flow from the value of human life. The distinctive value of human life, on the contractualist account, lies in the human capacity to assess reasons and justifications, to select among various reasons for wanting one's life to go a certain way, and thus to actively live and govern one's life (Scanlon 1998, p. 105). We have reason, then, to have certain attitudes toward, and give consideration to, the interests of others in our practical deliberations, namely, out of respect for the value of others as rationally self-governing beings. Failure to do so is a rational mistake, a failure to respond appropriately to all the relevant reasons for our behavior. This conclusion follows from the theory of value presupposed by contractualism and a specific characterization of the value of human life, neither of which are distinctively contractualist.

In answering why complying with morality matters to people who are morally motivated, contractualism holds that there are more than just rational reasons for respecting the value of another human being. Intuitively, there is a significant difference between failing to respect the value of a human and the kind of failure of respect exhibited by, for instance, proposing to film a rock video in the Sistine Chapel or building a McDonald's on the Great Wall of China. What accounts for the difference, according to contractualism, is the value of *mutual recognition*. Rational creatures living their lives in ways respectful of one another's value as rational creatures creates a special relation between them, a moral community of the kind that Immanuel Kant called the "Kingdom of Ends" and "a systematic union of various rational beings through common laws" (1902–, 4: 433). It is the kind of moral community that John Stuart Mill had in mind when he spoke of "unity with our fellow creatures." Respecting the value of others as persons, then, has a special importance for the morally motivated because they value the kind of relationship with others created by so living. This ideal of a moral community is at the heart of the contractualist characterization of moral reasoning.

Standards must guide individuals in their deliberations if they are to live on terms of respect for one another's value as persons. Contractualism characterizes these standards as principles for the general regulation of how individuals ought to deliberate in various situations.

It asserts that those who care about the justifiability of their conduct toward similarly motivated others cannot reasonably reject these standards as a basis for informed, unforced, general agreement. Thus, principles that the morally inclined cannot reasonably reject play an important interpersonal role in regulating how individuals should relate to one another. They do so by fixing the attitudes and treatment that individuals are entitled to legitimately demand, and have demanded, out of respect for each other's value as rational creatures. In other words, these principles fix legitimate expectations concerning how individuals should deliberate in various situations. On this account, one person *wrongs* another when he fails to regulate his deliberations as the other is legitimately entitled to expect.

Whether or not a principle cannot be reasonably rejected is assessed according to the implications (broadly construed) of licensing individuals to reason as required and permitted by the proposed principle. Contractualism is both more restrictive and more permissive than consequentialism concerning what counts as a relevant implication of a proposed principle. It is more restrictive in that it does not regard as relevant facts about the aggregate value of the outcome likely to result from general compliance with the principle. The only relevant considerations are those that have to do with the implications of a principle for the life of an *individual* with a particular point of view. Different relevant implications can emerge from consideration of a principle from different points of view. This restriction on relevant implications rules out appeals to the aggregate value of an outcome as relevant for assessing a principle. One outcome may be worse than another with respect to aggregate value without being worse from the point of view of each individual. Contractualism and consequentialism are thus diametrically opposed on the relevance of considerations having to do with the aggregate value of potential outcomes.

Contractualism is more permissive than consequentialism in counting, as relevant, considerations that have nothing to do with what is likely to happen as a consequence of individuals being licensed to treat one another in certain ways. Consider, for example, a principle that licenses a designated authority periodically to force randomly chosen individuals to serve as test subjects for dangerous medical experiments. In addition to the consequences for the lives of some unlucky individuals, contractualism will also allow as relevant consideration of the fact that such a principle would turn the bodies of individuals into a form of public property. That is, it would undermine the exclusive authority of individuals concerning decisions

about how their bodies are to be used, a prerogative that plays a fundamental role in an agent's understanding of his life as *his own*.

Assessing the validity of a principle requires both identifying the relevant considerations that ought to be taken into account in its assessment and combining them in a judgment about whether it is reasonable to reject the principle. Consequentialists claim that the right way to combine relevant implications of a principle is to aggregate their value. This sum is then compared to the aggregate value of the implications of possible alternatives. The valid principle is the one whose implications sum to the greatest aggregate value.

Contractualism adopts a different approach to this problem. Contractualism starts from the position that what the morally motivated person cares about is that his comportment toward another person be justifiable *to that person* as respectful of that person's value as a person. Justification *to another* requires that one's comportment toward the other be justified in light of what *that person cares about*. A principle is *justifiable to a person*, then, if he has reason to judge it to be justified (even if he himself does not recognize that reason) in light of the values that structure his particular point of view.

The central contractualist insight is that respect for the value of another as a person requires not merely that one take the implications of one's actions for that person's well-being into account, but that one be guided, in one's thinking about one's comportment toward that person, by a principle *justifiable to that person*. The impact of a possible principle on any person's well-being may be relevant to assessing the principle, but it will be so derivatively, as a consideration picked out as relevant by the master consideration of what is justifiable to that person. One's conduct may have negative implications for another, but if one has been guided by a principle justifiable to him, he has no grounds for complaint on the grounds that one has failed to give his interests the kind of consideration in one's deliberations that he is owed out of respect for his value as a person. If, in how one relates to another, one is guided by a principle that is justifiable to him, that principle can rightly be characterized as *authorized* by him.

Principles that no one can reasonably reject, then, enable individuals to relate to one another on terms of mutual respect for the value of one another as persons. They do so because a principle that no one can reasonably reject is justifiable to *any* individual from his point of view, provided at least that he values living with others on terms of mutual respect.

To arrive at a valid principle, we have to combine the implications of a proposed principle to arrive at an all-things-considered judgment about whether it is reasonable to reject the principle. At the heart of the contractualist approach to doing this is the requirement that a valid principle be justifiable to anyone from his own point of view. Assessing a proposed principle requires that one consider the point of view of the individual who stands to be most seriously burdened by it. Can such an individual reasonably reject the principle? On the contractualist account, that depends on the implications of a plausible alternative principle for those with other points of view. If every alternative principle to one that seriously burdens you will more seriously burden someone else, then you cannot reasonably reject the principle, as another individual's having to bear a burden that could be avoided by your bearing a lesser burden is justifiable *to you*. A valid principle is justifiable to the person who has the strongest reason for wanting to reject that principle.

This approach to how all the relevant implications of a principle are to be taken account of in an all-things-considered judgment of its validity stands in sharp contrast to that favored by consequentialist accounts. According to consequentialism, a principle that seriously burdens an individual can be justified by appeal to the aggregate value of the benefits secured under that principle for those with other points of view. Contractualism does not permit trade-offs of this kind among persons. A principle that seriously burdens you may secure benefits for others whose aggregate value outweighs the burden it places on you. But that fact has no bearing on whether the principle is justifiable *to you*, as it does not point to the viewpoint of another to whom any other principle, which does not so seriously burden you, would be justifiable. Under contractualism, our motivation for morality rules out aggregative considerations as relevant for the assessment of principles.

Consequentialism has a hard time making sense of commonsense prohibitions against treating others in certain abominable ways in circumstances where the consequences of doing so have great positive aggregate value. Nonconsequentialists argue that there is no problem in understanding the rationale for these prohibitions if one locates the basis for claims of wrongdoing in the very character of the prohibited way of treating others. One way of trying to articulate more clearly what the nonconsequentialist has in mind is the Kantian injunction to treat others, never as mere means, but always as ends in themselves. Contractualism, in locating the basis of a per-

son's claim to have been wronged in his having been treated in a way not justifiable *to him*, powerfully illuminates the compelling insight to which Kant's injunction draws our attention.

## CONVENTIONALISM

In the physical sciences, some very basic facts or principles appear to have a status that is difficult to categorize: not simply empirically discovered; not purely analytic (true by virtue of already established meanings); fundamental, but without quite being ordinary physical laws. Incompatible-looking alternative principles are conceivable; sometimes we can even see how an alternative physical framework could be built on them. Such principles are held, by some philosophers, to be true by *convention*. They are parts of our physical theories that had to be conventionally chosen by us over other incompatible postulates, whether or not we were overtly aware of this element of choice.

The most famous examples of putative conventional truths are to be found in our theories of space and time, and will be discussed below. But some are not directly related to space and/or time: in classical physics, Isaac Newton's famous 2nd law,  $F = ma$ , is an example. This law at first sight looks like it cannot be a convention, for surely, as the center of his mechanics, the 2nd law is far from true by stipulation. But in the Newtonian paradigm, the 2nd law served as ultimate arbiter of the questions (a) whether an external force is, in fact, acting on a given object; and (b) if so, what its magnitude was. While not necessarily immune to rejection or revision in the long run, this principle was nevertheless a postulate that

helped constitute the meaning of other terms such as "force," and functioned as something *akin to* a definition, with a warrant *akin to* a priority.

Conventionalism of the Duhem-Quine sort holds that one can *always* maintain the truth of the 2nd law (or any other conventional truth), come what may. The backing for this claim comes from the *holism* of scientific theory testing (Pierre Duhem) or more generally, of conceptual frameworks (W. V. O. Quine): Since the things we hold true form an interconnected web, any one belief or postulate that faces apparent disconfirmation may be preserved as "true," as long as we are willing to make enough compensatory adjustments among other beliefs. (For example, the 2nd law may be held true in the face of motions that appear not to conform to it, as long as we are willing to postulate the existence of hitherto-undiscovered forces acting on the relevant bodies.)

However, one can usually imagine circumstances in which unbearable tensions arise in our conceptual frameworks from the insistence on retention of the putative conventional principle, and one is effectively forced to give it up. If this is right, then the original claim of conventionality—that the principle in question is a mere stipulation or definition—looks like something of an exaggeration. Are there in fact *any* choices in the creation of adequate physical theory that are genuinely free, conventional choices (as, for example, choice of units is), without being completely trivial (as, again, choice of units is)? Many philosophers have thought that space-time structures give us true examples of such conventionality. The debates over conventionalism form a significant fraction of twentieth-century philosophy of space and time, and work continues in a wave of recent books and papers (Friedman 1999, Ryckman 2004). We cannot hope to do justice to the depth and complexity of the arguments of the major thinkers here, but will limit ourselves to introducing the main themes and key arguments, directing the reader to further resources in the bibliography.

### CONVENTIONALISM ABOUT SPACE

Before the eighteenth century all philosophers of nature assumed the Euclidean structure of space; it was thought that Euclid's axioms were true a priori. The work of Nikolai Lobachevsky, Bernhard Riemann, and Carl Friedrich Gauss destroyed this belief; they demonstrated, first, that consistent non-Euclidean constant-curvature geometries were possible, and later that even variably curved space was consistent and analytically describable. But what, exactly, does it mean to say that space is Euclidean or Riemannian? A naïve-realist interpretation can of course be

given: there exists a *thing*, space, it has an intrinsic structure, and that structure conforms to Euclid's (or Riemann's) axioms. But space, so described, is not observable in itself; only the material phenomena governed by physical laws are. When philosophers gave attention to this fact, they realized that our physical theories always contain assumptions or postulates that *coordinate* physical phenomena with spatial and temporal structures. Light rays in empty space travel in straight lines, for example; rigid bodies moved through space without stresses do not change their length; and so on. So-called *axioms of coordination* are needed to give meaning and testability to claims about the geometry of space.

The need for axioms of coordination seems to make space for conventionalism. For suppose that, under our old axioms of coordination, evidence starts to accumulate that points toward a non-Euclidean space (triangles made by light rays having angles summing to less than 180 degrees, for example). We could change our view of the geometry of space; but equally well, say conventionalists, we could change the axioms of coordination. By eliminating the postulate that light rays in empty space travel in straight lines (perhaps positing some “universal force” that affects such rays), we could continue to hold that the structure of space itself is Euclidean. According to the strongest sorts of conventionalism, this preservation of a conventionally chosen geometry can always be done, come what may. Henri Poincaré (1902/1952) defended the conventionality of Euclidean geometry; but he also conjectured that it would always be *simpler* to construct mechanics on assumption of Euclidean geometry. (Poincaré argued, on the basis of the work of Hermann von Helmholtz and Sophus Lie on free-mobility mechanics, that the possible geometries among which we must make a conventional choice are just three: Euclidean, Riemannian, and Lobachevskian. He thus did not consider the possibility of the variably curved space-time introduced by Albert Einstein in 1912).

Poincaré did not defend a wide-ranging, Duhem-Quine style of conventionalism; rather his view might better be thought of as neo-Kantian (as was also true of Hans Reichenbach in his first book on space and time [1920]). The Euclidean status of space is a convention that plays the role of a constitutive, a priori axiom with respect to mechanics and the rest of physics. By contrast, although he held it to be synthetic, arithmetic was *not* conventional for Poincaré: we have no choice but to regard it as true. But when it comes to the choice between Euclidean and (say) Lobachevsky geometry for real space, Poincaré's defense of the tenability of the Euclidean con-

vention becomes basically an instance of the Duhem-Quine thesis: by making compensatory adjustments in our physics (specifically, introducing “universal forces” of the right sort), we can continue to hold that space is Euclidean even if direct measurements with rods and light-rays do not conform to that geometry. We will explore this idea further via Reichenbach, its most vigorous proponent in the twentieth century.

Reichenbach introduces the basic argument for conventionalism with an example that has become a classic:

G represents a planar surface on which some 2-D beings live; we suppose that the surface is “really” flat almost everywhere, except for a non-flat hump centered around the point A. The people on the plane can “know” that they have this hump in their space because of the way triangles’ angles measure inside the hump. Using their measuring rods, they regard the segments A'B' and B'C' as equal in length.

Now we suppose that G is actually made of glass, and light shining from above casts shadows of everything on G onto the plane E below. People on E have their own measuring rods and so on. Let's suppose that, as it happens, the measuring rods on E behave exactly like the shadows of the E-rods: declaring AB congruent to BC, for example. Reichenbach has us suppose that there is a heating source under E that causes measuring rods to expand as they approach A, with no heat beyond the limits of the shadow of the hump. If the beings on E knew nothing of heat and how it expands measuring rods, what will they conclude? Like the G-people, they will conclude that their space has a non-Euclidean hump in it, centered on A.

The example brings to light the apparent impossibility—at least under the described circumstances—of determining whether one “really” lives in a curved space, or a flat Euclidean space with certain “universal” forces affecting things like measuring rods, light rays, and so on. (Reichenbach's “universal” forces affect every object in exactly the same way, and cannot be shielded out; they are clearly modeled on the force of gravity, for reasons we

will see below.) Now Reichenbach makes the key move in arguing for his conventionalism about physical geometry, and it is based on his verificationist empiricism: given that there is no way in principle to determine which of these is the case, we should reject the question itself as a mistake based on false presuppositions. There is no fact of the matter, in the case discussed, about whether  $G$  is “really” flat or rather “really” has a hump. A conventional choice must be made concerning whether to keep the geometry flat or not; after that, one can determine the presence (or absence) of universal forces as required.

We should note the irony here: in order to introduce his conventionalism, Reichenbach had to present us with hypothetical cases in which there *is* a nonconventional fact of the matter about the intrinsic geometry of space, then argue that we should disbelieve in these facts after all. Realists about space (or space-time) respond to Reichenbach precisely on this point: The fact that we cannot determine the geometry of space beyond any possibility of doubt, due to the logical possibility of other physical theories postulating a different geometry, does not entail that there *is no* fact of the matter—unless, of course, one subscribes to the most far-reaching of verificationist views of meaning and truth.

But Reichenbach is not quite so easily dismissed. The “intrinsic” geometries of  $G$  and  $E$  were introduced as a crutch for the imagination, to get us ready to see how the combination of a geometry  $G$  and a set of physical postulates about forces,  $F$ , are only testable (hence meaningful) together. Once the point is understood, we realize that our “intrinsic” geometries by themselves had no significance. The combination of  $G$  and  $F$  together, by contrast, is both meaningful and testable: the  $E$ -residents can certainly tell that their world is such that *if held to have a Euclidean space, then there are universal forces acting in the  $A$ -region; or if held to have no universal forces, then space is non-Euclidean in the region around  $A$* . Which they decide to adopt is up to them, and the decision is a conventional one (perhaps based on simplicity or convenience).

**ANTI-CONVENTIONALIST RESPONSES.** Roberto Torretti (1983) and others have criticized Reichenbach’s notion of a universal force, arguing that (a) gravity does not meet the criteria established by Reichenbach; and (b) physicists would never take such a stipulated, truly-unverifiable concept seriously. Recalling the analogy used by Reichenbach (and Poincaré before him) of the deformation of a measuring rod by heat, notice that real material objects respond differently to temperature changes: steel expands while a ceramic contracts when heated, for

example. The differential response of some materials to the physical “force” of heat is crucial to its playing a significant role in physics. Gravity, too, is a force that affects different objects differently: a meter-stick made of steel with ball-shaped ends will change its length little, if at all, when held vertical in a gravity field like the Earth’s; but a meter-stick made of foam rubber with steel ball-shaped ends will change significantly in the same gravity field. The force of gravity is indeed universal in the sense of (1) affecting all massive bodies equally *per unit of mass*, and in (2) being un-shieldable. But the universal forces Reichenbach discusses would appear to be rather different, affecting all bodies equally on a *per unit volume* basis, so as to change their sizes by exactly the same amount, regardless of internal constitution. Torretti argues that there are no forces in real physics that act in such a way.

Interestingly, though it was not known to Reichenbach, there are illustrations of potentially conventional elements that may be discerned in classical Newtonian gravitation theory, though not involving Reichenbachian universal forces. The arguably conventional choices are in fact two-fold (see Friedman 1983). First, one may add an arbitrary (constant) universal acceleration to every body in space: This acceleration changes no observable phenomena, and in fact is implemented simply by adding a term to the gravitational potential  $\Phi$ . This extra term in the potential generates a universal gravitational force that accelerates every object at the same rate—seemingly a real-science example of Reichenbach’s universal forces, but in fact different: The force does not deform any body’s shape or behavior relative to other bodies, hence does not change the Euclidean geometry of space. Physicists customarily chose  $\Phi$  so as to make such overall-acceleration equal to zero.

Secondly, mathematicians in the early twentieth century discovered how to transform Isaac Newton’s gravity theory into a curved-space-time theory analogous to Einstein’s General Theory of Relativity (GTR, about which more below): in this formulation, there are no gravity forces and instead the local geometry of space-time is curved, non-Euclidean. (Note however that this is only true of space-time, not space on its own—that remains flat, i.e., Euclidean.) Still, the example illustrates the conventionalist point: we might have had to choose whether to consider space-time flat/Euclidean, and let gravity be a universal force explaining why things do not always move on straight-line paths (geodesics); or instead, eliminate the “force” of gravity, allow that our space-time is curved, and hold that all bodies follow geodesics of the curved geometry of space-time. If we imagine that physics had

really turned out to show our world perfectly Newtonian, it is easy to see that we might find the conventionalist viewpoint attractive, compared to a realism that denies us the possibility of knowing what sort of space-time we live in, whether we are moving uniformly or instead with a frightful acceleration, and so forth.

*Conventionalism and GTR.* Discussions of conventionalism took a dramatic turn because of the work of Einstein. With its variably curved space-time, GTR obviously posed new challenges and opportunities for both sides on the conventionality of geometry. In the first half of the twentieth century GTR was widely viewed as vindicating a significant conventionalism or neo-Kantian “constitutive a priori” element in physics. In addition to Reichenbach, Ernst Cassirer, Moritz Schlick, and Adolf Grünbaum are some notable figures of twentieth-century philosophy who argued for the conventionality of space-time’s geometry in the context of GTR (see Ryckman [2004] for an extensive and nuanced discussion of this early interpretive wave). Recent scholars have tended to be skeptical that any nontrivial conventionalist thesis is tenable in GTR; Friedman, Torretti and Hilary Putnam are prominent examples here.

Grünbaum, a student of Reichenbach’s, recast the arguments for conventionalism in a non-epistemological form, more suited to the post-positivist climate of the 1960s and 1970s. He also brought forth a novel argument for the conventionality of geometry, based on the intrinsic *metrical amorphousness* of a continuous space. If space were composed of discrete atoms or chunks, it would thereby have a built-in metric. The distance between the ends of a meter stick would be determined by the number of space-atoms traversed by the line of its center, for example. But if, as most physical theories postulate, space(-time) is a continuum, then it cannot have any such built-in metric. (Grünbaum seems to be thinking of space as, intrinsically, just a topological manifold.) The metrical properties must be imposed extrinsically, by phenomena and bodies existing in the space (or space-time). And again, we must adopt conventions about which processes, bodies etc. are taken as constitutive for the geometry of space. See Grünbaum (1973) and Friedman (1983) for extensive discussion.

Einstein’s GTR gave impetus to conventionalism in several ways; here we will mention just one. Consider Einstein’s Equivalence Principle (EP), which says that a body that is uniformly accelerating (e.g., a rocketship) may consider itself as “at rest,” but in the presence of a gravitational field that pulls everything downward. Conversely, according to the EP, a body freely “falling” under

a gravitational force may equally well consider itself as “at rest” in a space without any gravitational forces. (The EP was, we see, implicit in our discussion of the two conventional elements in Newtonian gravity theory above.) A strong reading of this principle leads to the view that the existence or non-existence of a gravitational field is not a fact “out there” in the world, but rather something which we must arbitrarily decide. However, since gravitational fields (i.e., regions of local curvature of space-time) caused by bodies like planets and stars *can* be empirically distinguished from gravity-free regions—the EP is only true “locally,” and to first approximation in small regions—the apparent freedom to choose turns out to be illusory.

*Conventionality of Simultaneity.* But it was in 1905, rather than 1915, that Einstein gave the greatest boost to conventionalism. In the astounding first few pages of “On the Electrodynamics of Moving Bodies,” the paper that introduced the Special Theory of Relativity (STR) Einstein overthrew the Newtonian view of space-time structure—and, in passing, noted that *part* of the structure with which he intended to replace it had to be chosen by convention. That part was *simultaneity*. Einstein investigated the operational significance of a claim that two events at different locations happen simultaneously, and realized that it must be defined in terms of some clock synchronization procedure. The obvious choice for such a procedure was to use light-signals: Send a signal from event A for observer 1, have it be received and reflected back by observer 2 (at rest relative to 1), event B, and then received by 1 again at event C. The event B is then simultaneous with an event E, temporally midway between A and C.

Or is it? To suppose that it is, is to assume that the velocity of light on the trip from A to B is the same as its velocity from B to C (or, more generally, that light has the same velocity in a given frame, in all directions). This seems like a very good thing to assume. But can it be verified? Einstein thought not. All ways of directly measuring the one-way velocity of light seemed to require *first* having synchronized clocks at separated locations. But if this is right, we are going in circles: we need to know light’s one-way velocity to properly synchronize distant clocks, but to know that velocity we need antecedently synchronized clocks.

To break the circle, Einstein thought we needed to make a conventional choice: We *stipulate* that event E is simultaneous with B (i.e., that light’s velocity is uniform and direction-independent). Other choices are clearly possible, at least for the purposes of developing the

dynamics and kinematics of STR. Following Reichenbach, these are synchronizations with  $\epsilon \neq \frac{1}{2}$  ( $\epsilon$  being the proportion of the round-trip time taken on the outbound leg only, freely specifiable between 0 and 1 exclusive). Adopting one of these  $\epsilon \neq \frac{1}{2}$  choices is equivalent to stipulating that the velocity of light is different in different spatial directions, without offering any physical reason for the difference, which some philosophers and physicists would find objectionable. It is also a recipe for calculational misery of a very pointless kind. But the Einstein of 1905, and many philosophers since then, thought that such a choice cannot be criticized as objectively *wrong*. Ultimately, they say, distant simultaneity is not only frame-relative, but partly conventional. It is important to see how different the situation is from Newtonian physics, in which there is no upper limit to the velocity of causal signals. In Newtonian physics, as long as we prohibit objects from moving “backward” in time, the existence of arbitrarily high velocities means that, given a specific event *here*, only one instant of time *there* can be chosen as simultaneous; that is, there is no scope for conventionality of simultaneity at all.

Many philosophers have been skeptical of the conventionality of simultaneity in STR. In 1967 Brian Ellis and Peter Bowman argued that slow clock transport offers a means of synchronizing distant clocks that is independent of the velocity of light. Their idea was this: in STR, of course, when a clock is accelerated from rest in a given frame up to some constant velocity, then decelerated to rest again at a distant location, there are the notorious time-dilation effects that prevent us from regarding the clock as having remained in synch with clocks at its starting point (the accelerated clock will have fallen behind the rest-clock—though this can, again, only be *directly* verified if it is brought back to its starting place for comparison with the rest clock). And calculation of the size of the effect depends on having established a distant-simultaneity convention (i.e., a choice of  $\epsilon$ ). So it looks as though carrying a clock from observer 1 to observer 2 will not let us break the circle.

But Ellis and Bowman noted that the time dilation effect tends to zero as clock velocity goes to zero, and this is independent of  $\epsilon$ -synchronization. Therefore, an “infinitely slowly” transported clock allows us to establish distant synchrony, and measure light’s one-way velocity. Infinitely slow transport is not, of course, a practical method for synchronizing clocks. The point is rather this: Since we can prove mathematically that the time dilation effect goes to zero as velocity of transport approaches zero, we can establish the *conceptual* point that the one-

way velocity of light is non-conventional. Conventionalists were not persuaded, and the outcome of the fierce debate provoked by Ellis and Bowman’s paper was not clear (Norton 1986).

In 1977 David Malament took up the conventionalist challenge from a different perspective. One way of interpreting the claim of conventionalists such as Grünbaum is this: The observable *causal structure* of events in an STR-world does not suffice to determine a unique frame-dependent simultaneity choice. By “causal structure” we mean the network of causal connections between events; loosely speaking, any two events are causally connectable if they *could* be connected by a material process or light-signal. In STR, the “conformal structure” or light-cone structure at all points is the idealization of this causal structure. It determines, from a given event, what events could be causally connected to it (toward the past or toward the future). Grünbaum and others believed that the causal structure of space-time by no means singles out any preferred way of cutting up space-time into “simultaneity slices.”

Malament showed that, in an important sense, they were wrong. The causal/conformal structure of Minkowski space-time *does* pick out a unique frame-relative foliation of events into simultaneity slices. Or rather, more precisely, the conformal structure suffices to determine a unique relation of *orthogonality*. If we think of an  $\epsilon$ -choice as the choice of how to make simultaneity slices relative to an observer in a given frame, then Malament showed that the conformal structure is sufficient to define a unique, orthogonal foliation, which corresponds to Einstein’s  $\epsilon = \frac{1}{2}$  choice. But most conventionalists do not view Malament’s result as a refutation of their view (Janis 1983), in part because Malament’s proof starts from assumptions that are arguably already in violation of the spirit of the conventionalist’s view.

In recent years philosophers have begun to consider whether quantum theories may shed light on the debates concerning simultaneity; see Gunn and Vetharanim (1995) and Karakostas (1997) for arguments for and against the idea that quantum field theory refutes the conventionalist claim. Bain (2000) shows that while it is true that one can formulate quantum field physics in coordinate systems corresponding to  $\epsilon \neq \frac{1}{2}$  simultaneity, by choosing the *generally* covariant formulation of the theory (i.e., a formulation that is valid, roughly speaking, in any coordinate system whatsoever), doing so requires the introduction of a new mathematical object or “field,” whose role is basically to represent the standard orthogonal simultaneity slices. That is, while one can nominally

“choose” a simultaneity standard different from  $\epsilon \neq \frac{1}{2}$ , the compensatory adjustments one is forced to introduce in order to make the theory work are such that one can see the “true” temporal structure lurking just under the surface. Conventionalists and anti-conventionalists disagree, of course, over whether the scare-quotes may be removed from the “true” in this verdict.

## CONVERSATIONAL IMPLICATURE

The concept of conversational implicature is due to the work of Paul Grice, and in particular to his paper “Logic and Conversation,” which was delivered in 1967 and instantly became highly influential, although it was not published until 1975. A key goal of this paper was to defend the traditional logical understanding of connectives like *and* against what he saw as the excesses of ordinary language philosophy. He did this by drawing a sharp distinction between what is strictly speaking *said* and what is *conversationally implicated*. Consider sentence (1), below.

(1) Amanda and Beau fell in love and got married.

An utterance of (1) will typically suggest that the falling in love preceded the marriage. However, if *and* has its bare logical meaning, (1) may be true even if the marriage was initially loveless. According to Grice, (1) might indeed be true under these circumstances—because, strictly speaking, *and* contributes no more than its logical meaning to what is said. Grice claimed that the extra suggestion of temporal order was a conversational implicature. Conversational implicatures are an important part of communication, but (according to Grice) they have no effect on truth value. This is because they are not a part of what is strictly speaking said.

Grice argued that conversational implicatures arise from our adherence to (and presumption that others will adhere to) what he called the Cooperative Principle: “[m]ake your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged” (1989b, p. 26). (He took this principle to govern conversation, but he also took it that the principle would have correlates in other cooperative endeavors.) In its broadest outline Grice’s idea was that we presume that others are being cooperative—and we will generally make whatever supplementary assumptions are required to maintain this presumption. This presumption is what

allows for the communication of conversational implicatures.

Grice takes it that we generally follow the Cooperative Principle by following four more specific maxims of cooperation (which, like the Cooperative Principle itself, he takes to have correlates in other endeavors):

Quantity: Make your contribution as informative as (neither more nor less informative than) is required (1989b, p. 26).

Quality: “Try to make your contribution one that is true”: “do not say what you believe to be false” and “do not say that for which you lack adequate evidence” (1989b, p. 27).

Relation: “Be relevant” (1989b, p. 27).

Manner: “Be perspicuous”: “1. Avoid obscurity of expression; 2. Avoid ambiguity; 3. Be brief (avoid unnecessary prolixity); 4. Be orderly” (1989b, p. 27).

Any of these maxims may play a role in generating conversational implicatures.

Grice characterizes conversational implicature as follows, and most scholars have followed him in this characterization.

A man who, by (in, when) saying (or making as if to say) that *p* has implicated that *q* may be said to have conversationally implicated that *q*, provided that:

(1) he is to be presumed to be following the conversational maxims, or at least the Cooperative Principle;

(2) the supposition that he is aware that, or thinks that, *q* is required to make his saying or making as if to say *p* (or doing so in *those* terms) consistent with this presumption; and

(3) the speaker thinks (and would expect the hearer to think that the speaker thinks) that it is within the competence of the hearer to work out, or grasp intuitively, that the supposition mentioned in (2) is required.

(GRICE 1989, PP. 30–31)

To see how all of this machinery works in the generation of a conversational implicature, one must return to an utterance of (1).

(1) Amanda and Beau fell in love and got married.

Typically, the audience will assume that the speaker is being cooperative (so condition 1 is met). A cooperative speaker will follow the maxim of Manner, and the maxim

of Manner dictates orderly presentation. If one is being orderly, one will generally present events in the order in which they occurred, so the audience must assume that the speaker thinks that Amanda and Beau’s love predated their marriage. (Condition 2 is met). The speaker surely realizes that the audience is capable of working this out, so condition 3 is met. A typical utterance of (1), then, will implicate something like (1\*).

(1\*) Amanda and Beau fell in love and *then* got married.

There are a variety of ways that conversational implicatures may be generated. The above mechanism does not rely on the speaker’s utterance being one whose explicit content would be uncooperative, but this latter sort of implicature (created by violating or flouting a maxim) is also an important one. It is crucial, for example, to irony, hyperbole, and understatement.

## KINDS OF CONVERSATIONAL IMPLICATURE

Grice distinguished two main kinds of conversational implicature, *generalized* and *particularized*. Generalized conversational implicatures are ones that are *usually* carried by a certain word or phrase, while particularized conversational implicatures depend far more heavily on context. (Grice also allowed for nonconversational implicatures, such as *conventional* implicatures, with no role whatsoever for context. These are not of concern here.) The example discussed so far, involving (1), is that of a generalized conversational implicature: utterances of sentences involving *and* will usually carry the suggestion of temporal order that it is present in this example. Particularized implicatures depend far more heavily on context. Suppose you are hiring for a philosophy job, you ask me what I think of my student Charla, and I reply with nothing but (2).

(2) Charla reads a lot.

(2) is clearly not adequately informative, given your question—philosophy jobs require a great deal more than reading. By violating the maxim of Quantity in this way, I conversationally implicate that Charla is not a good philosopher. But in a different context, there would be no such implicature (consider, for example, a context in which I was asked for names of people who might like to join a book group). Because the implicature depends so heavily on context, it is particularized rather than generalized.

A great deal of work has been done, especially in linguistics, on generalized conversational implicatures, and

various mechanisms for their generation. Some of the most important work on this topic is by Laurence Horn (1972) and Stephen Levinson (2000). Generalized conversational implicatures have also played a particularly important role in philosophy. For Grice, these implicatures were especially important for their role in explaining certain problematic intuitions—like the intuition that (1) is false if the marriage preceded the love. He argued that generalized conversational implicatures are especially difficult to distinguish from what is strictly speaking said and that they may therefore give rise to mistaken intuitions. Philosophers since Grice have followed up on this thought by using generalized conversational implicatures in explanations of recalcitrant intuitions in a wide variety of areas.

It is worth noting that many cases that Grice took to be ones of generalized conversational implicature are very much disputed. For example, Robyn Carston (1991) has argued for a notion of saying (or, in her preferred terminology, *explicating*) on which the meaning of *and* is just what Grice would have taken it to be, yet nonetheless an utterance of a sentence like (1) *says* (rather than implicates) that Amanda and Beau's love preceded their marriage.

(1) Amanda and Beau fell in love and got married.

Carston's work on such examples is a part of a broader debate on the notion of what is said, which is not addressed here. But for some other approaches that also result in examples like the above counting as said, see Jeffrey King and Jason Stanley (2005), François Recanati (1989), and Dan Sperber and Dierdre Wilson (1986). For objections to reconstruing such generalized conversational implicatures as a part of what is said, see Kent Bach (2001), Laurence Horn (1992), Stephen Levinson (2000), Michael O'Rourke (2003), and Jennifer Saul (2002b).

## TESTING FOR IMPLICATURE

Grice does not offer necessary and sufficient conditions that would allow one to test conclusively whether a given claim is a conversational implicature. However, he does offer certain necessary conditions for conversational implicature that can provide partial tests, and these have been widely accepted. Two especially important ones are cancelability and calculability. For more on testing for conversational implicatures, see Jerrold Sadock (1978).

**CANCELABILITY.** Because all conversational implicatures depend at least to some extent on context, it is always possible to cancel a conversational implicature by indicating either explicitly or implicitly that the implica-

tures should not be taken as present. For example, one might utter (1C):

(1C) Amanda and Beau fell in love and got married, but not in that order. Because (1C) contains an explicit cancellation of the conversational implicature standardly carried by (1), that implicature will not be carried by an utterance of (1C).

This contrasts with the case of saying. An attempt to “cancel” something that is said results only in a contradiction. To see this, consider an utterance of (1C\*):

(1C\*) Amanda and Beau fell in love and got married, but they didn't get married.

Applying this test shows us that the claim that Amanda and Beau got married is definitely not a conversational implicature, while the claim that their love preceded their marriage may well be.

While failure of the cancelability test does indeed indicate that one is not dealing with a conversational implicature, passing the cancelability test cannot be taken to decisively establish that one is dealing with a conversational implicature. There are at least two reasons for this. First, a case of disambiguation may resemble one of cancellation, as in (3):

(3) He is in the grip of a vice, but not the mechanical kind.

Second, speaking loosely may result in an appearance of cancellation. Grice's own example (1989a, p. 44) concerns the fact that one may acceptably say, “Macbeth saw Banquo, even though Banquo was not there to be seen,” even if it is known by all that Banquo merely hallucinated. Because one might be using the verb “see” in a loose way, this apparent cancellation does not indicate that utterances involving “see” merely implicate that what is seen exists.

**CALCULABILITY.** According to Grice, a putative conversational implicature is not a conversational implicature unless it is possible for audience to work out that the presence of the implicature is required in order to understand the speaker as cooperative. This calculation is meant to draw on knowledge of the linguistic meaning of the sentence uttered, the maxims of conversation, relevant background information, and the specific context. If no explanation can be given of how an audience would perform a calculation like this, a hypothesis that a particular conversational implicature is present must be rejected.

This necessary condition is also widely accepted. But its exact interpretation is a matter of some controversy. In

particular, there is disagreement over what it requires psychologically on the part of the hearer: must the hearer actually have distinct conscious representations of what is said and what is conversationally implicated (as argued by François Recanati in his work (1989)? Or are the requirements much more minimal (as argued by Kent Bach (2001), Manuel Garcia-Carpintero (2001), and Kenneth Taylor (2001)? The calculability requirement has proved very important: it has been used, for example, to argue for a more expansive conception of what is said (as in Recanati's work, as well as Robyn Carston's [1991]); to argue for and to object to particular invocations of conversational implicature; and (as in Wayne Davis's [1998]) to raise quite general concerns about the viability of Grice's theory of implicature.

**GRICE'S TAXONOMY.** It is very common to maintain that speaker meaning must divide exhaustively into what is said and what is implicated. Thus, any claim that the speaker means but does not say must be an implicature. (It need not, however, be a conversational implicature, since it could be a conventional implicature.) It is not entirely clear, however, that this is the right way to understand relationship between speaker meaning and implicature. For objections to this view of the relationship, see Kent Bach (1994) and Jennifer Saul (2002b).

## CONWAY, ANNE

(1631–1679)

Anne Conway (Anne Finch, Viscountess Conway), the English philosopher, was born in London. Her education was primarily informal and self-directed. Her associates included Henry More, Ralph Cudworth, Francis Mercury Van Helmont, William Harvey, and Robert Boyle, the latter two as physicians for her serious headaches. Later in life she scandalized More by becoming a Quaker.

### WORK AND INFLUENCE

Conway's sole published work, *The Principles of the Most Ancient and Modern Philosophy*, published posthumously in 1690, shows the influence of the Cambridge Platonists, Kabbalism, and Neoplatonism. It criticized Thomas Hobbes, Benedict de Spinoza, and René Descartes, and influenced Gottfried Wilhelm Leibniz, who, during the year he was introduced to her work by Van Helmont in 1696, adopted her term *monad* and used it in a quite similar way (Merchant 1979). A notable difference between their uses of the term is that, while Leibniz's monads are purely spiritual, Conway's are both physical and spiritual.

Leibniz refers directly to Conway in his *New Essays* (book 1, chap. 1) as one of the better advocates of vitalism.

## METAPHYSICS

Conway begins the *Principles* by asserting without proof the existence of a perfect God, the description of which is influenced by Neoplatonism and Kabbalism. Conway's God is one of three kinds of substance, each with its own essence. God is a complete, self-sufficient fountain that necessarily emanates Christ, the second kind of substance, and through the mediation of Christ, who shares some attributes with God, others with creatures, necessarily emanates creatures—the third kind of substance. Because emanative creation is creation “out of” God rather than “out of” nothing, creatures have a share of the divine attribute of life. Since all creatures are of the same kind of substance, they have a single essence, differing only modally from one another. Thus, spirit or mind and body are not “really distinct.” There are many degrees of corporeity, and thus “a Thing may more or less approach to, or recede from the State and Condition of a body or a Spirit” (Conway 1982, p. 192). Conway draws the further conclusion that creatures are interconvertible: A horse, for example, can turn into a bird and spirits can turn into bodies (p. 177).

Not only God's creative act, but all of God's actions flow automatically from God's nature. Thus, God does whatever does not involve a contradiction. Conway's deity, like Leibniz, is timeless. Both Conway and Leibniz consider time to be relative to succession and motion; they consider succession and motion to be inferior analogues of eternity and the divine will, respectively, and thus to belong only to creatures (Conway 1982, p. 161).

Conway employs the concept of mediation, introduced in her account of creation, to explain action at a distance as well as causation between bodies and spirits. All created substances, in addition to sharing an essence, are interconnected by means of “Subtiler Parts,” which are the “Emanation of one Creature into another.” These mediated connections facilitate action at a distance and form “the Foundation of all Sympathy and Antipathy which happens in Creatures” (Conway 1982, p. 164). Conway offers, by contrast to the mechanical philosophy, a fairly direct account of the intelligibility of causation based on the concepts of similarity (or sympathy) and mediation. Similarity between cause and effect, as in the case of causation among bodies, renders causation directly intelligible, “because Things of one, or alike Nature, can easily affect each other.” Mediation is

required in the case of mind-body causation, because a soul is a “Spiritual Body” (pp. 214–215).

Since Conway regards interconnection as primitive, she requires no detailed explanations of causal interactions. Here she contrasts markedly with mechanistic philosophers' demands for explanations using motion and passive matter as primitives. Conway nonetheless incorporates causation by motion into her overall account of causation: Motion, especially vital motion, and divine emanation do not differ intrinsically from one another but are analogically related.

## COPENHAGEN INTERPRETATION

The Copenhagen interpretation is the standard textbook interpretation of quantum mechanics. The term covers a range of divergent views, loosely related to Bohr's complementarity interpretation. The consensus of the physics community is that Einstein lost the debate to Bohr about the “completeness” of quantum mechanics at the Solvay conference of October 1927, and that Bohr's analysis of the experimental situation in quantum mechanics in terms of the notion of complementarity allows one to make sense of a universe that is indeterministic ‘all the way down,’ so that quantum states (that in general assign

probabilities between 0 and 1 to the outcomes of experiments) are as complete as they can be.

It is difficult to pin down the Copenhagen interpretation. Heisenberg—who seems to have coined the term “Copenhagen interpretation” (see Howard’s “Who Invented the Copenhagen Interpretation” for a discussion)—concedes differences between his own position and Bohr’s, but concludes that “we really meant the same.” The term is generally taken to cover such radical views as Wigner’s, that “the quantum description of objects is influenced by impressions entering my consciousness” and John Wheeler’s notion of a “participatory universe”:

The dependence of what is observed upon the choice of experimental arrangement made Einstein unhappy. It conflicts with the view that the universe exists ‘out there’ independent of all acts of observation. In contrast Bohr stressed that we confront here an inescapable new feature of nature, to be welcomed because of the understanding it gives us. In struggling to make clear to Einstein the central point as he saw it, Bohr found himself forced to introduce the word ‘phenomenon.’ In today’s words Bohr’s point—the central point of quantum theory—can be put into a single, simple sentence. ‘No elementary phenomenon is a phenomenon until it is a registered (observed) phenomenon.’ It is wrong to speak of the ‘route’ of the photon in the experiment of the beam splitter. It is wrong to attribute a tangibility to the photon in all its travel from the point of entry to its last instant of flight. A phenomenon is not yet a phenomenon until it has been brought to a close by an irreversible act of amplification such as the blackening of a grain of silver bromide emulsion or the triggering of a photodetector. In broader terms, we find that nature at the quantum level is not a machine that goes its inexorable way. Instead what answer we get depends on the question we put, the experiment we arrange, the registration device we choose. We are inescapably involved in bringing about that which appears to be happening.

(WHEELER 1983, PP. 184–185)

It is doubtful that Bohr would have endorsed Wheeler’s formulation as a friendly amendment to complementarity. In a cautionary remark about misleading terminology, he writes:

In this connection I warned especially against phrases, often found in the literature, such as “disturbing of phenomena by observation” or “creating physical attributes to atomic objects by measurements.” Such phrases, which may serve to remind of the apparent paradoxes in quantum theory, are at the same time apt to cause confusion, since words like “phenomena” and “observations,” just as “attributes” and “measurements,” are used in a way hardly compatible with common language and practical definition.

(BOHR 1948, P. 237)

### THE REJECTION OF EINSTEIN’S REALISM

The common strand linking these different positions is the rejection of Einstein’s realism—the “ideal of the detached observer,” as Pauli put it somewhat pejoratively in a letter to Max Born (dated March 30, 1954). Einstein’s position can be characterized by two informal independence principles: A separability principle and a locality principle. The separability principle is the principle that if two physical systems are spatially separated (or, in a relativistic setting, space-like separated), then each system can be characterized by its own properties, independently of the properties of the other system. That is, each system separately has its own “being-thus,” as Einstein put it: A characterization in terms of certain properties intrinsic to the system, insofar as it is a separable system. The locality principle is the requirement that no influence on a system can directly affect another system that is spatially separated from it. In particular, a measurement performed on a system cannot alter any properties of another system that is spatially separated from it. The Copenhagen idea is that, in some sense (notwithstanding Bohr’s discomfort with the terminology), the dynamical variables of quantum mechanics—the so-called “observables” of the theory—“only have values when you look,” where the notion of “looking” is understood in a certain way (depending on the version: As involving the specification of a classically describable experimental set-up, or an interaction with a macroscopic measuring instrument that does not involve an ultimate conscious observer, or a measurement process that does involve the activity of a conscious observer, etc.). This claim is justified by citing examples of quantum interference characterized by Heisenberg’s uncertainty relations, such as the double-slit experiment, or beam splitter experiments, or by appealing to the irreducible disturbance of a measured system in a quantum mechanical measurement interaction.

## MEASUREMENT AND INTERFERENCE

Now it is generally recognized that the mere fact that measurements disturb what we measure does not preclude the possibility that observables have determinate values, or even that measurements might be exploited to reveal these values in suitably designed measurement contexts. (The “disturbance” terminology itself suggests the existence of determinate values for observables, prior to measurement, that are “disturbed” or undergo dynamical change in physical interactions.) And there is no warrant in the theory for interpreting the Heisenberg uncertainty relations for observables like position and momentum as anything more than a constraint on the possibility of preparing ensembles of systems in which these observables are simultaneously “sharp”—that is, as anything more than a constraint on the reciprocal distribution of the determinate values of these observables in quantum measurements.

Even interference phenomena, by themselves, say nothing about whether or not observables have determinate values in the absence of measurements, unless some interpretative principle is introduced. The usual story, in the case of a double-slit photon interference experiment, for example, is that you get the wrong distribution of hits on the screen behind the slits if you calculate the distribution on the assumption that each individual photon goes through one or the other of the two slits, when the photon is prepared in a quantum state that is represented algebraically in the theory as a linear sum (superposition) of a state in which the photon goes through slit 1 and a state in which the photon goes through slit 2. The photon is supposed to exhibit “wave-particle duality” and “go through both slits at once” to produce the characteristic interference pattern on the screen, where the photon finally manifests its presence as a particle. In passing through the slits, the photon behaves like a wave, a physical influence spread out over both slits, but in hitting the screen, it behaves like a particle, something localized at a point.

The loophole in the argument is the assumption of a specific link between attributing a determinate value to a quantum observable (like position, in the case of a photon going through one of two slits), and attributing a specific quantum state to the photon. This depends on an interpretative principle, the so-called “eigenvalue-eigenstate link,” that a quantum system has a determinate value (an “eigenvalue”) for an observable if and only if the quantum state is in a specific state called the “eigenstate” of the observable associated with the specific eigenvalue. If we reject this principle, then we can attribute a

determinate value (an eigenvalue) to the observable associated with the photon going through slit 1 or slit 2, exclusively, without assigning the associated state (the eigenstate) to the photon. This is precisely what observer-free hidden variable interpretations like Bohm’s theory accomplish.

Interference *per se* represents no obstacle to the simultaneous determinateness of noncommuting observables. The justification for assuming constraints on the simultaneous determinateness of quantum mechanical observables comes, rather, from the hidden variable ‘no go’ theorems of Kochen and Specker (1967) and Bell (1964), which severely limit the assignment of values to observables.

## IS THE COPENHAGEN INTERPRETATION INSTRUMENTALIST?

For Bohr, a quantum “phenomenon” is an individual process that occurs under conditions defined by a specific, classically describable experimental arrangement, and an observable can be said to have a determinate value only in the context of an experiment suitable for measuring the observable. The experimental arrangements suitable for locating an atomic object in space and time, and for a determination of momentum-energy values, are mutually exclusive. We can choose to investigate either of these “complementary” phenomena at the expense of the other, so there is no unique description of the object in terms of determinate properties.

Summing up a discussion on causality and complementarity, Bohr writes:

Recapitulating, the impossibility of subdividing the individual quantum effects and of separating a behaviour of the objects from their interaction with the measuring instruments serving to define the conditions under which the phenomena appear implies an ambiguity in assigning conventional attributes to atomic objects which calls for a reconsideration of our attitude towards the problem of physical explanation. In this novel situation, even the old question of an ultimate determinacy of natural phenomena has lost its conceptual basis, and it is against this background that the viewpoint of complementarity presents itself as a rational generalization of the very ideal of causality.

(1949, p. 31)

Pauli characterizes Bohr’s position this way:

While the means of observation (experimental arrangements and apparatus, records such as spots on photographic plates) have still to be described in the usual ‘common language supplemented with the terminology of classical physics,’ the atomic ‘objects’ used in the theoretical interpretation of the ‘phenomena’ cannot any longer be described ‘in a unique way by conventional physical attributes.’ Those ‘ambiguous’ objects used in the description of nature have an obviously symbolic character.

(1948, pp. 307–308)

The complementarity interpretation can be understood as the proposal to take the classically describable experimental arrangement (suitable for either a space-time or a momentum-energy determination) as defining what Bohr calls a quantum “phenomenon.” A current approach is to refer to the macroscopic character of our measuring instruments, and to show that the nature of the interaction between such systems and the environment is of a specific sort that results in a physical process called “decoherence” that ensures the “classical” character of the instrument. Some version of this idea is incorporated into the Copenhagen interpretation, sometimes extended by claims such as Wheeler’s. According to this view, then, the properties we attribute to a quantum object after a measurement depend partly on what we choose to measure, not solely on objective features of the system itself. To echo Pauli, the properties are “ambiguous” or merely “symbolic.”

At first blush it would seem that the Copenhagen interpretation is thoroughly anti-realist, and in some contemporary versions straightforwardly instrumentalist. However, Don Howard in “Who Invented the Copenhagen Interpretation” has argued persuasively that Bohr’s complementarity interpretation, as distinct from the Copenhagen interpretation, should be construed as a realist interpretation of quantum mechanics. For the contemporary philosophical debate on the Copenhagen interpretation, see Cushing (1994) and Beller (1999).

## COPERNICUS, NICOLAS

(1473–1543)

Nicolas Copernicus, or Mikolaj Kopernick, was a Polish clergyman, physician, and astronomer, and the proponent of a heliocentric theory of the universe. He was born at Torun (Thorn) on the Vistula. He studied liberal arts, canon law, and medicine at the universities of

Kraków (1491–1494), Bologna (1496–1500), and Padua (1501–1503) and received a doctorate in canon law from the University of Ferrara in 1503. Through the influence of his uncle, the bishop of Ermland, Copernicus was elected *in absentia* as a canon of the cathedral of Frauenburg in 1497. By 1506 he had returned to Poland, serving as physician to his uncle until 1512, when he took up his duties as canon. Copernicus's duties as canon involved him in the complex diplomatic maneuverings of the time and in the administration of the cathedral's large estates. In his own day he was more widely known as a physician than as an astronomer. He was one of the few persons in northeastern Europe to have a knowledge of the Greek language, and the one book he published without the urging of colleagues was a Latin translation of the poems of Theophylactus Simocatta, a seventh-century Byzantine poet. Copernicus's competence in economics was shown in some reports on money, presented to the Prussian diet, in which he anticipated a form of Gresham's law.

Copernicus's interest in astronomy was probably aroused at Kraków by the mathematician Wojciech Brudzewski and spurred on at Bologna by the astronomer Domenico Maria da Novara. Copernicus's first documented astronomical observation was made in Bologna in 1497. Twenty-seven such observations were used in his major treatise; others he recorded in the margins of books in his library. By 1514 he was so well known as an astronomer that he was asked by Pope Leo X to assist in the reform of the calendar, a task he declined because the motions of the sun and the moon had not yet been sufficiently determined.

Although Copernicus's major work, *De Revolutionibus Orbium Coelestium Libri IV*, was not published until 1543, the year of his death, he had been developing his theories at least from about 1512, the approximate date of his *Commentariolus* (a short outline of his system which he gave in manuscript copies to a few trusted friends). The first published account of his system was the *Narratio Prima* of his disciple and biographer (the biography is no longer extant), Georg Joachim Rheticus, in 1540. It was Rheticus who finally induced Copernicus to allow the publication of his major work.

## LATE MEDIEVAL ASTRONOMY

The difference between Copernicus's theory and the then prevailing Ptolemaic system of astronomy can be stated briefly. The Copernican system was heliocentric rather than geocentric and geostatic; it placed the sun close to the center of the universe and Earth in orbit around the center, rather than postulating an immobile Earth at the

center of the universe. But the full significance of this statement can be understood only via an examination of the *ad hoc* character of late medieval astronomy. Such late scholastic thinkers as Robert Grosseteste, Thomas Bradwardine, Jean Buridan, Nicholas Oresme, and Nicholas of Cusa had perceived the theoretical virtues and explanatory power of the heliocentric principle, as had Ptolemy himself long before. They understood the imperfections of the Ptolemaic techniques; yet they conceded that observational evidence did not clearly favor either theory—as was the case until the late sixteenth century. On scriptural grounds these thinkers accepted orthodox geocentrism; but they aired, more fully and deliberately than any of their predecessors, the arguments in support of terrestrial movement. They played *advocatus diaboli* with precision and imagination.

But prior to Copernicus astronomy was a piecemeal undertaking. Such problems as the prediction of a stationary point, or of an occultation, were dealt with one at a time, planet by planet. There was no conception that one planet's current stationary point might be related to another planet's later occultation. Techniques were employed as needed, and problem solving was not systematically integrated. Copernicus's theory changed this piecemeal approach forever. He effected a Kantian revolution in astronomy perhaps even more than Immanuel Kant effected a Copernican revolution in philosophy. Copernicus relocated the primary observational problem, that of explaining the apparent retrograde motions of the planets, by construing the motions not as something the planets "really" did "out there," but as the result of our own motion. Earth's flight around the sun makes other circling objects sometimes appear to move backward in relation to the fixed stars. Although either the Ptolemaic or the Copernican theory could be reconciled with sixteenth-century observations, Copernicus's view did not require investing those planets with queer dynamical properties, such as retrogradations-in-fact; a planet that actually halted, went into reverse, halted again, and then proceeded "forward" would be a strange physical object indeed. Rather, in Copernicus's view, all planets, including Earth, had the same kind of motion—a simple motion that explained the observed retrogradations.

It had been clear even to the ancients that the view that Earth was in the exact center of the universal system and that all celestial bodies moved about Earth in perfect circles could not generate predictions and descriptions even remotely close to the observed facts. In order to generate the right predictational numbers as well as tractable

orbital shapes, the Ptolemaic astronomers made a number of ad hoc assumptions. They moved Earth from the exact center of the planetary array; they used the geometrical center of the system as a reference point from which to calculate planetary distances; and they invented a third point, the *punctum aequans* (a mere computational device without physical significance, a device that Copernicus described as “monstrous”), around which the centers of the planetary epicycles described equal angles in equal times. No mechanisms known in nature or in art, however, have one center from which distances are determined, another from which velocities are determined, and a third from which observations are made. Moreover, the location of all these points and the choice of angular velocities around them were fixed arbitrarily and ex post facto simply to cope with each new observation as it turned up.

Even had Ptolemaic astronomy achieved perfection in predicting and describing, it was still powerless to explain planetary motion. One might ask how a theory that could describe and predict perfectly could in any way lack explanatory power; but Copernicus would have distinguished between the mere capacity of a theory to generate accurate numbers, and its further ability to provide an intelligible foundation for comprehending the phenomena studied. Even had the Ptolemaic system been able to predict accurately any future position of each moving point of light, Copernicus would still have asked what these points of light were, and what systematic mechanical interconnections existed between them.

An imaginative scholar, aware of the many difficulties posed by the Ptolemaic system as it had been developed over the years, and knowing (as Copernicus did) the accounts of ancient heliocentric theorists, might have only been expected to continue to seek improvements within the Ptolemaic system by incorporating promising heliocentric devices from his Scholastic predecessors (if he knew them) and from the ancients. Any gifted astronomer of Copernicus’s day bent on improving astronomy “from the inside” would thus have had to take heliocentrism seriously.

In fact, Copernicus’s books and Rheticus’s summary might be viewed as an articulate and systematic expression of much late medieval planetary thinking. The ties with fifteenth-century Scholastic thought are everywhere apparent. But the primary insight of *De Revolutionibus*, although not novel, was boldly carried out and very much sharpened in detail. It was a comprehensive attempt to make the science of that day work better; it was not explicitly a plan for a new science of tomorrow. The dra-

matic consequences, largely unanticipated by Copernicus, are a tribute to his thoroughness as a student of nature and not to any self-conscious desire to level the orthodoxy around him.

### THE COPERNICAN ALTERNATIVE

Copernicus was led to conclude that, in view of the plethora of epicycles required by the Ptolemaic system to account for the observed motion of the heavenly bodies, it must contain some basic error. He found that the assumption of a moving Earth, however absurd and counterintuitive it appeared, led to a much simpler and aesthetically superior system. Imagine yourself on the outer edge of a merry-go-round, sitting in a swivel chair. The constant rotation of the chair, when compounded with the revolution of the chair around the center of the merry-go-round, would generate—to say the least—complex visual impressions. Those impressions are compatible either with the motion as just described or with the supposition that it is the chair which is absolutely fixed and that all of the visual impressions stem from the motion of the merry-go-round about the chair-as-center and of a like motion of the walls of the building in which it is housed. The actual observations could be accounted for by either hypothesis. But what is easy to visualize in this example was extraordinarily difficult to comprehend in astronomical terms. That it was Earth that rotated and twisted, and revolved around the sun, seemed contrary to experience, common sense, and Scripture. Yet it was this simple alternative hypothesis that, for reasons demanded by astronomy, Copernicus espoused.

### COPERNICUS’S REVOLUTION

Fundamentally, then, Copernicus argued that the observational intricacies of planetary motion were not real, but merely apparent. This argument made planetary motion simpler to comprehend but our own motion more intricate and therefore harder to believe. That was the fundamental objection to Copernicus’s innovation.

But one must be quite clear about the nature of the theory. It was not a celestial dynamics, even in the sense that Johannes Kepler’s theory of the causes of planetary motion (in terms of primitive spokes of force radiating from the sun) was a celestial dynamics. Copernicus, like his predecessors, was no astrophysicist; he was concerned with positional astronomy—the kinematics of planetary appearances, the motions of stellar lights against the black bowl of the sky and the underlying geometry that would, with a minimum of ad hoc assumptions, make those motions intelligible. So, both the *Almagest* and the *De Rev-*

*olutionibus* were concerned with planetary kinematics exclusively—the latter in a systematic way, the former in the manner of a recipe collection. And even as a kinematic theory, Copernicus's theory was less adequate than those of Tycho Brahe and Kepler. He believed that the planets moved in perfect circles, an assumption shattered by Kepler's discovery of elliptical orbits. There is nothing in Copernicus to compare with Kepler's second law—that planets sweep out equal circumsolar areas in equal times. Nor is there anything to compare to Kepler's third law, correlating the time a planet requires to circle the sun with its distance from the sun. (And only when Kepler's three laws were added to the Galileo-Descartes law of inertia, and Isaac Newton's law of universal gravitation, was there developed a genuine celestial mechanics.) Copernicus's contributions consisted in a redeployment of the established elements of Ptolemaic positional astronomy. It is in this sense that he has been, and should be, viewed as the last great medieval astronomer.

### SIMPLICITY OF COPERNICUS'S THEORY

Copernicus's theory was not psychologically simpler than competing systems. A moving Earth, and a sun and stars that do not "rise" and "circle" us, seemed contrary to experience. Also, a theoretical apparatus that linked all astronomical problems instead of leaving them to be faced one at a time could not constitute an easier system of calculation. Indeed, in the sixteenth century, heliocentrism was psychologically far more complex than the theories men were accustomed to.

Was Copernicus's conception perhaps simpler in that, as a formal theoretical system, it did not require primitive new ideas for each new problem or for the times when old problems led to difficulties? It invoked nothing like a *punctum aequans*; that is, it invoked fewer independent conceptual elements (primitive terms) merely to explain aberrant calculations than did other astronomies. But this point is insufficient to explain the sense in which Copernicus's system manifests "simplicity." Computational schemes had been proposed by Caelio Calcagnini and Geronimo Fracastoro that were simpler in that they were built on smaller sets of primitive notions. But they were so inadequate to the observational tasks of astronomy that it would have been as idle to stress their simplicity as it would be today to press for the theoretical adoption of John Dalton's atom because of its simplicity; the issue of simplicity does not arise except between theories that are comparable in explanatory and predictational power.

It has been urged that Copernicus's theory was numerically simpler, in that it required only 17 epicycles to the Ptolemaic 83. But the Ptolemaist, because he addressed his problems singly and without regard for the configurational complexities of taking all planets at once, never had to invoke 83 epicycles simultaneously. The number was usually no more than 4 or 5 per individual calculation.

This error is analogous to that involved in referring to a Ptolemaic "system" at all. Such a system results only from taking all individual calculating charts for the separate planets, superimposing them, running a pin through the centric "Earthpoint," and then scaling the orbits up or down so they do not collide. This scaling is determined by a principle of order wholly unconnected with any part of the Ptolemaic epicycle-on-deferent technique. In contrast, Copernicus's system locates the planets in a circumsolar order such that their relative distances from, and their angular velocities around, the sun are in themselves sufficient in principle to describe and predict all stationary points, retrograde arcs, occultations, and the brightening and dimming of the planetary lights. Thus, since Copernicus linked all planets, and invented systematic astronomy, he had to invoke all the epicycles his theory needed en bloc. The number of epicycles in any calculation would tend to be greater, not less, than that required in a corresponding Ptolemaic problem.

Copernicus's scheme is systematically simpler. It required more independent concepts than some others, but these were deductively interlocked. Copernicus was astronomy's Euclid. He constructed out of the disconnected parts of astronomy as he found it a systematic monument of scientific theory. The *De Revolutionibus* is psychologically and quantitatively more complex than anything that had gone before, but it was deductively simpler. What Euclid had done for geometry, and what Newton was later to do for physics, Copernicus did for positional astronomy.

### IMPORTANCE OF THE THEORY

It has been argued that, as formalizations, the Copernican and Ptolemaic theories were strictly equivalent (D. J. de S. Price 1959), geometrically equivalent (A. R. Hall), even "absolutely identical" (J. L. E. Dreyer). But characterizing the theory as no more than "an alternative frame of reference plus some anti-Aristotelian philosophy" obscures the sense in which the heliocentric system and the geocentric systems of the sixteenth century were really equivalent. They were not equivalent in the sense that every consequence of the one was also derivable from the other.

Even when construed as mere geometrical calculations on paper, what the Ptolemaist would generate within his theory as corresponding to a stationary point in Mars's orbit is not congruent with what the Copernican would generate. The orbits were accorded different shapes in both theories, so points on those shapes, although viewed at the same angle from Earth, will not be superimposable. Nonetheless, every line-of-sight observation inferable within the one theory is completely inferable in the other. As positional astronomy, the two theories were observationally equivalent; no astronomer then could distinguish the two by comparing them with known facts. (Even today the Nautical Almanac is virtually a textbook of geocentric observation-points.) But the theories were neither formally equivalent nor physically equivalent, and certainly not absolutely identical. This is a difference that should make a difference to a philosopher.

With Sigmund Freud, man lost his Godlike mind; with Charles Darwin his exalted place among the creatures on Earth; with Copernicus man had lost his privileged position in the universe. The general intellectual repercussions of this fact are more dramatic than any consequences within technical astronomy, where one can speak of the Keplerian "revolution" but of not more than a Copernican "disturbance."

For the broad history of ideas, however, the implications of Copernicanism can hardly be exaggerated. Even religious revolutionaries such as Martin Luther and Philipp Melanchthon came to view Copernicus's position with abhorrence. His views challenged the literal interpretation of Scripture, the philosophical and metaphysical foundations of moral theory, and even common sense itself. The result was a massive opposition, learned and lay, to the reported ideas of Copernicus. It was the slow, sure acceptance of the technical *De Revolutionibus* by natural philosophers that ultimately quieted the general clamor against heliocentrism. Without the riotous reaction against it, Copernicus's book might have been but a calm contribution to scholarship somewhat like Pierre Simon de Laplace's *Mécanique céleste*. In the sixteenth and seventeenth centuries, however, the name Copernicus became a battle cry against the establishment in religion, in philosophy, and in natural science. It was a cry amplified in the world of wider scholarship and theology—far beyond Copernicus's original pronouncements. For Copernicus epitomized the well-trained, thorough, and rigorous sixteenth-century natural philosopher. He sought to make the theories he had inherited work better than when he found them. The history of ideas is charged with such figures. The difference is that Copernicus was

presented with a theory that was incapable of further internal revision and improvement. The only recourse was fundamental overhaul—the consequences of which we still feel today.

## CORBIN, HENRY (1903–1978)

The French Islamicist and philosopher Henry Corbin was born in Paris on April 14, 1903. He studied with such French scholars as Étienne Henry Gilson, Emile Brehier, and Louis Massignon. To expand the scope of his studies, he learned over a dozen classic and modern languages. His interest in philosophy took him to Germany where he made an acquaintance with Ritter, Karl Löwith, Alexan-

der Kojve, and Martin Heidegger. He translated several works of Heidegger into French, including *What Is Metaphysics*.

Corbin's main philosophical interest during the 1930s was the relationship between philosophy and mysticism. This was a major factor in his decision to study Islamic philosophy. Louis Massignon, then the head of Islamic studies at Sorbonne, introduced him to the works of the twelfth century Muslim philosopher Shihāb al-Dīn Yahyā al-Suhrawardī (d. 1191). Suhrawardī founded a philosophical school called the School of Illumination and sought to combine philosophical analysis with mystical experience—a theme that runs through Corbin's works.

In 1940, during World War II, Corbin went to Istanbul, Turkey, to study the manuscripts of Suhrawardī's works. He stayed in Turkey for the next five years. Then in 1945 he went to Tehran, Iran, where he founded an institute of Iranian studies under the French-Iran Institute. This is the beginning of Corbin's lifelong involvement with what he came to call "Persian Islam" (*islam iranien*). Iran became a spiritual birthplace for him.

Corbin was a prolific writer. Even though his scholarly works are mostly devoted to the philosophical exposition of Islamic or "Oriental" thought, they are permeated by his lifelong concern to resuscitate the mystico-philosophical outlook of such mystical philosophers as Suhrawardī, Ibn al-'Arabi, Mullā Ṣadrā, and Emmanuel Swedenborg. One key term in Corbin's thought is *mundus imaginalis* (the 'alam al-khayal of the Muslim philosophers). Not to be confused with "imaginary" world, *mundus imaginalis* refers to an intermediary stage between the purely intellectual and empirical worlds. For Corbin, this is the realm of angels and spiritual visions where sensible forms become immaterial and intelligible forms take on an "imaginal" character and dimension. This is where heaven and earth meet in the metaphysical sense of the term. Corbin believed that the European intellectual tradition has lost sight of this crucial concept, severing its relation with the "angelic world" and lending religious justification to the Cartesian dualism of body and soul.

In his readings, Corbin followed the tradition of spiritual hermeneutics (*ta'wil*), "returning" words to their original meanings and thus going back to the "beginning." He called himself a phenomenologist in the sense of "removing the veils of ignorance," (*kashf al-mahjub*). In his philosophical quest, Corbin gave some of the best examples of what is sometimes called comparative philosophy, and his immense knowledge of European

and Asian philosophies allowed him to do much more than simply compare or juxtapose different ideas and concepts.

## CORDEMOY, GÉRAUD DE (1626–1684)

Géraud de Cordemoy, a French lawyer, historian, and philosopher, was born in Paris. From about 1657 on, he frequented Cartesian circles and soon developed some distinctive (but seemingly un-Cartesian) theses, such as atomism and occasionalism. He met Bishop Jacques Bénigne Bossuet in October 1668 and through him became *lecteur ordinaire* to the dauphin in 1673. During this period he was engaged, at Bossuet's order, on a biography of Charlemagne, which was understood as involving a complete history of the French monarchy. He did not finish the work, though it was completed and published posthumously in two volumes by his oldest son, Louis-Géraud, along with other unpublished manuscripts and a three-volume collection of his works. Cordemoy was elected to the Académie Française in 1675. His fame rests on his attempts to extend Cartesian philosophy to the fields of language and communication, in *Discours physique de la parole* (1668), and on his advocacy of Cartesian orthodoxy, such as the doctrine of animal-machines and the consistency of Cartesianism with Genesis in *Lettre écrite à un savant religieux* (1668), but above all, Cordemoy is known for the views he defended in *Le discernement du corps et de l'ame* (1666).

For René Descartes, the principal attribute of body is extension and that of mind is thought. The first half of this tenet was thought to entail the impossibility of both atoms and the void: atoms, because extension was considered indefinitely divisible, and the void, because space was identified with the extension of bodies. Cordemoy offered a variation of Cartesian mechanical philosophy—everything in the physical world is explained in terms of

the size, shape, and motion of particles—but one that required atoms and the void. He rejected the indefinite division of body and the Cartesian identification of space with extension. He distinguished body and matter, matter being an assemblage of bodies, and claimed that bodies as such were impenetrable and could not be divided or destroyed.

He even criticized the Cartesian principle of individuation of bodies as shared motion, pointing out that a body at rest between other bodies would have to constitute a single body with the other bodies, even though one has a clear and natural idea of a body at rest between other bodies. Cordemoy proposed that shape, rather than motion, distinguishes the indivisible atoms. Cordemoy further reduced all forms of motion to local motion, arguing that no body has motion by itself. The prime mover—ultimately God—is necessarily a mind, though one's mind is not capable to begin, stop, or accelerate a motion; it can only change its direction. According to Cordemoy, this change of direction or “determination” of motion is not a change in the quantity of motion. The application of this analysis to the problem of the union of the soul and body led Cordemoy to occasionalism: Changes in the soul occur on the occasion of motions in its body, and vice versa.

Cartesians, such as Robert Desgabets and Nicolas Malebranche, criticized Cordemoy's atomism, though others, such as Gottfried Wilhelm Leibniz, praised it. Leibniz rejected Cordemoy's physical atoms, but spoke of Cordemoy as recognizing something of the truth when he tried to save the substantial unity of bodies; according to Leibniz, something lacking extension is required for the substance of bodies, otherwise there would be no source for the reality of phenomena. Other aspects of Cordemoy's philosophy were options generally discussed at the time; Cartesians, such as Johannes Clauberg and Louis de La Forge, had already proposed versions of occasionalism. But Cordemoy produced a more systematic treatment, starting from the physics of motion, which anticipated a number of Malebranche's theses, including the soul knowing itself directly by consciousness, but without a clear idea, and the existence of the body being known only indirectly, as the object of faith.

## CORDOVERO, MOSES BEN JACOB (1522–1570)

Moses ben Jacob Cordovero, the Jewish legalist and mystic, was the outstanding systematizer of the kabbalah. The place of his birth is not known; his father probably was

among the Jews expelled from Cordova, Spain. Cordovero's career centers in Safad, the little town in Palestine that had a period of glory in the sixteenth century. Here, after studying with three distinguished rabbinical teachers—Joseph Caro, Jacob Berab, and Moses di Trani—he was ordained at an early age and became one of the leading figures of the community. His kabbalistic studies were begun at the age of twenty, under the direction of his brother-in-law, Solomon Alkabez, and became the major concern of the remainder of his life. Isaac Luria, who was to become the key figure in a new, more theosophic version of kabbalistic teachings, was originally a pupil of Cordovero.

Cordovero wrote at least ten important kabbalistic books, of varying lengths, during his lifetime. From the philosophic point of view, the greatest of these was *Pardes Rimmonim* (A Garden of pomegranates; first printed at Kraków, 1591). This large book attempted to present a systematic exposition of kabbalistic ideas and to justify them by deductive rational argumentation instead of the usual methods of kabbalistic exegesis. The word *Pardes* (PRDS) in the title acrostically represents the four modes of interpretation of Scripture: *peshat*, literal interpretation; *remez*, allegorical, or hinting, interpretation; *derash*, homiletical interpretation; and *sod*, mystical interpretation. Among the subjects emphasized by Cordovero in his treatment are God's unity, God's will, God's knowledge and thought, God's wisdom and goodness, God's many names, and God's relation to creation; the emanations (*sephirot*), both individually and collectively, the reason for there being precisely ten emanations, and the mystery of their multiplicity in unity; the Shekinah; angels; soul; being; prophecy; the relation of correspondence between the upper and lower worlds and the necessity of each to the other; the Law and the commandments; the mysteries of the Law; the secrets of the Hebrew alphabet; man and Israel; righteousness; time; freedom and bondage; the service of God. Cordovero was one of the first writers to stress the idea of *zimzum*, the voluntary self-shrinkage of God to make room for the material world.

Because of his rational discussion of all these subjects and his successful philosophic justification of them, in terms of his own presuppositions, Cordovero may well be regarded as the climactic figure of the earlier period of kabbalistic speculation. To what extent he was also intrigued by the more practical or "magical" aspects of kabbalah, we cannot tell.

## CORRESPONDENCE THEORY OF TRUTH

The term "correspondence theory of truth" has circulated among modern philosophical writers largely through the influence of Bertrand Russell, who sets the view (which he himself adopts) that "truth consists in some form of correspondence between belief and fact" against the theory of the absolute idealists that "truth consists in *coherence*," that is, that the more our beliefs hang together in a system, the truer they are.

### ANCIENT AND SCHOLASTIC VERSIONS OF THE THEORY

The origins of the word *correspondence*, used to denote the relation between thought and reality in which the truth of thought consists, appear to be medieval. Thomas Aquinas used *correspondentia* in this way at least once, but much more often he used other expressions and preferred most of all the definition of truth that he attributed to the ninth-century Jewish Neoplatonist Isaac Israeli:

*Veritas est adaequatio rei et intellectus* (truth is the adaequation of things and the intellect). At one point he expanded this to *adaequatio intellectus et rei, secundum quod intellectus dicit esse, quod est, vel non esse, quod non est*. This is an echo of Aristotle's "To say of what is that it is not, or of what is not that it is, is false; while to say of what is that it is, and of what is not that it is not, is true." Other Scholastics sometimes said that a proposition is true when and only when *ita est sicut significat* ("the thing is as signified"); this too is in line with the Aristotelian account, in which "is" is not restricted to the meaning "exists"—the definition also covers the point that to say of what is so that it is not so, or of what is not so that it is so, is false; while to say of what is so that it is so, and of what is not so that it is not so, is true. This simple statement is the nerve of the correspondence theory; we shall continually return to it.

PLATO. Aristotle did not originate the correspondence theory but took it over from Plato's *Sophist*. There it was developed with an eye on a rejected alternative—not the coherence theory, which is a comparatively late invention (G. E. Moore is probably correct, in his "Truth" article in Baldwin's *Dictionary*, in tracing its vogue to Immanuel Kant), but one that we may call the existence theory, which also crops up in the *Theaetetus*. In this latter dialogue Socrates tries to find what differentiates true from erroneous belief, and the first suggestion he considers is that whereas true belief is directed toward what is, false belief is directed toward what is not. This view is rejected on the ground that just as to see or hear what is not is to see or hear nothing, and to see or hear nothing is just not to see or hear at all, so to "think what is not" is to think nothing, and that is just not to think at all, so that erroneous thought, on this view, would just not be thinking at all.

The same theory is considered in the *Sophist*, but here an alternative is put forward. Thought is compared with speech (it is the soul's dialogue with itself), and the important thing about speech is that in order to be true or false it must be complex—only complete statements are true or false, and these must consist of both nouns and verbs. (These points are also stressed by Aristotle.) As simple examples of complete statements, Plato gives "Theaetetus is-sitting-down" and "Theaetetus is-flying." The first of these is true because Theaetetus is sitting down, and the second is false because he is not flying. This escapes the difficulties of the existence theory because it abandons the suggestion that thinking is a simple direction of the mind toward an object—if it were that, its verbal expression would not have to be a com-

plete sentence but could be just a name—and so opens up the possibility for thinking to be erroneous even though what is thought about, such as Theaetetus, is perfectly real.

The existence theory, however, dies hard and has continued to maintain itself, not merely as a rival to the correspondence theory but even more as something that theory is in constant danger of becoming. (The two views continually oscillate, for example, in the early work of Russell and Moore.) It is easy to equate the complexity of thinking with its having a complex object—for instance, Theaetetus's-sitting-down or Theaetetus's-flying—which exists if the thought is true and does not if it is not.

ARISTOTLE. There is no trace of the above slide or degeneration in Aristotle, nor even of a conscious resistance to it, but he has passages that have some bearing on it and that in any case develop a little further the correspondence theory itself. For example, having said that the distinguishing mark of a substance or individual thing is that it may have opposite qualities at different times, he resists a suggestion that statements and opinions would count as things by this criterion, since they may be at one time true and at another time false—for example, the statement or opinion that a person is sitting down will be true while he is doing so but false when he stands up. This, Aristotle suggests, is unfair, because what is in question here is not any genuine alteration in the statement or opinion itself, but rather in the facts outside it by which its truth or falsehood is measured. "For it is by the facts of the case, by their being or not being so, that a statement is called true or false."

Sometimes Aristotle represents the verification of statements by facts as a kind of causation. Causation, he says, differs from implication because even where implication is reciprocal we can distinguish the cause from the effect:

The existence of a man, for instance, implies the truth of the statement in which we assert his existence. The converse is also the case. For if he exists, then the statement in which we assert his existence is true, and conversely, if the statement in which we assert his existence is true, he exists. But the truth of the statement is in no way the cause of his existence, though his existence is in a way the cause of the truth of the statement. For we call the statement true or false according as he exists or not.

(CATEGORIES 14B15–20)

(What Aristotle calls a cause here is perhaps something more like a criterion.)

**MEGARIAN “LIAR” PARADOX.** The Platonic–Aristotelian correspondence theory was not long formulated when a distressing consequence, or apparent consequence, of it was pointed out by Eubulides, a member of the school of Megara, which seems to have conducted constant warfare against various basic Platonic–Aristotelian positions. Eubulides invited his hearers to consider a man who says “I am lying” or “What I am now saying is false.” According to the Platonic–Aristotelian view, this is true if what the man is saying *is* false—it is true if it is itself false—and false if what he is saying is *not* false—false if it is true. Therefore, in at least this one case, that view leads to the position that whatever we say about the truth or falsehood of an utterance entails its own opposite. We may note, too, that in this instance the Aristotelian one-sided dependence of the truth or falsehood of a proposition on the related matter of fact does not hold, since the related matter of fact in this instance *is* precisely the truth or falsehood of the proposition. This “paradox of the liar” was much discussed by both ancient and medieval writers and still presents a serious problem to anyone attempting to give a satisfactory general account of truth and falsehood.

**STOICS.** What is substantially the Platonic–Aristotelian account of truth is also found among the Stoics, but with modifications. The Stoics held that truth in the primary sense is a property of statements or *axiomata*, not in the sense of sentences but in the sense of what the sentences state or mean. These *axiomata* exist independently of their being expressed by sentences, and the “meanings” of false sentences exist just as much as the meanings of true ones—that is to say, *axiomata* include objective falsehoods as well as objective truths. (This is not, therefore, the existence theory.) Describing the Stoics’ account of truth from this point on, Diogenes Laertius says that the *axioma* expressed by “It is day” is true if it is day and false if it is not. This is an example rather than a general theory; Sextus Empiricus says that the kind of *axioma* called simple and definite—the kind that would be expressed by a sentence of the form “This *X Y*’s” (for instance, “This bat flies”)—is true when the predicate belongs to the object denoted by the demonstrative. This, however, only defines “true” for the simplest type of proposition. For other types we know that the Stoics laid down such rules as that an *axioma* of the form “Some *X Y*’s” is true if and only if there is some true *axioma* of the form “This *X Y*’s,”

and one of the form “*p* and *q*” is true if and only if both of its components are; but we do not know whether they regarded such rules as actually defining “true” for these forms. It is scarcely likely that they saw them as parts of a single “recursive” definition of truth, such as is found in Alfred Tarski, but they laid the foundations for such a development.

**MEDIEVAL LOGICIANS.** Such statements of truth conditions, as we now call them, were also laid down and discussed by the logicians of the later Middle Ages, although they generally treated truth as a property not of abstract *axiomata* but of spoken and written sentences. Besides the truth conditions of sentences containing “not,” “or,” and “some,” they considered those of sentences containing such expressions as “possibly” and verbs in the past and future tenses. They observed, for example, that while in general a past-tense statement *is* true if and only if the corresponding present-tense statement *was* true, and a statement that something *could have been* so *is* true if and only if the statement that it *is* so *could have been* true, there are exceptions to such rules. For example, “Something white *was* black” *is* true, but “Something white *is* black” was never true. The rule here is that a past-tense predication *is* true if the corresponding predication *was* true of the individuals to which the subject term now applies; for instance, “Something white was black” is true if “It is black” could have been truly said in the past of a thing that is now white. “It could have been that no proposition is negative” is true, since God might have annihilated all negative propositions; but “No proposition is negative” could in no circumstances have been true, since the mere existence of this sentence (which is itself negative) falsifies it. The rule is rather that a sentence *de possibili* is true if and only if things could have been as the corresponding unqualified sentence says they are.

The later medieval logicians also implicitly modified the Platonic–Aristotelian theory in order to cope with the “liar” and similar paradoxes. John Buridan, for example, although he preserved the formula that a sentence is true when *ita est sicut significat*, gave a somewhat un-Aristotelian twist to the meaning of *significat*. According to Buridan, the man who says “I am saying something false,” and says nothing else, really is saying something false, not because things are otherwise than as his sentence *significat formaliter* but because they are otherwise than as his sentence *significat virtualiter*. A sentence “virtually” signifies whatever follows from itself together with the circumstances of its utterance, and what follows from this particular sentence together with the circumstances of its

utterance is that it is both true and false; since this is never the case, things are not as it “virtually” says they are, and it is false.

### MOORE’S CORRESPONDENCE THEORY

In the twentieth century a particularly extended and fruitful discussion of the correspondence theory is found in a series of lectures given by G. E. Moore in 1910–1911. Here truth and falsehood first appear as properties of what are called propositions. Moore uses the term *proposition* to mean not an indicative sentence but what such a sentence *means*, an *axioma* in the Stoic sense. When we both hear and understand a spoken sentence, and both see and understand a written one, there is something apprehended by us over and above the sentence, and while this apprehension or understanding is the same kind of act in all cases, what is apprehended is in general different when different sentences (such as “Twice two are four” and “Twice four are eight”) are involved and therefore is distinguishable from the act of apprehending. We also “constantly think of and believe or disbelieve, or merely consider, propositions, at moments when we are neither hearing nor seeing any words which express them”; for example, when we “apprehend a proposition, which we desire to express, before we are able to think of any sentence which would express it.” In this lecture Moore is quite confident that “there certainly are in the Universe such things as propositions,” and that it is propositions rather than sentences or acts of belief that are true or false in the primary sense. We often say that beliefs are true or false, but this is only because the word *belief* is often used not for an act of believing but for what is believed; for instance, if we say that two different people have the same belief, we mean to identify what they believe rather than their respective acts of believing, and what is believed is simply a proposition in Moore’s sense. Acts of believing and sentences could, however, be said to be true or false in a secondary sense, when what is believed or expressed is a true or false proposition.

**MOORE’S LATER POSITION.** Moore returns to the subjects of true and false beliefs and the nature of propositions in later lectures in the series, but now he seems to move somewhat away from the position outlined above. He leads up to them with a problem he states as follows: “Suppose a man believes that God exists; ... then to say that his belief is true seems to be exactly equivalent to saying that it *is a fact* that God exists or that God’s existence is a fact” (*Some Main Problems in Philosophy*, p. 250). Quite generally it seems that “the difference between true and false beliefs is ... that where a belief is true, there

what is believed is a fact; whereas where a belief is false, there what is believed is not a fact” (ibid.). Even where a belief is false, however, there does seem to be something that is believed.

A man believes in God’s existence and it seems quite plain that he is believing in something—that there is such a thing as what he believes in, and that this something is God’s existence. It seems quite plain, therefore, that there *is* such a thing as God’s existence, *whether* his belief is true or false. But we have just seen that if his belief is false, then God’s existence is *not* a fact. And what is the difference between saying that there is such a thing as God’s existence and (saying) that God’s existence is a fact? (ibid.)

This is the problem of the *Theaetetus* all over again—if a false belief has no real object, how can it be a belief at all?

**DENIAL THAT PROPOSITIONS EXIST.** Moore raises the above question with regard to a more certainly false proposition, namely, that the hearers of his lecture were at that time hearing the noise of a brass band; and he then restates, but no longer with conviction, his earlier theory. We *could* say that there was indeed such a thing as their hearing a brass band then but that this was a proposition, not a fact. But, Moore argues, this theory admits in the case of the phrase “the fact that they are hearing a brass band” that what looks like the name of a real object of a possible belief is not one, so why should we not say this also of the phrase “the proposition that they are hearing a brass band”? Moore is thus led to the view that the subject–verb–object form of assertions about beliefs is misleading. His new theory, he says, “may be expressed by saying that there simply are no such things as *propositions*. That belief does *not* consist ... in a relation between the believer, on the one hand, and another thing which may be called the proposition believed” (ibid., p. 265). He cannot give any satisfactory alternative analysis of belief statements to supplant the one he has abandoned, but he thinks he can give an account of the truth and falsehood of beliefs without one.

**FALSE BELIEF AND FACTS.** In developing the account of truth and falsehood of beliefs, Moore considers the case of a friend believing that he has gone away for his holidays, and begins in a thoroughly Aristotelian vein. “If this belief of his is *true* then I *must* have gone away ... and, conversely, ... *if* I have gone away, then this belief of his certainly *is true*” (ibid., p. 274). And similarly, “if this belief is *false*, then I *can’t* have gone away ... and con-

versely, *if I have not gone away, then the belief that I have gone away certainly must be false*” (ibid., p. 275). However, this statement of necessary and sufficient conditions does not constitute a definition of truth and falsehood, for “when we assert: ‘The belief that I have gone away is true,’ we mean to assert that this belief has some property, which it shares with other true beliefs,” whereas “in merely asserting ‘I have gone away,’ we are not attributing any property at all to this belief” (ibid., p. 276). For “Plainly I might have gone away without my friend believing that I had; and if so, his belief would not be true, simply because it would not exist.” This objection, however, suggests that Moore’s having gone away would not after all be a sufficient condition, but only a necessary one, of his friend’s belief being true; and it could be met by defining the truth of his friend’s belief, not simply as Moore’s having in fact gone away but as this together with his friend’s believing it.

The problem remains, however, of generalizing this to cover all cases, which Moore goes about solving as follows: “We can see quite plainly,” he says, “that this belief, if true, has to the fact that I have gone away a certain relation which that belief has to no other fact,” a relation which cannot be defined in the sense of being analyzed, but with which we are all perfectly familiar and which “is expressed by the circumstance that the name of the belief is ‘the belief that I have gone away,’ while the name of the fact is ‘that I have gone away’” (ibid.). Moore proposes to call this relation correspondence, and “To say that this belief is true is to say that there is in the Universe *a* fact to which it corresponds, and to say that it is false is to say that there is *not* in the Universe any fact to which it corresponds” (ibid., p. 277).

**FACTS RATHER THAN PROPOSITIONS.** It is essential to Moore’s final account that although there are no propositions, there are facts. A belief, even if true, does not consist in a relation between a person and a fact, but the truth of a belief does. He is also at pains to insist that facts “are” or exist in the very sense in which, say, chairs and tables do. He concedes that as a matter of usage we find it natural to say “It is a fact that bears exist,” while we do not find it at all natural to say “That bears exist, is” (or “That bears exist, exists,” or even “The existence of bears exists”), but he thinks this simply reflects our acute sense of the difference in kind between facts and other things—they are real objects but objects of a very special sort. We also express their character by calling them truths, or by prefixing “It is true that” to them as an alternative to “It is a fact that.” This property of *being* a truth or fact is to be carefully distinguished from the “truth” which is pos-

sessed by some beliefs and which consists, as previously explained, in correspondence to a truth or fact.

## RUSSELL’S CORRESPONDENCE THEORY

In Moore’s account of truth and falsehood, it will be seen, there are two elements that are a little mysterious and that he is reluctantly compelled to leave in that condition—the correct analysis of belief statements and the nature of the correspondence that entitles us to use the same form of words in describing the content of a belief and in asserting the fact to which, if true, it corresponds.

Shortly before Moore gave these lectures, Russell had made an attempt to elucidate just these points. In the concluding section of a paper he gave before the Aristotelian Society in 1906, there is a hint of this explanation, which is more fully developed in various writings of the period 1910–1912. He suggests in the 1906 paper that a belief may differ from an idea or presentation in consisting of several interrelated ideas, whose objects will be united in the real world into a single complex or fact if the belief is true, but not otherwise, so that a false belief is indeed “belief in nothing, though it is not ‘thinking of nothing,’ because it is thinking of the objects of the ideas which constitute the belief.” In the later versions this is expanded to the view that a belief consists in a many-termed relation, the number of terms always being two more than that occurring in the fact to which, if true, the belief corresponds. For example, if it is a fact that Desdemona loves Cassio, then in this fact the two terms Desdemona and Cassio are “knit together” by the relation of loving, while if it is a fact that Othello believes that Desdemona loves Cassio, then the four terms Othello, Desdemona, the relation of loving, and Cassio are “knit together” in this fact by the relation of believing. The correspondence between the belief and the fact, when the fact exists and the belief is therefore true, consists in a certain characteristic semiparallelism between the ordering of the last terms of the belief relation and the ordering of the terms by their ordering relation in the fact. Knowing and perceiving, on the other hand, really are relations between the knower or perceiver and the fact known or perceived (which of course must *be* a fact for knowledge or perception to occur).

**CRITICISMS.** The above theory is open to a number of objections, some of which have been particularly well stated by P. T. Geach, and one of which, due in essence to Ludwig Wittgenstein, had already led Russell to abandon

the theory, in a course of lectures on logical atomism delivered in 1918.

*Belief and what is the case.* Russell's 1906–1912 theory—and indeed even Moore's more vague theory, of which it is a possible filling out—makes it altogether too mysterious that the very same words should be used to express what is believed and what is actually the case if the belief is true. (At most, there is in some languages a slight but regular formal alteration when the latter is put into *oratio obliqua* to give the former.) As Wittgenstein puts it (*Philosophical Investigations*, Para. 444), “One may have the feeling that in the sentence ‘I expect he is coming’ one is using the words ‘he is coming’ in a different sense from the one they have in the assertion ‘He is coming.’ But if it were so how could I say that my expectation had been fulfilled?”—that *the very thing* I expected had come to pass?

This severance of the senses of the *oratio obliqua* and *oratio recta* forms of the same sentence is exacerbated in Russell's account, as Geach points out, by its consequence that believing is not one relation but several, since the number of terms it requires differs with the number of terms required by the relation that occurs among its objects (for instance, while Othello's believing that Desdemona loves Cassio is a 4-termed relation, his believing that Desdemona gave Cassio a certain ring would be a 5-termed one). This difference arises even when we are only considering beliefs of which the apparent objects are simple relational propositions; still more radical differences would have to be admitted with believings apparently directed toward compound and general propositions. This point was, indeed, stressed by Russell himself from the outset and seems never to have been regarded by him as a serious objection to the theory, since in his 1918 lectures, even when he had abandoned the view that necessitated it, we find him saying that “belief will really have to have different logical forms according to the nature of what is believed” (*Logic and Knowledge*, p. 226), so that “the apparent sameness of believing in different cases is more or less illusory.”

There is here, it seems, a remnant of the ramified theory of types that Russell at first thought necessary to deal with such paradoxes as that of the “liar.” According to this theory, propositions are not only of different logical forms but also of different logical types, and “truth” and “falseness” must be differently defined for each type; indeed, even such ordinary logical functions as negation and conjunction must be understood differently according to the types of propositions to which they are attached. Even by the time he was exercising the influence

acknowledged in Russell's 1918 lectures, Wittgenstein had definitely abandoned this theory: “Any proposition can be negated. And this shews that ‘true’ and ‘false’ mean the same for all propositions (in contrast to Russell)” (*Notebooks 1914–1916*, p. 21).

*Verbs in judgments.* What Russell did successfully assimilate from Wittgenstein at this period was that in such judgments as that Othello believes that Desdemona loves Cassio, “both verbs have got to occur as verbs, because if a thing is a verb it cannot occur otherwise than as a verb.” He also says:

There are really two main things that one wants to notice in this matter that I am treating of just now. The *first* is the impossibility of treating the proposition believed as an independent entity, entering as a unit into the occurrences of the belief, and the *other* is the impossibility of putting the subordinate verb on a level with its terms as an object term in the belief. That is a point in which I think that the theory of judgment which I set forth once ... was a little unduly simple, because I did then treat the object verb as if one could put it as just an object like the terms. (*Logic and Knowledge*, p. 226)

“Every right theory of judgment,” as Wittgenstein puts it, “must make it impossible for me to judge that ‘this table penholders the book’ (Russell's theory does not satisfy this requirement)” (*Notebooks 1914–1916*, p. 96).

*Propositions in judgments.* Russell's objection ties up in two ways with Wittgenstein's that “a proposition itself must occur in the statement to the effect that it is judged.” In the first place, it is by inserting the “proposition itself” into the “statement to the effect that it is judged” that we enable the subordinate verb to occur as a verb and not disguised as an abstract noun. (It looks, in fact, as if these “two main things” that Russell says we must notice cannot be observed together.) We might put the two objections together thus: Because the use of abstract nouns is *always* something to be explained, it is more illuminating to say that “Othello ascribes unfaithfulness to Desdemona” (where “ascribes” is apparently a 3-termed relation with “unfaithfulness” as one of its terms) means exactly what is meant by “Othello believes that Desdemona is unfaithful” than it is to say that the second means exactly what is meant by the first.

*Facts as objects.* The second way in which the two objections come together is more complicated, and it can be gathered from an extended discussion of what may at first seem another point: that Russell's 1906–1912 theory,

like Moore's of 1910, still takes "facts" seriously as a special sort of object. On this point Russell's 1918 view is a little obscure. He seems not to have changed at all on this subject, and describes it as one of those truisms that "are so obvious that it is almost laughable to mention them," that "the world contains *facts*, ... and that there are also *beliefs*, which have reference to facts, and by reference to facts are either true or false" (*Logic and Knowledge*, p. 182). He sharply contrasts facts with propositions in this respect. "If we were making an inventory of the world, propositions would not come in. Facts would, beliefs, wishes, wills would, but propositions would not" (*ibid.*, p. 214). This last remark occurs in a criticism of an attempt by Raphael Demos to eliminate the *negative* fact that a certain piece of chalk is not red from the "inventory of the world" by equating it with the fact that the chalk has some other positive but incompatible color. "Even if incompatibility is to be taken as a sort of fundamental expression of fact," Russell says to this, "incompatibility is not between facts but between propositions. ... It is clear that no two *facts* are incompatible" (*ibid.*). And since propositions do not have being independently, this "incompatibility of propositions taken as an ultimate fact of the real world will want a good deal of treatment, a lot of dressing up before it will do." However, Russell's own alternative, that there are irreducibly negative facts—for instance, the fact that it is not the case that this piece of chalk is red—equally involves the consequence that there are facts that contain real falsehoods as constituents. This Russell himself pointed out in his 1906 paper, and it led him then to be more hesitant than he was later about dismissing the notion of objective falsehoods. Even if, he says in this paper, we can remove the suggestion that false beliefs have objective falsehoods for their objects:

There is ... another argument in favour of objective falsehood, derived from the case of true propositions which contain false ones as constituent parts. Take, e.g., "Either the earth goes round the sun, or it does not." This is certainly true, and therefore, on the theory we are considering, it represents a *fact*, i.e. an objective complex. But it is, at least apparently, compounded of two (unasserted) constituents, ... of which one must be false. Thus our fact seems to be composed of two parts, of which one is a fact, while the other is an objective falsehood. ("On the Nature of Truth," pp. 47–48)

The real moral of all this is surely that if propositions must go, facts must go, too; but Russell seems to shrink from this step.

Elsewhere in the 1918 lectures, however, he says that facts, although apparently real in a way in which propositions are not, have the extraordinary property that they cannot be named. In the first place, they are not named by propositions (sentences). For this he has a rather strange argument, taken from Wittgenstein. Whereas Moore thought of a false belief as one that corresponds to no fact at all, Wittgenstein held that a false statement does correspond to a fact, but in the wrong way. Hence, to quote Russell's exposition of the theory:

There are *two* propositions corresponding to each fact. Suppose it is a fact that Socrates is dead. You have two propositions: "Socrates is dead" and "Socrates is not dead." And those two propositions corresponding to the same fact, there is one fact in the world, that which makes one true and one false. ... There are two different relations ... that a proposition can have to a fact: the one the relation that you may call being true to the fact, and the other being false to the fact. (*Logic and Knowledge*, p. 187)

This means that a proposition does not name a fact, since in the case of a name, there is only one relation that it can have to what it names. Further,

You must not run away with the idea that you can name facts in any other way; you cannot. ... You cannot properly name a fact. The only thing you can do is to assert it, or deny it, or desire it, or will it, or wish it, or question it. ... You can never put the sort of thing that makes a proposition to be true or false in the position of a logical subject. (*ibid.*, p. 188)

## RAMSEY AND THE LATER WITTGENSTEIN

Russell's whole position, as it stands, is difficult to maintain. If there are really individual objects to which the common noun "fact" applies, and we can sometimes actually perceive them (Russell continued to hold this in the 1918 lectures), then if at the time of our perceiving one our language has no name for it, why can we not invent one and christen the thing on the spot? However, there is not just superstition, but something true and important, behind the statement of Russell and Wittgenstein that facts cannot be named, and they both identify it in the end. "When I say 'facts cannot be named,'" Russell admitted in 1924, "this is, strictly speaking, nonsense. What can be said without falling into nonsense is: 'The symbol for a fact is not a name.'" Or better, perhaps: to state a fact is not to name an object. Whatever may be the

case with “that” clauses, *sentences* aren’t names of anything; just as, whatever may be the case with abstract nouns, verbs are not names of anything—they are not names at all, but have other functions; naming is one thing, saying or stating another. Even Plato saw that this distinction was important.

But can we not *name what a sentence says*, for instance, by the corresponding “that” clause? Not really—“*what a sentence says*,” although a good sense can be given to it, is a misleading expression; when it means anything, it means “*how a sentence says things are*” or, better, “*how we say things are*” when we use the sentence in question. To *name* what we are saying is to *say* what we are saying, and to name what we are thinking or wishing is similarly to say what we are thinking or wishing. “I think that bears exist” is, therefore, not to be analyzed as “I think (that bears exist),” which suggests that “that bears exist” is one term of the relation expressed by “think” but rather as “I think that (bears exist),” where “bears exist” does not even look like a name (it looks like, and is, a sentence) and “think that” does not look like the expression of a relation. If Othello thinks that Desdemona loves Cassio, there is indeed a 3-termed relation between Othello, Desdemona, and Cassio (not, as Russell thought, a 4-termed one between Othello, Desdemona, Cassio, and loving), but this relation consists in his *thinking that she loves him*, that is, the relation is expressed by the whole complex verb “—thinks that—loves—,” not by the simple “—thinks that—,” which does not express any relation at all, since its second gap is not filled by the name of an object but by a sentence, which does not name but *says* what he thinks (how he thinks things are). The plain “thinks,” without the “that,” means nothing at all. I may, indeed, use forms of expression like “I think something that Jones doesn’t think” or “Something that Jones thinks is not true,” but the “thing” in this “something” is no more to be taken seriously than the “what” in “what I say”—these sentences, respectively, mean simply “For some *p*, I *think that p* and Jones does not think that *p*” and “For some *p*, Jones thinks that *p* but it is not the case that *p*.” The correspondence theory can now assume the simple form: “*X says (believes) truly that p*” means “*X says (believes) that p, and p*”; and “*X says (believes) falsely that p*” means “*X says (believes) that p, and not p*.”

RAMSEY. The above position was very lightly sketched in 1927 by Frank Plumpton Ramsey, who says in effect that the words *fact* and *true* in their primary use are inseparable parts of the adverbial phrases “truly,” “in fact,” “it is a fact that,” and “it is true that”; and these, attached to some sentence, say no more than this sentence says on its own.

“It is false that *p*” or “That *p*, is contrary to fact” similarly says no more than the simple “Not *p*.” Thus there are not only no falsehoods but no facts or truths either, any more than there is an entity called “the case” involved in the synonymous phrase “It is the case that.” This part of Ramsey’s view has led some writers to set it in opposition to the correspondence theory as a “no truth” theory, but Ramsey also discusses more complex uses of “true” in which there is something more like a juxtaposition of what a man says and what is so. In particular he considers the statement “He is always right”—“Whatever he says is true”—and renders this as “For all *p*, if he says that *p*, it is true that *p*,” and this in turn as “For all *p*, if he says that *p*, then *p*.” This may seem to require a further verb in its second clause, but there is already a “variable verb” implicit in the variable *p*.

WITTGENSTEIN. We may expand Ramsey’s discussion of the more complex uses of “true” by taking up a suggestion of the later Wittgenstein (which, indeed, we have already used a bit). In the *Tractatus*, Wittgenstein says that “the general form of propositions is: this is how things are.” In the *Investigations*, criticizing this identification, he reminds us that “This is how things are” is itself a proposition, an English sentence applied in everyday language, as in “He explained his position to me, said that this was how things were, and that therefore he needed an advance.” “This is how things are” can be said to stand for any statement and can be employed as a propositional *schema*, but only because it already has the construction of an English sentence. Wittgenstein continues, “It would also be possible here simply to use a letter, a variable, as in symbolic logic. But no one is going to call the letter ‘*p*’ the general form of propositions.”

“This is how things are,” although a genuine proposition, is nevertheless being employed only as a propositional variable. “To say that this proposition agrees or does not agree with reality would be obvious nonsense.” “This is how things are” is a propositional variable in ordinary speech in much the same way that a pronoun is a name variable in ordinary speech. In Wittgenstein’s example, the “value” of this “variable” is given by a specific sentence uttered earlier, much as the denotation of a pronoun may be fixed by a name occurring earlier. “I’m desperate—that’s how things are” is like “There’s Jones—he’s wearing that hat again.” “This (that) is how things are” is a pro-sentence. But we may also obtain a specific statement by “binding” this variable, as in “However he says things are, that’s how they are,” that is, Ramsey’s “For all *p*, if he says that *p*, then *p*.” We speak truly whenever things are as we say they are, and falsely when they are

not. There was a hint of this way of putting things when the later Scholastics equated *est vera*, said of a sentence, with *ita est sicut significat* or *qualitercumque significat, ita est*—“however the sentence signifies (that the case is), thus it is”—avoiding the possibly misleading “What the sentence says is so.”

These “misleading” forms, however, *need* not mislead us, once the whole picture has been spread out, and we can soften our earlier skepticism by agreeing that after all there *are* facts, and that there are falsehoods, if all that is meant by “There are facts” is “For some  $p$ ,  $p$ ” and by “There are falsehoods” “For some  $p$ , not  $p$ .” We can say, too, that there are both facts and falsehoods that have never been either thought or asserted, that is, we can insist on the objective or mind-independent character of propositions, if by this we mean that for some  $p$ , both  $p$  and it has never been thought or said that  $p$ . (We cannot, of course, give examples of such facts or falsehoods, for to do so would be to state them, and then they would not be unstated; but this is no more strange than that there should be people—as there certainly are—whose names we do not know, although we cannot in the nature of the case name any specific examples.) It is significant that Moore in his last years contrived to assimilate a Ramsey-like account of truth without losing any of his earlier sense of the mind-independent and speech-independent character of what is so. Propositions about propositions, he said in effect, are *not* propositions about sentences precisely because the words *proposition*, *true*, and *false* are eliminable—just because “The proposition that the sun is shining is true” is equivalent to and perhaps identical with the plain “The sun is shining,” it neither says anything about sentences nor entails that there are such things, since the sun could obviously *be* shining even if no one ever said so.

### TARSKI'S SEMANTIC THEORY

In the theories of Ramsey and the later Moore, truth is a quasi property of a quasi object. What is really defined in them is not a property of anything, but rather what it is to say with truth that something is so; it is an account of the adverbial phrase “with truth” rather than of the adjective “true.” The late medieval treatment of “true” as a straightforward adjective applying to straightforward objects—sentences—was revived in the twentieth century, and developed with extraordinary precision, elegance, and thoroughness, in a paper by Alfred Tarski that is one of the classics of modern logic.

“TRUE” AS A METALINGUISTIC ADJECTIVE. A sentence, Tarski points out, is true or false only as part of some particular language. The Schoolmen were sensitive to this point also; Buridan, for example, observed that if we neglect it, we will be trapped by such arguments as the following: “A man is a donkey” is a true sentence if and only if a man is a donkey; but “A man is a donkey” could have been a true sentence (since we could have used it to mean what we now mean by “White is a color”); ergo it could have been that a man is a donkey. Moore was fond of making similar points.

Further, Tarski argues, a sentence asserting that some sentence  $S$  is a true sentence of some language  $L$ , cannot itself be a sentence of the language  $L$ , but must belong to a metalanguage in which the sentences of  $L$  are not used but are mentioned and discussed. He is led to this view by the paradox of the “liar” which he presents, after Jan Łukasiewicz, as follows: He uses the letter  $c$  as an abbreviation for the expression “the sentence printed on page 158 [of his paper], line 5 from the top,” and the sentence printed there is “ $c$  is not a true sentence.” By the ordinary Aristotelian criterion for the truth of sentences, we may say “‘ $c$  is not a true sentence’ is a true sentence if and only if  $c$  is not a true sentence.” But “ $c$  is not a true sentence” is precisely the sentence  $c$ , so we may equate the preceding with “ $c$  is a true sentence if and only if  $c$  is not a true sentence,” which is self-contradictory. The contradiction is eliminated if we put “of  $L$ ” after “true sentence” throughout and deny the principle “‘ $c$  is not a true sentence of  $L$ ’ is a true sentence of  $L$  if and only if  $c$  is not a true sentence of  $L$ ” on the ground that  $c$  is not a true sentence of  $L$  under any conditions whatever, because it is not a sentence of the language  $L$  at all but of its metalanguage  $M$ .

Similar paradoxes lead to similar conclusions about such terms as “is a name of” or “signifies”—in fact, all terms that concern the relations between the expressions of a language and the objects which this language is used to describe or talk about. All such semantic terms must occur, not in the language that they concern, but in the associated metalanguage. This metalanguage must contain names for expressions in the object language and may also contain descriptions of the structure of such expressions; for instance, we might be able to say in it that one sentence is the negation of another, meaning by this that it is formed from that other by prefixing the expression “It is not the case that” to it. Tarski is attempting to state the conditions under which, for a given language  $L$ , we can define the term “true sentence” (and perhaps other semantic expressions) in terms of this basic metalinguistic apparatus, and in such a way as to entail all

sentences, in the metalanguage  $M$ , of the form “ $x$  is a true sentence if and only if  $p$ ,” where  $x$  is a *name* of some sentence of  $L$  (we need not write “sentence of  $L$ ” in the formula, since in  $M$  this is what “sentence” means), and  $p$  is the *translation* into  $M$  of this same sentence. ( $M$  could include  $L$  as a part of itself, in which case the sentences of  $L$  would be their own translations into  $M$ .) Note that this criterion of a satisfactory definition of truth, which Tarski calls the Convention  $T$ , is not itself such a definition in  $M$  of truth in  $L$ , since it talks *about* expressions of  $M$ , and about their relation to what they mean (they “name” sentences of  $L$ ), and so is itself not in the metalanguage  $M$  but in the meta-metalanguage.

Since in many (meta)languages we form the name of an expression by putting that expression in quotation marks, the following might seem to meet Tarski’s criterion: “For all  $p$ , ‘ $p$ ’ is a true sentence if and only if  $p$ .” This, one might think, would immediately yield such individual cases as “‘Snow is white’ is a true sentence if and only if snow is white” (given, of course, that “Snow is white” is a sentence of  $L$ ). This will not do, however, for by enclosing the fourteenth letter of the alphabet in quotation marks (however we use that letter elsewhere) we simply form the name of the fourteenth letter of the alphabet. Hence, what we get by instantiation of the proposed definition are, for example, the sentences “The fourteenth letter of the alphabet is a true sentence if and only if snow is white” and “The fourteenth letter of the alphabet is a true sentence if and only if snow is not white,” which together entail that snow is white if and only if snow is not white, a contradiction.

**“RECURSIVE” DEFINITION OF TRUTH.** If the language  $L$  contained only the two simple sentences “Snow is white” and “Grass is green,” plus such compounds as could be formed by prefixing “It is not the case that” to a sentence and by joining two sentences by “or,” we might offer the following “recursive” definition of “true sentence”:

- (1) “Snow is white” is a true sentence if and only if snow is white, and “Grass is green” if and only if grass is green.
- (2) The sentence formed by prefixing “It is not the case that” to a given sentence  $S$  is true if and only if  $S$  is not true.
- (3) The sentence formed by placing “or” between the two sentences  $S_1$  and  $S_2$  is true if and only if either  $S_1$  or  $S_2$  is true.

There is a mathematical device for turning such “recursive” definitions into ordinary ones, so this feature of the above need not worry us; but we are clearly not very far along if we have to begin by listing all elementary sentences and defining “true” for each of them.

Suppose we enrich  $L$  by adding “Snow is green” and “Grass is white” to the elementary sentences, and enrich  $M$  by calling “snow” and “grass” names and “is green” and “is white” predicates, and defining an elementary sentence as a name followed by a predicate. We may then alter (1) above to “For any name  $X$  and predicate  $Y$ , the sentence  $XY$  is true if and only if the predicate  $Y$  applies to the object named by  $X$ .” This, however, assumes that the metalanguage already contains the semantic expressions “names” and “applies to”; if it does not, we can only “define” them by saying that “snow” names snow, “grass” names grass, “is white” applies to  $X$  if and only if  $X$  is white, and “is green” applies to  $X$  if and only if  $X$  is green.

This is still not very satisfactory, but it is Tarski’s basic procedure, except that for his simplest  $L$  he takes a language in which there is only one predicate, the relative or two-place predicate “is included in,” and no names at all, but only variables standing for names of classes; sentences are formed from “sentential functions” by prefixing a sufficient number of universal quantifiers (“for all  $x$ ,” “for all  $y$ ”) to “bind” all the variables in the function. That is, the sentences in this language are ones like “For all  $x$ ,  $x$  is included in  $x$ ,” and ones in which “not” and “or” are used either inside or outside the quantifiers or both—“For all  $x$  and  $y$ , either  $x$  is included in  $y$  or  $y$  is included in  $x$ ” or “It is not the case that for all  $x$ , it is not the case that  $x$  is included in  $x$ ” (this last can be abbreviated to “For some  $x$ ,  $x$  is included in  $x$ ”). Tarski so defines “sentential function” as to cover sentences as special cases (they are simply those sentential functions in which all the variables are bound by quantifiers) and defines the “satisfaction” of a sentential function by a class or classes (a notion very like that of a predicate’s “applying to” an object) in such a way that the truth of a sentence becomes the satisfaction by *all* classes and groups of classes of the function which “is” the sentence in question.

To develop this in a little more detail: Tarski defines “sentential function” recursively, by saying that a variable followed by “is included in” followed by a variable is a sentential function, and so are expressions formed by joining sentential functions by “or” or by prefixing “It is not the case that” or a universal quantifier to a sentential function. “Satisfaction” is more complicated, for Tarski wishes to run together such cases as that the function “ $x$  is included in  $x$ ” is satisfied by the class  $A$  if and only if  $A$

is included in  $A$ ; “For all  $y$ ,  $x$  is included in  $y$ ” is satisfied by  $A$  if and only if for all  $y$ ,  $A$  is included in  $y$ ; “ $x$  is included in  $y$ ” is satisfied by the pair of classes  $A$  and  $B$  if and only if  $A$  is included in  $B$ ; “ $x$  is included in  $y$  or  $y$  in  $z$ ” by the trio of classes  $A$ ,  $B$ , and  $C$  if and only if  $A$  is included in  $B$  or  $B$  in  $C$ ; and so on. To cover all such cases he introduces the notion of an infinite numbered sequence of classes, numbers his variables, and says that the sequence  $f$  satisfies the function “ $v_m$  is included in  $v_n$ ” if and only if the  $m$ th member of  $f$  is included in the  $n$ th; the rest is done recursively— $f$  satisfies the negation of a function  $\Phi$  if and only if it does not satisfy  $\Phi$  itself, the disjunction of  $\Phi$  and  $\Psi$  if and only if it satisfies either  $\Phi$  or  $\Psi$ , and the universal quantification of  $\Phi$  with respect to the  $n$ th variable if and only if  $\Phi$  is satisfied both by  $f$  itself and by all sequences that are like  $f$  except in having a different  $n$ th term.

This last part of the definition is difficult but crucial. How it works can best be seen by considering a simple example. The function “ $v_1$  is included in  $v_2$ ” is satisfied by all sequences such that the first member is included in the second. The function “For any  $v_2$ ,  $v_1$  is included in  $v_2$ ” is satisfied by a sequence  $f$  if and only if  $f$  is one of the sequences satisfying the preceding function and the preceding function is still satisfied if we replace  $f$  by any sequence otherwise like it but with a different second term. This means, in view of what sequences satisfy the first function, that a sequence will satisfy the second function if and only if its first member is included in its second, whatever class that second member may be. Finally, consider the function “For all  $v_1$ , for all  $v_2$ ,  $v_1$  is included in  $v_2$ .” This is satisfied by a sequence  $f$  if and only if  $f$  satisfies the preceding function (the second) and if the preceding function is still satisfied if we replace  $f$  by any sequence otherwise like it but with a different *first* term. This means, in view of what sequences satisfy the second function, that a sequence will satisfy the third only if its first member is included in its second, whatever class either of them may be, that is, if and only if every class is included in every class. It is clear that if this function were satisfied by any sequence at all, it would be satisfied by every sequence whatever. (In fact, of course, it is not satisfied by all, and therefore not by any.) In some cases a sentential function will be satisfied by any sequence whatever, even though it contains free variables—as is the case with “ $v_1$  is included in  $v_1$ ”—but if it is thus satisfied and has all its variables bound—that is, is not merely a sentential function but a sentence—it will be, in Tarski’s sense, “true.”

TRUTH AND CORRESPONDENCE. Tarski goes on to consider a more complicated language in which there are variables of two logical types, and an ingenious extension of the notion of a sequence enables him to define “true sentence” for this language also; but when he comes to consider “languages of infinite order,” in which there are variables of an infinity of logical types, he has a proof (very similar to Gödel’s proof of the incompleteness of arithmetic) that any definition of either “truth” or “satisfaction” in terms of the basic material he allows himself would result in the provability of some sentence contravening his Convention  $T$ , that is, of the negation of some sentence of the form “ $x$  is a true sentence if and only if  $p$ ,” in which  $x$  is a name in the metalanguage of a sentence in the language studied and  $p$  is the translation into the metalanguage of the same sentence. Even with such a language, however, it is possible to introduce into the metalanguage the undefined semantic expression “true sentence” and so to axiomatize the metalanguage, thus enriched, that all sentences of the form indicated in the Convention  $T$  will be provable in it, and also desirable general theorems about truth, such as that “For any sentence  $x$ , either  $x$  is a true sentence or the negation of  $x$  is a true sentence.” “Truth,” introduced in this way, has something of the mysteriousness of the “correspondence” introduced without analysis by Moore, but Tarski has not merely a suspicion but a proof that, where “truth is understood as a property of sentences of the language in question, such acceptance of a semantic term without definition is inevitable.

### Bibliography

- Aristotle’s definition of truth is in his *Metaphysics* 1011b26 ff., and there are further discussions in *Categories* 4a10–4b19 and 14b12–23, and *De Interpretatione* 16a10–19. As to Aristotle’s Platonic sources, Plato states in the *Theaetetus* 188E–189A the problem solved in the *Sophist* 240D and 260C–263D.
- Thomas Aquinas’s echoes of Aristotle are in his *De Veritate*, Q. 1, A. 1, and *Summa contra Gentiles*, Book I, Ch. 59. Buridan’s *Sophismata* unfortunately has not been reprinted in modern times, but there are accounts of his treatment of the “liar” and similar paradoxes in E. A. Moody, *Truth and Consequence in Mediaeval Logic* (Amsterdam: North-Holland, 1953), and A. N. Prior, “Some Problems of Self-Reference in John Buridan,” in *Proceedings of the British Academy* 48 (1962): 115–126.
- G. E. Moore’s 1910–1911 lectures were published under the title *Some Main Problems of Philosophy* (London: Allen and Unwin, 1953); see especially Chs. 6 and 13–16. Bertrand Russell’s multiple relation theory of truth is developed in his “On the Nature of Truth,” in *PAS* (1906–1907): 28–49;

*Philosophical Essays* (London: Longmans, Green, 1910), Ch. 7; the introduction to the first edition of *Principia Mathematica* (Cambridge, U.K.: Cambridge University Press, 1910), pp. 42–45; and *Problems of Philosophy* (New York: Henry Holt, 1912). P. T. Geach's criticisms of the multiple relation theory are in his *Mental Acts* (London: Routledge and Paul, 1957), Sec. 13; Wittgenstein's, in his *Notebooks 1914–1916* (Oxford: Blackwell, 1961), pp. 21 and 96–97. Russell's recantation is in his 1918 lectures on *The Philosophy of Logical Atomism* (edited by R. C. Marsh), which is included in the collection *Logic and Knowledge*, also edited by R. C. Marsh (London: Allen and Unwin, 1956); see especially pp. 182, 187–188, 214, 218, 225–226. His “double correspondence” theory is in *The Analysis of Mind* (London: Allen and Unwin, 1921), Lecture 13. The more subtle views of the later Russell and Wittgenstein on propositions and facts appear in Russell's 1924 paper “Logical Atomism,” included in his *Logic and Knowledge* and in Wittgenstein's *Blue and Brown Books* (Oxford: Blackwell, 1958), pp. 30–38, and *Philosophical Investigations* (Oxford: Blackwell, 1953), Paras. 134 and 444.

The key passage from F. P. Ramsey is in his paper “Facts and Propositions,” included in *The Foundations of Mathematics*, edited by R. B. Braithwaite (London: K. Paul, Trench, Trubner, 1931), pp. 142–143. For later views of G. E. Moore, exhibiting some influence from Ramsey, see R. B. Braithwaite, ed., *The Commonplace Books of G. E. Moore* (London, 1962), pp. 228–231, 319, and especially 374–377. For the use of a Ramsey-type definition in the handling of paradoxes, see A. N. Prior, “On a Family of Paradoxes,” in *Notre Dame Journal of Formal Logic* 2 (1961): 16–32, and J. L. Mackie, “Self-Refutation—A Formal Analysis,” in *Philosophical Quarterly* (July 1964): 1–12.

Alfred Tarski's “The Concept of Truth in Formalized Languages” was first printed as a paper in 1931, then modified and enlarged in a German translation in 1935, of which there is an English version in his *Logic, Semantics, Metamathematics* (Oxford: Clarendon Press, 1956), Paper 7. Tarski states its main ideas less formally in “The Semantic Conception of Truth and the Foundations of Semantics,” in *Philosophy and Phenomenological Research* 4 (1944): 341–376. Notable comments on it include Max Black, “The Semantic Definition of Truth,” in *Analysis* 9 (March 1948): 49–63, and J. F. Thomson, “A Note on Truth,” in *Analysis* 9 (April 1949): 67–72.

## COSMOGONY

See *Cosmology*

## COSMOLOGICAL ARGUMENT FOR THE EXISTENCE OF GOD

The cosmological argument is actually a family of arguments that seek to demonstrate the existence of a sufficient reason or first cause of the existence of the cosmos. Among the proponents of the cosmological argument stand many of the most prominent figures in the history of western philosophy: Plato, Aristotle, Ibn Sīnā, al-Ghazālī, Maimonides, Anselm, Aquinas, Scotus, Descartes, Spinoza, Leibniz, and Locke, to name but some. The arguments offered by these thinkers can be grouped into three basic types: (1) what may be called the *kalam* cosmological argument for a first cause of the beginning of the universe; (2) the Thomist cosmological argument for a sustaining ground of being of the world; and (3) the Leibnizian cosmological argument for a sufficient reason why anything at all exists.

The *kalam* cosmological argument derives its name from the Arabic word designating medieval Islamic scholasticism, the intellectual movement largely responsible for developing this version of the cosmological argument. It originated in the efforts of Christian philosophers such as John Philoponus who, out of their commitment to the biblical teaching of *creatio ex nihilo*, sought to rebut the Aristotelian doctrine of the eternity of the universe. The argument aims to show that the universe had a beginning at some moment in the finite past and, because something cannot come out of nothing, must therefore have a transcendent cause that brought the universe into being.

By contrast the Thomist cosmological argument, named for the medieval philosophical theologian Thomas Aquinas, seeks a cause that is first—not in the temporal sense, but in the sense of rank. On Aquinas's Aristotelian-inspired metaphysic, every existing finite thing is composed of essence and existence and is therefore radically contingent. A thing's essence is a set of properties that serve to define what that thing is. Now if an essence is to be instantiated, there must be conjoined with that essence an act of being. This act of being involves a continual bestowal of being, or the thing would be annihilated. Essence is in potentiality to the act of being, and therefore without the bestowal of being the essence would not be instantiated.

For the same reason no substance can actualize itself; for in order to bestow being upon itself it would have to be already actual; a pure potentiality cannot actualize itself but instead requires some external cause. Although Aquinas argued that there cannot be an infinite regress of causes of being (because in such a series all the causes would be merely instrumental and so no being would be produced, just as no motion would be produced in a watch without a spring even if it had an infinite number of gears) and that therefore there must exist a first uncaused cause of being, his actual view was that there can be no intermediate causes of being at all, that any finite substance is sustained in existence immediately by the ground of being. This must be a being that is not composed of essence and existence and, hence, requires no sustaining cause. One cannot say that this being's essence includes existence as one of its properties, for existence is not a property, but an act, the instantiating of an essence. Therefore, one must conclude that this being's essence just *is* existence. In a sense, this being has no essence; rather it is the pure act of being, unconstrained by any essence. It is, as Thomas says, *ipsum esse subsistens*, the act of being itself subsisting. Thomas identifies this

being with the God whose name was revealed to Moses as "I am" (Exod. 3.15).

The German polymath Gottfried Wilhelm Leibniz, for whom the third form of the argument is named, sought to develop a version of the cosmological argument from contingency without the Aristotelian metaphysical underpinnings of the Thomist argument. "The first question which should rightly be asked," he wrote, "will be, *Why is there something rather than nothing?*" ("The Principles of Nature and of Grace, Based on Reason," §7, p. 527). Leibniz meant this question to be truly universal, not merely to apply to finite things. On the basis of his principle of sufficient reason (PSR) that "no fact can be real or existent, no statement true, unless there be a sufficient reason why it is so and not otherwise" ("The Monadology," §32, p. 539), Leibniz held that this question must have an answer. It will not do to say that the universe (or even God) just exists as a brute fact. There must be an explanation why it exists. He went on to argue that the sufficient reason cannot be found in any individual thing in the universe, nor in the collection of such things which is the universe, nor in earlier states of the universe, even if these regress infinitely. Therefore, there must exist an ultramundane being that is metaphysically necessary in its existence, that is to say, its nonexistence is impossible. It is the sufficient reason for its own existence as well as for the existence of every contingent thing.

## THE LEIBNIZIAN COSMOLOGICAL ARGUMENT

Undoubtedly, the most controversial premise in the Leibnizian cosmological argument is the PSR. The principle as stated in "The Monadology" has seemed, to many, evidently false. Not every fact can have an explanation, for there cannot be an explanation of what has been called the big conjunctive contingent fact (BCCF) that is itself the conjunction of all the contingent facts there are; for if such an explanation is contingent, then it, too, must have a further explanation; whereas if it is necessary, then the fact explained by it must also be necessary. But the explanation cannot have a further explanation, because the BCCF includes all the contingent facts there are; and the fact explained by it cannot be necessary, because the BCCF is contingent.

Some proponents of the cosmological argument have responded to this objection by abandoning the PSR and agreeing that one must ultimately come to some explanatory stopping point that is simply a brute fact, a being whose existence is unexplained. For example, Richard Swinburne (1991) argues that God, as the brute

ultimate, is the best explanation of why everything else exists, because as a unique and infinite being God is simpler than the variegated and finite universe.

But other theists have sought to defend the Leibnizian argument without retreating to the dubious position that God is a contingent being. They have either challenged the assumption that there is a BCCF or sought to provide an acceptable explanation of it. It may well be that the existence of a BCCF is inherently paradoxical (compare the set of all truths), so that its existence cannot just be assumed. But if there is such a fact, then the claim that its explanation cannot be found in a necessary truth presupposes that explanations must entail the facts they serve to explain. If some fact is materially implied by a necessary truth, then it may be explained by that truth without itself being necessary.

Some theists have suggested that the BCCF may be explained by the necessary truth that God has weighed the reasons for creating each world and has freely chosen which world to create. Moreover, the claim that the BCCF cannot be explained by some contingent truth assumes, even more controversially, that no contingent truth can be self-explained. The reason why the BCCF is true may be simply because each of its conjuncts is true; nothing more is needed to explain why the BCCF is true than the truth of its atomic constituents, each of which has an explanation for its truth. Or again, it may be supposed that the explanation for the BCCF is that God freely wills the BCCF. Because that explanation is itself a contingent fact, it is also a constituent of the BCCF willed by God. It may then be regarded as self-explained or its explanation may be that God wills that he wills the BCCF, which fact will also be a constituent of the BCCF to be similarly explained in terms of yet another conjunct. This regress seems to be as innocuous as a series of entailments such as its being true that it is true that *p*. The entire regress is contained in the BCCF and so is willed by God.

This debate is, in any case, somewhat academic because the cosmological argument does not depend for its success on anything so strong as Leibniz's own version of the PSR. For example, in their discussion of Hartry Field's anti-Platonist claim that it is an inexplicable contingency whether mathematical objects exist, Crispin Wright and Bob Hale (1992), while rejecting the demand for an explanation of something such as the BCCF, nevertheless maintain that explicability is the default position and that exceptions to this rule have to be *explicable* exceptions—some explanation is needed for why no explanation is possible. For example, they claim that if physical existence is at issue, Leibniz's question, "Why is

there something rather than nothing?" is an unanswerable question if a satisfactory explanation of why a physical state of affairs obtains has to advert to a causally prior situation in which it does not obtain, because a physically empty world would not cause anything. Wright and Hale believe that the demand for an explanation of the contingency of physical existence is preempted by the restrictive principle that "the explanation of the obtaining of a (physical) state of affairs must advert to a causally prior state of affairs in which it does not obtain" (Wright and Hale 1992, p. 128). Such a principle will be seen by the theist, however, as not at all restrictive, because the explanation of why the physical world exists can and should be provided in terms of a causally prior nonphysical state of affairs involving God's existence and will.

The proponent of the Leibnizian cosmological argument could generate an argument by holding, in conjunction with the above principle, that the obtaining of any physical state of affairs has an explanation. Or the proponent could claim that for any contingently existing thing, there is an explanation why that thing exists; or assert that everything that exists has an explanation of its existence, either in the necessity of its own nature or in an external cause; or, more broadly, maintain that in the case of any contingent state of affairs, there is either an explanation for why that state of affairs obtains or else an explanation of why no explanation is needed. All of these are more modest, nonparadoxical, and seemingly plausible versions of the PSR.

A simple statement of a Leibnizian cosmological argument might run as follows:

- (1) Anything that exists has an explanation of its existence, either in the necessity of its own nature or in an external cause.
- (2) If the universe has an explanation of its existence, that explanation is God.
- (3) The universe exists.
- (4) Therefore the explanation of the existence of the universe is God.

The version of the PSR in premise (1) is compatible with there being brute facts or states of affairs about the world. But there are two kinds of being: necessary beings, which exist of their own nature and so have no external cause of their existence, and contingent beings, whose existence is accounted for by causal factors outside themselves. Numbers might be prime candidates for the first sort of being, whereas familiar physical objects fall under the second kind of being.

Premise (2) is, in effect, the contrapositive of the typical atheist response to Leibniz that on the atheistic worldview the universe simply exists as a brute contingent thing. Atheists typically assert that, there being no God, the universe just exists inexplicably. Moreover, (2) seems plausible in its own right, for if the universe, by definition, includes all of physical reality, then the cause of the universe must (at least causally prior to the universe's existence) transcend space and time and therefore cannot be physical or material. But there are only two kinds of things that could fall under such a description: either an abstract object or else a mind. But abstract objects do not stand in causal relations. Therefore it follows that the explanation of the existence of the universe is an external, transcendent, personal cause—which is one meaning of “God.”

Finally, premise (3) states the obvious—that there is a universe. Because the universe exists, it follows that God exists.

It is open to the nontheist to retort that whereas the universe has an explanation of its existence, that explanation lies not in an external ground but in the necessity of its own nature; in other words, (2) is false. The universe is a metaphysically necessary being. This is an extremely bold suggestion. One may safely say that there is a strong intuition of the universe's contingency. A possible world in which no concrete objects exist certainly seems conceivable. People generally trust their modal intuitions on other matters with which they are familiar; if they are to do otherwise with respect to the universe's contingency, then the nontheist needs to provide some reason for such skepticism other than the desire to avoid theism.

### THE THOMIST COSMOLOGICAL ARGUMENT

Still, it would be desirable to have some stronger argument for the universe's contingency than modal intuitions alone. Could the Thomist cosmological argument help out here? If successful, it would show that the universe is a contingent being causally dependent upon a necessary being for its continued existence. The difficulty with appeal to the Thomist argument, however, is that it is difficult to show that things are, in fact, contingent in the special sense required by the argument. Certainly things are naturally contingent in that their continued existence is dependent upon myriad factors including particle masses and fundamental forces, temperature, pressure, entropy level, and so forth, but this natural contingency does not suffice to establish things' metaphysical contingency in the sense that being must continually be

added to their essences lest they be spontaneously annihilated. Indeed, if Thomas's argument does ultimately lead to an absolutely simple being whose essence is existence, then one may well be led to deny that beings are metaphysically composed of essence and existence if the idea of such an absolutely simple being proves to be unintelligible.

### THE KALAM COSMOLOGICAL ARGUMENT

But perhaps the *kalam* cosmological argument can reinforce the Leibnizian argument. For an essential property of a metaphysically necessary being is eternity, that is to say, existing without beginning or end. If the universe is not eternal, then, it could not be a metaphysically necessary being.

It may be countered that a being with a temporal beginning or end could be metaphysically necessary in that it exists in all possible worlds. But the notion of metaphysical necessity that underlies this suggestion fails to take tense seriously and may therefore seem inadequate. Metaphysicians have in recent years begun to appreciate the metaphysical importance of whether time is tensed or tenseless; that is to say, whether items in the temporal series are ordered objectively as past, present, or future, or whether, alternatively, they are ordered merely by tenseless relations of *earlier than*, *simultaneous with*, and *later than*. Possible worlds semantics is a tenseless semantics and so is incapable of expressing the significance of one's view of time and tense. In particular, it is evident that a truly necessary being, one whose nonexistence is impossible, must exist at every moment in every world. It is not enough for it to exist at only some moment or moments in every possible world; for the fact that there exist moments in various worlds at which it fails to exist shows that its nonexistence is not impossible. Furthermore, a truly metaphysically necessary being must exist either timelessly or sempiternally in any tensed world in which it exists, for otherwise its coming into being or ceasing to be would again make it evident that its existence is not necessary, even if it existed at every moment in worlds in which time had a beginning or end.

But it is precisely the aim of the *kalam* cosmological argument to show that the universe is not sempiternal but had a beginning. It would follow that the universe must therefore be contingent in its existence. Indeed, the *kalam* argument shows the universe to be contingent in a special way: It came into existence out of nothing. The nontheist who would answer Leibniz by holding that the existence of the universe is a brute fact, an exception to the PSR, is

thus thrust into the awkward position of maintaining not simply that the universe exists eternally without explanation, but rather that for no reason at all it magically popped into being out of nothing, a position that might make theism look like a welcome alternative.

The *kalam* cosmological argument may be formulated as follows:

- (1) Whatever begins to exist has a cause.
- (2) The universe began to exist.
- (3) Therefore, the universe has a cause.

Conceptual analysis of what it means to be a cause of the universe then helps to establish some of the theologically significant properties of this being.

Premise (1) seems obviously true—at the least, more so than its negation. It is rooted in the metaphysical intuition that something cannot come into being from nothing. Moreover, this premise is constantly confirmed in human experience. The conviction that an origin of the universe requires a causal explanation seems reasonable, for on the atheistic view, if the universe began at the big bang, there was not even the *potentiality* of the universe's existence prior to the big bang, because nothing is prior to the big bang. But then how could the universe become actual if there was not even the potentiality of its existence? It makes much more sense to say that the potentiality of the universe lay in the power of God to create it.

Often it is said that quantum physics furnishes an exception to premise (1), because on the subatomic level events are said to be uncaused. This objection, however, is based on misunderstandings. In the first place, not all scientists agree that subatomic events are uncaused. A great many physicists today are dissatisfied with this view (the so-called Copenhagen Interpretation) of quantum physics and are exploring deterministic theories like that of David Bohm (Cushing, et al, 1996). Thus, quantum physics is not a proven exception to premise (1). Second, even on the traditional, indeterministic interpretation, particles do not come into being out of nothing. They arise as spontaneous fluctuations of the energy contained in the subatomic vacuum, which constitutes an indeterministic cause of their origination. Thus, there is no basis for the claim that quantum physics proves that things can begin to exist without a cause, much less that the universe could have sprung into being uncaused from literally nothing.

Premise (2), the more controversial premise, may be supported by both deductive, philosophical arguments and inductive, scientific arguments. Classical proponents

of the *kalam* argument contended that an infinite temporal regress of events cannot exist, because the existence of an actually infinite number of things leads to intolerable absurdities.

It is usually alleged that this sort of argument has been invalidated by Georg Cantor's work on the actual infinite and by subsequent developments in set theory (e.g., Sobel). But this allegation gratuitously presupposes a Platonistic view of mathematical objects that the argument's defender is at liberty to reject. Cantor's system and set theory may be taken to be simply a universe of discourse, a mathematical system based on certain adopted axioms and conventions. The argument's defender may hold that whereas the actual infinite may be a fruitful and consistent concept within the postulated universe of discourse, it cannot be transposed into the spatio-temporal world, for this would involve counterintuitive absurdities. A fictionalist understanding of abstract objects or a divine conceptualism combined with the simplicity of God's cognition is at least a tenable alternative to Platonism.

A second argument for the beginning of the universe offered by classical proponents of *kalam* is that the temporal series of past events cannot be an actual infinite because a collection formed by successive addition cannot be actually infinite, an argument that eventually became enshrined in the thesis of Kant's first antinomy concerning time. Sometimes the problem is described as the impossibility of traversing the infinite. In order for one to have "arrived" at today, temporal existence has, so to speak, traversed an infinite number of prior events. But before the present event could arrive, the event immediately prior to it would have to arrive; and before that event could arrive, the event immediately prior to it would have to arrive; and so on ad infinitum. No event could ever arrive, because before it could elapse there will always be one more event that has had to have happened first. Thus, if the series of past events were beginningless, the present event could not have arrived, which is absurd.

It is frequently objected that this sort of argument illicitly presupposes an infinitely distant starting point in the past and then pronounces it impossible to travel from that point to today. But if the past is infinite, then there would be no starting point whatever, not even an infinitely distant one. Nevertheless, from any given point in the past, there is only a finite distance to the present, which is easily traversed.

But proponents of the *kalam* argument have not in fact assumed that there was an infinitely distant starting point in the past. The fact that there is *no beginning* at all,

not even an infinitely distant one, seems only to make the problem worse, not better. To say that the infinite past could have been formed by successive addition is like saying that someone has just succeeded in writing down all the negative numbers, ending at  $-1$ . And, one may ask, how is the claim that from any given moment in the past there is only a finite distance to the present even relevant to the issue? For the question is how the *whole* series can be formed, not a finite portion of it. To think that because every *finite* segment of the series can be formed by successive addition the whole *infinite* series can be so formed is to commit the fallacy of composition.

A third argument for the universe's beginning is an inductive argument based on contemporary evidence for the expansion of the universe. According to the standard big bang model, as time proceeds, the distances separating galactic masses become greater. It is important to understand that the model does not describe the expansion of the material content of the universe into a preexisting, empty space, but rather the expansion of space itself. This has the astonishing implication that as one reverses the expansion and extrapolates back in time, the universe becomes progressively denser until one arrives at a so-called singularity at which space-time curvature, along with temperature, pressure, and density, becomes infinite. It therefore constitutes an edge or boundary to space-time itself.

The history of twentieth-century cosmology has, in one sense, been a series of failed attempts to craft acceptable nonstandard models of the expanding universe in order to avert the absolute beginning predicted by the standard model. Whereas such theories are possible, it has been the overwhelming verdict of the scientific community than none of them is more probable than the big bang theory. There is no mathematically consistent model that has been so successful in its predictions or as corroborated by the evidence as the traditional big bang theory. For example, some theories, such as the oscillating universe (which expands and recontracts forever) or the chaotic inflationary universe (which continually spawns new universes), do have a potentially infinite future but turn out to have only a finite past. Vacuum fluctuation universe theories (which postulate an eternal vacuum out of which this universe is born) cannot explain why, if the vacuum was eternal, one does not observe an infinitely old universe. The no-boundary universe proposal of James Hartle and Stephen Hawking, if interpreted realistically, still involves an absolute origin of the universe even if the universe does not begin in a singularity, as it does in the standard big bang theory. More recently pro-

posed ekpyrotic cyclic universe scenarios based on string theory or M-theory have also been shown not only to be riddled with problems, but, most significantly, to imply the origin of the universe that its proponents sought to avoid. Of course, scientific results are always provisional, but there is no doubt that the defender of the *kalam* argument rests comfortably within the scientific mainstream.

A fourth argument for the finitude of the past is also an inductive argument, appealing to implications of physical eschatology. According to the second law of thermodynamics, processes taking place in a closed system always tend toward a state of equilibrium. The universe is, on a naturalistic view, a gigantic closed system, because it is everything there is and there is nothing outside it. What this seems to imply is that, given the probability that the universe will expand forever, the universe will in the finite future degenerate into a cold, dark, lifeless, highly dilute condition, as it asymptotically approaches equilibrium. Now if, given enough time, the universe will reach such a condition, then why is it not in such a condition now, if it has existed forever, from eternity? Because it is not in such a state, the universe must have begun to exist.

Some have tried to escape this conclusion by proposing an oscillating model of the universe that restores an appearance of youth to an infinitely old cosmos. But even apart from the physical and observational problems plaguing such models, the thermodynamic properties of such a universe imply the very beginning that its proponents sought to avoid—for entropy increases from cycle to cycle in such a model, which has the effect of generating larger and longer oscillations with each successive cycle. Hence, the oscillating model has an infinite future, but only a finite past.

Even if this difficulty were avoided, a universe oscillating from eternity past would require an infinitely precise tuning of initial conditions in order to last through an infinite number of successive bounces. A universe rebounding from a single, infinitely long contraction is, if entropy increases during the contracting phase, thermodynamically untenable and incompatible with the initial low entropy condition of the expanding phase. Postulating an entropy decrease during the contracting phase in order to escape this problem would require one to postulate inexplicably special low entropy conditions at the time of the bounce in the life of an infinitely evolving universe. Such a low entropy condition at the beginning of the expansion is more plausibly accounted for by the presence of a singularity or some sort of quantum creation event.

From the two premises it follows logically that the universe has a cause. Protagonists of *kalam* maintain that a conceptual analysis of what properties must be possessed by such an ultramundane cause enables one to recover a striking number of the traditional divine attributes, revealing that if the universe has a cause, then an uncaused, personal creator of the universe exists who sans the universe is beginningless, changeless, immaterial, timeless, spaceless, and enormously powerful. This creator will be, as Leibniz maintained, the sufficient reason why anything at all exists.

## COSMOLOGY

The term *cosmology* stands for a family of related inquiries, all in some sense concerned with the world at large. Two main subgroups of uses may be distinguished: those belonging to philosophy and those belonging to science.

"Cosmology" has received wide currency as a name for a branch of metaphysics, ever since Christian von Wolff, in his *Discursus Praeliminaris de Philosophia in Genere* (1728), gave cosmology a prominent place in his classificatory scheme of the main forms of philosophical knowledge and distinguished this branch from ontology, theology, and psychology. (See *Discourse on Philosophy in General*, translated by R. J. Blackwell, Indianapolis, 1963, Para. 77). Despite the severe strictures that Immanuel Kant leveled against the pursuit of rational cosmology in his *Critique of Pure Reason*, the term has continued to enjoy a standard use among many philosophers. For example, it occupies a central place in the manuals of scholastic philosophy; these adhere, for the most part, to the Wolffian scheme of classification of the branches of metaphysics. The term has been used, too, by many philosophers not in the scholastic tradition; for example, A. E. Taylor in his *Elements of Metaphysics* (London, 1903) assigns to cosmology the task of considering "the meaning and validity of the most universal conceptions of which we seek to understand the nature of the individual objects which make up the experienced physical world, 'extension,' 'succession,' 'space,' 'time,' 'number,' 'magnitude,' 'motion,' 'change,' 'quality,' and the more complex categories of 'matter,' 'force,' 'causality,' 'interac-

tion,' 'thinghood,' and so forth" (p. 43). Cosmology is sometimes understood even more broadly, as being synonymous with speculative philosophy in its most comprehensive sense. Thus in Alfred North Whitehead's *Process and Reality* (New York, 1929), whose subtitle is "An Essay in Cosmology," the attempt is made to construct a categorial scheme of general ideas "in terms of which every element of our experience can be interpreted" (p. 4).

In its second major use, the term *cosmology* designates a science in which the joint efforts of the observational astronomer and the theoretical physicist are devoted to giving an account of the large-scale properties of the astronomical or physical universe as a whole. The task of constructing models of the universe that are suggested by and tested by appeals to the observational findings of the astronomer distinguishes the enterprise of scientific cosmology from the a priori investigations of rational cosmology (as a branch of metaphysics) and the purely conceptual and categorial analyses of the speculative philosopher. Nevertheless, even scientific cosmology poses a number of philosophical questions. The sum of these—and they are principally methodological and epistemological in character—constitutes the philosophy of scientific cosmology. The present entry is concerned with the philosophy of cosmology in this sense. Attention will be focused on a central theme in this area: the question whether cosmology must employ a method different from that employed in other empirical sciences because of its distinctive subject matter, namely, the universe as a unique system.

#### DESCRIPTION OR EXPLANATION?

Is the familiar distinction between description and explanation (or the corresponding one drawn between sciences still in the early stages that are primarily descriptive, and those that have progressed to the predominating use of the explanatory aspects of theory) a distinction that can be profitably applied in giving an account of the logic of cosmology? No simple and unqualified answer can be given. For, on the one hand, cosmology, in attempting to gain knowledge of the universe as a whole, certainly is not content to rest with the observational reports of the astronomer, and therefore cannot be classed with the descriptive sciences. On the other hand, in advancing to the level of theory, as cosmology in a qualified sense certainly does, it is not primarily concerned with the explanation of laws—as is the case with other explanatory sciences.

If by description is meant giving an account of some single event or object in observational terms, or (in an extended sense of "description") formulating a generalization (law) in observational terms which refers to the observable or measurable properties and relations of a class of events, then cosmology, which is interested in giving an account of the universe as a whole, is not engaged in description. Even if we recognize, as we must, the descriptive activities of observational cosmology as a branch of observational astronomy, these fall short of giving us an adequate account of the universe as a whole. All that astronomy can give us is a description of the domain of objects and events within the range of its most powerful instruments. At the present time, however, these instruments, have not reached the limit, if there is a limit, to what is in principle observable. Moreover, even if the universe were in some sense finite and wholly explorable by actually or theoretically available instruments, the statement that what is thus observationally explored is in fact the universe as a whole would not be warranted by observational evidence alone. Such a statement could not, therefore, be part of the description of the universe, insofar as this description is a report of what is found. The claim that the universe is open to complete inspection requires the support of theory. It is a statement which is not included in the description, but is a rider to the description—to the effect that the description as given is of the universe as complete; considerations other than purely observational ones are needed to support this claim.

If cosmology is not content with description, does it then aim at giving explanations? Here our answer must be qualified. In the case of ordinary empirical generalizations, where there are multiple instances of some phenomenon of which we have examined a limited number, we say that the law supported by this evidence may be used as a reliable rule of inference. Since the law applies to a kind of subject matter, or a type of phenomenon, it can be upheld as a useful means for predicting and explaining those instances that can be brought within its scope. But in cosmology, the primary goal is not to establish laws. The universe, by definition, is a unique object or system. Cosmology does not undertake to establish laws about universes; at best one can establish laws about the constituents of the universe. The relation that the observable portion of the universe bears to the universe is that of part to presumed whole, rather than that of instance to law. Hence, if to explain means to bring an instance under a law, this mode of explanation, which is a characteristic concern of other branches of physical science, does not characterize cosmology.

Can it be said, then, cosmology aims at giving explanations in the sense in which theories are employed to explain laws? Here our answer, once more, cannot be a straightforward “yes” or “no.” The characteristic device employed by theoretical cosmology is a model of the universe, and a model in many respects functions precisely as a theory does. It is a conceptual construction that cannot be said to be a mere report of what is already found in observation, nor even an anticipated description of what might be found in future observations. Rather, it is a means for making the observational data themselves intelligible. However, the facts that the cosmologist wants to explain are not laws in the ordinary sense of the term, and so in this respect the purpose of a model of the universe is not identical with that of a theory in the ordinary sense.

Consider, for example, the question “Why is the apparent magnitude of galaxies correlated with their red shift?” This question asks for an explanation of an important datum of observation. The observed fact is sometimes called Hubble’s “law,” but it is a law only in the peculiar sense in which we refer to Kepler’s laws as “laws.” That is, Hubble’s law tells us something about a particular distribution or process of a unique set of objects, namely the system of galaxies, just as Kepler’s laws tell us something about the orbits of the planets in our solar system, not in any solar system. In general, however, laws of science are characterized by their universal form. They are unrestricted in scope and are not ostensibly tied to objects or events specifically located in some particular space-time region. Thus Newton’s law of gravitation, for example, says that for *any* two bodies, the gravitational force that holds between them is inversely as the square of their distance apart and proportional to their masses. Now when we deal with the system of bodies and processes that constitute the unique configuration we call the universe, we are not dealing with *any* configuration of events and objects; we are dealing with the configuration actually observed and given.

An interesting and important question that can be raised here, however, is whether the unrestricted laws of ordinary physics are not themselves, in a more profound sense, relatively restricted, since they apply to bodies or phenomena within the ultimately unique configuration that constitutes the physical universe. From this point of view, the study of cosmology sets the environment and limiting framework for all other branches of physical science. Hence it is not unreasonable to expect—as E. A. Milne, D. W. Sciama, and others have pointed out—that one may hope to understand the laws of physics them-

selves in terms of the unique background making up the universe studied in cosmology. Such a claim, however, is associated only with certain specific models, namely, the kinematic model as worked out by Milne and the steady state model as sketched by Hermann Bondi and Sciama, and therefore this idea of explaining all laws by a cosmological model cannot be held up as a working goal for all cosmological models. In fact, the majority of models developed within the framework of general relativity theory have not been designed to embody this feature.

## OBSERVATION AND THEORY

The study of cosmology has two lines of attack, that of the observational astronomer and that of the theoretical physicist. One might say that both the observational astronomer and the theoretical cosmologist are studying the universe, though from different vantage points, or that one supplies observational data about the universe that the other undertakes to interpret; but this is, at best, only a sketch of the situation and is in some ways seriously misleading. For it will not do to say that both the astronomer and the theoretical cosmologist are studying the universe, as if the universe is laid out for identification before them and the only difference between them is in approach and method. If we look more closely at the study of cosmology, the situation is rather different.

The observational astronomer is not confronted with the universe as an observationally complete whole. Instead, he obtains observational clues from various instruments about a large population of identifiable subsystems—namely, individual galaxies and clusters of galaxies. This population of observable entities is sometimes referred to as “the observable universe.” However, this phrase is not to be understood in the sense that we have independent means for identifying the universe and that we wish to refer to it insofar as it is being observed. “The observable universe” is not the same as “the universe observed.” What the astronomer reports on of relevance to cosmology is an observable population of galaxies and clusters of galaxies. These observational reports have to do with such matters as the spatial distribution of galaxies, their systematic motions, density, spectroscopic patterns, individual shapes, and stellar composition.

The population of subsystems that makes up the observable universe is now, as in a sense it must always be, a finite population. With the advance in the power and sensitivity of instruments, knowledge of the extent of this population and the refinement in the details of the reports about this population are improved. Although it is regarded as likely that further advances in observa-

tional resources will disclose a wider population of sub-systems similar to those already observed, it must be remembered that it is always possible for further observations to disclose as basic constituents of the universe astronomical units of a higher degree of inclusiveness than galaxies or clusters of galaxies, or even entities of an altogether different type from those heretofore disclosed. Whatever may be the case in the future, it certainly is the case at present that what comes within the observational reaches of the astronomer is definitely not the universe as an absolute whole, if there is in fact such a whole.

When we say that the theoretical cosmologist studies the universe in order to understand it or make it intelligible, what is it that he studies? He does not study the universe in any direct way, if that means having before him a readily identified object which he tries to comprehend, for example by subsuming it under some law. Nor, as we have just seen, does the universe he studies consist of a complete population of entities about which the observational astronomer furnishes him detailed reports. The theoretical cosmologist is not given information about the universe as a whole, nor even about what lies beyond the immediate range of the astronomer's instruments.

What then does he study? A brief and simple answer is to say that he constructs a model of the universe and that he studies the way in which this model may be used to interpret the observational data already available. The cosmologist will use his model to interpret the data assembled by the observational astronomer and to guide the astronomer in the search for further data. Insofar as the use of theoretical models proves satisfactory, we may say that cosmology has helped us to understand the universe and to make it intelligible. This is not to be understood, however, as meaning that even at the end of a relatively successful course of inquiry, the cosmologist has been able to confront the universe directly as some kind of readily identifiable object, system, or class of objects. What is to be understood by "the universe," in short, can only be approached and identified through the use of models, not independently of them.

## THE MODEL AND ITS CONSTRUCTION

The kind of model that the cosmologist constructs is wholly conceptual rather than material. It consists of different sorts of symbols including ordinary language, mathematical language, diagrams, and charts, all of which will normally be employed in presenting a given model. A model of the universe is not something that can be directly visualized or completely represented in a pic-

torial diagram. Consider, for example, a typical model in which use is made of a geometric mode of representation according to which the galaxies are treated as a set of mathematical points that trace out a set of geodesic curves in space-time. In this case, the metric of this set of points is given by the general Robertson-Walker expression for the space-time interval ( $ds$ ):

$$ds^2 = dt^2 - \left( \frac{R^2(t)}{c^2} \right) \left\{ \frac{dr^2 + r^2 d\theta^2 + r^2 \sin^2 \theta d\phi^2}{(1 + kr^2/4)^2} \right\}$$

where  $R(t)$  is the expansion factor,  $k$  is a constant whose value determines whether space is Euclidean or non-Euclidean,  $c$  is the velocity of light, and  $r$ ,  $\theta$ , and  $\phi$  are spatial coordinates. In addition to the specification of purely geometric or kinematic features, which are specified by introducing appropriate values for the curvature constant ( $k$ ) and the expansion factor ( $R(t)$ ), a model will also require some assignment of specific dynamic or gravitational properties to the entities thus represented. Additional formulas will then be required, and these will normally involve relativity theory or some equivalent branch of physics. It is clear that however much a simple diagram making use of dots and lines may serve to give us a visual representation of what we are talking about, this hardly suffices to encompass all those additional features of the model not included in the diagram.

Although the cosmologist cannot inspect the original, the universe itself, he nevertheless undertakes to make a model of it. How is this done? The answer is to be found by noting the various clues and sources to which the cosmologist appeals in determining the properties to be assigned to his model. These are of two principal types: observational clues provided by the astronomer, and theoretical principles thought to be of relevance to the cosmologic problem.

**OBSERVATIONAL CLUES.** In general, the observational data the astronomer gathers aid the cosmologist by suggesting ways of assigning certain idealized properties to the model, by providing empirically ascertained values for the constants and variables in the model, and by offering tests for the adequacy of the model as a tool for predicting observable matters of fact.

*Idealized properties.* The kinds of entities and their properties that the astronomer observes suggest to the cosmologist the lines to follow in developing a simplified and idealized conception of the universe. Let us take some examples. The galaxies, though of enormous physical bulk, may be considered for purposes of the model as

particles making up a continuous and perfect fluid. The advantage of treating the galaxies in this fashion is that it permits a great simplification of the problem, to which readily available mathematical tools of representation and calculation may be applied. Here, of course, the cosmologist adopts a technique that is universally adopted in other branches of physical science and with similar justification. If necessary, suitable corrections to this idealization can always be introduced when application is made of the model to “describe” the actual universe.

An important feature of the domain of galaxies already observed is their spatial distribution. The actual spatial distribution of the galaxies is roughly homogeneous and isotropic when fairly large volumes of space are considered. On a smaller scale, departures from homogeneity become more noticeable, in the clustering of the galaxies, for example. When still smaller volumes of space are investigated, homogeneity breaks down altogether. In general, then, the claim to the uniformity of distribution of galaxies can be upheld only if one takes a sufficiently large unit of volume, say  $3.5 \times 10^8$  parsecs in diameter. Yet in constructing his model, and as a first approximation, the cosmologist will assign a complete homogeneity to his model of the universe. The expression “cosmological principle” is commonly used to designate this feature of spatial homogeneity. Models that satisfy this cosmological principle, and thus possess the feature of spatial homogeneity, are known as uniform model universes.

When put into mathematical language, a uniform model universe is one possessing a constant curvature at a given moment of time. In the language of general relativity theory, since the density and pressure of material that make up the model are the same in all volumes of space at a given time, whatever their size, a geometric representation of this fact will involve the use of one or another of the spaces of constant curvature. All segments of space of the entire universe will have the same curvature. Such a model clearly requires a process of idealizing and simplifying the spatial distribution of bodies actually observed. For if we were to use the language of geometry to describe the actually observed spatial distribution, we should have to note the actual local departures from homogeneity or constancy of curvature.

In constructing a model of the universe that embodies the feature of spatial homogeneity or constancy of curvature, it is not enough to specify what that curvature is at the present moment of cosmic time. A fully determined model requires (in addition to other features) that the spatial properties of the universe be specified for any

point in its past or future. Here there are, broadly speaking, two possibilities. According to one, the spatial properties of the universe remain the same at all times; this view is upheld by those who adhere to the “perfect cosmological principle” and use it to define the properties of the steady state model. A second alternative is to adopt the cosmological principle in its more restricted form as designating merely spatial uniformity, as is the case with the orthodox cosmological models of general relativity. For such models, the entire history of the universe, from a spatial point of view, could be specified if one knew just one thing—the rate at which the distance between any two galaxies changes with time. In a universe characterized simply by the cosmological principle, since an observer would always find a spatially isotropic distribution of particles about him, the only basic feature subject to change is a temporally noticeable feature, namely, changes in the density of the distribution of particles. Such changes in the density might then serve to define a cosmic “clock.”

*Empirically obtained values.* A second important function that the appeal to observational data serves in the construction of cosmological models is that of yielding empirically obtained values for some of the constants and variables of theory. For example, in relativistic uniform models of the expanding universe, the defining characteristics of a particular model need to be specified by assigning values for the following quantities: the cosmological constant ( $\lambda$ ), the temporal pattern of the universe as determined by evaluating the function  $R(t)$ , the values for the velocity factor and the acceleration factor in the velocity-distance relation that specify how the galaxies are moving, the density ( $\rho$ ) and the pressure ( $p$ ) of the material and energetic content that fills the universe, and the curvature constant ( $k$ ). Observational evidence is, at present, either not available at all or not accurate enough to give sufficiently precise determinations for all of these terms. The cosmologist must, therefore, use whatever data is available to eliminate those models that are incompatible with present observations and to suggest lines of inquiry that will help to narrow the field down to those models that can be further tested by observation.

One overall condition for the acceptance of a model is, of course, the consistency of the empirically obtained values it proposes. In a particular model, a particular combination of empirically assigned curvature and density values, for example, may lead to a calculated “age of the universe” that will be inconsistent with an independently obtained estimate for the lower bound of such an “age”; the estimated time scale of the universe will be too

short. In general what is sought is a model all of whose empirically ascertainable values are mutually consistent within the available limits of accuracy.

*Empirical tests.* Finally, as a natural extension of the point just made, we see how the data obtained by the astronomer serve to test the calculated numerical values for quantities appearing in the cosmologist's equations or other qualitative predictions made on the basis of a given model. Thus whether the extremely remote galaxies at the horizon of the now observable population of galaxies have roughly the same characteristics as those that are nearer is an important question much discussed at the present time as a means for evaluating the rival claims of the steady state and evolutionary theories. The steady state theory claims that galaxies that are at the outer limits of observability should have roughly the same characteristics as those at lesser distances. According to various "evolutionary" models, those same remote galaxies, from which we receive light and other forms of radiation emitted billions of years ago, could, in effect, tell us about the earlier stages of the evolution of the universe. Since conditions at the time of emission were presumably different from what they are now, these very remote galaxies should display differences from those that are nearer to us in at least some of their properties, and these differences should give us valuable clues about the course of development of the universe as a whole. In this regard a number of delicate questions that are the subject of much controversy have arisen in current research.

**THEORETICAL IDEAS.** A second major source of ideas in the construction of cosmological models is to be found in the conceptual resources of mathematical physics. Here there are two broad possibilities that confront the cosmologist.

*Use of established principles.* As a first possibility, the cosmologist may turn to some already established body of physical theory as expressed in fundamental principles and derived laws. Such theory will normally have already been found to be successful in dealing with a variety of physical problems of lesser scope than, and wide differences from, the purely cosmological problem. The cosmologist will nevertheless propose to see to what extent the same general body of ideas may be used when applied to the distinctive subject matter of cosmology. He will investigate to what extent the universe as a physical system has a detailed structure that may be articulated and specified by means of the selected physical theory. For example, he may use Newtonian mechanics to construct a model of the universe. Isaac Newton himself drew, in a

general qualitative way, the cosmological consequences of using the inverse square law of gravitation as a guide. He argued that the universe, throughout its infinite space, must be filled by a more or less evenly distributed matter. For if all the matter that exists were to be confined to a finite "island" in an infinite "ocean" of space, it would have a center of mass toward which, in time, all matter would move by gravitational attraction. The fact is that no such motion is found, and Newton concluded, therefore, that matter is distributed uniformly throughout an infinite space.

At the present time, the primary and predominant source to which the cosmologist turns is the general theory of relativity as expressed in Albert Einstein's general field equations. These equations specify the relations between the space-time metric of any physical domain and its material or energetic content. The discovery of solutions to those field equations that are of special relevance to the cosmologic situation has led to the construction of several varieties of relativistic models. The other major use to which the field equations of general relativity have been put takes the form of the Schwarzschild solution. It was this solution that first afforded the opportunity for testing the predictive and explanatory powers of the theory as a whole. Karl Schwarzschild's solution is particularly applicable to a physical system such as we encounter in the solar system, namely, a single massive particle (the sun) in whose neighborhood we may study the behavior of much smaller masses (the planets) and light rays. The success of its predictions and explanations has been the primary basis for the confidence placed in the general theory.

To return then to cosmology: Within the broad class of homogeneous, or uniform, model universes we may distinguish the nonstatic models and the static models. Among the static models is Einstein's original model of 1917, which pictured the universe as finite and unbounded; in the light of the subsequent discovery of the mutual recession of the galaxies, it is no longer considered adequate. The nonstatic models include the ever-expanding-universe models that originate from zero or in some finite volume, and oscillating models that undergo alternate contractions and expansions. Within each of these groups, individuating characteristics for a particular model are to be found in the choice of values for the curvature, age, density, and cosmological constant. No single model has as yet been universally adopted.

*Creation of new principles.* The other broad possibility for furnishing theoretical ideas for cosmologic models is one in which the cosmologist, instead of appealing to

already established principles or laws, for example those of relativistic mechanics, undertakes to create afresh basic principles thought to be of special relevance to the cosmologic problem. By way of illustration, there is the conflict of the 1930s and 1940s between the way in which E. A. Milne sought to establish his kinematic model and the more orthodox procedures of relativistic cosmology. Although Milne did use the formulas of special relativity, he did not take these over directly from Einstein's own presentation; Milne attempted instead to derive them from what he thought of as more basic and primitive postulates. These postulates, he claimed, state the conditions for the measurement of time and for the communication of results by different timekeepers and observers.

A more recent example of the same sort of procedure is the steady state model of the universe proposed by Bondi and Thomas Gold in 1948. In support of this model, it is argued that since the universe is unique, there is no reason to believe that the laws which apply to smaller-scale physical phenomena, for example in laboratory terrestrial physics, or even in the domain of gravitational phenomena in the solar system, need be expected to apply to the universe as a whole. Therefore, instead of taking such laws as the point of departure in investigating the physical properties of the universe as a whole, it is suggested that the cosmologist can actually enjoy a far greater freedom than is believed possible in orthodox relativistic cosmologies. Let the cosmologist adopt any "laws" or principles which he believes are appropriate to the study of the universe as a whole, even though these may not have been established or confirmed in other (smaller-scale) areas of physical phenomena. The important thing is to see whether using these laws and principles leads to confirmable empirical results and whether they help to increase and deepen our understanding of the universe.

Those who favor this view (Bondi and Gold among others) determine some of the major features of the steady state model by appeal to the specially introduced postulate known as the perfect cosmological principle. This principle was not in prior use in other branches of physics but was introduced because of its special relevance to cosmology. (Fred Hoyle's model of the steady state universe proceeds along more conventional lines, at least in this respect. Although it differs from the expanding universe models of general relativity in abandoning the principle of the conservation of matter—in order to make possible the idea of the continuous creation of matter—it appeals for its basic physical principles, although

in modified form, to the field equations of general relativity.)

One general motive that seems to inspire the setting up of specially devised principles for cosmologic models is the desire to show that the science of cosmology is basic to all other physical sciences. Instead of appealing to other branches of physics for principles to be used in describing the features of the universe as a whole, it is thought desirable that one should be able, eventually, to show that the laws of ordinary physics can be linked with the properties of the universe as a whole. The universe would then disclose itself to be a unitary physical system within which it would be possible in principle to deduce ordinary physical laws from the principles of cosmology. Milne undertook to show how, for example, the inverse square law of gravitation, among other things, could be deduced from such more fundamental cosmological ideas. Similarly, within the framework of a steady state model, Sciama attempts to show how the local inertial properties of matter can be linked (as Ernst Mach originally proposed) with the distribution of masses in the universe at large.

From a logical point of view, there is no reason to discourage such efforts. On the contrary, the realization of such a goal would be of immeasurable significance for all of science, and one should in logic suspend judgment until such a program can be carried through with some fair degree of success.

Meanwhile, it is necessary to point out that some of the writers who favor this approach put methodological interpretations on the use and warrant for the specially devised principles that are not acceptable, whatever the eventual success or promise of the program as a whole. Thus Milne and Bondi, who support different models, are each concerned to stress what they take to be a special method for cosmology—as contrasted with other branches of physics. Milne, for example, thought of ordinary physics as employing an inductive method, whereas cosmology, he believed, should be based on a deductive method. Cosmology, he argued, should not employ the laws of ordinary physics to the extent that these are inductively warranted. This was his major complaint against what he took to be the faulty procedure of relativistic cosmologies founded on the "inductively established" principles of general relativity. In making this claim, Milne was in error, since the principles of general relativity theory are not, as he thought, ordinary inductive generalizations.

In fact, Milne's own appeal to "self-evidence" as the warrant for introducing his preferred cosmological prin-

ciples must be rejected, for the appeal is groundless and fails to support the certainty and uniqueness which he claimed for his principles. In constructing a model of the universe, the cosmologist is engaged in setting up a theoretical tool for dealing with the facts of observation. Whether he gets his theoretical principles by “borrowing” them from some other branch of physics or whether he creates them especially for the problem at hand is of secondary importance to what he does with these principles once he has them and how he evaluates the results he achieves. There is a common method that characterizes cosmology regardless of the particular model being proposed or favored, and it is precisely the same method which is employed in other branches of physics. Moreover, the same criteria of evaluation need to be brought to bear in the appraisal of results in cosmology as in other areas of science. Far from including any appeal to self-evidence or to similar rationalistic demands, a satisfactory model requires the constant support provided by observational evidence.

### COGNITIVE WORTH OF MODELS

Consideration of the goals set by scientific cosmology gives rise to a central philosophical question, that of determining the cognitive worth of any cosmological model. This is an epistemological question and may be put in terms of the traditional issues separating the realist and the conceptualist (or the instrumentalist). Should we say with the realist that cosmological models offer us an account of the structure of the independently existing universe, or, rather, should we say with the conceptualist that these models are simply useful means of presenting and interpreting observational data?

As a basis for clarifying the issue at hand, it will be helpful to point out a fundamental ambiguity in the use of the term *universe* itself. Employed without the qualifying adjectives “observed” or “observable,” it may have at least two quite distinct senses. One meaning of *universe* is “that to which the observed universe belongs”; another is “that which is characterized by a cosmological model.” So far as the realist is concerned, the two meanings are equivalent; in his view the universe defined by a cosmological model will be the same universe as the one described by the expression “that to which the observed universe belongs.” But the realist’s view of cosmological models cannot be assumed in advance to be the only tenable one. Thus the distinction suggested here has the merit of permitting us to keep this question open. If later a realist philosophy is accepted, the appropriate modifications can be made. Clearly, we do not need to commit

ourselves to the position that everything properly said of “the universe” in the sense of “that which is characterized by a cosmological model” can also be said of “the universe” in the sense of “that to which the observed universe belongs.” For example, we might want to attribute the property of being “a whole” or “an absolute totality” to the universe as characterized by a particular model, but not to the universe in the sense of that to which the observed universe belongs.

Cosmology aims at articulating the character of the universe *as a whole*. To that extent, then, it rests on the methodological postulate that the universe *is a whole*. The specific character of the whole will, of course, be variously described by various models. What remains fixed, however, is the assumption that the goal of cosmology is to characterize the universe *as a whole*. Therefore the statement “The universe is a whole” is in this context an analytic statement, a matter of definition. But note that it is a definition in which “the universe” is used to signify “that which is characterized by a cosmological model.” Not only does cosmology require that, as a matter of definition, the universe be thought of as a whole (in the sense of being intelligible in the way that mathematical classes, geometrical relations, or physical systems are); it also postulates that the universe as a whole is unique or absolute. This means that there is just one such class, pattern, or system, and that all other physical processes or systems of lesser duration or spatial extent are to be taken only as parts of this all-embracing whole. Since each model will so define the universe, it would be a misuse of language to speak of a plurality of universes. Again, of course, the precise structure of this unique or absolute whole will, at least in some respects, vary from model to model.

But what if “the universe” means “that to which the observed universe belongs”? Is the statement “The universe is an absolute, unique whole” still analytic? To this the answer must be no. For when we use “the universe” in this sense, we move from methodology to ontology. In contrast to the case of the universe as defined by a cosmological model, we are no longer committed by the basic methodological postulate of cosmology to saying that the universe *is a whole*. True, in setting up a science, it may be necessary to presuppose the existence of some pervasive structure as the object of study. Yet such a presupposition need not be binding on what the universe is existentially. So long as “the universe” means simply “that to which the observed universe belongs,” nothing in this meaning contains analytically the notion of its being a “whole” or an “absolute whole.” Indeed, even if we grant

that the observed universe is structured in some manner, this does not entail that the wider universe of which it is a part is also pervasively structured. Nor does the fact that we describe the observed universe as “part of” or “that which belongs to” something else require us to say that the universe to which it belongs is a unique or absolute whole. For our reliance on such terms as *part*, *whole*, and *belong* reveals merely that the mind, in reaching into the unfamiliar, must use analogies in order to relate the unfamiliar to what it already knows.

The universe as the “something more” than the observed universe may well be a complete, unique and intelligibly structured whole. But the claim that we are able to say so is something to which we need not commit ourselves. It is better left as an open question, since, strictly speaking, it is one on which we neither have nor can have any knowledge. Stipulating an affirmative answer by definition does not, of course, establish such knowledge.

Milton K. Munitz (1967)

## COSMOLOGY [ADDENDUM]

The key issue identified by Milton K. Munitz, whether cosmology should center on description or explanation, remains a central philosophical theme in the early twenty-first century. However, the context has changed dramatically since he wrote his entry, and that has changed the implications.

First, massive new data sets are available because of the extraordinary improvement of telescopes, detectors, and computer technology in the past three decades. Not only are optical, ultraviolet, and infrared observations of

galaxies possible in determining luminosities and spectra with unprecedented sensitivity but radio, X-ray, and gamma ray sky surveys are also possible. Galaxies have been detected up to a redshift of 6 and many quasar-stellar objects as well as multiple images of distant gravitationally lensed galaxies have been identified. Besides large-scale number-count and redshift surveys, the background radiation spectrum at all wavelengths have been measured. A key feature has been identification of cosmic blackbody radiation (CBR) with a perfect 3 degrees Kelvin (K) blackbody spectrum, which is isotropic to one part in 104 after allowing for Earth's motion relative to the rest frame of the radiation. Detailed observations have mapped its anisotropies over the whole sky at a sensitivity of better than one part in 105. Cosmology has changed from a data-poor to a data-rich subject.

Second, theory has developed dramatically, largely in a symbiotic relation with the observations, being used both to interpret them and to suggest new observations. This has happened in relation to gravitational theory, as regards astrophysics, and in relation to various branches of high-energy physics. This has changed the texture of cosmology from being essentially an exercise in geometry with an admixture of philosophy, to being a rich theoretical subject with relations to many branches of physics.

The cosmological application of Albert Einstein's theory of gravitation has been developed simultaneously. This theory predicted there must have been a start to the universe, but it was not clear if this was simply because of the special geometry of the standard (Friedmann-Lemaître) models of the universe, which are exactly isotropic and spatially homogeneous. More realistic models might show the prediction was a mathematical artifact. The singularity theorems developed by Roger Penrose and Stephen Hawking showed this was not the case: even for realistic geometries, classical gravitational theory predicts a beginning to the universe at a space-time singularity. Sophisticated perturbation theory was developed to underlie the theory of structure formation in the expanding universe, and dynamical systems studies related the behavior of whole classes of anisotropic models in suitable phase spaces, enabling identification of generic patterns of behavior.

The cosmological constant is a possible repulsive force term in the Einstein field equations. After Einstein discarded it in the 1930s, it was usually assumed to be zero until a decade ago, when observations of supernovae in distant galaxies showed the expansion of the universe is speeding up. The gravitational equations then imply presence of a cosmological constant or some equivalent

form of dark energy. There is no known physics reason why this force should exist at this level where it is just detectable—quantum field theory suggests it should be enormously larger. Perhaps the problem is that the wrong theory of gravity is being used.

Astrophysics studies the physics and evolution of galaxies, clusters of galaxies, and any intergalactic medium there may be. It has led to three important deductions. First, both the universe itself and the matter in it are evolving: Radio source counts preclude the steady state model proposed by Hermann Bondi, Thomas Gold, and Sir Fred Hoyle. Second, the dynamics of galaxies and clusters of galaxies is only compatible with observations if there is a large amount of dark matter present, felt by its gravitational effects but not emitting detectable radiation. In terms of the dimensionless density parameter,  $\Omega_{\text{dm}} = 0.3$ . This is less than the critical value = 1 separating universes that recollapse in the future ( $\Omega < 1$ ) from those that expand forever ( $\Omega > 1$ ) when the cosmological constant vanishes, but much greater than that for visible matter ( $\Omega_{\text{m}} = 0.02$ ). Third, the CBR is relic radiation from a hot early state of the universe, with matter and radiation held in tight equilibrium when the universe is ionized at redshifts greater than  $z_{\text{dec}} \approx 1100$ , but separately evolving for lower redshifts when electrons and nuclei are combined into atoms. The matter at  $z = z_{\text{dec}}$  formed the last scattering surface (LSS) in the early universe and emitted the CBR. The universe is opaque for  $z > z_{\text{dec}}$  but transparent for  $z < z_{\text{dec}}$ . Thus, the LSS delineates the visual horizon: One is unable to see to earlier times than its occurrence (because the early universe was opaque) or to detect any matter at larger distances than that one sees on the LSS (because of the speed of light limit on propagation of information).

The physics of the early universe (before decoupling) can be thought of in three stages. The hot big bang stage is the last one, when matter and radiation cooled from a high temperature ( $> 10^{12}\text{K}$ ) to 4000K on the LSS. Nuclear physics processes with pair production and weak interactions lead to a well-understood physical evolution. At about 109K nucleosynthesis took place: the creation of the light elements (deuterium, helium, and lithium) from protons and neutrons (heavy elements such as carbon only formed later in the interior of stars). Theory and observation are in excellent agreement provided the density of baryons is low:  $\Omega^{\text{bar}} = 0.02$ . This leads to an important conclusion: the much more abundant dark matter detected astrophysically cannot be ordinary matter made up of baryons. Many attempts have been made to identify its nature, but this is still unknown.

Particle physics processes dominated the preceding era when exotic processes took place such as combination of a quark-gluon plasma to produce baryons. Quantum field theory effects were significant then, and this leads to an important possibility: Scalar fields producing repulsive gravitational effects could have dominated the dynamics of the universe at those times. This leads to the theory of the inflationary universe, proposed by Alan Guth: an extremely short period of accelerating expansion preceding the hot big bang era, leading to a cold and smooth vacuum-dominated state and ending in reheating: conversion of the scalar field to radiation, initiating the hot big bang epoch. This inflationary process is claimed to explain some philosophical puzzles: why the universe is so special (with spatially homogeneous and isotropic geometry and a uniform distribution of matter) and why the space sections are so close to being flat (the sign of the spatial curvature is still unknown). This theory led to a major bonus: a proposal that initial tiny quantum fluctuations were expanded to such a large scale by inflation that they provided seeds initiating growth by gravitational attraction of large-scale structures such as clusters of galaxies. This theory makes clear observational predictions for the spectrum of CMB anisotropies, which have since been spectacularly verified.

Quantum gravity processes are presumed to have dominated the earliest times, preceding inflation. There are many theories of the quantum origin of the universe, but none has attained dominance. The problem is that there is not a good theory of quantum gravity, so all these attempts are essentially different proposals for extrapolating known physics into the unknown. A key issue is whether quantum effects can remove the initial singularity and make possible universes without a beginning. Preliminary results suggest this may be so.

Thus, the present dominant cosmological paradigm is a quantum gravity era followed by inflation, leading on to the hot big bang epoch and finally the observable universe domain. A wealth of observations supports this dominant theory, but some theoretical proposals are being made that have no observational support; sometimes it will be impossible to ever obtain such support. This happens both as regards physics and geometry.

The limits of physics testing are reached because accelerators on Earth attaining the energies relevant in the early universe cannot be constructed. Consequently, when considering physical processes at the time of inflation and earlier, the extrapolation of known physics into the unknown is relied on. Some things are assumed to be unchanged (e.g., the use of standard variational princi-

ples) and others as indefinitely mutable (any potential that is convenient may be used). Thus, the claimed link of cosmology to high-energy physics is potential rather than real. In particular, no specific particle or field has been identified as underlying inflation, and no experimental test is possible for the various mechanisms proposed for creation of the universe. There is only one universe, and what happens during a rerun with the same or different initial conditions cannot be observed.

The limits of what is observable is given by the visual horizon, as discussed by Munitz. However, most cosmological models make predictions of what lies beyond, and these predictions can never be observationally verified. This is particularly important in the case of the chaotic inflation theory proposed by Andrei Linde, which claims that the expanding universe domain is imbedded in a still-exponentially expanding inflationary universe in which there are embedded countless other expanding universe domains similar to this one, the whole forming a fractal-like structure. However those other domains cannot be seen, so this model is observationally unverifiable; furthermore, the underlying physics is experimentally untested. Adherence to this model implies the victory of theory over experimental tests and observational verification.

There is one case where this kind of spatial observational limit does not obtain. This is when a small universe occurs, that is, a universe that closes up on itself spatially for topological reasons and does so on such a small scale that one can see right round the universe since the time of decoupling. Then one can see all the matter that exists, with multiple images of many objects occurring. This possibility is observationally testable, and indeed there are weak hints in the CMB anisotropies that this could actually be the case. Checking if this is possible or not is an important task; the nature of the observational relationship to the universe is fundamentally different if it is true.

A key issue is whether the universe is special in geometrical and physical terms. The assumption that the universe is geometrically special was encoded in Edward Arthur Milne's cosmological principle, taken as a founding principle in cosmology until the 1960s. Then Charles W. Misner introduced the idea of a universe with generic initial conditions that was isotropized at later times by physical processes, giving a physical cause for its special geometry. This concept became central to the inflationary universe paradigm, but is only partially successful because universes that are anisotropic enough may never inflate and may not lead to ordinary thermodynamics. Some degree of geometric speciality must have occurred.

As regards physics, the key point is that only a restricted set of physical laws and boundary conditions will allow life to exist. This has led to the anthropic question: Why does the universe have that special character that is favorable to life? The only physically based answer is that there physically exists a multiverse: an ensemble of numerous universes with varying properties. If there is a large enough ensemble with enough variation, it becomes virtually certain that some of them will just happen to get things right so that life can exist. However, despite various ingenious suggestions, this proposal is observationally and experimentally untestable. Adherence to the multiverse idea to gain explanatory power is another triumph of theory and explanation over observational testing and description. There is no way to determine the properties of any other universe in the multiverse if they do indeed exist, for they are forever outside observational reach.

Some proposals claim there may be an infinite number of universes in a multiverse and many cosmological models have spatial sections that are infinite, implying an infinite number of particles, stars, and galaxies. This proposal involves, however, an idea that some have argued is incoherent. Thus, David Hilbert (1964), for example, argues that infinity is quite different from a very large number: The word *infinity* denotes a quantity or number that can never be attained, and so will never occur in physical reality. If so, then this last proposal is not only unverifiable, but such as cannot be true. On the contrary, many other scholars—such as José A. Benardete (1964)—argue that an actual infinity of things is possible.

## COSMOPOLITANISM

When the Cynic philosopher Diogenes of Sinope (c. 412–c. 323 BCE) was asked where he came from, he said "I am a citizen of the world" (Diogenes Laertius, *Lives of Eminent Philosophers*, bk. 6, chap. 63). The Greek term is "kosmopolitēs," the source of the English word "cosmopolitan." Cosmopolitanism is actually a range of views—moral, political, and cultural—affirming the importance and value of the community of all human beings. Against particular and local allegiance to the polis, city-state, or modern nation-state, the cosmopolitan would emphasize a general and far-reaching concern for humanity.

It remains unclear whether Diogenes' own view was meant to affirm a positive duty to humanity or only to deny the conventional obligations of citizenship associated with the polis. But the Greek Stoics, such as Zeno of Citium and Chrysippus in the third century BCE, developed the tradition by identifying the law of the cosmos with divine reason and extending world citizenship to everyone who lives in accordance with it. Roman Stoicism—especially as developed by Cicero, Seneca, Epictetus, and Marcus Aurelius—strongly influences modern cosmopolitanism by counting the possession of reason as a sufficient condition of membership in this foremost ethical community. Marcus Aurelius developed the idea of natural law as the common law of the polis of which all human beings are fellow citizens (*Meditations*, bk. 4). Nonetheless, the Roman Stoics readily acknowledged duties to one's country along with duties to humanity as a whole.

With advances of natural-law theory in the seventeenth century, international law, or the law of nations, got its first explicit modern statement in the theories of Hugo Grotius and Samuel Von Pufendorf. In the eighteenth century, Immanuel Kant, partly inspired by Stoicism, viewed all persons as members of a single community of rational agents, each of whom is free, equal, and independent. On these grounds he strongly criticized European colonialism and imperialism. In *Perpetual Peace* (1795), Kant argued for a federation of republics, each recognizing the human rights of all persons. (See Heater 1996 for a history of cosmopolitan thought.)

Cosmopolitanisms, as sets of moral, political, and cultural views, have developed significantly in the late twentieth century. Below are some of the most important arguments and distinctions made in recent debates, with particular emphasis on the core moral claims.

## MORAL COSMOPOLITANISM

Moral cosmopolitanism is characterized by three basic commitments. First, it is a species of moral individualism, maintaining that the basic units of moral concern are human individuals rather than groups or other collectivities. Second, it is egalitarian, holding that each individual counts equally from a moral perspective, that is, that no person is worth more than any other and that every person is entitled to equal consideration. Finally, cosmopolitans are moral universalists, who believe that the proper scope of moral concern encompasses all persons, regardless of their ethnic, racial, cultural, religious, and national affiliations. In short, moral cosmopolitanism affirms the equal worth of every human individual, quite apart from any subgroup to which they might belong, along with a commitment to impartial concern.

The great interest in these ideas is for their possible implications for an account of the basic moral and political obligations of persons. A dominant puzzle is the apparent contradiction between (1) widely recognized special obligations and associative duties, for example, ties to one's family members, friends, fellow citizens, and compatriots, and (2) general duties to individual human beings, regardless of membership in any of these communities. How are special duties compatible with the requirement of equal concern?

To address this question, it will be useful to flag two truths about cosmopolitanism. First, it can be defended by a deeper moral theory, including utilitarianism, a theory of human rights, contractarianism, and a Kantian account of fundamental obligations explained ultimately by the categorical imperative. Such defenses are exemplified by some of the most notable recent thinkers in this tradition: the utilitarian Peter Singer, the human-rights theorists Henry Shue and Thomas Pogge, the contractarian Brian Barry, and the Kantian Onora O'Neill. Charles Beitz is less easily classified: His moral cosmopolitanism at times has drawn on contractarian thought and lately has issued in a sustained focus on human rights as the appropriate language of international justice.

The second truth about cosmopolitanism is that it can come in strong and moderate varieties, both sharing a commitment to helping other human beings regardless of citizenship, nationality, ethnicity, race, religious affiliation, and geographical location (Scheffler 2001). Strong moral cosmopolitans believe that universalist, egalitarian individualism entails that the basic moral claims of all human beings are the same, and that any special regard for some persons over others must be justified by the role such regard plays in promoting the good of the human

community as a whole. As the prominent cosmopolitan Martha Nussbaum has said, the reason a cosmopolitan should show additional concern for the locals or fellow nationals "is not that the local is better per se, but rather that this is the only sensible way to do good" (1996, pp. 135–136). Moderate moral cosmopolitans, on the other hand, believe both that there are basic obligations toward all other human beings that each of us must recognize, and that particular affiliations—to family, nation, state, and so on—give rise to special duties justified independently of any instrumental value for promoting the good of humanity. On this view, associated duties do not derive from our universal duties to human beings in general.

David Miller's defense of nationality (1995, 2002) is a good example of a view strongly opposed to the idea that we have the same duties to each person in the world. For Miller, a nation is a community of belief, extended in history, active in character, tied to a particular homeland, and associated with a distinctive public culture. Compatriots share a common national identity and possess special reasons for recognizing duties to one another beyond those to persons generally. For one thing, nation-states involve institutionalized reciprocity, in which members contribute their efforts and wealth to the community for the benefit of fellow members. For another thing, nation-states pursue collective cultural projects involving distinctive choices about work, religion, and culture more generally, and these projects give rise to nationally different mixtures of burdens and benefits. The upshot of these two points is that fellow nationals owe to one another a range of duties that they do not owe to nonmembers, but these duties are compatible with the view that each person is due equal concern in virtue of their being human.

This dispute about the nature of cosmopolitan morality becomes especially acute in matters concerning just distribution. Here a range of views seem to deny the force or extent of cosmopolitan justice. Theorists such as Michael Walzer (1983) claim that these duties of distributive justice make sense only within the context of a community, such as a nation, within which the goods to be distributed are produced and shared. David Miller (1998) has defended the related view that some principles of distributive justice are comparative and some are noncomparative, and the comparative principles can apply only within communities and not globally. John Rawls (1999) has argued that the scope of distributive justice should be limited to the basic structure of a particular society conceived of as a self-contained cooperative venture for mutual advantage. On his view, justice beyond the nation-state is concerned with interstate rules aimed at

promoting toleration and peace worldwide, but questions about the distributive entitlements of particular individuals considered as such can gain no footing.

Such views seem to go beyond merely rejecting strong moral cosmopolitanism; they offer positive views that seem to minimize the substance of global duties of distributive justice. But it is precisely on the basic justice-related claims of individuals that something like strong cosmopolitanism appears most plausible. If one believes that all human beings possess the same rights to be free from torture, persecution, hunger, and homelessness, it seems natural to infer that our duties as human beings include aiming to bring about a world in which these rights are protected and promoted to the same extent for each and every person in the world. No amount of reciprocity between fellow nationals in one country can generate special duties to each other when there are countless foreign nationals suffering from deprivations of their basic interests. Moral cosmopolitanism and the idea of justice itself seem to share a fundamental commitment to impartial concern for all persons affected by an institutional framework. In a worldwide network of social, political, and economic institutions, distributive justice demands that each human being on the planet be entitled to concern from a perspective that includes their interests on a par with everyone else's. Special treatment for insiders is legitimate only if it can be justified to those excluded from it (Barry 1998, p. 145).

These sorts of considerations have led cosmopolitans to argue for strong obligations to alleviate the continuing dire suffering and death of millions of our fellow human beings. Peter Singer (1972) has defended the utilitarian view that we are morally required to stop such suffering where we can do so without sacrificing anything of comparable moral importance. The argument emphasizes the moral irrelevance of distance. A dying child on another continent obligates us just as much as a dying child next door. This cosmopolitan aspect of the case has been more readily accepted than the specifically utilitarian aspect of maximizing benefits, the demand for which has seemed difficult to square with commonsense views about the limits of moral obligation.

One influential line of argument proposed by Brian Barry (1973), Thomas Pogge (1989), and Charles Beitz (1999) has suggested that a consistent application of John Rawls's justly famous original-position argument for principles of distributive justice would lead in the direction of strong moral cosmopolitanism. If the Rawlsian veil of ignorance rules out knowledge of facts about oneself that unfairly skew one's choice of principles, then—

along with sex, race, class, and conception of the good—citizenship too ought to be obscured from the contractors' considerations. If principles of distributive justice should not privilege or disadvantage people on the basis of characteristics they possess for which they are not responsible, then their citizenship should not affect their life prospects. If Rawls is correct that inequalities should be allowed only when they maximally benefit the worst-off group, the scope of principles of justice should encompass the least advantaged in the world.

### POLITICAL COSMOPOLITANISM

There is a long tradition of favoring political institutions beyond the local or national—a view often allied with the need to promote global peace. While the positions of moral and political cosmopolitanism are distinct, political and legal proposals tend nonetheless to be linked to underlying moral views that emphasize the universal scope of concern for the interests of persons. Options for political cosmopolitanism take various forms, each an instance of the general institutional view that authority should be shifted from individual states to supranational political institutions (Beitz 1994, p. 124).

One option would be a single state encompassing the whole world. Immanuel Kant's rejection of a world state has been followed by later theorists, including John Rawls, who concurs with Kant's judgment that such a state would be either a global despotism or the backdrop for unending civil wars. But if duties to other persons have global scope, it seems reasonable to think that global institutions of some sort will be necessary to make sure that those duties are fairly distributed and that they achieve the goal of protecting human beings from avoidable harm.

Another approach is David Held's model of "cosmopolitan democracy" (2004), which envisages not a single world government but a range of reforms of international political and economic institutions in the name of democratic accountability, consent, and inclusiveness. Held's approach is distinctive in its appeal to democracy as the core value of global political legitimacy, but this is questioned by those who rank justice, rather than democracy, as the highest-ranking value underpinning any assessment of global political institutions.

### CULTURAL COSMOPOLITANISM

Cultural cosmopolitanism is a view about the conditions under which individuals can generate an identity and live a good life. It emphasizes that cultures are constantly changing and that individuals can benefit from mixing

elements from different cultural traditions. Strong cultural cosmopolitans believe that individuals can live well only by drawing on a range of cultural traditions and practices, while moderate cultural cosmopolitans hold that a range of good lives can be grounded in both this sort of openness to cultural variation and a more traditional, inward-looking existence with its settled cultural commitments (Scheffler 2001, Waldron 1992).

While the strong position is more contentious, both views deny that lives can be good only when lived within the confines of a particular cultural or national tradition. Consequently, this form of cosmopolitanism is relevant to evaluating cultural nationalism and its attendant claim to political self-determination (Caney 2005)

## CONCLUSION

The recent flourishing of cosmopolitan thought signals a recognition that any plausible account of politics, morality, distributive justice, and the good life for human beings should take seriously the idea that humanity is a community whose claims on us are both fundamental and far-reaching. A significant project for the future is developing a comprehensive account of the basis and implications of cosmopolitan political morality.

## COSMOS

From Anaximander on, early Greek philosophers regarded the structure and regular processes of the world as central to their accounts of nature. However, their understanding of this order differed considerably. These processes might be viewed as harmony or balance and as the result of growth or conflict or an intelligence, or they might be considered the result of random collisions of particles. The order might involve cycles or it might be a single continuous development from a primal state. In some philosophers, order itself exemplifies the goodness of the world. Many of these elements can be found in nonphilosophical cosmologies as well, such as the emergence of the world from waters in the Babylonian *Enuma Elish*, or the Genesis creation story. What distinguishes Greek philosophers is the variety of their attempts to describe the world as ordered, their reflection on what such an account must consist in, their consideration of

the role of divinity in their accounts, and the depth of their attempts to provide rich, unified, explanatory accounts of the world. Scholars do not know who first used the word “kosmos” to describe arrangements of the world or parts of it, but it came to be a common word in denoting this central concept.

Kosmos normally means “fine or beautiful arrangement or order” and can refer to an array of warriors, a haido, or a government; by extension, it can apply to cosmetic accessories or even to each of the ten officials in a Cretan senate (that is, the components of an arrangement). In Aristotle’s *Poetics*, it is a technical term for the spectacle of a play and also for ornamental diction. Early philosophers used the word to describe an order or arrangement in the world, but later “the kosmos” could refer to the world itself or at least to the most organized part of it, the heaven: “The kosmos is a system consisting of heaven and earth and the natures enclosed in these” (ps. Aristotle, *De mundo* 2).

The oldest extant, philosophical use of the word, to describe the balance of changes, occurs in Heraclitus (fr. 30), although a late doxographer, Aetius, says that Pythagoras was the first to name the enclosure of all things “kosmos.” Even if Aetius is right (the claim is rejected by most modern scholars), it is indeterminate whether in each case the philosopher meant to speak of all changing elements, or even all things, as an order (the general use) or instead of the arrangement of all things, the world (the privileged use). The latter seems unlikely in early authors, but becomes probable when Empedocles (fr. 134) speaks of intellect darting through the kosmos, and almost certain in Democritus, Diogenes of Apollonia, and Philolaus at the end of the fifth century. Hence, Xenophon could say around 385 BCE that Socrates did not discuss the nature of “the kosmos as the wise call it.” Similarly, Plato could have Socrates say that the wise call “kosmos” the whole of heaven, earth, gods, and man, as sharing community and friendship (*Gorgias* 507E–8A). A fundamental presupposition of the privileged use of “kosmos” is that the world is orderly and well arranged.

There is, however, a fundamental ambiguity even in the privileged use of “kosmos,” which also reflects philosophical debates about the nature of the world. In the fourth century BCE, “the kosmos” can be used to refer to the entire world or just the system of stars, planets, sun, and moon. For Plato and Aristotle, the sublunary world is unordered in comparison with the heaven and one task of the philosopher is to find the order it. The heaven is a better kosmos. But, depending on the interests of the text, the kosmos in some discussions might signify the entire

world. Thus Aristotle can also speak of “the kosmos encompassing the earth,” the region between the earth and the heaven (*Meteor.* A 2–8).

For Aristotle, as for most scientists until the sixteenth century, the world was spherical, consisting of three concentric layers, an outermost spherical shell for the fixed stars, then, contained within it, a spherical shell with the planets, sun, and moon and the apparatus by which they move (for Aristotle, an elaborate system of concentric spheres), and the sublunary sphere which has the earth as its center. Hence he distinguishes three senses of heaven (*De caelo* 9, 278b9–21), the limit of the periphery of the heaven or the spherical shell of the fixed stars (the first heaven), the spherical shell for the planets, sun, and moon are (the lower heavens), the sphere contained by the first heaven or the universe (all three layers). To these one may add the obvious first and lower heavens. It is plausible that in its privileged use, “the kosmos” could refer to any of these.

However, the universe need not be a kosmos, as is clear from ancient discussions of those philosophers who believed in many worlds, Democritus, Diogenes of Apollonia, and Epicurus. The many different systems of stars and earth are all “kosmoi,” but neither the disordered universe composed out of all of them nor what lies in between them is itself a kosmos. So too, for the Stoics, the universe is not a kosmos since the universe includes not just the finite world sphere, but also an infinite void outside. Only what they call “the whole,” the finite sphere encompassing the heaven and earth, is a kosmos (though within this “whole” there are three different arrangements they describe as a “kosmos”: god or the divine moving principle; the ordering produced by this god; and the unity of the two).

In Greek mathematical astronomy, the kosmos is just a mathematical object, so that the connotations of orderliness are irrelevant. The primary goal of Greek astronomers from Eudoxus (fourth century BCE) on include mapping the heavens, determining the sizes and distances of all the bodies of the world, and constructing geometrical models that explain the apparent motions and phases of the heavenly bodies. With few exceptions, such as heliocentric theories (Aristarchus, c. 270 BCE), the kosmos will be a rotating sphere with the earth as center and whose poles determine the daily rotation of the stars.

## COSTA, URIEL DA

(1585–1640)

Uriel da Costa, or Gabriel Acosta, an opponent of traditional religion, was born in Portugal to a New Christian family, that is, one forced to convert to Catholicism from Judaism. After completing studies at Coimbra, he held a minor church office. According to his autobiography, biblical studies led him back to Judaism, which he then expounded to his family as he deduced it from the Bible. The family fled to Amsterdam to escape the Inquisition and to practice their religion freely. Da Costa soon found that his biblical Judaism was in conflict with actual practices, which he claimed were too rigid and ritualistic. He attacked "the Pharisees of Amsterdam" and wrote a book arguing that the doctrine of the immortality of the soul was doubtful and unbiblical. The next year da Costa completed his *Examen dos tradiçoens Phariseas conferidas con a ley escrita* (Examination of the Traditions of the Pharisees Compared with the Written Law; 1624), a work considered so dangerous that the author was excommunicated by the Jews and arrested by the Dutch authorities as a public enemy of religion. He was fined, and the book was publicly burned. (Its contents can be reconstructed from a reply by Samuel da Silva.) In 1633 he sought readmission to the Jewish community. Though he had not changed his views, he needed the communal life, and so, he said, he would "become an ape among apes," and submit to the synagogue. However, he soon found himself doubting whether the Mosaic law was really God's law, and asking whether all religions were not human creations. He transgressed all sorts of Jewish regulations and observances, and finally was condemned for discouraging two Christians from becoming Jews. He was again excommunicated. In 1640 he submitted once more and underwent the most severe penance, first recanting

before the whole synagogue, then receiving thirty-nine lashes, and finally lying prostrate while the congregation walked over him. He then went home, wrote his autobiography (*Exemplar Humanae Vitae*), and shot himself.

Da Costa's tragic career has made him a symbol of the dangers of religious intolerance, as well as a precursor of modern naturalism and higher criticism. One romantic painting shows him as a kindly scholar, holding young Benedict de Spinoza on his knee, teaching him.

Almost all our information about da Costa comes from his autobiography, published in 1687 from a Latin manuscript. It is not known if it is the original text or an altered version. Very little other data have turned up concerning his actual relations with Amsterdam Jewry or Spinoza. I. S. Révah's 1962 study, based on Portuguese Inquisition records, indicates that da Costa's initial conversion was not, in fact, from Catholicism to biblical Judaism, but rather to a peculiar Iberian form of crypto-Judaism. Then, Révah suggests, in Amsterdam da Costa developed first a biblical Judaism, and later a variety of deism or natural religion.

Da Costa's influence, from the eighteenth century onward, has been mainly on religious liberals opposing traditional orthodoxies. It is his martyrdom, rather than his doctrines (which we hardly know), that has affected people. Considering the many intellectuals gruesomely killed by Protestants and Catholics, it is odd that da Costa has stood out as *the* example of a freethinker destroyed by religious bigotry. Possibly Enlightenment and romantic thinkers could better accept a hero victimized by Judaism than one victimized by their own previous Christian traditions.

## COUNTERFACTUALS

See Appendix, Vol. 10

## COUNTERFACTUALS IN SCIENCE

The term *counterfactual* is short for "counter-to-fact conditional," a statement about what would have been true, had certain facts been different—for example, "Had the specimen been heated, it would have melted." On the face of it, claims about what would or could have happened appear speculative or even scientifically suspect because science is an investigation of reality grounded in experimental evidence, and by definition people have experimental access only to the actual universe. Yet, despite their implicit reference to alternative possibilities, many counterfactuals are scientifically respectable because the criteria determining whether they are true depend wholly on facts about the actual universe. Counterfactuals are often important in science because they appear implicitly in the definitions of certain specific concepts such as "solubility" and "biological fitness," and because they are closely related to general scientific notions such as "law of nature" and "causation."

The exact definition of *counterfactual* is controversial. In philosophy, a counterfactual is a statement that can be paraphrased in the form, "If *A* were true, then *C* would be true." They are distinguished from indicative conditionals, which take the form, "If *A* is true, then *C* is true." The difference in meaning consists roughly in the kind of facts one keeps fixed when considering the hypothetical situation *A*. To evaluate "If Napoleon Bonaparte had been born in Spain, France would have been ruled by democrats," one imagines Napoleon for some reason being born in Spain instead of Corsica and then speculates about alternative histories for France, ignoring what is known about the specifics of Napoleon's actual reign of power. But when evaluating the indicative, "If Napoleon

was born in Spain, France was ruled by democrats," one can imagine that somehow historians have made a mistake on this one issue of Napoleon's birth and retain other things known about Napoleon, such as his undemocratic rule of France.

Despite the clear difference in meaning between these two particular sentences, there is significant controversy about whether the distinction between indicatives and counterfactuals makes sense in general and whether it is the best way to categorize conditionals. Associated with such debates are subtleties regarding how truth applies to counterfactuals. For example, the name "counterfactual" is misleading in that one can use counterfactuals for situations that are known to be true. Believing "If the fish had mutated, it would have survived," is consistent with believing the fish did mutate. So, counterfactuals are not only about counter-to-fact possibilities, but sometimes about actual situations as well.

### RELATION TO LAWS

What makes counterfactuals especially suitable for science is that the truth of counterfactuals depends largely on the general patterns that science aims to describe. One can reasonably say that a particular sample of salt is soluble in water even when the salt has never been dissolved and never will, on the grounds that because of its chemical structure, had it been placed in a sufficient amount of pure water, it would have dissolved. One is justified in making claims about what the salt counterfactually would have done in virtue of what other similar samples of salt have actually done and that person's knowledge of nature's regularities. In this way, the laws of nature can be understood as governing not only actual happenings but also what may have happened.

In one early philosophical treatment, Nelson Goodman tried to explain counterfactuals as a kind of elliptical expression. He thought counterfactuals such as, "Had I struck this match, it would have lit," should be understood as, "I struck this match and the laws of nature are true and ... logically entails that the match lit," where the ellipses represent some unstated but true facts. In a typical situation one may complete the sentence as, "I struck this match, and the laws of nature are true, and the match was dry, and there was sufficient oxygen in the air, and the match had the proper chemicals in the tip, entails that the match lit." The value of Goodman's account is that it captures the idea that counterfactuals in science express consequences of actual or hypothetical facts following from the laws of nature.

A major problem with this account, as Goodman himself recognized, is that it fails to give any constructive advice about how to pick out the right facts to insert into the ellipses. Why should one insert the fact that the match was dry and infer that the match would have lit, rather than insert that the match did not light and infer that the match would have been wet? Because there is no principled way of answering this question, Goodman's theory is of limited value as a guide to determining the truth of counterfactual statements. Also, because many counterfactuals have nothing to do with laws ("If the circumference were only half as large, the radius would be ...") and some require the actual laws to be abandoned ("If there were no friction ..."), the elliptical account is not a general account of counterfactuals, and it was not immediately obvious how it would fit into a larger account.

### SIMILARITY APPROACHES

The dominant approach to elucidating the meaning of counterfactuals is to think of them as having truth conditions given by similarity relations among possible worlds—that is, hypothetical universes—and more controversially that some more or less tractable notion of similarity tells how to evaluate specific counterfactuals. The justification for this is primarily formal. Robert Stalnaker and David Lewis developed a compelling family of logic systems describing counterfactual conditionals that do a remarkable job of justifying a wide range of intuitively plausible reasoning patterns. It is a feature of the logic that it can be interpreted using a notion of similarity among possible worlds. The way it works roughly is that the counterfactual "If *A* were the case, then *C* would be the case," is true when the worlds most similar to actuality among those where *A* is true are also worlds where *C* is true. Consider, "If this bird had three legs, it would have more legs than wings." The worlds where *A* is true are all the worlds where the bird has three legs, including worlds where it has three legs and three wings, worlds where it has three legs and four wings, and worlds where it has three legs, two wings, transparent feathers and a metallic beak. Intuitively, the minimal departure from actuality is for it to have one extra leg without any change to its wings, and so using common sense, one would say this counterfactual is true.

This illustration of how to determine whether a counterfactual is true involves an appeal to one's offhand, pretheoretical judgements of similarity, an appeal not mandated by the role similarity plays in the formal logic. It is a significant speculative leap to suppose that which counterfactuals are true depends on what human beings

find similar. Nevertheless, inspired by David Lewis's work, there has been a serious philosophical research program dedicated to finding a plausible refinement of people's ordinary similarity concept to justify the usage of counterfactuals and more important to use counterfactuals in elucidating other concepts, such as causation.

### CAUSATION

A large part of science is figuring out what causes what. The role of counterfactuals in this project is to express dependencies among logically independent elements of reality, dependencies that are often causal. In the vast literature on causation, counterfactuals appear in different roles, not all of them central. One tradition concerning causation is to take causal connections between facts or events to be primitive elements of reality holding together the pattern of various particular facts. In this tradition, counterfactuals are not crucial to the formulation or definition of causation, although they are useful for expressing consequences of causal relations.

Where counterfactuals become most important are in theories where causes are understood as the byproduct of physical processes that are themselves not fundamentally causal in nature. This tradition is compelling because fundamental physics uses equations establishing mathematical relationships between physical entities in a way that does not obviously indicate what causes what. Here a theory about counterfactual relationships between events can be constructed as part of a story that tells how the mathematical relations in physics could possibly account for truths such as "Lightning causes thunder."

Some theories of causation are literally counterfactual accounts of causation. They argue that the causal connection is really due to a counterfactual dependence relation. An event *E* counterfactually depends on the event *C* whenever if *C* had not happened, *E* would not have happened. In one famous version of the theory—by David Lewis—causation is identified with having a chain of events that are counterfactually dependent on one another, but other variations on the connection between causation and counterfactual dependence are possible. While counterfactual accounts need to successfully explain many aspects of causation, for them to be even superficially plausible, they need to explain the causal asymmetry—why in ordinary circumstances causes precede their effects. In counterfactual accounts, the difficult part of that explanation is to say why in an ordinary case of causation such as lightning causing thunder, one does not also have the lightning counterfactually depending

on the thunder, wrongly entailing that thunder causes lightning.

Explaining why thunder does not cause lightning is difficult if one follows the orthodoxy of using anthropocentric ideas of similarity as a guide to counterfactual truth. It is plausible that lightning counterfactually depends on thunder because a possible world with a bolt of perfectly silent lightning is intuitively stranger than a world with just one less bolt of lightning. This shortcoming for the counterfactual account of causation may be corrected by giving up on using naive judgements of similarity and instead concocting a suitable theory of similarity that fits the needs of causation. David Lewis's theory in "Counterfactual Dependence and Time's Arrow" (1979) has been a popular model for developing such an account. In following this strategy, the attempt is to defend the more general hypothesis that counterfactuals ordinarily exhibit a temporal asymmetry that in turn explains the difference between cause and effect.

### COUNTERFACTUAL ASYMMETRY

When one considers how things may have been had only  $X$  not happened, typically one envisions alternate histories with an identical past where for some reason  $X$  did not happen. One then speculates how these alternate histories may have played out, leaving the future as open as the laws and circumstances allow. The practice of evaluating counterfactuals this way is asymmetric, treating the future but not the past as counterfactually dependent on the present.

Because there are counterfactuals having nothing to do with time, such as "If the variable  $x$  had been equal to three, then  $x+1$  would have been equal to four," it is known that time asymmetry is not a part of the logic or meaning of counterfactuals per se. In a sense, it is wholly up to a person to choose whether he or she evaluate a given counterfactual symmetrically or asymmetrically. Nevertheless, it is an objective fact that nature tends to reward people for using the asymmetric ones. For example, it is sometimes useful to think, "If I were to shield myself now, I would avoid the next volley of arrows," and not so useful to think, "If I were to shield myself now, I would have avoided the previous volley." In this sense, counterfactual asymmetry is a natural fact perhaps amenable to scientific explanation. The project is to determine which physical structures vindicate the practice of evaluating counterfactuals asymmetrically. This includes determining to what extent the asymmetry is an aspect of people's particular perspective on nature, and to

what extent the asymmetry is a feature of broader physical conditions and laws.

One idea is that there are fundamentally random processes that make the future chancy in a way that the past is not. This is problematic because although chances seem to imply a sense of openness for the future, it is not clear how chances imply a fixed past. Perhaps the intuition about chance in this case presupposes a theory where the past is given special fundamental significance as being in some sense more real than the future, or real in a different way. Spelling out such a deep metaphysical difference between past and future has proven difficult in itself, and clarification of its connection to chances has been problematic because the application of chances in science does not seem to require any such distinction.

Another group of proposed candidates for the explanation do not take counterfactual asymmetry to be a fundamental fact about reality or time itself, but as a contingent feature of the particular environment. A suggestion by Lewis is that typical processes exhibit a pattern where future facts "overdetermine" past facts in the sense that they give redundant evidence of the past. For example, after an explosion, there are many fragments around, each of which individually suggests an explosion, but there are often only a few facts beforehand that imply an explosion will occur—for example, a burning fuse.

Another idea is that counterfactual asymmetry is explained by cosmological facts, such as the universe is expanding from a smooth distribution of matter just after the big bang. This idea draws some plausibility from nature's two classes of time asymmetries. The first kind is a local asymmetry—a fact that applies directly to the physical process taking place. Examples of this first kind include chancy transitions in the physical state, and time-asymmetric evolutions such as one sees in certain high energy particle experiments involving weak decays. The second kind is an asymmetry in the boundary conditions. Irreversible phenomena such as mixing gasses or a hot and cool object settling to a single temperature are explained only when one posits special boundary conditions. Specifically, the explanation for why people regularly see thermodynamic asymmetries comes by way of the physics of the distant past being constrained in a way that the future is not. The connection to counterfactuals is that one's reason for thinking that causation is asymmetric comes from one's experience with asymmetric macroscopic phenomena, exactly the kind of phenomena whose asymmetries are explained by boundary conditions and not by local asymmetries. Hence, it is plausible to think that special facts about the beginning of the uni-

verse are a critical component of why counterfactuals and causation treat the past as more fixed—that is, why nature rewards people for evaluating counterfactuals in a way that treats the past as fixed.

These strategies that attempt to explain counterfactual asymmetry by way of contingent physical circumstances are interesting in that they allow for at least some counterfactual dependence of the past on the future. This seems reasonable because one wants to allow for counterfactual differences that arise from ordinary processes. If the population were greater right now than it actually is, this would have been because people would have had more children, not because people would have magically popped into existence. While having some counterfactual dependence of the past on the present is good for matching up the theory of counterfactual evaluation with pretheoretical intuitions about counterfactuals, it highlights a difficulty with the desired uses of counterfactual asymmetry. If the past counterfactually depends on the present, and the difference between cause and effect is purely given by the counterfactual asymmetry, then one would seem to have backwards causation, such as thunder causing lightning. So either counterfactual asymmetry can't do the job of grounding the cause-effect asymmetry or causation is a less robust notion than is ordinarily thought, defined with respect to a temporal asymmetry that at best is justified only in certain special cases—for example, human decisions—where there is little or no significant backwards dependence.

## COURNOT, ANTOINE AUGUSTIN

(1801–1877)

Antoine Augustin Cournot, the French mathematician, economist, philosopher, and educator was born in Gray, Haute Saône. He was educated at *collèges* at Gray (which now bears his name) and Besançon, and at the École Normale Supérieur in Paris. In addition to teaching at the universities of Lyon and Paris, he was head of the *Académie* at Grenoble and rector of the *Académie* at Dijon and succeeded André Marie Ampère as inspector general of studies. An able student of mechanics (including astronomy) and of mathematics, he applied probability theory to problems in both the physical and the social sciences. His work in economics early secured his reputation in that field, and he is now generally regarded as a founder of econometrics; as a philosopher he remains much less known.

Cournot is identified by Jean de la Harpe as a critical realist. This designation would be peculiarly appropriate were it not for the fact that this name has been taken by a group of American philosophers whose position is notably unlike that of Cournot in important respects. Since the term *critical realist* is equivocal, it may be advisable to refer to Cournot as a critical rationalist. Cournot is a realist of sorts in his metaphysics and more rationalist (albeit critically so) than empiricist or positivist in his epistemology. For him knowledge is a function of reason. The senses furnish neither the basis nor the criteria of knowledge, which not only can but does extend beyond their limits. Yet the senses do make important contributions to knowledge, especially by restraining its claims by challenging overextended speculations by confronting them with what William James aptly called "brute facts." Cournot rejects all dogmatic philosophies, whether rationalist or empiricist. Knowledge requires a continuing appraisal of all principles to determine both their grounds and the range of their legitimate applications. Specifically, he examines the established sciences to see whether they have any basic concepts in common. He discovers three such concepts—order, chance, probability. These three concepts lie at the heart of Cournot's philosophy and suffice to account for his rejection of many earlier and contemporary alternative positions. He rejects the idealistic basis and implications of Immanuel Kant's philosophy, but he accepts the critical intent of the Kantian program.

For Cournot, order is a basic category which, as "objective reason," relates to the nature of things and, as

“subjective reason,” to the means through which we apprehend that nature. The major function of philosophy is to examine and criticize the efforts of subjective reason to know objective reason, making sure among other things that such closely related and often confused principles as “reason” and “cause,” “rational order” and “logical order,” are clearly differentiated in both their meaning and their function. We have knowledge when we apprehend the objective reason of things, but such knowledge is rarely complete and certain. Therefore, our knowledge is relative and probable, not absolute and apodictic, but it nonetheless rests on objective grounds, not on forms or categories native to the mind itself.

Cournot’s unusual and cogent use of probability draws attention to a fundamental moderating element in his philosophy. His treatment of probability is developed most extensively in his *Exposition* (1843) and is used ingeniously and productively in his *Essai* (1851), *Traité* (1861), and *Matérialisme, vitalisme, rationalisme*. Long before putting these views to philosophic use, Cournot had applied them to problems in astronomy and in various fields of social studies, notably in economics, where he applied them with lastingly important results.

The calculus of probabilities is related to both order and chance. Both order and probability have plural meanings. Order as a category of the objective reason of things must not be confused either with logical order—that is, with the order essential to a formal system of ideas—or with causal order, by which Cournot means essentially what Aristotle called “efficient cause.” The reason for a phenomenon must be distinguished from its cause, from the conditions or circumstances which give rise to it. *Cause* is related to the particular and unique; *reason* is related to the universal and abstract aspects of phenomena that are the ground for laws of general and fundamental relations among them, relations that are necessary, but not in themselves sufficient, conditions for the production of specific phenomena. Probability is of two sorts, mathematical and philosophical. Mathematical probability applies to those relatively rare situations in which the number and relative frequency of various possibilities can be numerically determined. Philosophical probability—which may attain practical, but never demonstrable, certainty—applies to the vastly more numerous cases in which such numerical determination is not possible. It involves an appraisal of evidence in terms of rational cogency where probabilities persuade and win the acquiescence of reasonable persons even though the relevant evidence is neither quantifiably manipulatable nor conclusive. We live continuously and

inescapably with such probabilities; philosophical criticism is also largely concerned with them. In either case probability is a function of objective factors and conditions and not solely of our ignorance or other subjective factors, although these do contribute to our need to deal with probabilities of both types.

Of Cournot’s three basic ideas, that of chance is least adequately developed. It is unfortunate that there is no specific and clear definition of this concept in its theoretical function, yet what the concept refers to is not at all unclear. Numerous examples leave no doubt about the meaning of the term as Cournot uses it. A chance occurrence is one in which there is an unpredictable conjunction of independent series of events, each series being internally related and having a determinable nature. However complete our knowledge of each independent series, events resulting from unpredictable conjunctions among them are contingent, unpredictable, fortuitous. Such events have causes, but they are not reducible to laws. The absence of reasons for such events is irreducible, chance, like order, being an objective feature of the nature of things. This doctrine is one source of the pluralism in Cournot’s philosophy. In it he anticipates Émile Boutroux and suggests certain aspects of the philosophies of C. S. Peirce (for example, his “tychism”) and M. R. Cohen (whose general philosophical position is not unlike Cournot’s critical rationalism).

Another pluralistic aspect of Cournot’s thought is indicated in the title of his last philosophic work, *Matérialisme, vitalisme, rationalisme*. Countering the principles of Darwinian evolution, Cournot holds to the principle that living beings are distinguished from nonliving things by a unity and form suggestive of finality and by a vital principle inexplicable in physical and chemical terms. Here Cournot anticipates both Henri Bergson and the emergent evolutionists, notably Samuel Alexander and C. Lloyd Morgan.

In his consideration of such concepts as form, unity, simplicity, and symmetry, Cournot moves toward a transrationalism—that is, toward a view in which ideas that go beyond normal rational analysis and use, such as finality, purpose, and God, find a place. This development is consistent with, indeed perhaps it is a consequence of, his pluralism and his implied doctrine of levels and with his rejection of any reductionist view as these are evidenced by his assertion that the phenomena of life involve something not present in nonliving phenomena. Such ideas as simplicity and symmetry are relevant to rational investigation, to the discovery of the order and reason of things, as in the probabilistic assessment and choice between

otherwise equally adequate alternative hypotheses. In this sense such concepts are regulative ideas of reason. But Cournot argues that they are more than this, and in his treatment of these concepts he moves from a logic of reason toward an aesthetic of reason, in which the concept of order has a connotation more extensive than reason can explore. What effect does such a transrationalism have on the claimed objective existence of chance, the second concept so fundamental to Cournot's philosophy as a whole? None. Why this is the case is not adequately developed in Cournot's works, although a hint is found in *Exposition*: God lays out the laws or rational elements of reality and leaves to objective and inexpugnable chance the details of fortuitous occurrences. Therefore, even such a superior intelligence would, like man, be unable to foresee contingent events, although unlike man its assessment of what is contingent would not be complicated by subjective factors of the sort which inescapably limit and affect human judgment.

In developing his philosophy, Cournot deals with the nature of language, ethics, and aesthetics and with various social institutions and factors which contribute to civilization. He also discusses the nature of science, history, and philosophy and considers at some length the irreducible distinctions between them. His *Considérations* is a peculiarly interesting account of his handling of various historical matters.

## COUSIN, VICTOR

(1792–1867)

Victor Cousin, the French philosopher and historian, was born in Paris and educated at the Lycée Charlemagne and the École Normale, where he studied under Pierre Laromiguière. He began his teaching career in 1815, assisting Pierre Paul Royer-Collard in his course on the history of philosophy at the University of Paris. Cousin studied German and read Immanuel Kant and F. H. Jacobi; but he was especially attracted to the works of Friedrich Wilhelm Joseph von Schelling, whose thought

had a permanent influence upon him. A trip to Germany in 1817 brought him into personal contact with both Schelling and G. W. F. Hegel, a fact which was later responsible for the accusation that he had rejected French philosophy in favor of Germany's. In 1821 Cousin was removed from his position because of his supposed antigovernmental views, and he used his freedom to make another trip to Germany. While there he was imprisoned, on charges that have never been entirely clear, but was freed after six months. Returning to France, he spent his time writing his philosophical and historical works and editing the works of other philosophers, including Proclus (6 vols., 1820–1827) and René Descartes (1826, 11 vols.), and beginning his translation of Plato (13 vols., 1822–1840). In 1828 he was restored to his post and from then on had an influential career as lecturer. He became a spokesman for the *juste milieu*, as he called it, which in philosophy meant eclecticism. Cousin's power increased when in 1840 he became minister of public instruction, director of the École Normale, and a member of the Institut de France. He was not only the most famous French philosopher of his time but also supreme dictator of who should teach philosophy and what should be taught. He had become, moreover, a power in the whole educational system of France when he published a report on Prussian education (1833). (This report was later translated into English in 1834 and distributed to the schools of Massachusetts by an act of the legislature.) At the advent to power of Louis Napoleon in 1848 Cousin retired from active teaching and spent his time in literary studies.

### ECLECTICISM

Though Cousin started his career as a pupil of Laromiguière, it was the commonsense philosophy of Thomas Reid, as interpreted by Royer-Collard, that was the source of his own doctrine. To Cousin common sense was a fusion of the best that had been done in philosophy, combining the empiricism of sensationalism in epistemology with the spiritualism of religion. The epistemology of Étienne Bonnot de Condillac and his school, Cousin felt, because it made the spirit of man a simple passive victim of external forces, had led them to atheism and materialism, both of which were to be condemned. Atheism and materialism could not give men those permanent principles that would guide their moral life. Such principles were to be found only if men realized that their minds were active as well as passive, their activity consisting in their use of their a priori categories of substance and causality.

Though it is likely that Cousin got the idea of the complementary active and passive aspects of mentality from Schelling, he himself attributed it to Maine de Biran's self-scrutiny. This gave him a French origin for doctrines which were to guide French professors. Maine de Biran's active will, Cousin maintained, was balanced by sensibility, which "implies" the existence of an external world. Sensibility and active will were accompanied by reason, and thus Cousin revived the traditional threefold analysis of the mind. Corresponding to the three faculties was a threefold division of philosophical problems into that of the good, the beautiful, and the true. In his book *Du vrai, du beau et du bien* (1853) Cousin argued that these problems were united in a whole which absorbed what was valid in sensation (John Locke), reason (Plato), and the heart (for which he named no sponsor). These three parts of the soul are not independent of one another. Reason requires both sensation and the heart, sensation requires reason and the heart, and the heart requires both reason and sensation. By analogy epistemology, ethics, and aesthetics are all intertwined and inseparable except for purposes of exposition.

### POLITICAL PHILOSOPHY

The political philosophy of Cousin was expressed in *Justice et charité*, a brief tract that he wrote as one of a series published by members of the Académie des Sciences Morales et Politiques in 1848. This tract is based on the same metaphor of the interdependence of separate things. The purpose of all the tracts in this series was to substantiate the right to property, the well-being of family life, popular freedom, and progress. Cousin opposed the idea of equality, the right to work, and governmental aid. Justice is the protection of natural rights, but every right implies a complementary duty. Men are all free, but their freedom resides only in the search for truth, in religious beliefs and practices, and in property. Justice demands that these rights be respected and protected by the state. On the other hand, charity demands that we abuse none of these rights, that we individually seek the truth and not perpetuate error, that we give others the religious freedom that we demand for ourselves, that we respect others' property as we would have them respect ours. In short, law is futile if it is not obeyed, and we cannot obey a law that is not enforced. Respect for the law is like charity in that it has no limits; for charity extends to all men and to liberty in all its forms.

## AESTHETICS

Cousin was a strong believer in absolute beauty. His ideal work of art was the Apollo Belvedere. Art, he believed, is neither an imitation of nature (sensationalism) nor edification (moralism), but rather a vision of “the infinite.” Though all arts utilize matter, they communicate to it “a mysterious character which speaks to the imagination and to the soul, liberates them from the real, and bears them aloft either gently or violently to unknown regions.” These unknown regions are the country of God, the world of the ideal. Though this passage might seem to ally Cousin with the Romantic school, in fact it led him to give highest praise to the classicists of the seventeenth century. He was clearly under the influence of J. J. Winckelmann, who also admired the Apollo Belvedere as the *summum* of all ideal beauty and believed that all praiseworthy artists put into their works of art the ideal beauty of Plotinus. Cousin saw in beauty, as did Hegel, a sensuous manifestation of the Absolute, though he expressed it in different language.

At the same time Cousin admitted that one must not exaggerate the idealism of a work of art. All works of art speak to the senses as well as to the heart. The ideal must be presented to us in sensible form and it must also be agreeable to our feelings. A work of art that is beautiful was for Cousin a concrete presentation of the unity he found in eclecticism. Consequently, art that did not realize the potentialities of the sensuous, the rational, and the sentimental would not be of as high a rank as art that did. The conclusion was that poetry was the highest of all the arts. Its power of words is such that it can stimulate images, feelings (affections), and thoughts at one and the same time. It is thus a synthesis of all human powers.

## HISTORIOGRAPHY

The pioneering editorial work of Cousin, mentioned above, made accessible to the public manuscripts that had been previously hidden in libraries. His eclecticism served him well in this field, for with the exception of the sensationalists of the eighteenth century, there were few philosophers of the past in whom he could not find some truth.

Cousin’s *Philosophie sensualiste au XVIII<sup>e</sup> siècle* (1819), a course of lectures, is the most biased of his historical studies, but still treats of Locke, Condillac, Claude-Adrien Helvétius, Saint-Lambert, and Thomas Hobbes in an interesting manner. His criticism of Locke, that Locke was unable by the very nature of his epistemology to account for universal and necessary ideas, Cousin’s analysis of Condillac’s notion that deduction is always tauto-

logical, and even Cousin’s attacks on Helvétius are carefully based on the texts and are far from superficial. Fundamentally his objection to these thinkers was the pragmatic, moral, and religious consequences of their premises, an objection which obviously sprang from his own moral and religious convictions. His *Cours de l’histoire de la philosophie* (1829) was considered a work serious enough to be analyzed and commented upon by Sir William Hamilton in the *Edinburgh Review*, and, indeed, its exposition of the technique of historiography was thorough and based on a perception of genuine historical problems.

Cousin made the mistake of dividing all possible philosophies into four kinds—sensualism, idealism, skepticism, and mysticism—and thus helped to influence his successors in this area toward thinking of philosophies as always productive of systems. This division led Cousin to look for a unitary idea pervading each system, though the idea in question might be a simple metaphor or a theory of the origin of ideas which exfoliated into an ethics, aesthetics, theology, or other theoretical construct. Like Hegel, Cousin was given to envisioning philosophical systems as “expressive” of ages and peoples, as if an age or a people were homogeneous. Yet at the same time he admitted the heterogeneity of what he called populations as distinguished from peoples, the latter being unified in their beliefs and outlooks on the world’s problems, the former being diversified or, as he would put it, not yet unified. Where there was diversity, there was nevertheless a predominant idea in every epoch, but alongside of it existed other ideas “playing a secondary but real role.”

Each people, Cousin maintained, was given, presumably by God or by the inevitable course of history, an idea to represent, and its history was the realization of this idea. This idea expresses itself in all human concerns—in philosophy, religion, science, art, and morals. It is almost certain that Hegel was the source of this theory, though Cousin made no mention of his influence. He was willing, however, to give great credit to J. J. Brucker, Dietrich Tiedemann, and W. G. Tennemann; these last two, he believed, expressed a history of philosophy associated with Locke and Kant, respectively. As for the nineteenth century, Cousin held that it would not have its own history of philosophy until it had a representative philosophy. That philosophy would be a union of the two traditions referred to by Cousin as the nucleus of a “vast and powerful eclecticism.”

It is customary to treat Cousin with patronizing disdain, and it is true that he was always ready to compromise with political power and adjust his conclusions and,

indeed, his methods of research to what he believed to be expedient. He succeeded in excluding from his “regiment,” as he called it, philosophers whose views were not harmonious with his own. Thus neither Auguste Comte nor J. G. F. Ravaisson-Mollien nor Charles Renouvier, to cite but three names, were able to become members of the teaching staff of the University of Paris. On the other hand, Cousin did stimulate research into the classics of philosophy, and his very chauvinism turned men’s attention to such neglected figures as Maine de Biran. His eclecticism was not real, for he rejected any philosophy whose supposed religious and ethical effects he thought were undesirable. Yet his notion that every philosophy contained some truth induced his pupils to look into them all and gave them a catholicity of interest that was unusual and almost unique.

### Bibliography

With the omission of his editions of classical authors and literary studies, Cousin’s works include *Fragments philosophiques* (Paris: A Sautet, 1826); *Cours de l’histoire de la philosophie*, 3 vols. (Paris: Pichon et Didier, 1829), which together with *Cours de l’histoire de la philosophie moderne*, 5 vols. (Paris: Ladrangé, 1841) contains many titles also published separately; *Justice et charité* (Paris: Pagnerre, 1848); and *Du Vrai, du beau et du bien* (Paris: Didier, 1853).

For literature on Cousin, see P. F. Dubois, *Cousin, Jouffroy, Damiron, souvenirs publiés avec un introduction par Adolphe Lair* (Paris: Perrin and Cie, 1902); Paul Janet, *Victor Cousin et son oeuvre* (Paris: Calmann Lévy, 1885); and Jules Simon, *Victor Cousin* (Paris: Hachette et Sie, 1887), which has been translated under the same title by M. B. Anderson and E. P. Anderson (Chicago: A.C. McClurg, 1888). For a generally hostile approach, from a positivistic point of view, see Lucien Lévy-Bruhl, *History of Modern Philosophy in France*, translated by G. Coblence (Chicago and London: Open Court, 1924), Ch. 12; for a favorable account see John Veitch and X, “Cousin, Victor,” in *Encyclopaedia Britannica*, 11th ed. (Chicago, 1910).

## COUTURAT, LOUIS

(1868–1914)

Louis Couturat, the French philosopher and logician, studied at the École Normale Supérieure and earned an *agrégé* in philosophy and a licentiate in mathematics. He taught philosophy at the universities of Toulouse and Caen but soon gave up teaching in order to devote all of his time to his own researches.

Couturat first attracted attention with his important doctoral thesis, *L’infini mathématique* (Paris, 1896). At a time when the mathematicians were still questioning the validity of Georg Cantor’s theories and when the majority of French philosophers, led by Charles Renouvier, were resolute advocates of finitism, Couturat presented a vigorous case in behalf of an actual infinite. In opposition to the formalist theories of number of Julius Dedekind, Leopold Kronecker, and Hermann Helmholtz, he bases number on magnitude—not on a strictly spatial intuition but on magnitude considered as the object of a “rational intuition.” This is why, of the various generalizations of number—the arithmetical, the algebraic, the geometrical—he regards the geometrical as the most rational. His reasoning consisted of offering the actual infinite as a new generalization of number, analogous to those that resulted in signed numbers, fractions, irrationals, and imaginaries. All of these numbers at first seemed to be arithmetical nonsense, but they took on meaning once they were recognized as suitable for representing new magnitudes and for allowing various operations on them that were hitherto impossible. The justification for infinite numbers is that they are indispensable for maintaining the continuity of magnitudes.

From this point on, Couturat’s studies proceeded in three areas closely associated in his mind—the history of philosophy, logic and the philosophy of mathematics, and the development of a universal language.

After writing an essay (his Latin complementary thesis) on the myths of Plato, he devoted himself to Gottfried Wilhelm Leibniz, the great infinitist, whose reinterpretation he undertook independently of Bertrand Russell but at the same time and in the same sense. As indicated by the title of his book *La logique de Leibniz* (Paris, 1901), Couturat had at first intended simply to study the precursor of modern logic. He soon perceived, however, that Leibniz’s “logic was not only the heart and soul of his system, but the center of his intellectual activity, the source of all his discoveries, ... the obscure or at least concealed hearth from which sprang so many *fulgurations*.” The manuscripts he discovered at

Hanover, a copious collection of which he published in *Opuscles et fragments inédits de Leibniz* (Paris, 1903), further strengthened Couturat in this conviction. Considering only Leibniz's known, celebrated works, if we wish to find the real root of his system, we must look not to the *Monadology* or the *Theodicy* but to the *Discourse on Metaphysics*, together with the *Correspondence with Arnauld*, which is, as it were, a commentary on the *Discourse*. Taking the old formula *praedicatum inest subjecto* in all its rigor, Leibniz held that every true proposition can be resolved into identities provided one pursues its analysis to the end. Contingent or factual truths differ from the necessary truths of reason only in respect to the infinite length of the analysis, an analysis which God alone is able to complete. Couturat showed, with supporting texts, that all the theses of the Leibnizian metaphysics are obtained from this position and derive their unity from it. The system thus appears as a panlogism.

It is likewise to his interest in Leibniz that we may ascribe, indirectly, Couturat's important study "La philosophie des mathématiques de Kant," published in the *Revue de métaphysique* (1904) on the centennial of Immanuel Kant's death. In *L'infini mathématique* Couturat had already criticized the Kantian antinomies that claim to establish the impossibility of an actual infinite. He now concluded that "the progress of logic and mathematics in the nineteenth century has invalidated the Kantian theory and decided the issue in favor of Leibniz" and his ideal of a completely "intellectualized" mathematics. The majestic edifice of the three *Critiques* lacks the indispensable basement of a logic on a level with science. "The brass colossus has feet of clay."

Deploring the fact that C. I. Gerhardt, in editing Leibniz, had separated the mathematical writings from the philosophical, Couturat could not but associate himself with the task assumed by the newly founded *Revue de métaphysique*? of working for a *rapprochement*, unfortunately broken off in the nineteenth century, between philosophers and scientists. After the establishment of the *Revue* in 1893, scarcely a year passed when he did not publish one or more articles in this spirit (some thirty at the time of his death, plus three that appeared posthumously). Rather than present original views, he dedicated himself with great disinterestedness to making known the views of others, mainly foreigners. He explained to French philosophers the mathematical logic of Giuseppe Peano, the universal algebra of Alfred North Whitehead, and the foundations of geometry and the principles of mathematics according to Russell. He vigorously defended both the new logic (to whose diffusion he con-

tributed with his *L'algèbre de la logique*, Paris, 1905) and the Russellian logic. This involved him in a celebrated controversy with his former teacher Jules Henri Poincaré. Although at the time Poincaré was often able to score against his opponent, subsequent developments in logic and mathematics have been more favorable to Couturat on many points.

Couturat's admiration for Leibniz, who dreamed of a universal language; his adherence to logic that he saw as the source of an algorithm disengaged from the contingencies and irregularities of the natural languages; his participation in the organization of the first International Congress of Philosophy (Paris, 1900); his active collaboration with André Lalande in the preparation of the *Vocabulaire technique et critique de la philosophie* (Paris, 1926); and his rationalism, which one may characterize as militant in the sense that his purpose was less to rediscover reason in things than to work to make it rule among men—all these converging concerns led him to devote himself more exclusively to a task which became a veritable apostolate for him—the creation and adoption of an international auxiliary language by the rationalization of Esperanto and Ido. He prepared himself for this mission first by studying and then by publishing, in collaboration with Léopold Léau, the *Histoire de la langue universelle* (Paris, 1903). After 1900, Couturat was the moving spirit of the Délégation pour l'Adoption d'une Langue Auxiliaire Internationale, initiated by Léau, and later of the Akademie di la Lingue Internaciona Ido. In 1908 he founded and directed until his death the monthly review *Progreso*, written in the reformed language and designed to propagate it. The opposition of many Esperantists and the death of Couturat, which happened to come at the very moment when a war that exacerbated national particularisms was breaking out, caused the abandonment of the project. His friends and admirers have often regretted that Couturat should have expended so much effort in vain and sacrificed his wide talent to a noble dream.

## CRAIG'S THEOREM

In mathematical logic, Craig's Theorem—not to be confused with Craig's Interpolation Theorem—states that any recursively enumerable theory is recursively axiomatizable. Its epistemological interest lies in its possible use as a method of eliminating "theoretical content" from scientific theories.

### PROOF OF CRAIG'S THEOREM

Assume that  $S$  is a deductively closed set of sentences, the elements of which may be recursively enumerated thus  $F(0), F(1), \dots, F(n), \dots$  where  $F$  is a recursive function from natural numbers to sentences (we assume that expressions, sentences, etc., have been Gödel-coded in some manner). The set of theorems of an axiomatic theory is automatically recursively enumerable. But in general a recursively enumerable set is not automatically recursive. An example of a recursively enumerable set that is non-recursive is the set of logical truths in a first-order language with a single dyadic predicate. This follows from Church's Theorem, which states that the general notion of first-order validity is undecidable. However, through a trick devised by Craig, we can define a recursive set  $\text{Craig}(S)$  whose deductive closure is  $S$ . Let  $A$  be a sentence and  $n$  a natural number. Let  $A^n$  be the  $(n+1)$ -fold conjunction  $A \wedge \dots \wedge A$ . The sentence  $A^n$  is logically interdeducible with  $A$ . Next consider sentences of the form  $F(n)^n$ . Define  $\text{Craig}(S)$  to be  $\{F(n)^n: n \in \mathbb{N}\}$ . The deductive closure of  $\text{Craig}(S)$  must be  $S$ , since each element of  $\text{Craig}(S)$  is equivalent to an element of  $S$ . Next we give an informal decision procedure for membership in  $\text{Craig}(S)$ . Given a sentence  $A$ , to decide whether  $A \in \text{Craig}(S)$ , first check if  $A$  has the form  $B^n$ , for some sentence  $B$  and number  $n$ . Through unique readability this is checkable, and if

$A$  is not of this form then  $A \notin \text{Craig}(S)$ . So suppose that  $A$  is of the form  $B^n$ . We calculate  $F(n)$ , and if  $B$  is indeed  $F(n)$  then  $A \in \text{Craig}(S)$ . And otherwise  $A \notin \text{Craig}(S)$ . The existence of a decision procedure for membership in  $\text{Craig}(S)$  implies that  $\text{Craig}(S)$  is recursive. The set  $\text{Craig}(S)$  is therefore a recursive axiomatization of the theory  $S$ .

**CRAIGIAN ELIMINATION.** The logical positivists held that, under a logical reconstruction, a scientific theory is an axiom system formulated in a language  $L(O, T)$ , in which extra-logical predicates and function symbols are classified as either  $O$ -terms, for observational properties, or  $T$ -terms, for theoretical properties. Statements in  $L(O, T)$  can be classified as observational, theoretical, or mixed, depending upon the presence or absence of  $O$ -terms or  $T$ -terms. Deleting theoretical terms yields a sub-language  $L(O)$  whose sentences express observational or empirical claims about the world. Assume that the property of being an  $L(O)$ -sentence is recursive. Consider a recursively enumerable theory  $S$  in  $L(O, T)$ . The empirical content of  $S$  is the set of  $L(O)$ -theorems of  $S$ . This is a subtheory of  $S$  obtained by a restriction on a recursive property. So it is recursively enumerable too. According to Craig's Theorem there is a recursive set of  $L(O)$ -sentences whose deductive closure is the empirical content of  $S$ . According to these assumptions we can therefore recursively axiomatize the empirical content of any given scientific theory  $S$ , obtaining a recursive axiom system  $\text{Craig}(S)$ , known as the Craigian reaxiomatization of  $S$ 's empirical content.

### PHILOSOPHICAL SIGNIFICANCE OF CRAIGIAN ELIMINATION

Instrumentalism or positivism about science involves a scepticism towards the non-observational content of a scientific theory. Lacking such content the Craigian reaxiomatization  $\text{Craig}(S)$  provides an object of rational belief compatible with instrumentalist or positivist scruples. Note that this elimination method need not be based on an observation/theory distinction. With obvious modification it can be used as a way of eliminating, for example, the mathematical content from a scientific theory formulated using mathematical predicates and quantification over sets, functions, and so forth, or as a way of eliminating theoretical content from a psychological theory that refers to mental states, and so on. Craigian reaxiomatization offers a possible elimination strategy for a variety of instrumentalist positions.

## CRITICISMS OF CRAIGIAN ELIMINATION

Of the aforementioned there are two methodological criticisms. First, even if the original theory *S* is presented in a simple manner, the reaxiomatization *Craig(S)* will be complex and thus will violate the canon of *simplicity* which we might impose on admissible theories. Second *Craig(S)* is *parasitic* upon the original theory *S* and so does not really stand alone from the original theory. Indeed *Craig(S)* is a bizarre theory, having infinitely many axioms of the form *A*”, where *A* is an empirical consequence of *S*. Hartry Field refers to Craigian reaxiomatization as “bizarre trickery” and complains that *Craig(S)* is “obviously uninteresting, since [it] does nothing towards explaining the phenomenon in question in terms of a small number of basic principles” (Field 1980, p. 8). A third criticism is that Craigian elimination rests on a mistaken conception of scientific theories, namely a *syntactic view* of theories. This criticism has been urged by Bas van Fraassen, who writes “empirical import cannot be isolated syntactically ... the reduced theory [*Craig(S)*] is not a description of the observable part of the world of *S*; rather it is a hobbled and hamstrung version of *S*’s description of everything” (van Fraassen 1976, pp. 87–88). A final criticism attacks the tenability of the observation/theory distinction required. A simple example of this is that although “red” seems a paradigmatic observational term, we can nonetheless speak of red blood cells, which are too small to be visible to the naked eye (see Putnam 1962).

With respect to certain assumptions discussed above concerning the notion of “empirical content,” *Craig’s Theorem* tells us that we can reaxiomatize the empirical content of a scientific theory, thereby eliminating apparent reference to unobservable objects and properties. However this elimination procedure has not found many adherents, and it seems safe to say that the significance of Craigian elimination is primarily pedagogical.

## CRATYLUS

Cratylus, an Athenian, was contemporary with Socrates but was probably considerably younger. He was, according to Aristotle, a follower of the doctrines of Heraclitus, and Plato, in his youth, was closely associated with him. Aristotle implies that this was before he came under Socrates’ influence, although later sources put the influence of Cratylus upon Plato after the death of Socrates.

Cratylus took as his starting point the doctrine of the flux of phenomena (here assumed to have been a genuine doctrine of Heraclitus, despite G. S. Kirk’s objections), and he capped Heraclitus’s saying that one cannot step twice into the same river by adding “nor once either.” His reason clearly was his contention that the river is changing even as you step into it. He ended by coming to the view that one ought not to say anything, but only move the finger, since no true statement can be made about a thing that is always changing. According to Aristotle, upon whose evidence the above account rests, Plato took from Cratylus the belief, which he maintained even in later years, that all sensible things are always in a state of flux and that there is no knowledge about them.

Plato in the *Cratylus* attributes to him the doctrine that everything has a right name of its own, fixed by nature, and somehow or other this one right name will point to the nature of the thing named.

At an early stage it became clear to modern critics that the contention that there is a right name that indicates the true nature of a thing is apparently inconsistent with the doctrine of a Heraclitean flux in phenomena, since this flux would prevent a thing from having an abiding nature. Attempts to explain this contradiction in Cratylus’s position have been numerous. Frequently it has been supposed that Cratylus either did not have a doctrine of words at all or else did not believe in the flux doctrine.

All such explanations seem misguided. Aristotle makes it clear that the final step—the refusal to use words—came after a previous period when Cratylus was already a Heraclitean. The implications of Plato’s account are also clear; Cratylus at the time of the dialogue had long been interested in the doctrines of Heraclitus, and he

also held the theory of words attributed to him. It might be that he failed to realize the inconsistency at the stage represented by the dialogue, and, when the inconsistency became clear, subsequently proposed to abandon speech. More probably, at the time of the dialogue he inclined to the view to which he is clearly attracted when Socrates mentions it, namely, that words themselves in some sense flow, and so point to the flowing nature of the objects to which they refer (*Cratylus*, 437D).

## CREATION AND CONSERVATION

Many religions view the universe as the creation of a divine being or beings. The value of such a view is manifold. Among other things, it implies that the world is at least partly a product of divine planning and governance. To the extent that this is so, the world can be expected to be an orderly place, made for a purpose and ruled by providence. Thus, humans can anticipate that what befalls them in earthly life will not have occurred by accident, that their fortunes and destiny are, at least in some measure, divinely ordained. The idea of divine governance of the world also offers a possible basis for grounding principles of moral conduct; finally, if human destiny is in the hands of a higher power, there is at least hope of a life beyond the grave.

The doctrine of creation characteristic of the Judeo-Christian-Islamic tradition is a very strong one, for at least three reasons. First, these religions understand the universe to be entirely the product of one God. Second, creation is understood to be *ex nihilo*—that is, the universe is not fashioned out of any preexisting thing. Third, the world is not just created by God "in the beginning," but is also sustained in being by him for its entire existence; thus, the fact that the world is able to persist beyond the present moment is as much owing to the cre-

ative action of God as is the fact that it exists at all. Taken together, these claims indicate that divine governance of the world is unified, close, and thorough, with implications about both the nature of the world and God's relation to it. These implications are related in turn to a number of problems in philosophical theology and to certain aspects of contemporary scientific cosmology.

### THE COSMOLOGICAL ARGUMENT

No single account of creation could ever portray the richness of the Western philosophical tradition on the matter. There are, however, a number of common themes. Typically, treatments of God as creator begin with an argument for the existence of God—usually some version of either the teleological argument, which is based on premises about order or purpose in the universe, or the so-called cosmological argument, which invokes God as an uncaused first cause of all things. The latter argument shall be examined first.

The cosmological argument is traditionally presented as a deductive argument. Put very roughly, it asserts the following:

- (1) The universe of our experience need not have existed—that is, that its existence is contingent.
- (2) The existence of contingent things must have an explanation.
- (3) The only or best explanation for the existence of the universe is the creative activity of a necessarily existing "first cause."
- (4) Therefore, there is such an entity or being.

Further, it is held, this being is in fact the personal God of traditional Western monotheism.

Of the premises of this argument, the first seems plausible. The second is a version of the principle of sufficient reason. It is needed if the argument is to be deductively valid, but in the end it is probably damaging to the argument. The principle of sufficient reason is not a necessary truth, and so cannot be known a priori; any effort to establish its truth a posteriori is apt to be inconclusive, in part because the truth of the principle depends precisely on whether it holds with regard to cases such as the existence of the universe, which is precisely the point at issue.

Suppose, then, that premise number two is dropped. What remains is best interpreted as a kind of inductive argument, an inference to the best explanation, according to which the existence of the universe is a result of the

causal activity of a necessary being. In such an argument, it is best to separate two claims that are implicit in the third premise above:

(3a) The creative activity of a necessarily existing first cause is sufficient to explain the existence of the universe.

(3b) No alternative hypothesis is sufficient to do the job.

With this clarification, and premise number two now out of the way, an appropriate conclusion might now be something like:

(5) Relative to the evidence of experience, we have better reason for thinking there is a necessarily existing first cause of the universe than for thinking otherwise.

Because this is an inductive argument, the conclusion no longer follows necessarily from the premises. In this, however, it is no different from any inductive argument, including many that we find quite persuasive—for example, arguments for the existence of subatomic particles or even for exotic and unexpected phenomena such as quantum entanglement. No doubt, a skeptic may treat this feature as a reason for denying the conclusion, but that is not a point of interest. A skeptic can find a reason to deny any conclusion. A second important point is that the God postulated in the argument is described as a necessary being—that is, a being whose existence is necessary or a being that exists by its very nature. Some philosophers have questioned whether such a being is possible, and that is an issue worthy of consideration. It would, however, be logically misguided to greet this argument with the question, “What caused God?” By definition, a necessary being is existentially self-sufficient: It neither has nor requires a cause. Admittedly, it is not obvious that a necessarily existing first cause of the universe ought to be identified with the personal God of traditional belief. Proponents of cosmological arguments have, however, been well aware of this point; medieval demonstrations of a creator—that of Thomas Aquinas, for example—were often followed by lengthy consideration of what characteristics might appropriately be attributed to such a being.

Perhaps the most interesting issues about the cosmological argument concern premises 3a and 3b. Whether, as 3a asserts, the activity of a creator God explains the existence of the world will depend on how we understand that activity. Presumably, it does not consist in a sequence wherein God first commands that the universe exist, and the command then causes its existence. For if, as is usually

supposed, causal relations are themselves contingent, then God would first have to create the causal mechanism by which his commands gain efficacy. This would require another command, and a vicious regress would ensue. How, then, should the activity of creation be understood? One attractive possibility is an analogy with human creation: for example, a writer envisioning a drama, a composer inventing a melody, or a scientist coming up with a hypothesis. On this kind of view, the first cause would indeed have to be conceived as personal, since the world would owe its existence to a knowing will, of which it would be the *content* as well as the product. That is to say, unlike the products of human creation, the universe would have its existence in God both as a concrete reality and as something known.

Premise 3b must itself be established inductively: That is, we must canvas the known alternatives to the hypothesis of a creator and show that they do not work. Of course, even if we succeed, it may be that some as yet undiscovered explanation for the existence of the world will be found superior to any invoking a creator God. Still, the cosmological argument is greatly strengthened if alternative hypotheses can be eliminated. Historically, the most favored alternative by far has been the hypothesis that the world had no temporal beginning but rather is infinite in duration, its existence at each moment being a causal consequence of the immediate past, from which it is generated in accordance with scientific law. In fact, however, this alternative is all but indefensible. Scientific laws, classically at least, are not diachronic: That is, they do not speak of causes that occur at one moment and effects at another. Action and reaction are simultaneous in Newton’s scheme. The application of net force produces acceleration at the instant of application; if at  $t$  an object is not acted upon by a net force, then it is at rest or in uniform rectilinear motion at  $t$ .

We can, of course, deduce the state of a closed system at a later time if we know its state at  $t$ , but only if we *assume* as a premise that the mass/energy of which it is constituted will continue to exist. Nor will it do at this point to invoke conservation principles. For, again, the law that mass/energy is conserved holds only of closed systems—that is, systems in which, *ex hypothesi*, mass/energy is neither gained nor lost. Conservation laws are not, however, mere tautologies. They tell us something very important: that physics is not about things just *being*, but about how they change; and that although we may learn a great deal from science about the development of the universe over time, and the ways in which the items of our experience combine and separate and

change, physics has next to nothing to tell us about the existence of things.

A second difficulty with the alternative hypothesis is that we have no idea what it would be like for the universe to be able to bootstrap itself into the future by sustaining its own existence. No one has ever described a mechanism by which this could occur; and if one should deny the need to do so—invoking, say, a principle of “existential inertia” by which, once in existence, things “naturally” tend to continue existing—the explanation becomes empirically vacuous, a mere redescription of the phenomenon to be explained. Finally, even if one temporal stage of the universe could give rise to a succeeding one, the question that drives the cosmological argument would go unanswered.

For the problem is not why the universe exists at this moment, but why it exists at all. If I ask you why the bordelaise sauce in the upper container of a double boiler is hot, you may fairly explain that it is heated by the boiling water in the lower container. If I ask you why the water is boiling, you could in principle reply that this is in fact a triple boiler: that the water is heated by still further water, boiling merrily another level below. But if I ask you how heat gets into the system at all, it will not do to postulate an infinity boiler, for water is never anything but contingently hot. You have to come to something essentially hot—fire, perhaps—to answer my question. Similarly, if the problem is to explain the existence of contingent things, an infinite sequence of them is of no avail. Only if we postulate a necessary being will an explanation be possible.

## CONSERVATION

If these points are correct, then the traditional cosmological argument is in a considerably stronger position than is often supposed. Its plausibility is the same, moreover, whether the past duration of the universe is finite or infinite. If there is never a natural accounting for the existence of contingent things, then at any moment of their existence, only the activity of a necessary being can explain them. This is the essence of the religious doctrine of conservation, according to which God is as much responsible for the persistence of the universe as for its being there at all. Many have thought, however, that the doctrine of conservation leads to a serious difficulty. If God is, at each moment, the cause of all that exists, what place can there be for natural causes? It is unreasonable to think God is causally responsible for the present existence of my chair unless he is also responsible for its properties. Indeed, the seventeenth-century philosopher Nicolas

Malebranche argued that nothing else is possible, that it is self-contradictory to suppose God could create a chair that is neither at rest nor in motion, and has no color or mass or any other property characteristic of a chair. But if God is creatively responsible for all the properties of the chair at each moment of existence, are not natural causes simply redundant? God’s will as creator must, after all, be presumed completely efficacious. But if it is, what efficacy is left to natural causes?

Malebranche’s answer was blunt: none. He held a doctrine known as *occasionalism*, according to which the events we ordinarily take to be causes (for example, my pushing on the chair) are only occasions for God to exercise his own causal power (to create the chair in motion), the only causal power that is legitimately efficacious. But occasionalism has uncomfortable consequences. Perhaps the worst is that if it is true, we do not perceive the world in the way we think we do—that is, by the action of the things in it on our senses. Rather, our sensations are caused in us by God so as to match what is going on in the world. And then we are only a step away from the idealism of George Berkeley: that is, from moving to the conclusion that the so-called physical universe must be superfluous to God’s plan, then denying its existence and attempting to reduce its contents to nothing but sets of ideas.

It is possible, however, to avoid occasionalism if the suggestion of the previous section is correct: that natural causation is not a matter of conferring existence to begin with. Much more plausible accounts are possible. In the realm of physical action in particular, causal interaction may be viewed as a matter of energy transfer, wherein quantities presumed to be conserved—motion, momentum, charge, and the like—are transmitted from one entity to another. As such, what we normally take to be causal processes (one billiard ball imparting motion to another, to cite the classic example) count as genuine exercises of causal power yet do not carry the suggestion of one event conferring existence on another. The case of perception, where what is caused is something mental, is notoriously more difficult. But if a similar solution can be found there, we have every reason to think both natural and divine causation can be accepted without setting up a false competition between them.

## CREATION AND SCIENTIFIC COSMOLOGY

Philosophical arguments for the existence of God are widely understood to be reinforced by two recent developments in scientific cosmology. The first is the so-called

big bang theory, according to which the universe of our observation constitutes a kind of continuous explosion that commenced some 15 billion years ago from an initial singularity in which the entirety of space-time was compressed to a state so dense as to be indescribable by any known principles of physics. This theory is now well confirmed, and it implies that the universe did indeed have a temporal beginning—so radical a beginning, in fact, that it would be scientifically meaningless to speak of a time prior to the big bang.

That the universe had a temporal beginning is in line with many religious creation narratives. Theists have therefore tended to treat the big bang theory as confirmation of their views, holding that it is far more plausible to postulate a creator to explain the world's beginning than to claim it "just happened." Opponents have found the appeal to such a cause unscientific. Some have argued that, in fact, a divine act of creation is not possible, because even a divine cause must precede its effect, and the big bang allows for no time prior to itself. Others have posed mathematical models for the universe's origin that would avoid the claim of an initial singularity and the attendant implication of a temporal beginning.

The suggestion that a proper science ought not to be postulating a creator has much to be said for it; science is fairly taken to be solely concerned with natural phenomena and natural explanations of them. Theists who take comfort from big bang theories need not, however, be deterred by such a delimitation of scientific purview, given that they seek an explanation for the existence of the entire natural order—something a science thus delimited cannot in principle provide. As for the claim that even a divine cause must precede its effect, that seems mistaken. On the contrary: if, as is argued above, the laws that govern natural processes are synchronic rather than diachronic, then even natural causation must be understood in a way that makes cause and effect simultaneous—in which case any support for the claim that a divine cause must precede its effect vanishes. Humans may eventually come to understand the genesis of the cosmos according to some model other than the standard big bang. But the alternatives presently available face problems of internal coherence and of testability, and so have yet to offer strong competition.

The second development in cosmology that is often taken to support claims of a creator is the realization that living beings of the sort with which we are familiar owe their existence to a wondrously exacting fine-tuning of various physical parameters. For example, if the ratio of the universe's rate of expansion to its total mass were

increased or decreased by only one part in a million, there would be no stars and planets to support life. If the strong nuclear force were increased by just 1 percent, it would have been impossible for carbon to form; an increase of 2 percent would have ruled out the formation of protons from quarks. On the opposite side, a decrease of 4 percent would have allowed no atoms other than hydrogen to form.

Examples like this can be multiplied at considerable length, and the likelihood that all the requirements for life that they embody should be satisfied in one universe is exceedingly remote. The fact that our universe does exactly that has therefore been held to justify a teleological argument for the existence of God. That is, it is argued that the only way to explain the fine-tuning of our universe for life is to postulate an intelligent creator who designed it to be so. Opponents have countered that the universe visible to us may be only one of a great many worlds, perhaps even an infinite number, in which many or even all possible combinations of basic parameters are displayed. If so, then the fine-tuning of our world might be "explained," at least in the weak sense that the appearance of such a universe would be made more likely, or even certain. In addition to being plainly ad hoc in character, these speculations too present problems of testability—not to mention the difficulty of truly explaining the existence of such an ensemble of worlds by specifying a mechanism that could cause it to appear, and guarantee its exhaustiveness. Like the big bang, however, the issue of fine-tuning is a subject of intense interest, and there is doubtless a good deal more to be said about both.

## CREATIVITY

It has often been claimed that genuine creativity is largely if not entirely a matter of inspiration—the sudden, involuntary, and inexplicable outpouring of innovative ideas and actions. In many expressions of this thesis, including Plato's, the source of this outpouring is a sacred instance—a spirit or muse—while in other versions it is the unconscious mind. The antithesis to such inspirationist theses is the rationalist doctrine that all creativity is ultimately reducible to a form of calculation or more or less deliberate problem-solving.

Although both the extreme inspirationist thesis and the rationalist antithesis have adherents, many investigators find an intermediary position more tempting. Inspirationist theses are hard to square with basic, naturalist inclinations and with a commitment to scientific research. That creative behavior is complex and hard to explain does not mean that it is essentially mysterious or could never be modeled with some modest measure of accuracy. Inspirationism is further challenged by evidence that most if not all significant episodes of innovation require industry, rational thought, and action. Extreme rationalist accounts, on the other hand, confront testimony regarding the involuntary and sudden onslaught of important new ideas, such as vivid accounts

of inspiration's "sudden illumination" offered by Pyotr Il'ich Tchaikovsky (1970 [1878]), Henri Poincaré (1952 [1908]), Albert Einstein, and scores of other impressive informants. Yet some of these same sources identify rational elements of creativity, as when Tchaikovsky goes on to underscore the necessity of daily, strenuous efforts. How to balance such divergent insights and data in a synthetic account of creativity remains a matter of great controversy.

## UNDERSTANDING CREATIVITY AND CREATION

A nontrivial problem is that of specifying how the terms *creativity* and *creation* are to be understood in the first place. While there is widespread agreement that creative acts and their products must be new or innovative, there is disagreement as to the sense in which this is true, as well as with regard to other conditions on creativity. In what way are all creative acts novel or original? Although every particular action is new in the sense that this particular event never happened before, genuine creativity involves something far less common. Saying that creative acts must never have been performed before is not only vague, but overly restrictive. Is not someone's wholly independent repetition of a great discovery creative? With this question in view, Margaret A. Boden distinguishes between historical and psychological creativity. An act is *historically* creative, she proposes, only if it has never been had before by anyone else in all of human history. In contrast, *psychologically* creative acts may replicate previous inventions.

Even if one agrees to focus on what Boden calls psychological creativity—a move disputed by some theorists, including Mihály Csikszentmihályi—there remains the problem of coming up with a nontrivial elucidation of the novelty clause. To that end, Boden attempts to characterize radical psychological novelty in terms of the creative act's transformation of "a conceptual space," by which she means the principles that unify and structure a given domain of thinking and action. She contrasts the relatively uncreative writer who produces a new and interesting novel while conforming entirely to the rules of some established genre, to a genuinely creative writer who creates a strikingly new work that transforms generic patterns and establishes a new literary category. Boden further contends that what sets off the genuinely creative transformations of conceptual spaces is that their results could not have been thought before by the person working within that space. Given that a conceptual space is governed by a system of constitutive rules, its transfor-

mation entails that at least one of these rules is dropped or violated in a genuinely creative act. Jon Elster (2000) also explores the relation between creativity and rules or constraints of various sorts, arguing that originality—which may be either sterile or of genuine value—involves not merely a rebellious violation, but the revolutionary replacement of constraints.

David Novitz (2003) challenges Boden's proposal and identifies counterexamples. Some inventions, such as Thomas Edison's creation of the phonograph and Henri Matisse's use of color in his paintings, are not plausibly described as having arisen within a rule-governed conceptual space. Matisse, after all, was playing around with color combinations he found pleasing, hardly a pursuit organized by a system of rules. And some actions that do arise within a rule-governed practice or "space," such as a chess player's invention of a new opening, may nonetheless be genuinely creative. Thus if Boden's discussion offers insight into some forms of creativity, it does not adequately cover all of them.

Novitz defends an alternative, "recombination" theory of creativity. He proposes that creative acts are novel in the sense that they are not predicted by, and are surprising to a given population. Alternately, creative acts are those which would have been surprising had the members of the population become aware of them. Novitz does not specify how the population in question is to be identified, but does remark that the members of the population must have some familiarity with some of the ideas or objects that get recombined in the creative act. Another alternative is to say that it is the invention's creator or creators who must be surprised by the discovery.

Novitz argues that it is a mistake to associate creativity with the making of art. Many creative acts and inventions have nothing to do with the fine arts, and much art-making, or creation, is routine and devoid of creativity. Novitz joins a long tradition in specifying that genuine creativity must, in addition to manifesting a novel or surprising recombination of ideas or objects, bring forth a result having some real, positive value: "Creative acts are valued positively because they are intended to, and have the potential to, satisfy actual human needs and desires" (2003, p. 186). Novitz also allows that creative acts may also display a form of intrinsic value in addition to such instrumental value. These points are not, however, uncontroversial, as some authors are willing to allow that a fiendish or malicious invention, or intentionally immoral act, could be creative. Some forms of creativity may be useless. Nor is it clear that a viable conception of

creativity need entail strong, realist commitments in the theory of value.

## THE NATURE OF THE CREATIVE PROCESS

Additional controversy surrounds proposals concerning the nature or basic structure of the creative process or processes. One key issue has to do with the question whether the expression "the creative process" really refers to a single type of process or activity. Francis Sparshott (1981), John Hospers (1984–1985), and others state that there is no such thing as a single, determinate process involved in all creative acts, but instead, different sorts of processes having little or nothing in common. Another controversy concerns the extent to which creative activity can be adequately described as a species of problem-solving or means-end rationality. Vincent Tomas rejects the idea that artistic creation is "a paradigm of purposive activity" (1958, p. 2). David Ecker's description of the creation of art as "qualitative problem-solving" (1963) is critiqued by Monroe C. Beardsley (1965), who deems it a mistake to think that creative thinking, in the arts at least, is characteristically a matter of means-end calculations. Even if the sought-for aesthetic and artistic effects do depend on the artist's manipulation of some medium or media, creative work is not throughout guided by the effort to realize some preconceived goal or end: it would be unusual if the precise quality of the final painting were in the painter's mind from the start.

Various investigators have contended that there is a characteristic creative process having a hybrid nature. In an account popularized by Graham Wallas in *The Art of Thought* (1926), this process breaks down into four discrete stages. Creativity requires, first of all, apprenticeship and preparation: even the most brilliant innovator must learn his or her craft. Second comes "incubation," a stage in which the creative person stops working consciously on some problem, allowing unconscious processes to predominate. The result, when circumstances are favorable, is illumination or inspiration, the moment when some unexpected and innovative idea "pops" into mind. In the final stage of "verification," the creator assesses and revises what inspiration has yielded. As Beardsley observes, it would be wiser to replace talk of four linear stages with the idea of an interplay between two alternating phases, namely, preconscious invention and conscious criticism and selection of the latter phase's results. This is similar to Paul Valéry's contention that creative art-making is always a matter of both the spontaneous emergence of ideas, and conscious, means-end adjust-

ments and rearrangements of the latter (1957–1960 [1938]). Only their relative proportion varies, he adds.

Psychologists and cognitive scientists continue to attempt to provide models of complex creative processes in various domains, including musical composition, the formation of scientific hypotheses, the visual arts, and storytelling (for surveys, see Albert and Runco 1999; Boden 2004). The greatest challenge is perhaps that of providing detailed explanations and effective simulations of the processes that underlie and generate moments of inspiration, or “popping.” Psychologists working in a range of traditions, including Gestalt theory, psychoanalysis, associationism, cognitive psychology, interactionism, systems theory, and so on, have devised elaborate labels for the mind’s unconscious generation and selection of novel ideas. Some of these traditional insights have been revived in the development of computer simulations using connectionist and other approaches (Martindale 1995). And in a philosophical vein, Berys Gaut (2003) explores the Kantian connection between creativity, genius, and the imagination, taking metaphor’s linking of diverse domains as a paradigm.

## CREIGHTON, JAMES EDWIN (1861–1924)

James Edwin Creighton, an American idealist philosopher, was born in Pictou, Nova Scotia. Creighton was educated at Dalhousie College, Halifax (A.B., 1887), where one of his teachers was Jacob Gould Schurman, whom he later followed to Cornell University. He was appointed fellow in philosophy there in 1888 and studied in Leipzig and Berlin, returning to Cornell in 1889 as an instructor. He received his Ph.D. in 1892 with the thesis “The Will; Its Structure and Mode of Operation,” and became associate professor. In 1895 he was elected Sage professor of logic and metaphysics, succeeding Schurman, and held that chair until his death. He received LL.D. degrees from Queens University (1903) and from Dalhousie (1914). While Creighton was dean of the graduate school at Cornell from 1914 to 1923, his flexible policies stimulated student initiative, but the administrative demands on his time limited his literary output. He

was coeditor of the *Philosophical Review* from 1892 until 1902, when he became sole editor, and he was American editor of *Kantstudien* from 1896 until his death.

Convinced that the intellectual life is a social venture, Creighton was a cofounder of the American Philosophical Association and in 1902 became its first president. His vigorous instruction influenced the development of philosophy in American education through the efforts of his students, twenty-two of whom honored him with a volume of articles, *Philosophical Essays* (New York, 1917), commemorating twenty-five years of his teaching.

Creighton's "speculative idealism" grew out of his view that philosophical inquiry must occur in the context of the history of ideas and must begin with "the standpoint of experience." But experience is not a simple, isolated particular which can be understood by analysis. Finite individuality has system implicit in it, and can be understood as a part of the order of the universe. It is unity in plurality and identity in difference. It is permeated with meaning. In short, Creighton identified it as the "concrete universal."

Thus, with Bernard Bosanquet, Creighton held that philosophical judgments are ways in which experience progresses toward its goal of intelligibility, and the task of such judgments is to disclose the implications of the dynamic coordinates of experience: mind, nature, and other selves. Reality cannot be identified with mind, will, or personality but must be comprehended as a system in which each entity plays a part as an individual and as a significant function of the purposeful whole. Epistemological problems traceable to Immanuel Kant's emphasis on the centrality of the knowing subject are artificial because mind by its very nature is already in touch with reality. Subject and object cannot be viewed as ontologically discrete but are correlative. Accordingly, Creighton dissociated himself from neorealism, which regards truth as a quality of single propositions; from pragmatism, which fails to see that thought modifies the internal structure of experience itself; and from Berkeleyanism and other "mentalist" idealisms, which interpret nature as a phase of mind, thereby transforming experience unnecessarily into an order of ideas instead of accepting objective reality as a direct intuition. Such idealisms, even Josiah Royce's absolutism, issue in subjectivism and thus deny the objective world. Creighton maintained that this conclusion would render all thought chaotic because the objective order is the presupposition of all rationality.

Appointed to the Carus lectureship in 1924, Creighton planned to develop his views on historical method in philosophy, but death intervened. He wrote

virtually nothing on ethics, aesthetics, or religion, unlike his idealist contemporaries, but certain details of his system can be inferred from his excellent critical discussions of competing movements.

## CRESCAS, HASDAI

(1340–1410)

The Spanish rabbi and philosopher Hasdai Crescas was born in Barcelona, the scion of a distinguished family. He exercised considerable influence both in the Jewish community and at the Aragonese court. After the 1391 persecution of the Jews, in which his only son perished, Crescas moved to Saragossa, where he engaged in literary activity until his death.

Crescas's purpose was to defend Judaism from both internal and external subversion. To this end he composed his Spanish "Refutation of the Principles of Christianity" (extant only in Hebrew translation), a rational critique of Christian dogmatic theology, and his masterwork, *The Light of the Lord (Or Adonai)*, conceived as an introduction to a legal code that was never composed. Crescas

wrote in the tradition of those thinkers, such as Judah Halevi and Nahmanides, who rejected the rationalistic compromising of Judaism with the teachings of Aristotle, but he differed from them in that he chose to combat the philosophers on their own ground. In this respect his position may be compared with that of Muhammad al-Ghazālī in Islamic philosophy. The *Light* is arranged as a dogmatic treatise, beginning with an exposition of the primary concept of God's existence and unity and followed by expositions of certain fundamental and subordinate doctrines. The first section, in which Crescas presents and criticizes the twenty-six basic propositions of physics which Maimonides (*Guide*, Part II, Introduction) culled from Aristotle, is concerned less with advancing a new system than with indicating the inadequacy of those of his forerunners. Crescas conceived of time as duration independent of motion and insisted on the possibility of a vacuum based on a conception of space as extension independent of body. These two notions enabled him to establish the existence of infinite time and space, thereby destroying the concept of the Aristotelian prime mover. Furthermore, the debate over creation ex nihilo is dismissed as futile since, in any event, all is derivative from God, who is the only necessary existent.

Crescas maintained both the literalness of the Biblical attributes and God's unity by advancing the Kalam-like theory of essential attributes compatible with God's absolute simplicity. These attributes are related to the subject as light rays are to the source of luminescence, one being inconceivable without the other, and are bound together by the unifying principle of the divine goodness. It is this goodness or perfection which characterizes the Divinity, rather than the Aristotelian concept of self-thinking thought.

The return of Crescas to the biblical conception of God is best exemplified in his treatment of the problem of the conflict between divine foreknowledge and human free will. Maimonides had taken refuge in the notion that God's knowledge has nothing in common with humanity's while Gersonides sacrificed divine knowledge of the future and the particulars to unconditional human free will. Rejecting both points of view, Crescas felt it unnecessary to reconcile divine knowledge (which he considered absolute) with free will but rather free will with causality. Definitely inclined toward determinism, he maintained that an act is contingent when considered in relation to itself but necessary in relation to its causes and to God's knowledge. Human consciousness of free will consists in the pleasure or disapproval felt when an act is committed.

Divine providence, prophecy, and immortality are not dependent on intellectual perfection, as in Maimonides and Gersonides, but rather on love and reverence for God, which is the purpose of the Divine Law and the universe. It is the substance of the soul itself, rather than the acquired intellect, which survives death.

Crescas's independence of Aristotle helped pave the way for such Renaissance thinkers as the younger Pico della Mirandola and Giordano Bruno. Of particular interest is Crescas's influence on the thought of Benedict (Baruch) de Spinoza, who knew his work well.

### **Bibliography**

The *editio princeps* of the *Or Adonai* (*Light of the Lord*) appeared at Ferrara in 1556 and has since been published several times. The first section, which deals with the 26 propositions, has been edited and translated into English by H. A. Wolfson in *Crescas' Critique of Aristotle* (Cambridge, MA: Harvard University Press, 1929). The section on free will was rendered into German by Philipp Bloch in *Die Willensfreiheit von Chasdai Crescas* (Munich, 1879). Crescas's thought has been surveyed in M. Waxman, *The Philosophy of Don Hasdai Crescas* (New York: Columbia University Press, 1920) and M. Joel, *Don Hasdai Crescas' religionsphilosophische Lehren in ihrem geschichtlichen Einflusse dargestellt* (Breslau: Schletter, 1866). His influence on Spinoza has been discussed by Joel in *Zur Genesis der Lehre Spinozas* (Breslau: Schletter, 1871) and by D. Neumark in "Crescas and Spinoza," in *Essays in Jewish Philosophy* (Cincinnati, OH, 1929). For a full bibliography, see *Encyclopedia Judaica* (Berlin: Eschkol, 1928), Vol. V, pp. 698ff., 708.

## CRESCAS, HASDAI [ADDENDUM]

Hasdai Crescas takes a radical anti-Aristotelian position, and yet he himself presents conclusions that are threatening to the traditional understanding of religion. For example, in attacking the views on the creation of the world by Maimonides and Gersonides he ends up presenting a theory that allows for an eternal world. The world could be eternal in the sense that it would be eternally dependent on God. According to Crescas there is no difficulty about the existence of a vacuum before the creation of the world, and so it is no good objecting to Aristotle that something

could not come from nothing. He even contemplates the possibility of this world being only one of a number of worlds, each existing along with the others.

Crescas is unusual also in accepting the existence of the infinite, a concept that many Aristotelians think suggests an absurdity, and the discovery of which is taken by Aristotelians to indicate an impossibility in the argument. The concept of infinity allows Crescas to envisage an infinite space in which a vast variety of worlds could exist.

Still, the qualms about infinity that his predecessors held had allowed them to argue for the necessity of a first cause, since otherwise the series of causes and effects would continue infinitely. Crescas's attack on Aristotle led him to propose a range of ideas and arguments that were to play a major part in the acceptance of new ways of thinking not only in philosophy but also in science.

## CRITERIOLOGY

"Science of criteria" or "criteriology" is a term, originally neoscholastic, for a theory of knowledge in which judgments are warranted or justified simply by conforming to certain criteria for correct judgment. These criteria are general principles that specify what sorts of considerations ultimately confer warrant on some judgments and that tend (tacitly) to guide self-reflective persons in checking and correcting their judgments. The epistemologist's task is to formulate these principles by reflecting on the considerations present and absent in various judgments we intuitively think of as warranted and unwarranted.

Different criteria may deal with different subject matters, degrees, and sources of warrant (e.g., in perception, memory, inference). Ultimately, there must be warranting considerations other than inferability from other warranted judgments. These must be internally accessible through introspection or reflection without relying on further warranted judgments. They will not be considerations such as whether nature designed us to be reliable judges but ones such as whether we ostensibly see or recall something or intuitively grasp or clearly and distinctly conceive something.

Many epistemologists argue that critical considerations need not guarantee truth or confer certainty, and whatever warrant they confer may be defeated. For instance, if one ostensibly sees something red, one is prima facie or defeasibly warranted in judging that one actually sees something red. The judgment might not be warranted when, despite ostensibly seeing something red, one has evidence that the illumination makes everything look red. We need additional principles specifying what considerations defeat warrant.

However, if criterial considerations do not guarantee truth, what makes a set of principles genuinely warranting? Putative common contingent features such as their overall reliability rest warrant on something beyond mere conformity to these principles and may allow for alternative principles. Criteriologists (e.g., Pollock 1974, 1986) often appeal to controversial, nonscholastic, views about concepts and truth influenced by Ludwig Wittgenstein. Criteria are internalized norms (rules) about when to make and correct judgments ascribing a concept. They characterize what persons must, in order to have a particular concept, tacitly know how to do in their judging and reasoning and be tacitly guided by. Criteria individuate our concepts and thus are necessarily correct. Although warranted judgments need not be true, we have no idea of their truth completely divorced from what undefeated criterial considerations warrant. Critics often respond: Surely this norm conformity must have a purpose beyond itself, like accurately representing the world?

## CRITICAL REALISM

*Critical Realism* is the title of a book by Roy W. Sellars published in 1916. The name was adopted by a group of philosophers who shared many of his views on the theory of knowledge. *Essays in Critical Realism: A Cooperative Study of the Problem of Knowledge* by Durant Drake, A. O. Lovejoy, J. B. Pratt, A. K. Rogers, George Santayana, C. A. Strong, and Sellars was published in 1920.

### BACKGROUND

Much of the epistemological debate since the seventeenth century stems from the matter-mind dualism of René Descartes, who argued that what we know first and most surely is not a physical world but the existence of our own minds, and of John Locke, who argued that we are immediately acquainted only with our own ideas. Starting from these assumptions, how can one know a physical world external to the mind, if, indeed, such a world exists at all? Critical Realism is a chapter in this long debate. Some philosophers, finding it impossible to bridge the gap from a mental world to a material reality that transcends it, turned to some form of subjectivism or idealism; at the beginning of the twentieth century the dominant philosophy in Britain was the Neo-Hegelian idealism of F. H. Bradley and Bernard Bosanquet, and in America it was the voluntarism of Josiah Royce, the personalism of George H. Howison and Borden Parker Bowne, or the pragmatism of William James. But idealism, uncongenial to common sense and to ordinary interpretations of

physical science, was followed by a reaction. Scientific knowledge seemed to support philosophical realism rather than idealism.

Shortly before the emergence of Critical Realism a group of philosophers, calling their view the New Realism, argued that even if it is true that whenever something is being perceived, it is an object for a mind, it does not follow that it has no existence except by being perceived. Hence, the idealist commits a fallacy if he concludes that the whole world is nothing but ideas from the truism that when something is known, it is an object for a mind. The American new realists, then—and here they could claim the support of such important British thinkers as G. E. Moore and Bertrand Russell—maintained that elements in perception can at the same time be elements in the physical world. Things do not cause ideas in us, as Locke would have said, so that we first know only ideas and then try to infer from them the nature of the real world which is never directly perceived. Rather, knowing is more akin to selecting, or throwing a light upon, aspects or parts of a world already there to be selected or illuminated by the light of consciousness.

### THE CRITICAL REALIST POSITION

The critical realist agrees with the new realist in holding that there is an objective physical world; their disagreement is chiefly on the question of the relation of the datum of knowledge to its object. Physical things, or parts of them, cannot be directly presented to us in perception. Considering the great variety of what is perceived—the double image, the partially submerged bent stick, the toe that is felt after the leg has been amputated—under various conditions by both normal persons and those who are, for example, inebriated or color-blind, are we to say that the real world actually contains all that is disclosed in all these circumstances? And is there no such thing as error? The trouble is that the "direct" realist, by identifying the immediate data of knowledge with elements of the physical world, is trying to account for the universe with an insufficient number of categories or kinds of entities. The knower, whether he is conceived as an organism and a part of nature or as a mind, does not "take in" the physical world. According to Santayana, the datum is an essence, a Platonic universal, which has an identity by being just the character it is, whether it characterizes one or many things in nature or characterizes no existent whatsoever. The datum, the immediately intuited evidence of reality, cannot be numerically identical with any part of that reality.

It is on this epistemological point that the critical realist opposes both the idealist and the direct realist. Whatever exists and whatever its character may be, no datum, or essence, given in experience exists, at least not in the sense in which we say that the objects of perception exist. As Santayana says in *Scepticism and Animal Faith*, “Existence is never given.” When the astronomer talks about the moon, he does not mean by “the moon” the yellow disk image that may come to your mind; no doubt, a different image will come to the mind of your companion. If both of you understand the astronomer, “the moon” will mean to both of you, and to the astronomer, the same object to which your thoughts or perceptions are referred—namely, the distant satellite of Earth to which you ascribe certain physical properties. The words or images are the symbols of a meaning, but the essence of the word or image is not, in general, the essence of its meaning. The essence of the meaning is intended to be, but in cases of error will not be, the essence of the actual moon in the sky. This distinction, perhaps difference, between the nature of an image or sense datum and the nature of the object known by means of it is still more obvious when we consider feelings instead of visual images. When sympathizing with a person who has a toothache, we do not say, “I feel the way you feel”; we say, “I know how you feel.” Knowing about another person’s toothache is not having a toothache.

In perception, as distinguished from thought or conception, there is a tendency to identify image with meaning, so that an effort of analysis is required to separate image, meaning, and object. Paradoxically, the meaning is often psychologically prior to the image. For example, we may perceive a penny as round and as “out there” before noting that in the given perspective it presents an elliptical image. We can then analyze the situation into the image (elliptical), the meaning (round), and the belief that a round object was out there. Error is possible because there may be no object having the same essence as that contemplated in the meaning we have given to the elliptical image that was presented to us. A resolute skeptic who doubts all existence cannot be proved to be mistaken, but if he is consistent, he should be as skeptical of the existence of other minds and even of his own living self as he is of a physical world. Since the idea of change is no guarantee of actual change or process, he should arrive at an inarticulate solipsism of the present moment.

Yet there is no doubt that philosophers as well as laypeople normally believe in the existence of themselves and other minds and ascribe at least some of the characters they intuit to things that exist in space at present or

past times. In memory and in the belief in history, the referent of present thoughts is a world of things and events believed to be existentially real and independent of any intuitions, present or past. An actual past or future is not given in any datum, but when one speaks, as David Hume did, of having or of being a succession of perceptions, one posits the existence of a temporal series of events and thereby instantiates in existence one or more essences. To ascribe existence to an essence as such would be a logical or categorial error; it would equally be a logical error to assert that an essence had been intuited by some mind or that some event or perception had occurred and at the same time deny that there is any factual temporal existence. The ontological status proper to essences is timeless subsistence. Actual intuitions come to exist on particular occasions, but knowledge of what they mean, says Santayana, “involves a leap of faith and action from the symbol actually given in sense or thought, to some ulterior existing object.”

In *Essays in Critical Realism* Santayana argued that a child reaching for the moon is in quest of an object deployed in a physical world along with the outstretched arm and other bodies. If the moon did not transcend experience, if what is experienced were itself the object striven for, it would already be attained, and there would be no biological need to employ the presently intuited essence as a symbol for an existence still to be reached. There would be no knowledge about anything nor any need for it. If there is any validity in our scientific and commonsense beliefs, our intuitions are engendered in a biological organism by a natural environment. Matter in flux embodies now one essence, now another, and the set of propositions that describes all that exists at all times constitutes the realm of truth. Truth is therefore that part of the realm of essence that happens to characterize existence, and to have knowledge is to believe what is true.

But believing a proposition does not guarantee its truth, beyond the truth of the fact that it is believed. The terms of our beliefs are, in general, symbolic rather than literal representations of nature. Does it make any difference, then, if we clothe nature with intuited essences that are more fanciful than true as long as they are signals for successful action? If a pragmatist at this point suggests that truth means no more than the verification in later experience of the anticipated result of action guided by the earlier experience, the realist cannot agree. The pragmatist does agree with the realist that in knowing there is a reference beyond the immediate having of perceptions, but for the pragmatist the consummation of knowing, the successful working of an idea, does not go beyond

experience; the referent of an idea is another experience. This avoids the problems of a mind-matter dualism and avoids the unanswerable question: How can we know when our ideas correctly represent external things? But the realist sees the pragmatist position as a reversion to idealism and subjectivism and will have none of it. If the pragmatist, to escape idealism, speaks in naturalistic terms, he admits all that the realist asks for. Lovejoy quotes William James: "Practically our minds meet in a world of objects which they share in common" (*Essays in Radical Empiricism*, New York, 1912, p. 79) to show that the practical man, going about his business of solving problems, must assume the existence of an external world; it is important that he discover what its properties were antecedent to and independent of the inquiry in which that discovery is made. Phenomenalism and positivism, sharing with pragmatism the view that the referent of all that can be meaningfully said about real existence must be, in principle, capable of being found in direct experience, are likewise rejected by the critical realist.

How, then, is knowledge of an external reality possible? The critical realist maintains that Locke erred in taking his own ideas to be the objects of knowledge. Knowledge, Locke said, is nothing but the perception of the agreement or disagreement of our ideas. When he comes to a discussion of "knowledge of real existence," however, he is forced to abandon his own definition, and true knowledge becomes the correspondence between ideas and external things. The critical realist argues that Locke should have recognized that when ideas are used in knowing, as distinguished from being merely entertained or had as an experience, there is always reference to an object other than themselves. But merely insisting that data have a referent beyond themselves does not tell us why we should believe one interpretation of them to be a truer description of the facts than any other interpretation. In his more skeptical mood Santayana tells us that knowledge is only faith mediated by symbols, yet in *The Realm of Matter* he sets forth what he takes to be the "indispensable properties of substance." Presumably, he means literally true properties. Substance has parts external to one another and, being in flux and unequally distributed, constitutes a spatial and temporal field of action. These are very nearly those primary qualities that Locke had said resemble the ideas the mind has of them, and if the critical realist seems to have a better case for his position than Locke had, it is chiefly because the sciences have supplied us with a detailed account of the mechanism of perception.

The scientist finds by actual experiment that the date of emission of light from the star, the distorting intervening media between the star and the observer, and the physiological peculiarities of the observer's body all condition what turns up at what time in the experience of the observer. But this scientific account cannot be used by the critical realist to support his position without begging the question. What is proved is that whenever something is found in our world, we can also find something else related to it; scientific knowledge consists of finding what is related to what. This supports the critical realist's thesis that experience depends upon a reality outside all possible experience only if it is assumed from the outset that the experimental data used by the astronomer and by the physiologist are experienced effects of a physical star and a physical organism. The scientist could interpret his explanatory theories on idealist or pragmatist, instead of on critical realist, assumptions. Hence, it is not what the scientist finds, but the epistemology he happens to assume, that supports critical realism. The best that can be said for this realist assumption is that it may be the most economical way to predict and control our experiences and that it may even be the truth about reality.

#### DIFFERENCES AMONG CRITICAL REALISTS

Some of the critical realists, including Sellars, believe that their position is not best interpreted, even by some within their own camp, when a curtain of essences, ideas, or sense data is drawn between the perceiver and the objects he wants to know by means of such data. For in that case, as in Locke's representative perception theory, the essences or ideas are themselves the only possible objects of knowledge. Sellars would escape this difficulty by what he believes to be a more adequate account of perceiving. When a biological organism has sensations—that is, is affected by an object in the environment with which it must come to terms—the sensation functions as information about the object that caused it. Perception is a response; it is an act of taking the sensation as the appearance of the external object. It is not the sensation or the sense datum that appears; it is by means of the sensation that the object appears. A sophisticated analyst might make the qualities of the sensation the object of his study, but then he is no longer using them to decipher things.

Sellars finds an ally in the English philosopher Gilbert Ryle, who follows common sense in the belief that we perceive trees and hands, not sense data. Here it would seem that Sellars has left the critical realists to join the direct realists, but he would insist that he is not taking

either a direct presentational view or a Lockean representational view. The mediating role of sensation, which determines how the object will look, is not to be ignored. We look *with* our sensations but not *at* them.

In addition to some differences about the role of essences and of sense data, the critical realists are not all in accord on questions of metaphysics. Sellars and Santayana could be called metaphysical monists because for them only one kind of substance—matter—exists. The psyche of which Santayana speaks is the conscious material organism. Sellars thinks of the so-called mental functions not as being carried on by a substantial mind but as ways in which biological organisms, after a long evolutionary development, have learned to respond to stimuli.

Lovejoy, on the other hand, maintains that only a psychophysical dualism is a tenable corollary of an epistemological dualism; only a mind could have sensations and thoughts and intend or mean objects by them.

There has, then, been considerable divergence in the views of thinkers who were, and many who still are, called critical realists. Some have drawn closer to the positions of the direct realists in America or in Britain, and it may be that the label will cease to characterize a definite epistemology.

## CRITICAL THEORY

"Critical theory" is used to refer to the diverse body of work produced by members and associates of the Frankfurt Institute for Social Research after Max Horkheimer became its director in 1930. The first generation of what came to be called the Frankfurt school included, in addition to Horkheimer, such prominent figures as Theodor Adorno, Herbert Marcuse, Walter Benjamin, Erich Fromm, Leo Löwenthal, Franz Neumann, Otto Kirchheimer, and Frederick Pollock. The most influential members of the second generation are Jürgen Habermas, Karl-Otto Apel, and Albrecht Wellmer. As the variety of backgrounds and interests might suggest, critical social theory was conceived as a multidisciplinary program linking philosophy to history and the human sciences in a kind of "philosophically oriented social inquiry," as Horkheimer put it. Though very strongly influenced by Immanuel Kant and neo-Kantianism, Georg Wilhelm Friedrich Hegel and German idealism, Max Weber and Sigmund Freud, it was understood as a renewal of Marxism inspired in part by the earlier work of Georg Lukács and Karl Korsch. This updated Marxism would take account of the altered historical realities of advanced capitalism and integrate areas of inquiry neglected by traditional Marxism, such as philosophy and political theory, cultural studies (including studies of mass culture), and social psychology (appropriating psychoanalysis for social theory). With the rise of National Socialism, the institute moved briefly to Geneva and Paris in 1933 and

then in 1934 to Columbia University in New York, where its journal, the *Zeitschrift für Sozialforschung*, continued to be published until 1941, the last volume in English. Early in the 1950s, Horkheimer and Adorno reestablished the institute in Frankfurt. Habermas became an assistant there in 1955.

The original project of a critical social theory advanced by Horkheimer was a version of Karl Marx's *Aufhebung* of philosophy in social theory and practice. Philosophy was to become a sociohistorical, practically oriented critique of reason and its claimed realizations. While the dominant forms of reason were often distorted in the interests of dominant classes, the aim of critical theory was, not simply to negate them, but, by examining their genesis and functions, to transform them and enlist them in the struggle for a better world. The insistence on the "truth content" of the "bourgeois ideals" of freedom, truth, and justice, the refusal to abandon them as mere ideology, was severely tested by the horrors of World War II. Early in the 1940s, in their collaborative reflections on the "dialectic of enlightenment," Horkheimer and Adorno offered a much more pessimistic view of the history of reason. Keying on a tendency that Weber had emphasized, the relentless spread of "instrumental" rationality, they revered Marx's positive evaluation of scientific-technological progress. It was now seen as the core of a domination that had spread to all spheres of life and, in the process, had immobilized the potential agents of social change. In this "totally administered society" with what Marcuse later called its "one-dimensional man," critical theory could at best reveal the unreason at the heart of what passed for reason, without offering any positive account of its own.

Habermas's work since the 1960s might be viewed as an attempt to avoid this impasse by introducing into critical theory a fundamental shift in paradigms from the philosophy of the subject to the theory of communication and from means-ends rationality to communicative rationality. This serves as the basis for an altered diagnosis of the ills of modernity—as rooted, not in rationalization as such, but in a one-sided rationalization driven by economic and administrative forces—and an altered prescription for their cure, the democratization of public opinion and will formation in an effectively functioning public sphere, where issues of general concern are submitted to rational, critical public debate.

## CROCE, BENEDETTO

(1866–1952)

Benedetto Croce was the best-known Italian philosopher of the twentieth century. His universally and justly celebrated book on aesthetics, *Estetica come scienza dell'espressione e linguistica generale* (1902), which became the first volume of his systematic "philosophy of the spirit," was a foundation stone in the great revival of historical idealism in Italy between 1900 and 1920. In a long and diligent life devoted almost entirely to scholarly studies, Croce gained an international reputation in the fields of aesthetics, literary criticism, cultural history, and historical methodology; and he exercised in these areas an influence so pervasive that it cannot yet be definitively estimated.

### LIFE AND WORKS

Born at Pescasseroli, in the Abruzzi, of a family of wealthy landowners, Croce never needed to earn a living. He displayed an early bent for literary and historical research but never seriously entered on an academic career, preferring to be master of his own course of study. From 1883—when his parents were killed, and he himself buried and injured, in an earthquake—until 1886 he lived with his uncle Silvio Spaventa (brother of the philosopher Bertrando) in Rome, and for a time he attended the university there. At the university he came under the influence of Antonio Labriola, who led him to the study of Johann Friedrich Herbart and, later, of Karl Marx. These studies left a lasting mark on his philosophy. After 1886 he lived permanently in Naples.

In 1893 Croce published his first philosophical essay, "La storia ridotto sotto il concetto generale dell'arte"

(History brought under the general concept of art), a title that foreshadowed the main concerns of his mature thought. In 1898, while working on a book on Marx (*Materialismo storico ed economia marxista*), he entered into correspondence with his younger contemporary, Giovanni Gentile, who was similarly occupied. Thus began a friendly collaboration that lasted twenty-five years. In 1900 came the first sketch of Croce's *Aesthetic*. In 1903 he founded the journal *La critica*, and in 1904 he became an editorial adviser to the publishers Laterza of Bari. For the rest of his life he exercised an ever-increasing influence on the literary and academic world through these two channels.

Even as the volumes of Croce's philosophy of spirit were being published, his association with Gentile was leading him to a reexamination of G. W. F. Hegel. He published his results in 1907 (*Ciò che è vivo e ciò che è morto nella filosofia di Hegel*) and made appropriate revisions in his *Estetica* and in his *Logica come scienza del concetto puro* (1905). *Filosofia della pratica, economia ed etica* appeared at Bari in 1909. In 1911 he published *La filosofia di Giambattista Vico*—Giambattista Vico was the other major influence on his thought—and in the succeeding years he wrote the essays that appeared at Bari in 1917 as the culminating volume of his system, *Teoria e storia della storiografia*.

In 1910 Croce was made a life member of the Italian senate, but he was not then actively involved in politics. He was a neutralist prior to Italy's entry into World War I in 1915; and in the postwar crisis, he became minister of public instruction in Giovanni Giolitti's last cabinet (1920–1921). With Gentile's help, Croce drafted a reform of the school system, rejected at the time but later incorporated in the fascist *Riforma Gentile* of 1923–1924. Naturally, therefore, he regarded the first fascist administration with some benevolence. His breach with fascism (and with Gentile) came with the establishment of an overt dictatorship in January 1925. He drafted a celebrated "Protest" against Gentile's "Manifesto of Fascist Intellectuals" and thus became identified as the chief antifascist intellectual, a role he worthily maintained through more than fifteen years of almost complete political isolation and retirement. He emerged briefly in 1929 to speak in the senate against the concordat with the Vatican. After the fall of fascism he became a leader of the revived Liberal Party and served once more as a cabinet minister for a short period in 1944.

During his years of isolation, Croce wrote voluminously and his thought developed significantly. His aesthetics reached its final form only in *La poesia* (1936). His

opposition to fascism is often apparent in his literary criticism, but it expressed itself more naturally in his historical writing and in theoretical reflection on politics and history, where it led to vital developments in his thought.

Croce celebrated his eightieth birthday by founding and endowing the Institute for Historical Studies, which is still located in his former home. In spite of a serious stroke in 1950, he went on working right up to his death.

## AESTHETICS

When Croce's philosophical interests were first aroused in 1893, he was a historical and literary scholar who accepted most of the assumptions of the French positivism then dominant in the circles in which he moved. But controversy led him to ask himself whether history was an art or a science, and he made a decisive choice in favor of the idealist view of the great Hegelian philosopher of art and literary historian Francesco De Sanctis (1817–1883). Initially, his idealist aesthetics was set in a context of a realistic metaphysics, of which there were still some signs in the *Aesthetic* of 1902; but the attempt to expound his view systematically, combined with his discovery of Vico and rediscovery of Hegel, led to the development of his full-fledged idealism. Thus, his aesthetic theory was the original foundation of his philosophy of spirit, although it might fairly be argued that the theory of moral judgment became more fundamental in the final form of his system. Croce himself distinguished four phases in his reflections on aesthetics. Some critics have held one or more of the later phases to be inconsistent with his system as a whole, but they will here be viewed as part of a continuous and essentially consistent evolution.

**AESTHETIC INTUITION.** It is characteristic of idealist aesthetics to regard aesthetic experience as a kind of cognition. Following Vico and De Sanctis, Croce regarded it as the primitive form of cognitive experience. Intuition is a nonconceptual form of knowledge; it is the awareness of a particular image either of outward sense (a person or a thing) or of inner sense (an emotion or a mood). Intuitions possess a kind of ideal being and validity that is independent of and ontologically prior to any question of existence or nonexistence. Croce's use of the term *intuition* derived directly from Immanuel Kant's use of *Anschauung*, and he originally thought of the external world as a Kantian manifold of sensation, which we organize into distinct perceptions through the intuitive faculty of imagination. Thus, history was initially "subsumed under the general concept of Art," as the subform of art that is concerned with the ordering of intuitions of

actual existence. He soon abandoned this position, but if Kant's theory of space and time as the "forms of intuition" through which the sensible manifold is organized is recalled, it can be seen how Croce's view applies to the plastic arts, which he often seemed to ignore. His own background and interests were predominantly literary, and his theory frequently seems specifically devised to meet the needs of literary critics who have to deal with poems, which are uniquely individual entities created in the conceptual (or logically universal) medium of language. Croce himself fostered this illusion by insisting that aesthetics was "the general science of language." This is a very Pickwickian contention on his part, since the conceptual function of words and symbols in factual communication—which must surely be regarded as fundamental in a general theory of *language*—is specifically excluded from his "science of expression"; and all forms of nonconceptual communication—even nonverbal ones—are included in it.

**LYRICAL INTUITION.** If it had not been for his overriding concern with poetry, Croce might never have advanced to the second phase of his aesthetics, the theory that all intuition is "lyrical" in character. The problem he faced was essentially one of defining what it is that is non-conceptually communicated in poetry by way of language. His answer was that poetry communicates emotions and moods, it expresses for cognitive contemplation different aspects of the practical personality of man. Here the "circle of the spirit," the doctrine that man's theoretical activity has his practical reality as its one and only object, comes into view. By means of this doctrine, Croce was able to dispense with the last residues of naive realism present in his basically Kantian epistemology. Some doctrine of this sort was certainly needed if the view that art is nonconceptual cognition was to be maintained. As Croce said in 1908, in his lecture announcing the doctrine, "An image that does not express a state of mind has no theoretical value." But the need might well have appeared less pressing, and the solution less natural and obvious, if he had not always thought primarily about poetry.

It is easy—especially if one reads only the *Breviary of Aesthetics* (1912), as many English-speaking students do—to misinterpret Croce's theory that all art is lyrical as a type of romanticism, which he was, in fact, absolutely opposed to. His doctrine was that art is the expression of emotion, not just for its own sake but as a special kind of cognitive awareness. He was seeking a middle way between the intellectualist errors of classical theorists, with their artificial canons, rules, and genres (all of which

he categorically rejected), and the emotional excesses of the romantics, with their glorification of immediate feeling. His critique of classical intellectualism is easily grasped; but it is a mistake to think, as some critics have, that his "lyricism" is radically inconsistent with his own systematic rationalism. Unlike Gentile, Croce always refused to identify intuitions as "feelings" or to formulate his theory in terms of "feeling" at all, because he held that "feeling" was an ambiguous concept which when clarified referred to the practical impulse that is the content of intuition.

**COSMIC INTUITIONS.** How can the expression of emotion produce cognitive awareness? This was the problem that Croce faced in the third phase of his thought—his theory that all intuition has a "cosmic" aspect. Again, some doctrine of the sort was required by his basic thesis that intuition is cognitive of particulars without reference to their existential status. Simply as images they provide experience of the universal human spirit. This self-validating character, this reference to universal humanity (not as an abstract nature or essence but as the activity of the spirit revealing itself in personal experience and in history as a whole) is what Croce called the cosmic aspect of genuine intuition. Some intuitions, however, are more directly cosmic than others and are hard to characterize in terms of specific emotions; this was the classical counterweight against lyrical romanticism in Croce's thought. It was apparently suggested to him by an essay of Wilhelm von Humboldt on Johann Wolfgang von Goethe, and he applied it in critical studies of such masterpieces as *Faust* and the *Divine Comedy*. Oddly enough, however, it was neither Dante Alighieri nor Goethe, but Ariosto, who served as Croce's paradigm of the cosmic poet. Croce earnestly desired to avoid confusion between the proper lyrical unity of a poem and the logical coherence of a philosophical system. His own critical practice even provides some justification for the view that the whole cosmic phase of his theory was an aberration. The truth is rather that it was an inescapably necessary complement of his general view and that his critical practice suffered from an antiphilosophical bias.

**LITERATURE AND ART.** The final phase of Croce's aesthetic theory is the theory of literature in *La poesia*, which forms the negative corollary of his theory of intuition. Much that is ordinarily classified as art was, in Croce's view, not properly art at all because in it the purity of intuitive cognition is subordinated to various practical ends, such as entertainment or intellectual and moral instruction. For instance, he declared the *De Rerum*

*Natura* to be a work of literature, not of art; and although this is an extreme case of his critical bias, it is easy to see what led him to it, since the passionate conviction and practical aim of Lucretius are evident in every line of the poem.

## LOGIC OF HISTORY AND THE SCIENCES

As aesthetics is the science of pure intuition, so logic is the science of pure concept; and as pure intuition is the form in which we imaginatively express some particular aspect of the human spirit, so pure conception is the form in which we rationally evaluate these particular manifestations and relate them to one another and to the spirit as a systematic unity. Thus on the one hand, conceptual cognition presupposes intuition because it requires intuitions as its material; and on the other hand, aesthetics, the science of intuitive cognition, is only a subdivision of logic because beauty is a form of the pure concept. Concepts presuppose intuitions but are not derivable from them; and any evaluation or correlation of intuitions—even the categorizing of them as intuitions—presupposes concepts. This is the “dialectic of the distincts,” which Croce insisted was more ultimate and fundamental than the Hegelian dialectic of opposites. His model here was Kant, rather than the often-cited Vico. For Vico, as for Hegel, poetic cognition was already an immature form of reason, or, in other words, reason develops out of it; whereas for Croce, as for Kant, the two functions were quite distinct and interdependent, although not equally primitive. Croce’s aesthetics was a new transcendental analytic, and his logic was a new deduction of the categories.

**KNOWLEDGE.** For Croce, however, the words *reason* and *knowledge* meant something very different from what they meant to Kant. Croce’s work was a “critique of historical reason,” and the knowledge that he regarded as genuine was historical knowledge. It is only to historical judgments that the predicates “true” and “false” are properly applicable. According to Croce, the scientific knowledge of Kant’s *Critique* was a myth, and belief in this myth was one type of logical error. (Croce offered an exhaustive analysis of the types of logical error as a sort of negative proof of his own deduction.) Science and scientific investigation are forms of practical activity, not of cognition. They cannot be genuinely cognitive because they are founded on pseudo concepts, not on the genuine forms of the pure concept.

Thus, for example, if a child reports that “the cat is on the mat,” this is a statement of historical fact and its truth or falsity can be established. But if a scientist says, “The cat is a mammal with such and such properties,” the words *cat* and *mammal*, together with all the property-terms, are abstract universals, artificial summaries of actual aesthetic and historical experience. These abstractions are enormously useful in practical experience—indeed, they are vital to the intelligent planning of our lives—but they could only be the basis of genuine knowledge if we were endowed with the kind of rational intuition into the “real essences” of things that is described in Plato’s myths.

The forms of the pure concept are the distinct forms of the spirit itself, since only a proof that some form of the spirit is “distinct” in Croce’s sense could establish the a priori validity of a proposed category or standard of judgment. There are four such forms and, hence, four ways in which our experience can be cognitively categorized and evaluated. Any proper element of experience can be considered from two theoretical and two practical points of view; it can be evaluated intuitively, rationally, economically, or morally.

**ERROR.** In his theory of error, Croce followed René Descartes and Antonio Rosmini. He regarded all genuine error as caused by the intrusion of practical motives into theoretical contexts. He was primarily concerned with philosophical errors, such as the belief that science is knowledge or the belief in myth (a historical narrative possessing absolute significance), which he took to be the origin of religion. About mistakes in historical interpretation, his view appears to have been that (if the historian advances his hypotheses in a properly tentative spirit) they are not really errors but stages in the development of truth.

**PHILOSOPHY AND HISTORY.** Under the influence of Gentile, Croce accepted the Hegelian identification of philosophy with the history of philosophy and reduced even the a priori judgments of his own logic (for example, that there are four forms of the spirit) to the status of historical judgments. He did this because he held that no one could “close the gates of truth” against further progress. Yet he never accepted Gentile’s view that this formal concession to the future meant that all deductions of “the forms of the spirit” were mistaken; he remained convinced that his logic possessed an eternal validity. In his view, the unity of philosophy and history was a unity of distincts.

## ECONOMICS AND LAW

The most fundamental of all distinctions in Croce's philosophy is the distinction between theory and practice. Goaded by the actual idealists who sought to unify theory and practice in the "pure act," Croce tried to justify this distinction by arguments that were largely wasted, because his opponents did not really deny the distinction any more than he denied the unity. The only point at issue was the more general question of whether the unity arose from a dialectic of opposed moments or of distinct forms.

**ECONOMIC UTILITY AND VITALITY.** It has already been shown how the circle of the spirit first appeared when Croce recognized practical impulse as the presupposed content of intuition. It would seem to follow that the practical manifestation of the spirit is somehow more primitive than the spirit's theoretical functions; but the implication is, at best, only a partial truth, for Croce claimed also that the primitive form of practical activity—economic volition—presupposes both forms of theoretical activity. He had learned from his long study of Marx and of the English classical economists that the calculation of economic utility is a rational process and that economic action involves historical judgment. The practical impulse that intuition presupposes, considered in itself, is not yet the conscious action of the spirit; it is only the blind urge of organic life out of which the spirit emerges. But the origin of volition in vitality is what accounts for the independence that Croce always ascribed to economic utility as a distinct spiritual form. Critics objected from the beginning that there was a paradox involved in treating utility as an autonomous form of value. There is no such thing as simple usefulness; there is only usefulness for some purpose. It is really life or vitality that is the primitive category of action. In later writings Croce recognized this, but he continued to hold that economic action is the first form of action in the true sense.

In spite of Croce's insistence that the "utility" of the economists is a fundamental philosophical category, his logic does not allow the admission of economics itself as a genuine philosophical science. The work of economists, like that of all other scientists, belongs to the category of utility itself, not to that of truth. "Economic man" is a paradigm case of a pseudo concept.

**LAW AND UTILITY.** It is more surprising, perhaps, to find the concept of law subsumed under that of utility in Croce's system. The Kantian model, which we have

appealed to several times, might lead us to expect moral law as the universal form of practical consciousness. Law in fact functions as a transitional notion in Croce's system because it may be obeyed either from motives of duty or from motives of expediency. Croce held, however, that in the making and execution of law we should be guided strictly by considerations of social utility, since no one can make a genuinely moral judgment about what is right for a whole class of cases defined abstractly. Laws are of necessity framed in terms of the pseudo concepts of economics and social science; even the moral habits and rules we adopt as our own guides are similarly abstract. They belong among the instruments of life, not among its purposes. Because so much of the work of government is also instrumental, Croce tried at first to formulate a purely economic theory of political action in general. This view he subsequently abandoned.

## ETHICS AND POLITICS

Moral action and moral judgment are the distinct universal forms of practical consciousness corresponding to economic action and economic rationality. The dialectic of the distinction is closely analogous to that of the two theoretical forms. There can be economic acts that are not moral (for example, historical explanation of an *immoral* act is bound to be at the economic level); but there cannot be moral acts that have no vital utility (asceticism or abstract moralism is a moral error). On the other hand, practical activity cannot concretely achieve rationality at the economic level without superseding that level. There can be no theory of economic life except from an independent ethical point of view. This is shown by the inconsistency of utilitarian ethics, which attempts to justify individual self-sacrifice by smuggling in moral principles that have not themselves been accounted for. Confined strictly to the economic level, rational people would live in the Hobbesian state of nature, and all the consequences of Hobbesian philosophy would follow.

Moral, as distinct from economic, consciousness is the awareness of some definite act as a duty overriding private inclinations. Moral judgment declares the act to be a duty because it embodies some universal spiritual value (which may fall under the category of beauty, truth, or social utility or be a distinctively moral good). Whatever category the value belongs to, if the act is a moral duty, there is always a sense of "harmony with the Universe." The moral point of view is the final all-embracing awareness of the spirit as a whole, in its wholeness; hence this is the point of view from which true history can be written.

FREEDOM. Because he held that all true judgment is historical, Croce could do little except offer historical illustrations of his view. Reflection on the nature of history itself and on the reason for rejecting scientific concepts as pseudo concepts, however, throws further light on goodness as a distinct category of the spirit. Science fails to be genuine knowledge because the spirit in all its forms always exhibits spontaneity and individual uniqueness. At the moral level, this spontaneity becomes conscious freedom and self-possession. History is “the story of liberty,” and freedom is another name for the good as a distinct form of value.

ETHICO-POLITICAL HISTORY. Gentile buttressed an ethical theory similar to Croce’s with the Hegelian conception of the national state as an ethical organism and as the bearer of the spirit in history. Croce admitted that if one interpreted the concept “state” broadly enough, this was a legitimate way of viewing it. But he was initially more inclined to think of politics as an economic art or technique of directing selfish passions into orderly channels (as if there were no conflicting moral ideals in political life). The advent of fascism taught him that both of these extreme views were mistaken. Politics does involve moral consciousness, but the absorption of all morality into the “ethical state” is a “governmental concept of morality” unacceptable in a society of free men. The true bearer of the spirit is the individual moral agent, and the state contains the dialectic of practical life as a whole (economics and ethics). The ethical universal is only fully revealed in the history of the state so conceived. Political life, as the unity in which all spiritual activities (even poetry) have a place, is raised to the ethical level in the consciousness of the historian who writes ethico-political history. This is the complete expression of the spirit in which philosophy and history are unified. Croce’s work as a historian, particularly in *La storia del regno di Napoli* (History of the Kingdom of Naples; 1925), illustrated how this concept applies to periods of decadence as well as periods of progress.

The “circularity of the spirit” might seem to require that this form of historical consciousness become the content of poetic intuition. But Croce never made this point, and he does not seem to have held this view. The circle of the spirit, as he describes it, closes by returning from vitality to poetry. Ethico-political history transcends the circle altogether because it is the perfected consciousness of the spirit in its circularity.

## Bibliography

### WORKS BY CROCE

- Croce’s *Opere complete* as of 1965 consists of 67 volumes.
- La storia ridotta sotto il concetto generale dell’arte*. Naples, 1893.
- Materialismo storico ed economia marxista*. Palermo, 1900.
- Translated by C. M. Meredith as *Historical Materialism and the Economics of Karl Marx*. New York: Macmillan, 1914.
- Estetica come scienza dell’espressione e linguistica generale*. Bari: Laterza, 1902. Translated by Douglas Ainslie as *Aesthetic*. New York, 1909; 2nd complete ed., 1922.
- Logica come scienza del concetto puro*. Naples, 1905. Translated by Douglas Ainslie as *Logic*. New York, 1917.
- Ciò che è vivo e ciò che è morto nella filosofia di Hegel*. Bari, 1907. Translated by Douglas Ainslie as *What Is Living and What Is Dead in the Philosophy of Hegel*. London: Macmillan, 1915.
- Filosofia della pratica, economia ed etica*. Bari: Laterza, 1909.
- Translated by Douglas Ainslie as *Philosophy of the Practical*. New York, 1913.
- La filosofia di Giambattista Vico*. Bari: Laterza, 1911. Translated by R. G. Collingwood as *The Philosophy of Giambattista Vico*. New York: Macmillan, 1913.
- Breviario di estetica*. Bari: Laterza, 1913. Translated by Douglas Ainslie as *The Essence of Aesthetic*. London: Heinemann, 1921. First published in *The Book of the Opening of the Rice Institute*. Houston, TX, 1912.
- Teoria e storia della storiografia*. Bari: Laterza, 1917. Translated by Douglas Ainslie as *History—Its Theory and Practice*. New York: Harcourt Brace, 1921.
- Contributo alla critica di me stesso*. Naples, 1918. Translated by R. G. Collingwood as *Autobiography*. Oxford: Clarendon Press, 1927.
- Frammenti di etica*. Bari: Laterza, 1918. Translated by Arthur Livingston as *The Conduct of Life*. New York: Harcourt Brace, 1924.
- Goethe*. Bari: Laterza, 1919. Translated by E. Anderson. London: Methuen, 1923.
- Ariosto, Shakespeare, Corneille*. Bari: Laterza, 1920. Translated by Douglas Ainslie. New York, 1920.
- La poesia di Dante*. Bari: Laterza, 1921. Translated by Douglas Ainslie as *The Poetry of Dante*. New York: Holt, 1922.
- Elementi di politica*. Bari: Laterza, 1922. Translated by Salvatore Castiglione as *Politics and Morals*. London: Allen and Unwin, 1946.
- La storia del regno di Napoli*. Bari: Laterza, 1925.
- Aesthetica in nuce*. Bari, 1928. Translated by R. G. Collingwood as “Aesthetics,” in *Encyclopaedia Britannica*, 14th ed. New York and London, 1929. Vol. VII.
- Storia d’Italia dal 1871 al 1915*. Bari: Laterza, 1928. Translated by Cecilia M. Ady as *History of Italy 1871–1915*. Oxford: Clarendon Press, 1929.

*Storia d'Europa nel secolo XIX*. Bari: Laterza, 1932. Translated by Henry Furst as *History of Europe in the Nineteenth Century*. New York: Harcourt Brace, 1933.

*La poesia*. Bari: Laterza, 1936.

*La storia come pensiero e come azione*. Bari: Laterza, 1938.

Translated by Sylvia Sprigge as *History as the Story of Liberty*. London: Allen and Unwin, 1941.

*My Philosophy*. London: Allen and Unwin, 1949. Essays selected by R. Klibansky and translated by E. F. Carritt.

#### WORKS ON CROCE

Borsari, Silvano. *L'opera di Benedetto Croce*. Naples: Istituto Italiano per gli Studi Storici, 1964.

Caponigri, A. R. *History and Liberty*. London: Routledge and Paul, 1955. A study of the historical works.

Nicolini, Fausto. *Benedetto Croce*. Turin, 1962. A definitive biography.

Orsini, G. N. G. *Benedetto Croce, Philosopher of Art and Literary Critic*. Carbondale: Southern Illinois University Press, 1961. A masterly survey of Croce's aesthetic writings.

Piccoli, R. *Benedetto Croce*. London: J. Cape, 1922. Still the best general introduction to Croce, but it covers only the period from 1893 to 1920.

*H. S. Harris (1967)*

## CRUSIUS, CHRISTIAN AUGUST (1715?–1775)

Christian August Crusius, the German Pietist philosopher and theologian, was born at Leuna, Saxony. Educated in Leipzig, he was appointed extraordinary professor of philosophy there in 1744, and professor of theology in 1750. Crusius initiated the third wave of Pietist attacks on Wolffianism by a series of dissertations (1739–1745), and continued it in his four main philosophical works (1744–1749). He later turned to theological studies, lost interest in philosophy, and founded a new theological school, the Biblicoprophetical school, which partially diverged from Pietism. He later became *canonicus* at the Meissen Theological Seminary.

Crusius's reputation in his own time and his influence on his contemporaries was second among Pietist philosophers only to Christian Thomasius. The collaboration of his close follower, A. F. Reinhard, with Pierre-Louis Moreau de Maupertuis and the Berlin Academy in their polemics against Wolffianism established a link between Christian Wolff's Pietist and academic opponents. Several later philosophers acknowledged Crusius as their teacher, although they combined a Crusian background with more advanced trends of French and English origin. These thinkers contributed considerably to the

renewal of German philosophy after the dissolution of the Wolffian school. In theology Crusius's influence was even stronger.

Crusius's importance was forgotten or suppressed soon after his death, especially among theologians, and has not yet been fully reestablished because of the hostility of the subsequently dominant rationalist and philological schools to the trend of his theology. As a philosopher, Crusius was nearly voted into oblivion, along with most other minor eighteenth-century philosophers, by idealistic historiographers. He was rediscovered by the new philological historiographers, chiefly in connection with his influence on Immanuel Kant.

### ORIGIN OF CRUSIUS'S THOUGHT

After 1730, Wolff and his school began to recover from his expulsion from Halle University in 1723, and from the loss by most of his pupils of their professorships, an attack launched for personal and political reasons by his Pietist opponents. The Pietists were gradually deprived of official support and were more and more restricted to theoretical controversy with Wolff. However, Wolff's system of philosophy was a much more modern, comprehensive, and technically refined body of doctrines than those in the obsolete and clumsy treatises of Thomasius, Franz Budde, and Andreas Rüdiger. A far-reaching reform in the doctrine and quality of Pietist philosophy was needed for it to face the Wolffian doctrine and counteract it successfully. Crusius's teacher, A. F. Hoffman (1703–1741), developed the logical doctrines of Thomasius and Rüdiger, taking into account Wolff's new philosophical techniques and achievements and accepting some of his doctrines, in his own *Vernunft-Lehre* (Leipzig, 1737). Crusius's own logic was inspired by Hoffman's refined and comprehensive handbook, whose quality and thoroughness substantially met the most modern requirements. Hoffman's early death prevented him from publishing the treatises on the other branches of philosophy that he had announced in 1734, but Crusius proceeded along Hoffman's lines, both improving and completing his lifework. Crusius provided the Pietist school with a renewed, efficient, and modern theoretical platform that temporarily assured its philosophical survival, outlived orthodox Wolffianism, and led to a far-reaching change in German philosophy.

### METHODOLOGY AND LOGIC

Crusius's methodology, the foundation of his philosophical attitude, was based on two central ideas, both originating in the Pietist tradition. Philosophy is not, as it was

for Wolff, a pure “science of possible things insofar as they are possible,” but is based on existing things. Second, human understanding has very narrow limits; theoretical certainty is impossible concerning many fundamental points whose only foundation is moral certitude or revelation. The mysteries of religion are not only beyond human reason, as Wolff claimed, but also contradict it. Something may be unthinkable for human reason that is not so for God or in itself.

Crusius held that the most general principle of human knowledge is neither the principle of identity nor the principle of contradiction, but a principle concerning what we can and cannot think: What cannot be thought at all is false, and what cannot be thought of as false is true. Our notions of identity and contradiction are based on this principle, which he called the principle of *cogitabilitas*. It is an inner criterion, depending on the nature of the human understanding.

Crusius further held that human reason cannot reach ultimate truth. Knowledge begins with experience, both inner and outer, and in many cases is stopped in its analysis of an order of facts by certain notions that, although they are not simple in themselves, cannot be further analyzed by man. Even if an analysis is completed and man does reach some simple basic notion, this notion cannot be demonstrated or deduced from a unique source. Each notion must be intuited singly by connecting it with concrete examples.

It is therefore impossible, according to Crusius, to assume that the method of philosophy is identical with the method of mathematics. Mathematics deals with very simple properties of things and its objects are exhaustively defined, whereas many notions relating to objects of philosophical thought can neither be known with intuitive distinctness nor analyzed by man. Again, mathematics proceeds only by demonstration and solely on the basis of the principle of identity. Philosophy, on the other hand, frequently must revert to moral certainty and is based on several different principles and on the knowledge of fact.

The main characteristics of Crusian logic, as expounded in his *Weg zur Gewissheit und Zuverlässigkeit der menschlichen Erkenntnis* (Way to certainty and reliability of human knowledge; Leipzig, 1747), follow from these views. Crusius connected logic with methodology. His logic contained much empirical psychology and many informal concrete and practical rules for obtaining or verifying knowledge, including rules for experimentation. Because Crusius so limited the field of theoretical demonstration, he presented a highly developed logic of

probability (which he called moral certitude), covering, among other topics, induction, hypothesis, and the reliability of testimony. The last was essential in the justification of revelation.

Both for Crusius and for Wolff, knowledge derived only from the senses, but the main characteristics of Crusius’s methodology allowed his successors to be much more receptive to English and French empiricism, sensationalism, and commonsense philosophy than were orthodox Wolffian rationalists. This receptivity was partially due to John Locke’s strong influence on Thomasius, but the ethical and mystical sources of these Pietistic attitudes was most important.

## METAPHYSICS

Crusius, in his *Entwurf der nothwendigen Vernunftwahrheiten* (Sketch of necessary rational truths; Leipzig, 1745), divided metaphysics into ontology, theology, cosmology, and pneumatology, in explicit opposition to Wolff’s ordering of the metaphysical sciences.

**ONTOLOGY.** Ontology begins, not with first principles, but with the notion of a thing in general, directly connected with the notion of a “really given thing.” Only after introducing these notions did Crusius discuss essence, existence, and causality. Crusius regarded existence as indefinable and as a primary notion arising from sensation.

In his discussion of causality, Crusius expounded a principle of determining reason, his version of Gottfried Wilhelm Leibniz’s principle of sufficient reason. Crusius held, against Wolff, that a sufficient reason suffices only for free actions insofar as they are free. Rational truths and natural events not depending on free causes need a more cogent foundation, a determining reason. This principle does not derive from the principle of identity, but rather from what we must conceive or what we cannot conceive as united or separate, and thus from a new case of the principle of *cogitabilitas*. Crusius, aiming at a sharper distinction between mechanism and free actions, held that the real nature of causality is unknown and that our knowledge of causal connections is based on the constant conjunction of two events in experience. This, of course, cleared the path for the members of his school to accept the Humean critique of the causal connection.

Crusius’s ontology reveals a general characteristic of his metaphysics. His was not a monolithic system beginning with a single principle and deducing from it all subsequent notions and propositions, as was Wolff’s. Rather, it was founded both on several independent principles

and on a multitude of elementary notions that could be defined only by an appeal to reality (by their concrete representation)—notions such as existence, space, time, and force; or, in psychology, the particular powers of the soul, some mental faculties, and pleasure and pain. Through Hoffman Crusius derived this view from Locke's doctrine of simple ideas, but he supposed that the number of elementary notions (which he once called categories) could be infinite.

**THEOLOGY.** Rational theology followed immediately after ontology, instead of being—as for Wolff—the final section of metaphysics, because Crusius held that God's existence is a necessary foundation for cosmology and pneumatology. Crusius denied the Ontological Argument: God's existence can be proved by moral evidence only, and his attributes cannot, properly speaking, be understood by humankind—among other things, positive infinity is beyond human reason. The human notion of God is partially relative and partially negative; nevertheless, it is certain. God is different from created beings both in degree and in essence. Among the attributes of God, Crusius stressed his free will, which is limited by the principle of contradiction and by his goodness. In God and God alone, intellect and will are a single power.

**COSMOLOGY.** Crusius held that matter is composed of a multitude of simple substances. Simple material substances are extended, and the infinite divisibility of matter is impossible. Simple substances have an essential, though not absolutely necessary, force. They act upon each other only by motion and contact. Physical space and time are real, but they are neither independent beings (substances), nor properties, nor relations (all of these concern the metaphysical essence of things). Space and time are intimately connected with existence; they are conditions of things insofar as such things exist. There is no real space or time without substance to fill it; outside the real world there is only possible (not sensible) space or time, which is infinite and filled by God. There are empty spaces in the world (otherwise movement would be impossible), but they are only physically—and not metaphysically—empty, because they are filled with God's presence. Mathematical space and time are distinct from physical space and time, and are abstracted from the relations of things.

Crusius was trying to offer a new set of solutions to the difficulties of the traditional doctrines of substance, of space and time and their limits, and of the void, while avoiding the concepts of *res extensa*, Leibnizian monads, and atoms, as well as the contradictions presented by the

real space and time of René Descartes and Isaac Newton and the ideal space and time of Leibniz and Wolff. His doctrine resembled that of Locke, but it was a mixture of well-chosen elements of the traditional views connected by doubtful subtleties.

**PNEUMATOLOGY.** In his pneumatology, or rational psychology, Crusius rejected Thomasius's spiritual materialism but retained some of its characteristics. He held that finite spirits are simple unextended substances, but that they fill a space and share with material substances the power of motion. Thus, a real interaction between spiritual and material substances is possible, and the doctrines of preestablished harmony and occasionalism are unnecessary. The human soul is an independent substance with two fundamental powers, thinking and willing, both of which are a complex of several independent lesser powers.

Crusius was, in general, very cautious in his pneumatology, and frequently appealed to the limitations of human reasoning. For instance, he held that the immortality of the soul could be proved only if God's existence were presupposed—that is, by an appeal to moral certitude.

#### NATURAL PHILOSOPHY

Crusius's treatise on natural philosophy, *Anleitung, über natürliche Begebenheiten ordentlich und vorsichtig nachzudenken* (Introduction to regular and prudent reflections on natural events; 2 vols., Leipzig, 1749), was by far the least original of his works. Nevertheless, he was the first important Pietist philosopher to accept mechanism. In this work, Pietist philosophy finally renounced animism and adopted the more modern Cartesian and Leibnizian views, although it was still opposed to Newton's theory of gravitation. Crusius stressed the difficulties of physics and the purely hypothetical character of much of our knowledge of the particular laws of nature.

#### ETHICS

Crusius's first major work was a treatise on ethics, *Anweisung, vernünftig zu leben* (Instructions for a Reasonable Life; Leipzig, 1744). Hoffman's influence on Crusius is clear. Ethics, for Crusius, is not based on reason alone, but also on revelation. Natural duties have been imposed on humanity through God's free choice.

**THE WILL.** Crusius split Wolff's empirical psychology into two parts. He incorporated the first part, concerned with the cognitive power, into logic. The second, con-

cerned with the will, he placed in ethics. Moral goodness consists in the conformity of the human will with God's will. The human will is a power to act on the understanding, on the body, and on the will itself, but its connection with the understanding is not altogether clear. We are immediately conscious of freedom, which is the main property of the human will. The will is moved by sufficient reason, which does not necessitate, and therefore the will is free.

**DUTY.** The second section of the *Anweisung*, on ethics proper, discusses human duties. An action is moral if it is done out of obligation only, and not in quest of happiness. Virtue is formally conditioned by a coincidence of human will and divine law, and is materially conditioned by love for God. Divine law is known through conscience, which is an immediate power of moral judgment founded on a sort of common sense called moral taste. Evil originates in a wrong use of free will, which, when it submits to unreasonable impulses, corrupts human understanding and the true representation of goodness.

A third section of the *Anweisung* was devoted to moral theology; a fourth, to natural law; and a fifth, to prudence, which was closely studied in Thomasius's school and partially corresponded to Kant's technical imperatives.

## REVEALED THEOLOGY

In his revealed theology Crusius united orthodox Pietist doctrines with those of a dissident Pietist, J. A. Bengel (1687–1752). Bengel and Crusius carried to an extreme the Pietist belief that the Bible is an organic whole inspired by God and historically true throughout. The Pietists held that Scripture is the only source of theological truth, and rejected all exegetical developments, even those of Protestant divines. No rational criticism of the Bible was permitted; its meaning could be penetrated only by a kind of empathy or inner light. Crusius stressed a theology of history, founded on biblical prophecies, that tried to explain the whole history of Christianity and to reveal its future aim in a second coming of Christ.

## CRUSIUS'S INFLUENCE ON KANT

Recent historical scholarship has stressed Crusius's importance in Kant's development, and the view that Kant's philosophy was rooted in Wolff's system has been more and more questioned. Recent research has shown that Kant, educated in the Pietistic, eclectic, and anti-Wolffian milieu of Königsberg University, was mainly trying in his precritical development (1745–1768)—despite

the nonorthodox Wolffian influence of his teacher, Martin Knutzen—to counteract Wolffian philosophy in an increasingly original way. He therefore appealed both to recent anti-Wolffian trends—to Maupertuis and his Berlin circle and through Maupertuis to Newton—and to Crusius, the new leader of Pietist philosophy and only nine years his senior, whose reputation grew tremendously from 1744 on.

Crusius's influence on Kant consists in six main points, some of which were also held by other Pietist philosophers or by Maupertuis. Crusius stressed the limits of human understanding, a theme that recurs in Kant's writings under different forms from 1755 on. He rejected the Ontological Argument, as did Kant after 1755, and he later rejected all theoretical proofs of God's existence. He assumed a multiplicity of independent first principles; Kant did so after 1755. He denied the importance of formal logic, and simplified it. He rejected the possibility of defining existence, and accepted a multiplicity of simple notions. He rejected the mathematical method as applied to philosophy. Kant adopted these last three positions in 1762.

Kant's Crusianism reached its climax in his *Untersuchung über die Deutlichkeit der Grundsätze der natürlichen Theologie und der Moral* (Investigations concerning the Distinctness of the Fundamental Principles of Natural Theology and Morals; Berlin, 1764), written in 1762. By 1763 Kant's enthusiasm for Crusius's philosophy was waning, but he did not reject the six tenets above and was still influenced by Crusius on individual points as late as the 1770s. J. Bohatec has claimed that Crusius's doctrines in revealed theology exerted some influence on Kant's late works in religion.

## CUDWORTH, RALPH

(1617–1688)

Ralph Cudworth was one of the leading figures among the Cambridge Platonists, a group of seventeenth-century philosopher theologians. He was born in Aller, Somerset, to a minister who had been a fellow of Emmanuel College, Cambridge. Educated at home by his stepfather, John Stoughton, until 1632, he then entered Emmanuel College. There he was influenced by Benjamin Whichcote, founder of the Cambridge Platonist school. In 1639 he was elected a fellow of Emmanuel, and received the bachelor of divinity degree in 1645, defending for his examination Whichcote's thesis that good and evil are eternal and immutable. This examination, with its opposition to any system that makes morality contingent on will, whether human or divine, already betrays Cudworth's distance from the rigorous Calvinism with which Emmanuel College had always been associated. Nevertheless, Cudworth did have some sympathy with political aspects of the Puritan cause. He was appointed by Parliament master of Clare College and Regius professor of Hebrew in 1645, and served as advisor to Oliver Cromwell's secretary of state on several government appointments. In 1647 he was invited to preach to a sharply divided House of Commons.

In his sermon of March 31, 1647, Cudworth urged parliamentarians not to legislate on doctrinal matters, arguing that salvation depends not on speculative details but on living a life of Christlike love and forbearance. This emphasis on morality over doctrine was characteristic of the Cambridge Platonists and influential for the later Latitudinarian divines. Cudworth was appointed master of Christ's College in 1654, and succeeded in retaining his appointment at the time of the Restoration. He remained in the post until his death in 1688. In 1654 Cudworth was married. None of his sons survived him, but his daughter, Damaris, later Lady Masham (1658–1708), took custody of her father's writings and became a philosopher in her own right. Intimate friend and correspondent of John Locke, she published *A Discourse concerning the Love of God* in 1696.

#### METAPHYSICS

Cudworth's massive *True Intellectual System of the Universe* (1678) was the only one of Cudworth's principal writings to be published during his lifetime. Lengthy as it is, the published volume represents only the first installment of a three-part project originally sketched by Cudworth, with the parts devoted respectively to attacking

mechanistic or atomistic determinism, theological determinism (Calvinism), and Stoic determinism. The *True Intellectual System of the Universe* in its published form constitutes a defense of theistic atomism and an attack on “Hylopathic” atheism. Hylopathic atheism, which claims that all things can be explained by reference to material atoms, with no need to invoke spirit or incorporeal substance, was an important target because it was represented in Cudworth’s own day by Thomas Hobbes. A secondary target of the book is “Hylozoic” atheism, differing from Hylopathic in attributing life to matter, but still materialistic, and worthy of Cudworth’s notice because of its recent revival by Benedict Spinoza. Rather than engage directly with Hobbes or Spinoza, Cudworth’s argument is directed against ancient schools of philosophy, and much of it consists in a *consensus gentium* argument; atheism is an anomaly or aberration from an original truth that has been acknowledged from the beginning. This original true system accepted atomism, but only as an account of matter or corporeal reality. Properly understood, atomism reveals matter to be essentially passive or inert, thus making clear that only the existence of incorporeal substance can explain the origin, motion, and organization of matter.

While interested in the *ancient theology* argument that Plato’s insights (particularly what Cudworth regarded as a concept of the Trinity in Plato) derived originally from divine revelation through Moses, Cudworth was finally content to claim that there is a natural *prolepsis* or anticipation of the idea of God existing throughout all times and places. Atheism is thus a willful destruction of this *prolepsis*, and Hobbes and Spinoza are not new threats, but reincarnations of old foes. The other leading philosophical thinker among the Cambridge Platonists, Henry More (1614–1687), devoted more direct attention to Spinoza’s thought than did Cudworth, and differed from Cudworth as well in seeking, along with Joseph Glanvill (1636–1680), empirical evidence for the existence of incorporeal substances in cases of witchcraft and demonic possession.

In embracing atomism, Cudworth was making common cause with Cartesian dualism and rejecting scholastic accounts of substantial forms. Mind cannot be simply a property of material objects. For Cudworth, though, it is passivity, not extension, that essentially constitutes matter, and it is activity, rather than self-consciousness, that essentially constitutes incorporeal substance. The key challenge facing Cartesian dualism was to account for the interaction between body and soul, corporeal and incorporeal substance. Cudworth’s solution was to appeal to

active incorporeal powers that mediate between wholly passive matter and self-conscious soul, creating a vital union between them. Each finite soul has a finite field of action—its own body.

An analogous solution allows Cudworth to articulate the relationship between God and the world. While God is not bound to physical creation as a finite soul is bound to its body, Plastic Nature does serve as an intermediary between God and world that, like the lower powers of the soul, allows for a vital connection between the two. Critical of Descartes’s suggestion that the existing ordered universe could have originated from a single initiating divine act, Cudworth argued that an ongoing divine influence was necessary if the material universe was to maintain an ordered motion. At the same time, God is not required, as in *occasionalism*, to attend directly to each and every detail of order in the universe. *Plastic Nature*, an unconscious power that pursues not its own but divine purposes, imposes order and finality on the material world. Nothing works according to mere chance, but according to final causes, divine intentions mediated by Plastic Nature.

Cudworth’s Plastic Nature is similar to More’s *Hylarchic Principle*, but Cudworth did not follow More’s contentions that both material and immaterial substance are extended and that space is infinite. The concept of Plastic Nature was influential for biologist John Ray and for philosophical biology generally up through Darwin. Pierre Bayle attacked Cudworth’s plastic powers as atheistic in tendency in eliminating the need for direct divine action to account for purpose displayed in the physical world. Denis Diderot and Jean d’Alembert’s *Encyclopédie* (1751–1772) included a detailed account of Cudworth’s theory, and the theory may, via Paul Janet, have influenced modern doctrines of the unconscious.

On the one hand, Cudworth cannot be finally understood as opposing the new philosophies of Hobbes and Spinoza merely on the basis of allegiance to an outmoded neoplatonism; his *consensus gentium* argument advances at the same time a contemporary position. On the other hand, the baroque erudition displayed in the *True Intellectual System of the Universe* was out of step with the leaner philosophical style of his contemporaries. This did not prevent the work from achieving significant influence in its own day, and in fact the text served for several generations as a key resource on Greek philosophy. But it did in the nineteenth and twentieth centuries often mean that Cudworth’s importance as an interlocutor of Hobbes, Spinoza, and Descartes was not fully appreciated.

## EPISTEMOLOGY

Cudworth's Platonist epistemology is developed at length in *A Treatise of Eternal and Immutable Morality*. The *Treatise* was published in 1731 at the behest of Cudworth's grandson, Lady Masham's son. Cudworth argues against empiricism that knowledge is more than a mirroring or representation of reality, and that the mind is more than a blank sheet of paper upon which the objects of sense are inscribed. Knowledge can never arise solely out of sense experience. When we sense, we sense particulars, but when we know, we know by means of universals. Cudworth insists that universals must precede the empirical particulars that they organize and make sense of; they are not abstracted from particulars, for this act of abstraction would be unmotivated and undirected unless one already knew the universal at which one was aiming. Sense allows the soul to perceive the appearances of things, but not clearly to comprehend them.

The universals of which we have knowledge are eternal and immutable. But the fragmented nature of human nature points beyond itself to God. Given the eternal and immutable nature of intelligible ideas, they cannot solely be modifications of limited and finite intellects, which only come to know them in time, if at all. It is God's infinite and eternal mind that, in perceiving itself, eternally perceives these ideas. Rather than innate ideas, human souls possess innate activities or tendencies, a capacity to exert themselves so as to participate in a limited way in divine self-knowledge. Human persons do not, though, arrive at knowledge by comparing their ideas with ideas in the mind of God. Pointing out the impossibility of such a comparison, Cudworth insists simply on clear intelligibility as the criterion of truth. Descartes, Cudworth argues, fell into circularity in seeking further to defend the criteria of clarity and distinctness by proving that God is not a deceiver. The criterion of clear intelligibility is self-evident and depends on no external support.

## ETHICS

As the title of *A Treatise* suggests, among the eternal and immutable ideas that may be known as clearly intelligible are moral principles. In fact, Cudworth's epistemological discussion is occasioned and motivated by his concern to defeat voluntarist and relativist accounts of morality. This concern reached back to Whichcote, but Cudworth was both much more learned than Whichcote about ancient and more recent Platonism and much more connected to contemporary philosophical discourse. As in the *True Intellectual System of the Universe*, one of Cudworth's key targets is Hobbes, who argues that right and wrong are

relative concepts, based solely in convention. Cudworth also attacks "diverse modern theologers" who argue that morality is created by divine fiat, naming among them William of Ockham and Pierre d'Ailly and one contemporary theologian, the Polish Jan Szydłowski. The Calvinistic theology of Cudworth's Puritan contemporaries is a looming unnamed target. Descartes's argument that the natures and essences of things, including moral good and evil, must depend on the contingent will of God in order not to be independent of God, receives particular criticism. Following Plato's *Euthyphro*, Cudworth argues that things are not good because they are willed by God; rather, God wills things because they are good. It is either eternally true or eternally false that something is good; no act of will can change this. The good is not, though, an external constraint on divine freedom, but God's essential nature.

If the *True Intellectual System of the Universe* was originally intended as a comprehensive critique of all forms of determinism, Cudworth's many manuscripts defending "freewill" represent his efforts to articulate a positive account of free human action and a moral psychology to accompany that. None of these manuscript treatises were published during Cudworth's lifetime, and it is unclear how widely they may have circulated. Lady Masham may well have shared them with Locke and Shaftesbury. The shortest of the manuscripts was published in 1838 as *A Treatise of Freewill*, testifying to ongoing interest in Cudworth's thought. In an innovative move, Cudworth rejects traditional faculty psychology; the will and understanding are not distinct faculties in the soul, but activities of the soul. Drawing on Stoic terminology, Cudworth argues that the soul's *hegemonikon* or ruling power "is the soul as comprehending itself, all its concerns and interests, its abilities and capacities, and holding itself, as it were in its own hand, as it were redoubled upon itself" (p. 178). It is through this reflexive capacity that the soul is able to adjudicate among conflicting passions, dictates of conscience, and inferences of reason, and act as a unified self. Cudworth considers that in identifying this capacity for reflexive deliberation he has successfully shown that persons are not determined by any "antecedent necessary causes" (p. 179). It is far from clear that this is so, although Cudworth's account of the *hegemonikon* does make it possible to speak intelligibly of the soul's self-determination and moral responsibility.

For Cudworth, moral agency and thus moral responsibility rest on the capacity to survey in a comprehensive way possible courses of action and to pass judgment on

which is best. Only action that issues from such reflection can properly be regarded as one's own. God neither has nor needs a *hegemonikon*, being simple and unified. God's freedom consists in unfailingly acting according to God's own perfect nature, and God's self-determination in the fact that nothing outside of God determines divine action. Insofar as human self-determination takes the form of an active pursuit of the good, human persons come to participate increasingly fully in God and God's goodness. Thus human "freewill" can be employed in order to arrive at a more perfect, more godlike, freedom.

## CULVERWEL, NATHANAEL (1618?–1651?)

Nathanael Culverwel, the religious and moral philosopher commonly if rather misleadingly described as a Cambridge Platonist, was probably a son of Richard Culverwel, rector of St. Margaret's, in London, although neither his parentage nor the date of his birth is certain. He

certainly grew up in a Calvinist atmosphere. In 1633 he was admitted to Emmanuel College, Cambridge, where he encountered the teachings of Benjamin Whichcote, the spiritual leader of Cambridge Platonism. Ralph Cudworth was slightly junior to him as an undergraduate at Emmanuel but was elected to a fellowship three years before Culverwel's election in 1642. John Smith was of the same generation. Culverwel's contemporaries refer in somewhat obscure terms to troubles that beset him in later life; these may have included some sort of mental breakdown. He died not later than 1651.

Culverwel published nothing during his lifetime. Shortly after his death, however, William Dillingham prepared for publication a discourse titled, in Culverwel's typically metaphorical style, *Spiritual Opticks: or a Glasse discovering the weaknesse and imperfection of a Christians knowledge in this life* (1651). This was sufficiently successful to encourage Dillingham to proceed to the publication of a manuscript by Culverwel, composed, Dillingham says, about 1646, which was obviously intended, although incomplete, to be a book—*An Elegant and Learned Discourse of the Light of Nature*. In the same volume Dillingham included a number of Culverwel's sermons. Prefixed to the *Discourse* is an essay by Culverwel's brother Richard that asserts that in its present form the *Discourse* is somewhat misleading, since the praise of reason which it contains was to have been followed by another section in which the limitations of reason would have been more strongly insisted upon. That judgment is borne out by the tone of Culverwel's sermons, which are severely Calvinist.

The *Discourse*, as it stands, is an elaboration of Whichcote's favorite quotation (from Proverbs 20:27), which Culverwel translates as "The understanding of a man is the candle of the Lord." Insofar as it is critical of those who "blaspheme reason," the *Discourse* is written in Whichcote's spirit. However, its philosophical tone is in many respects Aristotelian rather than Platonic; Culverwel sharply criticizes the "fanciful ideas" of "the Platonists," under which heading he almost certainly includes his Emmanuel colleagues. (None of them had yet published, so that although—unusually for his time—Culverwel makes precise references to such near-contemporaries as Lord Herbert of Cherbury, Lord Brooke, and Sir Kenelm Digby, he could not refer to the Cambridge Platonists in similarly definite terms.) When Culverwel speaks with enthusiasm of Plato, it is of the *Laws* or the *Republic* rather than of John Smith's favorite, the *Phaedo*; quite unlike Smith or Cudworth he rarely pays any attention to the Neoplatonists. On the other hand, he writes

with great approval not only of Aristotle but also of the Scholastics, especially Thomas Aquinas and Francisco Suárez, and even of Francis Bacon, to whom the Platonists were generally strongly opposed.

He differs from the Platonists on four crucial points. The first is epistemology; he disagrees with them, as he puts it, about “the time at which the candle of the Lord is lighted.” It is true that at an early stage in the *Discourse* (Ch. 7) he writes: “There are stamped and printed upon the being of man some clear and indelible principles, some first and alphabetical notions, by putting together of which it can spell out the law of nature,” a passage which it is natural to read as a defense of innate ideas. Later, however, in Chapter 11, he argues quite explicitly against the doctrine of innateness, even in the modified form in which Platonists like Cudworth held it. First principles—which he describes as having “so much of certainty in them, that they are near to a tautology and identity”—arise, he argues, “from the observing and comparing of objects”; these principles are not inherent in our minds. He strongly criticizes Plato and René Descartes in Chapter 14 for “too much scorning and slighting” of sensations. Sensation, he admits, is no more than “the gate of certainty,” but only through this gate can certainty enter the soul. Otherwise, the soul would remain “a blank sheet.”

Second, he criticizes the Platonist tendency to diminish the gap between human and divine by treating the human soul as having a degree of divinity, as being, insofar as it is rational, an ingredient in divine reason. The candle of the Lord, he argues, is lit by God but is no part of God’s light. God’s light is like the sun; a candle is but a wavering, imperfect light even when it is at its brightest. Men cannot hope to be godlike, the ideal the Platonists set before themselves.

This is connected with the third point of difference. Culverwel continued to be a Calvinist; he continued to believe, therefore, that no human being is worthy of salvation. In a sermon titled “The Act of Oblivion,” addressed to a congregation presumed to belong to the elect, he says that God “might have written thy name in his Black Book, with fatal and bloody characters, and made his justice glorious in thy misery and damnation”; God had chosen otherwise because he so chose, not because any members were deserving of a higher destiny. If God has chosen to save Socrates, he argues, this can only be because God gave a private revelation to him, not because Socrates was a worthy man. God may well have chosen to save Aristophanes rather than Socrates. God’s decrees, Culverwel insists, are absolute; it is ridiculous to

suppose that a man can save himself from the damnation decreed for him merely by exercising an act of choice, by choosing to be good. Nothing could be further from the spirit of Cambridge Platonism than Culverwel’s unmitigated Calvinism.

Finally, and this again is connected with his Calvinism, Culverwel’s emphasis as a moral philosopher is on law rather than on reason. He agrees with the Platonists, it is true, that some acts are good in their own nature and that some relationships are peculiarly just and rational; however, the performance of such acts, he argues, does not constitute a moral good. Essentially, he says, morality is a matter of obedience to rule, and there can be rules only when there is a lawgiver. The obligatoriness of moral laws depends upon the fact that they are commanded by God. Even though the lawgiving is itself a rational act, even though moral laws are based upon the lawgiver’s apprehension of “the eternal relations of things,” even though it is by our reason that we discover their nature, command, not reason, is still the foundation of morality. A capacity for obeying rules, he suggests, is the distinguishing mark of a rational being; moral rules apply to men, not to animals, just because men are capable of following rules. But human rationality does not in any way constitute the obligatoriness of the rules.

Following Hugo Grotius, Culverwel devotes a great deal of attention to the concept of a natural law and its relation to the laws of nations. In the *Discourse*, as his argument proceeds, the importance of law comes more and more to the fore, and the importance of reason recedes, although Culverwel takes the two to be intimately connected. For Culverwel, as for so many of his antirationalist successors, Abraham’s sacrifice of Isaac is the crucial case. This was decreed, and the decree had to be obeyed, he argues, even though it goes against all our concepts of a rational morality; “the candle durst not oppose the sun.”

One can discern a tension in Culverwel’s work between his Calvinism and the Platonism he had learned from Whichcote. A very similar tension between empiricism and rationalism, between the concept of law and the concept of reason, is manifest in John Locke, and it is more than likely that Locke was strongly influenced by Culverwel’s *Discourse*, most obviously, but by no means exclusively, in the *Essays on the Law of Nature*, which he wrote in 1660.

## CUMBERLAND, RICHARD

(1631–1718)

Richard Cumberland, the bishop and moral philosopher, was born in London, the son of a London citizen. Educated at St. Paul’s School, in 1648 he entered Magdalene College, Cambridge, where, distinguishing himself both by his scholarship and by his capacity for friendship, he was elected a fellow in 1656. He first studied medicine, but he finally decided to enter the church, accepting preferment in 1658 to the rectory of Brampton, Northamptonshire, and in 1667 to the rectory of All Hallows at Stamford, Lincolnshire. In 1661, Cambridge appointed him one of its twelve official preachers, and he kept in close touch with Cambridge intellectual life. Cumberland earned the reputation of being an exceptionally staunch Protestant. Report has it that the attempt of James II to reintroduce Roman Catholicism into England produced in him a dangerous fever. Such zeal did not go unrewarded under William III, and although quite without personal ambition, Cumberland was consecrated as bishop of Peterborough on July 5, 1691. He performed his episcopal duties with diligence until his death in 1718.

Jewish history was Cumberland’s main interest. In 1686 he published *An Essay towards the Recovery of the Jewish Measures and Weights*. His domestic chaplain and son-in-law Squier Payne published in 1720 *Sanchoniatho’s Phoenician History*, translated with a commentary by Cumberland. This monument of misplaced scholarly ingenuity derived its immediate inspiration from Hugo Grotius. With no qualms about the authenticity as history of Sanchoniatho’s cosmogony, Cumberland devoted himself to identifying its personages with characters in the Old Testament. A sequel, *Origines Gentium Antiquissimae; or Attempts for Discovering the Times of the First Planting of Nations*, appeared in 1724.

Cumberland’s sole philosophical work, *De Legibus Naturae* (1672), was designed, as the subtitle explains, as a refutation of Thomas Hobbes—the first full-length philosophical reply to Hobbes to be published. Written in an inelegant Latin, badly printed, ill-organized, intolerably diffuse, Cumberland’s treatise did not attract much contemporary attention. In 1692, with Cumberland’s approval, James Tyrrell prepared an abridgment and translation as *A Brief Disquisition of the Law of Nature*, hoping to draw attention to Cumberland’s main ideas. But the abridgment was a poor one (in addition, Tyrrell’s own views were mingled with Cumberland’s) and failed in its main purpose. Eighteenth-century philosophers were more interested in Cumberland’s work than his contemporaries had been; he anticipated their ambitions and preoccupations. A complete English translation was prepared by John Maxwell in 1727, and what has become the standard translation was published, with copious annotations by John Towers, in 1750. A French translation by Jean Barbeyrac (1744) ran into two editions.

Cumberland’s point of departure is Grotius’s *De Iure Belli et Pacis* (1625). Grotius, or so Cumberland interprets him, had based his demonstration of the existence and binding force of natural laws upon the consensus of civilized opinion. Very conscious of Hobbes, Cumberland sets out to supplement Grotius by demonstrating that natural laws are founded on “the nature of things,” as distinct from the commands of sovereign rulers. To that extent Cumberland’s aims coincide with Ralph Cudworth’s, but unlike Cudworth he does not base his argument on Platonic metaphysics. Nor does he criticize, as did the Cambridge Platonists, the mechanical worldview; indeed, he wholeheartedly accepts it. He thinks of his approach as scientific and nonmetaphysical. He sets out to construct an ethics that, although Christian, is independent of revelation and, although demonstrating that morality is eternal and immutable, is based on “the evi-

dence of sense and experience.” These were to be the typical eighteenth-century specifications for a satisfactory moral theory.

Cumberland begins by arguing that there is a single natural law from which all moral laws can be derived—the law, namely, that an agent secures his own good by the promotion of the good of the whole to which he belongs. If this single law is based on “the nature of things,” if its truth can be demonstrated from experience, then, he thinks, morality rests secure. And, he argues, experience reveals to us—he draws upon his medical training to illustrate the point—that the parts of a whole secure their own welfare only when they work for the good of the whole to which they belong. A bodily organ, for example, is at its healthiest when it is most effectively securing the health of the body. This truth men could recognize, so Cumberland argues against Hobbes, even in a state of nature. Thus, the foundation of moral laws is not the will of the sovereign.

Benevolence, Cumberland further maintains, is natural to humankind. Even brute animals, indeed, devote themselves to the welfare of their fellow brutes. A state of nature, therefore, would not be, as Hobbes suggested, a war of all against all; their human instincts, not the pressure of a sovereign will, lead men to cooperate with their fellow men in society. Certainly, Cumberland admits, men sometimes act in opposition to the good of the whole, just as an organ of the body will sometimes infect, rather than work toward the health of, the organism of which it forms a part. The fact remains, however, that the “natural impetus of man” is toward securing the common good, just as the general tendency of a bodily organ is to make the body healthier. The legislator’s rewards and punishments, like medicine, are directed toward correcting abnormalities; they are not the original springs of moral action.

All moral concepts, Cumberland tries to show, are definable in terms of the single natural law that men secure their own welfare by pursuing the common good. An act is “naturally good” if by virtue of its own nature it tends toward the common good; it is “right” if it is the shortest way to that end; it is “morally good” if it conforms to the natural law. Particular virtues are similarly deducible from the obligation of pursuing the common good; to show that the common good ought to be our objective is at the same time to show that we ought to be law-abiding, just, temperate, and obedient to God.

Most of what were to be the leading eighteenth-century moral theories can be found somewhere suggested, if nowhere fully worked out, in *De Legibus Natu-*

*rae*. Cumberland argues in detail that moral principles are analogous to the propositions of mathematics, and Samuel Clarke learned much from him on this point. Cumberland also sketches a moral calculus of the sort Francis Hutcheson was to employ; there are many resemblances between his moral philosophy and the third earl of Shaftesbury’s; he has been described as the first systematic utilitarian; the organic theory of morality and of the state is conspicuous in his work; resemblances between Cumberland and Benedict de Spinoza are easy to detect.

Accounts of his moral philosophy differ widely, depending on which of the manifold tendencies in his thinking commentators stress. In Cumberland’s own eyes, however, the crucial points are (1) there is a law of nature, defined as a proposition of “unchangeable truth and certainty ... which lays firm obligations upon all outward acts of behaving, even in a state of nature”; (2) this law enjoins upon us the pursuit of the common good and assures us that by pursuing the common good we achieve happiness and personal perfection; (3) observation of the world, including man’s nature, demonstrates the truth of this law; (4) all other moral precepts are applications of the law of nature to particular forms of human action.

## CYNICS

“Cynics,” the “dog philosophers” of the Greek and Roman world, so called almost certainly from the nickname of Diogenes of Sinope, were not a continuous school of theoretical philosophy but an erratic succession of individuals who from the fourth century BCE to the sixth century CE preached, through ascetic practice and mordant denunciation of established convention, a more or less similar way of life designed to lead to the happiness of the individual. Consequently there is no established doctrinal canon by which to define an “orthodox” Cynic, and the ancient but still lively debate as to whether Antisthenes or Diogenes was the founder of Cynicism is an unreal one. Nevertheless, despite marked variations of stress and tone in individual exponents, Diogenes was always regarded as the arch-Cynic, and a sufficient number of characteristic attitudes recur to identify the movement.

The nature of the existing evidence of Cynicism is highly unsatisfactory. The written works with which Diogenes was credited have not survived, and doxographies are few and of uncertain origin (for example, Diogenes Laërtius, Bk. 6, 70–73). Since Diogenes’s life was his main testament, the largest class of evidence is anecdotal, with all the uncertainties and elaborations of an oral tradition. Information of his pupils and of Cynics of the third century BCE is tantalizingly fragmentary. Even the comparatively abundant material on contemporary Cynicism from the first century CE comes from outside the movement, from sympathizers of such diverse interests as Epictetus, Dio Chrysostom, and Julian, or from satirists such as Lucian.

## TEACHING

The Cynics believed that happiness was found in “virtuous” action, which was the practical expression of self-realization (*arete* and “know thyself”). This state was in turn produced by a rational awareness of the distinction between natural and artificial values. External and physical goods such as wealth, reputation, pleasure, conventional duties arising from family, property, or state, and all traditional inhibitions, whether social or religious, were condemned as unnatural tyrannies that fettered a man through desire, indulgence, and the ignorance of a confused and corrupt society—the three causes of

human misery. Freedom was secured by “following nature” by means of self-discipline whose end was self-sufficiency (*autarkeia*); since man was vulnerable and perverted through his emotions and desires, happiness could be guaranteed only by the understanding and strength of mind to want nothing, lack nothing. And since the artificial currency of human standards was thought to be, not an indifferent factor, but an active corruption to be eradicated, Cynics wished not merely to devalue the coin (like Socrates and the Stoics), but to deface it (*paracharattein*); hence, the most characteristic feature of Cynicism was an asceticism that sought to reduce physical wants to a minimum, as in the case of the animals after which Cynics were named, and to achieve spiritual independence like gods.

Independence was not to be achieved, however, by the withdrawal of a hermit; the Cynic engaged in an active crusade that required a continual training (*askesis*) to harden the body and temper the spirit in the very face of temptation, and thus to free the natural “perceptions” and capacities for virtuous actions. The toiling, painful effort of this moral struggle (*ponos*) was categorized as a good, the steep short cut to virtue, which evoked the only natural pleasure; and the legend of Herakles’s life of service spent in successfully overcoming labors was sanctified as an ideal of freedom and self-fulfillment. He and the Cynic, whether slave or oppressed, ruled himself as his own master and, therefore, was the ideal king among men. Essentially individualistic and largely antisocial in advocating independence from any community, Cynicism was the most radical philosophy of spiritual security offered to fill the social and moral vacuum created in the fourth century BCE by the dissolution of the city-state political organism. Yet there was a strong philanthropic impulse in the movement in the sense that the gospel of Herakles, the ideal king, was a spiritual evangel for all men, to be preached by personal example. The Cynic saw himself as “scout and herald of God,” dedicating his own labors as a reconnaissance for others to follow; he was the “watchdog of mankind” to bark at illusion, the “surgeon” whose knife sliced the cancer of cant from the minds of others. Cynics deliberately adopted shamelessly shocking extremes of speech and action to jolt the attention and illustrate their attack on convention.

Fearlessness in criticism was a virtue, useful to further Cynic ideals, but it was also open to abuse, as was the license of affected shamelessness. There was always a real danger that the negative, denunciatory side of Cynicism would predominate, the more so since happiness was most often described as freedom from misery, and virtue,

practical wisdom, and right reason remained somewhat nebulous terms. The Cynics did not offer arguments to intellectuals, whose theories they despised as useless. Rather, they offered the ideal practical example of autonomy of will through their own actions, bringing by the very vilification of luxury and sensual indulgence and by the justification of poverty, spiritual hope to the poor, disenchanting and oppressed. Thus the more formal types of philosophical instruction were abandoned and three new literary genres fostered: the *chreia*, or short anecdotal quip with a pungent moral tang; the diatribe, or popular sermon in conversational style; and Menippean satire.

## HISTORY OF THE MOVEMENT

The most influential of Diogenes's converts was Crates of Thebes. Joined by his wife in a life devoted to Cynic ideals, he earned by his humanity and good works the affectionate name of "Door-Opener." He wrote philosophical tragedies and poetry about a Cynic paradise named the island of Pera. In the third century BCE. Bion of Borysthenes, a wandering preacher, was "the first to tart up philosophy" by popularizing the diatribe; Menippus of Gadara initiated a new type of satire mingling serio-comic themes in prose and verse (his works are lost); Cercidas of Megalopolis applied Cynic ideas to practical politics by proposing reforms attacking social inequalities in the refounding of his city; the fragments of Teles, a dull Megarian schoolmaster, throw some light on Bion and earlier Cynics. After a quieter, although not dormant, period Cynicism revived in the first century CE with some encouragement from Stoicism: Demetrius was prominent in the Stoic-flavored opposition to the emperor in the seventh decade; Dio Chrysostom found solace for his exile in an amalgam of Cynic and Stoic practice; Epictetus, the Stoic, admired Diogenes.

The second century records the apogee of Cynic influence and extravagance. The leading figures differed sharply. The philanthropy and popularity of Demonax of Cyprus contrasted with the brutal scorn of Oenomaus of Gadara. Peregrinus Proteus, a convert from Christianity, was an irrepressible radical with a touch of the mystic; he burned himself to death before huge crowds at the Olympic festival. These were men of ideals; but Lucian and Julian also record with disgust a raffish of confidence tricksters and professional beggar-preachers masquerading under the Cynic uniform of cloak, knapsack, and stick. The peculiar animal-divine polarity of Cynicism attracted both saints and rogues. In the history of Greek thought Cynicism was most influential on the development of Stoicism, first through Zeno and then much later

with Epictetus, who gave noble expression (3.22) to the most uncompromisingly radical ethic that anyone attempted to put into practice in the ancient world.

It is tempting to recognize Cynic traits in other civilizations, as Onesicratus, the admiral and historian of Alexander, did on encountering the gymnosophist Indian fakirs. In medieval times, the mendicant friars are more apposite than anchorites, especially when one considers the complementary virtues of Franciscans and Dominicans (*Domini canes*).

## CYRANO DE BERGERAC, SAVINIEN DE (1619–1655)

Savinien de Cyrano de Bergerac, a soldier, man of letters, and freethinker, was born in Paris, where he died thirty-six years later; he resembled only superficially the hero of Edmond Rostand's romanticized drama (1897). Hostile to the formal authoritarian education to which he had been subjected at the Collège de Beauvais, he was persuaded to serve in the army, where he gained a considerable reputation as a duelist and writer of verses. His military career came to an end when he was wounded at the siege of Arras in 1640. Between 1642 and 1651 he studied philosophy assiduously, with special stress on Pierre Gassendi and René Descartes, and was, according to some, a pupil of Gassendi himself. Descartes's principle of methodical doubt, Gassendi's rehabilitation of Epicurus, and the attendant influence of a newly translated Lucretius were all forces providing a common philosophical denominator which drew Cyrano closer to his fellow *libertins*—Gabriel Naudé, François La Mothe Le Vayer, and Molière, among others. At the same time he was emerging as a burlesque poet of consequence and a redoubtable political writer who first attacked and then defended the Machiavellian statecraft of Cardinal Mazarin. In 1652 he entered the service of the Duc d'Arpajon under whose protection he brought out in 1654 his *Oeuvres diverses*, which included the boldly rational *Lettre contre les sorciers* and a farcical comedy, *Le pédant joué*, from which Molière borrowed two passages for *Les fourberies de Scapin*. In 1654 Cyrano also published an intellectually challenging and ideologically daring tragedy, *La mort d'agrippine*. A falling beam, dislodged by accident—or perhaps intentionally—brought death a year later.

Cyrano's reputation as an intellectual libertine, propagator of subversive ideas, satirist of man and his foibles, and as a figure in the vanguard of scientific thought—already firmly established before 1655—received increased notoriety with the posthumous appearance of *L'autre monde, ou les états et empires de la lune et du soleil*, which described imaginary voyages to the moon and the sun, respectively. The first of the two parts of this work was made public in truncated form by the author's friend Le Bret in 1657. The second part, either unfinished or censored (the original manuscript has vanished), was published in 1762.

Despite borrowings and suggestions from a variety of sources, Cyrano's work, particularly when compared

with that of many of his contemporaries, is strikingly original. Subscribing to the still little known and highly controversial Copernican theory, he adhered to the principle that all is relative in the universe and attacked religious and philosophical anthropocentrism. In fact he was the first to link closely together a criticism of the religion of Moses and the philosophy of Aristotle. In the man-machine–beast-machine debate, he stressed the idea of continuity among all living creatures. A forerunner of Denis Diderot's materialism, he outlined a calculation of probability according to which atoms, by means of chance and infinite time alone, could, in their innumerable combinations, create the organized world known to man. Furthermore he demonstrated an awareness of the forces of gravitation, the laws of which Isaac Newton was to discover and define several decades later. But he did not have Gassendi's gift for observation and experimentation or Descartes's aptitude for mathematics. He was more a popularizer of science than a true scientist. Indeed, he was the originator of science fiction.

The chief significance of Cyrano lies in the fact that he epitomized the general mental attitudes among the freethinkers of his period: enmity toward tradition, interest in ethical and scientific progress, and fondness for philosophical abstractions. As such he was eminently representative of those engaged in a protracted intellectual struggle which revealed the great trend of the French critical spirit—a spirit that was to gain increased momentum in the eighteenth century and to approach fulfillment with the publication of Diderot's encyclopedia.

## CYRENAICS

The Cyrenaics were a school of philosophy founded by Aristippus of Cyrene in the first quarter of the fourth century BCE. Although he had two sons, Aristippus designated his daughter Arete as his intellectual heiress. She in turn bestowed the succession on her son Aristippus, called “the Mother-taught.” Apparently it was mainly he, a contemporary of Aristotle, who developed the more technical aspects of Cyrenaic doctrines. Cyrenaics were always included in lists of philosophical schools drawn up by the historians even though they had no fixed headquarters (unlike the Academy, the Lyceum, the Garden, etc.). There were several subschools referred to by the names of individuals, as Hegesiacs, Annicerians, and so on. They seem to have carried on the tradition of the Sophists of Socrates’ time, being loosely associated itinerant teachers offering, for fees, instruction in general culture and on particular philosophical doctrines. Their pupils were supposed to learn from them how to live the good life, specifically, how to get along with anybody in any circumstances, as their founder put it.

The Cyrenaics were hedonists. They regarded it as self-evident that pleasure is the goal of life, for pleasure and avoidance of pain are what all living creatures seek by nature. The sage best knows how to attain a life of as many pleasures, interspersed with as few pains, as feasible and how to bear the pains when they come, as come they must. Unlike the Epicureans, the Cyrenaics regarded pleasure not negatively as mere absence of pain—dead people are in that condition—but as positive feeling, notably what is experienced in eating, drinking, and sex.

The younger Aristippus formulated a physiological analysis. There are three kinds of internal bodily motions: rough, smooth, and intermediate, which he compared to a tempestuous sea, a gently undulating sea, and doldrums respectively. Pleasure is the perception, by “internal feeling,” of smooth motion; pain, of rough motion. Pleasures thus are particular present-moment happenings in individuals. These motions and their perceptions include satisfactions and dissatisfactions not so obviously internal to the body, such as gratitude and the pleasure one takes in the prosperity of one’s country. The Cyrenaics noted that thought, not simply perception, enters into pleasure/pain distinctions. For example, watching a man really dying is painful, but to see an actor “die” on stage may be pleasurable. Nevertheless, plainly corporeal pleasures and pains are, in general, more intense, which is why they are prescribed as rewards and punishments.

Like his teacher Socrates, the elder Aristippus did not concern himself with natural science, which he deemed useless for furthering the good life. His grandson justified this rejection by advancing a skeptical theory of knowledge, of greater present-day interest perhaps than Cyrenaic ethics, for it is the closest ancient forerunner of modern phenomenalism and subjectivism. The only things one knows infallibly and certainly, he held, are one’s feelings. These are internal states of the body. Things outside us produce the feelings—the Cyrenaics never doubted the external world—but one cannot know what those things are in themselves and how they operate. Something not yellow in itself may produce the sensation of yellow in a person with jaundice, and so on through the usual litany. Strictly, then, when in the presence of snow, one ought to say not “I see something white” but rather “I am being whitened” or, even better, “I am being affected whitely.” Statements of these forms are the only ones knowable as absolutely true or false. Furthermore, if someone else in the same situation says—sincerely, let us assume—that he too is being affected whitely, then he speaks the truth, but from this it cannot be inferred that his feeling is identical to one’s own. We apply the word “white” conventionally in the context of snow, but we have no way of knowing that the feeling it refers to is identical in everyone. Thus although the Cyrenaics did not explicitly raise the problem of other minds, in maintaining this possibility of an inverted spectrum they came close.

Cyrenaic skepticism helped also to justify Cyrenaic hedonism. Choices, as Socratics insisted, should be based on knowledge, not opinion or conjecture. But the scope of knowledge is limited to feelings, including pleasure and pain. Therefore, it is not only natural but rational to base our choices on pleasure and pain.

The most notable later Cyrenaics were Hegesias, Anniceris, and Theodorus, all active at the turn of the fourth to third century BCE. Hegesias, called “the Death Persuader,” was an ancient Schopenhauer. From hedonism, surprisingly but straightforwardly, he deduced an unmitigated pessimism. The only good is pleasure; the only evil is pain. But as things are and must be, pains so predominate over pleasures that a life adding up to a pleasurable net balance is impossible. Therefore, suicide is eminently rational. Hegesias wrote a book, *The Man Starving Himself to Death*, in which the title character describes in detail the unavoidable ills of life. It was said that he lectured on this theme with such eloquence that some of his auditors killed themselves, whereupon the Greek king of Egypt, Ptolemy I Soter (“the Savior”), for-

bade him to deliver any more such addresses. Thus Hegesias perhaps had the dubious honor of being the first professor to have had his academic freedom curtailed by the government. He did not kill himself. There is a further similarity to Arthur Schopenhauer in his counsel “We should not hate people, but educate them.”

Anniceris altered Cyrenaic hedonism by putting mental pleasures on a par with bodily ones, or even preferring them. Moreover, he softened the Cyrenaic egoism, declaring that the sage might forgo particular pleasures for the sake of friendship (as Epicurus maintained). He was credited with having ransomed Plato when that philosopher was for sale in the slave market of Aegina, though there are chronological and other difficulties with the story.

Theodorus, Anniceris’s pupil, took free speech and the flouting of conventional pieties to an extreme even for the Greeks. He said that the sage would not fight for his country, for why should he put his wisdom at risk of extinction for the sake of the stupid masses? (Theodorus, unlike Hegesias, did not say no to life.) Aristippus had said that if all the laws were abrogated, the sage would continue to behave as before. Theodorus turned this proto-Kantian ethic all the way around, declaring that the sage might steal, commit adultery, even pillage temples if the occasion demanded—such acts being evil not by nature but only supposedly so to restrain the stupid. Extending his teacher’s view on precedence among pleasures, for pleasure/pain he substituted joy/sorrow (primarily mental feelings) as the basic ethical contrast. He even went so far as to hold, as the Cynics did, that matters of the body are “indifferent.” Threatened with crucifixion after he insulted Lysimachus, king of Macedon and in consequence ruler of Athens at the time, Theodorus contemptuously replied that it did not matter to him whether

he rotted in the ground or in the air. (The threat apparently was not carried out.) But in place of Anniceris’s amiability he reinstated hard-boiled egoism, claiming that the sage, being self-sufficient, has no need of friends.

With Diagoras of Melos and Euhemerus of Tegea, also a Cyrenaic, Theodorus was one of only three Greek thinkers who unequivocally proclaimed that there are no gods or demons at all, thereby earning the sobriquet “the Atheist.” At a party in Athens, Hipparchia, wife of Crates the Cynic and a philosopher in her own right, chopped logic with him, saying, “What would not be wrong when done by Theodorus would not be wrong when done by Hipparchia. Now, it would not be wrong for Theodorus to strike himself. Therefore it would not be wrong for Hipparchia to strike Theodorus.” Theodorus made no answer but instead pulled up her dress. (Doing so was not, or not merely, a display of classical male chauvinism, for it would not have been wrong for Hipparchia to pull up her own dress.)

The modifications by Anniceris and Theodorus brought the Cyrenaics so close to Epicurean views that it is not surprising that we hear no more of them as a distinct school after the first half of the third century BCE, when it was displaced by the Epicurean school.

## DAI ZHEN (1723–1777)

Dai Zhen, styled Dongyuan, was a critical-minded neo-Confucian in the Qing period. He is noted as a critic of neo-Confucianism of the Song (960–1279) and Ming (1368–1644) periods and made original contributions to the critical exposition of the philosophy of Mencius (c. 371–c. 289 BCE). Even though not known as a philosopher in his own time, his work in neo-Confucian criticism and exposition received more attention after Hu Shi wrote about his philosophy in the 1930s.

Dai Zhen was born in the Huizhou area of Anhui Province at a place known as Longfu (Tunxi) of Xiuling County. Although Huizhou was prosperous and produced outstanding academic talents, Dai Zhen, coming from a poor family with no academic traditions, received no good formal schooling. His success as a scholar derived from his own dedication to self-study.

Dai Zhen wrote *Yuan shan* (*Inquiry into Goodness*), his first philosophical treatise, from age 33 to age 41. With this work as a foundation, Dai Zhen then introduced quotations from the classics to support his philosophical points, and this later work, together with *Yuan shan*, became *Xuyan* (Prefatory words). Consolidating and con-

centrating on *Mengzi* (The book of Mencius), he sorted out and expanded *Xuyan* into a philosophical commentary on the key notions of *Mengzi*, producing “*Mengzi*” *ziyi shuzheng* (Commentary on the meanings of terms in *Mengzi*). This was his last work, which he completed at age 44.

Although Dai Zhen strongly objected to the abstract use of principles (*li*), he did not deny the importance of reason when applied correctly to concrete matters. But how does one acquire an understanding of reason and principle? The answer is twofold: by correctly reading the classical texts on which doctrines of moral reasoning are based and by clearly reflecting on what reason and principle concretely signify. One must first authenticate the classical texts and semantically and philologically determine their meaning. Only then can one correctly read and interpret them. In this sense textual criticism is highly relevant to understanding the principles and moral reasoning embodied in the texts of the classical philosophers.

The usefulness of textual criticism for understanding reasons and principles is, of course, no explanation of the rise of textual criticism in the Qing period. Most well-known textual critics were not interested in discovering or rediscovering the principles and moral reasoning of

the classical texts. But for Dai Zhen, textual criticism is essential for such discovery. He wrote, "The ultimate idea of the classics is the Way. We use words [*ci*] to understand the Way. We use the linguistic study of the text [*xiaoxue wenzi*] to understand the words. From such study we come to understand the discourse, from the discourse we come to understand the mind and intent of the ancient sages" (1995, p. 378). Hence, for Dai Zhen, the purpose of textual criticism of a classic is to retrieve the original meaning of the text. On this basis one can then come to understand the moral reasoning and principles behind the texts.

Dai Zhen was perhaps the first modern Chinese scholar to formulate a textual hermeneutics that combines historical linguistics with philosophical reflection for reading classical texts. He was also one of the earliest pioneers in philosophical hermeneutics in the whole world.

Another important philosophical contribution of Dai Zhen's was his objection to separating reason from feelings and desires in Song and Ming neo-Confucianism and hence his stress on understanding in terms of human feelings and desires. This position came from his deep appreciation of the naturalistic cosmology of the *Yijing* (Book of changes), where he found sources of human nature and human reason. He took the productivity of life (*shengsheng*) as the most basic fact of reality. The purpose of this productivity gives purpose to the interplay of yin and yang and is called the Way, he explained. This interplay results in the unceasing transformation of life and the ordering of things (*tiaoli*) in heaven and on earth. From the productivity of life and the ordering of things Dai Zhen derives the virtues of humanity (*ren*) and moral reason (*yi*), which he regards as inherent in these two processes.

## DAMASCIUS

(c. 462–c. 538)

Damascius was a neoplatonic philosopher and the last head of the Academy in Athens. He was born around 462 CE in Damascus and studied in Alexandria and Athens. In 515 he became head of the Academy, which, through his reforms and teaching, would see a final flourishing. After the closing down of the Academy by Emperor Justinian in 529, Damascius and six colleagues went into exile at the court of King Chosroes in Persia. They returned in 532, having been granted the freedom to continue their philosophical work. Damascius died in Syria sometime after 538.

His writings include the "Life of Isidore" (Isidore was his teacher and predecessor), in which he offers a privileged insight in the history of the pagan Platonic school in the fifth century CE; and commentaries on Plato (preserved are those on the *Parmenides*, the *Philebus*, and the *Phedo*). He is, however, mainly known for his treatise "On the First Principles" (*De principiis*), an ingenious philosophical speculation about the first causes of all things.

Damascius had no ambition to develop a better metaphysical system than his predecessors. His own thought is primarily aporetic: He raises critical questions in the margin of the doctrine of the principles, as it had been developed in the neoplatonic tradition, and confronts the doctrine with all sorts of difficulties. When he ventures a solution—and on many issues he can be original (for instance, his doctrine on time)—he again puts that solution into a question with new aporias (or doubts). Damascius's work is in many ways a critical analysis of the position of Proclus, who, in his view, was too preoccupied with logical coherence and system building. He raises questions about the One and multiplicity, about procession and return, about triads of principles,

and about concepts such as power—not in order to discredit all philosophical discourse skeptically, but to clarify what is inadequate in the formulations of his predecessors.

The most fundamental aporia is discussed at the beginning of the treatise: Is the first principle itself a part of the whole of which it is the principle? But if it is a part, how could it still have the status of a principle? If it is outside the whole, how can we understand that the whole originates from it? The first principle, it seems, is neither principle nor cause, nor does it fit in any other category used to explain relations between beings: It is an ineffable “nothing” we have to postulate beyond the one whole. This “ineffable” is even beyond the “One” that is the first principle of all things.

More than any other Platonic philosopher, Damascius is aware of the precarious nature of all rational discourse when people deal with questions that go beyond the limits of what they can experience. More than any other, he explored the boundaries of rationality; he tried, by all means, to say what could not be said, because about the first principles one can only speak using analogies and “indications” (*endeixeis*), which are as such unfitting to indicate divine realities.

Damascius’s sharp critical mind does not, however, bring him to skepticism. If philosophical systems remain tentative and fragile, there is also the mythological tradition and religious practice, to which Damascius remains devoted. Damascius is, together with Proclus, our main source on Chaldean and Orphic theologies. In many ways his work is a wonderful swan song of pagan Hellenism.

## DANTE ALIGHIERI

(1265–1321)

Dante Alighieri, the author of the *Divine Comedy*, was born in Florence of a middle-class family with some pretensions to nobility. It is likely that he frequented the church schools, and he probably spent a year at the University of Bologna. He fought in the battle of Campaldino (1289) and a few years later married Gemma Donati, by whom he had at least three children. He took part in the government of his native city, serving on various city councils (1295–1297, 1301), as prior (1300), and as ambassador to San Gimignano (May 1300) and later to Rome (October 1301), where his mission was to negotiate with the pope to bring about a just peace between the warring factions of White Guelphs and Black Guelphs. Aided by the intervention of Charles of Valois, the Blacks took over the city and Dante, a White, went into exile. He wandered from court to court of medieval Italy, with especially long sojourns at Verona and at Ravenna, where he spent the last three years of his life. He seems to have served his patrons as adviser and on occasion specifically as ambassador; it was after an embassy to Venice on behalf of Guido da Polenta, Lord of Ravenna, that the poet died.

By choice Dante might well have devoted himself to political life: circumstance deprived him of this opportunity and constrained him to put his great gifts to the service of letters; his masterpiece, the *Divine Comedy*, is generally regarded as the supreme poetic achievement of the Western tradition and has assured his fame. His *Vita Nuova* is the story of his idealistic love for Beatrice, presumably of the Portinari family, who married Simone de’ Bardi and died in 1290. The *Convivio*, composed after the author went into exile, is a didactic work; the *De vulgari eloquentia* is a milestone in the history of linguistics, being the first serious study of a vernacular tongue; and the *De monarchia* is the vehicle for Dante’s expression of his political theory. Mention should also be made of his *Rhymes*, a collection of verses of varying kinds—some purely lyrical, some moralistic, and some, one might say, philosophical.

To what extent Dante may properly be considered a philosopher depends on one’s definition of the term. Richard McKeon does not consider him such “by the crucial test that, despite the philosophic doctrines that crowd his poems, scholars have been unable to agree concerning what his attitude toward the philosophers he uses is.” But this is to make a very special category of philosophers. The best statement of Dante’s attitude is found at the

beginning of the *Convivio* (Banquet), where he represents himself not as one of the great (scholars and philosophers) who actually sit at the banquet table but rather as one who, sitting at their feet, passes on to others the crumbs that he is able to pick up. This would make him on the one hand at least an eager student of philosophy and on the other what we should now call a popularizer, if the term may be used without disparagement. And within the great area of philosophy his major interest was in ethics and politics. Let us concede that in the field of pure speculation his mind was alert and curious rather than original. Like his contemporaries he was for the most part content to follow Aristotle as interpreted by Thomas Aquinas, with recourse to what he thought of as “Platonic” where it suited him. His use of his authority, his stature as a poet, and his influence, which still endures, make it worthwhile to study his philosophical posture in some detail.

### THE VITA NUOVA AND CONVIVIO

If a drive to seek eternal truth, permanent universals, and order in things is the proper attribute of a philosopher, as it would seem to be, then Dante’s claim to the cherished title is reasonable. Perhaps his first work, the *Vita Nuova*, is the most dramatic example of this precisely because, paradoxically, it is not a philosophical work at all. It is a love story of intimate and personal nature, grounded, it would seem, in historical fact but taking on the air of a spiritual parable; its immediate sources are not in works of philosophy but in the love cult of the Middle Ages. Yet the construction and the apparatus betray a disciplined intent; the prose and poetry are mingled in a strict architectural pattern; and each of the poems is followed by an analysis composed in the tradition of Scholasticism. Digressions on the nature of personification and the meaning of certain terms are evidence of what one might fairly call the philosophical manner. Beatrice herself becomes in the course of the confessional narrative something very close to a theological and thus a quasi-philosophical concept.

It is, however, the *Convivio* that is the most purposefully “philosophical” of Dante’s canon. It was inspired, the author tells us, by the reading of Cicero and Boethius, and Dante in fact seems to see himself as having much in common with the latter, also a victim of political injustice, and as turning to the same source for consolation. It is noteworthy, too, that Dante, like Boethius, attempts—consciously, one suspects—to set philosophy free from its entanglement with Christian theology. His definition of philosophy in the third tractate goes back to Pythagoras,

and in Book IV, in the course of enumerating the virtues appropriate to the successive ages of man, he turns to the pagans (such as Aeneas and, very strikingly, Cato), to exemplify such virtues. All but startling is his eulogy: “And what earthly man was more worthy than Cato to signify God? Truly none.” Such an attitude toward the “ideal pagan” dramatizes the author’s celebrated exposition of the two beatitudes (II, 4): one in speculation and contemplation, the other in proper conduct of the active life; the former is “higher” than the latter, which, however, clearly is not “subordinate”: “It is typical of Dante,” says Étienne Gilson, “to base the autonomy of an inferior order on its very inferiority.”

In this connection the plan of the *Convivio* (if it may be called a plan, for, unlike most of Dante’s works, the book seems to have grown of itself) is very revealing of the author’s concept of the uses, if not the nature, of philosophy. The first tractate is highly personal, stating that the genesis of his interest was his need for consolation in his exile and his feeling that his “image” in Italy had suffered somewhat from the youthful and impassioned portrait that emerged from the pages of the *Vita Nuova*. In the second tractate he avows that in effect philosophy, “the fairest and noblest daughter of the universe,” is the new lady who has replaced Beatrice in his heart. In the third tractate he discusses the meaning of philosophy, which he finds to signify “love of and zeal for wisdom,” adding that philosophy has “as its subject understanding and as its form an almost divine love of the thing understood.” Presumably “understanding” can be applied to the various fields of study Dante had enumerated in the second tractate, composing an ingenious correlation between the sciences and the heavens of the Ptolemaic system. Of these branches the highest for any medieval theologian (theology itself is in the empyrean, beyond the physical cosmos) would be metaphysics, but it is significant that Dante brackets it with physics in the starry heaven and puts ethics in the loftiest physical sphere, the *primum mobile*, morality being “the science that disposes us rightly for the other sciences” even as the crystalline heaven sets in motion all the other spheres. In fact, the largest part of the work, the fourth treatise, is given over to a study of true nobility, its source and its effects.

Dante finds this human excellence to be not the Aristotelian “inherited wealth and good manners” but rather a God-given grace, the nature of which is evident in its fruits. The fruits, which are enumerated in chronological order, are all of such a nature as to be properly called social virtues. Dante’s ideal is not a mystic or a visionary but, in the best sense of the term, a man of the world, liv-

ing in a community and serving it to the best of his ability—certainly an Aristotelian concept. Only in the stage of “decrepitude” does Dante say that the good man’s thoughts should turn to God and the afterlife, and even this passage, beautiful as it is, has about it a tone more pagan than Christian. It is noteworthy that all the men chosen to exemplify the appropriate virtues are men of action, in many cases pagans but also including such ambiguous characters as Lancelot and Guido da Montefeltro, the *condottiere*. Thus the *Convivio*, dedicated to the glorification of philosophy, ends by being a rule of good living, high-minded, to be sure, but practical as well. Noteworthy too is the rather lengthy excursus of Book IV (Chs. 4–5) that is inserted to justify the Roman Empire. Dante finds historical correspondences between the empire and the church, affirms that Christ chose to come to Earth at the time the world was best governed and at peace (that is, under Augustus), and concludes with a panegyric to Rome. This is the more interesting because some of his data are traceable to St. Augustine, whose view of imperial Rome was quite opposite.

#### THE *DE MONARCHIA*

The *De monarchia*, developing the latent and the tentative attitudes of the *Convivio*, may well contain Dante’s most original contribution to philosophical thought. Written, it seems likely, either during or shortly after Henry VII of Luxembourg’s descent into Italy (c. 1313), it is an eloquent defense of the imperial cause or, more accurately, principle. The work is divided into three parts: in the first Dante shows the necessity for the rule of one monarch in temporal affairs; in the second he argues that for historical reasons such a monarch should be the Roman emperor; and in the third he defends the thesis that the emperor, although he owes deference to the pope, should not be subordinate to the pontiff in temporal matters.

It is the first book that is the most fascinating to the student of Dante the philosopher. Briefly, the main argument is that peace is a necessity if humanity is to actualize its potential intellect in the highest degree; and there can be no assurance of peace, national rivalries being what they are and greed being as strong as it is, unless the world is governed by one prince, supreme above all nations and beyond the temptations of *cupiditas*. In the course of defining the collective potential intellect, Dante invokes the name of Averroes, thus laying himself open to a charge of heresy (and indeed the *De monarchia* was solemnly burned and remained on the Index for many years).

Gilson, however, has well made the point that the collective potential intellect of humanity as conceived by Dante was not a “being,” as was the “possible intellect” (or kind of oversoul) of Averroes, but rather a “community.” Indeed, in the course of his arguments in the first book Dante follows Thomistic reasoning, but unlike Thomas, who never so much as mentioned the word *emperor*, he applies it to secular purposes. Conceding the superiority of contemplation over action and, by inference, of the spiritual over the temporal, he nevertheless stresses the importance of the machinery necessary to perfect the fulfillment of man’s proper endowment in the active life and his happiness in this world. So too at the end he readily concedes that the emperor owes the pope the respect of a younger brother, but while thus indicating that the spiritual life is superior, he seems also to imply that it is separate and independent; both pope and emperor would, in his theory, derive their authority directly from God. The result is in fact a kind of political facet of the Averroistic double truth, as contemporary critics were quick to point out. Gilson, for whom Dante is no Averroist, nevertheless commends him for seeing clearly “that one cannot entirely withdraw the temporal world from the jurisdiction of the spiritual world without entirely withdrawing philosophy from the jurisdiction of theology” and adds that Dante’s perception of this fact gives him “a cardinal position in the history of mediaeval political philosophy.” In this sense and with a practical intent characteristic of Dante, the *De monarchia* reaffirms the underlying thesis of the *Convivio*.

#### THE DIVINE COMEDY

It has been argued by some critics that the *Divine Comedy* is in essence a repudiation of the secular and independent *Convivio* and *De monarchia* and is evidence of a kind of “Conversion” of the poet, resulting either from some inner crisis or from his despair at the defeat of Henry VII. Perhaps if we say that in the *Comedy* the substance of the earlier works is utilized as a preparation for the vision, a basis for the mystic superstructure rather than as a finality in itself, we may speak of “conversion,” but not, in the opinion of this writer, if the word carries any suggestion of rejection. It is true that the devotional element is novel and important: the intercession of the Virgin Mary makes it possible for the poet to undertake the supernatural journey and to enjoy the vision that crowns it. The vision itself is of a mystical nature, adumbrated perhaps in the *Vita nuova* but totally absent from the “philosophical” works. Concern with purely theological matters—the Incarnation, predestination, divine justice, and the like—

bulk large in the *Comedy*, which also contains (in *Paradiso* XI) a very interesting example of the *contemptus mundi* posture, otherwise quite uncharacteristic of Dante. The poet is also very careful to point out the error of the belief in Averroistic oversoul (*Purgatorio* XXV). Such elements have led to discussion of Dante's Augustinianism as opposed to his Thomism. (T. K. Swing has argued that in his manipulation of these doctrines "Dante is the first to accomplish a consistent elucidation of the teleological destiny of the Christian soul through a metaphysical scheme.") It is true that the presence of St. Bernard as Dante's last guide and, as it were, sponsor for his ultimate vision, gives dramatic emphasis to the Neoplatonic or Augustinian strain. But if the substitution of rapture for reason represents the victory of Augustine over Thomas, it also carries us beyond the limits of philosophy and perhaps out of the area of our proper concern here.

We may yet affirm, in the face of all such elements as noted, that the *Comedy* is, in the author's intent, primarily an exposition of ethics; the letter to Can Grande specifically defines it as having for its subject "man, liable to the reward or punishment of Justice, according as through the freedom of the will he is deserving or undeserving." And in this area the frame of reference is, as it was in the *Convivio*, Aristotelian and Thomistic—not without some original sallies of Dante's own. The presence in the *Paradiso* of the Latin Averroist Siger of Brabant, for example, may be interpreted as an affirmation of the autonomy and dignity of the "contemporary profane science" (Pierre Mandonnet) of Aristotelian philosophy. But from the point of view of ethical investigation, the *Inferno* is the most interesting part of the work, for here, dealing not with the way of salvation, which is no longer possible to the damned, nor with the ultimate doctrines, interesting only to saints, Dante is in a sense free to formulate his own code of morality. Clearly his inclusion of pagans and other non-Christians in hell indicates his intent to establish a code of behavior for all men; his hell is nonsectarian, broadly speaking. His main divisions of incontinence, violence, and fraud are ingeniously worked out from a combination of Aristotle, Cicero, and Thomas; interesting too is his creation of the "vestibule" for the lukewarm spirits and his peopling of the limbo with the souls of the virtuous pagans. Nor does the "converted" Dante abandon his appreciation of the second beatitude; not only do the pagans in limbo enjoy quite a comfortable immortality but Cato, so much revered in the *Convivio*, reappears as the guardian of purgatory, where he symbolizes free will; and, most startling of all, in the heaven of Jupiter the Trojan Ripheus is shown as an example of the "baptism of desire" that would make it

possible for a good man, totally ignorant of the Mosaic or Christian message, to win salvation. To be sure, this is rare and does not avail to save Vergil or Aristotle, but on the other hand salvation in Christian terms also is ultimately a matter of predestined grace: without being unorthodox, Dante, in the example of Ripheus, has revealed his deep concern for ultimate justice. Indeed, the analysis of sin in the *Inferno*, as Kenelm Foster has pointed out, has its genesis in a conception of justice and presupposes society. The souls in the *Inferno* have "injured" others, have broken the social fabric in one way or another; even the heretics seem to be there because they have misled their followers rather than because of their own arrogant pride (a sin not specifically classified in the *Inferno*). We may also remark that Dante's concern for the good life on Earth does not desert him: The theory of the two "suns" necessary for the proper illumination of humankind reappears in the *Purgatory*; the emperor is glorified (a reserved seat awaits Henry VII in the celestial rose); and certain cabalistic prophecies indicate Dante's hope for a *dux* who will lead the temporal world back to order and sanity. "The *Divine Comedy* is as much a political as it is a religious poem," says A. Passerin d'Entrèves, and surely in that climactic work both politics and religion are seen *sub specie philosophiae*. If Dante is not a true philosopher, he is certainly a magnificent amateur.

## DANTO, ARTHUR (1924–)

Arthur Danto's contributions to the philosophy of art have been shaped by his experiences as art maker, art critic, and art lover. He earned a bachelor's degree in fine arts from Wayne State University in 1948. For the next decade, his woodcuts were shown in such important venues as the Art Institute of Chicago, the Detroit Institute of Arts, Los Angeles County Museum, the Museum of Fine Arts in Boston, and the National Gallery of Art in Washington, D.C. During this period of active art-making, he completed a doctorate in philosophy at Columbia University in 1952 and began his half-century-long appointment in the Columbia philosophy department.

One of Danto's central aims for the first thirty years of his career was to render the ideas of nineteenth- and twentieth-century continental philosophers such as Hegel, Nietzsche, and Sartre accessible and useful to analytical philosophers. Danto's writing about these figures is clear and often critical. He has also published penetrating overviews of core fields such as the philosophy of science, the philosophy of action, the theory of knowledge, the philosophy of history, and philosophical psychology.

Nevertheless, this philosopher remained an artist and passionate art lover. He had come to New York to study philosophy just when that city emerged as the center of innovative achievement in the art world. The art Danto encountered in the museums and galleries he frequented was conceptually challenging.

Andy Warhol's 1964 work *Brillo Box* provoked a key question: What makes *Brillo Box*—a replica of the box used to ship packages of Brillo pads—a work of art, suitable for display in a museum or gallery, when perceptually indiscernible objects—the actual Brillo boxes created en masse by the manufacturer—are relegated to grocery displays or storerooms? This is a philosophical query, but also an integral part of experiencing *Brillo Box* as art, for the art lover encountering *Brillo Box* is initially transfixed by questions about its status.

Danto's famous essay "The Art World" (1964) initiated an answer that he refined and elaborated over the ensuing fifteen years. Danto asked how commonplace objects that never could have been art in earlier times not only had gained the possibility of being art by 1964 but also appeared to be the art necessary for that time. Danto presumes that philosophy should accept, not correct, the phenomena of art-world practice and discourse. Therefore, the traditional questions of philosophy of art and philosophical aesthetics must be transformed to fit the art world's realities.

Danto's more fully elaborated position, first presented in full in *The Transfiguration of the Commonplace* (1981), is that art history and art theory contribute experiential (albeit not sensuous) properties to certain objects. These properties make the difference in experiencing objects as art. Absent being experienced at the appropriate art-historical moment, and through the lens of compelling art-theoretical understandings that offer illuminating interpretive hypotheses, objects do not rise to the status of art.

Seeing affinities between Danto's focus on art-world practice and his own view that it is artists, critics, and curators who decree which objects should be treated as art, George Dickie heralded the advent of the institutional theory of art. Danto's view differs from Dickie's in many ways, however. For example, a key idea in Danto's, but not in Dickie's, thought is that art distinctively embodies meaning, or at least embodies questioning.

Danto takes modern art's history to be a quest for answers about the general (transhistorical) nature and identity of art. Art in our time has achieved a philosophical self-consciousness that acknowledges rather than veils ontological questions about its own nature. But in pursuing its own ontology, art transcends its limits and is transfigured into philosophy. Persisting in this transgressive aim, art subsequently executes its own end, turning its back on philosophical anxiety about what art must be. Art thereby is liberated to place itself freely in the service of a multiplicity of values rather than to embrace a single

value that is uniquely aesthetic. Danto's theory of the end of art is empirical, not prescriptive. He explains where art has arrived, and why, rather than directing where art should go. In such a pluralistic age as our own, when everything is possible, what principles should guide the art critic? This question, traditionally a concern of philosophical aesthetics, is of special interest to Danto because of another artworld role he fills, that of art critic. In 1984 Danto became the art critic for *The Nation* magazine. Much of his writing since that time has been criticism of works of art or reflections on art criticism. His *Encounters and Reflections: Art in the Historical Present*, a collection of art criticism, won the National Book Critics Circle Prize for Criticism in 1990.

In general, Danto's art criticism is about understanding artistic processes, not assessing aesthetic outcomes. Some philosophers fault him for stamping his philosophy of art with his style of art criticism and thereby giving artistic considerations priority over aesthetic values. Others praise him for developing a philosophical theory of art into which enlightening art criticism is tightly woven. Danto seeks to explain rather than steer the direction of art. Art criticism, as Danto understands the practice, deploys artistic judgment to detect an object's content and explain how the object embodies or presents what it is about. Yet Danto himself offers no developed philosophical analysis of artistic embodiment, neither of the process nor of the criteria of success. His signature stance is to observe from the intersect of philosophy and criticism. His strategy is to gently and genially compel art criticism to confront its own implicit abstractions and generalizations, while persuasively propelling philosophy to engage with the puzzling particulars of the world of art.

## DARWIN, CHARLES ROBERT (1809–1882)

Charles Robert Darwin, the British biologist whose theory of organic evolution revolutionized science, philosophy, and theology, was born at Shrewsbury. He attended the universities of Edinburgh and Cambridge but was not attracted by his medical studies at the first or by his theological studies at the second. Near the end of his undergraduate days he formed a friendship with J. T. Henslow, professor of botany at Cambridge, "a man who knew every branch of science" (*Autobiography of Charles Darwin*). This association, together with an enthusiasm for collecting beetles and a reading of works by Wilhelm von Humboldt and John Herschel, generated in him "a burning zeal to contribute to the noble structure of Natural Science." The opportunity to do so on a large scale arose when Henslow secured for him the post of naturalist "without pay" aboard the H.M.S. *Beagle*, then about to begin a long voyage in the Southern Hemisphere. Thus, between 1831 and 1836 Darwin was able to make extensive observations of the flora, fauna, and geological formations at widely separated points on the globe. This experience determined the course of his life thereafter and laid the foundation for many of his fundamental ideas. On his return he lived in London for six years, where he became acquainted with leading scientists of the day. Sir Charles Lyell, Sir Joseph Hooker, and T. H. Huxley were among his most intimate friends. In 1842 he took up residence at Down, a secluded village in Kent. Here, during the forty years until his death, he conducted the researches and wrote the works that made him famous. He was buried in Westminster Abbey close to the grave of Sir Isaac Newton.

Darwin's productivity, despite recurrent bouts of illness, was prodigious. His publications ranged over such diverse subjects as volcanic islands, coral reefs, barnacles, plant movement, the fertilization of orchids, the action of

earthworms on the soil, the variation of domesticated animals and plants, and the theory of evolution. Even if he had never written *The Origin of Species* (1859) and *The Descent of Man* (1871), he would still be regarded as one of the great biologists of the nineteenth century. Of course, it was these two books that made him the initiator of a revolution in thought more far-reaching than that ushered in by Nicolas Copernicus. He established beyond reasonable doubt that all living things, including man, have developed from a few extremely simple forms, perhaps from one form, by a gradual process of descent with modification. Furthermore, he formulated a theory (natural selection), supporting it with a large body of evidence, to account for this process and particularly to explain the “transmutation of Species” and the origin of adaptations. As a result, the biological sciences were given a set of unifying principles, and man was given a new and challenging conception of his place in nature.

It was characteristic of Darwin that he came to these conclusions by his own observations and reflections. When he embarked on the *Beagle*, his outlook was “quite orthodox.” He accepted without question the fixity of species and their special creation as depicted in Genesis. Doubts began to arise in his mind during the ship’s visit to the Galápagos Archipelago in 1835, when he noticed that very small differences were present in the so-called species inhabiting separate islands. The doubts were reinforced by his observation of fossils on the Pampas and the distribution of organisms on the South American continent as a whole. He was “haunted” by the idea that such facts “could be explained on the supposition that species gradually became modified.” In July 1837 he “opened his first notebook” to record additional facts bearing on the question, but it was not until he happened to read Thomas Robert Malthus’s *Essay on Population* in October 1838 that he found an explanatory theory from which the above “supposition” followed. He then proceeded to formulate the principle of natural selection, which is simply “the doctrine of Malthus applied with manifold force to the whole animal and vegetable kingdoms.” Darwin never professed to have invented the idea of organic evolution, of the mutability of species, or even of natural selection. What he did profess was to have produced the first scientific proof that these ideas apply to the living world.

Unlike some lesser men of science, Darwin was not inclined to rush into print in order to establish a proprietary right to his theory. His modesty and single-minded desire to find out the truth forbade any such action. Accordingly, the theory underwent several preliminary formulations. It was first set down in a short abstract in

1842 and two years later was expanded into an essay that both Lyell and Hooker read. Early in 1856 Lyell advised Darwin to write a full-length account of his views. It was when this manuscript, which would have been “three or four times as extensive” as *The Origin of Species*, was about half finished that Alfred Russel Wallace’s paper, which contained virtually the same ideas that Darwin was working out, arrived at Down from the Malay Archipelago. The resulting crisis was resolved by having a joint communication from the two men read at a meeting of the Linnaean Society on July 1, 1858. Between September of that year and November 1859, Darwin “abstracted” the large manuscript and produced his classic. *The Origin of Species* appeared on November 24 in an edition of 1,250 copies, all of which were sold on the first day. Ultimately, six editions containing many revisions were published.

Despite the interest that *The Origin of Species* excited, it was by no means universally approved at first. In the scientific world support for it came from Darwin’s friends, but others expressed opposition that often took the form of objections to the modes of explanation and proof employed in the work. Darwin’s use of historical or genetic explanations, his implicit adoption of statistical conceptions (“population thinking,” as it is now called), and his practice of introducing conjectures or “imaginary illustrations” to buttress his argument were repugnant to biologists who held that scientific explanation must consist in bringing directly observed phenomena under general laws. Believers in this oversimplified model also disliked his notion of “chance” variations and his repudiation of “any law of necessary development.” Before long, however, the cumulative force of Darwin’s arguments, augmented by the case put forward in *The Descent of Man*, convinced the great majority of biologists, so that opposition from this quarter had disappeared by 1880.

The popular reaction to Darwin’s theory focused on its religious and ideological implications. These were recognized to be hostile to the Establishment. Hence, Darwin found himself enthusiastically supported by radicals, rationalists, and anticlericals and vehemently attacked by reactionaries, fundamentalists, and priests. He shrank from entering into this controversy, which was altogether distasteful to him, but T. H. Huxley, who enjoyed crossing swords with theologians, took a different stand. Appointing himself “Darwin’s bulldog,” he relentlessly pursued such antievolutionists as Bishop Wilberforce and W. E. Gladstone. His efforts had a good deal to do with creating the image of Darwin as an enemy of the Bible, the church, and Christianity.

This image was, in fact, fairly close to the truth. Darwin's religious beliefs, as he relates in his *Autobiography*, underwent a change from naive acceptance of Christian doctrines to reluctant agnosticism. In the two years following his return from the voyage of the *Beagle* he was "led to think much about religion." Doubts were engendered in his mind about the historical veracity of the Gospels, the occurrence of miracles, and the dogma of everlasting damnation of unbelievers (which he calls "a damnable doctrine"). By reflection on such matters he "gradually came to disbelieve in Christianity" and wondered how anybody could wish it to be true.

A similar erosion occurred in connection with his belief in the existence of a personal God. When he wrote *The Origin of Species*, Darwin accepted a vague theism or deism. In the last chapter he speaks of laws having been "impressed on matter by the Creator" and of life's powers "having been breathed by the Creator into a few forms or into one." He was thus able at the time to deny that it was his intention "to write atheistically." Yet it was also clear to him that the theory of natural selection exploded the old argument for theism based on the presence of design in the organic world. The vast amount of suffering and misery that exists seemed to him a strong argument against any belief in a beneficent First Cause. He had moods in which it seemed difficult or impossible to conceive that "this immense and wonderful universe, with our conscious selves, arose through chance." In the end, however, he concluded "that the whole subject is beyond the scope of man's intellect. ... The mystery of the beginning of all things is insoluble by us; and I for one must be content to remain an Agnostic."

Darwin's reflections on religion, although not systematic, provide a good example of his intellectual integrity. "I have steadily endeavored," he wrote in his *Autobiography*, "to keep my mind free, so as to give up any hypothesis, however much beloved (and I cannot resist forming one on every subject), as soon as facts are shown to be opposed to it." That statement might well serve as his epitaph.

## Bibliography

### WORKS BY DARWIN

*The Autobiography of Charles Darwin* (London, 1958) was edited by his granddaughter Nora Barlow, who restored the material omitted from the original. The original *Autobiography* was first published in 1887 as part of the *Life and Letters of Charles Darwin*, but many passages of the manuscript were omitted because they contained candid and caustic judgments of persons and of the Christian religion. These omitted passages, amounting to nearly six thousand words, were restored in the 1958 edition.

*The Life and Letters of Charles Darwin* (2 vols., New York: Basic Books, 1959) was edited by Francis Darwin. The 1959 edition has an introduction by George Gaylord Simpson.

Among the many editions of *On the Origin of Species* are a facsimile of the first edition, with an illuminating introduction by Ernst Mayr (Cambridge, MA: Harvard University Press, 1964), and a variorum text of the six editions, edited by Morse Peckham (Philadelphia: Univ. of Pennsylvania Press, 1959). The *Origin* is also available in paperback with a foreword by George Gaylord Simpson (New York, 1962).

For the voyage of the *Beagle* see *Charles Darwin's Diary of the Voyage of H.M.S. Beagle* (Cambridge, U.K.: Cambridge University Press, 1933), which was edited from the manuscript by Nora Barlow, and Nora Barlow's edition of *Charles Darwin and the Voyage of the Beagle* (London: Pilot Press, 1945), for which she has written an introduction.

Darwin and Wallace's *Evolution by Natural Selection* (London: Cambridge University Press, 1958) has been edited, with an introduction, by Gavin De Beer. This volume contains the Linnaean Society papers.

### WORKS ON DARWIN

For works on Darwin see Alvar Ellegård's *Darwin and the General Reader* (Göteborg, Sweden, 1958) and Gavin De Beer's excellent *Charles Darwin: Evolution by Natural Selection* (London: T. Nelson, 1963).

## DARWIN, ERASMUS

(1731–1802)

Erasmus Darwin, an English physician, man of science, and poet, was the grandfather of Charles Darwin, whose evolutionary views he partly anticipated, and of Francis Galton. Like Charles he was educated at Cambridge, where he took the M.B. degree in 1755. For more than forty years he practiced medicine at Lichfield and Derby and gained a wide reputation for his skill, intellectual vigor, and originality of character. Among his friends were Jean-Jacques Rousseau, whom he met in 1766, and Joseph Priestley. He corresponded with both men. In 1784 he founded the Philosophical Society at Derby to stimulate interest in the sciences. He wrote copiously,

with varying degrees of success. His chief prose works are *Zoonomia or the Laws of Organic Life* (2 vols., London, 1794–1796) and *Phytologia or the Philosophy of Agriculture and Gardening* (London, 1799). Two long poems embodying his views about the origin and development of life, *The Botanic Garden* (London, 1789) and *The Temple of Nature* (London, 1803), were not taken seriously by his contemporaries, although Darwin himself was rather proud of them. Samuel Taylor Coleridge likened the poems to “mists that occasionally arise at the foot of Parnassus” and coined the word *darwinizing* to describe their biological speculations. After his death Erasmus Darwin was forgotten until interest in his ideas revived as a result of the fame of his grandson Charles.

An important feature of Erasmus Darwin’s work is the relation it establishes between early evolutionary theory and the embryological controversy of the preformationists and the epigenesists. In “Of Generation,” Chapter 39 of *Zoonomia*, Darwin argues against the doctrine that each new individual is already “preformed” on a minute scale in the reproductive cell from which it is developed. He defends an epigenetic position according to which new individuals develop by utilizing material from the environment to generate new parts. Hence, there is a transformation of a relatively undifferentiated egg into a complex organism. From this position it is only a short step to the view that life in general has evolved by a similar transformation.

Darwin actually took this step but did not provide a systematic justification of it. His writings are a curious mixture of observed facts, sober scientific judgments, and extravagant speculations, all designed to support the conclusion that living things, different from one another as they now are, originated from one “primal filament” that existed long ago. Through the ages organisms have altered to meet altered conditions of life. The result has been a continuous perfecting of their capacities. “This idea of the gradual formation and improvement of the animal world accords with the observations of some modern philosophers” (*Zoonomia*, Vol. I). An evolution of life has undoubtedly occurred.

Among the items of evidence adduced to support this contention are some that anticipate matters later embodied in *The Origin of Species*. Thus, Erasmus Darwin calls attention to such phenomena as the metamorphosis of tadpoles into frogs, the changes produced by the domestic breeding of animals, the specialized adaptations to climatic conditions, and, above all, “the essential unity of plan in all warm-blooded animals.” These things oblige

us to believe that all organisms have been derived from “a single living filament.”

Embedded in Darwin’s work are the rudiments of a theory about the causes of evolution. What he says foreshadows the more finished theory of the Chevalier de Lamarck. Environmental stimuli act on organisms that are endowed with the unique power of “irritability or sensibility.” The organisms respond in accordance with their wants, desires, and dislikes. Thus, the bodily characteristics required to satisfy the organisms’ demands are produced. These characteristics are inherited by some members of succeeding generations and favor them in the struggle for existence, which is depicted in lurid terms by Darwin in *The Temple of Nature*.

The facts that man’s body bears traces of his evolution from lower forms of life and that Earth itself appears to have come into being gradually by the operation of natural processes in no way led Darwin to doubt the existence of “the Great Architect” of the cosmos. His solid and complacent deism enabled him to regard God as simply “the Great First Cause,” who infused spirit and life into the primal filament and gave it the potentiality to evolve. “The whole of nature may be supposed to consist of two essences or substances, one of which may be termed spirit and the other matter” (*Zoonomia*, Vol. I, Section 1). The “whole of nature” was designed by the Great Architect. Indeed, God “has infinitely diversified the works of His hands, but has at the same time stamped a certain similitude on the features of nature, that demonstrates to us, that the whole is one family of one parent.”

Darwin’s views mark the close of the era of romantic speculation about natural history and the advance into an era of systematic observation and generalization. He did not, however, succeed in formulating any enduring principles. Perhaps his major achievement was acquiring the characteristics of scientific curiosity, independence of mind, and intellectual power that were transmitted to his descendants.

## DARWINISM

The term *Darwinism* has both a narrow and a broad meaning. In the narrow sense, it refers to a theory of organic evolution presented by Charles Darwin (1809–1882) and by other scientists who developed various aspects of his views; in the broad sense, it refers to a complex of scientific, social, theological, and philosophical thought that was historically stimulated and supported by Darwin's theory of evolution. Biological Darwinism—the first sense—was the outstanding scientific achievement of the nineteenth century and is now the foundation of large regions of biological theory. Darwinism in the second sense was the major philosophical problem of the later nineteenth century. Today, Darwinism no longer provides the focus of philosophical investigation, largely because so much of it forms an unquestioned background to contemporary thought.

Darwin's theory is an example of scientific innovation that has had reverberations into the farthest reaches of human thought. It is fair to say that every philosophical problem appears in a new light after the Darwinian revolution. In order to outline the connections between biological and philosophical Darwinism, it will first be necessary to describe Darwin's own views and to discuss various criticisms that were directed against them. It will then be possible to describe Darwinism in the broader sense, and to distinguish the various ways in which the scientific theory has afforded material for philosophical inquiry.

### DARWIN'S THEORY

The theory of the origin of species by means of natural selection was the discovery of Darwin and Alfred Russel Wallace (1823–1913). Both Darwin and Wallace had stated the theory in a series of papers delivered before the Linnaean Society on July 1, 1858. The members of the Linnaean Society listened without enthusiasm and apparently without much understanding, but in fairness to them, it should be observed that Wallace and Darwin did not present their theory forcefully on this occasion. Some

of the shattering implications of the theory were not drawn in detail, and the evidence in its support, which Darwin in particular had amassed, was barely hinted at. Wallace's paper "On the Tendency of Varieties to Depart Indefinitely from the Original Type" was a discussion of a widely accepted argument in favor of the "original and permanent distinctness of species," namely, that the varieties that are produced by artificial selection in domesticated species never vary beyond the limits of the original wild species, and that whenever artificial selection is relaxed, the domesticated varieties revert to the ancestral form. These facts were interpreted by naturalists as evidence for an innate conservative tendency in nature that kept all variation within the bounds defined by the unbridgeable gaps between species.

But, Wallace argued, the view that artificial selection can produce only new varieties, never new species, rests on the false assumption that naturalists possess a criterion for distinguishing the species from the variety. Moreover he stated, "This argument rests entirely on the assumption that varieties occurring in a state of nature are in all respects analogous to ... those of domestic animals, and are governed by the same laws as regards their permanence or further variation. But it is the object of the present paper to show that this assumption is altogether false." Overproduction, together with heritable variations, some of which are better adapted to the circumstances of life, will tend to make varieties depart indefinitely from the ancestral type, bringing about changes that will eventually amount to the origin of a new species. Wallace accounted for the reversion of domestic varieties by pointing out that the ancestral type is better adapted to life "in a state of nature," and consequently the very same principles that bring about progress in nature also bring about the reversion of domestic varieties.

Wallace aimed his argument precisely at the philosophical presupposition that for so long had stood in the way of a proper interpretation of natural selection, namely, that the species—being the exemplar of a divine archetype—is as well adapted as it could be and, consequently, that variation away from the type will automatically be selected against. Natural selection, according to this interpretation, is an agency of permanence, not change. One of Wallace's, as well as Darwin's, most original contributions consisted in breaking the hold of this idea.

Wallace's argument is implicit in Darwin's Linnaean Society papers, but the focus is different. Instead of challenging accepted opinion, Darwin added up well-known

facts. With great eloquence he described the prevalent overproduction of animals and plants: “Nature may be compared to a surface on which rest ten thousand sharp wedges touching each other and driven inwards by incessant blows.” The wedges are held back by large numbers of “checks” that bring about the death, or prevent the mating, of individuals. “Lighten any check in the least degree, and the geometrical powers of increase in every organism will almost instantly increase the average number of the favored species.” He called attention to the extreme heritable variability of animals under domestication. In nature there is also variation, although no doubt not as much. Some variants will be better adapted to their environments than others and will tend to survive and propagate. “Let this work of selection on the one hand, and death on the other, go on for a thousand generations, who will pretend to affirm that it would produce no effect?” To the effects of this natural selection, Darwin added the effect of “the struggle of males for females.”

Both Wallace and Darwin had stated the essence of the theory of the *Origin of Species* (1859). The *Origin* itself is mainly a sober, scrupulously fair, and thoroughly documented elaboration and defense of the doctrine of natural selection presented in the Linnaean Society papers. Darwin set out to accomplish three things: (a) to show that evolution has in fact occurred; (b) to describe the mechanism of evolution; and (c) to account for the major facts of morphology, embryology, biogeography, paleontology, and taxonomy on the evolutionary hypothesis.

**THE FACT OF EVOLUTION.** Darwin freely admitted that we do not directly observe the process of evolution. The time needed even for the origin in nature of a new variety is far too long. Consequently, the case for the occurrence of evolution is simply the same as the case for its scope and mechanism, and Darwin did not have access to direct evidence for the efficacy of natural selection—a gap that was not filled until the twentieth century. Darwin argued that life is too short for direct evidence but that certain facts force the conclusion upon us that there must be evolution; and if we adopt the hypothesis, a wide range of hitherto unconnected facts may be given a uniform explanation.

**THE MECHANISMS OF EVOLUTION.** Darwin described three mechanisms that tend to effect the evolution of populations. These are natural selection, sexual selection, and the inheritance of characteristics acquired during the lifetime of the individual organism.

**Natural selection.** In the *Origin* Darwin placed the greatest weight on evolution by natural selection. It operates in conjunction with sexual selection and the inheritance of acquired characters and, Darwin argued, there are some features of organisms that could have developed only by natural selection. Indeed, it seems that the theory of natural selection was partially inspired by his observations on the *Beagle* voyage (1831–1836) of local variations, particularly in the islands of the Galápagos Archipelago, that could not be accounted for on Lamarckian grounds.

The theory of natural selection as Darwin presented it may be summarized as follows: (1) Populations of animals and plants exhibit variations. (2) Some variations provide the organism with an advantage over the rest of the population in the struggle for life. (3) Favorable variants will transmit their advantageous characters to their progeny. (4) Since populations tend to produce more progeny than the environment will support, the proportion of favorable variants that survive and produce progeny will be larger than the proportion of unfavorable variants. (5) Thus, a population may undergo continuous evolutionary change that can result in the origin of new varieties, species, genera, or indeed new populations at any taxonomic level. Darwinian natural selection may accordingly be defined as a differential death rate between two variant subclasses of a population, the lesser death rate characterizing the better-adapted subclass.

Darwin was careful to present evidence for every hypothesis in his account of natural selection. It was especially necessary to argue that natural populations do exhibit the requisite amount of variation and that the variation is heritable. He cited, among other things, the extreme variability of domestic plants and animals and the well-known fact that new varieties can be propagated. He admitted that the causes of variation were unknown; but he argued that changing environmental conditions greatly increase variability by action on the reproductive system, thereby providing material for natural selection when it is most needed. This is “indefinite variability.” In addition, there is “definite variability,” due to the direct action of the environment on the body of the organism. “Definite variations” are heritable; they provide material for natural selection and, being responsive to the environment, are more likely than chance variations to be adaptive.

“The laws governing inheritance,” he remarked, “are for the most part unknown.” This lack of knowledge turned out to be the most serious obstacle to the further development of the theoretical foundations of selection

theory in the nineteenth century; but, as Darwin noted, although the laws of inheritance were unknown, a number of the phenomena of inheritance were known, and those were probably all that were required for the theory of natural selection. Most important is the obvious fact that progeny bear an overwhelming resemblance to their parents, although they differ in some degree. In addition, Darwin was familiar with the intermittent appearance of hereditary characters, with sex-linked and sex-influenced characters, and with the tendency for a character to appear in the progeny at the same developmental stage that it appears in the parents.

For natural selection to be an agency of change rather than an agency of permanence, it is necessary that some variations from the ancestral type represent better adaptations. Darwin pointed out that, in fact, every organism could be better adapted to its ordinary environment; and that, moreover, environments change.

Pre-Darwinian taxonomy ascribed a very special significance to the species, as against varieties, genera, and the higher taxonomic groups. The species was regarded by the pious as the unalterable work of God; the limits laid down by the diagnostic features of any species established the limits of possible variation within the species. Thus, although any biologist would be willing to countenance the origin of new varieties or subspecies, brought about by the operation of biological laws, most were unwilling to admit the possibility of the origin of new species by natural processes. The title of Darwin's book was aimed precisely at this conception. Like Wallace, he argued that there is no difference in principle between the diagnostic characters of varieties and species; therefore, to admit the origin of new varieties amounts to admitting the possibility of new species—and if new species appear, so may new genera, families, and so on. He cited the existence of “doubtful species”—groups that cannot be definitely placed at either the variety or species level—and the general inconsistency of taxonomists in the identification of species.

**Sexual selection.** In the Linnaean Society papers Darwin described the second mechanism of evolution as the “struggle of males for females.” The theory was developed further in the *Origin*, and it occupied some two-thirds of the pages of his *Descent of Man and Selection in Relation to Sex* (1871). In these later statements of the theory, the struggle of males for females is a special case of a more general phenomenon. Suppose that a population is divided in some proportion between males and females and suppose for the sake of simplification that all of the males and females are equally well endowed for the strug-

gle for survival. Now, Darwin argued, it may happen that either the males or females are unequally endowed with some characteristic that will increase their propensity to leave progeny. There will then be selection in favor of that characteristic, even though it will not be favored by natural selection. All such cases Darwin calls “sexual selection.” It is clear that different sorts of characteristics can influence the probability of having offspring. Some individuals, for example, may possess behavior patterns that lead to the fertilization of a larger percentage of eggs or have more efficient organs of copulation. Or they may have some advantage in the competition for mates—migratory male birds may arrive early at the breeding grounds and be ready to receive the more vigorous females, leaving the culls for their tardy brothers; or the females may for some reason prefer plumage or displays of a certain character; or some males may aggressively drive away other males; and so on. Finally, some characteristics that are also useful in the struggle for survival might also be useful in the competition for mates; for example, the antlers of male deer may do double duty against both rivals and predators.

Darwin appeals to sexual selection in order to account for the evolution of such things as mating rituals and secondary sexual characteristics, such as breeding plumage in birds. He regards it as especially significant in the evolution of man. The loss of body hair, for example, is attributed to systematic choice among man's ancestors of mates that exhibited large regions of bare skin.

*The inheritance of acquired characters.* Darwin's work was plagued by ignorance and misinformation concerning the laws of heredity. The principles of segregation and independent assortment, which form a cornerstone of contemporary evolution theories, were discovered by Gregor Mendel in 1864; but his paper remained unnoticed until 1900. Moreover, although “sports” were well known to biologists, the concept of mutation had not been clearly formulated. Consequently, the modern theory of the origin of genetic variation in populations was not available to Darwin; instead, he suggested that some variations are due to the action of the environment on the germplasm and that others are due to the effects of use and disuse. For example, if an animal's skin is tanned by sunlight, this may induce changes in its germplasm that will result in its progeny possessing pretanned skin; or if a wolf develops his muscles by chasing rabbits, his pups may inherit larger muscles. These mechanisms, if they exist, would account for some variability. But they would also account for some evolutionary change even in the absence of natural or sexual selection. Since, accordingly,

there seemed to be no sound reason for rejecting the inheritance of acquired characters and since the doctrine would aid in explaining both variability and evolutionary change, Darwin was led to adopt it and to give it increasing weight in his later years. This aspect of Darwin's views is often labeled Lamarckism, but the Chevalier de Lamarck himself, although he did accept the inheritance of the effects of use and disuse, did not accept the doctrine of the direct action of environmental factors on the germplasm.

**THE SCOPE OF EVOLUTIONARY THEORY.** It is clear that Darwin regarded his theory as revolutionary. He believed that all the traditional branches of biology would be transformed and deepened; familiar phenomena would take on a new significance; apparently unconnected facts could be regarded as mutually related. Even the vocabulary of the older biology would acquire new meanings: "The terms used by naturalists, of affinity, relationship, community of type, paternity, morphology, adoptive characters, rudimentary and aborted organs, etc., will cease to be metaphorical, and will have a plain signification." Natural history would acquire the fascination, not of a catalog of *curiosae*, but of a labyrinth that may be charted.

When we no longer look at an organic being as a savage looks at a ship, as something wholly beyond his comprehension; when we regard every production of nature as one which has had a long history; when we contemplate every complex structure and instinct as the summing up of many contrivances, each useful to the possessor, ... when we thus view each organic being, how far more interesting—I speak from experience—does the study of natural history become!

And not only would the old biology be put on a new foundation; whole new fields of research would become possible. For example, "Psychology will be securely based on the foundation ... of the necessary acquirement of each mental power and capacity by gradation. Much light will be thrown on the origin of man and his history."

The major part of the *Origin* is devoted to the detailed application of the theory of natural selection to a range of biological phenomena. It is impossible to give more than a general impression of the thoroughness, detail, and diversity of Darwin's evidence. The modern reader cannot fail to be impressed not only by Darwin's immense learning but also by his subtlety of insight—his ability to locate those phenomena that lend his theory the most striking support.

The *Origin* as a whole provides, on the one hand, a sweeping portrait of the history and biology of living things, a portrait whose internal balance and consistency are easily discernible. On the other hand, Darwin fills selected regions of his portrait with careful detail, exhibiting the applicability of his theory to a variety of phenomena. These two aspects of his work constitute both the argument for the fact of evolution and the argument for the truth of his account of its mechanisms.

In the broad portrait Darwin shows how the main facts of known fossil successions, the relation of living fauna and flora to recent fossil forms, the geographical distribution of species, the connection between morphology and function, and the major features of embryological development are explicable by his theory. He applies it in detail to such phenomena—to mention only a few—as rudimentary organs, insect metamorphosis, the divergence of island and mainland forms, and sexual dimorphism. He provides us with a discussion of taxonomy that is philosophically superior to many contemporary accounts, arguing, among other things, in favor of the special significance for the taxonomist of embryological and phylogenetic studies.

Darwin was always sensitive to the effect that his views might have on the general public. In composing the *Origin* he decided to avoid the whole topic of man's evolution; the book would be a sufficiently bitter pill without explicitly treating a subject that was "so surrounded with prejudices." His only explicit reference to man was the remark quoted above, that "light will be thrown on the origin of man and his history." Darwin's successors, however, were not so cautious. Sir Charles Lyell (1797–1875) discussed the question in 1863. Shortly thereafter, Wallace published his paper "The Origin of Human Races and the Antiquity of Man Deduced from the Theory of Natural Selection." T. H. Huxley (1825–1895) and a number of Continental morphologists, particularly Ernst Haeckel (1834–1919), produced a series of studies aimed at showing the similarity of man and the anthropoid apes and giving speculative reconstructions of man's ancestry. Thus, by the date of Darwin's *Descent of Man* (1871), the controversy over man was in full swing, and there were already a number of alternative theories that Darwin had to consider, such as whether the races of men are distinct species.

Darwin showed a wise unwillingness to acknowledge any known nonhuman species, living or extinct, as ancestral to man. We have so far examined, he argued, only animals that have diverged from the prehuman stock. For instance, the anthropoid apes and man have a common

ancestor, but its remains have not been found. Nor did he identify species that are ancestral to the primates, the mammals, or even the vertebrates. He did trace a general line of descent: Old World ape, a lemurlike animal, some “forms standing very low in the mammalian series,” marsupials, and monotremes. No true reptile is an ancestor of man. All the classes of vertebrates may have been derived from a remote ancestor similar to the larvae of the tunicates. With a flash of romanticism, Darwin wrote: “In the lunar or weekly recurrent periods of some of our functions we apparently still retain traces of our primordial birthplace, a shore washed by the tides.”

In the *Descent of Man* evolution by the inheritance of acquired characters and by sexual selection plays a larger role than in the *Origin*. Darwin admitted that he had been accused of overrating the importance of natural selection, but added, “whether with justice the future will decide.” His relative retreat from natural selection was probably occasioned by two factors: first, his doubts as to whether Earth is old enough for evolution by natural selection without substantial help from faster mechanisms; second, his belief that man is in many ways less the child of violent nature than his ancestors, a belief that requires considerable appeal to sexual selection and to the development of moral and spiritual qualities through social usage.

### CRITICISMS OF DARWIN'S THEORY

In spite of the resistance that Darwin's theory aroused on other than scientific grounds, the weight of his arguments was largely—but with many notable exceptions—sufficient for the younger generation of biologists. In 1872, in the sixth edition of the *Origin*, Darwin was in a position to write, “At the present day almost all naturalists admit evolution under some form.” It was, like any novel and important theory, carefully scrutinized for empirical weaknesses. We shall describe the major ones and indicate how they were dealt with.

The most damaging scientific objections were the following:

- (1) Darwin had no direct evidence for the effectiveness of natural selection, let alone for the origin of new species.
- (2) Darwin could not show a single species that was transitional between two known species.
- (3) Complex organs, such as the vertebrate eye, could not have evolved by stages, since they would have been useless at any preliminary stage and hence

would have given their possessor no selective advantage.

- (4) If evolution has taken place, then some evolutionary trends must have continued past the point of usefulness to the organism. Such trends could not be accounted for by Darwinian selection.
- (5) Earth is not old enough for evolution to have taken place.
- (6) Evolution by natural selection is incompatible with the laws of inheritance.
- (7) There is no inheritance of acquired characters.

The first two objections were commonly raised in the nineteenth century; they are genuine questions that require some sort of answer. Darwin, however, was not in a position to answer them in a way that would satisfy everybody, since the weight that one assigns to them depends in part upon personal preference.

**INDIRECT EVIDENCE.** With regard to the first objection Darwin pointed out that natural selection cannot be directly observed; we can only present indirect evidence in its favor. On this point he was mistaken. Natural selection has been directly studied in the twentieth century, both experimentally (in fruit fly populations, for example) and in nature (for instance, the development of so-called industrial melanism). But even today Darwin's and Wallace's contention that evolution by natural selection can pass the species limit has no direct support. Darwin recognized, however, that it is no fatal objection to a theory if some of its components are not subject to direct verification.

**TRANSITIONAL SPECIES.** On the second criticism—the absence of forms intermediate between species—Darwin had a double-barreled answer. He admitted that, for instance, we know of no forms intermediate between man and the apes. But we have innumerable examples of species that are in process of giving rise to new species, namely, those that have varieties or subspecies. These polytypic species (as they are now called) are intermediate between other species which, to be sure, have not yet evolved, but which are in process of evolving.

When it was further objected that we ought to have better examples of demonstrable ancestors of existing species, Darwin appealed to the incompleteness of the fossil record. This is the correct answer, but one that is hardly satisfying to a skeptic. Again, the weight that one would assign to the objection depends upon personal preference.

**DEVELOPMENT OF COMPLEX ORGANS.** Darwin was well aware of the difficulty in accounting for the origin of structures that would be useless, even deleterious, until they were essentially complete. The eye, he wrote, gave him “a cold shudder.” In such cases as the eye, however, he had no alternative but to appeal to natural selection. Therefore, he was compelled to argue that in point of fact all the earlier stages in the evolution of the eye were useful in the struggle for survival. Darwin himself provided us with the standard textbook example: he constructed a plausible sequence of stages that could have led to the human eye. Each stage is a functional eye; and something similar to each stage does exist in one or another living species. The criticism has the form, “Such and such *could not* have happened.” It can be countered piecemeal, by showing in a variety of cases how it *could* have happened.

**ORTHOGENETIC TRENDS.** A great many of Darwin’s critics accepted the fact of evolution but entered reservations concerning his account of the mechanisms of the process. The reservations were of several types. Some rejected “Lamarckism,” by which they meant simply the inheritance of acquired characters; they were known as the Neo-Darwinians. Others doubted that there was such a process as sexual selection. Still others, however, believed that there must be an evolutionary process that Darwin had not identified at all. The evidence consisted in the existence of apparently nonfunctional evolutionary trends. Trends that continue over long periods and that are relatively straight-lined—for example, increasing size in horses and increasing length of sabers in the saber-toothed cat—came to be called orthogenetic trends. The question was whether orthogenetic trends could be accounted for on Darwinian principles.

Wallace argued (in “Geological Climates and the Origin of Species,” *Quarterly Review*, 1869) that the development of man’s brain could not be so accounted for. Man’s apelike ancestors, he argued, had reached a certain stage of evolution and then, over a period of some ten million years, remained largely unchanged except for a steady orthogenetic increase in the size and complexity of the brain. This was an unprecedented episode in the history of life, for it freed man from those ordinary pressures of natural selection that so often led to close specialization and ultimate extinction. Moreover, the brain acquired abilities that could not have been exercised in a primitive environment, such as the power to construct speculative systems of ideas or the insight into spiritual reality. These are present in modern man, but would have been useless in man’s primitive ancestors. Natural selection operates only on abilities that are actually so exercised as to give an

advantage in the struggle for life. “An instrument,” Wallace concluded about the brain, “has been developed in advance of the needs of its possessor.” Later he wrote: “A superior intelligence has guided the development of man in a definite direction, and for a special purpose, just as man guides the development of many animal and vegetable forms.” Thus we avoid the “hopeless and soul-deadening belief” that man is the product of “blind eternal forces of the universe.”

Darwin looked upon this as a failure of nerve, a hankering after miraculous origins for man. “I can see no necessity for calling in an additional and proximate cause in regard to man,” he wrote in a letter to Wallace. Nevertheless, Wallace’s position, fitting as it did the efforts of many theologians to come to grips with Darwinism, gained a number of adherents, and although the main line of evolutionary theory has bypassed it, even now versions of Wallace’s position turn up from time to time.

Wallace had argued that the evolution of the brain was an orthogenetic trend that outstripped its usefulness. Others argued that trends sometimes continued even after they had become positively deleterious. A favorite example was the teeth of the saber-toothed cat, which, it was alleged, were valuable as weapons up to a certain length, but which finally became detrimental by interfering with feeding. There would be selection against increased tooth length under these conditions; consequently, it was argued, some cause other than natural selection must have operated. A variety of theories were proposed—for example, those of Karl Nägeli (1817–1891) and E. D. Cope (1840–1897). These theories posited an otherwise unknown internal principle of change, which was compared to the laws of embryological development, to the principle of inertia, or, as with Henri Bergson, to creative spiritual activity. Since the theories accounted for nothing other than the alleged orthogenetic trends, they have always had a peripheral position in the history of evolutionary thought. Moreover, subsequent analysis of orthogenesis has shown that in most cases the trends are in fact adaptive; and in those cases where they are not adaptive, contemporary theory provides various possible sorts of explanation compatible with the doctrine of natural selection, such as the explanation that if a trend affects only adults past the breeding age, it will not be selected against.

**AGE OF EARTH.** In 1865 William Thomson, Lord Kelvin, published a paper titled “The Doctrine of Uniformity in Geology Briefly Refuted.” Its argument was aimed at Lyell and his followers, who had maintained that Earth as we

now find it is not the result of a series of catastrophes, but is the outcome of the ages-long operation of geological processes that we can still observe. This viewpoint, known as uniformitarianism, was widely accepted among geologists even before the publication of the *Origin*, having been impressively established in Lyell's *Principles of Geology* (1834). It was in fact an earlier application of the idea of evolution. But uniformitarianism required vast reaches of time; consequently, Kelvin was prodding its weakest point when he argued that Earth could not be as old as the geologists supposed. Grant, Kelvin argued, that Earth was once a molten sphere; then it could not have solidified much over twenty million years ago, or it would now be cooler, through dissipation of its heat, than we actually find it. The biological consequences were clear: there was not enough time for evolution to have produced the forms we now see.

Darwin was deeply concerned by this reasoning. As far as he could tell, it was perfectly sound; on the other hand, he was perfectly convinced that Earth had supported life for a much longer time. His later emphasis on Lamarckism was probably an attempt to provide an evolutionary process that was swifter than natural selection. But this was a half measure; in fact, Darwin simply swallowed what he believed to be a contradiction—a not uncommon occurrence in the history of science. It turned out that Kelvin's argument was mistaken, since he was unaware of an additional source of heat within Earth, namely radioactive decay.

**LAWS OF INHERITANCE.** As noted above, the evolutionists of the nineteenth century worked in ignorance of the principles of genetics discovered by Mendel; this lack was by far the most serious theoretical gap in the Darwinians' arguments. It now appears that no fundamental innovation in evolutionary theory was possible until the gap was filled. Biologists of the nineteenth century accepted a rough theory of blending inheritance, that is, the view that the characteristics of the progeny of sexual crosses were intermediate between the characteristics of the parents. This theory was seldom explicitly defended, since everyone was familiar with a variety of phenomena that were incompatible with it, for example, blue-eyed children of brown-eyed parents. Nevertheless, when biologists theorized at all on the subject, the theory produced was ordinarily a vague and suitably guarded version of the theory of blending inheritance.

In 1867 Fleeming Jenkin ("The Origin of Species," *North British Review*) pointed out that the blending theory was incompatible with the theory of natural selection

as ordinarily presented by the Darwinians. He argued that if favorable variations appeared in a population, their characteristics, even if favored by natural selection, would soon be lost in the vast population pool by crossing with individuals of the normal type. Assume, for instance (as Jenkin did), that a white man is greatly superior to a black man and that a white man is shipwrecked on a black-populated island. "He would kill a great many blacks in the struggle for existence; he would have a great many wives and children.... But can anyone believe that the whole island will gradually acquire a white, or even a yellow population?" Jenkin's argument in essence is this: the white man's children will be darker than their father; and it is impossible on the blending theory that their descendants could become lighter, whatever the effects of natural selection might be.

Again, Darwin was forced to admit the strength of a powerful objection that he was unable to counter directly. At best, he could only argue that natural selection would be effective if adaptive variations were sufficiently common; the black island could become white, for example, if there were a steady influx of shipwrecked sailors. He actually had no evidence that adaptive variations were sufficiently common; instead, he retreated more and more to the Lamarckian theory that variation is due to the effects of activity in the environment and would accordingly be largely adaptive.

Unlike the answer to Kelvin's objection, which could not have been offered in the nineteenth century, the answer to Jenkin was available but remained unknown except to a few, who did not see its significance. Mendel's paper on plant hybridization established an alternative to the blending theory of inheritance. Mendel showed that there were discrete genetic factors that pass unchanged from generation to generation and are hence not subject to Jenkin's swamping effect. Mendel had established that the character of these factors (genes) is not changed by other factors in the germplasm and that the factors segregate independently of one another in gamete formation. (He was unaware of the phenomenon of linkage.) Researchers of the literature on heredity recovered Mendel's work in 1900; and in 1904 William Bateson (1861–1926), in *Genetics and Evolution*, applied Mendel's laws to the theory of natural selection, thus answering Jenkin's objection.

The new genetics turned out to be far more significant for the theory of evolution than merely answering Jenkin's objection. The history of scientific Darwinism in the twentieth century was mainly the story of a series of advances in genetics, and the working out of their conse-

quences for evolution. Mendel's laws were correlated with the behavior of the chromosomes in meiosis; the concepts of chromosome and gene mutation were introduced; linkage was discovered and understood; and statistical methods were employed in the analysis of the dynamics of genetic change in natural populations. One major gain of these developments was a systematic understanding of the origin and maintenance of genetic variability—the question that was so troublesome for Darwin. Another was the final decline of the Lamarckian aspect of Darwinism.

**ACQUIRED CHARACTERS.** The Neo-Darwinians had already denied the inheritance of acquired characters, but their evidence against it, like the Neo-Lamarckians' evidence in its favor, was largely anecdotal. August Weismann (1834–1914) had presented the theory that life is essentially a continuous stream of germplasm that from time to time gives rise to whole organisms; the organisms die but the germplasm is immortal. The stream can divide (gamete formation) and merge (fertilization), thus accounting for variability. This view was employed by Weismann and others as a theoretical argument against the inheritance of acquired characters, for it is an easy step from the continuity of the germplasm to its independence of somatic influences. The emergence of Mendelism shed a new light on Weismann's theory. The mechanism of "immortality"—self-replication of chromosomes—was elucidated, and evidence accumulated that the chromosomes were indeed uninfluenced, or influenced only randomly, by somatic factors.

### PHILOSOPHICAL DARWINISM

We have considered Darwinism as a biological theory; we may now consider its wider intellectual connections. These are many and complex, so it will be necessary to select the most important—those which now seem to be enduring ingredients of speculative thought or those which struck the people of the later nineteenth century with the greatest force. The differences between the climate of opinion—the ordinary presuppositions, ideas about the proper pattern of argument, assumptions as to proper method, in short, the worldview—of the mid-nineteenth and twenty-first centuries is large, comparable in degree to the differences between the Middle Ages and the Renaissance. Of course the change had many causes, but the advent and absorption of Darwinism, while in part an effect of other currents, was also one major cause.

We shall consider the connections of Darwin's theory in three major regions: scientific cosmology, theology, and social doctrine.

**SCIENTIFIC COSMOLOGY.** Scientists have general views about the way things are. The scientists of any historical period are likely to share a common set of views, with, of course, individuals differing over one or another point to some degree. These general views, insofar as they concern a subject matter of professional scientific interest and insofar as they are capable of influencing method, methodology, or empirical formulations, may be called cosmological. They differ from the ordinary statements of a science (for example, "organisms overproduce," "acquired characters are not inherited") in degree of determinateness. They are so formulated that they are exempt from immediate verification and falsification but subject to specification, by means of a series of semantical decisions, into determinate, verifiable propositions. A good example of such a cosmological proposition is "Nature makes no jumps," or "Nature has no gaps." Darwin, unlike many of his contemporaries, was fond of making this remark (in Latin); he employs it in the Linnaean Society papers and subsequently quotes it again and again. It constitutes part of Darwin's cosmology and is a point on which the nineteenth century was deeply divided. It is clear that the sense of the proposition is not sufficiently determinate, as it stands, for verification. But it can be construed to mean, for instance, that evolution is gradual or that the apparent gaps between living species can be filled if we consider a sufficient stretch of history.

These properties of cosmological belief have important implications. First, it is possible to arrive at a cosmology by a process akin to generalization—an empirical statement can be construed as the determinate form of an indeterminate proposition, which in turn can be applied to new subject matters. This is the formal pattern of the influence of science on cosmology. Second, the precise verbal formulation of a cosmological belief is relatively unimportant; indeed, it can affect thought without being explicitly formulated at all. For cosmological beliefs do not function as premises of empirical arguments; rather, they impart color to empirical argument, affecting its form and conceptual materials.

Darwin's biological theory was itself supported by prior developments in cosmological belief. The theory of evolution by natural selection did not occur to Darwin in an intellectual vacuum. Most important of these cosmological beliefs was uniformitarianism, the belief that nature operates everywhere and always by the same sorts

of law. This view Darwin had imbibed from Lyell's *Principles of Geology*; it became cosmological by construing the geological theory as exhibiting a general truth about the way things, including living things, are. This particular belief is already a powerful stimulus to look at organic nature as the outcome of a historical process, although, to be sure, the belief does not entail this conclusion.

A second belief, which Darwin inherited and was seen to support, was the necessity of taking time seriously. This meant, among other things, that the past is long. By the date of the *Origin* there was little actual evidence on the age of Earth, let alone the age of the universe. Outside scientific circles, the prevailing view was that Earth and universe were the same age, something on the order of thousands of years. As long as this is accepted, evolution is evidently most improbable. Some geologists, in particular James Hutton (1726–1797), had, on the other hand, argued that Earth is infinitely old—an important argument, since it helped to accustom scientists to the possibility of vast stretches of time and change. Geologists after Hutton were willing to help themselves to as much time as they needed, and Darwin gladly followed suit.

Taking time seriously, however, gained a deeper meaning after the publication of the *Origin*, namely, that change is a fundamental feature of nature. This constituted part of the cosmology of every Darwinian. It meant that the process of change is not merely the reshuffling of preexisting materials in accordance with physical law but that the materials themselves are subject to alteration. For instance, as applied to biology it meant that the fundamental form, the species, did not merely exhibit eternal law but changed in such a way that new regularities of behavior replaced the old. In the favored terminology of the nineteenth century, we may say that taking time seriously meant that the laws of nature are subject to change.

Structures and patterns of behavior, then, have to be regarded as historically conditioned. This is the cosmological aspect of the most characteristic post-Darwin view of method, the insistence upon the investigation of origins, together with the view that such investigation can be scientific. Thus, we find the development of the idea of a human prehistory, the application of elaborate schemes concerning, as they were called, stages of development—spiritual, social, political, moral—and the belief that, at least in outline, the future of man may be successfully charted.

Pre-Darwinian biological theory was strongly influenced by the view that all living things are patterned after an eternal idea or archetype. This was held not only for

the species but also for other taxonomic categories and for anatomical structures as well. Taxonomists were fond of describing, for example, the ideal vertebrate or mollusk; and morphologists described the ideal organ. One of the achievements of Darwinism was to break the hold of this notion on taxonomic and anatomical theory. Darwin was finally able to write, in *Descent of Man*, “A discussion of the beau ideal of the liver, lungs, kidneys, etc., as of the human face divine, sounds strange to our ears.”

**THEOLOGY.** The expressed doctrines of theology are related to empirical propositions as cosmological doctrines are related to the natural sciences. The role of Darwin's theory as a generator of such indeterminate beliefs naturally is well exemplified in theology. On the one hand it was immediately taken to be in prima facie opposition to a number of theological doctrines, especially the following: the uniqueness of man as God's supreme creation; the importance of natural theology; and the dominant theory, in Protestant circles, that the Bible is an authoritative source of beliefs about the natural world.

The first theological reaction to Darwinism can only be described as one of outrage; but by the close of the century, theologians having decided that since they must live with Darwinism, they ought to love it, the outlines of a reconciliation had been sketched. Even further, Darwinism was allowed to guide the formation of a new brand of theology. We shall consider first the reaction.

As we have seen, Darwin's readers were quick to grasp the consequences of the *Origin* for man himself. These consequences immediately aroused the most intense feelings. These feelings were quite justified, for Christian theology demands that man be considered unique; and his uniqueness was universally interpreted as ontological separateness from the rest of creation. The geologist Adam Sedgwick (1785–1873), for example, spoke no more than common opinion when he wrote in 1850 that man is a barrier to “any supposition of zoological continuity—and utterly unaccounted for by what we have any right to call the laws of nature.” The Darwinians not only argued that man is continuous with the animal kingdom and subject to the laws of nature; they also asserted that his mental, moral, and spiritual qualities evolved by precisely the same processes that gave the eagle its claws and the tapeworm its hooks. Such opinions were a threat to the deepest level of Christian doctrine, and were bound to be, until man's uniqueness could be given a new theological interpretation.

Moreover, the furor over the animal nature of man was heightened, especially in Britain, by local circum-

stances. T. H. Huxley compared man and the ape with endless zest, knowing how the comparison annoyed his opponents. For apes and monkeys were thought to be oversexed and obscene; in addition, the British took very seriously the principle that a man's standing in the world is dependent on the standing of his ancestors. Thus the literature of the period is enlivened by comic remarks, such as, "Are you descended from an ape, Mr. Huxley, from your mother's or your father's side?" (Bishop Wilberforce) and "You can't wash the slugs out of a lettuce without disrespect to your ancestors" (John Ruskin). But the symbol of the ape squatting in one's family tree was no more than an expression of dismay at being swallowed up in the infinite forms of nature. The twentieth century did not fully regain its equanimity on this point. Pius XII wrote that a Catholic may accept a doctrine of evolution, but should beware of doubting that there was a first man and woman. And consider this passage from the speech of William Jennings Bryan at the Scopes trial (1925): "We are told just how many species there are, 518,900. ... and then we have mammals, 3,500, and there is a little circle and man is in the circle, find him, find man."

The edifice of traditional theology was touched at other points. Early-nineteenth-century theologians placed heavy weight on the cooperation of science and religion. The clergyman-naturalist was a familiar figure. It was thought that the intricacy and systematic interconnections of nature exhibited the handiwork of God; to study them was an act of piety. More specifically, natural teleology was the mainstay of natural theology. William Paley's *Natural Theology* (1802) is a good example. He holds that God's creation is totally good, that the organs of living things are almost perfect, that all animals have their just share of happiness, and that all this demonstrates with thousandfold certainty the existence and beneficence of God. An older natural theology tended to see evidences of God's design throughout nature; but Paley, and others after him, such as Thomas Chalmers in the *Bridgewater Treatises* (1834), rest their case on the structure of living things: consider, they suggest, the hand, the heart, the eye (especially the eye); they are complex and adapted for their functions to a degree that transcends all possibility of chance correlation.

By hindsight this attitude appears curiously self-defeating as well as vulnerable. The religiously inspired examination of organic adaptation was precisely one factor that led to Darwin's account of the origin of adaptation. His theory made the last citadel of divine teleology in nature untenable except, of course, for a few holdouts;

but it was also widely interpreted as refuting all natural teleology, especially by the German materialists. "Chance" had been defined by Paley as "the operation of causes without design," and on this definition Darwinism leaves the origin of species to chance.

Theology in the middle half of the nineteenth century was especially vulnerable to Darwinism on a second point, namely, its extreme Biblicism and, even further, its literalism in biblical interpretation. It hardly needs saying that Darwinism is incompatible with any literal construction put upon either the Old Testament or the New Testament. The laity and most of the clergy, however, insisted upon such constructions. Matthew Arnold quotes the following as prevailing opinion in England: "Every verse of the Bible, every word of it, every syllable of it, every letter of it, is the direct utterance of the Most High"—a view Coleridge describes as "Divine ventriloquism." The matter was not so extreme outside of Britain, but the fact remains that Protestant education and practice relied heavily on the study and interpretation of the Bible.

The intellectual compromise that gradually emerged seems obvious today; the problem was not to think of it but to accept it. It consists in admitting that man is part of nature and that he is indeed, even in his spiritual aspects, the outcome of an evolutionary process. But lowly origins do not detract from a unique present. And the process of evolution is either guided, as Wallace suggested, or is itself the mode and manner of God's creation. Indeed, it was sometimes argued that Darwinism provides us with an elevated conception of God. Canon Charles Kingsley, for example, wrote to Darwin as follows: "I have gradually learnt to see that it is just as noble a conception of the Deity to believe that he created primal forms capable of self-development ..., as to believe that He required a fresh act of intervention to supply the *lacunas* which He Himself had made." This passage is quoted by Darwin with some changes in later editions of the *Origin*. As Kingsley also put it, Darwin allows us to get "rid of an interfering God—a master-magician, as I call it" in favor of a "living, immanent, ever-working God."

The final step in this direction was to give God an even more intimate metaphysical connection with natural process. This step had been taken by previous philosophers—Benedict (Baruch) de Spinoza and G. W. F. Hegel, for example; but it was repeated under the aegis of Darwinism by Bergson, Alfred North Whitehead, and a number of Protestant thinkers. The problem of a divine nature that is both perfect and yet incomplete is one contemporary heritage of Darwinism.

**SOCIAL DOCTRINE.** The social thought of the later nineteenth century drew so heavily from the theories of evolution that its major ideas became known as social Darwinism. The 1850s were a period of revolutionary fervor in the streets as well as the academies, and political ideologists seized on Darwin as their major intellectual spokesman. His views, or rather selected aspects of them, presented ideal material for application to ethical, economic, and political problems.

It is convenient to divide social Darwinism into a political right and left, using these terms in their rough, contemporary editorial-page sense. In adopting Darwinism to social questions, it must be admitted that the right wing had the best of the bargain. In Europe these were the men whose interests were vested in hereditary privilege and in the factories and institutions of the industrial revolution. On the grounds of these interests they defended themselves against any attempt to justify social revolution, governmental control, unionism, or socialism in any of its many nineteenth-century forms. The ideology that was developed, with the help of Darwinism, in order to facilitate this defense also committed them, in various combinations, against such things as child-labor legislation, poor laws, compulsory safety regulations, and public education. A similar ideology provided the United States with its justification for the undisturbed economic expansion, speculation, and competition that we associate with the robber barons.

On the other hand, Darwinism was employed by the social reformers. Karl Marx wanted to dedicate the first volume of *Das Kapital* to Darwin. George Bernard Shaw, although he criticized the theory of natural selection, defended his socialism with the help of his version of Bergson's creative evolutionism. The reformers saw Darwinism as the final demonstration that no particular economic or political institution—however hallowed by tradition or supported by existing theories—need be regarded as unalterable. The forms of society, like the forms of life, are local, temporary, and functional and may accordingly be changed (for the better) without shaking the foundations of the cosmos.

In short, the biology and cosmology of Darwinism was capable of being all things to all men. It enjoyed this status by virtue of its ability to inspire and lend a measure of apparent scientific support to the following major ideas:

(1) The vision of a science that was historical, and at the same time a rigorous application of natural law, inspired a new vision of a science of society. Herbert Spencer (1820–1903), whose evolutionism antedated the

*Origin*, became the symbol of this ideal wedding of history and sociology. He drew elaborate comparisons between social structures and the forms of living organisms and saw societies as undergoing a progressive evolution in which egoism would be gradually replaced by altruism through a mechanism analogous to the inheritance of acquired characters. Sociology stood in relation to society as evolutionary biology stood to the phenomena of organic nature.

(2) The process of natural selection, interpreted as the survival of the fittest, provided a means for explaining social process. The American political economist William Graham Sumner (1840–1910), for example, saw society as the outcome of a social struggle in which each man, in pursuing his own good, can succeed only at the expense of others. The fittest in this social struggle are the ruthless, the imaginative, the industrious, the frugal. They climb to the top, and it is right that they should do so. The idle, infirm, and extravagant are losers, not adapted to the realities of their world, and thus legitimately subject to elimination by "social selection." Sumner presents society with an alternative: either "liberty, inequality, survival of the fittest," or "not-liberty, equality, survival of the unfittest." Self-made millionaires are the paradigm of the fittest. They are "a product of natural selection, acting on the whole body of men to pick out those who can meet the requirement of certain work to be done."

This doctrine of the financially successful as the cream of the universe naturally had a sympathetic audience. John D. Rockefeller, Andrew Carnegie, and Theodore Roosevelt were supporters, although Roosevelt believed that the unfit were entitled to some protection.

(3) Darwinism provided a rationale for Adam Smith's doctrine of the "Invisible Hand." Smith had supposed that while each man follows his innate tendency to "truck, barter, and trade," men's efforts would automatically dovetail in such a way that the economic good of society as a whole would be served. And Darwin had shown that the net result of each organism's engaging in a struggle for its own welfare was continuous evolution of the species as a whole in the direction of better adaptation to its environment. The political implications of this viewpoint are clear.

The central ethical question raised by the social Darwinists is this: granted that man is subject to natural law, and even granted further that he is subject to some form of natural or social selection, can one legitimately derive from this such policies as *laissez-faire*? Alfred Russel Wallace had argued that with the advent, under divine guidance, of man's brain, the evolution of man was no longer

controlled by natural selection, so that inference from the doctrine of natural selection to ethical policy would be illegitimate. Huxley provided a similar argument: Man represents an island of cultural evolution in a sea of Darwinian change. These issues have largely passed into history, however, due to the philosophical point that whether or not to support a law of nature is not a question for decision.

The fate of Darwinism since the twentieth century has been mixed. Social Darwinism is of no more than historical interest. It is rightly regarded as philosophically naive and, moreover, as concerned with social questions that are not of contemporary interest. The same is largely true of the theological battles over the significance of evolution. Current theology exhibits a sublime indifference to the questions that agitated Huxley and Bishop Wilberforce. It must be pointed out, however, that modern theology is free to pursue other problems because of the clarification of the status of man and of the relation of science to theology that emerged from the Darwinian debate.

In biological theory proper, Darwin's theory remains secure. His Lamarckism is no longer accepted, if we discount some periodic revivals in the former Soviet Union; and the doctrine of sexual selection is still a matter of some debate. But the major theory of the *Origin*, evolution by natural selection, is the framework of modern evolutionary theory. This modern account—sometimes called the synthetic theory and sometimes, rather confusingly, Neo-Darwinism—accepts in toto the doctrine of natural selection as described above but develops it in a manner that Darwin himself could not have envisaged. The synthetic theory may fairly be described as Darwin's theory of natural selection, deepened by the absorption of twentieth-century genetics and systematically applied to the whole range of biological phenomena.

The absorption of genetics accounts for the novel developments in the doctrine of natural selection itself. Darwin thought of natural selection fundamentally as differential survival, and he regarded the organism as the natural unit that is subjected to selective pressures. With the advent of Mendelian genetics, and especially of the statistical study of the genetics of populations, these two Darwinian conceptions underwent a significant change. From the geneticist's point of view, differential survival is subordinate to differential reproduction of genetic materials; evolution is simply temporal change in the genetic constitution of a population. The simplest model of evolutionary change would be the following: Suppose that we have in a population two alleles,  $a_1$  and  $a_2$ , of a gene  $a$ ,

and that  $a_1$  is present in the proportion  $p$ , and  $a_2$  in the proportion  $1-p$ . Then any temporal change in the value of  $p$  would be a case of reproductive differential between  $a_1$  and  $a_2$ ; and it would be an evolutionary change in the population. Some biologists simply identify such differential reproduction with natural selection, in which case sexual selection is a special case of natural selection. The natural unit of selection becomes the gene rather than the whole organism.

This conception of natural selection is not incompatible with Darwin's. Differential survival is still the major cause of differential reproduction of genes; and there is still a clear and obvious sense in which the organism is the fundamental unit of natural selection. But the new conception of natural selection facilitates the discussion of a large range of questions, for example, the roles of isolation and migration in evolution; the effectiveness of very small selective advantages; the roles of gene mutations, sex-linkage, and dominance; and so on. The modern theory has much to say on these topics that could not have been foreseen by Darwin, but nothing that he could not readily endorse.

## DAVID OF DINANT

The materialistic pantheist of the Middle Ages David of Dinant taught at Paris near the beginning of the thirteenth century. Apart from this fact, almost nothing is known of his life. It is uncertain whether he derived his name from Dinant in Belgium or Dinan in Brittany. His major work, *De Tomis, Hoc Est de Divisionibus*, is probably identical with the *Quaternuli* condemned at a provincial council in Paris in 1210, and his writings were among those banned at the University of Paris in 1215 by the papal legate, Robert de Courçon. Our knowledge of his ideas is largely derived from Albert the Great, Thomas Aquinas, and Nicholas of Cusa.

David developed his philosophy at a time when Latin Christian thought was facing an almost unprecedented challenge from rival world views. Neoplatonism, introduced into the medieval West by John Scotus Erigena and popularized in the twelfth century by numerous translations of Arabic works, was the first great non-Christian system to impress the medieval mind, but by the early thirteenth century Aristotelianism loomed large, and other Greek philosophies were not unknown. Attempts were made to blend the Christian doctrine of creation with these doctrines, notably with the Neoplatonic theory of emanation, with the result that the distinctive character of the biblical conception of the relation between the world and God was at least occasionally obscured.

The title of David's *De Tomis* suggests some indebtedness to Erigena's *De Divisione Naturae*, and David's pantheism may well have been inspired to some extent by his reading of Erigena's work. His thought seems, however, to have been more strongly influenced by ancient Greek materialism, as described in Aristotle's *Physics* and *Metaphysics*, and by certain Aristotelian ideas dialectically manipulated in the manner of the early medieval logicians.

David's interpretation of reality was essentially monistic. He first divided the objects of knowledge into three classes and then presented individual objects within each class as mere modes of a primary reality. Thus, bodies are modes of matter (*hyle*), souls are modes of mind (*nous*), and eternal substances or separated forms are modes of God. Furthermore, these three primary realities are themselves essentially one being or substance.

David supported this doctrine by a dialectical argument based on the logical notion of a "difference" (*differentia*) that, when added to a genus, forms a species. Such *differentiae*, he argued, can be predicated only of composite beings. God, mind, and prime matter, however, are all simple realities, and can therefore include no *differentiae*. Consequently, they must be substantially identical.

David's monism may be further characterized as materialistic. In his view, neither God nor matter possesses form, since beings determined by form are individual, composite substances. God and matter, therefore, cannot be known by an assimilation of their forms through abstraction. If in fact the intellect knows both God and matter, the explanation must be that it is already identical with them. Furthermore, if both God and matter are unformed, they are nothing but being in potentiality. Being in potentiality, however, is the definition of prime matter. Properly speaking, then, the ultimate reality, which is at once God, mind, and matter, is best described as matter.

## DAVIDSON, DONALD (1917–2003)

Donald Davidson was born in 1917 in Springfield, Massachusetts, and graduated from Harvard in 1939. After serving in the United States Navy, Davidson returned to Harvard, where he wrote his doctoral dissertation on

Plato's *Philebus* (1990a). After he received his PhD in 1949, Davidson went on to do extensive work in decision theory, in collaboration with Patrick Suppes and others. After many years at Stanford, and somewhat shorter stays at Princeton, Rockefeller, and Chicago, Davidson in 1981 moved to the University of California at Berkeley, where he was appointed Willis and Marion Slusser Professor of Philosophy. Davidson lived in Berkeley for the rest of his life, continuing to produce important work until his death in 2003.

The early confrontation with the methodological challenges of giving empirical application to rational-choice theory had a lasting influence on Davidson. It is apparent in his later formulation of philosophical questions regarding action, the mental and linguistic meaning. Davidson's views on these matters have gradually come to articulation through a series of papers presenting detailed arguments pertaining to specific problems. In each of three areas of philosophy, Davidson elaborated a set of closely interconnected and highly influential doctrines. This entry looks briefly at each area in turn, emphasizing certain general features characteristic of Davidson's philosophical approach. The entry concludes with a glance at key themes of Davidson's later work, in which he elaborates an anti-representationalist conception of mind and of philosophy.

### THE CAUSAL THEORY OF ACTION

Davidson's view, first set out in print in *Actions, Reasons, and Causes* (1963), is that individuals must consider the reasons for their actions—combinations of propositional attitudes, paradigmatically belief-desire pairs—to be also their causes. In this and related papers Davidson granted a main premise of the anti-causalist view prevailing at the time, that the teleological form of action-explanation makes such explanation irreducibly different from the nomological form characteristic of explanation in the natural sciences. What is distinctive about action-explanation is that it identifies the events involved (the action and its explanatory antecedent) in terms that reveal them to be part of a rational pattern. Davidson proceeded to challenge anti-causal orthodoxy, however, by arguing that it does not follow from this irreducible difference that action explanation is not a species of causal explanation.

A striking aspect of Davidson's view is the claim that the appeal to reason on which action explanations turn will be genuinely explanatory only insofar as the particular events thus rationally related are also related as cause and effect, and hence, for Davidson, may also be charac-

terized by nomologically related descriptions. But Davidson insisted that the explanatory efficacy of a reason-explanation in no way depends on one possessing the law-evincing descriptions of the particular events in question. Indeed, in the typical case one enjoys the full benefits of effective action explanation without the slightest idea of what those descriptions might be. Davidson's work thus reconciles the following three fundamental claims.

First, when an event is cited in successful explanation of another event, the former is a cause of the latter. Second, causal relations between events entail nomological relations between them. Third, *explanans* and *explanandum* in action explanations are captured in terms that cannot be subsumed under strict law. This reconciliation trades on a particular conception of the relation between cause and law. If two events are causally related, they are so related no matter how described. The nomological relation, however, obtains between kinds of events; laws, as Davidson said, are linguistic, and so while causal relations are extensional, and causally related events necessarily fall under what he terms strict laws (that is, laws that are "free from caveats and *ceteris paribus* clauses ... treating the universe as a closed system" (1993 [2005a], p. 191), they instantiate such law only under some appropriate description. Hence, the descriptions under which two causally related events appear in successful action explanation may be such that no amount of knowledge of strict causal law would allow one to infer the action from knowledge of the conditions cited in the explanation of it (1963a; 1993; 1995).

### ANOMALOUS MONISM

A crucial element in Davidson's account of action is the distinction between a particular event and the descriptions that sort particular events under kinds. This same distinction is central also to his claims about the nature of the mental and its relation to the physical. In "Mental Events" (1970) and subsequent papers (1991b, 1993), Davidson argued that what it is to be a mental event is to be an event that falls under a mental predicate; that is to say, for Davidson, an event is mental just in case it falls under a description that ineliminably involves an intentional term. Correspondingly, what it is to be a physical event is to fall under a physical predicate. Physical predicates are of diverse kinds; a subset of physical terms are the predicates of developed physics. They form an ideal vocabulary the constitutive purpose of which is to track the causal structure of the world by displaying all events as they fall under maximally strict laws.

Since Davidson conceived of events as extensionally identified spatio-temporal particulars constituting nodes in the causal network, W. v. O. Quine's basic ontological dictum expresses also for Davidson an important truth; it is the unique business of physics to aim for full coverage. What this means for Davidson is that all events, qua nodes in the causal network, must be describable in the terms of physics. Yet some events are also mental, and Davidson argued that his physicalism supports no reductionist or eliminativist conclusions. For while all particular mental events are also particular physical events, no particular *kind* of mental event is a particular *kind* of physical event. The reason for this is that intentionality, which for Davidson is the mark of the mental, is constituted, in his view, by one's efforts to characterize fellow creatures as rational according to an inter-subjective standard. One is able to view fellow language-users thus because an individual has at his or her disposal two kinds of conceptual resources. One keeps track of other people by keeping tabs on objective environmental relations in which human beings are all embroiled in various and changing ways. At the same time, one is able to deploy a set of concepts—of belief, desire, and so on—which allows one to construct accounts not just of objective environmental relations, but also of how these relations appear to someone to be.

This system of double bookkeeping allows an individual to absorb a great deal of variation and irregularity in human behavior by accounting for objective anomalies in terms of subjective variables. But this strategy remains informative and useful only insofar as the essential discrepancies between subjective perspective and objective reality that interpretation exploits are prevented from becoming arbitrary or chaotic—were that to happen, the subjective would lose its explanatory purpose, it would simply mark the place where explanation ends.

This is why the interpretive construction of the subjective perspective must be tightly constrained; as Davidson stated, making sense of others "we will try for a theory that finds [them] consistent, believer[s] of truths, and lover[s] of the good (all by our own lights, it goes without saying)" (1970 [1980a], p. 222). This constraint on the application of intentional terms is often referred to as the "principle of charity." It reflects the fact that only the attitudes (though not only the rational attitudes) of a recognizably rational subject may be invoked in a genuinely explanatory way to account for the subject's behavior. Moreover, as Davidson later emphasized, because rationality considerations govern an individual's application of propositional-attitude concepts, these concepts

are irreducibly causal, “identified in part by the sorts of action they are prone to cause, given the right conditions” (1991b [2001], p. 216).

As he further pointed out, “the right conditions” are themselves not independently characterizable. The phrase, marking the interdependence of the application conditions of mental predicates, remains an ineliminable qualification of the sort of platitudinous generalizations that express the content of our psychological terms. By contrast, Davidson argued, the application of the predicates of physics—aimed at the formulation of strict law—cannot itself depend on causal concepts (1991b). The application conditions of terms related by strict empirical law must be independently specifiable. The real difference, then, between the mental and the physical, and the reason for the irreducibility of one to the other, stems from the fact that the vocabulary of physics and the vocabulary of psychology have evolved under the pressure of distinctively different interests. What one wants from the former are modes of description that allow people to interact with each other as persons. What one wants from the latter are laws “as complete and precise as we can make them; a different aim” (1991b [2001], p. 217).

## TRUTH AND MEANING

In the philosophy of language, Davidson is associated with the view that an individual may account for linguistic competence by appropriately characterizing the evidence available to and resources required by an idealized interpreter (1973). There are two fundamental aspects to this position. What, Davidson asked, might one know such that by knowing it one would be able to say what a speaker of a given language meant by some arbitrary utterance? His answer is a theory of truth for that language, an account of the logical structure of a language of the sort that Alfred Tarski demonstrated how to construct (1967a; 1990b; 2005b). The condition of adequacy for such a theory is an adaptation of what Tarski called “convention T.” One has, Davidson proposed, a theory of meaning for a given language L provided one has a theory that entails for each sentence of L an instance of the schema, “s is true in L if and only if p.” In this schema, s would be replaced by an expression that mentions a sentence of L (for example by means of quotation marks), and p replaced with any sentence of the language in which the theory is stated that is true if and only if the sentences mentioned by s is true. Such a theory provides, based on finite resources, a recursive characterization of the truth conditions for any sentence of L. While all that

is demanded by convention T is that the theorems of the theory—known as T-sentences—capture co-extension of truth-values, “the hope,” as Davidson said, “is that by putting appropriate formal and empirical restrictions on the theory as a whole, individual T-sentences will in fact serve to yield interpretations.” (1973, [1984], p. 124).

This proposal has spawned a great deal of work in formal semantics, guided by the aim of accounting for natural-language idioms in terms of their deep structure, or logical form, which makes explicit their truth-theoretical composition. For Davidson, the notion of logical form is extremely powerful; constrained on the one hand by one’s intuitions concerning entailment relations, and on the other by the logical resources of Tarskian truth-theory construction, the uncovering of logical form functions as a crucible within which crystallize the ontological categories human language commits a person to. So for example, support for an ontology of events takes the form of an argument that one cannot account for the entailment relations intuitively characteristic of action sentences within the logical confines of a Tarskian theory of truth for a language unless one is willing to see such sentences as quantifying over events (1967b).

If a theory of truth is to serve as a theory of meaning for a language, one needs to know how an interpreter may arrive at such a theory for a language she does not know. What is required for a recursive truth-theory to have empirical application? This question points to the other main aspect of Davidson’s conception of linguistic understanding, an aspect where Quine’s influence is most apparent. Observing the utterances of a speaker but knowing neither what the speaker means nor what the speaker believes, the interpreter will face endless alternative explanations of any observed piece of behavior. However, she can narrow the range of possibilities dramatically, by assuming that the speaker’s behavior, including the speaker’s linguistic behavior, embodies a rational response to salient features of her environment. This assumption of rationality is defeasible with respect to any particular attribution within the context of the construction of a theory of the meanings of someone’s words and the contents of the person’s thoughts. Davidson’s point is emphatically not that one is never irrational, or that the irrational cannot be interpreted. Rather, the lesson is that irrationality is conceptually parasitic, diagnosable only against a background of reason (1982b; 1985). Thus, in what Davidson called radical interpretation, the interpreter may inductively construct a theory of truth for the speaker based on observations of behavior only by assuming that the speaker’s mental

life—her thoughts, actions and utterances—constitutes a largely rational whole (1973; 1980b). This assumption, compulsory for the radical interpreter, is often referred to as the principle of charity.

Even while minimizing the irrationality of her subject in accordance with charity, the radical interpreter will be able to produce for a speaker alternative theories of belief and meaning, theories that comport equally well with the empirical evidence (i.e., with the speaker's utterances and their contexts). This indeterminacy Davidson regards as innocuous; the salient facts about meaning and mind are what such differing theories have in common. If alternative theories are empirically equivalent, this means that there is more than one way of stating the facts that interpretive theories are designed to capture. This is no threat to the viability of interpretation (1974a; 1979; 1990b; 1991b).

## CHALLENGES

With respect to Davidson's view of action, the most serious objection holds that Davidson's theories cannot indicate how action explanation actually can be explanatory at all. The point of the objection is that one cannot reconcile the three fundamental claims regarding explanation, cause, and law to which Davidson's work is committed (see aforementioned text). One claim—advanced, for example, by Jerry Fodor—is that informative action explanation must somehow draw on the explanatory power of nomic relations, in which case Davidson's irreducibility-claim would be threatened. An alternative view—defended by anti-causalists like George Wilson—is that the explanatory force of reason-explanation is *sui generis*, and does not depend on reasons being causes. This would jeopardize Davidson's conception of event monism.

With regard specifically to anomalous monism, Jaegwon Kim and others have argued that Davidson's view renders the mental causally inert. So reason explanations cannot really be explanations at all, since Davidson believed that any genuine explanation of an event, including an action, must pick out actual causal relations. Partly because of their different views on the individuation of events, this conflict is difficult to assess. However, if one grants Davidson his fundamental claims—that is, that the difference between the mental and the physical is a matter of vocabulary of description, and that events should be extensionally conceived—then his concept of supervenience ensures that a change in the truth value of the relevant kind of mental predicate ascription will entail some difference or other in causal relations. Natu-

rally, alternatives to Davidson's Humean conception of causality and of the relations between causality and law are frequently at play in criticisms of Davidson's account. Davidson relied on this conception both in arguing for anomalous monism and in reconciling the irreducibility of action-explanation with a causal view of action.

As for Davidson's philosophy of language, there have been objections at various levels to the idea that a theory of meaning for a language must take the form of a Tarskian truth-theory. Even while accepting the proposal that a theory of meaning should take the form of a theory of truth, one may ask, for example, why theorists should restrict themselves, in producing a formal semantics for a language, to the resources of first-order predicate calculus. A great majority of scholars now doubt the prospects of an account of natural language semantics couched in purely extensional terms.

## ANTI-REPRESENTATIONALISM

Davidson's contention that theories of truth as Tarski defined them give the structure of theories of meaning is best viewed as a pragmatic methodological commitment. What supports Davidson's most innovative philosophical conclusions is the more general point that one must understand meaning in terms of truth, in conjunction with his insistence—following Quine—on a third-person perspective to meaning and mind. This view makes the conditions of interpretation constitutive of content. Together, these commitments yield an account of the concept of truth constrained by the methodological requirements of interpretation. This account contrasts both with traditional correspondence theories and with epistemic accounts of the sort advanced, for example, by Hilary Putnam. It is also distinct from disquotationalist or deflationist theories such as that of Paul Horwich (1990b; 2005b).

The significance of these core commitments is readily apparent in Davidson's argument aimed to discredit the duality of representational scheme and empirical content on the grounds that it presupposes the notion of an untranslatable language (1974b). If truth and meaning are interlocking concepts whose features are illuminated by an account of the methodology of an ideal interpreter, the idea of alternative representations of reality that are mutually semantically impenetrable is not coherent. This argument also marks a dividing line between Davidson and Quine. For the metaphysical opposition between what is given to the mind on the one hand, and the processes brought to bear on that given, on the other hand, is the very duality in terms of which empiricism

faces its defining challenge, namely to articulate a coherent notion of sensory evidence (1982a). On this fundamental score, Quine has remained within the bounds of empiricism (1990c). Davidson, on the other hand, has gone on explicitly to reject the basic metaphor of mind as inner space on which empiricism rests. For Davidson the hold of this metaphor reveals itself in the persistence of the interdependent notions of mental states as representational and of truth as correspondence, which, in turn, inextricably entangle philosophy in the problems of relativism and skepticism (1986a; 1987; 1988; 1990b; 2005b).

Davidson's alternative to the representational view of mind is most succinctly expressed in the thesis that there is thought only when there is actual communication (1989a; 1989b; 1991a; 1991b; 1992). On this controversial view, knowledge of one's own mental state, knowledge of the so-called external world, and knowledge of the mental states of others appear mutually interdependent (1991b). This blocks the very possibility of a skeptical or relativist challenge from arising, insofar as these are typically constructed around arguments that purport to show the impossibility of deriving any one of the three kinds of knowledge from either or both of the other two. This impossibility is something Davidson's work accepts—indeed insists on. Against the skeptic or relativist his claim is simply that the three forms of knowledge stand or fall together; denying one is to deny all, and to deny all is just to deprive our intentional concepts of any application.

This position rests on two key claims. One is that shared linguistic understanding is a prerequisite for any standard of objectivity (1991b). Such a standard gives content to the very distinction exploited by the propositional-attitude verbs between what is and what seems from some perspective to be, and hence, on Davidson's conception, is a prerequisite of thought. The other is the claim that the idea of shared linguistic understanding presupposes actual communication (1986b). The mental is thus what one reveals when one subjects a certain vaguely delimited range of causal relations to a particular kind of description, the terms of which presuppose the mutual recognition of subjects interacting in a shared world.

This view carries with it the commitments to event monism, to the constitutive role of rationality for content, and to a view of human agents as an integral part of the natural world, that have always been evident in Davidson's work. The distinction between extensionally conceived particulars and their descriptions remains pivotal. But the upshot is fundamentally at odds with the

governing metaphors of modern epistemology-centered philosophy: "A community of minds," Davidson concluded, "is the basis of all knowledge; it provides the measure of all things." And he added: "It makes no sense to question the adequacy of this measure, or to seek a more ultimate standard" (1991b [2001], p. 218). However one assesses the plausibility of the considerations Davidson offers in support of this position, cognizance of the thorough-going externalism on which it is based should lead one to see it not as a species of antirealism or idealism, but as a profound rejection of foundationalist aspirations. Systematically linking the content of one's concepts to one's communicative practices as agents in the world, Davidson's work articulates a recognizably pragmatist view of mind, nature, and philosophy.

## DEATH

Although most of the great philosophers have touched on the problem of death, few have dealt with it systematically or in detail. Frequently, as in the case of Benedict (Baruch) de Spinoza, an author's views on the subject are known to us from a single sentence; and at almost all stages in Western history we are likely to discover more about the topic in the writings of men of letters than in those of technical philosophers. Whether this relative reticence on the part of philosophers should be attributed to a general lack of interest or to other causes is a moot point. Arthur Schopenhauer, who was the first of the major philosophers to deal extensively with the subject, declared that death is the muse of philosophy, notwithstanding that the muse is seldom avowed. And the existentialist philosophers from Søren Kierkegaard to the present have more or less consistently endorsed Schopenhauer's contention; Albert Camus's declaration in *The Myth of Sisyphus* (1942) that suicide is the only genuine philosophical issue is an extreme but notable case in point. On the other hand, most contemporary Anglo-American analytic philosophers probably regard the paucity of materials on death as evidence of the subject's resistance to serious philosophical inquiry. In general, they wish to exclude the subject of death from the area of legitimate philosophical speculation, either as a part of their campaign against metaphysics or on the grounds that the subject can be more adequately dealt with by psychologists and social scientists. The psychologists and social scientists have, in fact, recently given signs of a willingness to explore the question. One such indication was a symposium on the psychology of death at the 1956 American Psychological Association Convention, which resulted in the publication in 1959 of an anthology including contributions from scholars in a wide variety of fields. Unfortunately, as several of the contributors to this volume lamented, the number of experimental studies actually undertaken has been disappointingly small.

## THE KNOWLEDGE OF DEATH

The primary concern of most philosophers who have dealt with the question of death has been to discover ways in which we may mitigate or overcome the fear it tends to inspire. There are, however, several other loosely related problems that have also tended to excite interest or controversy and that it will be advisable to discuss first. How does man learn of death? Is death a natural phenomenon, or does it require explanation in nonnatural terms? What specific psychological or social conditions tend to heighten the awareness and fear of death?

**AWARENESS OF DEATH.** The clearest and simplest answer to the first of these questions was given by Voltaire, who stated: “The human species is the only one which knows it will die, and it knows this through experience” (*Dictionnaire philosophique*). Although some persons have questioned whether man is the only animal who knows he will die, arguing that certain of the lower animals appear to show some vague presentiment of approaching extinction, it appears to be unquestioned that man alone has a clear awareness of death and that man alone regards death as a universal and inevitable phenomenon. The interesting question is how man knows he will die. The view that experience alone gives knowledge of death derives support from the ignorance of death displayed by many children and from anthropological data indicating that many primitive peoples refuse even as adults to regard death as necessary or universal. However, a number of twentieth-century philosophers contested this view, especially Max Scheler and Martin Heidegger, who argue that the awareness of death is an immanent, a priori structure of human consciousness. Although neither of these authors offers anything in the nature of scientific evidence for his position, it is not easily refuted; for, if one grants current notions about levels of consciousness, apparent ignorance of death may be interpreted as merely superficial and attributed to some form of repression. Moreover, the imperfect knowledge of death among primitive peoples is a fact that could be used against those who argue that the knowledge of death comes from experience, since the hazards of their lives expose primitive peoples to an earlier and greater experience of death than is common among civilized men. At the very least it must be granted that the knowledge of death depends not only upon experience but also upon a level of mental culture that makes it possible to interpret experience accurately.

Ironically, Sigmund Freud, who more than anybody else has habituated us to think in terms of levels of consciousness and has thereby rendered credible the idea that knowledge of death may exist despite apparent ignorance, stated that the consciousness, not the apparent ignorance, of death is merely superficial, the unconscious being firmly convinced of its immortality. How Freud could reconcile this belief, which dates from the period of World War I, with his later belief in the unconscious death wish is not clear.

**DEATH: A NATURAL PHENOMENON?** Is death a natural phenomenon? Most persons today tend to find this question a bit foolish. It is noteworthy, however, that most primitive peoples attribute death to the agency of

gods or demons who are jealous of human achievements. Equally significant is the Christian explanation of death as punishment for the sins of Adam. It should also be observed that if by a “natural” phenomenon one means a fact that can be fully understood and explained by empirical inquiry, death is not a natural phenomenon for Heidegger or Scheler. This reluctance to explain death in terms of natural causes has an interesting parallel in the reluctance to explain life itself naturalistically, and the religious or metaphysical perspectives that give rise to nonnaturalistic interpretations of life tend also to occasion nonnaturalistic interpretations of death.

**VARIATIONS IN CONSCIOUSNESS OF DEATH.** Are there great variations in the awareness or fear of death from person to person, from epoch to epoch, from culture to culture? If so, how are these variations to be explained? Surprisingly, very little attention has been given to these questions. The most interesting and almost the only hypothesis on this topic is that of Johan Huizinga and Paul-Louis Landsberg, who, each in his own way, link the consciousness of death to individualism. According to these authors, the consciousness of death has been most acute in periods of social disorganization, when individual choice tends to replace automatic conformity to social values; they point especially to classical society after the disintegration of the city-states; to the early Renaissance, after the breakdown of feudalism; and to the twentieth century. This hypothesis has yet to be fully confirmed or disconfirmed by careful historical and anthropological study. However, it is true that late antiquity, the early Renaissance, and the twentieth century made unusually great contributions to the literature on death.

### THE FEAR OF DEATH

With respect to the fear of death, the great divide is between those who argue that only the hope of personal immortality will ever reconcile men to death and those who argue that the fear of death may be mitigated or overcome even when death is accepted as the ultimate extinction of the individual person. The second group, which is remarkably heterogeneous, may be subdivided according to the techniques recommended for allaying fears.

**THE EPICUREANS.** One of the oldest of the “solutions” to the fear of death was that of Epicurus and his followers. According to Epicurus, the fear of death is based upon the beliefs that death is painful and that the soul may survive to experience pain or torture in an afterlife.

Since both of these beliefs are mistaken, it suffices to expose them as such. Although death may be precipitated by painful disease, death itself is a perfectly painless loss of consciousness, no more to be feared than falling asleep. And since the soul is merely a special organization of material atoms, it cannot survive physical destruction. “Death,” Epicurus said, “is nothing to us. ... It does not concern either the living or the dead, since for the former it is not, and the latter are no more” (*Letter to Menoeceus*). It is hardly necessary to point out that many persons have questioned Epicurus’s conception of the soul and consequently have rejected his views with respect to its immortality. The principal criticism, however, is that the Epicureans have falsely diagnosed the cause of humankind’s fear of death. Death terrorizes us, not because we fear it as painful, but because we are unwilling to lose consciousness permanently. The twentieth-century Spanish existentialist philosopher Miguel de Unamuno reports that “as a youth and even as a child, I remained unmoved when shown the most moving pictures of hell, for even then nothing appeared to me quite so horrible as nothingness itself.”

**THE STOICS.** The later Stoics, especially Seneca, Epictetus, and Marcus Aurelius, offered a more complicated and elusive view of death. Seneca said that to overcome the fear of death we must think of it constantly. The important thing, however, is to think of it in the proper manner, reminding ourselves that we are but parts of nature and must reconcile ourselves to our allotted roles. He recurrently compared life to a banquet from which it is our obligation to retire graciously at the appointed time, or to a role in a play whose limits ought to satisfy us, since they satisfy the author. The fear of death displays a baseness wholly incompatible with the dignity and calm of the true philosopher, who has learned to emancipate himself from finite concerns. Essential to the Stoic outlook was the Platonic view that philosophizing means learning to die; that is, learning to commune with the eternal through the act of philosophic contemplation.

Although much of Stoic thinking on death crept into later Christianity, the contemporary Christians saw in this thinking a sinful element of pride. Death, Augustine said, is a punishment for human sin, and the fear of death cannot be overcome except through divine grace. Others find it highly questionable whether one can reasonably accept the metaphysical underpinnings of the Stoic view, most especially the belief in a providential order of Nature.

**SPINOZA.** A third solution is that of Spinoza. He wrote: “A free man thinks of nothing less than of death, and his wisdom is not a meditation upon death but upon life” (*Ethics*, Prop. LXVII). Since Spinoza did not elaborate, it is possible to argue almost endlessly about the precise import of this famous remark. Most often, however, it is interpreted to mean that men can and should allay the fear of death simply by diverting their attention from it, and some persons have argued that by his nature man tends to—perhaps must—follow this advice. François de La Rochefoucauld, for instance, averred that man can no more look directly at death than he can look directly at the sun. One fundamental criticism of this position comes from the Stoics and the existentialists, both of whom maintain that the fear of death can be allayed only by facing it directly. A second criticism consists in pointing out that the fear of death is frequently an involuntary sentiment that cannot be conquered by a merely conscious decision or a bare act of will. It is not enough to tell people not to think of death; one must explain how they can avoid thinking of it.

**DEATH AND THE GOOD LIFE.** This brings us to a fourth view on death, a view that was felicitously put by Leonardo da Vinci. Just as a day well spent brings happy sleep, so, he said, a life well spent brings happy death. Painful preoccupation with death has its source in human misery; the cure is to foster human well-being. A happy man is not seriously pained by the thought of death, nor does he dwell on the subject. This view was held by many Enlightenment thinkers, most notably the Marquis de Condorcet. It also appears to be the view of most pragmatists and of Bertrand Russell.

There are two counterarguments. The first is the theme prevalent in several branches of Christianity concerning the total impossibility of attaining happiness on Earth. The second is the even more familiar and prevalent Christian theme that in order to achieve happiness in this life, one must first conquer the fear of death. Happiness, therefore, is not a cure; it is a consequence of the cure.

**DEATH WITHOUT CONSOLATION.** In sharp contrast to this last position is that of a long line of nineteenth-century and more recent philosophers, from Schopenhauer to contemporary existentialists. For them human well-being or happiness, at least as traditionally conceived, is totally impossible to achieve; and if the individual is to experience such rewarding values as life does permit, he must uncompromisingly embrace the tragedy of the human condition, clearheadedly acknowledging such evils as death. Like the Stoics, these authors would

have us think constantly of death. Unlike the Stoics, however, they do not offer us the consolation of belief in a providential order of nature. From the standpoint of Being or Nature, the death of the individual is totally meaningless or absurd.

For Schopenhauer the finite, empirical self is a manifestation of a cosmic will that has destined man to live out his life in suffering or painful striving. The only remedy is to achieve a state of indifference or pure will-lessness—a state best known in moments of pure aesthetic contemplation but to which the awareness of death substantially contributes.

According to Friedrich Nietzsche, the superior man will not permit death to seek him out in ambush, to strike him down unawares. The superior man will live constantly in the awareness of death, joyfully and proudly assuming death as the natural and proper terminus of life.

Heidegger and Jean-Paul Sartre, like most existentialists, urge us to cultivate the awareness of death chiefly as a means of heightening our sense of life. The knowledge of death gives to life a sense of urgency that it would otherwise lack. The same point has been made by Freud, who compared life without the consciousness of death to a Platonic romance or to a game played without stakes.

Heidegger makes the additional claim, although here Sartre parts company with him, that the awareness of death confers upon man a sense of his own individuality. Dying, he says, is the one thing no one can do for you; each of us must die alone. To shut out the consciousness of death is, therefore, to refuse one's individuality and to live inauthentically.

### **Bibliography**

Jacques Choron, *Death and Western Thought* (New York: Collier, 1963), is a fairly comprehensive review of what Western philosophers have had to say on the subject of death. It is especially recommended for its wealth of

quotations. Herman Feifel, ed., *The Meaning of Death* (New York: McGraw-Hill, 1959), is an anthology containing many contemporary essays by psychologists, sociologists, and workers in allied fields.

Russell's views on death may be found in "The Art of Growing Old," in his *Portraits from Memory and Other Essays* (London: Allen and Unwin, 1956) and in "What I Believe," in his *Why I Am Not a Christian* (London: Allen and Unwin, 1957).

Heidegger's views will be found in his *Being and Time* (New York: Harper, 1962), Part II, Ch. 1; Sartre's in his *Being and Nothingness* (New York: Philosophical Library, 1956), pp. 531–553.

An interesting work by a Roman Catholic existentialist is Paul-Louis Landsberg, *Essai sur l'expérience de la mort* (Paris, 1951).

Freud's views are expressed in "Thoughts for the Times on War and Death," in *Standard Edition of the Complete Psychological Works of Sigmund Freud*, edited by James Strachey and Anna Freud (London: Hogarth Press, 1957), Vol. XIV, 288–317.

Johan Huizinga, *The Waning of the Middle Ages* (London, 1952), provides the best account of that author's reflections.

For an analysis of primitive attitudes toward death, see Lucien Lévy-Bruhl, *Primitive Mentality*, translated by Lilian A. Clare (London: Allen and Unwin, 1923).

## DEATH [ADDENDUM]

In recent decades death has garnered considerable philosophical attention in three principal areas: medical ethics, value theory, and metaphysics.

In medical ethics, interest has centered on determining the criterion of death. The most common criterion for the death of human beings is irreversible loss of consciousness, but this postulate remains controversial for those who see humans principally as animals rather than as conscious beings. A human animal may be said to be alive even if he or she is not conscious. The meaning of "irreversibility" is also controversial. Would Jane Doe be dead if she lost consciousness but her consciousness could be recovered if she were injected with a serum that will not be invented for another thousand years? Medical ethicists have also debated the relevance of the principle of double effect regarding situations in which a doctor is the cause of death. Followers of the principle of double effect will allow morphine to be administered to a patient in order to stop his suffering, even allowing for the possibility that the morphine will kill the patient. But this outlook does not countenance such an injection if the patient's death is the main objective of the act.

In the theory of values, the argument of Epicurus (341–270 BCE) still engenders controversy. Epicurus argued that if death is the annihilation of a person, then the death cannot be bad for that person. For something to be bad, there must be some thing or person for whom it is bad, but if the person who has died has ceased to be, then (for that person) there is no bad or evil. Epicurus employed this argument to alleviate the fear of death. Epicurus also argued that just as one does not fear or bemoan one's nonexistence before birth, one ought not to lament one's nonexistence after death.

Epicurus's reasoning has elicited a number of counterarguments. Some have argued that death is bad for the person insofar as it involves missed opportunities or possibilities. The death of a person involves his absence, and such an absence can be a bad state of affairs even if it is not bad for the person or for others. It has also been suggested that the Epicurean bid for a symmetry of neither regretting past nonexistence or future nonexistence is not plausible because a person may well wish she had been alive in some earlier era.

Philosophical reflection on death has implications for an overall theory of values, involving questions about rights (if the dead have ceased to be, do they have any rights whatsoever?), promise-keeping (do you have a duty to keep a promise to someone who has ceased to be?), and the environment (should environmental harms be understood principally in terms of the death of individual animals and plants or of species)?

Still other thinkers have wrestled with the issue of whether or not the death of humans is in fact a case of annihilation. This debate has unfolded mainly among specialists in the metaphysics of personal identity, philosophy of mind, and philosophy of religion. Dualist conceptions of human nature—according to which there is a distinction between a person or soul or mind on the one hand and his or her body on the other—allow for the possibility that the physical body may be annihilated without destroying the person or soul or mind. The case for dualism and the coherence of disembodiment has been bolstered by reports of out-of-the-body experiences (OBE). Even if the empirical testing of such OBEs is inherently problematic, some dualists have appealed to the apparent coherence of such reports in arguing that disembodiment is a *bona fide* possibility. Philosophical speculation on the afterlife contains a great deal of debate on the coherence of competing thought experiments. It may appear that materialist accounts of persons, according to which a person *is* his or her body, are ill-suited to lending any credibility to an afterlife scenario, but late-

twentieth-century philosophers have challenged this conclusion. Some have argued that a physical object (such as a human body) can cease to exist and then be re-created. This process entails what has been called a “gap inclusive” or “intermittent” identity, for it posits an interval when a person temporarily ceases to exist.

Philosophers have also advanced a constitutional argument, according to which human beings are material objects because they are constituted exclusively by material objects. The constitutional relationship is not one of strict identity, so it is possible for the same thing (a person) to survive the change of his or her constitutive parts. Some argue that a person (understood as a material body) can survive the loss of his or her present body or perhaps come to have a new body or even be reconstituted by nonphysical individuals. The philosophical investigation into the possibility of an afterlife is often located in the broader philosophical enterprise of weighing the merits of naturalism, theism, and various nontheistic religious traditions.

## DECISION THEORY

Decision theory provides a general, mathematically rigorous account of decision making under uncertainty. The subject includes rational choice theory, which seeks to formulate and justify the normative principles that govern optimal decision making, and descriptive choice theory, which aims to explain how human beings actually

make decisions. Within both these areas one may distinguish individual decision theory, which concerns the choices of a single agent with specific goals and knowledge, and game theory, which deals with interactions among individuals. This entry will focus on rational choice theory for the single agent, but some descriptive results will be mentioned in passing.

## DECISION PROBLEMS

It is standard to portray decision makers as facing choices among acts that cause desirable or undesirable consequences when performed in various states of the world. Acts characterize those aspects of the world that an agent can directly control. States specify contingencies beyond her control that might influence the consequences of acts. Each combination of an act  $A$  and state  $S$  fixes a unique consequence  $A(S)$  that describes the result of doing  $A$  in  $S$ . When there are only finitely many acts and states the decision situation can be represented as a matrix:

	$S_1$	$S_2 \dots$	$S_n$
$A_1$	$A_1(S_1)$	$A_1(S_2) \dots$	$A_1(S_n)$
$A_2$	$A_2(S_1)$	$A_2(S_2) \dots$	$A_2(S_n)$
$A_3$	$A_3(S_1)$	$A_3(S_2) \dots$	$A_3(S_n)$
$\vdots$	$\vdots$	$\vdots$	$\vdots$
$A_m$	$A_m(S_1)$	$A_m(S_2) \dots$	$A_m(S_n)$

The agent decides the row, the world decides the column, and these together determine the consequence.

In any well-formed decision problem (1) the value of each consequence is independent of the act and state that bring it about, (2) each consequence is sufficiently detailed to settle every matter about which the agent intrinsically cares, (3) neither acts nor states have any value except as a means for producing consequences, and (4) the agent will not believe that she has the ability to causally influence which state obtains. When these conditions are met, the agent's goals and values affect her decision only via her desires for consequences, and her beliefs influence her choice via her uncertainty about which state obtains. The agent will use her beliefs about states to select an act that provides the best means for securing a desirable consequence.

For theoretical purposes, it is useful to idealize the decision setting by assuming that the repertoire of actions is rich. Specifically, for each consequence  $c$  there is a constant act  $[c]$  that produces  $c$  in every state of the world, and, for any acts  $A$  and  $B$ , and any disjunction of states  $E$ , there is a mixed act  $A_E \cup B_{\neg E}$  that produces  $A$ 's consequence when  $E$  holds and  $B$ 's consequence when  $\neg E$  holds.

While real agents will typically be unable to realize such *recherché* prospects as these, imagining that decision makers have attitudes toward them often helps one determine which realistic acts should be performed.

This model applies to one-choice decisions made at a specific time. Early decision theorists believed that sequences of decisions made over time could be reduced to one-shot decisions among contingency plans, or strategies, but this view now has few adherents. The topic of dynamic decision making lies beyond the scope of this entry. For relevant discussions, see Peter Hammond (1988), Edward McClennen (1990), and James M. Joyce (1995).

## SUBJECTIVE EXPECTED UTILITY

The central goal of rational choice theory is to identify the conditions under which a decision maker's beliefs and desires rationalize the choice of an action. According to the standard model of decision-theoretic rationality, an action is rational just in case, relative to the agent's beliefs and desires, it has the highest subjective expected utility of any available option. This subjective expected utility (SEU) theory has its roots in the work of Blaise Pascal, Daniel Bernoulli, Vilfredo Pareto, and Frank P. Ramsey, and finds its fullest expression in Leonard J. Savage's *Foundations of Statistics* (1972). According to SEU a rational agent's basic desires can be represented by a utility function  $\mathbf{u}$  that assigns a real number  $\mathbf{u}(c)$  to each consequence  $c$ . The value of  $\mathbf{u}(c)$  measures the degree to which  $c$  would satisfy the agent's desires and promote his or her aims.

Likewise, the agent's beliefs can be characterized by a subjective probability function  $\mathbf{P}$  whose values express the agent's subjective degrees of confidence, or credences, in the states of the world.  $\mathbf{P}$  is assumed to be unique, and  $\mathbf{u}$  is unique once the choice of a unit and a zero for measuring utilities are fixed. Given  $\mathbf{P}$  and  $\mathbf{u}$ , the expected utility of each act  $A$  is a weighted average of the utilities of its consequences, so that  $\mathbf{Exp}_{\mathbf{P},\mathbf{u}}(A) = \sum_{i=1} \mathbf{P}(S_i)\mathbf{u}(A(S_i))$ . According to the core doctrine of SEU, the choice of an act is rational only if it maximizes the chooser's subjective expected utility, so that  $\mathbf{Exp}_{\mathbf{P},\mathbf{u}}(A) \geq \mathbf{Exp}_{\mathbf{P},\mathbf{u}}(B)$  for all acts  $B$ . This should not be taken to suggest that the agent sees herself as maximizing expected utility, or even that she has the concept of expected utility. SEU does not propose expected utility maximization as a decision procedure, but as a way of assessing the results of such procedures. Rational decision makers merely act as if they maximize subjective expected utility; they need not explicitly do so.

## REPRESENTATION OF RATIONAL PREFERENCE

A central challenge for SEU is to find a principled way of characterizing credences and utilities. Following the lead of Ramsey (1931), the standard solution involves proving a representation theorem that shows how an agent's beliefs about states and desires for outcomes are related to her all-things-considered preferences for acts. The agent is assumed to make three sorts of comparative evaluations between acts: She might strictly prefer  $A$  to  $B$ , written  $A > B$ , weakly prefer  $A$  to  $B$ ,  $A \succsim B$ , or be indifferent between them,  $A \approx B$ . These relations hold, respectively, just in case the agent judges that, on balance,  $A$  will do more than, at least as much as, or exactly as much as,  $B$  will to satisfy her desires and promote her aims. The totality of such evaluations is the agent's preference ranking.

Early decision theorists, motivated by a misguided scientific methodology, thought of preferences as operationally defined in terms of overt choices, so that, by definition, an agent prefers  $A$  to  $B$  if and only if (iff) she will incur a cost to choose  $A$  over  $B$ . Even though this sort of behaviorism remains firmly ensconced in some areas of economics, it has been widely and effectively criticized (Sen 1977, Joyce 1999). In the end, preferences are best thought of as subjective judgments of the comparative merits of actions as promoters of desirable outcomes. While such judgments are closely tied to overt choice behavior, the relationship between the two is nowhere near as direct and unsophisticated as behaviorism suggests.

The representation theorem approach seeks to justify SEU by (1) imposing a system of axiomatic constraints on preference rankings, (2) arguing that these express requirements of rationality, and then (3) proving that any preference ranking that satisfies the axioms can be associated with a probability  $P$  and a utility  $u$  such that each of  $A >$ ,  $A \succsim$ ,  $A \approx B$  hold iff, respectively,  $Exp_{P,u}(A) >$ ,  $\geq$ ,  $= Exp_{P,u}(B)$ . An agent whose preferences can be represented in this way evaluates acts as if she were aiming to maximize expected utility relative to  $P$  and  $u$ .

## FRAME INVARIANCE

All versions of SEU share a common set of core principles. The first says that logically equivalent redescription of prospects should not alter preferences.

*SEU<sub>1</sub> Frame Invariance.* The evaluation of an act should not depend on how its consequences happen to be described.

People often violate this constraint. Consider the following two decision framings due to E. Shafir and A. Tversky (1995):

- You receive \$300, and are then given a choice between getting another \$100 for sure or getting \$200 or \$0 depending on the toss of a fair coin.
- You receive \$500, but are then forced to choose between returning \$100 for sure or returning \$200 or \$0 depending on the toss of a fair coin.

Since both decisions offer a sure \$400 or a fifty-fifty chance of \$300 or \$500, SEU<sub>1</sub> requires agents to make the same choice in each case (though it does not tell them which choice to make). As it turns out, most people make the safe choice in the first case and take the sure \$400, but they make risky choice in the second case by taking the fifty-fifty gamble. Cognitive psychologists attribute this violation of SEU<sub>1</sub> to the following two irrational tendencies of human decision makers:

*Divergence from Status Quo.* People are more concerned with incremental gains and losses, seen as changes in the status quo, than with total well-being or overall happiness.

*Asymmetrical Risk Aversion.* People eschew risk when pursuing gains, but to seek risk when avoiding losses.

Under the first description, where the status quo is \$300, people see themselves as trying to secure an additional gain, and so opt for the safe alternative. Under the second description, where the status quo is \$500, people see themselves avoiding losses, and so incline toward the risky choice. These divergent attitudes are irrational given that the options are effectively identical.

## VALUE INDEPENDENCE

The second principle requires each act to have a value that depends only on the values and probabilities of the outcomes it might cause.

*SEU<sub>2</sub> Value Independence.* If the agent prefers  $A$  to  $B$  in a decision where  $C$  is not an option, then she should still prefer  $A$  to  $B$  even if  $C$  is an option, provided that  $C$ 's inclusion does not provide any information about state probabilities.

Apparent counterexamples to SEU<sub>2</sub> as a requirement of rationality always involve violations of the proviso. For example, R. Duncan Luce and Howard Raiffa (1957) discuss a diner who, thinking he is in a greasy spoon, prefers salmon to steak, but then orders steak when told that snails are on the menu. SEU<sub>2</sub> is vindicated by the obser-

vation that the availability of snails provides the diner with evidence for thinking that he is in fine restaurant, and this alters his views about the comparative merits of the salmon and steak. Other common violations of  $SEU_2$  are clearly irrational. For example, D. Redelmeier and E. Shafir (1995) show that physicians are less likely to prescribe ibuprofen to patients in pain when they have the option of prescribing the inferior drug piroxicam than when piroxicam is unavailable. While this sort of behavior does not discredit  $SEU_2$  as a normative principle, it does show that it is inaccurate as a description of human behavior.

## ORDERING

The third principle rules out preference cycles in which  $A > B$ ,  $B > C$ , but  $A > C$ , and it requires that the preference ranking be complete in the sense that exactly one of  $A > B$ ,  $A \approx B$  or  $B > A$  always hold.

$SEU_3$  *Ordering*. Preference rankings completely order the set of acts.

Though some dispute anticyclicality, and Peter C. Fishburn (1991) even develops an acyclic decision theory, the prohibition against cycles remains among the most widely accepted principles of rational preference. On views that equate preferences and choices, preference cycles are irrational because they leave the agent open to exploitation as a “money pump”: she will freely trade  $C$  for  $B$  and  $B$  for  $A$ , and then pay a fee to exchange  $C$  for  $A$ , thereby getting nothing for something. Even if choice is not equated with preference, cycles are still problematic. Many seemingly rational cycles treat preferences as partial, rather than all-things-considered evaluations. For instance, one might prefer an expensive shirt to a moderately priced one on the basis of style, and prefer the moderately priced shirt to a cheap shirt on the basis of durability, but prefer the cheap shirt to the expensive one on the basis of price. Here what seems to be a rational preference cycle is really a failure to integrate considerations of style, durability, and price into an all-things-considered value judgment.

Failures of evaluative discrimination can also seem to generate rational preference cycles. Suppose a vinophile, who cares only about how his wine tastes, cannot taste any difference between wine  $A$  and wine  $B$ , or between wine  $B$  and wine  $C$ , but can taste that  $C$  is better than  $A$ . It is tempting to think that the vinophile should be indifferent between  $A$  and  $B$  and between  $B$  and  $C$ , but should prefer  $C$  to  $A$ . A clearer understanding of the situation shows that this is incorrect. A person should only be indifferent between prospects when he lacks any reason,

on balance, for preferring one to the other. The vinophile, however, has reason to favor  $B$  over  $A$  since  $B$  is indistinguishable in taste from a wine superior to  $A$ . He also has reason to favor  $C$  over  $B$  since  $B$  is indistinguishable from a wine inferior to  $C$ . Properly speaking, then, the vinophile is not indifferent between  $A$  and  $B$  or between  $B$  and  $C$ : his preferences run  $B > A$ ,  $C > B$ , and  $C > A$ , but neither  $A \approx B$  nor  $B \approx C$  is true.

One might worry that the vinophile’s reasons seem insufficient to justify strict preferences. It would, for example, be silly for him to pay anything to trade a bottle of  $A$  for a bottle of  $B$  (unless he could convert the latter into a bottle of  $C$  for a small enough fee). While this is a legitimate concern, it tells against completeness rather than anticyclicality. When an agent cannot precisely discriminate the qualities of prospects on which his evaluations depend, or when these qualities are themselves vague or indeterminate, his preference ranking will be incomplete: for certain options, all three of  $A > B$ ,  $A \approx B$ , and  $B > A$  will fail. Sometimes both  $A > B$  and  $B > A$  will fail as well, in which case the agent has no views about the comparative merits of  $A$  and  $B$ . Alternatively, as in the vinophile example, the agent might determinately weakly prefer  $B$  to  $A$  even though he neither strictly prefers  $B$  to  $A$  nor is indifferent between them. So, while  $A \approx B$  and  $B > A$  each entail  $B > A$ , the latter is consistent with the falsity of both  $A \approx B$  and  $B > A$ . Besides indeterminacy or vagueness in values, incompleteness in preferences can arise via an imprecision in credences. In both sorts of cases it can be perfectly rational to have an incomplete preference ranking.

One response to these considerations, which is advocated in Isaac Levi (1980), Richard Jeffrey (1983), and Mark Kaplan (1983), is to construe  $SEU_3$ ’s completeness clause as a requirement of coherent extendibility. Instead of asking an agent to completely order acts, one demands merely that there be at least one complete preference ranking (usually there will be many) that satisfies all other requirements of rationality, and that agrees with the agent’s preferences whenever she has definite preferences. One then represents vague or indeterminate preferences by giving up the idea that the agent’s attitudes can be modeled by a single probability/utility pair (given a unit and zero for utility). Rather, there will be a representing set  $R$  of  $(P, u)$  pairs that agree with the agent’s preferences in the sense that, for any options  $A$  and  $B$ , each of  $A >$ ,  $A \approx$ ,  $A <$   $B$  hold iff, respectively,  $Exp_{p,u}(A) >$ ,  $\geq$ ,  $= Exp_{p,u}(B)$  holds for every  $(P, u)$  pair in  $R$ . Act  $A$  is unambiguously choice worthy only if maximizes expected utility relative to every  $(P, u)$  pair in  $R$ . It is admissible when it maxi-

mizes expected utility relative to some such pair. There is no generally accepted procedure for handling situations where no admissible act is unambiguously choice worthy. Some theorists would say that the agent's beliefs and desires are too indefinite to justify any choice as rational. Others, most notably Levi (1980), maintain that principles of decision making that outrun expected utility maximization come into play in this situation. For example, Levi allows agents to decide among admissible options using *maximin*, that is, by selecting the act whose worst consequence is at least as good as the worst consequence of any alternative.

COMPARATIVE PROBABILITY

The next principle of SEU forges a link between rational preference and rational belief. A wager on event  $E$  is an act of the form  $[c]_E \cup [d]_{\neg E}$  where  $[c] > [d]$ . Such a wager produces the desirable consequence  $c$  in every state consistent with  $E$  and the undesirable consequence  $d$  in every state consistent with  $\neg E$ . Intuitively, a person should prefer such a wager more strongly the more likely she takes  $E$  to be. More precisely, given any events  $E$  and  $F$ ,  $[c]_E \cup [d]_{\neg E}$  should be preferred to  $[c]_F \cup [d]_{\neg F}$  exactly if  $E$  is more probable than  $F$ . The following axiom is meant to ensure that this is so.

*SEU<sub>4</sub> Comparative Probability.* Assuming  $[c] > [d]$ , if the agent prefers  $[c]_E \cup [d]_{\neg E}$  to  $[c]_F \cup [d]_{\neg F}$ , she must also prefer  $[c^*]_E \cup [d^*]_{\neg E}$  to  $[c^*]_F \cup [d^*]_{\neg F}$  for any consequences such that  $[c^*] > [d^*]$ .

SEU<sub>4</sub> can seem implausible when the values of consequences vary with the world's state. Suppose, for example, that  $c$  and  $d$  are monetary fortunes that one might have in ten years, say  $c = \$500,000$  and  $d = \$400,000$ . Let  $E$  and  $F$  be hypotheses about the cumulative rate of inflation over the decade:  $E$  puts the figure at 60 percent, while  $F$  puts it at 10 percent. Even if one regards  $E$  as the more probable hypothesis, one might still prefer to wager on  $F$  since one's fortune will be worth more if  $F$  is true.

There are two standard responses to this problem. Savage (1972) maintains that decision problems of this sort, in which the values of consequences depend on states, are ill formed. He argues any such problem could be transformed into a well-formed decision by a suitable subdivision of consequences. In the previous example,  $c$  would be split into  $c_1 = "\$500,000$  after cumulative inflation of 60 percent," and  $c_2 = "\$500,000$  after cumulative inflation of 10 percent." Alternatively, one might opt for a state-dependent utility theory, which replaces SEU<sub>4</sub> by a weaker condition and allows the values of consequences

of vary with states (for details, see Karni 1993; Schervish, Seidenfeld, and Kadane 1990).

INDEPENDENCE AND THE SURE-THING PRINCIPLE

The most controversial tenet of SEU is the independence axiom:

*SEU<sub>5</sub> Independence.* Preference among acts that have exactly the same consequences when  $E$  is false should depend exclusively on what happens when  $E$  is true. If  $A_E \cup C_{\neg E}$  is preferred to  $B_E \cup C_{\neg E}$  for some act  $C$ , then  $A_E \cup D_{\neg E}$  is preferred to  $B_E \cup D_{\neg E}$  for all acts  $D$ .

To illustrate, consider the following act types, where  $c, d, c^*$  and  $d^*$  are known consequences, and  $x$  ranges over possible consequences.

	$S_1$	$S_2$	$S_3$
$A_x$	$c$	$d$	$x$
$B_x$	$c^*$	$d^*$	$x$

SEU<sub>5</sub> says that an agent's preference between  $A_x$  and  $B_x$  should not depend on  $x$ 's value. More generally, it requires agents to have well-defined conditional preferences:  $A$  is preferred to  $B$  in the event of  $E$  just in case  $A_E \cup C_{\neg E} > B_E \cup C_{\neg E}$  for some (hence any)  $C$ .

SEU<sub>5</sub> has the following intuitive consequence:

*Sure-Thing Principle:* Let  $E_1, E_2, \dots, E_n$  be mutually exclusive, collectively exhaustive events. If  $A$  is weakly preferred to  $B$  conditional on each  $E_p$ , then  $A$  is weakly preferred to  $B$  simpliciter. Moreover, if  $A$  is strictly preferred to  $B$  conditional on some event that is not judged certainly false, then  $A$  is strictly preferred to  $B$ .

Independence and the sure-thing principle have been quite controversial. Some apparent failures of SEU<sub>5</sub> arise in ill-formed decision problems whose states are not independent of acts. For example, imagine a man who has to drive home from a party where alcohol is being served. He likes to drink, but worries about getting home safely. Suppose he frames his decision like this:

	Car accident	No accident
Drink	-100	1
Teetotal	-101	0

Since the consequences of drinking are better than those of refraining both in the event of an accident and otherwise, it looks as if the sure-thing principle advocates

drinking, which is clearly bad advice given that drinking increases the probability of an accident. Problems of this sort led Jeffrey (1983) to develop an evidential version of decision theory in which independence is only valid for decisions in which acts provide no evidence about the occurrence of any state. Reflections on Newcomb problems, in which acts and states are causally independent but evidentially correlated, led causal decision theorists like Robert Stalnaker (1981), Allan Gibbard and William Harper (1978), and Brian Skyrms (1980) to insist that the two principles be restricted to decisions in which the choice of an act has no causal influence over states.

The most famous objections to  $SEU_5$  are the paradoxes of Maurice Allais (1953) and Daniel Ellsberg (1961), which seem to show that SEU rules out certain rational attitudes toward risk and uncertainty. An act involves risk when the agent knows the objective probabilities with which its consequences will obtain. It involves uncertainty when the agent's information allows a range of possible risk profiles for consequences.  $SEU_5$  entails that, insofar as decision making is concerned, all legitimate considerations of risk and uncertainty are fully captured in expected utilities. The Allais and Ellsberg paradoxes suggest, to the contrary, that risk and uncertainty are nonseparable quantities: one cannot express them as weighted averages of their values conditional on disjoint events. If this is correct, then an agent need not have any fixed preference between the act types  $A_x$  and  $B_x$  because  $x$ 's value might provide information about the relative risk or uncertainty of the two options, and this information might justifiably influence the agent's preferences.

The Allais paradox envisions an agent who chooses between  $A$  and  $A^*$  and then between  $B$  and  $B^*$  (with the know probabilities listed).

	0.10	0.01	0.89
$A$	\$1,000,000	\$1,000,000	\$1,000,000
$A^*$	\$5,000,000	\$0	\$1,000,000
$B$	\$1,000,000	\$1,000,000	\$0
$B^*$	\$5,000,000	\$0	\$0

Empirical studies show that people systematically violate independence when presented with such choices. They "play it safe" and select  $A$  over  $A^*$  in the first choice, but favor the riskier option  $B^*$  over  $B$  in the second. The standard rationale for these choices assumes (1) that there is more risk involved in choosing  $A^*$  over  $A$  than there is in choosing  $B^*$  over  $B$ , and (2) that it is rational minimize this risk even when doing so violates independence.

Ellsberg's paradox shows something similar with respect to judgments of uncertainty. Suppose a ball will be drawn at random from an urn that holds thirty red balls and sixty white or blue balls in an unknown proportion. One chooses between  $C$  and  $C^*$  and then between  $D$  and  $D^*$ .

	Red	White	Blue
$C$	\$100	\$0	\$0
$C^*$	\$0	\$100	\$0
$D$	\$100	\$0	\$100
$D^*$	\$0	\$100	\$100

Here most people prefer  $C$  to  $C^*$  and  $D^*$  to  $D$ . Interestingly, when gains are replaced by losses, people still violate independence, but both choices are reversed. People thus seem to prefer risk to uncertainty when they have something to gain, but prefer uncertainty to risk when they have something to lose. Those who regard Ellsberg's paradox as a counterexample to SEU maintain that such nonseparable preferences for risk over uncertainty or uncertainty over risk are entirely rational.

Some proponents of SEU (see Broome 1991) respond by arguing that the consequences in the Allais and Ellsberg paradoxes are underdescribed. For example, the standard pattern of preferences in Allais can be rationalized by noting that, when the 0.01 event occurs, agents who choose  $A^*$  over  $A$  may feel regret (because they passed up a sure thing), while those who choose  $B^*$  over  $B$  will feel no regret (because they probably would have ended up with nothing anyhow). For such agents, the decision matrix really looks like this:

	0.10	0.01	0.89
$A$	\$1,000,000	\$1,000,000	\$1,000,000
$A^*$	\$5,000,000	\$0 with regret	\$1,000,000
$B$	\$1,000,000	\$1,000,000	\$0
$B^*$	\$5,000,000	\$0 without regret	\$0

Likewise, if an agent feels uneasy when gains ride on uncertain prospects (or losses ride on risky prospects), then the correct description of the Ellsberg problem is this:

	Red	White	Blue
$C$	\$100	\$0	\$0
$C^*$	\$0 with uneasiness	\$100 with uneasiness	\$0 with uneasiness
$D$	\$100 with uneasiness	\$0 with uneasiness	\$100 with uneasiness
$D^*$	\$0	\$100	\$100

If these matrices accurately describe the decisions, then neither the Allais or Ellsberg paradoxes provide a genuine counterexample to  $SEU_5$ .

These sorts of rationalizing responses are weakened by their dependence on substantive assumptions about the psychology of risk, uncertainty, and regret that are not universally accepted (see Loomes and Sugden 1982, Weber 1998). An alternative is to argue that the usual preferences in the Allais and Ellsberg paradoxes are simply irrational. In Allais, for example, agents assume that the disparity in risk between  $A$  and  $A^*$  exceeds the disparity in risk between  $B$  and  $B^*$ . This may be a mistake. One way to determine differences in risk is to consider the costs of insuring against the incremental risk one incurs by trading one option for another. Someone who switches from  $A^*$  to  $A$  in Allais can offset this risk by purchasing an insurance policy that pays out \$1,000,000 contingent on the 0.01 event. Notice, however, that the risk incurred by switching from  $B^*$  to  $B$  can be offset by the same policy. Since a single policy eliminates both risks there is reason to think that the actual change in risk is the same in each case. Similar things can be said about the Ellsberg choosers, who implicitly assume that they decrease their uncertainty more by switching from  $C^*$  to  $C$  than they do by switching from  $D^*$  to  $D$ . So, if one measures disparities in risk or uncertainty by the costs of insuring against it, then SEU is safe from the Allais and Ellsberg examples.

Opponents of SEU will, of course, deny that risks should be measured by the costs of insuring against them. Ultimately, the issue will be resolved by the development of a convincing measure of risk. While there is a well-known theory of risk aversion within SEU, there is no universally accepted method for quantifying risk itself. The best work in this area, which builds on M. Rothschild and J. E. Stiglitz (1970), suggests that risk is indeed separable.

## ALTERNATIVES TO SEU

While subjective expected utility theory remains firmly ensconced as the standard model of rational decision making for individuals, a number of alternatives have been developed. One kind of approach seeks to relax independence while preserving most other aspects of SEU. Especially noteworthy here is the “generalized expected utility analysis” of Mark Machina (1982), and the “weighted utility model” of Soo-Hong Chew and Kenneth R. MacCrimmon (1979). Alternatively, one can reject maximizing conceptions of rationality altogether and see decision making as matter of *satisficing* relative to fixed constraints. For example, G. Gigerenzer et al. (1999) seek to replace the single all-purpose prescription to maximize expected utility by an ecological model of

rationality in which decision makers employ a set of simple, highly localized decision heuristics. These heuristics efficiently generate choices that produce desirable consequences in the contexts where they tend to be employed, but they can go badly awry when used in out of context. For discussion of further nonstandard decision theories, see Robert Sugden (2004).

Interesting though these alternatives are, none has seriously challenged the normative status of SEU. Though highly idealized, and far from adequate as a description of human behavior, SEU remains the best overall account of rational decision making.

## DECONSTRUCTION

Deconstruction is a philosophical-critical approach to textual analysis that is most closely associated with the work of Jacques Derrida in philosophy and the Yale School (Paul DeMan, J. Hillis Miller, Geoffrey Hartman) in literary theory and criticism. Derrida draws the term *déconstruction* from his interpretation of Martin Heidegger as a way to translate two Heideggerian terms: *Destruktion*, which means not destruction but a destructuring that dismantles the structural layers in a system; and *Abbau*, which means to take apart an edifice in order to see how it is constituted or deconstituted. For Derrida, then, deconstruction, in the context of philosophy, refers

to a way to think the structured genealogy of philosophy's concepts while exposing what the history of these concepts has been able to obscure or exclude. By displaying those concepts that the philosophical tradition both authorizes and excludes, a deconstructive reading seeks to work within the closed field of metaphysical discourse without at the same time confirming that field. Instead, it allows a text to dismantle itself by exposing the internal inconsistencies and implicit significations that lie concealed within the language of the text.

One way to understand deconstruction is in terms of a critique of the binary, oppositional thinking that, for Derrida, is central to the history of philosophy. This is to say, each term in the Western philosophical/cultural lexicon is accompanied by its binary opposite: intelligible/sensible, truth/error, speech/writing, reality/appearance, mind/body, culture/nature, good/evil, male/female, and so on. These oppositions do not peacefully coexist, however: one side of each binary opposition has been privileged and the other side devalued. A hierarchy has been established within these oppositions, as the intelligible has come to be valued over the sensible, mind has come to be valued over body, and so on. The task of deconstruction is to dismantle or deconstruct these binary oppositions: to expose the foundational choices of the philosophical tradition and to bring into view what the tradition has repressed, excluded, or—to use the Derridean terminology—marginalized.

As a critical practice, the deconstruction of these oppositions involves a double movement of overturning and displacement. The first phase initiates an overturning of the hierarchy that valorizes the term traditionally subordinated by the history of philosophy: for example, privileging writing over speech, signifier over signified, or the figurative over the literal. But this privileging is temporary and strategic, for in overturning a metaphysical hierarchy, deconstruction seeks to avoid reappropriating the same hierarchical structure; it is the hierarchical oppositional structure itself that underwrites the metaphysical tradition, and to remain within the binary logic of metaphysical thinking will only reestablish and affirm these oppositions. The second phase of deconstruction destabilizes the inversion by showing the arbitrary nature of the process of hierarchical valorization itself and displaces the hierarchy altogether by intervening with a new "undecidable" term—for example, *différance*, *trace*, *pharmakon*, *supplement*—that resists the formal structure imposed by the binary logic of philosophical opposition. Much of Derrida's early work involves elucidating the play of these undecidables: the play of *différance*, which both differs

and defers; the play of the trace, which is both present and absent; the play of the *pharmakon*, which is both poison and cure; the play of the supplement, which is both surplus and lack. By displaying the choices by means of which the philosophical tradition constitutes itself as a tradition, Derridean deconstruction opens the possibility to think difference other than as opposition and hierarchy.

Within literary criticism, the deconstructive method is used to show that the meaning of a literary text is not fixed and stable. Instead, by exploring the dynamic tension within a text's language, literary deconstruction reveals the literary work to be not a determinate object with a single correct meaning but an expanding semantic field that is open to multiple, sometimes conflicting interpretations.

## DE FINETTI, BRUNO

(1906–1985)

Bruno de Finetti, an Italian mathematician, was born in Innsbruck, Austria. On the death of his father, the six-year-old de Finetti and his mother moved to Trento (then in Austrian possession). At thirteen he suffered severe osteomyelitis in the left leg; surgery left him permanently lame. In 1923 he entered the Politecnico di Milano to study engineering, his father's and grandfather's profession. In his third year he transferred to the new University of Milan, from which he graduated in 1927 with a degree in applied mathematics. While still an undergraduate he published the first of a series of articles on Mendelian population genetics, developing the first mathematical model with overlapping generations.

From graduation until 1931 de Finetti worked at Rome's Istituto Centrale di Statistica. This was a period of intense and productive research, resulting in publication of a series of mathematical and foundational works on probability. The mathematical works made his name internationally known. The foundational works set out the subjectivist interpretation of probability that he was to advocate all his life. Two stand out: "Sul significato soggettiva della probabilità" (1931) and the remarkable "Probabilismo" (1931), remarkable not least, but certainly not only, for its fascist peroration.

Between 1931 and 1946 de Finetti worked in the actuarial office of the Assicurazioni Generali insurance

company in Trieste. At the same time he taught at the Universities of Padua and Trieste. In this period de Finetti's range widened to include actuarial and financial mathematics, economics, the automation of actuarial procedures (an interest reflected in the postwar years in his advocacy of computing and the use of simulation methods in statistics), and mathematics education. From the early 1950s his works became better known in the English-speaking world, thanks to the advocacy of the American statistician Leonard Savage. In 1947 de Finetti was appointed to the chair of financial mathematics in Trieste. In 1954 he moved to the Faculty of Economics at the University of Rome "La Sapienza"; in 1961 he transferred to the Faculty of Sciences in which he was a professor of the theory of probability until his retirement in 1976. De Finetti died in 1985.

In the 1970s de Finetti was active in Italian politics, standing as a parliamentary candidate for the Radical Party; for a while he edited the party's *Notizie Radicali*. On one occasion a judge ordered his arrest for antimilitarist campaigning.

What de Finetti's life exhibits is a concern for the tying of ideas to applications. The cornerstone of the radical subjectivist interpretation of probability, summed up in de Finetti's claim (in the preface to the English translation of his *Teoria delle probabilità* [1974]), "PROBABILITY DOES NOT EXIST" is that only concepts that can be given an operational, practical significance are meaningful. The radical subjectivist denies the meaningfulness of talk of objective, unknown probabilities. Probability is degree of belief/credence/conviction. De Finetti, as Frank Plumpton Ramsey before him (in work unknown to de Finetti), gave a Dutch book argument to show that a rational person's degrees of belief satisfy the axioms of the probability calculus: degrees of belief are revealed in the betting odds the person considers fair; a rational person does not bet so as to lose money with certainty; fair betting quotients avoid certain loss just if they satisfy the axioms of the probability calculus. Conditional probabilities are handled by conditional bets, bets that are canceled if a given event does not occur. (This led de Finetti to a logic of conditional events:  $B|A$  is true if  $A$  and  $B$  are both true, false if  $A$  is true and  $B$  is false, and neither if  $A$  is false, corresponding to the cases when the bet on  $B$  conditional on  $A$  is won, lost, and canceled. The idea has resurfaced from time to time in work on the indicative conditional of natural language and on production rules in computer science.)

One axiom is the subject of dispute. In Andrei Nikolajevich Kolmogorov's (1903–1987) *Foundations of the*

*Theory of Probability* (1933) the axiom that probabilities add across a countably infinite partition is adopted as mathematically expedient. De Finetti urged its rejection. Much is known of the consequences of giving up this axiom, but de Finetti's line has not won general acceptance.

Not a philosopher by training, de Finetti found parallels to his thought in the Italian pragmatists Mario Calderoni and Giovanni Vailati (a mathematician), and the man-of-letters Giovanni Papini. Later he saw Humean connections in his influential work on exchangeable and partially exchangeable sequences of events and random variables. A sequence of events of  $N$  types is partially exchangeable if the probability that  $n_1$  events of the first type,  $n_2$  events of the second type,  $\dots$ , and  $n_N$  events of the  $N$ th type all occur depends only on the numbers  $n_1, n_2, \dots, n_N$ . For exchangeability,  $N = 1$ . De Finetti sees this notion as the subjective analogue of (and correction to) talk of independent trials with unknown probability and as making mathematically precise David Hume's account of induction and causation. This comes about through representation theorems. Take the case of an infinite sequence of exchangeable events. From the probability, for various  $n$ , that  $n$  events all yield favorable outcomes, one can infer the probabilities of  $r$  favorable outcomes in  $n$  trials,  $0 \leq r \leq n$ . The distributions of these relative frequencies for different  $n$  tend, as  $n$  increases, to a limit distribution that functions exactly as a distribution over an unknown probability, so that the probability of any definable event is the expectation with respect to this distribution of the probability it would have were one dealing with a sequence of independent events of constant probability. Exchangeability is preserved as one conditionalizes on the outcomes of any finite number of trials, so, provided the initial limit distribution assigns a nonzero probability to an interval containing it, one obtains a sequence of limit distributions increasingly weighted toward the observed relative frequency as the number of observed instances increases. This encapsulates de Finetti's account of learning from experience and inductive inference, his "translation into logic-mathematical terms of Hume's ideas" (1938, p. 194).

With the acceptance by today's philosophers of science of semantic realism and, increasingly, pluralism in the philosophy of probability, de Finetti's eliminativist reading of what is now called the de Finetti representation theorem is little in favor. But there has been a huge increase in the application both to scientific reasoning generally and to statistics in particular of the subjectivist

interpretation of probability, usually under the name Bayesianism.

## DEFINITION

The problems of definition are constantly recurring in philosophical discussion, although there is a widespread tendency to assume that they have been solved. Practically every book on logic has a section on definition in which rules are set down and exercises prescribed for applying the rules, as if the problems were all settled. And yet, paradoxically, no problems of knowledge are less settled than those of definition, and no subject is more in need of a fresh approach. Definition plays a crucial role in every field of inquiry, yet there are few if any philosophical questions about definition (what sort of thing it is, what standards it should satisfy, what kind of knowledge, if any, it conveys) on which logicians and philosophers agree. In view of the importance of the topic and the scope of the disagreement concerning it, an extensive reexamination is justified. In carrying out this conceptual reexamination, this article will summarize the main views of definition that have been advanced, indicate why none of these views does full justice to its subject, and then attempt to show how the partial insights of each might be combined in a new approach.

All the views of definition that have been proposed can be subsumed under three general types of positions, with, needless to say, many different varieties within each type. These three general positions will be called "essentialist," "prescriptive," and "linguistic" types, abbreviated as "E-type," "P-type," and "L-type," respectively. This clas-

sification is not intended as a precise historical summary, but merely as a useful schema for stating some of the problems and disputes. Thus, some outstanding philosophers may very clearly belong to one of these types. Others who, for the purposes of this article, are placed in a certain class hold positions varying considerably from the presentation to be given. It must therefore be borne in mind that not all the criticisms that will be made apply to all philosophers included in the class being criticized. Writers whose accounts of definition fall largely under the E-type include Plato, Aristotle, Immanuel Kant, and Edmund Husserl. Those who support P-type views include Blaise Pascal, Thomas Hobbes, Bertrand Russell, W. V. Quine, Nelson Goodman, Rudolf Carnap, C. G. Hempel, and most contemporary logicians. Supporters of L-type views include John Stuart Mill (in part), G. E. Moore (in part), Richard Robinson, and most members of the school of linguistic analysis.

According to essentialist views, definitions convey more exact and certain information than is conveyed by descriptive statements. Such information is acquired by an infallible mode of cognition variously called “intellectual vision,” “intuition,” “reflection,” or “conceptual analysis.” Prescriptive views agree with essentialism that definitions are incorrigible, but account for their infallibility by denying that they communicate information and by explaining them as symbolic conventions. Although linguistic views agree with essentialism that definitions communicate information, they also agree with prescriptivism in that they reject claims that definitions communicate information that is indubitable. The linguistic position is that definitions are empirical (and therefore corrigible) reports of linguistic behavior.

## ESSENTIALISM

An essentialist account was first proposed by Socrates and Plato. Socrates is renowned for having brought attention to the importance of definitions. His favorite type of question, “What does (virtue, justice, etc.) mean?” became the characteristic starting point of philosophical inquiry. But Socrates did not make clear what kind of answer he was looking for. In Plato’s *Euthyphro* Socrates is reported to have said that the kind of answer he expected to his question “What is piety?” was one giving an explanation of “the general idea which makes all pious things to be pious” and “a standard to which I may look and by which I may measure actions.” He did not explain, however, what he meant by “idea” and “standard” nor how one produces an “idea” or a “standard” when one is defining a term. Richard Robinson, in his book *Plato’s*

*Earlier Dialectic* (p. 62), has suggested that the question “What is X?” is more ambiguous than Socrates realized and that it may be answered in all sorts of ways, depending on the context in which it is asked.

PLATO. Plato’s attempts in his later dialogues to explain the meaning of the Socratic question “What is X?” constitute the celebrated Theory of Forms, the trademark of Platonic metaphysics and epistemology. In a passage of central importance (*Republic* VI), Plato distinguished two kinds of objects of knowledge (sensible things and forms) and two modes of knowledge (sense perception and intellectual vision). Sensible things are objects of opinion, while abstract forms are objects of philosophical knowledge. Physical objects, shadows, and images are imperfect and ephemeral copies of forms; our perceptual knowledge of them is an inaccurate approximation to our knowledge of their abstract archetypes. Definitions describe forms, and since forms are perfect and unchanging, definitions, when arrived at by the proper procedure, are precise and rigorously certain truths. Empirical statements describe objects of perception and are therefore only more or less reliable approximations to truth.

*Models and copies.* Plato’s analogy between definitions and empirical descriptions—an analogy upon which all E-type theories of definition rest—is supplemented by a second analogy between the relation of a model to a copy and the relation of a definition to an individual predication. This analogy was suggested by Socrates when he asked for “a standard to which I may look and by which I may measure actions.” Plato describes the process of coming to know as if it were like the procedure of a craftsman producing a piece of sculpture or a house. The sculpture is a “copy” of the subject who models for it; the house is in one sense a “copy” of the architect’s blueprint, in a somewhat different sense a “copy” of a small-scale model, and in still a third sense a “copy” of the idea in the mind of the builder. Plato’s frequent references to the arts and crafts in his exploration of conceptual problems indicate that the analogy of the model-copy relation plays a central role in his theory of knowledge.

Thus, Platonic essentialism provides two sets of answers (both of which rest on metaphors) to the questions “What kind of statements are definitions?” “What purpose do they serve?” and “How are they to be judged as good or bad?” It suggests primarily that definitions are descriptions of objects that are somehow analogous to tables, chairs, and other familiar things; that these definitions serve the purpose of providing descriptive informa-

tion about their objects; and that they are confirmed by a mode of cognition somehow analogous to sense perception, yet independent of the sensory organs. Secondly, Platonic essentialism specifies the relation between the objects of definitions and those of empirical descriptions by characterizing the former as models of which the latter are “copies.”

*Adequacy of the model metaphor.* Metaphors are apt or inapt, illuminating or misleading, according to two criteria: (1) the number and importance of the known points of resemblance between the things compared; and (2) the number and importance of previously unnoted facts suggested by the metaphor. To what extent does Plato’s metaphor of the unseen model satisfy these criteria?

The primary term of comparison in Plato’s metaphor is the abstract form or universal that a definition allegedly describes. The secondary term is the model for a painting or, alternatively, a tailor’s pattern. As the painter looks to his model and the tailor to his pattern, the philosopher can look to the forms for the specifications that identify things as instances of one class rather than another, as well as for exact information about the properties of that class.

What are the known points of resemblance between forms and models, on which this metaphor is grounded? Merely to ask this question is already to see that the metaphor is defective from the start, since there cannot possibly be *any* literal points of comparison. The Platonic forms, unlike models and patterns, have no observable properties by virtue of which they can be said to “resemble” anything at all. Thus, if the model metaphor has any value, it must lie entirely in what the metaphor suggests, rather than in its literal grounds.

Primarily, the model metaphor suggests that definitions and their corollaries constitute all there is to knowledge. Whenever a question of fact or of judgment is raised in the Platonic dialogues, it is treated as a problem of definition. For example, when, in the *Euthyphro*, Socrates and Euthyphro argue about the propriety of a son’s prosecuting his father for murder, Socrates proceeds as though the issue could be settled by arriving at a clear definition of piety—as though one could then look at the definition, look at the action, and decide whether they coincide. We can identify a portrait or a garment by comparing it with its model or its pattern, but we cannot classify and judge an action in the same way. Description and evaluation are seldom matters of identification by comparison with a pattern. In this respect Plato’s essentialism is misleading rather than illuminating.

The metaphor of the unseen model also suggests that definitions provide us with precise and rigorous knowledge in the way that blueprints make possible a high degree of uniformity and precision in productive arts such as architecture. But definitions increase precision only when they change the original meanings of words for technical purposes. Generally speaking, a definition can be no more precise than the concept it defines, at the risk of shifting to a different concept. Our concept of what constitutes an adult is vague; if we try to make it precise by specifying an exact age at which childhood is divided from adulthood, we merely lose sight of what we started out to talk about by replacing the concept of maturity with that of having passed a certain birthday.

The model metaphor is not entirely misleading; it suggests at least one genuine resemblance between the terms it compares. The relation between definitions and empirical descriptions is, in one respect, rather similar to the relation between portraits and their models. We judge a portrait (to some extent) by noting whether the portrait looks like the model; we verify the empirical description “This table is round” by looking at the table to see whether it has the properties definitive of tables and of roundness. But if we are asked, “Is that person a good model?” or “Is that definition a good definition?” we cannot look toward anything of which the model is himself a portrait, and we cannot look at a definitional form of which the particular definition is itself an instance. Definitions are not evaluated in the same way as empirical descriptions, just as models are not judged in the same way as their portraits. Thus the analogy between definitions and empirical descriptions from which Platonic essentialism starts eventually contradicts itself.

ARISTOTLE. One can find in Aristotle’s works anticipations of every later theory of definition, but he gave high priority to his own brand of essentialism, whereby he explained the nature of “real” as distinguished from “nominal” (that is, prescriptive or linguistic) definition. Like Plato, Aristotle stressed the similarity between definitions and statements of fact, and he assumed that definitions convey precise and certain information. But Aristotle employed a different supporting metaphor to explain the special nature of definitions. The most noteworthy feature of his many discussions of definition is his insistence that a real definition should provide a causal explanation of the thing defined. In the *Physics*, Aristotle distinguished four types of causes—formal, material, final, and efficient. He characterized the first three types as “internal,” while efficient causes are (usually) “external” to their effects. Internal causes are not available to

public inspection, but must be discovered in abstract intuition. The causal explanation provided by a real definition is in terms of one or more of these three internal types of cause.

**Definition and causality.** It is not easy to explain just what Aristotle meant by “internal cause.” Part of what he seems to have meant is that, unlike “incidental” causes, internal causes are necessary for their effects. But it is by no means clear what sense of necessity is involved in this instance. To explain this necessity as causal would be a case of circular reasoning. On the other hand, to say that the necessity is logical seems only another way of saying that the effect is definable in terms of its cause, which is again circular reasoning. As an example of a causal definition, Aristotle defined a lunar eclipse as the privation of the moon’s light because of the interposition of the earth between the moon and the sun (*Posterior Analytics* 90a). This example confirms the suggestion that for something to be an internal causal is for it to be part of a definition. But the difficulty then arises that definition has been explained by internal causality, internal causality by necessity, and necessity by definition. Thus, Aristotle’s eclipse leaves us in the dark about definition.

**Classification and explanation.** The trouble is that the idea of internal causality is a metaphor. An essential cause is not “internal” to the thing defined as a kernel is inside a nut, but only metaphorically “inside.”

This metaphor suggests two important but dubious principles: that scientific knowledge consists entirely of definitions and their corollaries and that systematic classification is identical with theoretical explanation. If to define a term is, at the same time, to provide a causal explanation of what it denotes and if the classification of a thing in terms of its species and differentia is sufficient for deducing the laws of its behavior, then the work of scientific inquiry is completed when a comprehensive system of classification has been constructed. Thus, Aristotle wrote in the *Posterior Analytics* (90b) that “Scientific knowledge is judgment about things that are universal and necessary, that the conclusions of demonstration *and all scientific knowledge* follow from the first principles” and that “the first principles of demonstration are definitions” (italics added).

That scientific knowledge is not entirely derivable from a set of definitions and that systematic classification is only one small aspect of scientific procedure need hardly be argued. Aristotelian concepts of causality and explanation have been almost completely expunged from modern science, and causes are conceived of in quite different ways. But it is not the archaic character of Aristotle’s

use of “cause” and “explanation” that concerns us here. It is largely a matter of terminological convenience whether we continue to use these words in the Aristotelian manner or confine them to the procedures of modern physical science. In regard to the problem of clarifying the functions and criteria of definitions, however, Aristotle’s claim that definitions reveal the internal causes of their definienda must be criticized not as a false, but as a misleading, metaphor, for it dissolves the very distinctions which it is intended to explain—namely, the distinction between definitions and empirical statements of fact, that between the method of evaluating definitions and the method of confirming factual hypotheses, and that between the distinctive functions of definition and the general aims of scientific inquiry.

**IDEAS AND CONCEPTS.** A third metaphor that has been employed in the support of E-type views of definition originated in Cartesian dualism. René Descartes himself leaned toward a prescriptive account of definition, which will be considered later. But John Locke, Kant, Husserl, and other philosophers who accepted the Cartesian division between the “inner world” of the mind and the “outer world” of physical events took the essentialist position that philosophical inquiry should provide information about a special set of objects (“ideas” for Locke, David Hume, and Husserl; “concepts” for Kant, Heinrich Rickert, and G. E. Moore) discoverable by an infallible mode of cognition (“reflection” for Locke and Husserl; “analysis” for Hume, Kant, Rickert, and Moore).

According to Locke, the outer world of material objects and their motions is describable by the laws of physics, while the inner world of ideas is describable by the laws of psychology that are discovered by reflection on the contents of the mind. These contents are simple and complex ideas; the task of philosophy is to analyze complex ideas into their simple elements and to describe their mode of combination.

Kant distinguished between “analytical” and “synthetic” definitions, regarding the former as the identification of the simple elements (predicates) out of which concepts are formed by the understanding and the latter as the formation of rules of serial order that provide the synthetic a priori postulates of mathematics and physics.

The philosophers under consideration, like their predecessors, assumed that definitions convey knowledge of objects (ideas, images, essences, concepts, or meanings) whose special nature guarantees precision and certainty and that this remarkable kind of knowledge is acquired through a special mode of cognition (reflection,

introspection, intuition, or conceptual analysis). The literal content of the private-world metaphor thus seems to be identical with that of the essentialist metaphors already considered. The differences between the private-world and essentialist metaphors (other than terminological ones) must be sought in the suggestive implications of the metaphor. But there is an important difference between philosophers such as Locke, Hume, and Husserl, who reserve the word *definition* for conventions of word usage and do not consider their introspective analyses of ideas to be definitions, and those such as Kant, Rickert, and C. I. Lewis, who regard philosophical definitions as products of conceptual analysis.

Both groups employ the Aristotelian distinction between real and nominal definitions, except that members of the first group avoid calling the results of their introspective studies “definitions” because they think of them as descriptions of the workings of the mind analogous to descriptions of a clock that has been taken apart for inspection. They think of the special mode of cognition by means of which they discover how simple ideas are organized into complex ideas as inner vision or grasp, which is analogous to sight and touch. But members of the more abstractly minded group compare the special faculty by which real (or analytic or explicative) definitions are discovered to the experience (familiar to logicians and mathematicians) of recognizing logical relation, rather than comparing it to any type of sense perception. They speak of “understanding the meanings of words,” of “logical analysis,” of “understanding what is contained in a concept,” rather than of seeing or grasping the “contents of the mind.” There are, then, two kinds of world imagined by these theorists: a world of privately visible or tangible ideas, sense data, secondary qualities, and so forth and a world of abstract concepts or meanings. Some, like Kant, Husserl, and, most systematically, C. I. Lewis, posit both kinds of worlds.

What then do these two metaphors suggest, and how illuminating are their implications? The metaphor of the private world of sense data that is allegedly described by definitions of complex ideas suggests that such definitions, like reports of hallucinations, dreams, and other private experiences, must be taken at face value (provided that they are sincerely and consistently expressed), since they cannot be checked by public observation. This would account for the unchallengeable character of definitions and their analytic corollaries, in contrast to the corrigibility of empirical statements. But this view deprives definitions of any claim to objective validity and entails that every person has a right to his own defini-

tions, in the same way that everyone has a right to his own dreams.

The metaphor of the world of concepts and meanings also attributes a self-certifying character to definitions but fares better with respect to the commonsense fact that we balk at some definitions and accept others—for the recognition of logical relations, no matter how intuitive, is a socially shared experience. We immediately and privately understand, see, or grasp that a statement of the form  $P \cdot Q$  implies a statement of the form  $Q$ , but we can also argue the fact and summon evidence (in the form of postulates of a logical system) to prove it. But this metaphor, which of all those we have considered comes closest to not being a metaphor at all and blends imperceptibly into a prescriptive concept of definition, suggests both too much and too little. It suggests that definitions are logical truths and possess logical certainty. But although some definitions are worse than others, all logical truths are normatively equal. Moreover, the metaphor fails to indicate how definitions can be evaluated other than by their formal consistency (the standard by which we confirm a system of logical truths). Yet a definition of a cow as a three-legged animal would be universally rejected on grounds having nothing to do with inconsistency. The denial of a logical truth can be shown to involve a contradiction, but the denial of a definition leads to contradiction only if one has already accepted the definition. Although consistency is a sufficient condition for a system of logical truths, it is merely a necessary condition for sound definitions; yet no additional conditions are provided by logistic phenomenalism.

## PRESCRIPTIVISM

E-type views claim that definitions are statements and that they make assertions that can be pronounced true or false. Essentialists, however, have difficulty explaining how and why definitions differ from ordinary statements of fact, and hence they fall back on metaphors. P-type theories avoid this trouble by denying that definitions are statements of any kind. The prescriptivist assimilates definitions to imperative sentences rather than to declarative sentences and endows them with the function of syntactic or semantic rules for prescribing linguistic operations.

There are two main varieties of prescriptivism. The nominalist variety explains definitions as semantic rules for assigning names to objects, while the formalist variety regards definitions as syntactic rules for abbreviating strings of symbols. P-type views of definition can be traced back to the Greek Sophists and Sceptics, but this article will concentrate on the modern sources of these

views. The rebirth of science in the seventeenth century was accompanied by a sweeping rejection of medieval thought, in particular the medieval concept of definition as the penetration by metaphysical intuition into a realm of changeless forms. The nominalist theories of language employed by Sophist and Cynic contemporaries of Plato to undermine belief in the objectivity of knowledge, and again by the more radical medieval Scholastics to subvert the control of theology over science, became, in the seventeenth century, a cornerstone of the reconstruction of knowledge on a new scientific foundation.

Seventeenth-century writings on definition are not entirely free of the influence of classical essentialism. Seventeenth-century prescriptive theories of definition try to avoid the obscurities of essentialism by repudiating the informative role of definitions, but they cannot provide adequate criteria for distinguishing good definitions from bad without presupposing some sort of informative role for them.

**NOMINALISM.** For Francis Bacon and Hobbes, definitions possessed a therapeutic function, as a means of clearing up or avoiding ambiguous, vague, and obscure language. Regarding semantic confusion as the main source of intellectual trouble, they proposed to clear the way for a new system of knowledge by subjecting existing concepts to the test of definitional reduction to observable and measurable properties. Definition was thus a surgical knife for cutting away metaphysical encrustations, as described by Bacon in paragraph 59 of the *Novum Organum*:

But the idols of the market-place are the most troublesome of all: idols which have crept into the understanding through the alliances of word and names, and this it is that has rendered philosophy and the sciences sophistical and inactive. Whence it comes to pass that the high and formal discussions of learned men end oftentimes in disputes about words and names: with which it would be more prudent to begin, and so by means of definitions reduce them to order.

Thomas Hobbes also stressed the clarifying role of definitions, taking geometry as his model. In the *Leviathan* he wrote:

Seeing then that truth consists in the right ordering of names in our affirmations, a man that seeketh precise truth had need to remember what every name he useth stands for ... or else he will find himself entangled in fforads as a bird in lime twigs. And therefore in geometry, which

is the only science which it hath pleased God hitherto to bestow on mankind, men begin at settling the significations of their words: which settling of significations they call *definitions*, and place them in the beginning of their reckoning.

Definitions thus clear up ambiguities and “settle significations,” rather than communicate information about a realm of essences. They are introduced at the beginning of inquiry, as in geometry, rather than at the culmination of inquiry, as in metaphysics and Aristotelian natural science.

According to Hobbes, all knowledge consists in the “right ordering of names in affirmation.” A proposition connects one name to another, and an inference adds or subtracts one proposition from another. The structure of scientific thought thus maps the structure of the physical world. It would seem then that, for Hobbes, all scientific knowledge is derivable from definitions. Yet Hobbes also stressed the role of perception in knowledge. The solution to this paradox lies in Hobbes’s conception of naming. All inquiry is deductive except for the assignment of names to things, and it is to the assignment of names that we must look for the empirical sources of knowledge. But it follows that definitions as assignments of names must be as informative for Hobbes as they are for Plato or Aristotle. This conclusion leads to a further paradox, for, according to Hobbes, definitions provide no information at all; they express conventional decisions to use particular signs as names of particular objects.

There is an ambiguity in Hobbes’s account of definitions that must hamper any attempt to reduce definitions to assignments of names. In order to make definitions entail all the propositions of scientific knowledge, Hobbes had to include, in the notion of naming, all the cognitive functions that we ordinarily distinguish from naming. He first compared the highly abstract and sophisticated definitions of concepts in mathematics and natural science to simple naming procedures such as baptism. Then, in order to account for the conspicuous differences between the two kinds of procedures, he was compelled to reinject into the notion of naming the very distinctions he set out to eliminate. The reduction of definitions to assignments of names only *appears* to solve the problem of whether definitions are informative: It first suggests that definitions are as arbitrary as acts of naming and then suggests that naming is, after all, not always arbitrary.

**EARLY FORMALISM.** Although the language used by the Cartesians of the seventeenth century in discussing defi-

nitions was similar to that of Bacon and Hobbes, their emphasis and direction of interest was different. Bacon and Hobbes were primarily concerned with the role of definitions in achieving semantic clarity, the Cartesians were more interested in the role of definitions in deductive inference. They developed a conception of definitions as theoretically dispensable abbreviations whose value lies solely in the notational economy they make possible. Cartesian references to “names” are rather misleading since, unlike Hobbes, the Cartesians did not regard assignment of names as the initial and fundamental process of inquiry from which the rest of knowledge is derived. This role was taken over by axioms and postulates that relate “simple” (i.e., indefinable) terms to each other, definitions then being introduced as rules for substituting brief expressions for logical complexes of simple terms.

Descartes did not give much attention to the subject of definition. In rejecting classical syllogistic logic as the framework of scientific inference, he abandoned the emphasis on terms or classes as the basic units of inference in favor of propositional units. The simplest inference became, for Descartes, the intuitive recognition of the implication of one proposition by another. Consequently, postulates replaced definitions as the foundation of deductive science, and essential definitions ceased to represent the highest goal of knowledge.

Pascal’s analysis of the nature and function of definitions made explicit the view of definition implicit in Descartes’s theory of knowledge. The main elements of Pascal’s discussion are formalistic. However, it is not free of ambiguity with respect to the purely notational role of definitions as against the informative role ascribed to them by essentialists.

Pascal’s theory of definition is expounded in a brief essay, *De l’esprit géométrique* (*Oeuvres*, 14 vols., Léon Brunschvicg and E. Boutroux, eds., Paris, 1904–1914). He began by distinguishing two types of definition, *définitions de nom*, which he claimed to be the only type appropriate in science, and an unnamed type that seems to be what Aristotle called “real,” the type favored by essentialists, about which he thereafter says nothing more.

*Définitions de nom* are said to be “mere impositions of names upon things that have been clearly indicated in perfectly intelligible terms,” as, for example, the definition of “even number” as “number that can be divided by two without remainder.” Such definitions, Pascal claimed, are conventional labels that need have nothing in common with the things they name. They communicate no information about their *nominata*, expressing merely the deci-

sion of the writer to use them in the prescribed manner. The sole limitation on *définitions de nom* is that they be internally and mutually consistent.

When he discussed the methodology of definition, Pascal no longer regarded the relation between language and reality as purely conventional. We must make sure “not to define things that are clear and are understood by everyone.” Geometry provides the model for definitional procedure. “It does not define such things as *space, time, motion, number, equality* ... because these terms so naturally designate the things to which they refer, for those who understand the language, that the intended clarification would be more likely to obscure them than to instruct.” One might think that, in saying “space naturally designates” its referent, Pascal meant that the word *space* is so familiar that everyone understands what it signifies. But why, then, should he interdict any definition of “space”? If definitions are notational conventions, there could be no objection to stipulating a new use of the word. Indeed, the ordinary use of “space” is quite different from its technical use in mathematics. Why, then, is it improper to define either the ordinary or the mathematical use? Surely, Pascal was not thinking of the word *space*, but of space itself as an irreducible entity that cannot be analyzed into simpler components, and if so, then he was thinking of definition not as a notational convenience, but as an informative mode of analysis.

The Cartesian theory of knowledge by which Pascal was guided conceives of the world as a system of elements combined according to mathematical laws to form complex objects and events. While Descartes stressed the analytical reduction of complex propositions to simple ones (i.e., axioms), Pascal joined definitions to axioms as the basis from which the deductive reconstruction of science should start. But common to all the Cartesians is the assumption that knowledge is a mathematical mapping of the structure of nature. In the light of this epistemological atomism, the conventional character attributed to definitions contrasts sharply with the requirement that they correspond to an antecedent natural order—a requirement that leads back to essentialism.

MODERN FORMALISM. The formalistic conception of definitions as rules of notational abbreviation was only vaguely anticipated by seventeenth-century philosophers, who failed to separate this purely syntactic procedure from epistemological considerations such as mapping the order of nature. Only in recent times have formalistic discussions of definition been purified of epistemological assumptions, by (among others) Russell, Alfred North

Whitehead, W. V. Quine, Rudolf Carnap, C. G. Hempel, and Nelson Goodman. But it remains doubtful whether this purely formalistic view either is or can be consistently maintained.

Russell and Whitehead, in *Principia Mathematica* (Vol. I, p. 11), define a definition as follows:

A definition is a declaration that a certain newly introduced symbol or combination of symbols is to mean the same as a certain other combination of symbols of which the meaning is already known. ... It is to be observed that a definition is, strictly speaking, no part of the subject in which it occurs. For a definition is concerned wholly with the symbols, not with what they symbolize. Moreover, it is not true or false, being the expression of a volition, not of a proposition.

This characterization of definition is not consistently syntactical. It defines *definition* in terms of sameness of meaning, while claiming that a definition “is concerned wholly with the symbols, not with what they symbolize.” Later in the same passage, Russell and Whitehead declare:

In spite of the fact that definitions are theoretically superfluous, it is nevertheless true that they often convey more important information than is contained in the propositions in which they are used. This arises from two causes. First, a definition usually implies that the *definiens* is worthy of careful consideration. ... Secondly, when what is defined is ... something already familiar ..., the definition contains an analysis of a common idea. (p. 12)

The first and last sentence in the passage above express a nonsyntactical attitude toward definitions. Definitions turn out to be highly informative, and we seem to have returned to an essentialist view of the matter. But a further qualification has been attached, namely, “when what is defined is ... something already familiar.” In fact, two types of definition are being considered, one being a rule of notational abbreviation and the other an “analysis of an idea.” But if some definitions are “analyses of ideas” and are highly informative, then these are the important kinds of definitions, and the formalist view proclaimed at the outset loses its force.

Similar difficulties attend the efforts of other modern logicians to deal with the problem of definition from a purely formal point of view. Thus, W. V. Quine, after asserting that “a definition is a convention of notational abbreviation,” qualified his statement as follows:

Although signs introduced by definition are formally arbitrary, more than such arbitrary notational convention is involved in questions of definability; otherwise any expression might be said to be definable on the basis of any expressions whatever. ... To be satisfactory ... a definition ... not only must fulfill the formal requirement of unambiguous eliminability, but must also conform to the traditional usage in question. (“Truth by Convention,” in *Readings in Philosophical Analysis*, edited by H. Feigl and W. Sellars, New York, 1949, p. 252)

Nelson Goodman took the same position and fell into the same difficulties:

In a constructional system ... most of the definitions are introduced for explanatory purposes. ... In a formal system considered apart from its interpretation, any such definitional formula has the formal status of a convention of notational interchangeability once it is adopted; but the terms employed are ordinarily selected according to their usage, and the correctness of the interpreted definition is legitimately testable by examination of that usage. (*The Structure of Appearance*, p. 3)

In common with many other logicians, Quine and Goodman distinguish between the function of definitions “in a formal system” and their function when the system is interpreted—that is, when definite meanings are assigned to the symbols of the system. But this distinction overlooks the fact that from a purely formal standpoint, there is no such thing as a definition at all. Before it is interpreted, the formula that we interpret as a definition is just a string of marks. From a “purely formal standpoint,” not only is there no difference between a definition and a notational abbreviation, but there is no difference between a definition and *any* other kind of formula. There are only various strings of marks, some permitted by the rules of formation of the system, others excluded by these rules. Consequently, the distinction made by Quine and Goodman between definitions in a formal system and those in an interpreted system is seriously misleading.

Rudolf Carnap and C. G. Hempel have tried to clarify the difference between informative definitions and mere notational abbreviations by distinguishing between “old” and “new” concepts. Definitions of old concepts are called “explications” by Carnap and “rational reconstructions” by Hempel, while both call definitions of new concepts “notational conventions.” When we are

“explicating” or “reconstructing” a concept, our definitions are subject to evaluation by the criteria of conformity to usage and increase of precision (Rudolf Carnap, *The Logical Syntax of Language*, p. 23). When definitions are introduced solely for the purpose of abbreviation, only the criterion of consistency applies. One must therefore wonder why Carnap and Hempel should bother to call notational abbreviations “definitions,” since they have nothing whatever in common with explications.

Perhaps the answer to this question lies in the logical difficulties lurking within the notion of explication. What does it mean to “reconstruct” or “explicate” a concept, and what precisely is the difference between “old” and “new” concepts? If definitions of old concepts must conform to established usage, are they not true or false statements about language usage, in which case the distinction between definitions and empirical statements disappears? These problems lead naturally into the linguistic theory of definition.

### LINGUISTIC THEORIES

Anticipations of a linguistic view of definition may be found in classical writings (for example, in Aristotle’s discussion of “nominal definition”) and in the nominalist and formalist positions previously considered. But while early nominalism attempted to reduce all the varied functions of words to that of proper names and thus to reduce meaning to the arbitrary assignment of a name to an object, formalism added linguistic considerations as an inessential afterthought. The first step from nominalism to an L-type view proper was taken by John Stuart Mill, although his formulations are permeated with elements of both nominalism and essentialism. A further step was taken by G. E. Moore, but Moore’s discussion also contains a heavy strain of essentialism. The clearest formulation of the linguistic view was provided by Richard Robinson in his book *Definition*, which has the distinction of being the only book in the English language devoted to this subject.

In his *System of Logic*, J. S. Mill defined “definition” as follows: “The simplest and most correct notion of a Definition is, a proposition declaratory of the meaning of a word: namely, either the meaning which it bears in common acceptance, or that which the speaker or writer ... intends to annex to it” (10th ed., p. 86).

Mill then explained that a definition is a “verbal proposition” that “adds no information to that which was already possessed by all who understood the name (defined)” — a tautology that Mill mistook for an important observation. But, unlike the thoroughgoing prescrip-

tivist, Mill did not regard definitions as purely conventional stipulations, at least insofar as terms in general use are concerned:

It would, however, be a complete misunderstanding of the proper office of the logician in dealing with terms already in use, if we were to think that because a name has not at present an ascertained connotation, it is competent to anyone to give it such a connotation at his own choice. The meaning of a term actually in use is not an arbitrary quantity to be fixed, but an unknown quantity to be sought. (p. 91)

At this point, Mill conceded that some definitions are not mere “declarations” but convey some kind of information about “unknown quantities to be sought.” Mill gave two reasons for this departure from prescriptivism. The first consideration involves him in a tug of war between nominalist and linguistic theories. “Since names and their significations are entirely arbitrary, such (verbal) propositions are not, strictly speaking, susceptible of truth or falsity, but only of conformity or disconformity to usage or convention; and all the proof they are capable of is proof of usage” (p. 92).

In this instance, Mill first denied and then asserted that definitions are informative. If “all the proof they are capable of is proof of usage,” then they *are* capable of proof after all, despite his initial disclaimer of this possibility.

Mill’s second reason for ascribing at least a quasi-informative function to some definitions resembles, to some extent, the phenomenalist conception of definition as analysis of complex ideas into simple constituents. Mill wrote:

A name, whether concrete or abstract, admits of definition, provided we are able to analyze, that is, to distinguish into parts, the attribute or set of attributes which constitutes the meaning both of the name and of the corresponding abstract. ... We thus see that to frame a good definition of a name in use is not a matter of choice but of discussion ... not merely respecting the usage of language, but respecting the properties of things, and even the origin of these properties. (p. 91)

The source of Mill’s shifts of emphasis and inconsistencies lies in the ambiguity of his notion of meaning. At times he identified the meaning of a term with the object it “names,” at other times with the customary usage of the word, and at still other times with an abstract object or “idea” capable of being divided into simpler parts. Thus,

depending on which conception of meaning he had in mind, he thought of a definition as the stipulation of a name, a report of linguistic usage, or the analysis of a complex idea into its constituent parts.

G. E. MOORE. The extent to which G. E. Moore's approach to definitions can properly be called "linguistic" is debatable. Moore placed less stress on the linguistic aspect of definition than later philosophers such as Gilbert Ryle, Peter Frederick Strawson, and Robinson, who were influenced by Moore's analytical method. For Moore, as for Socrates, the clarification of language was only a means toward the discovery of deeper philosophical truths. But there can be no doubt that Moore inspired others to concern themselves with language and that his painstaking attention to the nuances of words was the most distinctive feature of his work.

In his *Principia Ethica*, Moore characterized "analytical" definitions (the kind produced by philosophical analysis) as follows: "Definitions of the kind that I was asking for, definitions which describe the real nature of the object or notion denoted by a word and which do not merely tell us what the word is used to mean, are only possible when the object or notion is complex" (p. 7).

In order to indicate the kind of descriptive information that he expected philosophical definitions to provide, Moore offered an example that is as misleading as it is famous: "When we say ... 'The definition of horse is "a hooved quadruped of the genus *Equus*" ... we may mean that a certain object, which we all of us know, is composed in a certain manner: that it has four legs, a head, a heart, a liver, etc., all of them arranged in definite relations to one another" (p. 8).

This passage is curious; it suggests that an analytical definition lists the physical parts of the thing defined. The example, however, gives the species and differentia of the class of horses but does *not* mention any physical parts. In commenting on this passage in his *Reunion in Philosophy* (p. 184), Morton White has observed that Moore shifted inadvertently from logical to physical complexity.

In later writings, Moore maintained that concepts are the proper subject matter of definition. "To define a concept," he wrote, "is the same thing as to give an analysis of it" ("Reply to My Critics," in *The Philosophy of G. E. Moore*, pp. 664–665). It is not easy to tell just what Moore meant by "concept analysis." For the analysis of a concept, he offered three criteria that add up to the relation of synonymy of expressions. Thus, despite his explicit effort to find an informative function for definitions that goes beyond the explanation of how words are used, it is not

unreasonable to conclude that all that his obscure notion of "analyzing a concept" finally comes to is linguistic clarification. In denying that analytic definitions "merely tell us what the word is used to mean," Moore was rejecting the view that definitions are generalizations about common usage and suggesting that they have a more explanatory function. But he never made clear what that function is.

In the only full-length volume in English devoted to the study of definition, Richard Robinson formulated a purely linguistic account of definitions as reports of word usage. But he thought it necessary to supplement his main view with a "stipulative," or prescriptive, account. The reasons for his vacillation are that reports of usage are empirical generalizations, while definitions are, if acceptable at all, necessary truths, and that stipulations are uninformative, while definitions are highly informative. Thus, neither the linguistic nor the prescriptive interpretation accounts for all features of definitions. But the mere juxtaposition of the two can hardly overcome the defects of each taken separately.

#### A PRAGMATIC-CONTEXTUAL APPROACH

Linguistic theories of definition brought needed attention to the close relation between definitions and the meanings of words, but they erred in identifying meanings either with objects or concepts allegedly denoted by words or with linguistic usage. A correct theory of definition would unite the partial insights of E-type, P-type, and L-type views without relying on misleading metaphors, denying the obvious informative value of definitions, or reducing definitions to historical reports of linguistic behavior.

Why should essentialists and linguistic philosophers claim that definitions convey knowledge, while prescriptivists deny that they do? In some sense of the word *knowledge*, anyone would agree that definitions communicate knowledge. The problem is to identify a special sense of "knowledge" that is appropriate to definitions but does not require us to postulate obscure essences or to reduce definitions to historical reports. This special kind of knowledge may be knowledge of how to use words effectively. Use, unlike usage, is functional. As Gilbert Ryle has observed, there are misuses and ineffective uses, but there is no such thing as a misuse or ineffective usage ("Ordinary Language," in *Philosophical Review* 42 [1953]). Usage is what people *happen* to do with words and is determined by habits, while use is what *should* be done with words and is governed by rules. To

explain the right use of a word, as distinct from merely reporting its usage, a definition must give the rules that guide us in using it. In this respect definitions are rules, rather than descriptions or reports.

All three traditional theories of definition assume, mistakenly, that if definitions convey knowledge, then the knowledge they convey is of the same type as that conveyed by ordinary statements of fact. Essentialists conclude that the knowledge conveyed by definitions is descriptive knowledge of essences, linguistic philosophers conclude that it is descriptive knowledge of language usage, while prescriptivists maintain that definitions do not convey knowledge of any kind. There has been a strikingly similar three-way dispute over the status of value judgments: nonnaturalists hold that value judgments convey knowledge of an abstract realm of “values”; naturalists maintain that they convey knowledge of observable causal relations; and emotivists assert that they convey no knowledge whatsoever. Arguments about whether definitions and value judgments convey true or false information mistakenly presuppose that all information must be of the descriptive type, thus overlooking the fact that cookbooks, military manuals, Sunday sermons, and do-it-yourself instruction sheets all convey, in various ways, the kind of normative information that Ryle has called “knowledge-how” in *The Concept of Mind* (Ch. 2). Practical or ethical advice may be regarded as stating rules that inform us how to act effectively, while definitions provide rules that inform us how to speak or write effectively. In either case it may be said that the information conveyed is subject to being evaluated as good or bad, but not to being verified as true or false.

**APPLICATIONS OF A CONTEXTUALIST VIEW.** The three views of definition distinguished above fail to provide adequate criteria for distinguishing good definitions from bad ones. They assume that the criteria of a good definition can be stated independently of the specific context in which the definition is offered and the purpose it is intended to serve. But no brief list of criteria can be given that would enable us to judge at sight whether a definition is adequate. The most we can do on a general level is to classify the kinds of rules of use that definitions provide and the kinds of discursive purposes they serve, and to say generally that definitions are good if and only if they serve the purpose for which they are intended.

Thus, an evaluation of a definition must begin with the identification of the point or purpose of the definition, and this requires knowledge of the discursive situation in which the need for the definition arises. We use

words to incite ourselves and others to action, to express and share emotions, to draw attention to things, to memorize, to make inferences, to evoke and enjoy images, to perform ceremonies, to teach, to exercise, and to show off. It is when we are unsure of the most effective use of an expression for one of these purposes that we seek a definition.

**LINGUISTIC RULES.** Rules governing the uses of words can be sorted into three main types: (1) referring rules, which aid us in identifying the things or situations to which a word may be applied; (2) syntactical rules, which govern the ways in which a word may be combined with other words to form phrases and sentences; and (3) discursive rules (the most difficult to formulate), which indicate when we may use language metaphorically (as in poetry) and when we must use it literally (as in science), as well as indicating differences of category or logical type (for example, the rule that one cannot predicate human qualities such as intelligence of inanimate things such as machines) and indicating when a word should be used in one sense rather than another (for example, *space* in mathematics as distinguished from physics). Discursive rules are the genuinely philosophical rules.

**Rules for defining.** The practical value of any account of the nature of definition is to be found in the clarity of the standards it provides for judging when a definition is good or bad. How does the pragmatic-contextualist account fare in this respect?

A number of rules of thumb for evaluating definitions have become canonical in the literature on the subject despite the fact that they make no clear sense in terms of any of the traditional views. The following rules can be found in practically every textbook on logic. They were first suggested by Aristotle in his *Topica* and have survived without change by sheer weight of tradition:

- (1) A definition should give the essence or nature of the thing defined, rather than its accidental properties.
- (2) A definition should give the genus and differentia of the thing defined.
- (3) One should not define by synonyms.
- (4) A definition should be concise.
- (5) One should not define by metaphors.
- (6) One should not define by negative terms or by correlative terms (thus, one should not define north as the opposite of south, or parent as a person with one or more children).

*Significance of the rules.* Rule 1, which makes sense only according to the essentialist theory, is nevertheless accepted by many writers who hold a prescriptive or linguistic view of definition, although these writers usually mean that a definition should indicate the properties that *define* the meaning of the term in question rather than those that just happen to hold true of the objects to which the term applies. But in such a case, the rule is vacuous; it asserts only that a definition should define rather than describe.

Rule 2 deserves its high status only if one accepts Aristotle's extension of biological classification to metaphysics, but it retains a limited value when it is reinterpreted in linguistic terms. We may understand "genus" to mean what Ryle has called the logical grammar of a term. The term defined need not be the name of any natural species or, for that matter, any object whatsoever. In defining words such as *function*, we do not identify a class of objects. We define a function as a certain type of relation, thus indicating that whatever can be said about relations in general can also be said about functions in particular. We thus provide a rule of syntax governing the word *function*, indicating with what other words it may be combined. The differentia of function—namely, that the relation is many-one between two variables—is a referring rule (criterion of identification) that helps us to identify the situations or formulas to which the term *function* may be applied. But it is wrong to think that the genus and differentia are necessary for a good definition. What must be stated in a definition varies with the definition's purpose. The genus may already be known and only the differentia needed or vice versa. Moreover, there are types of definition, such as contextual and recursive definition, that cannot be expressed in genus-differentia form. Contextual and recursive definitions provide rules for substituting a simpler expression for each of an infinite number of complex expressions of a given type.

*Synonyms.* The rule that forbids defining by a synonym makes sense only on the contextualist view of definitions as rules of use, although it has long been cited by supporters of the traditional views. The same books that cite this rule also insist that the definiendum must be logically equivalent to the definiens. But a synonym is just an expression that is logically equivalent to a given expression. The trouble seems to be that the term *synonym* is employed in a vaguely restricted sense to signify not just any logically equivalent expression, but a very brief one. Thus, we often find the injunction, "Do not define a word by a single other word." But this formulation, while sufficiently clear, is misleading. Is a two-word definition, such

as "phonograph disc" for "record," a case of defining by a synonym or not? Just how many words may the definiens contain if it is not to violate this rule?

To make matters worse, the prohibition of synonyms is inconsistent with rule 4, which demands that a definition be concise; indeed, the more concise the definiens, the more it looks like a synonym. However, we can understand a rule only if we know what specific purpose the rule is intended to serve. A contextualist view of definitions provides the following solution to the conflict between conciseness and nonsynonymity:

Single-word definitions are seldom useful because a person who does not know the rules governing the definiendum, is not likely to know the rules governing the definiens. The more words there are in the definiens, the more likely it is that those for whom the definition is offered are familiar with some of the words and thus understand some of their rules of use. Everyone has experienced the frustration of looking up a word in a dictionary and being confounded by some equally unfamiliar synonym.

But why should definitions be concise if the greater the number of words, the greater are our chances of at least partial comprehension? One obvious answer is that brief explanations are easier to remember. A second answer is that a lengthy definiens is more likely to suggest some rules of use that are inessential to the definiendum. But the most important consideration has to do with the kind of discursive context in which the definition is employed. In mathematics and in other formal contexts such as jurisprudence and contractual language, the purpose of most definitional equations is to abbreviate discourse or notation. In such cases it is a virtue rather than a defect for the definiens to be long and complicated, since it is precisely this fact that makes the definiendum worth introducing as an abbreviation. Moreover, the complexity of the definiens is less likely to produce confusion in technical contexts because of the great pains taken to preserve consistency and precision of language. In contrast, the rule of conciseness is more appropriate to informal discourse, in which definitions are intended to translate or otherwise clarify an expression unfamiliar to some of the participants. In informal discourse, the definiens should be brief, while in formal contexts, the longer and more complicated the definiens, the more useful the definition. Clearly, one can make little sense of criteria of good definitions without specifying the context in which and the purpose for which a definition is needed.

*Figurative language.* Why should a definition avoid figurative language? This traditional injunction is proba-

bly a result of the concentration of classical philosophy on formal discursive contexts such as mathematics and natural science, in which figures of speech are usually out of place. But in informal contexts such as conversation, literature, public debate, and even the less technical discussions of scientists, figurative language may well be the most effective way of getting a point across, and it is certainly the only way to define expressions whose meaning is essentially figurative (for example, *fathead* may be defined as “a fool puffed up with vanity”). No literal definiens can do justice to the nuances of natural discourse, as every translator knows from bitter experience.

**Negative and correlative terms.** Why not define by the use of negative or correlative terms? This injunction, in contrast to rule 5, holds for informal discourse and becomes senseless when applied to formal discourse. It is perfectly proper in mathematics or logic to define “ $\neg p$ ” as “the negation of  $p$ ” or to define “ $F^{-1}(x)$ ” as “the inverse of the function  $F(x)$ .” The reason for prohibiting negative and correlative definitions in informal contexts is that a person who is unclear about the rules of use of the definiendum would be just as puzzled about the rules of use of a negative or correlative definiens.

**Meaning equations.** In light of the preceding discussion, it is advisable to look again at the problem of synonymy. It has already been noted that every meaning equation—that is, every definition of the form “ $E$ ” means (or means the same as) “ $x, y, z$ ”—provides a definiens that is synonymous with its definiendum. The very point of the definition is to assert this synonymy and thus to transfer the rules of use already known to govern the definiens to the presumably less familiar definiendum. In order to make sense of the traditional injunction against synonymous definitions, we found it necessary to interpret the synonymy in question as a special and restricted subtype of synonymy, measured by the number of words in the definiens. But although it is absurd to require that a meaning equation must not offer synonyms (in the general sense of “synonym”), it is quite sensible to cast doubt on the usefulness of meaning equations. Meaning equations provide a kind of definition misleadingly called “explicit,” in contrast to axioms and postulates, which are frequently regarded as “implicit” or “partial” definitions.

It is unfortunate that meaning equations have come to be called “explicit” definitions, because their function, as we have seen, is to transfer rules of use from definiens to definiendum without articulating the rules in question, so that the rules remain implicit. The most explicit

kind of definition, the kind that actually states the rules governing the use of an expression, is a very complicated matter. Outside of technical contexts, it is doubtful whether complete definitions of this kind can ever be provided. On the other hand, it is just as doubtful whether a complete articulation of all the rules of use of the definiendum need be given. We seldom, if ever, require more than one or a few rules of reference, logical grammar, or relevant discourse that happen to be obscure to us in a particular context. Thus, meaning equations are frequently neither the most valuable nor the most appropriate kind of definition. In technical discourse, contextual, recursive, and operational definitions play a far more important role than mere notational abbreviations. And in nontechnical contexts, such as teaching a child or a foreigner the use of a word, definitions by illustration, by enumeration of instances or enumeration of subclasses, and by an indefinite number of other devices (depending on the ingenuity and linguistic sensitivity of the parties concerned) are usually more appropriate and effective than meaning equations. The evaluation of specific definitional procedures remains an important task for philosophically minded experts in each field of discourse and inquiry.

## DEGREES OF PERFECTION, ARGUMENT FOR THE EXISTENCE OF GOD

The proof for the existence of God from degrees of perfection, sometimes called the Henological Argument, finds its best-known expression as the fourth of Thomas Aquinas's "Five Ways" in his *Summa Theologiae* Ia, 2, 3. It is here quoted in full:

The fourth way is based on the gradation observed in things. Some things are found to be more good, more true, more noble, and so on, and other things less. But comparative terms describe varying degrees of approximation to a superlative; for example, things are hotter and hotter the nearer they approach what is hottest. Something therefore is the truest and best and most noble of things, and hence the most fully in being; for Aristotle says that the truest things are the things most fully in being. Now *when many things possess some property in common, the one most fully possessing it causes it in the others: fire*, to use Aristotle's example, *the hottest of all things, causes all other things to be hot*. There is something therefore which causes in all other things their being, their goodness, and whatever other perfections they have. And this we call God.

### COMPARATIVES AND SUPERLATIVES

A distinctive feature of the Fourth Way is the principle that "comparative terms describe varying degrees of approximation to a superlative"; for example, suppose "whiter than" is such a comparative term. The judgment that bond paper is whiter than newsprint would then be more adequately expressed as "The color of bond paper is closer to *pure white* than is the color of newsprint." How-

ever, the new comparative term “closer to” (that is, “more closely resembles,” “more similar to”) is used in exactly the same sense when none of the things compared is a superlative, for example, in “The color of bond paper is closer to the color of newsprint than the color of newsprint is close to the color of lemons,” and here “closer to” obviously does not describe a degree of approximation to pure white. If “closer to,” used to compare colors, does describe degrees of approximation to a superlative, the superlative must be the greatest possible similarity between colors, that is, qualitative identity of colors. Perhaps the initial judgment should then be expressed “The similarity between the color of bond paper and pure white is closer to the *greatest possible similarity* than is the similarity between newsprint and pure white.” But here there is still a comparative term, “closer to,” used to compare similarities between colors. It seems impossible to define a comparative term by means of a superlative without using another comparative term, and we are on our way to an infinite regress. If all comparative terms describe degrees of approximation to a superlative, then any comparative judgment implicitly refers to infinitely many superlatives.

But perhaps not all comparative terms describe degrees of approximation to a superlative. Suppose “closer to” (as used to compare colors) does not, and therefore the infinite regress can be cut short. Then “closer to” can be used to define “whiter than,” and the definition need not refer to pure white, or to any other superlative. This is a reason for denying that “whiter than” describes a degree of approximation to a superlative. The definition runs as follows:

First it must be given, perhaps simply by fiat, that color *B* is whiter than color *A*. *B* need not be pure white, or superlatively white. Then any color *X* is between *A* and *B* if and only if both *X* is closer to *A* than *A* is close to *B* and *X* is closer to *B* than *B* is close to *A*. If *X* is between *A* and *B*, then *X* is whiter than *A*, and *B* is whiter than *X*. If *X* is different from both *A* and *B* and is not between *A* and *B*, then (1) *X* is whiter than *B* if and only if *X* is closer to *B* than *X* is close to *A* and (2) *A* is whiter than *X* if and only if *X* is closer to *A* than *X* is close to *B*. Two colors, *X* and *Y*, can be compared with respect to whiteness by (1) comparing *X* with the initially given pair in the manner just described and (2) similarly comparing *Y* with either the pair *A* and *X* or the pair *B* and *X*.

Superlative terms can be defined by means of comparatives more easily than comparative terms can be defined by means of superlatives. For example, “Brand *X* is the whitest bond paper if and only if Brand *X* is whiter

than any other bond paper.” Or “Brand *X* is the whitest bond paper if and only if no other bond paper is whiter than Brand *X*.” On the second definition there can be more than one whitest bond paper. On the first definition there can be only one; and it is therefore possible that nothing satisfies the first definition. Such nonequivalent forms of definition are possible whatever the kind of superlative term defined; either form may be used if it is not confused with the other. Both definitions above define a relative superlative term. *Whitest* is defined with respect to a certain class, the class of bond papers. Since not only bond paper is white, neither definition rules out the possibility that something other than bond paper is whiter than the whitest bond paper. A universal superlative term is defined with respect to the class of everything of which the corresponding comparative term is predicable. For example, “*X* is the whitest thing if and only if nothing is whiter than *X*.” Both relative and universal superlative terms can be absolute superlative terms. An absolute superlative term is defined by means of a modal term such as *possible* or *can*. “*X* is pure white if and only if it is not *possible* for anything to be whiter than *X*.” There are as many senses of an absolute superlative term as there are relevant senses of *possible*.

Any comparative term can be used to define some superlative term. For example, “greater than” can be used to define “greatest prime number”: *n* is the greatest prime number if and only if *n* is a prime number and there is no prime number greater than *n*. But it has been proved that there is no greatest prime number—that the predicate “greatest prime number” cannot be truly predicated of any number. This raises a general question: How can we know whether a particular superlative term could possibly be truly predicated of something? One can define “pure white,” but this gives no assurance that there might possibly be something that is pure white. Perhaps we do not know what we are talking about when we talk about “pure white”; for perhaps there can be nothing to talk about, just as there can be nothing to talk about when we talk about “the greatest prime number.” A superlative term should be suspected of not being truly predicable of anything possible unless there is a reason to think otherwise, and such a reason is not provided by the fact that the superlative term can be defined by a perfectly understandable comparative term.

Such a reason is sometimes provided when the superlative term can be defined without using any corresponding comparative or superlative terms. Definitions of this sort will usually, perhaps always, employ a universal quantifier. For example, “An object is (absolutely) *pure*

gold if and only if *all* its atoms are atoms of gold. A *perfect* reflector is one that reflects *all* the light falling on it." Definitions of the form "Something is pure \_\_\_\_\_ if and only if it contains no impurities" or "something is a perfect \_\_\_\_\_ if and only if it has *no* imperfections" will not do by themselves. The terms "contains *no* impurities" and "has *no* imperfections" are as problematic as the particular superlative terms they define and should be used without qualms only if they can be characterized independently. "Absolutely pure minestrone soup" can be defined as "minestrone soup completely free of impurities," but this is no help until we have a complete list of possible impurities. Aniline dyes are definitely impurities in soups. Some batches of minestrone soup are therefore definitely purer than others. But starting from an incomplete list of possible impurities, there is no obvious way, other than by arbitrary stipulation, of making a complete list. It seems that "absolutely pure minestrone soup" can therefore be given a clear sense only by stipulation. We do not need to give it a clear sense in order to talk sensibly about some batches of soup being purer than others.

A comparative term is often much clearer than the corresponding superlative term; one can often know how to use a comparative term without at all knowing how to use the corresponding superlative term. It seems reasonable to deny that such comparative terms describe degrees of approximation to a superlative.

## PERFECTIONS

Thomas stated his principle quite generally, but presumably he would have been willing to qualify it. He argued himself that there can be nothing that is unlimited in size (*Summa Theologiae* Ia, 7, 3) and he would deny, reasonably, that the comparative term "longer than," for example, describes degrees of approximation to a superlative. The argument from degrees of perfection does not lead to the heretical conclusion that God is pure white or pure red. Still less does it lead to the impossible conclusion that God is both pure white and pure red or that God is both perfectly circular and perfectly triangular. The argument is concerned only with perfections whose predication does not imply any sort of imperfection. If a thing is white, it must be extended; if extended, it must be divisible; and if divisible, it must be perishable. Perishability is an imperfection, and therefore whiteness, like all other properties that exist only in something extended, can exist only in things less than completely perfect. Perfections that involve absolutely no imperfection are sometimes called "transcendental perfections." The traditional list includes being, unity, truth, goodness, nobility, and

sometimes beauty and intelligence. Thomas thought that anything, a member of any genus, and God, who is not a member of any genus, could have these perfections. For Thomas's argument the principle about comparison need be true only of the transcendental perfections.

The principle about comparison is generally dubious, and it is particularly dubious with the transcendental perfections. Goodness, for example, is sensibly predicated of something only when it is understood as being of some kind. One who asserts of something "It is good" should be prepared always to answer the question "A good *what*?" Things of a certain kind are good in virtue of having certain characteristics; things of another kind in virtue of having others. Thus, if comparisons of goodness describe degrees of approximation to a superlative, then comparison with respect to any of the different characteristics admitting of degrees in virtue of which different kinds of things are good must also describe degrees of approximation to a superlative. The restriction of the comparative principle to transcendental perfections is not much of a restriction.

Those who do not subscribe to a Thomistic metaphysics, or to one like it, will not find any reason to accept the principle that comparisons of perfections describe degrees of approximation to a superlative. It is not surprising that Thomas's philosophy contains enough material to construct more arguments for God's existence than he formulated explicitly. Some of these back up the Fourth Way. For example, Thomas's philosophical theology makes great use of the Aristotelian distinction between act and potency: "Each thing is perfect according as it is in act, and imperfect as it is in potency" (*Summa contra Gentiles* I, 28, 6). Furthermore, something whose actuality is less than complete must be caused by something else with at least as much actuality (I, 28, 7). Bearing these two principles in mind, the argument from degrees of perfection can be reformulated as follows:

Some things are found to be more perfect than others. Thus, some things have less than the superlative degree of perfection. Since a thing's perfection is its actuality, these things have less than the superlative degree of actuality. Something whose actuality is less than complete must be caused by something else with at least as much actuality. The resulting hierarchy of causes cannot be infinite, so there must be a first cause whose actuality is complete, who is pure act, and who therefore has all perfections in a superlative degree. And this we call God.

Thus reformulated, the Fourth Way resembles the First Way, the argument from efficient causality, and the Second Way, the argument from change. And it is susceptible to the same sorts of familiar objections raised against them. These objections, however, may seem less forceful against the Fourth Way than against the other arguments. A modern reader who is untroubled by the idea of an infinite hierarchy of efficient causes may well balk at the idea of an infinite hierarchy of increasing perfection. And one who claims that a proof of a first cause does not prove *God's* existence may admit that a proof of an absolutely perfect being does. However, this does not make the argument from degrees of perfection more convincing than the other proofs. The argument is now generally neglected, and a modern nonbeliever is not likely to be much influenced by it. For its premises will seem plausible only to one who accepts metaphysical principles, which in turn will seem plausible only to one who has a prior belief in the existence of God.

The reformulation of the Fourth Way given earlier brings out the relevance of the relation between comparative and superlative to other parts of Thomas's system. A central doctrine of Thomas's philosophical theology is that God is *pure act*, that there neither is nor could be any potency in him. Even if it is granted that we can learn, from Aristotle's and Thomas's examples, how to compare some things as being more or less in act, this gives us no reason to suppose that the superlative term "pure act" is intelligible or that it could possibly apply to something.

### Bibliography

The Fourth Way seems the most Platonic of Thomas Aquinas's Five Ways. See, for example, Plato, *Phaedo*, 100–101. Two books in English on Thomas's relation to Plato are Arthur Little, *The Platonic Heritage of Thomism* (Dublin, 1950), and R. J. Henle, *Saint Thomas and Platonism* (The Hague: Nijhoff, 1956). The Fourth Way is the major topic of Little's book. Henle's book has a very complete bibliography.

The principle that comparative terms describe varying degrees of approximation to a superlative appears several times in Thomas's *Summa contra Gentiles* (I, 28, 8, I, 42, 19; I, 62, 5). It does not, however, appear in the very compressed argument for God's existence (I, 13, 34), where an argument from degrees of truth is attributed to Aristotle. Aristotle's *Metaphysics* II, 993b25–30, a passage mentioned in both the *Summa Theologiae* and the *Summa contra Gentiles* versions of the argument, does seem adaptable to Thomas's purposes. *Metaphysics* IV, 1008b31–1009a5, mentioned only in the *Summa contra Gentiles* version, does not. Aristotle probably should not be counted among the philosophers who employed or would be willing to employ the argument

from degrees of perfection to prove the existence of a perfect being.

Several arguments from degrees of perfection appear in the writings of Augustine; see, for example, Bk. V, Sec. 11, and Bk. VIII, Sees. 4 and 5, of *De Trinitate*, the work of Augustine's referred to in the preface of Anselm's *Monologion*. Anselm's arguments from degrees of perfection appear in the first four chapters of the *Monologion*.

The Blackfriars edition of Thomas's *Summa theologiae* (New York: McGraw-Hill, 1964–; only a few of the projected 60 vols. have been published so far) has the Latin text, along with a new English translation. The second volume, Ia. 2–11 (New York: McGraw-Hill, 1964), translated by Timothy McDermott, contains appendices by Thomas Gilby, "The Fourth Way" and "Perfection and Goodness."

Thomas's doctrine of "analogical" predication is usually invoked to explain the notion of a transcendental perfection. This, as well as the act-potency distinction, is discussed in Knut Tranøy, "Thomas Aquinas," in *A Critical History of Western Philosophy*, edited by D. J. O'Connor (New York: Free Press of Glencoe, 1964), and further references are given.

The Fourth Way is the least widely accepted of Thomas's proofs for the existence of God. References to the disputes are given in Étienne Gilson, *The Christian Philosophy of St. Thomas Aquinas* (New York: Random House, 1956). See also Gilson's *Elements of Christian Philosophy* (New York: Doubleday, 1960).

René Descartes presented a proof for the existence of God from the degrees of perfection found in ideas. See his *Third Meditation*, his *Principles of Philosophy*, I. xviii., Objection II of the second set of *Objections to the Meditations*, and his *Reply* to this objection.

## DEISM

*Deism* (Lat. *deus*, god) is etymologically cognate to theism (Gr. *theos*, god), both words denoting belief in the

existence of a god or gods and, therefore, the antithesis of atheism. However, as is customary in the case of synonyms, the words drifted apart in meaning; theism retained an air of religious orthodoxy, while *deism* acquired a connotation of religious unorthodoxy and ultimately reached the pejorative. Curiously, however, the earliest known use of the term *deist* (1564) already had this latter intent, although it was by no means consistently retained thereafter. The situation is complicated by a late eighteenth- and nineteenth-century technical metaphysical interpretation of deism, in which the meaning is restricted to belief in a God, or First Cause, who created the world and instituted immutable and universal laws that preclude any alteration as well as divine immanence—in short, the concept of an “absentee God.” A further complication has been the acceptance of natural religion (religion universally achievable by human reason) by many eminent Christian theologians throughout the course of many centuries. Such theologians also believed in revelation and in personal divine intervention in the life of man, a position that had been made clear and authoritative by St. Thomas Aquinas. No sharp line can be drawn between the doctrines of such rationalistic theologians and those of deists, especially those who termed themselves “Christian deists.” Nor is it accurate to maintain that the historical deists (mainly of the seventeenth and eighteenth centuries), like the philosophical deists, altogether denied the immanence of God, even though they did tend to become more and more critical of the necessity of any revelation and of the Hebraic-Christian revelation in particular. It is therefore necessary to distinguish between the two types of deists. The remainder of this entry will be devoted to a survey of historical deism.

### EARLY HISTORY OF DEISM

To attempt to disentangle the antecedents of historical deism—intertwined as they are with rationalistic natural religion on the one hand, and with skepticism on the other—would indeed be foolhardy. Skepticism itself might end in Pyrrhonism or atheism or fideism. It is safe to generalize, however, that any tendency away from religious dogmatism, implicit faith and the mysterious, and in the direction of freedom of thought on religious matters, was in some measure a premonitory symptom of deism.

The earliest known use of the word *deist* was by Pierre Viret, a disciple of John Calvin, in his *Instruction chrétienne* (Geneva, 1564), Vol. II, “Epistre” (signed, Lyons, December 12, 1563). Viret regarded it as an

entirely new word that (he claimed) the deists wished to oppose to *atheist*: According to him, the deist professes belief in God as the creator of heaven and earth but rejects Jesus Christ and his doctrines. Although those unidentified deists were learned men of letters and philosophy, they were bitterly attacked by Viret as monsters and atheists. This definition and commentary was given wide circulation through Pierre Bayle’s citation in his article on Viret in the *Dictionnaire historique et critique* (1697; English translation, 1710). The word *deist* remained unknown in England until 1621, when it appeared in Robert Burton’s *Anatomy of Melancholy* (III. iv. II. i). After discussing atheists and near-atheists, Burton continues: “Cousin-germans to these men are many of our great Philosophers and Deists,” who, although good and moral, are yet themselves atheists. These “great Philosophers and Deists” likewise remain unidentified. A century and a half later, David Hume (1711–1776), in his *History of England*, ventured to name James Harrington, Algernon Sidney, and Sir John Wildman, among others, as the reputed leaders of the deists under the Commonwealth. The first interpretation of *deist* in both French and English as a euphemism for *atheist* was not followed by Dr. Samuel Johnson, who, in his *Dictionary* (1755), defined *deist* as “a man who follows no particular religion but only acknowledges the existence of God, without any other article of faith.”

The first appearance of *deism* seems to have been in John Dryden’s preface to his poem *Religio Laici* of 1682, where he equated it with natural religion. Dr. Johnson agreed: “The opinion of those that only acknowledge one God, without the reception of any revealed religion.” Neither Dryden nor Johnson, evidently, regarded deism as disguised atheism. The notion of deism, however, if not the word itself, is to be found in one form or another throughout the Renaissance until, in the late seventeenth century, the Englishman Charles Blount openly acknowledged that he was a deist.

Beginning in the early sixteenth century, general contributions to the development of deism include such broad movements as anti-Trinitarianism, Unitarianism, secularism, anticlericalism, Erastianism, Arminianism, and Socinianism, the rise of the sects, and the general revolt against authority. It may be argued that all of these currents and undercurrents were united in the increasing trend away from religious persecution and toward religious toleration, the glorification of the natural powers of man, and the endorsement of the right to think and to publish freely on all religious and political subjects.

## DEISM IN BRITAIN

The British deists constituted no conspiracy and formed no school of thought; they were highly individualistic, frequently unknown to one another, and sometimes at odds with one another. They were less systematic philosophers than thoughtful writers on practical moral, religious, and political issues. In 1704 the rationalist Anglican theologian Samuel Clarke distinguished four varieties of deists: those who denied providence; those who acknowledged providence in natural religion but not in morality; those who, while denying a future life, admitted the moral role of the deity; and finally, those who acknowledged a future life and the other doctrines of natural religion. The following summary of the leading deists will testify to the general truth of Clarke's subtle distinctions.

## LEADING BRITISH DEISTS AND THE RISE OF DEISM.

**Lord Herbert of Cherbury.** Lord Herbert (1583–1648) never called himself a deist and had but a single acknowledged disciple, Charles Blount; nevertheless, he exerted considerable influence and deserves the title of “the father of English deism” bestowed on him in 1714 by Thomas Halyburton in *Natural Religion Insufficient*. Lord Herbert's *De Veritate, Prout Distinguitur a Revelatione, a Verisimili, a Possibili, et a Falso* was published in Paris in 1624, in London in 1633, and again in 1645. The first edition, therefore, postdated Burton's avowal of the existence of many deists by three years. In the expanded London edition of 1645, Herbert laid down the religious Common Notions that constitute the rationalistic basis of deism and that were to be assumed, if not always acknowledged, by virtually all succeeding deists. These principles are (1) that there is one supreme God; (2) that he ought to be worshiped; (3) that virtue and piety are the chief parts of divine worship; (4) that man ought to be sorry for his sins and repent of them; (5) that divine goodness dispenses rewards and punishments both in this life and after it. These truths, he argued, are universal, and may be apprehended by reason. Revelation is not openly repudiated, but by implication is rendered supererogatory. (Somewhat incongruously, however, Herbert prayed for a sign from Heaven that would grant permission to publish *De Veritate*, and was satisfied that he had received it.) Herbert treated Scripture as ordinary history, ridiculed bibliolatry, and overtly attacked priestcraft, and disavowed faith as a basis for religion. His *De Religione Gentilium* (1663) is one of the earliest studies of comparative religion.

**Propagation of Deism.** Although precise documentation is not available, deism was ripening between the time of Herbert and Blount, through such various and overlapping influences as humanism in general, the philosophy of Thomas Hobbes, the idealism of Harrington, the naturalistic biblical exegesis of Benedict de Spinoza and others, the corruption of the clergy, the widespread religious rationalism of the Cambridge Platonists and other Latitudinarians, the “sweet reasonableness” of John Locke, and the scientific approach of Isaac Newton—all of which were contributing to religious and political toleration. By the close of the seventeenth century, a new and memorable influence was added—the pervasive presence of the skepticism of Bayle. The first direct attack on British deism, Bishop Stillingfleet's *Letter to a Deist* (1677), acknowledges that owing to the being and providence of God but expressing “a mean esteem” of the Scriptures and the Christian religion had become a common theme.

**Charles Blount.** Beginning in 1679, Blount (1654–1693) was an indefatigable propagandist who, in the battle for freedom on all fronts, learned to resort to indirect methods in order to keep clear of the law. His *Summary Account of the Deist's Religion* (1693), which appeared posthumously during the same year in which he committed suicide, is his most outspoken work.

The year 1610 marks the last burning of heretics in England. Yet the matter of legal suppression of heterodox works is of vital importance in understanding and assessing the writings of the deists. The strict Press Licensing Act of 1662 was allowed to drop by 1695, but the blasphemy laws were still in effect. The ecclesiastical courts had the power to imprison heretics for a period of six months; in 1676 Lord Chief Justice Hale ruled that through common law the Court of King's Bench had jurisdiction over blasphemy, because Christianity is “parcel of the laws of England”; and finally, in 1698 a vicious statute was enacted under which any acknowledged Christian who made any accusation whatsoever against the Christian religion could be rendered incapable of holding office, of taking legal action, of purchasing land, and, if the blasphemy was repeated, would be made to suffer three years' imprisonment without bail. Such repressive measures drove the heterodox into various evasive techniques. Irony, innuendo, ridicule, raillery, allegorical interpretation of the Scriptures, fictitious analogies, frequent use of the dialogue and epistolary forms, the claim to be “Christian deists,” pseudonymity, and anonymity not only successfully hampered legal

prosecution but also made it difficult for modern historians to ascertain the genuine beliefs of the writers.

After Herbert and Blount, the foremost British deists were John Toland, Anthony Collins, and Matthew Tindal, and of somewhat less consequence, William Wollaston, Thomas Woolston, Thomas Chubb, Thomas Morgan, Henry St. John Bolingbroke, and Peter Annet. Others, such as the earl of Shaftesbury and Bernard Mandeville, have been labeled deists with some justification, and many others without justification, even including orthodox clergymen who emphasized natural religion, expressed scruples about specific biblical passages or voiced doubts about specific biblical miracles.

**John Toland.** Toland (1670–1722) produced in 1696 his most famous deistical work, the very title of which spells out its major thesis: *Christianity not Mysterious: Or a treatise Shewing That there is nothing in the Gospel Contrary to Reason, Nor above it: And that no Christian Doctrine can be properly call'd a Mystery*. The treatise is basically rationalistic and is reminiscent of Herbert's *De Veritate*. It opposes not only biblical mysteries, but also challenges the validity of the biblical canon and points out corruptions in biblical texts. It mocks the implicit faith of the Puritans and their bibliolatry, and severely censures the vested interests of priests of all denominations. Philosophically, Toland was in the tradition of Giordano Bruno, René Descartes, Spinoza, Gottfried Wilhelm Leibniz, and, to a lesser extent, of Locke. Eclectic and somewhat inconsistent in his opinions, he was a freethinker and a deist, a materialist and a pantheist (the first use of the word *pantheist* is found in 1705 in his *Socinianism truly stated*). With his great learning, Toland became a figure of international renown, for the first time bringing deism to a wide reading public through a profusion of bold controversial publications.

**Anthony Collins.** Collins (1676–1729) was a well-to-do and well-educated gentleman and magistrate. At the age of twenty-seven he earned the respect and friendship of Locke. Two early works, *An Essay concerning the Use of Reason* (1707) and *Priestcraft in Perfection* (1709), prepared the way for the more famous *Discourse of Free-Thinking* (1713), in which the right to think and publish freely is examined chiefly as it pertains to religion. Enthusiasm and superstition are considered more evil than atheism; modern science and the Protestant Reformation are presented as examples of courageous freethinking that have relieved many from age-old errors, including witchcraft; and priests are blamed for trivial quarreling among themselves over biblical interpretations and are held responsible for many corrupt texts. An impressive

list of freethinkers is furnished from the ancient Greeks, Romans, and Hebrews; from the Church Fathers; and from the moderns, ranging from Michel Eyquem de Montaigne to John Tillotson and Locke.

Collins defended his style of writing in *A Discourse concerning Ridicule and Irony in Writing* (1727); his philosophical doctrine of necessitarianism (wherein he differs from the doctrine of free will espoused by most deists) is developed in a *Philosophical Inquiry concerning Human Liberty* (1715) and a *Dissertation on Liberty and Necessity* (1729); and his biblical criticism, mainly of the supposed fulfillment of Old Testament prophecies in the New Testament, in the *Discourse of the Grounds and Reasons of the Christian Religion* (1724) and the *Scheme of Literal Prophecy Considered* (1725). Collins is unquestionably the most readable and urbane of the British deists.

**Matthew Tindal.** A law fellow at All Souls College, Oxford, and advocate at Doctors' Commons, Tindal (1657?–1733) was the most learned of the British deists, as well as the most significant historically. His *Christianity as Old as the Creation: Or, The Gospel A Republication of the Religion of Nature* (1730), composed in dialogue form, was at once recognized as "The Deist's Bible," and elicited over 150 replies, the most famous of which is Bishop Joseph Butler's *The Analogy of Religion* (1736). Although a declared admirer of Locke, Tindal deduces the being and attributes of God by a priori reason. As man reasons downward from the knowledge of the attributes of God to knowledge of himself, the religion of nature, including all the moral precepts requisite for leading the life of virtue and achieving ultimate salvation, then follows. Scripture, replete with ambiguities, is not only unnecessary but is actually confusing to men of reason; and according to Tindal, all men of whatever education or status in life are capable of Right Reason. Some Old Testament heroes are inspected in detail and are found wanting in virtue; even some New Testament parables are subjected to critical comment. Tradition is repudiated as a basis for Christianity, since it can be used equally as the basis for any and all religions. The customary deistical castigation of priestcraft is combined with this repudiation of tradition. Tindal, a rationalist, always maintained the title of "Christian deist."

**LESSER ENGLISH DEISTS.** The remaining British deists, already named, each made some personal contribution to the movement, however small.

**William Wollaston.** A graduate of Sidney Sussex College, Cambridge, Wollaston (1660–1724) took holy orders, but through the unexpected inheritance of a large

fortune he was able to devote himself to moral philosophy and general learning. His *The Religion of Nature Delineated* (1724) was well received by Queen Caroline the Illustrious, as well as by the public at large. It was attacked, however, by the American deist Benjamin Franklin and was subjected to ridicule by Lord Bolingbroke, the British deist. Unlike most deistical treatises, it contains no biblical criticism of any sort. Almost purely rationalistic, it has obvious affinities, in a simplified form, with Herbert of Cherbury's religious Common Notions. Man knows truth (that is, things as they are) by means of reason; vice, or the denial of things as they are, is a lie. To seek happiness is man's duty, because happiness, or the excess of pleasure over pain, is part of man's approach to truth. Man is by nature not fundamentally selfish; his search for truth must take into account the happiness of others. It is altogether likely that Bishop Butler, in *The Analogy of Religion*, had Wollston at least partly in mind when he reproved extreme religious rationalism as "that idle and not very innocent employment of forming imaginary models of a world, and schemes of governing it."

**Thomas Woolston.** Woolston (1670–1731), fellow of Sidney Sussex College, Cambridge, and Christian divine, was a deist of another stamp. A disciple of Anthony Collins, who had spearheaded the assault on biblical prophecies, Woolston extended the assault to biblical miracles. Influenced by the writings of the Greek Church Father Origen, he interpreted Scripture allegorically, was subsequently deemed out of his mind by his adversaries and, as a result, in 1720 was deprived of his fellowship. In 1705 he first employed the allegorical method in *The Old Apology for the Truth of the Christian Religion against the Jews and Gentiles Revived*, and later published a series of anticlerical tracts against those who spurned it. But it was a series of six *Discourses On the Miracles of our Saviour, In View of the Present Contest between Infidels and Apostates* (1727–1729) that brought prosecution by the government, ending in 1729 with a conviction of blasphemy. Sentenced to a fine of £100, imprisonment for one year, and security for good behavior during life, he died in jail in 1731, unable to pay the fine. A fighter for freedom of thought and publication for all, Woolston ironically fell the victim of his own principles. The six *Discourses* take a colloquial and frequently witty dialogue form, with a fictitious learned Jewish rabbi presenting Woolston's queries concerning fifteen New Testament miracles. Woolston's madness may possibly have been real (in which case his sentence was truly infamous), but his tracts read more like the strong convictions of a strong mind. He was one of two of the leading British deists (the other being Annet) to suffer punishment by the government.

**Thomas Chubb.** An Arian and "Christian deist," Chubb (1679–1746) was a self-educated and humble artisan. Writing for the common people, Chubb was also able to hold his own with the educated upper classes, divines, and scholars. He mastered the widespread rationalism of the early eighteenth century and propagated its basic ideas through prolific publication, as is observable in such works as *A Discourse concerning Reason, With Regard to Religion and Divine Revelation* (1731) and *An Enquiry Into the Ground and Foundation of Religion. Wherein is shewn, that Religion is founded in Nature* (1740). Another approach is taken in *A Discourse on Miracles, Considered as evidence to prove the Divine Original of a Revelation* (1741), a work influenced by Toland and Woolston. Although he is skeptical of the Hebrew revelation, Chubb is never skeptical of the Christian, as is manifested in *The True Gospel of Jesus Christ asserted* (1732) and *The True Gospel of Jesus Christ Vindicated* (1739). In these two tracts, Chubb employs natural religion as proof of Christian religion. He defends the miraculous propagation of primitive Christianity against the aspersions of the deist Tindal. A believer in free will, Chubb was answered at considerable length by the eighteenth-century American theologian Jonathan Edwards in *A Careful and Strict Enquiry into The modern prevailing Notions of the Freedom of Will* (1754).

**Thomas Morgan.** A Welsh "Christian deist," divine, and medical doctor, Morgan (d. 1743) came from a poor family (as did Chubb and Annet). Morgan combined the religious Common Notions of Lord Herbert with some of the principles of historical biblical criticism found in the writings of Toland and Chubb. He opposed Chubb, however, on the question of free will. Morgan's chief contributions to the deistical controversy are to be found in *The Moral Philosopher, in a Dialogue between Philalethes, a Christian Deist, and Theophanes, a Christian Jew* (1737), and its two sequels. His general historical criticism of Scripture stresses the many ambiguities that permit many different interpretations of biblical texts by believers who truly attempt to understand their significance. All history, therefore, is simply probability, and infallibility is fostered by priestcraft for selfish purposes. Toleration, reasonableness, and freedom are necessary to combat superstition and persecution.

**Henry St. John, Viscount Bolingbroke.** Tory statesman, historian, and wit, Bolingbroke (1678–1751) left his philosophical and religious compositions to be published posthumously in 1754 by David Mallet. Regarded by Dr. Johnson as a "blunderbuss" against religion and morality, Bolingbroke's *Works* were regarded by

Hume as unoriginal and feeble. In the twentieth century, Voltaire's long-alleged great indebtedness to Bolingbroke has been discredited, and the claim that Alexander Pope's *Essay on Man* was founded on Bolingbroke's *Fragments or Minutes of Essays* has been vigorously challenged. As a philosopher Bolingbroke is a rationalist, but a curiously inconsistent one. In one passage he states that only Right Reason can demonstrate the Being of Deity, yet in another, that only empiricism can prove the Being of Deity. Paradoxes abound: No universal revelation has ever been made, but modern religion can benefit by the study of primitive religions—for example, of China and Egypt. Like all the deists, Bolingbroke regarded the baneful influence of priestcraft as a major cause of the corruption of religious texts and religious traditions. With Bolingbroke, the course of British rationalistic deism, stemming from that of Lord Herbert in the middle of the seventeenth century, up to the middle of the eighteenth century, had been pretty well played out, but there was always opportunity for remorseless repetition and intensified publicity.

**Peter Annet.** Schoolmaster Annet (1693–1769) may be regarded as the last of the old-line deists. An outspoken freethinker, Annet advocated the freedom to divorce and, in a long series of tracts, attacked the Resurrection of Jesus and the character and conversion of St. Paul. His truculent assault on the credibility of all miracles in general, and those of the Old Testament in particular, carried on in *The Free Enquirer* of 1761, brought a governmental charge of blasphemous libel to which Annet pleaded guilty. The inhumane sentence against a man aged seventy included imprisonment for a month, two pilloryings, hard labor for a year, a fine, and bonds of security for good behavior during life. Annet survived this flagrant miscarriage of justice with its attendant humiliation and returned to schoolmastering until his death. The ascription to him of the authorship of the notorious *History of the Man after God's own Heart* (1761) has been disproved by modern scholarship. Although he contributed little fresh to the deistical movement, Annet, like Chubb, wrote directly to the people in their own language.

**THE RATIONALISTIC CLIMATE OF OPINION.** Little has been said so far about the rationalistic “orthodox” of the seventeenth and eighteenth centuries, those Latitudinarians, who were closely akin to the deists, except on the one crucial point of raising objections against Christian revelation. Nevertheless, both groups were united in a contemptuous rejection of Tertullian's dictum, *credo quia impossibile est*; in this respect, there was no warfare

between reason and religion. In a 1670 defense of the orthodox rationalists, a Latitudinarian was succinctly defined as “a gentleman of a wide swallow.”

**Ralph Cudworth.** Cudworth (1617–1688) may be taken as representative of the small but important band of Cambridge Platonists who sought to synthesize the spirit of Christianity with that of Greek philosophy by affirming that reason is spiritual as well as intellectual. Cudworth distinguishes between fundamental and non-fundamental religious doctrines: “I persuade myself, that no man shall ever be kept out of heaven, for not comprehending mysteries that were beyond the reach of his shallow understanding; if he had but an honest and good heart, that was ready to comply with Christ's commandments” (*A Sermon before the House of Commons, March 31, 1647.*) In *The True Intellectual System of the Universe* (1678), Cudworth argues cogently against fatalism. His posthumous *Treatise concerning Eternal and Immutable Morality* (1731) derives morality from natural law rather than from the positive precepts of revelation. Another member of the group, Benjamin Whichcote, states their position admirably: “If you would be religious, be rational in your religion.” In short, the Cambridge Platonists stood for reason and moderation.

**John Tillotson.** Tillotson (1630–1694), archbishop of Canterbury and great champion of Anglicanism, employed rationalistic arguments against the Catholic use of tradition and authority. Observing that these same arguments could be turned against Christianity itself, the deists frequently seized upon Tillotson's authority and quoted his arguments in this new context. Collins went so far as to name him the man “whom all English freethinkers own as their head.”

**THE NEW SCIENCE.** It might be expected that the New Science, which had made such great strides from Nicolas Copernicus to Newton, would have precipitated warfare between science and religion as it did in the nineteenth century, following Charles Darwin's *Origin of Species* (1859). But insofar as Britain was concerned, such was not the case, for Francis Bacon had enunciated the principle of a rigid dichotomy between science and religion that, on the whole, was adhered to during the seventeenth century. Indeed, science was more generally used as a bulwark for Christianity than the reverse—notably, in the case of the Latitudinarians. Newton himself was a student of Old Testament prophecies and believed in the Scriptures as inerrant guides.

The “skeptical chemist” Robert Boyle wrote orthodox religious tracts, one of which had the ancillary pur-

pose of proving that by being “addicted” to experimental philosophy, a man is assisted rather than indisposed to being a good Christian. In 1691 Boyle endowed a lectureship for the proof of the Christian religion against the attacks of infidels. Great efforts were made to replace a priori reasoning with the argument from design. Richard Bentley, the first Boyle Lecturer, corresponded with Newton in preparing *The Folly of Atheism and what is now called Deism* (1692). William Derham’s two lectures, *Physico-Theology* (1713) and *Astro-Theology* (1715), continued the effort. Nevertheless, the bulk of the Boyle Lectures, from the beginning to 1732, are almost purely rationalistic, as, for example, Clarke’s *Demonstration of the Being and Attributes of God* (1704) and *Discourse concerning the Unchangeable Obligations of Natural Religion, and the Truth and Certainty of the Christian Religion* (1705). Collins gibed that until Clarke’s “demonstration” of the existence of God, nobody had doubted the fact; and Franklin, in his autobiography, acknowledged that he became a deist after reading some of the Boyle Lectures. The New Science, in effect, had relatively little influence on the course of the deistical controversy, since neither side squarely faced the problem of the relationship of science to religion.

**THE DECLINE AND FALL OF REASON.** Rationalistic refutations of deism were prolific and formidable but achieved relatively little because they had so much in common with those of deism. Tindal had forced upon the apologists acceptance of the natural sufficiency of reason in theology. Thus, if deism was to be defeated, it had to be from a citadel other than that of an infallible and universal reason. One of the infrequent replies to Tindal’s direct challenge, “Dare any say that God is an Arbitrary Being, and His laws not founded on the eternal reason of things?” (*Christianity as Old as the Creation*) was *The Case of Reason, Or Natural Religion Fairly and Fully Stated* (1731). Its pietistic author, William Law (1686–1761), better remembered for his *A Serious Call to a Devout and Holy Life* (1729) and as a forerunner of John Wesley (1703–1791), totally disavowed Right Reason in the areas of morality and religion, and argued for historical evidence and implicit faith.

Bishop Joseph Butler (1692–1752) offered in the *Rolls Sermons* (1726) an important reevaluation of the authority of conscience and in the *Analogy of Religion* (1736) a matter-of-fact defense of Christianity; he sought to prove by analogy that all deistical objections against revelation were equally applicable to natural religion. The danger of this argument (which employed some of the methods of science and of Lockean empiricism) was that

it might conceivably drive readers to become skeptical of both kinds of religion, to espouse atheism, or to retreat into implicit faith.

Bishop George Berkeley’s (1685–1753) *Alciphron, or the Minute Philosopher* (1732), with its subtitle “Containing an Apology for the Christian religion against those who are called Freethinkers,” is a brilliant series of polemical dialogues, but it contains little of his highly controversial and much misunderstood philosophical denial of abstract ideas and of “matter,” for which Berkeley was frequently accused of being a skeptic. His *The Analyst* (1734), addressed to an “infidel mathematician” (presumably Edmund Halley), adopts the hazardous method of defending orthodoxy by asserting that the axioms of mathematics are as irrational and incomprehensible as the mysteries of Christianity.

Law and Butler had paved the way for antirationalistic assaults on deism, the former through faith, the latter through matter of fact. The argument for faith was implemented in *Christianity Not Founded on Argument* (1742) by Henry Dodwell (“the younger”), who had as little use for historical proofs as for intellectual proofs. According to Dodwell, the Boyle Lectures, like all rationalistic efforts, had only succeeded in spreading infidelity; external proofs have no real evidential value; probability reigns; so in the final analysis, there is no other way to approach religion, than to believe because you wish to believe. With Dodwell’s appeal to emotionalism, the “enthusiasm” of Wesley was just around the corner.

Conyers Middleton (1683–1750), Anglican clergyman, and equally antirationalistic, pressed the historical argument against external proof of the validity of religious claims in his *Free Inquiry into the Miraculous Powers which are supposed to have subsisted in the Christian Church from the Earliest Ages through several successive Centuries* (1749). Professedly denying the supernatural powers associated with the growth of Catholicism, Middleton could scarcely have been unaware that the same arguments could also be used to attack Gospel miracles, and that there is in actuality no breach between sacred and profane history.

Fatal blows to the Age of Reason (as differentiated from the Age of Enlightenment) came simultaneously on two levels—intellectually, from Hume and emotionally, from Wesley. What might be termed the deistical side of Hume can most readily be seen in “Of Miracles” and “Of a Particular Providence and of a Future State” (1748), “The Natural History of Religion” (1757), and *Dialogues concerning Natural Religion* (1779), the last of which comes to the purposefully lame conclusion “that the

cause or causes of order in the universe probably bear some remote analogy to human intelligence.” Natural religion, whether of the rationalistic or matter-of-fact variety, can lead only to doubt, uncertainty, and suspension of judgment. In reality, of course, Hume was no deist, but rather an antideist, a skeptic who destroyed the vulnerable a priori basis of deism.

At about the same time, Wesley attacked deism through “enthusiasm,” the doctrine of continuous personal inspiration and inner conversion of the soul: “By grace are ye saved through faith.” The fatal blows had been delivered; the Age of Reason had fallen and deism was dead. Or was it? The question will be taken up after brief considerations of deism in France, Germany, and America.

### DEISM ON THE CONTINENT

The term *Enlightenment* was unknown in Britain during the eighteenth century, although its spirit was plainly manifest. When it did appear in the nineteenth century, it was employed in the derogatory sense of shallow and pretentious intellectualism coupled with unreasonable contempt for tradition and authority. In eighteenth-century France and Germany, on the contrary, full-fledged movements of *Éclaircissement* and *Aufklärung* were under way and were winning important intellectual and political victories. The present section will confine itself, insofar as possible, to religion and will deal with only a few predominant thinkers.

**VOLTAIRE.** Without stopping to investigate such sixteenth-century precursors as Jean Bodin, Rabelais, Pierre Charron, and Montaigne, or such seventeenth-century precursors as Descartes, Pierre Gassendi, Bernard Le Bovier de Fontenelle, and Bayle, it is well to proceed directly to François-Marie Arouet, universally known as Voltaire (1694–1778), the greatest of the French deists. Banishment to England (1726–1729) by order of the ancien régime put the already widely known poet, playwright, *philosophe* (and later, historian and novelist) into the scientific atmosphere of Newton, the philosophical and religious atmosphere of Locke and some of the earlier deists (Voltaire had already known Bolingbroke in France), and the literary neoclassical atmosphere of Jonathan Swift and Pope. Much impressed by the relatively tolerant attitudes of the English as compared to the rigid censorship of the ancien régime, Voltaire published in London in 1733 *Letters concerning the English Nation*. A surreptitiously arranged French version of 1734, *Lettres philosophiques*, speedily burned by the common hang-

man, was Voltaire’s first bombshell against governmental and church tyranny. Thereafter, his remorseless battle cry of *Écrasez l’infâme!* was to be heard throughout a long life of polemic.

Although he consistently used the word *theist* in reference to himself, Voltaire was a deist in the tradition of the British deists, never attacking the existence of Deity but always the corruptions of church and priestcraft. As late as 1770, in a letter to Frederick the Great voicing strong disapproval of the avowed atheism of many of the *philosophes*, Voltaire repeated his conviction that if God did not exist, it would be necessary to invent him. The *Lettres philosophiques* eulogizes the Quakers as ideal deists for their freedom of thought and their freedom from dogmatism and clericism; attacks Blaise Pascal’s Pyrrhonism, which leaves man only the alternative of implicit faith; praises the philosophical empiricism and religious reasonableness of Locke; and seeks to convert the scientists of France to the Newtonian system. Other writings on religion and morality, *Poème sur la loi naturelle* and *Poème sur le désastre de Lisbonne*, both of 1756, as well as the famous novel *Candide* (1759), assail the doctrine of philosophical optimism and, indeed, of divine benevolence. Believing as he did in a natural religion based on reason, Voltaire’s chief onslaughts were upon dogmatism, superstition, fanaticism, and tyranny. His *Traité sur la tolérance* (1763), a classic denunciation of oppression, occasioned by the infamous Calas *affaire* of 1762, was followed in 1764 by the witty and effective *Dictionnaire philosophique*. Like most of the so-called deists, Voltaire was fundamentally a humanist seeking to better the condition of humankind.

**JEAN-JACQUES ROUSSEAU.** Novelist, political writer, deist, *philosophe* and anti-*philosophe*, Rousseau (1712–1778) remains one of the most inscrutable literary and philosophical geniuses of all time—a supreme individualist doting upon his own uniqueness. Born a Protestant, he became a Catholic, and finally a deist. His *Confessions* reveals that it was the reading of Voltaire’s *Lettres philosophiques* that first incited him to study, to think, and to become a dedicated man of letters.

In touching solely upon Rousseau’s role as a deist, it is fitting to examine the “Profession of Faith of a Savoyard Vicar,” part of the fourth book of *Émile, ou de l’éducation* (1762). The first book had opened with the affirmation that everything is good as it comes from the Author of all things, but that everything degenerates in the hands of man. The fourth book seeks to develop and clarify this thesis, using, for prudential purposes, a vicar as

spokesman. Jettisoning metaphysical proofs of God and subscribing to no strict system, the vicar simply feels God within himself, as a world governor of will, intelligence, power, and goodness. This beneficent deity is to be worshiped from the heart, and not through artificial forms. Yet it is paradoxically evident that while mere animals are happy, superior man is miserable. Why? asks the vicar. He replies to his own question that far from being a simple uncompounded creature, man is actually a being of contradictions. Self-love is natural to him, but a sense of justice or conscience or inner light is innate; he has the power to will things, but does not always exert this power to enforce his will.

Man, therefore, is the author of evil: Born good, he acquires vice. God, infinitely powerful, is infinitely good and supremely just. To emulate God in seeking justice is man's only source of happiness. In this respect, natural religion, learned through conscience, is sufficient. Christian revelation, on the one hand, is fraught with difficulty, mystery, obscurity, and dogma. Its majesty, sublimity, and beauty, on the other hand, bear witness to its divinity: It is not a manmade invention; indeed, it remained Rousseau's "pillow-book" throughout life. Rousseau, in brief, is a sentimental and primitivistic, rather than a "hard," rationalistic deist. Yet, in substance, his "soft" sentimental deism is actually not far removed from the religious Common Notions of Lord Herbert or even from Spinoza's Doctrines of Universal Faith.

Rousseau's device of using the Savoyard vicar as spokesman for his own deism was unsuccessful; *Émile* was publicly burned and an order was issued for the arrest of the author, who was forced to flee the country. Except for his much later autobiographical writings, *Émile* was Rousseau's last major work.

ATHEISM. Aside from Voltaire, who subscribed to "hard" deism, and Rousseau, who dispensed the "soft" variety, the *philosophes* were not deists at all. To them, deism was but the starting point on the road to atheism. Their militant atheism, as well as their dogmatic belief in constant and inevitable progress and the perfectibility of man, shocked Gibbon and Hume, and greatly disturbed both Voltaire and Rousseau. The names of Jean Le Rond d'Alembert and Denis Diderot (editors of the *Encyclopédie*), Baron d'Holbach (and his "atheistical club"), Claude-Adrien Helvétius, F. M. Grimm, Julien Offray de La Mettrie, ...tienne Bonnot de Condillac, and Marquis de Condorcet can hardly be excluded from the list of atheistical *philosophes* or, at least, those well on the road to atheism. Deism in France, although considerably influ-

enced by deism in England, was much more extreme both religiously and politically, simply because England had already made considerable social progress. In France, deism was part and parcel of the general move toward materialism, freedom of thought and publication, freedom from the tyranny of the ancien régime in the affairs of state and church, that ultimately exploded in the Revolution.

DEISM IN GERMANY. The course of the *Aufklärung* differed in major respects from the analogous movements in Britain and France, and developed later. Under the domination of the earlier Leibniz-Wolff philosophy, rational supernaturalism generally prevailed. After 1740 (the year of the accession of Frederick the Great, the first modern freethinking king), numerous translations of the British deists and of their orthodox refuters (as indicated in G. W. Alberti's *Briefe betreffend den allerneusten Zustand der Religion und der Wissenschaften in Gross-Brittannien* of 1752–1754, J. A. Trinius's *Freydenker-Lexicon* of 1759, and U. G. Thorschmid's *Freidenker-Bibliothek* of 1765–1767) introduced a new influence. Although the German *philosophes* were widely read, there was little of French radicalism in either their religious or political thinking. Among out-and-out deists (called *Freidenkers*, or Free-thinkers), the names of Karl Bahrtdt, Johann Eberhard, Johann Edelmann, and Hermann Samuel Reimarus must be mentioned.

**Hermann Samuel Reimarus.** The apology of Reimarus (1694–1768) for natural religion as opposed to atheism and materialism, written in 1755, was Englished in 1766 as *The Principal Truths of Natural Religion Defended and Illustrated*. His direct attacks on Christianity, through a painstaking study of New Testament texts, included "On the Object of Jesus and His Apostles" and "On the Story of the Resurrection," and were published posthumously (1774–1778) by Gotthold Ephraim Lessing as *Fragments of an Anonymous Work found at Wolfenbüttel*.

**Gotthold Ephraim Lessing.** Lessing (1729–1781), distinguished man of letters and author of the *Laokoon* (1766) and *Nathan the Wise* (1779), was a freethinker in the nonabusive sense of the term. He should probably not be classified as a typical deist, since he professed belief in natural revelation in his last publication, *The Education of the Human Race* (1780), and at the close of his life he is said to have privately acknowledged pantheistic beliefs. Lessing's lifelong friend Moses Mendelssohn (1729–1786), a Jewish freethinker, is customarily classified as a deist in the loose usage of the term.

**Immanuel Kant.** The case of Immanuel Kant (1724–1804), the greatest of the German philosophers, is highly instructive. Born and educated as a religious Pietist, he came under the influence of Newtonian physics and always remained interested in science. In theology his three most famous critiques, stimulated by the “mitigated scepticism” of Hume, agree with Hume in principle. The *Critique of Pure Reason* (1781) presses beyond Hume in criticizing proofs of the existence of God; the *Critique of Practical Reason* (1788) is concerned with moral experience in natural religion; and the *Critique of Judgement* (1790), in a sense, mediates between the first two. Kant’s position as a “Christian deist,” however, is best expressed in *Religion within the Limits of Reason Alone* (1792–1794). The limits of religion, basically naturalistic, are set in conscience or practical religion. Christianity is stripped of mystery and tradition and is treated as a purely moral religion—in fact, the only purely moral one; God is the moral Creator of the world, and it is the duty of the good man to worship him. Kant’s transcendental philosophy is beyond the scope of this entry, but it is relevant to say that Kant was the leader of the *Aufklärung*, which he defined as the freeing of man from the self-imposed bondage of the mind, and proclaimed as its motto *sapere aude* (“dare to know”).

## DEISM IN THE UNITED STATES

The works of the British deists, as well as those of the defenders of the faith, were well known in American intellectual circles, commencing with the second quarter of the eighteenth century. In the latter half of the century, Voltaire’s “hard” deism and, especially, Rousseau’s “soft” deism were widely disseminated; but the atheism of the *philosophes* made little headway. The Great Awakening, triggered by the preaching of Edwards in 1734 and bolstered by the preaching of the English Methodist George Whitefield, militated against orthodox Puritanism and in favor of republicanism both in religion and politics, but the atmosphere of rationalism still prevailed. Before the Revolution, however, deism made relatively little progress. Among the intelligentsia at Harvard, nevertheless, the Dudleian Lectures were established in 1755 for the purpose of explicating natural religion. Alarms sounded by the orthodox that deism was sweeping the country were unjustified. However, the Treaty of Paris in 1763 and the French alliance at the time of the Revolution undeniably quickened the spread of radical Gallic ideas.

## MAJOR AMERICAN DEISTS.

**Benjamin Franklin.** Franklin (1706–1790), man of letters, scientist, and diplomatist, as early as 1723 acknowledged himself a deist to intimate friends but circumspectly continued church attendance throughout life, thereby setting the conservative pattern followed by most of the leaders of the colonial and Revolutionary periods. In London in 1725 Franklin published his *Dissertation on Liberty and Necessity, Pleasure and Pain* in opposition to the free-will doctrine of the British deist Wollaston. However, Franklin shortly repudiated and suppressed this juvenile work. When he was about twenty-two, he drafted “Articles of Belief and Acts of Religion,” a creed not unlike Lord Herbert of Cherbury’s religious Common Notions and one that sustained him for life. Prudence and practicality characterize all of Franklin’s publications and actions. *Poor Richard’s Almanack* (1732–1757) is the essence of common sense, or how to get along in the world without unduly disturbing society; his list of virtues by no means coincides with the Christian virtues.

**Thomas Jefferson.** Framers of the Declaration of Independence, diplomatist, vice president and twice president of the United States, and member of the Episcopal Church, Jefferson (1743–1826) was in reality a deist, rationalist, and, above all, a humanitarian. He compiled but never published what later came to be known as *The Jefferson Bible, being The Life and Morals of Jesus Christ of Nazareth*. This little work, a cento of clippings from the Gospels of Matthew, Mark, Luke, and John pasted in a blankbook, extols Jesus as a man for his moral teachings, omits ambiguous and controversial passages, and, while rejecting many of the supernatural elements, presents the core of Christian morality and is genuinely religious in tone. Religion, for Jefferson as well as for Franklin, was essentially a utilitarian moral code.

**George Washington.** Washington (1732–1799), general and first president of the United States, was a deist of a similar stripe. Although he always maintained a church pew, he was one of the leading statesmen who advocated total separation of state and church and who saw to it that no reference to Christianity or even to Deity was made in the Constitution. In answer to a direct question from a Muslim potentate in Tripoli, Washington acquiesced in the declaration of Joel Barlow, then American consul in Algiers, that “the Government of the United States of America is not in any sense founded on the Christian religion.”

**Thomas Paine.** Born in England, Paine (1737–1809) arrived in America in 1774, bearing a letter of introduction from Franklin. A political theorist, diplomatist, and man of letters, Paine was a deist, but not overtly until the

publication in Paris of his *The Age of Reason: Being an Investigation of True and Fabulous Theology* (1794–1796). The first of its two books, intended to rescue deism from the reigning French atheism, is a more or less scientific assault upon revealed religion in general as being supererogatory to natural religion. The second book carries the attack directly to both the Old and New Testaments, arguing that the Bible is not the word of God and depicting Christianity as a species of atheism. Paine wrote vigorously and extensively and was outspoken in carrying his message to the common people, whose battles he had fought on the political, social, and economic fronts as well. In *The Age of Reason* the battleground was not new but was considerably enlarged from that of any earlier British deist. The work offended readers in France and shocked many in England and America who were laboring under the delusion that the deistical controversy was over and that orthodoxy had triumphed. Paine was rewarded for his efforts by banishment from England and by social obloquy in America. The patriot who throughout a long and turbulent career had accomplished so much for the new country, the man who had so vigorously combated atheism, was held to be an atheist, infidel, radical, and drunkard.

**LESSER AMERICAN DEISTS.** Paine was not the first acknowledged American deist, for the year 1784 produced *Reason the Only Oracle of Man, or a Compendious System of Natural Religion*. Its author, Ethan Allen (1738–1789), Revolutionary hero and leader of the Green Mountain Boys, had acquired his deism through early reading of the British deists. His book is flagrantly anticlerical and anti-Christian; he argues that a rationalistic universal religion of nature that provides the fundamentals of morality is all-sufficient and needs no supplementation. Both the Hebraic and the Christian testaments are subjected to ridicule. Like Paine, Allen was not so much an original thinker as a fearless propagandist.

Beginning in 1793, the blind ex-Baptist preacher Elihu Palmer (1764–1806) led a fiery deistical campaign from the lecture platform and by publication against the divine authority of the Bible. In 1794 he rushed to the defense of Paine's *Age of Reason* and in 1801–1802 published *Principles of Nature; or, a Development of the Moral Causes of Happiness and Misery among the Human Species*. From 1803 to 1805 he edited a weekly deistical paper, *Prospect; or, View of the Moral World*. Palmer also organized the Deistical Society of New York. With his many speeches and tracts designed to disseminate deism among the lower classes, Palmer was a most unusual

deist, in that he was deliberately leading a popular crusade.

Philip Freneau (1752–1832), writer of patriotic verse, was also the American poet of the religion of nature and humanity, and his ideas were close to those of Paine. The very titles of such poems as “Belief and Unbelief: Humbly recommended to the serious consideration of creed makers,” “On the Uniformity and Perfection of Nature,” “On the Religion of Nature,” tell their own story, without need of commentary.

**DECLINE OF DEISM.** During the eighteenth century, Puritanism in America had begun to crumble under the combined attacks of the Great Awakening, Methodism, and deism. “The Triumph of Infidelity” (1788), the poem by Timothy Dwight, orthodox president of Yale University, bears weak witness to the strength of deism. Shortly after 1800 deism became submerged in a revival of enthusiastic evangelism, particularly in the frontier areas, where intellectual attainments were hardly predominant. In New England, Unitarianism began making headway under the influence of Joseph Priestley, who in 1794 had immigrated from England. But elsewhere emotionalism, conservatism, reaction, and fideism were triumphant.

## THE LEGACY OF DEISM

*Historical deism*, a term of many connotations, was essentially rationalism applied to religion, and as such was the counterpart to literary neoclassicism. Deism and neoclassicism flourished at approximately the same time, both stressing universality and shying away from particularity. In deism, this cardinal point meant that from the very beginning the Hebraic and Christian revelations were suspect, if not invariably attacked. Deism primarily put forth the view that the aim of religion is morality and that anything traditionally taught beyond morality is superfluous. The widely accepted distinction between constructive deism and critical deism, or, as it has also been put, deism before Locke and deism after Locke, or humanistic deism as opposed to scientific deism, will not survive the careful scrutiny and evaluation of leading deistical texts. Yet the prime position of Right Reason in deism did not prevent empiricism, in the form of scholarly examination of Scriptural texts and historicism, from assuming increasingly important roles. Edward Gibbon's purely naturalistic investigation into the early progress and establishment of the Christian religion in the famous (or infamous) fifteenth and sixteenth chapters of his *Decline and Fall of the Roman Empire* (Vol. I, 1776) was manifestly influenced, not only by the philosophical

skepticism of Hume, but also by the somewhat crude historical investigations of a number of the deists themselves.

One general development of the deistical movement, therefore, was the rise of “the higher criticism”: The Bible was no longer deemed sacrosanct, and its verbal inspiration no longer dogmatically assumed. A second development was the greatly intensified study of comparative religion. A third development was the rise of “the philosophy of religion,” spurred on by Hume’s demonstration that no matter of fact, including the existence of God, can be proved a priori.

In actuality, deism did not die; it did not even fade away, and it still exists in fact, though perhaps not in name, for those who say (with Voltaire) that there must be a God and those who say (with Rousseau) that they know there is a God. Nor was deism vanquished, as has so often been asserted, by the superior talents of its orthodox opponents, by the exhaustion of the subject, or by the incapacities of its protagonists: Certainly, among the English, at least, Toland, Collins, and Tindal were the intellectual equals of most of their adversaries. By and large, both orthodox and heterodox alike were rational theists of a somewhat naive variety. Charles Leslie’s *Short and Easy Method with the Deists* of 1696 proved, in actuality, neither short nor easy. The deists were long subjected to the *odium theologicum*, and the historians of the movement have almost without exception downgraded or slandered them socially as well as intellectually since the time of John Leland in the mid-eighteenth century. Even the foremost rationalists of the nineteenth century, Mark Pattison and Leslie Stephen (the latter produced the most complete and erudite history to date) are condescending. Rarely have the achievements of deism been acknowledged and appreciated, and then only in passing, in brief comments from specialized monographs, articles, and encyclopedia entries. No really satisfactory, complete, impartial, and scholarly account of the significance of the movement has as yet appeared.

Deism had somewhat different effects in different countries, depending on the different national cultural situations. By the close of the eighteenth century in England, it seemed, superficially at least, to have disappeared or gone underground. Yet in 1790, when Burke triumphantly asked, “Who born within the last forty years has read one word of Collins and Toland, and Tindal, and Chubb, and Morgan, and that whole race who called themselves Freethinkers? Who now reads Bolingbroke? Who ever read him through?” he was historically mistaken and premature in his inference. For in the nine-

teenth century, radical publishers such as William Benbow, William Hone, and, most notably, Richard Carlile (1790–1843), all of whom were political as well as religious reformers, flooded the popular market with periodicals (for example, *The Deist; or Moral Philosopher*, 1819–1820), pamphlets, and cheap reprints and excerpts from freethinkers of all ages, including the whole range of the British deists, the skeptical Hume, Voltaire and Rousseau of France, and Paine and Palmer of America. The campaign was continued by others throughout the nineteenth century and survives in the present century on a higher intellectual level by affiliations with Unitarianism, Fabian socialism, and rationalist and humanistic societies, among others.

In France, the true deism of Voltaire and Rousseau was overwhelmed by the atheism of most of the *philosophes*, a doctrine which inevitably contributed to the upheaval of the French Revolution. The course of these eighteenth-century developments may be said to be paralleled today, on the one hand, by widespread atheism and, on the other, by the militant anticlericism of even many of the devout. In Germany, early intellectual deism was followed by both the fideism of Friedrich Heinrich Jacobi and a new post-Humean variety of rationalism which began with Kant and the romanticists of the following century.

In America, deism was long submerged by evangelism among the semiliterate masses and by Unitarianism among the well educated. An aggressive antireligionism resurged in the 1870s with Robert Ingersoll, “the great agnostic,” and a host of followers, such as William Brann in Texas in the 1890s with his world-famous newspaper *Brann’s Iconoclast*. Today, rationalist and humanistic societies and Unitarianism are omnipresent.

With few exceptions, deists in all countries have been interested in political and social reform, and with the passage of time it has become virtually impossible to isolate the purely religious aspects. Deism remains a symptom of revolt against orthodoxy and dogmatism.

By way of summary and possible oversimplification, deism is the individual’s affirmation of his right to think for himself on all subjects and to communicate his thoughts to others for the general welfare. It is the affirmation of the principle of the oneness of humanity. It marks the rise of secularism and the beginning of modernity in theology. In this sense it is still viable, and although freethinking today claims a philosophical substratum different from the simple rationalism of the seventeenth and eighteenth centuries, it is akin in spirit to historical deism. The early rise of deism in all countries

was strongly abetted by the growth of the spirit of toleration, and deism, in its turn, has strongly contributed to the continued growth and acceptance of toleration of other views. Perhaps, in the most universal sense, this is the major legacy of historical deism to the modern world.

## Bibliography

### USEFUL ANTHOLOGIES

- Berlin, Isaiah, ed. *The Age of Enlightenment*. New York: New American Library, 1956.
- Brinton, Crane, ed. *The Portable Age of Reason Reader*. New York: Viking Press, 1956.

## DELEUZE, GILLES (1925–1995)

Gilles Deleuze, one of the most influential and prolific French philosophers of the postwar period, was born in Paris, and lived there, with a few exceptions, for the rest of his life. The son of a conservative, middle-class engineer, a veteran of World War I, Deleuze received his early elementary education in the French public school system. When the Germans invaded France, Deleuze's family was on vacation in Normandy, and he spent a year being schooled there. Deleuze traced his own initiation into literature and philosophy to his encounter with a teacher at Deauville named Pierre Halwachs (son of the sociologist Maurice Halwachs), who introduced him to writers such as André Gide and Charles Baudelaire. Early on, he later recalled, philosophical concepts struck him with the same force as literary characters, having their own autonomy and style, and he soon began to read philosophical works with the same animation and engagement as literary texts. During the occupation, Deleuze's older brother was arrested by the Nazis for resistance activities and deported; he died on the train to Auschwitz.

After the Liberation, Deleuze returned to Paris and undertook his *khâgne* (an intensive year of preparatory studies) at the prestigious Lycée Henri IV, and then studied the history of philosophy at the Sorbonne. He was taught by Jean Hippolyte and Ferdinand Alquié ("two professors I loved and admired enormously" [Deleuze, 1977, p. 12]), as well as Georges Canguilhem and Maurice de Gandillac, though like many of his peers he was as influenced by the writings of Jean-Paul Sartre as by the work of his academic mentors. He published his first book, *Empiricism and Subjectivity*, on David Hume, in 1953, when he was twenty-eight. In an era dominated by phenomenology and "the three Hs" (Hegel, Husserl, Heidegger), Deleuze's decision to write on empiricism and Hume was already a provocation, early evidence of the heterodox tendencies of his thought.

During the decade between 1953 and 1962—which he later referred to as "a hole in my life" (Deleuze 1990, p. 138)—Deleuze published little, moved among various

teaching positions in Paris and the provinces, and contracted a recurring respiratory ailment that would plague him for the rest of his life. In 1956 he married Fanny (Denise Paul) Grandjouan, a French translator of D. H. Lawrence, with whom he would have two children. In 1962 his groundbreaking study *Nietzsche and Philosophy* was published to considerable acclaim, cementing Deleuze's reputation in academic circles. In the decade that followed, Deleuze more or less published a book per year, most of them devoted to the work of a particular philosopher or writer: Kant (1963), Proust (1964), Nietzsche (1965), Bergson (1966), Sade and Masoch (1967), Spinoza (1968), and later Kafka (1975), Francis Bacon (1981), Michel Foucault (1986), and Leibniz (1988). *Difference and Repetition*, his magnum opus, appeared in 1968, followed by *Logic of Sense* in 1969.

In the same year, he met Félix Guattari, a militant psychoanalyst, with whom he wrote a number of influential books, including the two volumes of *Capitalism and Schizophrenia* (1972, 1980), which were overtly political texts written in the wake of the ferment of May 1968. The first volume, *Anti-Oedipus*, was a best-seller in France, and thrust Deleuze into the limelight as a public intellectual. In 1969 Deleuze took up a teaching post at the experimental campus of the University of Paris VII (at Vincennes and, later, St. Denis), where he gave weekly seminars until his retirement in 1987. Like Kant, he traveled little, and devoted his time to teaching and writing: Paris was his Königsberg, France was his Prussia. He shunned academic conferences and colloquia, insisting that the activity of thought took place primarily in writing, and not in dialogue and discussion. By 1993 his pulmonary illness had confined him severely, making it increasingly difficult to read or write; he took his own life on November 4, 1995.

Deleuze's writings were strongly grounded in the history of philosophy, but he read widely in contemporary science and mathematics, and was well known for his interactions with the various arts. His early work was in part a reaction against Hegel, and more generally against the then-dominant post-Kantian tradition in philosophy. Kant's genius, for Deleuze, was to have conceived of a purely *immanent* critique of reason—a critique that did not seek, within reason, “errors” produced by external causes, but rather “illusions” that arise internally from within reason itself by the illegitimate (transcendent) uses of the syntheses of consciousness. Deleuze characterized his own work as a philosophy of immanence, but argued that Kant himself had failed to fully realize the immanent ambitions of his critique, for at least two reasons.

First, Kant made the immanent field immanent to a transcendental subject, thereby reintroducing an element of transcendence, and reserving all power of synthesis to the activity of the subject. In his first book, *Empiricism and Subjectivity* (1953), on Hume, Deleuze pointed to an empiricist reversal of this relation: whereas Kant's question had been “How can the given be given to a subject?” Hume's question had been “How is the subject (human nature) constituted within the given?” Deleuze would later characterize his own position as a “transcendental empiricism”: the determination of an impersonal and pre-individual transcendental field in which the subject is itself the result or product of *passive syntheses* (of the body, habit, desire, the unconscious). Just as there is no universal reason but only historically variable processes of “rationalization” (Max Weber), so there is no universal or transcendental subject, but only diverse and historically variable processes of “subjectivation.” Deleuze summarized his empiricism in terms of two characteristics: the abstract does not explain, but must itself be explained; the aim of philosophy is not to rediscover the eternal or the universal, but to find the singular conditions under which something new is produced (creativity).

Second, Kant had simply presumed the existence of certain “facts” (knowledge, morality) and then sought their conditions of possibility in the transcendental. But already in 1789, Salomon Maimon, whose early critiques of Kant helped generate the post-Kantian tradition, had argued that Kant's critical project required a method of *genesis*—and not merely a method of conditioning—that would account for the production of knowledge, morality, and indeed reason itself—a method, in other words, that would be able to reach the conditions of *real* and not merely *possible* experience. Maimon found a solution to this problem in a principle of difference: Whereas identity is the condition of possibility of thought in general, it is *difference* that constitutes the genetic and productive principle of real thought.

These two Maimonian exigencies—the search for *the genetic conditions of real experience* and *the positing of a principle of difference*—reappear like a leitmotif in almost every one of Deleuze's early monographs. *Nietzsche and Philosophy* (1962), for instance, suggests that Nietzsche completed and inverted Kantianism by bringing critique to bear, not simply on false claims to knowledge or morality, but on true knowledge and true morality, and indeed on truth itself: “genealogy” constituted Nietzsche's genetic method, and the will to power was his principle of difference. *Bergsonism* (1966) argues that Bergson's con-

cepts of duration, memory, and *élan vital* constitute the dimensions of the multiplicities of the real. Against the “major” post-Kantian tradition of Fichte, Schelling, and Hegel, Deleuze in effect posited his own “minor” post-Kantian trio of Maimon, Nietzsche, and Bergson. In rethinking the post-Kantian heritage, Deleuze would also retrieve the work of a well-known trio of pre-Kantian philosophers—Hume, Spinoza, and Leibniz—although from a decidedly post-Kantian viewpoint.

Deleuze’s historical monographs were, in this sense, preliminary sketches for the great canvas of *Difference and Repetition* (1968), which marshaled these resources from the history of philosophy in an ambitious project to construct a metaphysics of difference. Normally, difference is conceived of as an empirical relation between two terms each of which has a prior identity of its own (“x is different from y”). In Deleuze, this primacy is inverted: identity persists, but it is now a secondary principle produced by a prior relation between differentials (*dx* rather than not-x). Difference is no longer an empirical relation but becomes a *transcendental* principle that constitutes the sufficient reason of empirical diversity as such (for example, it is the difference of potential in a cloud that constitutes the sufficient reason of the phenomenon of lightning). In Deleuze’s ontology, the different is related to the different through difference itself, without any mediation. Although he was indebted to metaphysical thinkers such as Spinoza, Leibniz, and Bergson, Deleuze appropriated their respective systems of thought only by pushing them to their “differential” limit, purging them of the three great terminal points of traditional metaphysics (God, World, Self).

Deleuze’s subsequent work was, to some degree, a working out of the metaphysics developed in *Difference and Repetition*. Deleuze considered himself a classical philosopher and conceived of his philosophy as a system—albeit an open and *heterogenetic* (non-totalizing) system—which might be summarized in terms of the following traditional rubrics, derived largely from Kant.

#### DIALECTICS (THEORY OF THE IDEA)

*Difference and Repetition* attempts to formulate a theory of Ideas (dialectics) based neither on an essential model of identity (Plato), nor a regulative model of unity (Kant), nor a dialectical model of contradiction (Hegel), but rather on a problematic and genetic model of difference. Ideas are what define the “essence” of a thing, but one cannot attain an Idea through the Socratic question “What is ... ?” (which posits Ideas as transcendent and eternal), but rather through “minor” questions such as

“Which one?” “Where?” “When?” “How?” “How many?” “In which case?” “From which viewpoint?”—all of which allow one to define the spatio-temporal coordinates of Ideas that are purely immanent and differential. The formal criteria Deleuze uses to define Ideas are largely derived from Leibniz and the model of the differential calculus, which provides a mathematical symbolism for the exploration of the real: things or beings are virtual and problematic multiplicities composed of singularities—events, which are prolonged in converging and diverging series, forming zones of indiscernibility where the multiplicities entering into perpetual becomings.

#### AESTHETICS (THEORY OF SENSATION)

What are the implications of a principle of difference for aesthetics? Kant had dissociated aesthetics into two halves: the theory of sensibility as the form of possible experience (the “Transcendental Aesthetic”), and the theory of art as a reflection on real experience (the “Critique of Aesthetic Judgment”). In Deleuze’s work, these two halves of aesthetics are reunited: If the most general aim of art is to “produce a sensation,” then the genetic principles of sensation are at the same time the principles of composition for works of art; conversely, it is works of art that are best capable of revealing these conditions of sensibility. Deleuze’s writings on the various arts—including the cinema (*Cinema I and II*), literature (*Essays Critical and Clinical*), and painting (*Francis Bacon: The Logic of Sensation*)—must be read, not as works of criticism, but rather as philosophical explorations of this transcendental domain of sensibility. Deleuze locates the conditions of sensibility in an *intensive* conception of space and a *virtual* conception of time, which are necessarily actualized in a plurality of spaces and a complex rhythm of times (for instance, in the nonextended spaces and non-linear times of modern mathematics and physics).

#### ETHICS (THEORY OF AFFECTIVITY)

Deleuze has similarly developed a purely immanent conception of ethics, an “ethics without morality.” If morality implies an appeal to transcendent values as criteria of judgment (as in Kant’s moral law), ethics evaluates actions and intentions according to the immanent mode of existence they imply. One says or does this, thinks or feels that: What mode of existence does it imply? This is the link Deleuze establishes between Spinoza and Nietzsche, his two great precursors as philosophers of immanence: each of them argued, in his own manner, that there are things one cannot do or think except on the condition of being base or enslaved, unless one harbors a

*ressentiment* against life (Nietzsche), unless one remains the slave of passive affections (Spinoza); and there are other things one cannot do or say except on the condition of being noble or free, unless one affirms life or attains active affections. The transcendent moral opposition (Good/Evil) is in this way replaced by an immanent ethical difference (good/bad). A bad or sickly life is an exhausted and degenerating mode of existence, one that judges life from the perspective of its sickness, which devalues life in the name of higher values. A good or healthy life, by contrast, is an overflowing or ascending mode of existence, capable of transforming itself depending on the forces it encounters, always opening up new possibilities of life, new becomings.

### POLITICS (SOCIO-POLITICAL THEORY)

This immanent conception of ethics leads directly into Deleuze's political philosophy, which he developed most fully in the two volumes of *Capitalism and Schizophrenia*, with Félix Guattari. *Anti-Oedipus* (1972), under the guise of a critique of psychoanalysis, is in effect an immanent reworking of Kant's theory of desire in the *Critique of Practical Reason*. Since the capacities and affectivity (desire) of individuals is always effectuated within concrete socio-political "assemblages"—one of Deleuze's fundamental political concepts—the political philosophy presented in *A Thousand Plateaus* (1980) takes the form of a typology of social assemblages (primitive societies, the State, nomadic war machines, capitalism) that provide conceptual tools for analyzing the complex dimension of the actual situation: How are its mechanisms of power organized? What are the "lines of flight" that escape its integration? What new modes of existence does it make possible? What relations does it sustain between desire and power?

### ANALYTICS (THEORY OF THE CONCEPT)

Finally, Deleuze's dialectic (the constitution of problems) leads directly into his analytic (concepts as cases of solution), which he presented in his late book *What Is Philosophy?* (1991, co-authored with Guattari). Deleuze defines philosophy as the art of creating concepts, as knowledge through pure concepts. But for Deleuze, the highest concepts are not a priori universals applicable to objects of possible experience (categories), but singularities that correspond to the structures of real experience. Concepts are self-referential—they posit their object in being posited—and are defined in terms of their consistency of their components (endo-consistency) and their relation

to other concepts (exo-consistency). Deleuze's analytic should be evaluated critically in relation to competing theories of the concept (Frege, Russell), which often make use of scientific functions or logical propositions as their model. His analysis of the concepts of "sadism" and "masochism" in his 1967 book *Coldness and Cruelty* (and his concomitant critique of the notion of "sado-masochism") provides an excellent case study of his differential approach to concepts.

## DEL VECCHIO, GIORGIO (1878–1970)

Giorgio Del Vecchio, the Italian legal philosopher, was born in Bologna, the son of the economist Giulio Salvatore Del Vecchio. He studied in Italy and Germany and taught in Ferrara, Sassari, Messina, Bologna, and at Rome, where he was a professor from 1920, rector of the university from 1925 to 1927, and dean of the faculty of law from 1930 to 1938. He was dismissed by the fascists in 1938 because of his Jewish background. He resumed teaching in 1944 but was dismissed again in 1945, this time as a former fascist; he taught again from 1947 to 1953. He was named professor emeritus in 1955. Del Vecchio founded the *Rivista internazionale di filosofia del diritto* in 1921 and was its editor; he founded the Istituto di Filosofia del Diritto of the University of Rome in 1933 and the Società Italiana di Filosofia del Diritto in 1936.

Del Vecchio was influential in turning Italian legal thought from nineteenth-century positivism. His own position has been described as neo-Kantian idealism and as humanist ethical idealism. According to Del Vecchio, the thinking subject is necessarily conscious of the *other*, not merely as object, but as itself a subject. Hence, mutual recognition and respect are necessary, and it is possible to deduce for the mutual relations of subjects not merely a logical form but also an ideal content of justice based on respect for personality. Law is the objective coordination of possible actions between subjects according to an ethical principle, which in its highest expression is the principle of justice. Psychologically, the idea of justice is a necessary aspect of consciousness, found in rudimentary form even among animals. Historically, the idea has been realized with varying degrees of positivity in human societies, and continual effort is needed to realize it in the changing specific conditions of life. There are instances of “involution” (regression), but history on the whole shows a progressive evolution toward the understanding and

realization of justice. These main ideas, stated in Del Vecchio’s early writings, were developed with a wealth of historical learning in his *Lezioni di filosofia del diritto* and *La giustizia*; in other writings he applied them to particular problems of legal and political philosophy.

Del Vecchio, like other veterans of World War I, joined the fascist movement when it arose because he saw it as a defense against Bolshevism, and it is unjust to consider him a representative of fascist philosophy. For a time he did hope, mistakenly, that the fascist “strong state” might realize the “ethical state” that, by harmonizing individual freedoms, would enhance individual personality. Throughout the fascist period, however, Del Vecchio’s fundamental teaching was unchanged; and he continued to assert the validity of natural law and to defend individual freedom against the statolatry of official fascist doctrine.

## DEMIURGE

*Demiurge*, an anglicized form of *δημιουργός*, the ordinary Greek word for a workman, craftsman, or artificer, is

commonly used in Greek literature from Homer onward. In Homer it is applied to heralds, soothsayers, and physicians as well as to manual workers; but in later Greek it primarily means a craftsman or maker, such as a carpenter or a smith. Its importance in the history of philosophy derives almost entirely from Plato's *Timaeus*, in which a Demiurge, or Craftsman, is represented as ordering and arranging the physical world and bringing it as far as possible into conformity with the best and most rational pattern. In two other places (*Republic* 530A and *Sophist* 265C) Plato uses the word *δημιουργος*, or the corresponding verb, in connection with divine creation; and it occurs in one passage in Xenophon's Socratic discourses (*Memorabilia* 1.4.9), but these are all casual and isolated references. For our understanding of Plato's conception of creation we must rely almost exclusively on the *Timaeus*.

The *Timaeus* is, in fact, Plato's only substantial essay in physical theory and cosmology. There is disagreement about the date of the dialogue and about its place in the chronological order of Plato's writings; but it is generally agreed to be later than the great group of middle dialogues, from the *Phaedo* and *Symposium* to the *Republic* and *Phaedrus*, in which Plato expounds his most characteristic metaphysical and ontological doctrines. The substance of these doctrines is repeated and underlined in the *Timaeus* itself, which makes a sharp division between the eternal, transcendent, intelligible, unchanging world of true being or reality and the temporal, phenomenal, sensible, unstable world of mere becoming. It was this very contrast between the world of Forms and the world of sense that had led Plato to neglect physical research and speculation; and when he does turn to this subject in the *Timaeus*, he repeatedly insists that even his own best efforts in this field cannot produce more than an *εἰκὸς μῦθος*—a “likely tale”—falling far short of the certainty and exactness that can be sought in mathematics and pure philosophy. He speaks of the whole doctrine of the *Timaeus* in the provisional, tentative manner in which he presents the eschatological myths of the *Gorgias*, *Phaedo*, *Republic*, and *Phaedrus*.

Against this background it may appear surprising that Plato ventured on these topics at all. His motives become plainer if we remember his own comments in the *Phaedo* (97C–99D) on the cosmology of Anaxagoras. Socrates first praises Anaxagoras for holding that *νοῦς*—Intelligence or Reason—ordered and arranged the world, imposing a rational plan on a preexisting chaos. He then complains that Anaxagoras did not pursue this line of thought to its proper conclusion: He uses Reason as a mere *deus ex machina* to explain the origin of the cosmic

process as a whole but does not give detailed teleological explanations of particular things and events, showing that everything is arranged for the best. Anaxagoras resorts instead to the purely physical explanations that had been used by his Ionian predecessors, which is like trying to explain why Socrates does not escape from prison wholly in terms of bones and sinews, without reference to intelligence, intention, motive, and morality. Aristotle makes a similar comment in *Metaphysics* I,3: Anaxagoras stands out among his contemporaries and predecessors “like a sober man among drunkards,” but he does not make proper use of his concept of cosmic *νοῦς*.

The *Timaeus* is Plato's attempt to carry out the program of rationalist cosmology that Anaxagoras had promised but had failed to fulfill. The Demiurge is portrayed as the agent who turns the initial chaos into a cosmos. Like a human craftsman, he arranges existing materials and does not create them. The conception of creation *ex nihilo* is foreign to the whole tradition of Greek thought. The Demiurge shapes his materials to conform as much as possible to the eternal intelligible model of the Forms. First, he makes other gods, the world soul that the cosmos requires as its motive principle, and the immortal part of the human soul. The created gods then complete the work by making physical things, including human bodies. The Demiurge's success is necessarily limited: the Reason that constitutes his pattern is opposed by a recalcitrant Necessity (*ἀνάγκη*) that hinders his work in something like the way in which a human craftsman may be frustrated by intractable materials—and no material is perfectly tractable. This obstacle to a faultless achievement by the Demiurge is also the main reason why Plato cannot hope to give more than a “likely tale” of the Demiurge's work.

It has been widely believed, from ancient times to the present day, that the Demiurge is a mythical figure and that Plato did not believe in the literal existence of such a creator-god. He is a personification of the Reason whose requirements he is represented as trying to embody in the nature of the cosmos. Even if he is literally meant, he must still be sharply contrasted with the creator-god of the Judeo-Christian tradition, not only because he is not in that sense a creator, but also because he is in no sense an object of worship.

It is more difficult to decide whether the process of creation is also mythical; whether Plato believed that the imposition of order on the physical world was a definite event that took place at some time in the past, or whether the narrative of the *Timaeus* is a presentation in chronological form of Plato's views about the relative value and

ontological priority of the various elements in the universe. According to this latter view, the story that bodies were created after souls would be a pictorial way of marking the inferiority of the body to the soul. Aristotle reports (*De Caelo* 279b33) that this was the tradition in Plato's Academy. The chronological picture is said to be used only for purposes of exposition, like a figure in geometry. Aristotle himself took the chronology literally, and he was followed in this by Plutarch; but the ancient authorities were nearly all on the other side.

Most modern scholars have disagreed with Aristotle, but he has had some notable supporters; and the question is still being debated. In support of the usual interpretation one may quote the parallel case of the *Republic*, where the building and dissolution of the ideal community is a pictorial means of presenting a logical analysis in chronological terms. Defenders of the opposite view point out that the word γέγονεν ("it came into being") gives an emphatic answer to the crucial question "Has the cosmos always been, or has it come to be, starting from some beginning?" (28B). However, the imagery of the *Republic* is equally emphatic. Once a man has chosen to represent one thing by painting a picture of another, the fact that he uses firm brush strokes and bright colors does not destroy its claims to be a picture.

The concept of the Demiurge was taken over by the Neoplatonists and by some Gnostic writers. To the Gnostics he was the evil lord of the lower powers, creator of the despised material world, and entirely separate from the supreme God. Their parody of the Demiurge as a clumsy imitator is blended with hostile satire of the Old Testament creator-God. Plotinus protested against their conception of the Demiurge as a source of positive evil in the world.

There is no clear case of any notable modern thinker whose teaching has been closely or directly influenced by the concept of the Demiurge, although there are hints of a similar idea in J. S. Mill's essay "Theism," where the word *Demiurgos* is applied to a God whose creative power is limited by the nature of his materials.

## DEMOCRACY

*Democracy* is difficult to define, not only because it is vague, like so many political terms, but more importantly, because what one person would regard as a paradigm case another would deny was a democracy at all. The word has acquired a high emotive charge in the last hundred years; it has become good tactics to apply it to one's own favored type of regime and to deny it to rivals. The most diverse systems have been claimed as democracies of one sort or another, and the word has been competitively redefined, to match changes in extension by appropriate changes in intention. However, there is still this much agreement: Democracy consists in "government by the people" or "popular self-government." As such, it would still be universally distinguished from, say, a despotism that made no pretense of popular participation—the despotism of Genghis Khan or of Louis XIV, for instance—or from a theocracy, like the Vatican. There remains plenty of room for disagreement, however, about the conditions under which the people can properly be said to rule itself.

In the first place, what is "the people"? In ancient Greece, the *demos* was the poorer people; democracy meant rule of the poor over the rich. This is still the usage of those who identify the people with the proletariat and democracy with the rule of the working class. The word *people*, however, is often used to differentiate the subject mass from the ruling elite, as, for instance, when John Locke speaks of a tyrannical government putting itself into a state of war with the people. In this sense, "the people" necessarily means the ruled. Can the people, however, be said *to rule itself* in the same sense as it is said to be ruled by monarchs, oligarchs, and priests? To rule is,

generally, to prescribe conduct for someone else. There is a sense, it is true, in which moralists speak of ruling oneself, when by a kind of metaphor they speak of reason governing the passions. Again, a former colony becomes self-governing when its people is no longer ruled by outsiders; but this is not inconsistent with its still being ruled by *native* masters.

The usual paradigm of a people governing itself is the direct democracy of ancient Athens. Admittedly, citizenship was a hereditary privilege, excluding slaves and metics, and it is very doubtful whether, without this limitation, the citizen body would have been small enough for it to have operated as it did. Aside from this, however, the Athenian people governed itself in the sense that every individual could participate personally in policy decisions by discussion and voting, in a face-to-face situation. Athenian procedures are held to have been democratic in the sense that everyone was supposed to have an equal opportunity to state a case and influence decisions, even if, in some cases, individuals had ultimately to accept decisions that they had previously resisted. So today, in a similar sense, if a school or a department is said to be democratically run, we should expect its head to consult his staff on important issues and to concur in decisions to which he himself is opposed when the weight of opinion is against him. Self-government for a small group consists in general participation in the deliberative process, in which each person's voice carries a weight appropriate not to his status but to the merits, in the judgment of others, of what he has to say. If, despite continuing disagreement, a decision is essential, then it must be arrived at by majority vote. For it is not consistent with equal participation in decision making for any one individual to be privileged to say in advance that regardless of the distribution of opinions, his own or that of his group must prevail. That privilege excluded, decisions may be reached by lot or by vote; and if by vote, the opinion of either the lesser or the greater number may prevail. Deciding by lot was in fact used in Athens to fill certain public offices; it is a way of giving everyone an equal chance where advantages or privileges cannot be equally and simultaneously enjoyed; but to decide policy by lot would make nonsense of the procedure of public discussion, which is as integral to the democratic process as the idea of equality. The same would apply to a rule whereby whatever opinion received the fewest votes would prevail; for what point would there be in persuasion if it had no effect on the outcome or, still worse, if it actually reduced the chance of one's view being implemented? If a democratic decision is thought of, then, as the result of a fair confrontation of

opinions, it must, at best, be generally agreed upon, and at worst, agreed upon by the majority.

## CONDITIONS OF POLITICAL DEMOCRACY

Obviously, the conditions of face-to-face democracy, with direct participation, cannot be fulfilled within the political structure of modern states, both because of the size of their populations and because of the specialized knowledge needed to govern them. So although everyone may agree on what makes a small group democratic, when it comes to applying the concept to mass organizations, there is plenty of room for different interpretations of the principles to be applied and of the way to realize them under these very different conditions. Democracy now becomes representative government, that is, government by persons whom the people elect and thereby authorize to govern them.

*Election* and *representation* are themselves complex notions, however. In one sense, to be representative of a group may mean no more than to possess salient characteristics common to and distinctive of most of its members. In another, quasi-legal sense, one person may be said to represent another if, according to some code of rules, the consequences attached to an act of the representative are precisely those that would be attached to the act had it been performed by the principal himself; the representative can, in this case, *commit* the represented. In yet a third sense, one may represent another by looking after his interests, with or without his authorization (for example, the representation of infants in law). Now, democratic representation need not imply representation in the first sense, that of resemblance. Since an elected member of a legislature is taken to represent those who voted against as much as those who voted for him, he need not resemble those he represents, even in his opinions. Nor does he commit them as if they themselves had acted; the fact of their having legal duties does not depend on the fiction that, if their representative votes for a law, they have personally agreed to it. Their legal duties remain even if their representative voted against it. Nor must we necessarily accept moral responsibility for what is done by those who politically represent us, for in voting against them, we may have done the only thing open to us to disavow them.

Political representation is closer to the third sense of the term—the representation of interests; a democratic representative is usually thought to have the duty to watch over either the interests of his constituents or, as a member of an assembly representing the whole people,

the interests of the people at large. Nevertheless, he could still represent the interests of a group of people without their having had any part in choosing him. Some members of colonial legislatures in Africa used to be nominated by the governor to represent the interests of the unenfranchised native population. Precisely analogous, from the standpoint of the liberal democrat, is the case of a single-party system, where the ruling party invites the electors to endorse the candidate it has chosen to represent them. No matter how zealously the representative watched their interests, this would not count as democratic representation, precisely because the electors had had no part in selecting him. This view of democracy, therefore, is not compatible with tutelage; it implies the possibility not only of rejecting but also of freely proposing candidates, if none put forward by others is acceptable. Choosing and rejecting representatives is, indeed, the central act of participation by the citizens of a mass democracy, from which any effectiveness that they might have in other respects derives.

Closely related to election is the notion of the *responsibility* of the democratic representative. This means, in practice, that representatives must submit themselves periodically for reelection and, as a corollary, that they must be prepared to justify their actions and to attend to the experience and needs of their constituents, whose good will they must retain so long as they wish to remain in office.

## DEMOCRACY AND POPULAR SOVEREIGNTY

It is often said that in a democracy the people's will is sovereign. But can the people be said to have a will? Opinions are divided on most things; there may be ignorance and apathy; on many questions only sectionally interested groups may have any clear opinions at all. Small groups, like committees, may reach agreed policies to which everyone feels committed; or in time of grave national danger, whole nations may discover a collective devotion to a single objective, overriding all conflicts of interests. However, although it might be intelligible to speak of a collective will in such cases, they are too limited or too rare to provide a framework for a general theory of democratic government. Such cases apart, one may speak of action, will, or decision in relation to collectivities only if their collective acts can be identified by some more or less formal procedure or if there are rules authorizing some identifiable individual to act *in the name of* the whole group. Thus, "Parliament has decided ..." presupposes rules determining who are members of Parliament, defin-

ing their roles, and giving their several actions a collective significance and validity as "legislation." Are there analogous procedures, by virtue of which the people can be said to act or to express a will? Only by voting and by applying the majority principle in elections and referenda. And of course, applied to any particular collection of individual votes, different systems of voting or different arrangements of constituency boundaries can yield quite different results, each in its own rule context expressing "the people's will." Nevertheless, some people consider a system democratic to the extent that it approximates to government by referendum, though they would agree that this could not work as a day-to-day procedure. The doctrine that a government ought not to initiate policy changes without putting them to a vote in a general election (or, in a stronger form, that having done so, it is entitled—or obliged—to implement them forthwith) is a practical application of the popular-sovereignty view of democracy. A possible corollary sometimes derived from this last view is that it is undemocratic to oppose or impede any government acting with the people's mandate. Moreover, since the people is sovereign, the traditionally important safeguards against the abuse of power become otiose; for, in Jean-Jacques Rousseau's words, "the sovereign, being formed wholly of the individuals who compose it, neither has nor can have any interest contrary to theirs." Popular-sovereignty theory is always, therefore, on the brink of totalitarianism, since—as the French Jacobin party showed—it is only a short step from proclaiming the sovereignty of the people to claiming the unlimited authority of its elected representatives, to proscribing opposition, and to denying individuals any rights other than those which the government with majority support deems fit.

There is, of course, another view, closer to the tradition of liberal individualism, which sees democracy as a way of safeguarding and reconciling individual and group interests. For James Madison, the virtue of the new Constitution of the United States was that it permitted no faction, not even a majority, to deprive minorities of their natural rights, since it demanded the concurrence in action of independent authorities. The constitution was designed to balance diverse interests against one another, so that none might ever become a dominant and entrenched majority. More recent pluralistic accounts of democracy (or of what R. A. Dahl calls "polyarchy"), while more sophisticated, follow a similar approach. To be democratic, policy-making agencies must be sensitive to a wide range of pressures, so that no interest significantly affected by a decision will be left out of account. Popular participation consists not merely in voting, but

also in wide consultation with interest groups and in the whole process of public criticism and governmental self-justification. Democracy, according to this view, requires the dispersal, not the concentration, of power; every voter has his quantum, making him worth the attention of those who want to govern. The people is not homogeneous, but a highly diversified complex of interest groups with crisscrossing memberships. It rarely makes sense to talk of the majority, except with reference to the result of a particular election or referendum, to describe how the votes were cast. A sectional majority, if there were one, would have no intrinsic claim to rule. To govern, a party would have to piece together an electoral majority; but every elector would have his own reasons for voting as he did, and no party could say in advance that, since it had no potential supporters among the members of some particular group, that group could, therefore, be safely neglected. Admittedly, wherever group divisions coincide over a wide range of interests (as, for instance, in many polyethnic societies), these conditions might not be fulfilled, and there might be a built-in majority and minority. In such a case, no party aiming at majority support could afford to uphold a minority interest, and democracy would tend to give way to majority tyranny. Thus, where popular-sovereignty theorists see the majority as the expression of the supreme will of the people, writers such as Madison, Alexis de Tocqueville, J. S. Mill, and, more recently, Walter Lippmann and the pluralists have seen it as either a myth or a potential tyrant.

### THE POSSIBILITY OF DEMOCRACY

According to elitist sociologists like Vilfredo Pareto, Gaetano Mosca, and Robert Michels, there is always, behind the democratic facade, an oligarchy, even though its members take turns at playing the key governing roles. Now obviously, in every organization leaders initiate action and followers concur, but the power relations between leader and led are not on that account always the same. Precisely because democracy is a form of political organization, it *must* also be a pattern of leadership; nevertheless, the way leaders gain and retain their authority; the extent to which their initiatives respond to the interests of those they lead; their need to listen to and answer criticism—these things distinguish a democracy in important ways from what we usually mean by an oligarchy.

For the Marxist, bourgeois democracy is a sham because equal political rights cannot equalize political power where economic power is unequal. This does not amount to saying that democracy is *necessarily* impossi-

ble, only that economic equality and a classless society are necessary conditions for it.

According to other critics, popular self-government is delusory because government calls for expertise that few voters possess. Most accept the directions of some party, to whose image they are irrationally committed, and are incapable of a rational choice of policy. However, except in the popular-sovereignty variant, democracy does not require the electors to choose policies. Their role is merely to choose governors whom they trust to deal fairly and efficiently with problems as they emerge, and to look for new governors when they are disillusioned. A party's public image need not be an irrational construct; it may accurately epitomize deep-rooted tendencies and traditional preferences and be a reliable guide to the spirit in which the party would govern.

### JUSTIFICATION OF DEMOCRACY

Democracy, it is sometimes said, asks too much of ordinary men, who would never be prepared to maintain the lively and informed interest in politics that ideally it demands. This, however, presupposes a particular view of the purpose and justification of democratic government. For some writers, as J. S. Mill, men and women cannot be fully responsible, adult, moral persons unless they are "self-determining," that is, concerned about the ways in which their lives are to be controlled. This view is a development from an older natural-rights theory of democracy, according to which (in the words of Colonel Rainborough, the Leveller), "Every man that is to live under a government ought first by his own consent put himself under that government," this being a condition for preserving his natural autonomy as a rational being. Or again, for democrats in the tradition of Rousseau, men achieve moral fulfillment only as participants in the collective self-governing process, helping to give expression to the "General Will" for the "Common Good"; failure in this constitutes failure in one's moral duty as a citizen.

There is, however, a more strictly utilitarian theory, sketched by Jeremy Bentham and James Mill and implicit in a good deal of the work of democratic political scientists today. According to this view, the test of the adequacy of a political system is whether it tends to provide for the interests of the governed and protect them against the abuse of power. Democracy, they maintain, is likely to do this better than other systems. Active participation has no intrinsic virtue. Mill would have limited the franchise to men over forty, on the grounds that the interests of women and younger men would be adequately safe-

guarded by their husbands and fathers, and therefore universal suffrage would be an unnecessary expense. For many modern writers, politics is a second-order activity: if things are going well, there is really no reason for people who prefer to spend their time on other things to devote it to politics. Political activity, indeed, is often most vigorous, as in Germany before 1933, when passions are high and democracy is in imminent danger of collapse. Apathy may be a sign of political health, indicating that there are no irreconcilable conflicts nor serious complaints. If there is ground for disquiet, it is only that apathy may become so habitual that democracy's defenses may be found unmanned in the face of some future attack.

This is a prudential model of democracy, in which satisfaction is maximized and conflicts reconciled by pressures bringing countervailing pressures into operation. It leaves out of account, perhaps, the sense in which democracy moralizes politics. Because decisions have to be publicly justified, political debate is conducted in moral terms, reviewing the impact of decisions on all interests affected, not just on this or that pressure group. Moreover, the quantum of power one has as a citizen can be represented not simply as a lever for personal or sectional protection or advantage, but also as a public responsibility; for even when one's own interests are not affected, one is still a member of a court of appeal. The bystanders in a democracy are, in a sense, the guarantors that a political decision shall not simply register the strongest pressure but shall be a reasoned response to diverse claims, each of which has to be shown to be *reasonable*, in the light of whatever standards are widely accepted in the community.

## DEMOCRACY [ADDENDUM]

It is widely agreed that democracy is a system of government in which the people rule. Since the term "democracy" is often also used to describe nonpolitical

communities—such as religious congregations, clubs, and athletic teams—democracy may be understood more generally to be a system in which the community is governed through the participation of its members. Thoroughly understanding democracy therefore requires answers to five key questions about this process of participation: What does democracy *presuppose*? What are the principal *instruments* that democracies must employ? What *conditions* are critical for its success? How can democracies be *appraised*? How can democracy be *theoretically defended*?

### PRESUPPOSITIONS OF DEMOCRACY

For a democracy to be realized in any context, the community to be governed must self-consciously recognize itself as such, those entitled to participate in its government must be identified as citizens or members, and the extent of the community's concerns, both geographical and theoretical, must be at least roughly agreed upon. In short, democracy presupposes *community*.

Democratic government is possible only if members of the community can participate in decision making. They must be able to communicate effectively and to grasp the relations of means to ends. Participating citizens will not always be rational, of course, but at a minimum, democracy presupposes that members of the community have a *capacity for rationality*.

### INSTRUMENTS OF DEMOCRACY

Democracies with many members must devise systems by which those members can reasonably effect their wills. All cannot speak; therefore some must speak and act for others. There are many kinds of representation (geographic, institutional, proportional, etc.). Whatever the manner of representation, every democracy of substantial size must have some *system of representation*.

Since there will be continuing and often serious disagreements among the participating members, every democracy must employ some *decision-making rules*. The rule of the majority, of the greatest number, is foremost among these, but other rules (qualified majorities, the rule of consensus, etc.) are also used in some contexts. A *system of representation* and *decision-making rules* within that system are essential instruments of every democracy.

### CONDITIONS FOR THE SUCCESS OF DEMOCRACY

Self-government will not be sustainable unless some conditions are widely (but not necessarily universally) met within the community that aims to be democratic.

Some *material* conditions must be realized, chiefly a degree of economic well-being sufficient to permit its members to devote the needed time and energy to self-government. Ideally, the economic system should support, and even encourage, general participation. Yet which economic systems best do this is a topic of unending controversy.

Some *constitutional* conditions are essential for democratic participation in decision making. Among these the most essential are universal (or almost universal) protection of the *right to vote* and the *right to speak freely*. Thus a central condition of democratic success is a widely respected and legally protected liberty of all to publish with little or no restraint, to engage in robust political debate, to criticize intensely and vigorously those presently in authority.

Some *intellectual* conditions must be realized if general participation is to be reasonably successful. *Information* needed for decision making must be widely available; secrecy must be minimized. Citizens must be able to use this information. Thus an inevitable goal of every democracy will be *education*, broad and deep.

Some *psychological* conditions must also be realized. Citizens must permit intense opposition and debate while retaining good will. Citizens must be generally disposed to keep their expectations reasonable, to invite experimentation, and above all to encourage and accept compromise. A democracy is not likely to succeed unless its members, by and large, have the flexibility and resilience to bear defeat with patience when all does not go their way.

In a perilous world, political democracies require some *protective* conditions. A democratic state must be able to ward off international enemies, and therefore must sometimes rely on (while carefully controlling) military forces that themselves are not democratically organized. There must be security against attacks from without and subversion from within, but to achieve such security without sacrificing constitutional liberties is the greatest modern challenge for political communities that hope to become or remain democratic.

### APPRAISING DEMOCRACIES

Self-government is a method of achieving the objectives of the members of a community. What they will seek cannot be known in advance. So appraising a democracy cannot depend on its goals, which we may despise. Democracies often make bad laws and sometimes behave immorally. The extent to which a community has

achieved a democracy may be appraised by estimating *the degree to which the will of its members is genuinely realized by its government*.

This yardstick of achievement has two principle dimensions. First, how *broadly* within the community is participation realized in fact? Excluding from participation any substantial fraction of the community directly undermines the self-government of the community as a whole. Breadth of participation is fundamental; universal participation is the ideal, never perfectly realized. Democracy is crippled when breadth is restricted by law, as when women could not vote or when serfs or slaves had no voice in community affairs. But democracy is also undermined when segments of the community are excluded in fact, even if not by law, as when ethnic minorities are oppressed in nations that profess democracy but informally limit participation. And when apathetic citizens ignore or abandon the process of participation, democracy is wounded.

Second, how *deep* is community participation? To gauge a democracy, one must estimate not only the number of citizens who vote, but also the quality of their interaction and discussion for the eventual vote. In a healthy democracy, elections are not the only manifestation of participation; member participation unceasingly goes on in the informal workings of its representative system.

Great breadth combined with substantial depth is exceedingly difficult to achieve, especially when the political community is very large, as most nations are. But that combination is the ideal against which every democracy (whatever its particular objectives) must be appraised.

## THE THEORETICAL DEFENSE OF DEMOCRACY

Even when the instruments of democracy are well devised and the conditions of its success are realized in good measure, there remains the question, Why should we want democracy? Answers of two kinds may be given: We may *vindicate* the process by showing that the outcomes of self-government tend to be more beneficial than those of its alternatives. We may *justify* the process by showing that democracy is the form of government most nearly in accord with our most fundamental moral convictions, that is, by showing that universal participation in government is morally right.

**VINDICATION.** Democracy, its proponents contend, is the one system most likely to achieve the objectives we seek through government. Among the alternatives, it is

the most likely to enact just laws, because all (or most) members are represented in the law-making process. It is the most likely to reach wise decisions (though, of course, it does not always or universally do so), because it provides maximal opportunities for all to contribute. Of all forms of government, it is the most likely to avoid violence and disorder, because all have opportunity to speak. And it is most likely to safeguard the freedoms of speech and conduct, just because those freedoms are so central to the democratic process itself. Democracies behave stupidly and badly at times, but all things considered and over the long run, they are likely to produce better outcomes for community members than those of any alternative system of government.

**JUSTIFICATION.** Democracy can be justified by showing that it is the one form of government that most fully gives to community members what they deserve, what is most fair to them. Democracy presupposes that community members are roughly equal—equal not in skill or strength, but in being persons with lives to live, and therefore equally entitled to a voice in community affairs. Only democracy can give them that voice. The autonomy that individuals prize in their lives is prized in the larger social sphere as well. In that larger sphere, autonomy can be realized only when the members of a community, through participation in common affairs, govern themselves.

## DEMONSTRATIVES

Demonstratives are one type of *indexical*. Like other indexicals, demonstratives can be used to refer to different objects on different occasions. Some examples of demonstratives are *that*, *this*, *you*, *he*, *she*, *there*, *then*, *this dog* and *that yellow house*.

### INDEXICALS AND DEMONSTRATIVES

Philosophers of language commonly distinguish between the *meaning* of a linguistic expression and its *referent*. For example, the definite descriptions *the president of the United States in 2003* and *the husband of Laura Bush in 2003* refer to the same individual (namely, George W. Bush), but differ in meaning. Indexicals (also known as *context-sensitive expressions*) lead many philosophers to distinguish between two different sorts of meaning. Consider the paradigm indexical *I* and suppose that Al and Bob both utter the sentence *I live in Chicago*. Their utterances of *I* have the same meaning, in one sense of *meaning*. Let us call the type of meaning that their utterances share *linguistic meaning*. But there are reasons to think that their utterances also differ in some other type of meaning. Al's utterance of *I* refers to Al, whereas Bob's utterance refers to Bob. Al and Bob also say different things: Al says that Al lives in Chicago, whereas Bob says that Bob does. Finally, one of their utterances may be true while the other is false. Let us call the type of meaning that their utterances do not share *content*. All utterances of *I* have the same linguistic meaning, but utterances that are produced by different speakers have different contents. Similarly for the sentence *I live in Chicago*.

A speaker's utterance of *I* refers to that speaker no matter what object he might want to refer to, even if he intends to refer to Napoleon Bonaparte as he utters *I* (because he mistakenly thinks that he is Napoleon) and even if he points at someone else as he produces his utterance. By contrast, the referent of a speaker's utterance of *he* depends on the speaker's intentions or pointing gestures. If Al intends to refer to George W. Bush, and points at Bush as he utters *He is a Republican*, then his utterance of *he* refers to Bush. If Al instead intends to refer to Bill Clinton, and points at Clinton, then his utterance of *he* refers to Clinton. Indexicals, such as *he*, whose reference and content depend on the actions or intentions of the speaker are commonly called *demonstratives*. Those that do not, such as *I*, are often called *pure indexicals*. David Kaplan (1989a, 1989b), whose work on indexicals is highly influential, claims that *he*, *she*, *this*, and *that* are demonstratives, whereas *I*, *today*, *tomorrow*, *yesterday*, *now*, and *here* are pure indexicals.

The pronouns *he* and *she* are often used as demonstratives, but they also have nondemonstrative uses. For instance, the pronoun *he* is used in roughly the same way as a bound variable of formal logic in the sentence *Every man thinks that he is handsome* (on the interpretation “for every man  $x$ ,  $x$  thinks that  $x$  is handsome”). The pronoun *she* is used as an anaphor in *Fiona sat down. She picked up a pencil*. It is controversial how these uses of *he* and *she* are related to their demonstrative uses.

## REFERENCE-FIXING FOR DEMONSTRATIVES

We previously observed that the reference of a demonstrative utterance depends on the speaker’s intentions or pointing gestures. Kaplan’s early work (1989b) tends to emphasize the importance of pointing gestures in determining reference. In this early work Kaplan says that an utterance of a demonstrative is typically accompanied by a *demonstration*, which is a public presentation of an object that is typically, though not always, a pointing gesture. The demonstration determines a demonstrated object (a *demonstratum*) in a context, and the demonstratum is the referent of the demonstrative, in the context. Kaplan’s later work (1989b) tends to emphasize the role of speakers’ intentions. According to it demonstrations are directed towards objects by *directing intentions* and it is directing intentions that determine the referents of demonstrative utterances.

One difficulty for the view that pointing gestures determine reference is that not all utterances of demonstratives are accompanied by pointing gestures. Kaplan’s early theory allows there to be demonstrations that are not pointing gestures, but unfortunately leaves unclear what demonstrations (in general) are. A problem for the view that directing intentions determine reference is that it is not clear what directing intentions are. Speakers typically have many different intentions when they utter demonstratives. When Gail utters *he*, she may simultaneously (1) intend to refer to Hal, (2) intend to refer to the man she sees, and (3) intend to refer to the man to whom others are referring with *he*. But these intentions may conflict, and it is unclear which of them (if any) is a directing intention.

## KAPLAN’S SEMANTICS FOR PURE INDEXICALS

Kaplan (1989b) presents a semantics for indexicals that attempts to describe their various meanings. We shall first consider how his theory works with pure indexicals, and then consider how to extend it to simple demonstratives.

(The following text concentrates on Kaplan’s informal remarks about the semantics of indexicals. His formal logical system uses the apparatus of possible-worlds semantics.)

Kaplan’s theory begins with the idea that a linguistic expression has a *content with respect to*, or *in*, a *context* of utterance. For instance, the word *I* has a content in every context, depending on who the agent of the context is. For every context  $C$ , there is an agent of  $C$ , a location of  $C$ , a time (or day) of  $C$ , and a possible world of  $C$ . The content of the word *I* in any context  $C$  is the agent of  $C$ , the content of *here* at  $C$  is the location of  $C$ , and the content of *now* and *today* at  $C$  is the time (day) of  $C$ . The linguistic meaning, or *character*, of an expression is a function whose value at any context  $C$  is its content in  $C$ . For instance, the character of *I* is a function on contexts whose value at any context  $C$  is the agent of  $C$ .

The content of a declarative sentence in a context is a *proposition*, which is an entity that can be an object of attitudes such as belief, doubt, and assertion. When a speaker assertively utters a sentence, she asserts the proposition that is the content of her sentence in her context, and if she is sincere, then she believes that proposition. On Kaplan’s (informal) semantics, propositions have constituent structures that resemble the constituent structures of sentences: Just as sentences have words as parts or constituents, so propositions have individuals, properties, and relations as parts or constituents. If the content of sentence  $S$  in context  $C$  is proposition  $P$ , then the constituents of  $P$  are (roughly) the contents, in  $C$ , of the words in  $S$ . For example, suppose that  $C^*$  is a context in which Inga is the agent. Then the content of *I laugh* with respect to  $C^*$  is a proposition whose constituents are Inga and the property of laughing. If Inga laughs in the possible world of context  $C^*$ , then *I laugh* is true in context  $C^*$ .

The sentence *I am speaking* is false in some contexts, according to Kaplan, because there are contexts in which the agent is not speaking. However, every agent of every context exists in the possible world of that context. Therefore, *I exist* is true in every context. Thus, Kaplan (1989b) claims that *I exist* is a logical truth. But the content of *I exist* in a context is (usually) not a necessary truth. For example, the content of *I exist* with respect to context  $C^*$  above is the proposition that Inga exists. This is not a necessary proposition. Therefore on Kaplan’s theory, the sentence *I exist* is a logical truth that fails to express a necessary truth in many contexts.

## EXTENDING KAPLAN'S THEORY TO SIMPLE DEMONSTRATIVES

One way to extend Kaplan's (1989a, 1989b) theory to simple demonstratives involves adding more items to contexts. (A second way, which will not be discussed here, involves Kaplan's dthat-terms.) For instance, one can suppose that every context has a sequence of demonstrata, and that the content of *that*<sub>1</sub> with respect to context *C* is the first demonstratum of *C*, the content of *that*<sub>2</sub> is the second demonstratum of *C*, and so on. One can then say that the character of *that*<sub>1</sub> is a function whose value at every context *C* is the first demonstratum of *C*, the character of *that*<sub>2</sub> is a function whose value at every context *C* is the second demonstratum of *C*, and so on. Similarly, one can suppose that every context has a sequence of addressees and that the content of *you*<sub>1</sub> is the first addressee, the content of *you*<sub>2</sub> is the second addressee, and so on.

There are two difficulties with this extension. First, We saw earlier that the referent of a demonstrative in a context is determined, somehow, by the pointing gestures and intentions of the speaker. The preceding theory assumes that every context has a sequence of demonstrata. But as Kaplan (1989b) points out, the agents of many contexts are not pointing at any objects and do not have any intentions that are relevant to determining a referent for a demonstrative. So it is highly artificial to suppose that every context contains a sequence of demonstrata. Second, the English word *that* is a single linguistic expression with a single linguistic meaning. But the previous theory instead provides an infinite number of distinct subscripted demonstratives (*that*<sub>1</sub>, *that*<sub>2</sub>, ...), each with its own character (Braun 1994).

## BELIEF AND DEMONSTRATIVES

Propositions that have individuals as constituents are known as *singular propositions*. Kaplan's theory says that singular propositions can be asserted and believed. This claim is problematic. Suppose that John is wearing a shirt with a large stain on its back. Suppose that he sees the back of his shirt in a mirror, but does not realize that he is viewing his own shirt. Then he may sincerely say *I am wearing a clean shirt and he is not wearing a clean shirt*, as he points at the person reflected in the mirror. On Kaplan's theory, John asserts and believes the contradictory singular proposition that John is wearing a clean shirt and John is not wearing a clean shirt. But surely he does not believe a contradictory proposition.

Gottlob Frege gives similar reasons for thinking that the content of a proper name is not its referent, but is

instead a sense that determines a referent. Kaplan (1989b) and John Perry (2000) respond to Fregean criticisms of Kaplan's theory and criticize Frege's theory of demonstratives.

## COMPLEX DEMONSTRATIVES

Complex demonstratives are expressions of the form *that CN*, where *CN* is a common noun phrase. Examples are *that car*, *that man who is wearing a baseball hat*, and *that yellow house*. Kaplan's theory does not mention complex demonstratives, and it is not entirely clear how they should be integrated into a theory of demonstratives. The major issue concerns the property expressed by the common noun phrase inside a complex demonstrative. Is this property a part of the content of the entire complex demonstrative? For instance, does the content of an utterance of *that yellow house* include the property of being yellow? Or, alternatively, is the content of the complex demonstrative simply the object to which the utterance refers?

On the one hand, it seems that a speaker's intentions and demonstrations are relevant to determining the referent of *that yellow house*. In this respect, *that yellow house* resembles the simple demonstrative *that*. We concluded earlier that the content of a simple demonstrative is just its referent. Therefore, We have some reason to think that the content of a complex demonstrative is also its referent and to think that the property of being yellow is not a part of the content of *that yellow house*. David Braun (1994) and Nathan Salmon (2002) argue for this view of complex demonstratives. On the other hand, the complex demonstrative *that yellow house* has a syntactic form much like the syntactic forms of the definite description *the yellow house* and the quantifier phrase *some yellow house*. Most philosophers think that the contents of *the yellow house* and *some yellow house* include the property of being yellow. That is some reason to think that the content of *that yellow house* also includes the property of being yellow. Jeffrey C. King (2001) argues for this latter view.

## DE MORGAN, AUGUSTUS

(1806–1871)

A British mathematician and logician, Augustus De Morgan was born at Madura, India, where his father was an army officer. After early education in the west of England, he entered Trinity College, Cambridge, in 1823 and graduated fourth wrangler in 1827. His refusal to subscribe to the religious tests then in force precluded him from further advancement at Cambridge, but he was fortunate enough to be appointed first professor of mathematics at the newly opened University of London. Because of his habit of resigning on matters of principle, he twice vacated this chair, once at the beginning and once at the end of his career; but he enjoyed, in the interval, the highest repute and affection as a teacher and had many pupils who later achieved distinction.

In addition to numerous important papers on the foundations of algebra and the philosophy of mathematical method, De Morgan was the author of several excellent elementary textbooks; a standard bibliography, *Arithmetical Books* (London, 1847); a large treatise on the calculus (London, 1842); and an enormous quantity of learned journalism, mostly in the shape of review articles in the London *Athenaeum* and contributions on mathematical and astronomical subjects to the *Companion to the Almanac* (1831–1857) and to the *Penny* (later *English*) *Cyclopaedia*. His best-known work in this line is the posthumously assembled *Budget of Paradoxes* (London, 1872), a still-diverting miscellany from the lunatic fringes of science and mathematics, originally serialized in the *Athenaeum*. Despite many years' service as secretary of

the Royal Astronomical Society, De Morgan was in general suspicious of official bodies and distinctions, never sought membership in the Royal Society, and declined an Edinburgh LL.D. Indifferent to politics and society—and professedly hostile to the animal and vegetable kingdoms as well—he nonetheless maintained an extensive scientific correspondence with such friends as William Whewell, George Boole, Sir John Herschel, Sir William Rowan Hamilton (the mathematician), and John Stuart Mill. His crotchets did little to disguise his exceptional benevolence and firmness of character or to inhibit his talents as a humorist and a wit.

De Morgan's outlook was that of a philosophical mathematician and historian of science; he did not claim to be a philosopher in any narrow sense of the term. He admired Berkeley and followed him to the extent of holding the existence of minds to be more certain, as a fact of experience, than that of a material world. But his general attitude to such questions may be gathered from his remark that, while he would not dissuade a student from metaphysics, he would warn him, "when he tries to look down his own throat with a candle in his hand, to take care that he does not set his head on fire."

In common with other mathematicians of his time, De Morgan realized that algebra could be conceived as a system of symbols whose laws could be codified independently of any arithmetical or other interpretation that might be given to them. His logic had a similar aim. Deeply versed in the history of logic, he was able to freshen and illuminate the subject by generalizing its traditional principles along mathematical lines. In this respect he ranks as the chief precursor of Boole; but his views attained notice chiefly through the controversy that arose when Sir William Hamilton (of Edinburgh) accused him of plagiarizing the doctrine of a quantified predicate.

De Morgan's *Formal Logic* (London, 1847) represents the best-known, though by no means the most mature, statement of his logical views. Among its many excellences, the chapter on fallacies is worthy of mention. De Morgan's later work is dispersed in pamphlets and periodicals, most notably in five memoirs contributed to the *Cambridge Philosophical Transactions* (Vols. 8–10, 1847–1863) and in his *Syllabus of a Proposed System of Logic* (London, 1860, reprinted in *On the Syllogism* (London, 1964). Though too largely concerned with polemics against Hamilton, and hampered by a notation that found no acceptance, these writings display much originality in the handling of negative terms, compound propositions, and numerous unorthodox varieties of syl-

logistic reasoning. Apart from the well-known “De Morgan laws” for the negation of conjunctions and disjunctions (or logical sums and products), the most important development was the recognition that the copula performs its function in the syllogism solely by virtue of its character as a transitive and convertible relation. De Morgan was led by this to examine the logic of relations in general and so paved the way not only for Peirce’s “logic of relatives” but for all that has since been done in this branch of the subject.

As a skilled actuary, who was often in demand as a consultant to insurance companies, De Morgan was not unnaturally interested in the mathematical theory of probability and the problems of applying it to the hazards of mortality and other types of experience. His treatise “Theory of Probabilities,” in the *Encyclopaedia Metropolitana* (London, 1837) and the more popular *Essay on Probabilities* (London, 1838) were among the earlier discussions of this topic in English (see further relevant chapters of *Formal Logic* and the papers on the evaluation of argument and testimony attached to the first two Cambridge memoirs above). De Morgan’s conception of probability was largely derived from Pierre Simon de Laplace, whose ideas (and errors) he was thus instrumental in propagating among his nineteenth-century successors. His method of approach was to construe the theory as an extension of formal logic, that is, as an investigation of the rules whereby propositions not absolutely certain affect the certainty of other propositions with which they are connected. He also employed the “inverse” procedures founded on Bayes’s theorem, whereby, from known factual premises, it is sought to conjecture the probabilities of their likely or possible antecedents. In attempting to quantify the degree of uncertainty involved, De Morgan identified it with the amount of belief that is, or rather, that ought to be attached to it by a rational person, and proceeded on this basis to discuss the compounding and derivation of partial beliefs in accordance with the mathematical rules of the calculus of chances. His view of the matter was thus both a priori and subjective, though not in the objectionably psychological sense that has sometimes been ascribed to him. There are better reasons for censuring the technical errors he fell into through uncritical reliance on the Laplacean “rule of succession” and “principle of indifference”; even here, however, his confidence in the mathematical apparatus was often less blindly trusting than that of the writers who preceded him.

De Morgan’s conception of scientific method may be gathered primarily from a review of Francis Bacon’s

works inserted in the *Budget of Paradoxes*. He there embraced what is essentially the modern “hypothetico-deductive” view of the subject; but one has to go to William Whewell before him or to W. S. Jevons after him to see it worked out in full.

### **Bibliography**

Apart from the works mentioned under the History of Logic entry there is not much literature on De Morgan. The best general accounts are in A. Macfarlane, *Ten British Mathematicians* (New York, 1916) and J. A. Passmore, *A Hundred Years of Philosophy* (London: Duckworth, 1957). The *Memoir* by his wife, Sophia Elizabeth De Morgan (London: Longmans, Green, 1882), contains an excellent account of him. The details of the quarrel with Hamilton may be found in Hamilton’s *Letter to Augustus De Morgan* (Edinburgh, 1847) and De Morgan’s *Statement in Answer* (London, 1847) or more readily in the appendices to De Morgan’s *Formal Logic*.

P. L. Heath (1967)

## DENNETT, DANIEL CLEMENT (1942–)

Daniel Clement Dennett obtained his first degree at Harvard, where, as he tells us in *Brainchildren* (1998), he vigorously resisted the most influential American philosopher of the twentieth century, Willard van Orman Quine. He then did a D. Phil. in Oxford in a brief two years under Gilbert Ryle, the most influential Oxford philosopher of his time, finishing in 1966.

His first book was *Content and Consciousness* (1969). These two words, *content* and *consciousness*, encapsulate much of Dennett’s mission. *Content* refers to the contents of the mind—all the beliefs, desires, values, emotions, hopes, expectations, memories, and so forth that make up the mind. *Consciousness* refers, of course, to consciousness. In Dennett’s view, the correct order in which to examine these topics is content first and then consciousness. Dennett’s central project is already clear in this book, the project of “naturalizing the mind.” This is the

project of showing that mind and consciousness are simply aspects of brain and behavior, just as much open to investigation by cognitive psychology and neuroscience as other aspects of cognition. He has never wavered in this commitment.

## CONTENT

Dennett's next book was a collection of essays, *Brainstorms*, written during the 1970s. This work helped launch a unique publishing enterprise, Bradford Books. Founded by Harry and Betty Stanton and subsequently absorbed by MIT Press, the Bradford insignia has become one of the most important collections of books in philosophy of mind and cognitive science in the English language.

*Brainstorms* begins with the first full articulation of Dennett's distinctive approach to mental content, the approach that he calls the intentional stance. According to Dennett, we can approach something in order to explain it from three stances: the physical stance, the design stance, and the intentional stance. Each has its own advantages and costs, but none is describing reality from the one correct perspective.

After editing, with Douglas Hofstadter, a charming collection of works by others on the mind, *The Mind's I* (1981), Dennett next turned to decision making and responsibility in an idiosyncratic little book called *Elbow Room: The Varieties of Free Will Worth Wanting* (1984). The book began life as John Locke Lectures in Oxford and espouses a brisk compatibilism between decisions being causally determined and decisions being free in any way that is "worth wanting." Interestingly, he returned to the topic of free will nearly twenty years later in *Freedom Evolves* (2003).

The year 1987 saw his second major collection of papers on content, *The Intentional Stance*. The papers in this collection are probably the most influential papers that Dennett has written. Near the end of the collection are two papers on evolutionary theory, a topic that was to loom large in his thinking in the 1990s.

Dennett's work on mental content has led him to questions about such topics as artificial content (AI [artificial intelligence]), the evolution of content, the relationship of content to the environment and brain (neuroscience), content in nonhumans (cognitive ethology), the nature of explanation in psychology and science generally, how content is represented and the different styles of mental representation, the relationship of repre-

sentations to the brain, and how we ascribe mental content to ourselves and others.

## CONSCIOUSNESS

At this point Dennett turned to consciousness, and a large book, *Consciousness Explained* (1991), ensued. For the first time, Dennett wrote a book deliberately aimed at a wide audience (it was not the last). Dennett laid out methods for studying consciousness, built a model of consciousness as a cognitive system, and discussed the nature of introspection (the consciousness we have of ourselves and our own mental states). He considered how consciousness evolved, pathologies of consciousness such as dissociative identity disorder (formerly multiple personality disorder), whether there is any real difference between how a mental state functions in us and how it feels to us (what philosophers call *qualia* or felt quality), what selves might be, the neural implementation of consciousness, and so on—just about every issue pertaining to consciousness.

This book has two main targets. One is the picture of conscious states that the tradition received from Descartes. This is the idea that there is something to a conscious state, some felt quality, that is unmistakably clear and clearly different from anything else in the world. The other is what Dennett calls the Cartesian theater, the idea that the conscious system is a kind of screen on which conscious states play before a little homunculus sitting in the middle of the theater. To replace the Cartesian picture in both its parts, Dennett proposed what he calls a Multiple Drafts Model (MDM) of consciousness. MDM treats consciousness as a kind of mental content, almost a matter of programming.

Dennett next wrote a shorter book pulling the two sides of his work together: *Kinds of Minds* (1996). Then he turned to a task that had been awaiting him for a long time: evolutionary theory. *Darwin's Dangerous Idea* (1995) was also published as a trade book and also enjoyed phenomenal success. Here Dennett argues for two main claims: (1) Darwin's theory of evolution is a "universal acid" that dissolves all manner of intellectual "skyhooks" and other pseudoscientific props that philosophers (and not just philosophers) have dreamed up to try to patch up hopeless theories; (2) yet contrary to those who see Darwin as the destroyer of all morality, the theory of evolution leaves one perfectly satisfactory approach to morality and political philosophy untouched: traditional western liberalism. Among the most important claims introduced in this book is that it is language that makes it possible for us to have our kind

of mind, a kind of mind that, by being able to cooperate with other minds and record the results of cooperation for others to build on, can figure out the physics of the universe, find cures for serious diseases, build Hubble telescopes and the Channel tunnel, and so on.

The book set off a stormy debate with Steven Jay Gould and others in the *New York Review of Books* in 1997. Gould insisted that Dennett had espoused an ultra-adaptationist position, assigning change in species to natural selection (selection on the basis of survival and reproductive fitness) over almost all other sources of change over time, such as cataclysmic changes in weather, exhaustion of habitats. Despite the heat that the debate generated (and some astonishingly uncollegial language), with the passage of time it now seems clear that the elements of agreement between the two of them are far greater than the elements of disagreement.

In the late 1990s, Dennett published another collection of essays, *Brainchildren* (1998), a remarkably diverse array of pieces mostly on consciousness and artificial intelligence. His most recent book is *Freedom Evolves* (2003). He is working on a book on religion. There are many sides to Dennett's contribution, but one of the most important is the way he challenges orthodoxies. He is a master at showing what is wrong with points of view with which he disagrees. One of his most characteristic techniques is to go after comfortable ideas with what he calls intuition pumps. Following is an example, the case of Mr. Chase and Mr. Sanborn:

Mr. Chase and Mr. Sanborn both used to like a certain coffee. More recently it has lost its appeal. The reasons they give seem to differ markedly. Chase: "The flavor of the coffee hasn't changed but I just don't like that flavor very much now." Sanborn: "No, no, you are quite wrong. I would still like *that* flavor as much as ever. The problem is that the coffee *doesn't* taste that way anymore." (reconstructed from Dennett 1988, p. 50)

Dennett's target is the idea that there is always a clear distinction between a conscious state, in this case how something tastes to us, and how we react to it. When we read about Mr. Chase and Mr. Sanborn, we are meant to say to ourselves, "Hmmm, maybe the distinction is not so clear after all." One is then meant to see that similar doubts arise all over the place.

An expert high-seas sailor and an accomplished pianist and choral singer, Dennett is far from retirement. In addition to his prolific authorship of books, Dennett

has written an average of ten papers per year for thirty-five years. He has taught at Tufts University for more than thirty years.

## DEONTIC LOGIC

*See* Modal Logic

## DEONTOLOGICAL ETHICS

Deontology is the view that because there are moral constraints on promoting overall best consequences, sometimes the right action is not the one whose consequences are best. The constraints that deontological theories emphasize are familiar from our everyday experience of morality: One ought to keep one's promises and be loyal to one's friends; one ought not to inflict unnecessary suf-

fering or to ignore one's debts of gratitude, and so on. Some deontological theorists see a unified basis for all such duties; others are frankly pluralist.

### THE MEANING OF "DEONTOLOGY"

Apparently coined by Jeremy Bentham in the nineteenth century, the term "deontology" initially was used to refer, quite widely, to the "science of duty." This wide usage reflects the word's two Greek roots: *deon*, meaning "needful" or "fitting," and *logos*, meaning "science" or "discourse." Within a century, the term gained its narrower meaning; even this wide use of the term, however, carries some definite commitments. These stem from each of its two roots: (1) It is fitting to be virtuous; but it is not part of the concept of virtue that virtue is always needful or morally necessary. In focusing on the needful, deontology may thus either leave the moral virtues to one side or demote them to a derivative status. In its concern with duty, deontology also either ignores, or treats as peripheral, the nature of moral success—described by some as happiness or *eudaimonia*, by others as perfected moral worth. Deontology's principal terms of assessment are, instead, deontic: they concern what ought to be the case and, more specifically, what people ought (morally) to do. (2) It is possible to speak or discourse about almost anything; but holding that there is a *logos* of duty suggests that moral duties may be correctly described in general terms. This suggestion runs contrary to the views of at least some contemporary moral particularists, who deny that there are any general truths about what people ought to do.

By the middle of the twentieth century, "deontology" acquired its more specific meaning, which refers to a particular conception or theory of our moral duties. To say that something is one's duty is to represent a type of action as necessary in some way, but how? C. D. Broad noted that there are at least two ways. One way is to represent the action as a means best suited to our attaining some good end that we ought, unconditionally, to pursue: This he called "teleological necessity" (from the Greek word *telos*, meaning "end"). Another is to represent the action as one that we ought, unconditionally, to take, irrespective of the consequences: This he called "deontological necessity." Of course, it is perfectly possible to embrace both of these types of moral necessity—as did, for instance, Immanuel Kant, who recognized both obligatory ends and strictly prohibited actions. Yet this contrast between two types of moral necessity may also be used to divide moral theories into two groups.

"Teleological" theories, as it has become commonplace to say, hold that the rightness and wrongness of actions is *wholly* determined by their tendencies to generate good. "Deontological" theories deny this, holding that the right action at least *sometimes* expresses deontological necessity, which stands independent of teleology—even a teleology that tots up *overall* goodness. As we have seen, the initial, wide use of "deontology" suggests that there are general ethical truths. In keeping with that suggestion, the more specific idea of deontological theory, as it is usually presented, invokes the idea of a general type of duty. One or more generally storable moral *constraints* prohibits certain ways of pursuing good results. In this way, we arrive at the conception of deontology stated at the outset: Deontology is the ethical theory, or family of ethical theories, according to which there are constraints on promoting overall best consequences that imply that sometimes the right act is not the one whose consequences are best.

This distinction between teleological and deontological theories does not cover all possible ethical theories—not even all of the non-particularist ones that focus on duty rather than virtue or happiness. On the one hand, there are other ways of resisting the idea that the right act is the one whose consequences are best. Philippa Foot (1985) and others have questioned the coherence of this apparently all-purpose notion of overall goodness: Does it really make sense to ask, for any two states of affairs or any two alternative actions, which is "better?" Another possibility (emphasized by Samuel Scheffler [1982]) is to hold that the basis for deviating from what is for the best is not a set of constraints or duties, but rather a set of prerogatives or permissions: Perhaps we sometimes have moral latitude to act in some merely acceptable ways. On the other hand, there are ways of developing consequentialism that drop any reference to teleological necessity: Perhaps we simply rank (some) alternative actions as better or worse, on the basis of whatever considerations apply, interpreting "consequentialism" simply as holding that we ought to take the best available alternative. If this abstract understanding of consequentialism is taken to the limit, the contrast between deontology and consequentialism will blur. To see why, we must shift from the meaning of deontology to the merits of the view.

### THE MERITS OF DEONTOLOGY

Deontological constraints are often called "agent-centered." The negative ones, for instance, direct people not to *do* certain things while not directing them to minimize the extent to which certain kinds of action *are done*.

Although these constraints are typically conceived as applying to everyone, that does not mean that they apply in the latter, impersonal, way, but only that they apply to each agent in the former, personal way. This distinction is implicit in St. Paul's principle from Romans 3:8, central in Alan Donagan's (1977) deontological theory: "Thou shalt not do evil in order that good may come of it." The principal difficulty in justifying deontology is to explain why agent-centered restrictions make sense. If breaking a promise or unnecessarily harming someone is a bad thing, then would not rationality dictate minimizing this type of bad, other things equal? Niccolò Machiavelli infamously wrote that princes need to learn how not to be good. They must be ready to use cruelty well in order to minimize cruelty in the long run; but perhaps the advice applies not only to princes. Should one not suffocate the crying child so as to prevent the evil soldiers from finding the refugees in the attic and killing them all? Such cases present what are known as "paradoxes of deontology."

Some deontological theorists simply deny that the paradoxes pose any problem: The deontological constraints stand on their own—as self-evident, a priori, or resting on divine authority—and entail nothing about minimizing bads. Others do attempt to defend deontology from the challenge posed by the paradoxes, in three ways. One is to defend the moral significance of the distinction between doing ill and allowing ill effects to happen. The doctrine of doing and allowing holds that, across a wide range of cases, there is a morally significant difference between the two. As Warren Quinn's (1993) sympathetic discussion reveals, it is not easy to explain why the bare difference between doing something and allowing something to happen should make a fundamental moral difference; a first step is to concede that the distinction matters only in certain contexts.

A second way to attempt to defend deontology is to develop Thomas Nagel's (1986) idea of "agent-centered" (or "agent-relative") *reasons*, which explain the point of deontological constraints. We can understand how certain moral reasons may not apply to everyone, but only to some people. This may be because of special relationships in which some people stand to others (friend, physician) or it may be because of the moral leeway we have to pursue what we care about. Perhaps the reasons that underwrite deontological constraints are similarly agent-relative. W. D. Ross (1988) suggested that each important deontological constraint reflects a different special relationship in which we can stand to others: as past benefactors, promisors, and so on. Alternatively, agent-relative reasons can be given a systematic place in moral theory.

For example, T. M. Scanlon's (1998) contractualist theory holds that the rightness of actions is determined by principles that could not be reasonably rejected by anyone motivated to reach reasonable agreement on principles. The reasons that individuals might reject proposed principles, he suggests, will naturally include some agent-relative ones. In either sort of deployment, however, there are grounds for worrying that the agent-relative reasons presuppose deontological constraints rather than really justifying them.

A third way to defend deontological constraints is to deny that all goods call for one to promote them. Some goods—some valuable things—may instead call upon us to respect or honor them. Kant's seminal contribution to deontological thinking was his insistence that rational persons are to be respected, as having a dignity that is beyond all price. Having said that, one *might* turn around and argue that human rational dignity, as an agent-neutral value, is to be promoted. That would be to turn away from deontology. In contrast, one might hold that the appropriate attitude to human dignity is, in turn, to respect *it*. Frances Kamm (1992) has argued that human dignity is best respected by ensuring the inviolability of persons' basic rights.

## THE PRIORITY OF RIGHT

As Kamm herself points out, resting deontological constraints on the value of human dignity begins to efface the distinction between deontology and consequentialist views. A fully abstract consequentialism can look to *any* relevant basis for holding that one alternative action is better or worse than another. Jamie Dreier (1993) has argued that the strictness of deontological constraints can easily be recast in a consequentialist mode by stipulating that some actions be ranked *lexically* better than others. Such an abstract consequentialism gives up the title to being a teleological view, as it does not develop its content on the basis of observed teleological necessities; but it remains recognizably consequentialist. Maintaining a firm contrast between deontological theories and consequentialist theories, therefore, depends upon resisting such an abstract recasting of consequentialism. Friends of deontology may want to understand "goods" or "goodness" somewhat more narrowly, as referring only to features of states of affairs or to values towards which the correct stance is promotion rather than respect, such as human well-being. The values that do not fall within the good—or at least some of them—may then be thought of as belonging to "the right"—the domain of rightness.

Accepting that there are values proper to the right, whose role is not to be promoted but rather to be honored and respected by the structure of duty, opens up many additional possible ways of defending deontology. Such an approach helps ground deontological constraints by relating them to some value, but in a non-teleological way; and this helps explain why we should care about acting morally. Barbara Herman (1993) has emphasized this layer in Kant's moral theory. Kant (1998) held that the a priori concepts of morality determine the content of the one unconditionally valuable thing, namely the good will, the will that acts from respect for the moral law. Although this value cannot, in Kant's view, be directly promoted, it helps characterize the value of acting morally. Our capacity to achieve this value also underwrites our dignity: We are worthy of respect because we are capable of acting with a good will. A contemporary example of this approach is Scanlon's contractualism. As noted above, Scanlon (1998) holds that the rightness of actions depends on whether they accord with principles that no one duly motivated to find agreement on principles could reasonably reject. What motivates us to act morally, on this interpretation? Scanlon's answer in *What We Owe to Each Other* is that it is "the positive value of living with others on terms that they could not reasonably reject" (1998, p. 162). This value seems to belong to the right, not to the good insofar as it is distinct from the right. Yet it is nonetheless something we might intelligibly care about. According to deontologists such as Kant and Scanlon, then, these considerations of rightness have a kind of structural priority over other types of value.

Henry S. Richardson (2005)

## DERRIDA, JACQUES

(1930–2004)

Although he was not altogether happy with the fact, Jacques Derrida's name has become synonymous with deconstruction. Derrida was born in El-Biar, near Algiers, in 1930. In 1949 he left for Paris and in 1952 began to study at the École Normale Supérieure, where he taught from 1964 to 1984. Beginning in 1975, Derrida spent a few weeks each year teaching in the United States. While at Yale University Derrida collaborated with Paul de Man (1919–1983), leading to the extraordinary impact that deconstruction has had on the study of literature in the United States, an impact that quickly spread to other disciplines and countries.

Derrida's record of publications is remarkable. In 1962 he wrote an introduction to a translation of Husserl's *Origin of Geometry* that in many respects anticipates the later works. In 1967 he published a further study of Edmund Husserl, *Speech and Phenomena*; a collection of essays, *Writing and Difference*; and a reading of Ferdinand de Saussure, Claude Lévi-Strauss, and Jean-Jacques Rousseau, *Of Grammatology*. A rapid succession of publications ensued, among the most important of which are *Dissemination* (1972), *Glas* (1974), *The Post Card* (1980), *Psyché* (1987), *Given Time* (1991), and *The Politics of Friendship* (1994). Derrida also published extensively on an increasingly broad range of subjects from literature and politics to art and architecture.

## STYLES OF DECONSTRUCTION

Deconstruction is neither a method nor a negative critique. It is better understood as a strategy for reading texts under the influence of Husserl, Martin Heidegger, Friedrich Nietzsche, Sigmund Freud, Emmanuel Levinas, and Saussure. In the early years of deconstruction many of the most important readings were devoted to these thinkers, all of whom, except for Husserl, were treated in Derrida's 1968 lecture "Différance." Derrida justified this cross-fertilization of disparate authors by saying that their names served to define contemporary thought. This practice came to be generalized as *intertextuality* and came to be further enhanced as Derrida, in each new text, drew heavily on his previous readings. Because Derrida's language is both cumulative and parasitic on the texts that he is reading, attempts to formulate Derridean doctrines are often misleading. Hence it is more appropriate to focus on his strategies.

Most of Derrida's writings operate by close reading, and their impact depends on the capacity of this reading to account for details that more conventional readings either ignore or explain away. In clear contrast, not only with most modern trends in philosophy, but also with a widespread image of him, Derrida was immersed in the history of philosophy. For Derrida this was the only way to avoid unwittingly repeating the most classic gestures of philosophy, a danger that threatens every attempt to ignore that history and begin philosophy anew. Deconstruction locates itself within traditional conceptuality in order to find the radical fissures that it believes can be traced in every work of philosophy. Derrida was drawn to the apparent contradictions of the tradition and made them the starting point of his readings, whereas a more conventional treatment tends to stop short as soon as a contradiction is identified. Much that is strange, and to some even offensive, about Derrida's analyses arises because he attempted to uncover the structures that organize and so transcend or exceed conventional reason.

Particularly in his early writings, Derrida presented his deconstructive readings of individual works in the history of Western philosophy as directed against a certain understanding of that history as one in which presence had been privileged. The priority of presence was reflected throughout the binary oppositions that structured Western thought: presence over absence, speech over writing, inside over outside, and so on. Derrida's strategy was to show that those texts that were supposed to have exhibited this privilege of presence also reflected a certain counter-tendency. So, for example, texts that on the surface appear to privilege speech over writing also

have moments in which the hierarchy was reversed. Following this reversal, Derrida sought to pass beyond the opposition to that which exceeds it: Hence, in the example given, he identifies what he calls a proto-writing, which is neither speech nor writing in the conventional sense, but that which is the condition of all forms of language.

Derrida drew his account of history of Western metaphysics in terms of presence from Heidegger, but in so far as Heidegger's account was directed toward the overcoming of metaphysics, Derrida located within that project an opposition between what was inside and outside metaphysics. He thus identified within the project of leaving metaphysics behind, a hierarchical opposition that was itself still metaphysical. By contrast, Derrida's own position was that one cannot stand unequivocally either within or outside metaphysics. This was reflected in his strategy of double reading. To any text that was conventionally conceived of as belonging to Western metaphysics, he added a new reading that showed how that same text could be understood as exceeding Western metaphysics, and to texts, such as those by Heidegger and Levinas, that presented themselves as passing beyond Western metaphysics, Derrida added a reading that drew them back into the conceptuality of Western metaphysics. The deconstruction lay not in the new reading alone, but in its juxtaposition with previous readings, which were not thereby supplanted so much as understood as belonging to the history of the text. This means that Derrida does not so much oppose the dominant reading, as that he adds another reading to it, so that the so-called double reading combats any attempt to locate the text in question either within or outside Western metaphysics.

There is, however, another style of deconstruction that has become increasingly widespread in Derrida's thought. It proceeds by the exploration of *aporias*, as will be illustrated later in a discussion of Derrida's conception of the gift. Because Derrida sometimes seems to give the aporias he investigates a universal status, deconstruction in this sense is no longer as attached to the conception of the history of philosophy as the history Western metaphysics, as was the case with his textual readings of philosophy. However, Derrida did not consider these two styles of deconstruction as independent of each other, so that it would be a mistake to suppose that he had abandoned the genealogical component of his work.

## THE SUPPLEMENT

*Supplement* is one of the key terms of Derrida's challenge to Western metaphysics, understood as a unified body of

thought that privileges presence. He used this term to problematize the philosophical quest for a simple origin as a self-sufficient source. He identified a “logic of supplementarity,” which is said to be “inconceivable to reason,” according to which the supplement, by delayed reaction, produces that onto which it is said to be added (*Of Grammatology*, pp. 179 and 259). The force of Derrida’s analysis relies heavily on the close readings of philosophical texts in which he uncovered this logic, most notably his reading of Jean-Jacques Rousseau in *Of Grammatology*.

The logic of supplementarity uncovers the rules that structure some of the apparent contradictions found in the texts of metaphysics. In the case of an author who courts paradox as readily as Rousseau, the task is particularly demanding. Derrida’s diagnosis is that Rousseau wants to resist the conclusions he nevertheless cannot avoid. As a result, Rousseau’s descriptions do not match with the declarations that reveal what he wants those descriptions to say. For example, Rousseau wants to identify the origin of language with speech and thereby make writing a “mere” supplement, but speech is itself a substitute for gesture, which is thereby, in a phrase whose apparent incoherence Derrida underlines, the primordial supplement. Derrida argued that instead of distinguishing Rousseau’s use of “supplement” as addition from its use as “substitute,” one should see the two senses as operating together (pp. 144–165). So, to continue with the example, much of what appeared contradictory in Rousseau’s account of the origin of languages is found to arise because Rousseau wanted to locate the origin of language in the languages of the south but found himself having to draw constantly on the supplementary principles that he had associated with the languages of the north. The languages of the north were, therefore, not simply an external addition, but an alterity that must have been lodged within the system from the outset.

Derrida has exhibited the logic of supplementarity in other metaphysical texts. For example, in *Speech and Phenomena* (1973), Derrida located this operation in Edmund Husserl’s account of language. Derrida identified a double tendency in Husserl, like that found in Rousseau. On the one hand Husserl wants to separate indication from solitary life, the strata of expression. On the other hand there are suggestions in Husserl’s text that indication is constitutive of expression. The deconstruction of Husserl performed by this double reading is not a critique any more than the reading of Rousseau is. Neither thinker is criticized for failing to recognize the logic of supplementarity as such, not least because this logic

has to be understood in terms of what metaphysics represses. The effacement of the primordial supplement is the condition of metaphysics, which thus can no longer be seen as a unity, as it was for Heidegger.

## THE TRACE

That *trace* is another notion that Derrida employed as part of his contestation of the tradition of Western metaphysics understood in terms of the priority of presence is clear from his use of the phrase “a past that has never been present” to explicate it. The phrase itself is already found in Maurice Merleau-Ponty’s *Phenomenology of Perception*, where it describes the unreflective fund of experience on which reflection draws. Derrida adopted the phrase in “Violence and Metaphysics” to explicate the notion of trace in the work of Levinas, who immediately introduced it into his own account.

Derrida employed various strategies to show that the trace challenges conventional thought. For example, in *Of Grammatology* (1976), when he introduced the concept of an originary trace or arche-trace, he underlined that it represents a contradiction because a trace, which is ordinarily possible only as an effect, is here posited as an origin. The point is to problematize the language and procedures of transcendental philosophy, especially transcendental phenomenology, on which the thought of the trace nevertheless depends for its articulation. This was already Levinas’s aim when he appealed to the trace in his account of the possibility of ethics in terms of the face of the Other. The trace is more than a sign of remoteness; it is an irrecoverable absence. Levinas was serving notice that the face surpasses the limits of phenomenology and yet can be approached only through phenomenology. Similarly, even though Derrida makes Freud’s failure to apply the effaceability of the trace to all traces a critical element of his reading, at the same time he explicitly recognizes Freud’s unconscious as transcending transcendental phenomenology, just as the structure of delay in the sense of deferred effect (*Nachträglichkeit*) cannot be construed as a variation on the present.

These examples show how in the 1960s Derrida developed his account of the trace by gathering together the thought of such thinkers as Levinas and Freud, but he subsequently moved away from this largely parasitic approach. Most notably in *Cinders*, Derrida took the impossible thought of the trace to a different level by explicating it as ashes, with clear reference to the Holocaust. In this way the trace comes to define our epoch even more definitively, than when he drew on the

thinkers who, as he had put it earlier, had helped to define our epoch.

### CRITICISM AND RESPONSES

If deconstruction's initial impact within the United States has been strongest in literature departments, this is in part because Derrida's conviction that absolute univocity is impossible is more readily welcomed by literary critics, who have always celebrated the multiplicity or meaning, than by philosophers, whose discipline has tended to encourage a reduction on controlling of equivocity. Whereas the dominant tendency in philosophy has been to mark different uses of a term in an effort to control the ambiguity, the deconstructive approach is to question the basis of any attempt to limit the associations of language. This approach has sometimes been confused with an invitation to so-called free play, in the sense of arbitrariness in interpretation, although Derrida has often rejected this way of reading his work. In exploring equivocity, Derrida is acknowledging and not ignoring the ambiguity of words. In the literary context the constraints of deconstruction are sometimes neglected for the freedom of literary experimentation. This is less common in Derrida than in some of his followers, but it has given ammunition to the critics of deconstruction.

The most persistent criticism of Derrida arises from his claim in *Of Grammatology* that "there is nothing outside the text" (p. 158). This has sometimes been understood to mean that all reference to the social and historical context is ruled out, and even that the text has no referent. It is easy to show that Derrida has never practiced such an extreme aestheticization of the text. What he did mean is explained in "Living On," in which he sets out the concept of a text as a differential network that overruns all the limits assigned to it (p. 84). This, the so-called general text, is not conceived as a totality. It does not have an outside, anymore than it has an inside. As Derrida explained in the 1988 afterword to *Limited Inc.*, there is nothing outside context, which is almost the opposite of what he is often accused of saying by many who do not share his philosophical background in phenomenology, psychoanalysis, or structural linguistics and yet fail to make allowance for that fact.

One of the most persistent criticisms raised against Derrida in the 1970s and 1980s was that his thought was ill-placed to address ethical and political issues. The understanding, widespread at that time, that Derrida's 1964 essay "Violence and Metaphysics," subsequently reprinted with revisions in the collection *Writing and Difference*, was critical of Levinas for his evocation of ethics

after Nietzsche and after Heidegger's *Letter on Humanism* seemed to block him from making any such contribution. This interpretation has now been abandoned in the face of Derrida's repeated invocations of Levinas in the course of his own efforts to contribute to an understanding of ethics. It is here that a form of deconstruction as the exploration of certain aporias has come into his own. Derrida takes up the idea of a duty to go beyond one's duty. So, for example, in *Given Time* Derrida introduced the aporia of the gift whereby a gift is only a gift and not a form of exchange if there is no return on the gift. Derrida pursued these conditions to the point where even being aware that one is making a gift of something would constitute a form of return, thereby making the gift impossible. Parallel studies of hospitality and forgiveness followed. However, it should always be remembered that, for Derrida, the impossibility of the gift or of hospitality, for example, does not mean that giving and hospitality do not happen. It means rather that they are singular events that exceed, and so cannot be explained in terms of what precedes them.

## DE SANCTIS, FRANCESCO (1817–1883)

Francesco De Sanctis, the Italian liberal politician and political and literary critic, was born near Naples. Although trained for the law, he turned to the study of Italian culture. He taught at the Military School of Naples, but his participation in the Revolution of 1848 led to his dismissal, a three-year prison sentence, and banishment. He taught and lectured in Turin and Zürich, and returned to Naples in 1860 as governor of the province of Avellino. As director of the Ministry of Public Instruction he brought scholars of great repute to the University of Naples and fought for the secularization of the public schools. After becoming editor of the newspaper *Italia* in 1863, he continued to champion reforms and helped to establish the modern Italian tradition of combining philosophy and worldly affairs. In 1868 De Sanctis returned to literary criticism. Several years later he completed his *Storia della letteratura italiana* (History of Italian literature). He accepted the chair of comparative literature at the University of Naples in 1872, but in 1877 he resumed his political career as organizer of a liberal opposition party, vice-president of the Chamber of Deputies, and minister of public instruction.

De Sanctis developed no systematic aesthetics or political philosophy. His principles of criticism are implicit in his essays. Literary truth, for De Sanctis, is realized in form, but literature's connection with political and social life is the substance of its meaning and the true

source of formal beauty. Form transforms an idea into art and is the instrument by which artistic truth is achieved; it is art itself. Content and ideas are, for artistic purposes, without truth. Form provides truth, artistic integrity, the capacity to project an experience or idea so as to bring it subjectively alive for an observer. It does so successfully when it is naturally wedded to the content and seems fused with it. Successful form is derived from the concrete vision of the poet as he reflects on a living experience of the language and forms of his age. This tie between the artist and his immediate image is the deepest source of true art. The language and ideas of art spring from and are shaped by the social and historical events against which they act in the mind of the artist. De Sanctis sought, by grasping history and language, to grasp the work of art as conceived by the artist. History, and specifically political history, provides the framework in which ideas are tested against each other and find concrete representation in artistic form.

Traditional criticism saw technical skill as the essence of poetry, but poetry is involved with the values of the moral, historical, and social orders it expresses and reflects. The philosophical commitments of the poet, his moods and personal objectives, are the stimuli, the raw materials from which an ordered piece of art is shaped. The essence of art is form, but form into which content has passed and fulfilled itself.

De Sanctis believed that the poet must be immersed in the life of his national community. The subject and object of art is the human being. The artist must study man, exhort him, laugh at him, understand him. The artist's manner of picturing human life gives art its truth; this truth is gained by mastery of the language of the age and absorption of its combinations and formal possibilities.

Although art is measured by aesthetic criteria, as a historical phenomenon it is subject to social and moral considerations. Therefore, De Sanctis was led from literary criticism to literary history to the history of Italian culture and ultimately to the relation and debt of Italian culture to Italian politics.

Politics, De Sanctis believed, is a reflection of the moral fiber of a nation. Political activities reflect a wider cultural context and have a special responsibility for that culture, through the power to stimulate or repress it. Politics is a national dialogue between the various sectors of the population. The capacity of the popular classes to participate in and guard a national political organism, to preserve its morality in the face of the tasks of national destiny, to absorb the style and content of past national leaders imprints the national style and goal on political behavior.

Many of De Sanctis's political essays are exhortations, expressions of concern over apathy and loss of morality in political life, as well as attempts to express the inner urgings of Italy. For De Sanctis morality and culture were intimately connected. Moral political activity carried out Italy's destiny, which its previous culture had marked for restored greatness. The politics of a great nation reflects its culture and is perpetually open to self-renewal through the participation of the bearers of that culture. If they cease to participate in the nation's political activity, the culture breaks down, and politics becomes immoral, politicians self-aggrandizing, and the people apathetic.

## DESCARTES, RENÉ (1596–1650)

In *Discourse on Method* (1637), his first published work, French philosopher and scientist René Descartes combined an intellectual autobiography with a popular presentation of the system he was to develop more rigorously in his *Meditations* (1641) and *Principles of Philosophy*

(1644). *Meditations* begins with a radical attempt to doubt all past beliefs, but finds a proposition that resists doubt in the existence of the self as a thinking thing. It then uses this initial certainty as a basis for arguing that God exists, that mind and body are distinct, and that we can achieve certainty in the sciences if we assent only to clear and distinct ideas, provided we have first shown that God would not deceive us about those ideas. The *Principles* uses the metaphysics and epistemology laid out in the *Meditations* as the foundation for an ambitious attempt to provide a scientific account of the entire world.

### CHILDHOOD AND FORMAL EDUCATION (1596–1618)

Descartes was born on March 31, 1596, in the village of La Haye, in Touraine, at the home of his maternal grandmother, with whom he lived after his mother's death in 1597. His father, Joachim Descartes, was a member of the gentry and a councilor in the parliament of Brittany whose duties required him to spend several months each year in Rennes. When René was four, his father remarried and moved to Rennes; René and two older siblings remained with his grandmother. We do not know much about his earliest years, but it appears that he was never close to his father, either as a child or as an adult. His grandmother died when he was about fourteen.

At ten, Descartes entered the Royal College at La Flèche, founded two years earlier by Henry IV and run by the Jesuit order. The first five years of the program were guided by the ideals of Renaissance humanism, and thus were devoted to studying Latin, Greek, and classical literature (especially Latin and the works of Cicero). The last three years were dedicated to instruction in numerous subjects, including:

- Thomistic-Aristotelian philosophy, including dialectic (Aristotle's *Organon*), natural philosophy (Aristotle's *Physics*; *On the Heavens* [*De caelo*]; and *On Generation and Corruption* [*De generatione et corruptione*], book I);
- Mathematics (arithmetic, geometry, and topics in applied mathematics, such as astronomy);
- Metaphysics (Aristotle's *On Generation and Corruption*, book II; *On the Soul* [*De anima*]; and *Metaphysics*);
- Moral philosophy (Aristotle's *Nicomachean Ethics* and the work of Jesuit casuists).

Study of Aristotle and Aquinas made extensive use of late-sixteenth- and early-seventeenth-century commentaries, especially those by the Jesuits at the University of

Coimbra. Sometimes the curriculum ignored aspects of Aristotle's thought difficult to reconcile with Christian doctrine. Instead of reading the theological portions of Aristotle's *Metaphysics*, whose remote God is not the creator of the universe, students read a creationist treatise from the first century CE, *On the World (De mundo)*, which was mistakenly ascribed to Aristotle. In other cases the problems were faced. Thomas Aquinas had interpreted Aristotle's teaching about the soul as consistent with the Christian doctrine of personal immortality. In the sixteenth century Pietro Pomponazzi had argued persuasively that Aquinas misread Aristotle and that Aristotle in fact held the soul to be mortal. Pomponazzi himself did not deny immortality; his official position was that philosophy could neither prove nor disprove the immortality of the soul, but that revelation made it certain. However, since he tended to identify Aristotle's views with those views that human reason would naturally reach unaided by revelation, he came perilously close to the doctrine of double truth associated with the Averroist tradition—the idea that philosophical truth and theological truth may conflict irreconcilably. The Jesuit curriculum called for the teachers in its colleges to attack the authority of such commentators.

Descartes may have drawn an unintended conclusion from these disputes. When he first began to work out his own theory of knowledge, he wrote, "Whenever two people make contrary judgments about the same thing, it is certain that at least one of them is wrong, and it seems that neither of them has knowledge. For if one had a certain and evident argument, he would be able to propose it to the other in a way which would in the end convince his intellect" (Adam and Tannery X, p. 363). The persistence of the dispute about whether immortality was consistent with an Aristotelian theory of the soul probably encouraged Descartes to develop his own anti-Aristotelian theory. His studies in mathematics may also have encouraged skepticism about Aristotelian natural philosophy. At La Flèche the teachers used the texts of the Jesuit mathematician Christopher Clavius (1538–1612), who argued that mathematics was superior to the other supposed sciences, because it succeeded in eliminating all doubt, and that the other so-called sciences demonstrated their uncertainty by their inability to elicit consensus.

At the time, the Jesuit colleges dominated secondary education in France and had an immense influence on the formation of a generation of leaders in politics, philosophy, and religion. Their primary mission was to combat the Protestant heresy, but they also reciprocated the King's support, defending his claims to absolute power.

The colleges required total immersion in the Jesuit educational program, permitting little contact with the outside world (parents included). Descartes had mixed feelings about this education. In his *Discourse on Method* he was quite critical of it, claiming it had not provided him with what he had hoped for—clear and certain knowledge of everything useful in life—but had instead left him embarrassed by many doubts and errors. It seemed to him that he gained nothing from his studies but an increasing awareness of his own ignorance. Still, he was careful to say he thought his school had given him as good an education as was then available, and he later recommended it to friends for their children.

Descartes completed the program at La Flèche in 1614. In *Discourse* he wrote that as soon as he was old enough to leave the control of his teachers, he completely quit the study of letters and sought what knowledge he could find either in himself or in the great book of the world. This is not entirely true. We do not know much about what he did in the years between 1614 and 1618, but we do know that he completed a degree in law at the University of Poitiers in 1616. His earliest biographer, Adrien Baillet, reports that Descartes spent the first year after leaving La Flèche in St. Germain-en-Lay, a village outside Paris. The Royal Gardens there contained remarkable statues, designed to move, play music, and even speak. Seeing these machines mimic the behavior of living, intelligent creatures may have helped make plausible to Descartes his later doctrine that animals are nothing but machines.

#### INFORMAL EDUCATION: ENCOUNTERING BEECKMAN (1618–1619)

In the summer of 1618 Descartes left France to join the army of Maurice of Nassau in the Netherlands. His legal studies would more naturally have led to a career in the law or government, possibilities he considered at various times in the next several years. But in 1618 military life was more enticing, with its opportunities to travel and to learn about the practical application of scientific theories. Maurice encouraged scientific research and employed one of the leading scientists in the Netherlands, Simon Stevin, to oversee his army's education in military technology. Among Stevin's scientific accomplishments were an experimental refutation (anticipating Galileo Galilei) of the Aristotelian theory that heavy bodies fall faster than light ones and his discovery of the "hydrostatic paradox": that the downward pressure of a liquid depends only on the height and base of its vessel and is independ-

ent of its shape. As a military engineer, Stevin developed a system of sluices to flood the fields, giving the Dutch a critical (if Pyrrhic) means of defense against invading armies. In 1618 the Dutch were still enjoying an extended truce in their war for independence from Spain, so Descartes saw no combat. In a letter from this period he wrote that he spent his time learning drawing, military architecture, and Dutch. But he also mentioned plans to write books.

The stimulus for this last ambition was his encounter with Isaac Beeckman, a Dutch scientist, several years his elder, whom he met in November 1618. In a letter to Beeckman, Descartes credits Beeckman with having roused him from his laziness, recalled to his mind the learning he had almost forgotten, and brought him back to serious pursuits. By the spring of 1619 Descartes was contemplating two works, one in mechanics, the other in geometry. In his enthusiasm, Descartes wrote to Beeckman and promised to embrace him as “the promoter and first author of my studies” (Adam and Tannery X, p. 162). Their later relations were not so cordial. In 1630 Descartes was to write Beeckman complaining that the older man was claiming too much credit for having been Descartes’s teacher. Though they later reconciled, Descartes makes no mention of Beeckman in the *Discourse*.

Why was Descartes’s encounter with Beeckman so important? First, as Beeckman put it, they shared a desire to “combine physics with mathematics in an exact way” (Gaukroger 1995, p. 69). Beeckman had been working on problems in this manner for some years and was delighted to find a like-minded colleague. One result was a short treatise that Descartes wrote on music, attempting to work out a mathematical relationship between the various sounds that appear pleasing to us in combination. He may have begun this treatise before he met Beeckman, but he finished it in December and presented it to Beeckman as a gift on New Year’s Day, 1619.

Their more normal pattern of interaction was that Beeckman would set up Descartes with a problem in mechanics or some related area, and invite him to solve it. For example, Beeckman recognized that bodies falling freely in a void would accelerate uniformly. So he posed the following problem: Suppose that a body moving in a void will move eternally (in opposition to Aristotelian physics, Beeckman assumed a version of the principle of inertia). Suppose further (again in opposition to Aristotle) that there is a void between a falling stone and the Earth, and that the stone covers a given distance in a given time. How far will it fall in half that time? As early as 1604

Galileo had worked out the correct law governing the free fall of bodies, which implied that the velocity of the falling body is proportional to the duration of time that it falls, but he did not publish this result until 1638. Descartes concluded that the velocity was proportional to the distance covered, a mistake that Galileo had also made in his first attempt to solve the problem. What is important here is that Beeckman was encouraging Descartes to engage in the Galilean project of discovering laws governing the motion of bodies, expressible in mathematical formulas.

Another area where Beeckman influenced Descartes involved his program of explaining macroscopic physical phenomena in terms of the mechanical properties of the microscopic particles composing them. This program—generally now called “the corpuscularian hypothesis” or “the mechanical philosophy”—had connections with ancient atomism, but differed from atomism in important respects. It did not assume that the component particles were indivisible, and as Descartes was to develop it, it did not assume the existence of a void. Moreover, whereas ancient atomism had regarded the size and shape of the atoms as the primary explanatory factors, the corpuscularians emphasized the speed of the particles and direction of motion.

One problem that Beeckman set for Descartes was to explain in corpuscular terms Stevin’s hydrostatic paradox. Descartes postulated that the weight of the column of water can be reduced to the force exerted by its particles in their tendency to downward motion and that each particle of water on the bottom of the container is connected with a particle on the surface by a unique line of particles along which the force (tendency to motion) is transmitted. It is surprising that Descartes thought this explanation worked. It seems plausible where the area at the surface and the area at the base are equal in size, but not in the cases that most require explanation, cases where the area at the surface is smaller (or larger) than the area at the base.

These examples give us an idea of the sort of study that Descartes might have included in the work on mechanics he was contemplating. His work in mathematics seems to foreshadow his discovery of analytic geometry, his most enduring contribution to the sciences. In a letter to Beeckman in March 1619, Descartes excitedly wrote that he hoped to discover “a completely new science,” one that would “provide a general solution of all possible equations, involving any sort of quantity, whether continuous or discrete” (Adam and Tannery X, pp. 156–157). The path to solving these geometric or

arithmetic problems seems to have involved using complex instruments, “proportional compasses.” Descartes devised compasses that not only solved the problem of dividing an angle into any number of equal smaller angles, but also solved cubic equations of varying degrees of complexity. He had not yet formulated the program, which he was to develop in his *Geometry*, of using algebraic means to solve geometric problems. But he had taken a step toward unifying arithmetic and geometry.

### FINDING A VOCATION IN GERMANY (1619–1620)

In the spring of 1619, as the Thirty Years War was just beginning, Descartes set out for Germany to join the army of Maximilian of Bavaria, the leader of the Catholic League. In the *Discourse* he tells us he attended the coronation of Ferdinand II as Holy Roman Emperor. As he was returning to the army, the onset of winter detained him in a place where he had no one to talk to and no cares to trouble him. Shut up all day in a stove-heated room, he was alone with his thoughts. This isolation produced the first of two major turning points in his life. In a document now lost that Baillet saw and preserved (apparently in a mixture of paraphrase and quotation), Descartes wrote that on November 10, 1619, while “full of enthusiasm,” he discovered “the foundations of a wonderful science.” Descartes left behind conflicting indications of what this discovery was.

The account in the *Discourse*, written seventeen years later, implies that Descartes’s discovery involved a decision that to make firm judgments in the sciences, he would have to rid himself of all his previous opinions and reconstruct his system of beliefs on new foundations, accepting nothing he had previously believed until he had squared it with reason. Too much of what he believed was based on uncritical acceptance in his youth of the opinions of others. The document Baillet saw—an account of three dreams that Descartes reported having had on the night of November 10, probably written not long after the event—doesn’t suggest a project of ridding himself of all his past opinions. Nor does Descartes’s earliest methodological work, *Rules for the Direction of the Mind*, which he apparently began around this time.

Of the three dreams, the most important was the last. In that dream Descartes found two books on a table. One he describes as a dictionary; the other was an anthology of poetry. When he opened the anthology, he found a poem by Decimus Magnus Ausonius (c. 310–395) that opens with the sentence *Quod vitae sectabor iter?* (“What path shall I follow in life?”) Descartes said that while he

was still asleep, he recognized he had been dreaming and began to interpret his dreams. He construed his discovery of the poem by Ausonius as indicating that he must choose the proper direction for his life. And the dictionary, which we should probably think of as more like an encyclopedia, he interpreted as representing a collection of all the sciences. The dream as a whole he took to indicate that the path he should choose in life was to pursue the sciences and demonstrate their fundamental unity. A fragment preserved from this period expresses that idea vividly: “The sciences now are masked, but if the masks were taken off, they would appear most beautiful. Someone who sees how the sciences are linked together will find them no harder to retain in his mind than the series of numbers” (Adam and Tannery X, p. 215). Descartes’s vocation was to unmask the sciences. The ambition to construct a unified system of all scientific knowledge was to guide him for the rest of his life.

### RULES FOR THE DIRECTION OF THE MIND (EARLIEST STAGES, 1619–1620)

Among the unfinished works Descartes left behind at his death was a treatise on methodology, which he apparently worked at, off and on, between 1619 and 1628: *Rules for the Direction of the Mind (Regulae, for short)*. He intended the *Regulae* to be a three part work, each part of which would consist of twelve rules. Although he completed only the first part and about half of the second part, this is the most substantial work we have from the period before 1629. Its parts often seem inconsistent with one another, apparently reflecting different stages of the work’s composition and the lack of any unifying revision. Nevertheless, the work sheds light on Descartes’s development and later thought. Our best current theory of its composition—resulting from the analyses of Jean-Paul Weber (1964) and John Schuster (1980)—holds that Descartes wrote a part of Rule Four first, perhaps before the night of the three dreams, that he completed most of Part One sometime during the period from 1619 to 1620, and that he then set the work aside for several years, returning to it in the period between 1626 and 1628, when he added Rules Twelve through Twenty-One. After that, he abandoned the work, for reasons we can only guess.

The second half of Rule Four (“Rule IV-B,” as it is now called, beginning at the bottom of Adam and Tannery X, p. 374) recounts Descartes’s first investigations of mathematics and his disappointment with the ancient mathematicians. He found in them many propositions about numbers that he recognized as true after doing his

own calculations and many conclusions about figures that his authors reached by logical arguments. But they did not explain why these things should be true or how they had discovered them. Descartes conjectured that the ancient mathematicians possessed an algebraic method of discovery they concealed because it made the discovery of mathematical truths too easy. They feared that revealing their method would diminish people's respect for their accomplishments. Rule IV-B is entirely concerned with the project of developing a general method for discovering mathematical truth.

The second stage of the *Regulae* is more ambitious, aiming to formulate a methodology that applies to *all* the sciences. They are all, he says, “nothing but human wisdom, which always remains one and the same, however much its objects may differ” (Adam and Tannery X, p. 360). The sciences are so interconnected and interdependent that it is easier to learn them together than separately. What someone seeking truth in the sciences must first do is to consider how to increase his “natural light of reason,” the cognitive abilities he is naturally endowed with. (“Ingenium,” the term traditionally translated as “mind” in the title, *Regulae ad directionem ingenii*, might more happily be translated as “native cognitive powers.”) Negatively, this means that we should rely only on intuition and deduction—that is, on propositions whose truth we can see distinctly, with certainty, when we attend to them carefully, without being confused by what our senses and imagination tell us, and on propositions that can be inferred from propositions of the first kind by a process of inference equally clear and certain.

Descartes claimed that the only genuine sciences discovered thus far were arithmetic and geometry. But he denied that these were the only areas where we could achieve absolute certainty by intuition and deduction. There are more intuitively certain truths than most people suspect. He gave as examples the propositions that he exists, that he thinks, and that a triangle is bounded by just three lines, among others. If we make proper use of such truths, not mixing them up with probable assumptions, we will be able to extend the certainty of mathematics to other areas. This was an attack, not only on reliance on the senses or imagination, but also on the scholastic use of “probable syllogisms,” whose premises needed only the support of a majority of the wise to be acceptable. Descartes thought that in difficult matters the minority is more likely to be right than the majority.

Positively, Descartes's central message is that we must conduct our investigations in an orderly way, gradually reducing complex and obscure propositions to simpler

ones, until we reach propositions simple enough that we can know them intuitively, that we can *see* their truth without the aid of other propositions. Once we have completed that reduction, we can work our way back, step by step, to the proposition whose truth or falsity we originally wished to determine. Suppose that the problem is to find the three mean proportionals between 3 and 48. We might not have any intuitions about the answer. But if we look for the single mean proportional between those numbers, 12, then we will have reduced the original problem to something more manageable, finding the mean proportionals between 3 and 12 and between 12 and 48. We can see easily enough that 3 is to 6 as 6 is to 12, and that 12 is to 24 as 24 is to 48. Seeing this enables us to see that 6, 12, and 24 are the numbers sought.

The visual metaphor here is deliberate. “Intuitus,” the Latin noun translated as “intuition” is derived from a verb, “intueri,” whose basic reference was to visual perception, though it was commonly extended to mental acts of consideration and contemplation in classical Latin. Descartes thought that we can learn how to better use our mental power of intuition by comparing it to vision. If we try to look at many physical objects at once, we see none of them distinctly. Likewise if we try to attend to many propositions in a single act of thought. We can improve our vision, both physical and mental, by focusing our attention on one simple object at a time.

Descartes emphasized that intuition is required not only for our knowledge of the premises of our inferences, but also in the inferential process itself. To have scientific knowledge of the conclusion of an inference, we must intuit not only the premises of the inference, but also the connection between the premises and the conclusion. To know by deduction that  $2 + 2 = 3 + 1$ , we must see not only that  $2 + 2 = 4$  and that  $3 + 1 = 4$ , but also that our conclusion follows necessarily from these premises. We cannot avoid relying on intuition by insisting, with the Scholastics, that our arguments possess formal validity. Descartes accepted the classical skeptical critique of syllogistic reasoning: that it is useless as a means of acquiring knowledge, because the formalization of the argument—the addition of a suppressed conditional or universal premise to transform an enthymeme into a formally valid syllogism—accomplishes nothing. If the suppressed premise is evident, it is unnecessary for the argument's validity. If the suppressed premise is not evident, then all that the formalization of the inference accomplishes is to increase the number of assumptions requiring proof.

### WANDERER YEARS (1621–1625)

After the initial burst of energy that produced the earliest stages of the *Regulae*, Descartes appears to have set the project aside for a while and to have produced no significant work. He traveled here and there, returning to France, visiting Italy (perhaps more than once), and finally returning to France for an extended stay in Paris. He sold the property that he had inherited from his mother, using the proceeds to secure a modest but regular income. This freed him from the need to earn a living. He probably made a pilgrimage to Loreto, Italy, fulfilling a promise made after the night of the three dreams. Apparently, he did not visit Galileo when he passed through Florence. But during this period he seems to have made the acquaintance of Marin Mersenne (a member of the Order of Minims, residing at a convent in Paris), who shared his interest in mathematics and the new mechanical philosophy.

In these years Mersenne was preoccupied with arguing against the radical, Pyrrhonian skepticism that Michel de Montaigne had popularized, which he regarded as a serious threat to religion and society. His “refutation,” summed up in *La vérité des sciences contre les sceptiques ou pyrrhoniens* (*The Truth of the Sciences*; [1625]), conceded to the skeptic that we cannot have certain knowledge of the essences of physical things, but insisted that we can have certain knowledge in mathematics (including such applied mathematical disciplines as geometrical optics). He also argued that sense experience provided the basis for knowledge of the physical world, so long as it claimed to be no more than knowledge of appearances, not of the essences of things. If Descartes was not familiar with the Pyrrhonian skeptical challenge before his association with Mersenne in the 1620s, he must have been aware of it by then.

### LIFE IN LIBERTINE PARIS (1625–1628)

When Descartes returned to Paris in 1625, he encountered a contentious intellectual scene. Not only were men like Mersenne concerned about the threat of Pyrrhonism, but Paris had just seen the trial of Théophile de Viau, a protestant poet whose writings contained suggestions of Lucretian atomism, a celebration of sensuality, and an advocacy of free thought. Only a few years earlier Giulio Cesare Vanini had been burned in Toulouse for spreading doctrines alleged to be materialistic. The “libertines,” as these and other freethinkers were called, were accused of holding scandalous religious opinions and of leading a debauched, hedonistic way of life—the natural consequence of their denial of (or skepticism about) the after-

life. One of Mersenne’s projects in this period was a lengthy attack on religious unorthodoxy, *L’impiété des Déistes, Athées et Libertins de ce temps* (*The Impiety of the Deists, Atheists, and Libertines of Our Time* [1624]). Using, no doubt, a very generous criterion for atheism, Mersenne estimated that in Paris alone there were then at least 50,000 atheists (the population of the whole city at the time was only about 300,000).

Whether or not the threat was as grave as Mersenne claimed, it provoked a response that sought to repress any kind of unorthodoxy. In 1624 three men attempted to hold a public debate in which they would have challenged various theses in Aristotelian natural philosophy. There was apparently considerable public interest in the proposed debate, for it is said to have attracted a crowd of eight or nine hundred people. But the Theology Faculty at the Sorbonne prevented it from occurring. The men were banished from Paris on pain of death; the *parliament* prohibited anyone from holding or teaching theses “contrary to the ancient approved authors, and from holding any public debate other than those approved by the doctors of the Theology Faculty” (Gaukroger 1995, p. 136). The penalty for violating this edict would be death.

Descartes does not seem, at this stage of his life, to have engaged in these culture wars. His main preoccupations, apparently, were with solving problems in geometrical optics and resuming work on the *Regulae*. Sometime during these Paris years he evidently discovered the law of refraction known as Snell’s law: When light passes from one medium to another, the sine of the angle of incidence is proportional to the sine of the angle of refraction. (Though Willebrord Snell discovered this law before Descartes, Descartes’s discovery was independent of Snell’s.) Knowledge of this law is required to solve a practical problem in optics, that of finding the anaclastic curve, the shape that the surface of a lens must have to collect parallel rays of light into a single focus. This knowledge was necessary to design a telescope that would provide a clearer image than existing telescopes did. When Descartes was doing this work, the telescope was a recent invention, dating back only to his years at La Flèche. Descartes was quite excited about the potential of the new scientific instrument for extending our knowledge of nature.

In his treatise on *Optics*, published in 1637 with *Discourse on Method*, Descartes tried to explain Snell’s law micromechanically, in terms of the tendencies to motion of the particles involved in the transmission of light rays and the laws of motion, which he held applied to tenden-

cies to motion as well as to motions. He also proposed a solution to the problem of the anaclastic curve: that the lenses should have a hyperbolic shape. His new studies in optics also had an impact on his revision of the *Regulae*, providing him with an example of the use of the method that extended its range from mathematics to physics.

### THE LATER REGULAE (1626–1628)

According to our best current theory of the composition of the *Regulae*, one change that Descartes made when he returned to this work was to add two examples of the method to Rule Eight in a passage now generally designated as “Rule Eight-C” (Adam and Tannery X, p. 393–396).

The first example deals with the problem of determining the anaclastic curve. Earlier rules prescribed that we gradually reduce complex and obscure propositions to simpler ones, till we reach an intuition of the simplest propositions, from which we can then retrace our steps till we achieve intuitive knowledge of the proposition we originally wished to know. Someone who follows this advice is supposed to see, first, that determining the anaclastic line depends on determining the relation between the angles of refraction and the angles of incidence. He will not be able to determine that relation by conjecture or by appeal to experience or by learning it from the philosophers. But he will make progress if he realizes that the relation depends on the change made in the angles by the difference of the media, and that this change depends on how a ray of light penetrates a transparent medium. Knowing how it penetrates that medium requires knowing the nature of light. Understanding light requires, finally, knowledge of what a natural power is in general.

In this passage Descartes did not say what a natural power is. Here he limited himself to claiming that because this is “the most absolute thing in the whole series,” the most basic item in the investigation, which does not depend on anything more fundamental, it is something we will be able to grasp intuitively. Once we have done that, we will be able to retrace our steps—using our understanding of natural powers to understand the nature of light, our understanding of light to understand how it penetrates transparent media, and our understanding of light penetration to understand how a change in the medium changes the path of a light ray—until we are finally able to answer the question about the anaclastic curve. Elsewhere in the *Regulae* (Adam and Tannery X, p. 402), Descartes suggests that understanding the concept of a natural power requires reflection on the local motion of bodies—the idea apparently being that bodies

always act on one another by transmitting motion from one body to another through contact.

The frequent talk of intuition and deduction in the *Regulae* is apt to suggest—what many people are inclined to believe on other grounds anyway—that Descartes’s scientific methodology is wholly a priori. But this is not true, even in the *Regulae*. Although Descartes says in Rule Eight-C that we cannot determine by experience the relation of the angle of refraction to the angle of incidence, the reason seems to have been that the question is too complex to be resolved by an appeal to experience. “We can have certain experiential knowledge,” he said, “only of things completely simple and absolute.” We might infer that we derive from experience our intuition of what in this case is most simple—of what a natural power is, of how bodies naturally act on one another in cases where this action is immediately intelligible.

When Descartes was developing his theory of light in the *Optics*, he frequently used analogies from experience. The transmission of light from a luminous body to the object of illumination is like the transmission of resistance through a blind man’s cane from the object in his path to his hand. The reflection of light from a shiny surface is like the motion of a tennis ball when it bounces off an impermeable surface. Refraction is like the motion of a tennis ball when it encounters a permeable surface. Not everything we observe is as immediately intelligible as these analogical cases are. The movement of iron filings subjected to the power of a magnet is mysterious. But it’s part of Descartes’s scientific program to try to understand such phenomena by reducing them to others that are readily intelligible. Insofar as Descartes appeals to common experience in support of these intuitions, his method in the sciences is not wholly a priori.

The other example that Descartes added when he returned to Rule Eight he describes as “the most notable of all.” Everyone who loves truth in the slightest degree, he said, should, set himself, once in his life (*semel in vita*), the task of determining what truths human reason is capable of knowing and what questions are beyond our cognitive powers. This will prevent him from always being uncertain about what the mind can do and save him from wasting time on matters our faculties are not capable of dealing with. Someone who undertakes this task will discover that nothing can be known prior to the intellect, since knowledge of all other things depends on it, and it does not depend on knowledge of them. But though Descartes asserted the priority of the pure intellect, he also acknowledged that we have other instruments of knowledge in addition to the intellect. In Rule

Eight-C Descartes said that there are two such instruments: the imagination and the senses. In the text that follows (from Adam and Tannery X, p. 396, 26, to the end of Rule Eight, commonly dubbed “Rule Eight-D” and apparently a rewrite of Eight-C), he added a third instrument: memory.

What is most striking about this passage is its difference from well-known later texts to which it is in other respects quite similar. Three times in Rule Eight (once in Eight-C, twice in Eight-D) Descartes used the phrase “semel in vita” to refer to a project that everyone who wants to use his cognitive powers well should undertake once in his life. Each time he describes the project, with minor variations, in Lockean terms, as one which requires us to determine the limits of the human understanding. Descartes used the same phrase, “semel in vita,” in the opening sentence of the First Meditation, also to refer to a project one should undertake once in one’s life. But in the *Meditations* the project involves, not determining the limits of the human understanding, but *overthrowing all the opinions he has haphazardly acquired over the years, so he can start anew, from firm foundations*. Three years later, in *Principles of Philosophy*, he used the same phrase, “semel in vita,” to again call all seekers after truth to the same overthrow of any past opinion in which they find even the smallest suspicion of uncertainty. As Descartes develops this project in the *Meditations*, it becomes clear that among the opinions to be rejected, at least provisionally, are those involving even the simplest truths of mathematics, which in the *Regulae* were paradigms of certainty. The call to radical doubt, undertaken in the hope of achieving absolute certainty—the most characteristic feature of Descartes’s published works—is nowhere present in the *Regulae*.

#### SEEKING SOLITUDE IN THE NETHERLANDS (1629–1633)

Toward the end of the Paris years Descartes attended a meeting that was to become the second major turning point in his life. The meeting, attended by many of Paris’s leading intellectuals, occurred at the palace of the papal nuncio. The speaker was a chemist/chemist named Chandoux, who attacked Aristotelian natural philosophy as an inadequate basis for chemistry and apparently proposed a mechanistic approach in its place. Contrary to what we might have expected from the ban on criticisms of Aristotle in 1624, most of those present, who included Mersenne and Cardinal Pierre de Bérulle, received Chandoux’s speech well. Descartes did not.

Bérulle noticed that Descartes did not share the group’s enthusiasm and asked why. After politely trying to excuse himself from saying what he thought, Descartes gave an extended critique of Chandoux, praising his desire to rescue philosophy from “the perplexity of the schoolmen” (Baillet, p. 69), but faulting him for replacing it with something merely probable. If merely probable arguments are allowed, he contended, it is easy to make the false appear true and the true false. He then challenged the company to give him an example of an incontestable truth. When they did, he produced a dozen probable arguments designed to prove its falsity. Then he asked them for an example of an evident falsehood. When they provided one, he showed the falsehood to be credible by another dozen probable arguments. The group then asked him whether there was any infallible way of avoiding sophisms. He replied that he knew of no more certain way than to use the method he commonly followed, which was derived from mathematics, and which he thought sufficient to provide a clear demonstration of all truths.

Descartes’s dialectical ingenuity made a deep impression on his audience, especially Cardinal Bérulle, who asked to see him privately. When they met later, Descartes claimed that if he continued his inquiries, the benefits to the public would be considerable. He could achieve results in medicine that would greatly improve people’s health and results in mechanics that would greatly lessen people’s labor. Bérulle replied that since God had given Descartes this extraordinary talent, he owed it to God and his fellow men to make full use of it. Descartes had been thinking about leaving Paris for some time. This conversation tipped the balance. He resolved to take up residence in the Netherlands, where he would find a more congenial climate and, more important, the solitude that would allow him to meditate without constant interruptions by his friends.

There is nothing up to this point to indicate that Descartes had entertained radical skepticism as a serious possibility. He must have been aware of the debates about Pyrrhonism and of some of the Pyrrhonist literature. But Baillet’s account of the Chandoux episode and Descartes’s own description of the event in 1631 both suggest a Descartes whose epistemology is very like that of the *Regulae*: dismissive of scholastic philosophy and of any reliance on probable arguments, confident of the certainty of mathematics and of the method he had modeled on his discoveries in mathematics. In his first years in the Netherlands, Descartes’s attitude on these issues changed, it seems.

We know from a letter to Mersenne in November 1630 that soon after Descartes moved there (probably during the winter of 1628–1629), he began what he described as “a little treatise on metaphysics,” in which he set out to prove “the existence of God and of our souls when they are separate from the body, from which their immortality follows” (Adam and Tannery I, p. 182). This “little treatise” sounds like an early version of the *Meditations*. It was evidently not complete at that point, and we do not know much about its specific content, but from an earlier letter to Mersenne (April 15, 1630) it appears that Descartes worked on this treatise for the first nine months that he was in the Netherlands.

In that letter of April 15, Descartes also described what seems to be a different “little treatise,” begun more recently. To provide himself with an extra incentive to finish it as soon as possible, he promises to send it to Mersenne by the beginning of 1633. Mersenne will be amazed, he says, that he is taking such a long time to write a treatise so short that it requires only an afternoon to read. This treatise was apparently focused on physics. But Descartes said that he would not have been able to discover the foundations of his physics if he had not approached them by first trying to know God and himself, and that he had discovered how to prove metaphysical truths in a way more evident than the proofs of geometry. This suggests, for the first time, that Descartes was trying to ground physics on metaphysics, specifically on a metaphysics that focuses on a knowledge of God and the self. It also suggests, for the first time, that there may be something defective about geometrical proofs, that considered apart from a metaphysical foundation, they may be less certain than the metaphysical proofs Descartes discovered.

Why did Descartes then think geometrical proofs might need a metaphysical foundation? The letter of April 15 contains a possible clue. For the first time Descartes stated a doctrine for which he was to become notorious: the creation of the eternal truths. He wrote to Mersenne that in his treatise on physics he would discuss several metaphysical topics; in particular, he would defend the view that the eternal truths of mathematics have been established by God just as a king establishes laws in his kingdom, that they depend entirely on him, no less than does the rest of his creation.

There has been much debate about what this doctrine means and why Descartes held it. But our present concern is its relation to the certainty of mathematics. When Descartes argued, in the First Meditation, that even mathematical truths are subject to doubt, he did not

invoke this doctrine that God created them. He simply appealed to the idea of God as an omnipotent being who created him, and who *could*, if God had chosen, have created him so imperfectly that his cognitive apparatus might lead him astray, even in the things that seem most evident to him. In the correspondence and elsewhere, we can see that Descartes thinks a proper understanding of omnipotence would conclude that it requires the ability to determine what the eternal truths are. But Descartes knows this was an unusual, controversial conception of omnipotence, and he did not deploy it in the First Meditation. In the *Discourse*, as he was about to justify his skepticism about mathematics, Descartes would write, “I don’t know whether I should tell you of the first meditations that I had [in the Netherlands], for they are perhaps too metaphysical and uncommon for everyone’s taste.”

Since Aquinas, the dominant view among Scholastics was that God has the power to determine, by his will, what contingent truths are true, but that his will does not determine what necessary truths are true. Those truths were supposed to be grounded in God’s intellect, in the ideas he has, not in his will. The meditator of the First Meditation approaches the question of what things are subject to doubt from the perspective of someone just beginning to philosophize, who presumably holds conventional views about what God’s omnipotence implies. Moreover, the ability to interfere with his creatures’ cognitive faculties would not seem to require God to have the power to create eternal truths. Surely, anyone with enough power to create the world of contingent beings must have the power to make one species of contingent being defective in its perception of necessary truths.

Skeptics nevertheless suggested that God’s power might extend to eternal truths and used that thought to ground a doubt about mathematics and any other truths we might think necessary. In his *Apology for Raymond Sebond*, one of Montaigne’s arguments for Pyrrhonian skepticism involves the claim that because God’s power is incomprehensibly great, we speak irreverently if we say that there is something he cannot do. Among the things that Montaigne suggested it would be impious to say God cannot do are to make two times ten not equal twenty, to go back on his word, to cause a man who has lived not to have lived. Montaigne did not say that God *created* the eternal truths. But he did say it is arrogance on man’s part to claim that God *cannot render false* the truths commonly classed as eternal. This category includes not only simple mathematical truths, but also metaphysical truths (such as “The past is immutable” and “Nothing is made of nothing”) and moral truths (such as “A perfect being

would not go back on his word”). And he uses these accusations of irreverence and arrogance to justify his claim that we ought to suspend judgment about everything, including these supposedly incontestable truths.

Descartes agreed with Montaigne that we do not do justice to God’s power if we say that there is something God cannot do. “We can assert that God can do everything within our grasp, but not that he cannot do what is beyond our grasp” (Adam and Tannery I, p. 146). To say that God’s power is limited to what we can comprehend would be rash and disrespectful. Descartes did not want to say that God can render the eternal truths false. They are immutable. But they are immutable because God’s will is immutable. So by the spring of 1630 Descartes thought there was a need to ground physics (including the truths of mathematics) in metaphysics, and his perception of this need was connected with his view that God’s power is incomprehensibly great. He thought that he had a way to accomplish this grounding, and he began, but did not complete, a draft of a treatise on metaphysics like the *Meditations* that would accomplish that.

### THE WORLD (1629–1633)

Descartes never did publish the treatise on physics he referred to in his correspondence as “*The World*” (or “my *World*”), but he used material from it in his *Optics* (1637) and *Meteorology* (1637) and *Principles of Philosophy* (1644). And portions of the work appeared after his death: one under the title *Le monde, ou Traité de la lumière* (The World, or Treatise on Light [1664/1979]), which reproduced the beginning of the treatise, another titled *Traité de Homme* (Treatise of Man [1662/1972]), which reproduced a later part of it. Here the entire physical treatise, as projected in the early 1630s, will be referred to as *The World*, and the title *Treatise on Light* will refer to the opening portion published in 1664.

*The World* originated in Descartes’s concern with the problem of explaining parhelia, the bright spots that sometimes appear in a solar halo, caused by the refraction of sunlight through ice crystals in the atmosphere. In the summer of 1629 a friend had shown him a description of this phenomenon and asked him what he thought of it. Descartes set aside work on his treatise on metaphysics to see what he could make of it:

My mind is not so strong that I can devote it to many tasks at once, and as I never make any discoveries except through a long train of diverse considerations, I must devote myself wholly to a subject when I wish to investigate some particular aspect of it” (Adam and Tannery I, p. 22–23).

His curiosity about parhelia led him first to inquire into meteorological phenomena in general (including the rainbow, another effect of refraction in the atmosphere) and then to the incredibly ambitious project of explaining “all the phenomena of nature, that is, the whole of physics.”

*The Treatise on Light* begins by arguing that there can be a difference between the visual sensation we have of something and what there is in the object that produces this sensation. The common view, he claimed, is that our ideas are completely like the objects from which they proceed. But there are many experiences which should cast doubt on this. For example, in the case of sound, most philosophers think that the cause of our auditory sensations is a vibration in the air, which does not resemble those auditory sensations at all. Descartes proposed that something similar is true of light.

The first step in discovering the nature of light is to identify the bodies that we know produce light. These seem to be the stars and fire. Because the stars are too remote to be easily observable, Descartes concentrated on fire. When we watch fire burning a piece of wood, we observe that it sets the minute parts of the wood in motion and separates them from one another. It transforms the smallest particles into fire, air, and smoke, and leaves the grosser particles as ash. Scholastic philosophers might have supposed that in addition to these mechanical processes, there is a form of fire or a quality of heat involved. But Descartes (applying Ockham’s razor) limited himself to what he saw as necessarily part of the process and did not postulate anything unnecessary to explain the phenomena. Since it is inconceivable that one body should move another except through its own motion, Descartes inferred that the body of the flame is composed of particles so small as not to be observable but moving so rapidly that, in spite of their small size, the force with which they act on the wood is great enough to disperse its particles. The motions of the flame particles cause both the light the flame produces and its heat, depending on which sense organs they encounter. But in neither case is there any resemblance between the cause and the idea.

Descartes observed that there is nothing anywhere in nature that is not changing. He suggested that the changes involved in combustion are not unusual: In many cases the cause of observable changes will lie in the motions of unobservable particles. The principle at the core of the mechanical philosophy is that all physical change is reducible to change of place in bodies, if not in bodies large enough to be observable, then in bodies so

small as to be unobservable. The fundamental differences among bodies are in the size, shape, and motion of their constituent particles.

Descartes distinguished three elements, which he called “fire,” “air,” and “earth.” These are not to be identified with the elements traditionally so-called or with the familiar substances commonly so called. Fire is a very subtle liquid, made up of the smallest, fastest moving particles, which have no determinate size or shape. This permits them to fill the gaps between the particles of the other elements and makes it unnecessary to allow for the existence of a void. Air too is a subtle liquid. Its particles are small and fast-moving compared with those of earth, but large and slow-moving compared with those of fire. They have a determinate size and shape; almost all of them are round. The particles of earth are the largest and have little or no movement. Descartes emphasized that he did not attribute the traditional qualities of heat and cold, moisture and dryness, to his elements. He took those qualities to require explanation themselves, by appeal to the size, shape, and motion of bodies or their constituent particles.

Having explained the basic elements of his physics, Descartes then asked us to imagine that God has created, somewhere in space, a new world, made only of such matter, and has distinguished the different bodies in this world from one another only by the different motions he has given to the different parts of its matter. There is no order in the initial state of this imaginary world. Descartes’s project was to show how a world like ours could emerge from this chaos, given only the laws of nature that God established when he created this world. (Genesis, of course, tells us how the world we are familiar with *was* created. Descartes professed to be interested only in exploring other ways God could have done it.)

The language Descartes used here—that God *established* the laws of nature—is reminiscent of the language he used in his letter to Mersenne, where he said that God established the eternal truths (referred to as “laws in nature”) as a king establishes laws in his kingdom. The comparison to a king suggests that there is something arbitrary about this act and may also suggest that the laws are subject to change. Descartes wanted the suggestion of arbitrariness, but he did not want the suggestion of mutability. Writing to Mersenne in 1630, he anticipated an objection that Mersenne might encounter when he publicized Descartes’s view (as Descartes encouraged him to do):

They will tell you that if God had established these truths, he could change them, as a king

makes his laws. To which one must reply: Yes, if his will can change.—’But I understand them as eternal and immutable.’—And I make the same judgment about God” (Adam and Tannery I, p. 145–146).

In the correspondence of 1630, Descartes invoked the immutability of God’s will to explain the immutability of the eternal truths. In *The World* he used it to give content to the laws of nature.

God, “as everyone must know,” is immutable. (Presumably, this could have been established by an argument from God’s perfection in the 1629 treatise on metaphysics.) This entails that he always acts in the same way. This, in turn, entails that he continues to preserve the objects he created in the same way he created them. That does not mean that things do not change. On the contrary, since God endowed some of these things with motion when he created them, it means that he preserves that motion. This fact, combined with the absence of a void, entails that when beginning to move, bodies also begin to change and diversify their movements through their encounters with other bodies.

Descartes claimed to derive three principal laws of nature from God’s immutability: (1) Each part of matter always continues to exist in the same state, so long as encounters with other bodies do not cause it to change. (2) When bodies push against one another, the total quantity of motion is preserved (one body cannot increase the motion of another body without losing as much of its own motion as it transfers to the other body). (3) Although the motion of a body is usually in a curved line, it always *tends to move* in a straight line. Because Descartes denied the existence of a void, he insisted that all motion must be “in some way circular.” Since there is no empty space for a body to move into, it can move only by displacing other bodies. Ultimately, each moving body must be part of a chain of moving bodies that forms a closed curve of some sort. Though Descartes deduced these laws from God’s immutability, which he presumably knew a priori, he also insisted that they agree well with what we find in experience. Aristotelian physics, he pointed out, assumes that motion will continue only as long as force continues to be applied to the moving object; so it has difficulty accounting for projectile motion.

From these assumptions about the nature of matter and the laws according to which matter moves, Descartes developed a theory about how a world like ours might have evolved from the chaos that he supposed God originally created in the hypothetical new world. Since that

world is a plenum, whose parts must displace other parts to move at all, and all motion must be in a closed curve, matter will naturally organize itself into vortices, masses of matter swirling, whirlpool-like, around a center. The element of fire will tend to concentrate at the centers of the vortices, composing the Sun and the stars; the element of earth will tend to form into large clusters, rotating around the centers of their vortices and carried along by particles of the second element. The planets are formed from such clusters, as are the comets. But the planets remain in one vortex, whereas the comets have motions that carry them from one vortex to another. This clearly heliocentric system implies not only that Earth rotates around the Sun, but also that our solar system is only one of many in the universe, each forming around the various stars, which are no longer embedded in a single sphere, as in the Aristotelian-Ptolemaic cosmology.

Descartes went on to offer explanations for the planets' rotations around their axes, the motions of satellites (moons) around their planets, the movement of the tides, weight, and light. The last he interpreted as resulting from the rotation of the Sun and the matter around it. This generates a radial pressure, which spreads outward from the Sun along straight lines from its center. He enumerated a dozen properties of light that he claimed this theory can account for: that it is propagated from all sides of the luminous body, to any distance, instantaneously, normally in a straight line, but subject to reflection when it encounters a body it cannot penetrate, and subject to refraction when it encounters a medium it can penetrate, and so on. The treatise as it has come down to us does not explain reflection and refraction but instead refers us to his *Optics*, published in 1637. In another work, *Meteorology* (1637), Descartes offered explanations of rainbows and of parhelia.

The work commonly known as the *Treatise of Man* was to have been part of *The World*, though it appears that it would not have come immediately after the *Treatise on Light*. We do not know how many intervening chapters are missing, but we can have a fair idea of their intended contents from the description of *The World* in Part Five of the *Discourse*. Among the topics covered would have been the formation of mountains, seas, springs, and rivers on Earth; the formation of metals in the earth and plants in the fields; and the nature of fire and its various properties, such as its ability to form glass from the ashes of the material it has burned.

The *Treatise of Man* was to have included accounts of both the body and the soul, though only the chapters dealing with the body survive. These chapters begin by

asking us to imagine that God created a statue or machine made of earth (the element), which he intended to make as much as possible like us. Just as the *Treatise on Light* tries to show that God could have produced a world that would look just like ours, using only the materials and mechanisms Descartes described, so the *Treatise of Man* tries to show that God could have produced machines that would have looked and behaved just like the human body, using only such means. Though an exception would be the functions that Descartes thinks need to be attributed to the rational soul, notably the intelligent use of language, he claimed to give a mechanistic explanation of all the animal functions that Aristotelian philosophy attributed to vegetative and sensitive souls: the digestion of food; the beating of the heart; the nourishment and growth of members; waking and sleeping; the reception of light, sounds, smells, heat, and so on, by the sense organs; the transmission of ideas of these qualities to the brain; the retention of these ideas in memory; the internal movements of the appetites and passions; and the external movements of the limbs (insofar as their explanation does not depend on the actions of the soul).

We cannot go into these explanations here, but two points about them deserve notice. First, we know from his correspondence that Descartes spent a lot of time during these years dissecting animals to learn anatomy. However much works like the *Regulae* encourage the picture of Descartes as a purely a priori scientist, and however much justice there may be in that picture, it is clear that in practice Descartes believed it was necessary for scientists to do a great deal of data collection. When Mersenne wrote saying that he knew people so dedicated to advancing the sciences that they were willing to make all kinds of experiments at their own expense, Descartes replied,

It would be very useful if some such person were to write the history of celestial phenomena, according to the Baconian method, describing exactly for us the present appearance of the heavens, without any explanations or hypotheses, reporting the positions of each fixed star in relation to its neighbors, and their differences in size, color, visibility, brilliance, and so on. He should tell us how far this accords with what ancient astronomers have written about it and what differences there are; for I have no doubt that the stars are constantly changing their relative position somewhat, in spite of being called fixed. (Adam and Tannery I, p. 251–252)

Descartes himself regularly offered hypotheses to explain phenomena. But he knew that a satisfactory explanation

of phenomena required good descriptions of the phenomena to be explained and that such descriptions required empirical inquiry. He might also have acknowledged that the necessary empirical inquiries would be guided by intuitions about what the ultimate explanation of the phenomena was likely to be. In this case, his call for a Baconian history seems to be guided by his conviction that the so-called fixed stars are not really fixed.

Second, although it may not be obvious that Descartes's scientific procedure in *The World* exemplifies his method, we can regard it as an extension of the method described in Rule Eight-C of the *Regulae*. Reflection on the problem of determining the anaclastic curve had persuaded Descartes that solving that problem would require understanding refraction, which would require understanding the nature of light and its transmission, and ultimately, understanding what a natural power is. In the *Regulae* Descartes was vague about what a natural power might be, suggesting only that it had something to do with local motion. When he began to write *The World*, his starting point was a similar problem in optics, explaining parhelia, which he must have realized would also involve understanding refraction. He already believed that understanding refraction required understanding the nature of light, and that understanding light required understanding what a natural power is. He then saw that understanding the concept of a natural power requires a full-fledged theory of the nature of bodies and the laws governing their motion, and that getting this right should enable him to explain all kinds of phenomena, both in the heavens and on Earth.

#### THE GALILEO AFFAIR AND ITS AFTERMATH (1633–1637)

Descartes never published *The World*, despite having worked hard on it for years and having achieved results he was very proud of. In 1616 the Church condemned as false and contrary to Scripture the Copernican doctrines that Earth moves and that the Sun is motionless. It prohibited a book by Paolo Foscarini that taught this doctrine, and suspended Nicolaus Copernicus's *On the Revolutions of the Heavenly Spheres* "until it should be corrected." Also, Cardinal Robert Bellarmine, in a private meeting with Galileo Galilei, ordered him to abandon the Copernican view. Descartes knew that the Copernican view had been censured. He probably did not know about Galileo's meeting with Bellarmine. He seems to have heard rumors that, in spite of the censure, some continued to teach the Copernican view "publicly, even in Rome."

In 1623 a Florentine cardinal friendly to Galileo became Pope Urban VIII. After discussions with the new pope, Galileo got permission to write a treatise on the Copernican system, provided he treat it as a mathematical hypothesis, no more than a convenient predictive device. Galileo apparently decided to test the limits of this permission. He wrote a dialogue in which one participant defended the Copernican theory, another defended the Ptolemaic theory, and a third played the role of uncommitted inquirer. His spokesman in the dialogue does not claim certainty for the Copernican theory. Moreover, he permitted his representative of orthodoxy to have the last word, proclaiming that, however plausible the pro-Copernican arguments might be, we can never know with certainty what the true explanation of the phenomena is. God, in his infinite power and wisdom, might have produced the phenomena in any number of ways. Finally, in the preface he claimed that his work treated the heliocentric theory as "a pure mathematical hypothesis," adopted for astronomical convenience, and that he was writing only to demonstrate that Italians were well aware of the scientific case for Copernicanism, and that the prohibition of 1616 had not been issued in ignorance. After long negotiations with the censors, he secured permission to publish his *Dialogue Concerning the Two Chief World Systems* in 1632.

But his precautions proved insufficient. It was evident to careful readers that he had crossed the line between hypothetical consideration and advocacy. In the spring of 1633 he was tried by the Inquisition on the charge of "vehement suspicion of heresy." What this language meant, in this case, was that he had presented views contrary to Scripture as if they were probable, but that there was some doubt as to whether he had the evil intention necessary for conviction of formal heresy. Found guilty in June, he was sentenced to house arrest for the rest of his life and required to abjure his errors.

In November 1633 Descartes wrote to Mersenne that he had tried to buy a copy of Galileo's *Dialogue*, which he heard had been published the year before. But when he looked for it, he learned that it had been confiscated and burned. He was so astonished, he said, "that I almost decided to burn all my papers, or at least, to let no one see them. For I could not imagine that he, who is an Italian, and even (as I hear) favored by the Pope ... could have been made a criminal simply because he wanted (as doubtless he did) to establish the movement of the earth" (Adam and Tannery I, p. 270–271). The doctrine of the Earth's movement, Descartes writes, is so connected with the other parts of his own *World* that he could not detach

it without making the remainder very unsatisfactory. If that doctrine is false, “all the foundations of my philosophy are, too, for they demonstrate it quite evidently.” When he learned several months later that Galileo had been condemned “even though he pretended that he proposed [the Copernican system] only hypothetically” (Adam and Tannery I, p. 271) he was especially concerned, since he had adopted a similar device himself, representing himself as merely telling a story about how God *could have* created a world like ours, while conceding that Genesis tells us how he *did* create it.

It is not clear what stage *The World* was in at this time. Descartes said that he had been on the point of sending it to Mersenne as a New Year’s present, if it could be copied in time. Perhaps it was nearer completion than the surviving parts would suggest. For a while Descartes held out hope that there may be a way to publish it. Perhaps this action of the Inquisition had not yet been ratified by the pope or by a Church council. If so, it may not have the full authority of the Church behind it. But eventually Descartes decided to abandon his treatise for the time being and adopt a different plan. He decided to publish a semiautobiographical treatise on method, to be supplemented by three short treatises demonstrating the power of his method: *Optics*, *Meteorology*, and *Geometry*.

#### THE DISCOURSE ON METHOD AND ITS ESSAYS (1637)

At age forty-one, with only thirteen more years to live, Descartes published his first works. Thus began the public career that would earn him a reputation as the father of modern philosophy. As we have noted, Descartes’s *Discourse on the Method of Conducting One’s Reason Well and Searching for Truth in the Sciences* is partly autobiographical, but it is not very reliable in this regard, for it omits important events (such as his relation with Beeckman, his three dreams, and his encounter with Chandoux); it projects into the past ideas that Descartes probably had only at a later date (such as the idea of overturning all his past opinions to reconstruct his beliefs on firmer foundations); and it is silent on ideas that Descartes feared might cause his readers to raise objections he did not want to deal with (such as the creation of the eternal truths). Descartes himself warned us not to take his work too seriously as autobiography when he wrote that he was presenting it “only as a history, or, if you prefer, a fable.” Descartes wanted us to read his work for its moral, for examples of conduct to imitate or avoid. But he also cautioned us that both fables and history have their dangers: Fables may make us think that something is possible

when it is not, and even the most accurate histories, because of their selectivity, may make us conceive plans beyond our powers.

Examples of conduct to imitate would be examples of how to conduct our reason when we seek truth in the sciences. Descartes offered four rules that he said he found sufficient in this search:

- 1) never accept anything as true which he did not know evidently to be true, including nothing in his judgments except what has presented itself so clearly and distinctly to his mind that he had no reason to doubt it;
- 2) divide the difficulties he was examining into as many parts as possible;
- 3) conduct his thoughts in an orderly way, beginning with the simplest objects, and ascending gradually to the most complex; and
- 4) make enumerations so complete and reviews so comprehensive that he was sure he had not left anything out. (Adam and Tannery VI, p. 18–19)

Presented thus baldly, these rules probably do not give enough direction to be very useful. And in a letter to Mersenne in February 1637, Descartes disclaimed any intention to *teach* his method in the *Discourse*. His purpose there was only to *talk* about it, and his purpose in the scientific essays that accompanied the *Discourse* was to show what could be accomplished through its use. Even the essays do not, for the most part, purport to show the method at work. As Descartes explained in a letter to Antoine Vatieer in February 1638, “I could not show the use of this method in [the three scientific treatises] because it prescribes an order for investigating things which is rather different from the one I thought I had to use to explain them” (Adam and Tannery I, p. 559). But Descartes made one exception to this generalization. He told Vatieer he had given a sample of the method in his discussion of rainbows in the eighth chapter of *Meteorology*.

In that chapter Descartes began by noting that rainbows occur not only in the sky but also in the air near us, whenever there are many drops of water in the air illuminated by the Sun. We know this from our experience with fountains. He inferred from this that the rainbow arises only from the way light rays interact with drops of water, and from there move toward our eyes. Previously in the *Meteorology* he had shown that these drops are round; he also knew, presumably from experience, that the occurrence of a rainbow is independent of the size of the drops.

These reflections suggested an experiment that enabled him to examine the phenomenon close up, in circumstances he could control.

He filled a large, round flask with water and positioned it so that the Sun was coming from behind him as he faced it. Then he situated himself in relation to the flask so that he observed a bright red spot at its bottom. He discovered that a line drawn from his eye to the bottom of the flask made about a 42-degree angle with a line drawn from the Sun to the flask's bottom. Furthermore, no matter how he moved—nearer to the flask or further away, to the right or to the left, even if he made the flask revolve around his head—he always saw a red spot at the bottom, so long as the angle between his line of vision and the line of the Sun's rays remained about 42 degrees. If he increased the angle, the red disappeared. If he decreased it slightly, the spot did not cease to be colored, but divided into two less brilliant parts of different colors (yellow, blue, etc.). From this he inferred that if all the air in that direction were filled with such round drops of water, a red spot would appear in each drop where the angle between the Sun's rays and the line of vision was about 42 degrees, producing a continuous circle of red spots. Similar circles of other colors would be generated in drops that were at slightly more acute angles.

Through further experiments with the flask, Descartes discovered that the red spot did not disappear when the light source was blocked, so long as light was permitted to enter at the top of the flask and leave at the bottom, and so long as certain paths within the flask were not blocked. He inferred that the appearance of red at the bottom was caused by refraction of the Sun's rays as they enter at the top of the flask, their reflection from a point at the back of the flask, and their refraction again at the bottom of the flask as they leave it to move toward the eye. He proposed a similar explanation for the production of the secondary bow, which appeared at an angle of about 52 degrees and had its colors arranged in reverse order. This, he inferred, arises from a combination of two refractions and two reflections.

So far the phenomena Descartes was trying to account for depended essentially on the refractive index of water in relation to air, a figure that he could calculate accurately. And so far his explanation of the phenomena was basically right. But he still had not explained what he called the principal difficulty: Why do only those rays refracted at a certain angle cause certain colors to appear? To resolve this difficulty, he undertook a series of experiments with a prism, a similar object also known to produce a spectrum of colors. The prism differed in various

ways from his flask, and these differences enabled him to eliminate as irrelevant certain features of the flask. To produce a spectrum of colors, it is not necessary that the medium through which the light passes have a curved surface, or that the light strike that medium at a particular angle, or that it be reflected, or that it be refracted more than once. But it is necessary that the light be refracted at least once.

At this point Descartes invoked his theory of the nature of light, that it is the action or movement of particles of air (the element), which must be imagined as little balls. These balls have two motions, one in the direction of their propagation, the other rotational. Different degrees of rotational motion produce different color sensations when they strike the eye. The differences in the colors produced when light is refracted arise from the fact that the refractive process imparts different degrees of rotational motion to the light particles. (For further details, see Gaukroger 1995, chap. 6.)

This part of Descartes's explanation has not fared well. But the example remains interesting in a number of respects. First, it illustrates Descartes's second and third rules: dividing a complex problem into as many parts as possible till you reach something simple and easy to understand, and then retracing your steps back to the complex phenomenon you were originally interested in. The complex phenomenon is the rainbow. The simple object is the individual drop of water seen to have one of the colors of the rainbow. By using a model of the simple object, which we can observe close up and manipulate, we can determine the conditions for its being seen as having the color it has, and we can determine how changing those conditions might produce different colors (or no colors at all). We then reconstruct the complex phenomenon from the simple model by recognizing that if we observed a mass of such simple objects in the sky, the ones observed at the right angle for producing a particular color would form a continuous circle of that color, and that other concentric circles of different colors would also be produced at different angles.

But this example also warns us that if we use the concepts of intuition and deduction to analyze our solution of this problem, we need to understand those concepts very broadly. Our understanding of how the simple objects behave involves a priori elements, insofar as we make use of geometry to deal with certain aspects of the problem (such as the shape of the bow). But it also involves numerous appeals to experience. It is by careful experiment that we determine that the same color is produced so long as the same angle is preserved, or that a

double refraction, combined with reflection, is involved in producing the primary bow, or that the refractive index of water in relation to air has the particular value it has. Our ordinary experience of fountains initially suggests a way of breaking the complex phenomenon down into simple elements. Experience is also involved, no doubt, in the theory of matter that Descartes's theory of light invokes. There is no a priori reason why there must be exactly three elements, having the properties that Descartes assumed they have. A priori considerations of simplicity and intelligibility speak for this theory when it is compared with the scholastic forms and qualities. But those considerations would not be sufficient to warrant acceptance of the theory if it were not capable of explaining a wide range of phenomena, as Descartes clearly thought it is.

The rules of the *Discourse*, then, are quite similar to the rules of the *Regulae*, provided that we interpret the concepts of the *Regulae* freely. But one notable feature of the *Discourse* is the absence of any explicit discussion of intuition and deduction. The ghosts of these concepts are present in the first rule, insofar as Descartes advises us to never accept as true anything we don't know to be evidently true, making no judgments except those that present themselves so clearly and distinctly to our minds that we have no reason to doubt them. This excludes reliance on merely probable assumptions. But it does not explicitly mention intuition or deduction. And it suggests a problem we have so far not considered, because so far it has not seemed to arise in the writings we have considered.

Throughout his work Descartes was clearly a foundationalist, at least in the minimal sense that he thought some of our beliefs are based on other beliefs we have, whereas some are not based on others. We can call the ones not based on others *basic beliefs*. Our basic beliefs provide the foundations for our system of beliefs; our derivative beliefs, the superstructure. This metaphor of our system of beliefs as like a building, which has foundations and a superstructure and might collapse if the foundations are not solid, is prominent in the *Discourse* and in the *Meditations*, but is only implicit in the *Regulae*, where Descartes presents arithmetic and geometry as the only genuine sciences yet discovered, superior to all other alleged sciences because of the certainty of their initial assumptions and the care with which mathematicians derive from those assumptions only conclusions clearly seen to follow from them.

But the *Regulae* does not have a criterion for distinguishing the absolutely certain from the merely probable.

It assumes that mathematics is more certain than the other sciences because it is concerned with objects so pure and simple that it need make no assumptions that experience has rendered uncertain. At that point, that is all that Descartes thought it necessary to say to justify reliance on the assumptions of mathematics. But in the *Discourse* (and the *Meditations*), he is concerned with a problem his earlier work had not considered. It is not the problem of the creation of the eternal truths, but a different skeptical problem.

We are not born with fully mature cognitive faculties. Rather our faculties develop gradually as we grow to adulthood. While they are developing, we accept, uncritically, many propositions from parents, teachers, and others whose authority we have come to respect. Then we learn, sadly, that these are not perfectly reliable sources. The propositions we accepted in this way can seem quite obvious. Nevertheless, they lack a firm foundation, and we can be mistaken about them, even when they seem most obvious. This reflection gives us a reason, not only for doubting the specific propositions we have accepted from others and everything based on them, but also for wondering whether our cognitive faculties, our basic capacities for distinguishing truth from falsity, are as reliable as we thought they were.

The *Discourse* not only identifies this problem; it offers a solution for it. Descartes was not content, in this work, simply to say that the basic beliefs we acquire through intuition are indubitable or evident. He wanted to show that we perceive some propositions so clearly and distinctly that there is no reason to doubt them, even on a generous conception of what might constitute a reason for doubt. So in Part IV of the *Discourse* he embarked on a project of rejecting as false anything in which he could "imagine the least doubt." This is what is called the method of doubt. He was very permissive in what he counted as a ground of doubt. He was prepared to allow that even "the most extravagant suppositions of the skeptics" provide some ground for doubt. If a belief can survive that permissive a test, we cannot reasonably demand anything more certain as a foundation for our beliefs. If we are to doubt, we must have some reason to doubt. But if we want what survives our attempt to doubt to be absolutely certain, we must be thorough about the attempt; we must allow even the most improbable possibilities to count as reasons for doubt.

This might seem to be a quixotic quest if Descartes had not apparently discovered something that resists his attempts to doubt it: that he, who is engaged in this methodical doubt, and thus is thinking, exists. So we

encounter what is commonly referred to as “Descartes’s *cogito*,” a label deriving from the Latin version (“*Cogito, ergo, sum*”) of an inference that appears in the *Discourse* in French: “*Je pense, donc, je suis*” (“I think; therefore, I exist”).

Though there is something very compelling about that inference, it is not clear exactly what Descartes was claiming as his initial certainty. In the *Regulae* he had cited both “I think” and “I exist” as truths known certainly by intuition; if that’s their status, then either proposition might be a suitable foundation for demonstrations. In the *Discourse* he seems to be inferring his existence from his thought, as if he can be certain of his existence because he can be certain that he thinks—and, moreover, certain that to think, it is necessary to exist (Adam and Tannery VI, p. 32–33). This suggests that his affirmation of his existence is the conclusion of the following demonstration:

- (1) To think, it is necessary to exist.
- (2) I think.
- (3) Therefore, I exist.

This way of thinking about the *cogito* naturally raises the question of how Descartes can be certain of the premises of this demonstration. The *Discourse* does not explicitly ask that question, but it does have what looks like an answer to it, as far as the first premise is concerned, where Descartes says that he sees very clearly that (1) is true. Though the *Discourse* has not offered any *theory* of intuition, this looks like an appeal to intuition, a faculty whose reliability we might have thought was put in doubt when Descartes questioned the certainty of simple mathematical truths.

The *Discourse* does not even *seem* to answer the question as it concerns the certainty of the second premise. But in a letter that Descartes wrote to Henri Reneri in 1638, the answer seems to be that when we are thinking, we cannot doubt that we are thinking (Adam and Tannery II, p. 38). This may suggest the following argument for the certainty of (2):

- (4) When we think, we cannot doubt that we think.
- (5) I am thinking.
- (6) Therefore, I cannot doubt that I am thinking.

But though Descartes often seems to accept (4), or propositions equivalent to it, there are times when he seems to reject such claims. Earlier in the *Discourse* he had written that “many people don’t themselves know what they believe; for the act of thought by which one believes a

thing being different from the act by which one knows that one believes it, the one often occurs without the other” (Adam and Tannery VI, p. 23). Moreover, the argument consisting of propositions (4) to (6), if offered as a demonstration of the certainty of (2), looks hopelessly question-begging: it assumes the truth (and certainty) of the proposition whose certainty it claims to prove. So the *cogito* argument of the *Discourse*, in spite of its fame and wide appeal, is problematic. Fortunately, the argument takes a different, and more attractive, form in the *Meditations*, as we shall see below.

The remainder of part IV gives a quick sketch of the argument Descartes would develop more fully and accurately in the *Meditations*. Having found one proposition that he knew to be true and certain, he provisionally formed a general rule: Whatever we conceive very clearly and very distinctly is true. Reflecting on his nature as a doubter, and hence as imperfect, he asked how he could have acquired his ideas of things other than himself. Most of them, he thought, he could have generated himself. But the idea of God is an exception. An imperfect being cannot cause itself to have the idea of a perfect being. So God must be the cause of his idea of God. God, therefore, must exist. To this causal argument he added a version of the ontological argument: If God is a perfect being, as we conceive him to be, then he cannot lack the perfection of existence. Having established the existence of God, he proceeded to argue that because everything real and true in us comes from a perfect being, the general rule he had provisionally adopted is correct: All our clear and distinct ideas must be true. And even those ideas that are not clear and distinct must have *some* foundation in truth. This account of Descartes’s metaphysics raises issues that are best pursued in the discussion below of the *Meditations*.

Parts V and VI of the *Discourse* are primarily concerned with Descartes’s *World*, which, he wrote, “certain considerations” prevent him from publishing. He tantalizes us with a summary of its contents, omitting any explicit mention of its Copernicanism, but strongly hinting that the Church’s condemnation of Galileo is the reason that he could not publish at that time. He did not mention either the Church or Galileo by name, but what he did say must have left little doubt in the minds of informed readers: “People to whom I defer and who have no less authority over my actions than my reason has over my thoughts have disapproved an opinion in physics, published not long ago by someone else” (Adam and Tannery VI, p. 60). Descartes did not say whether he accepted this opinion, but he did say that before the authorities’ censure he had not noticed anything in the work “preju-

dicial either to religion or to the state,” so nothing would have prevented him from publishing this opinion himself if his reason had convinced him it was true. This censure, he said, made him fear that he might have made some mistake in his own theories. And that, combined with a fear of getting involved in time wasting controversies, made him decide not to publish, at least at that time.

Descartes had clearly not given up all hope of publishing *The World* during his lifetime. He even suggested that he had a duty to publish it: If, as he thought, he was on the path to developing a correct and comprehensive physics, giving an account not only of the heavens, but of all the principal kinds of bodies here on Earth, the potential benefits would be enormous. Such a science would enable us to become “the masters and possessors of nature.” It would offer the hope of discovering new ways to maintain our health and prolong our lives. He saw only two obstacles to his achieving this goal: the brevity of life and the lack of observations. Though he presented the foundations of his physics as a priori (“To discover in general the principles or first causes of everything that exists or can exist in the world ... , I considered nothing but God alone, who created the world”), he reported that as he proceeded from the first causes, through the first and most ordinary effects deducible from them, to more particular things, he found that the only way he could discover the causes of the particular effects was to construct what Bacon called crucial experiments.

Descartes’s principles were so general that there were many ways he could deduce the effects from them. To determine which, among many possible ways to produce the effects, was the one God had chosen, he needed to set up situations where the alternative theories would have different observable consequences. To do that he would need money for research. Part 6 of the *Discourse* was, among other things, an appeal for money from public-spirited citizens who saw the value of his work and wished to aid him. But the whole project of the *Discourse* and its essays was also intended to generate such interest in his project that the Church would feel obliged to permit him to publish his *World* during his lifetime. Failing that, he would publish posthumously.

Other matters in Parts V and VI of the *Discourse* merit more discussion than they can receive here: Descartes’s discoveries regarding the circulation of the blood, which he made independently of William Harvey, and his affirmation that the fundamental laws of nature are necessary truths that must be observed in any world that God might have created. Here we must limit ourselves to noting his provocative doctrine that animals are

nothing but machines. In the portions of *The World* dealing with humankind, Descartes had tried to show that God could have produced machines that would have looked and behaved just as the human body does, using only matter of the kind Cartesian physics allows and the laws that follow from God’s nature. Descartes aimed to give a mechanistic explanation of many different animal functions, all the functions, in fact, that humans share with the lower animals. He did not think mechanism could explain all human activities. Some, notably the intelligent use of language, could be explained only by the presence of a rational soul embedded in the machine. We can be certain from their language use, Descartes thought, that the human-looking bodies around us are inhabited by rational souls. (He was not troubled by the problem of other minds.) But nonhuman animals, which do not display intelligent language use, lack a rational soul; they are nothing but complex machines, lacking even sensations of the kind we have.

This doctrine had a strong impact, most of it in ways that Descartes would not have welcomed. Some thought it absurd to draw such a sharp distinction between humans and the rest of the animal kingdom. Some accused the Cartesians of being cruel to animals, or at least of having no good reason not to be. And some argued that Descartes was right about lower animals, but wrong to think that humans are fundamentally different. They too are nothing but very complex machines.

## THE START OF CONTROVERSY (1637–1641)

After publishing the *Discourse* and its essays in June 1637, Descartes spent the next few years responding to criticisms of his work and, toward the end of the period, preparing to publish his *Meditations*. The criticism of the 1637 publications tended to focus, not on metaphysics or epistemology, but on his commitment to mechanistic explanations in science: of light, of the circulation of the blood, of animal behavior. In the early part of this period he tried to reassure friends in the Jesuit order that his work does not contain dangerous innovations. He boasted to Vatier (Adam and Tannery I, p. 564) that the faith had never been so strongly supported by human reasons as it was by his, and that transubstantiation, “which the Calvinists criticize as impossible to explain by the ordinary philosophy, is very easily explained by mine.” But by 1640, the Jesuit priest Pierre Bourdin’s criticism of his *Optics* had persuaded Descartes that he had to ‘go to war with the Jesuits’ (Adam and Tannery III, p. 752).

By that point Descartes had already begun revising his “little treatise” on metaphysics (the future *Meditations on First Philosophy*) and planned to circulate it privately among twenty or thirty theologians before making it public so that he could learn from their criticisms what needed to be corrected or added before publication (Adam and Tannery II, p. 622). Descartes told Mersenne that his book on metaphysics was to contain “all the foundations of my physics,” but cautioned him not to tell people that, “for those who favor Aristotle might make more difficulty about approving them. I hope that readers will gradually get used to my principles, and recognize their truth, before they notice that they destroy Aristotle’s principles” (January 28, 1641; Adam and Tannery III, p. 298).

Descartes was particularly keen to have the Sorbonne’s approval of his work. This may seem out of character, for in the *Discourse* he said that since God has given each of us some capacity for distinguishing truth from falsity, he felt obliged not to be content with accepting the opinions of others (Adam and Tannery VI, p. 27). Presumably this is an obligation we all have. But experience had persuaded him that he needed the support of the authorities to get people to read his work carefully and to free himself from having to reply to quibbling, malicious critics (Adam and Tannery III, p. 184, 237–238).

When the *Meditations* first appeared in August 1641, the original plan had changed. Instead of circulating his work first among twenty or thirty theologians to get objections that might lead to changes, Descartes delegated most of the preliminary circulation of the work to Mersenne, who selected a smaller number of critics, not all theologians. Instead of modifying the text in the light of this criticism, Descartes left the text largely untouched, publishing the objections he received and his replies after the main text. Each critic could see the preceding objections and replies in composing his own.

The author of the first set of objections was a Dutch Catholic theologian named Johan van Kater (Johannes Caterus). Mersenne himself is generally credited with having written some or all of the anonymous second and sixth sets of objections. The third, fourth, and fifth sets of objections were written by Thomas Hobbes, Antoine Arnauld, and Pierre Gassendi, respectively. Those were the only objections included in the first edition. When the second edition appeared in 1642, there was an additional set of objections, by Father Bourdin, accompanied by Descartes’s irate replies. Descartes was not a man to suffer fools gladly, and he found it easy to believe that his critics were fools. Sometimes he was right.

## MEDITATIONS ON FIRST PHILOSOPHY (1641)

The title page of the first edition claims that Descartes was publishing it “with the approval of the learned” and that in his work he would demonstrate both the existence of God and the immortality of the soul. Neither of these claims was true. Though he and Mersenne tried, they were not able to get the approval of the Theology Faculty at the Sorbonne. While Descartes did offer several arguments for the existence of God, he did not even attempt to prove the immortality of the soul. Both these mistakes were corrected on the title page of the second edition, which appeared in the following year. But it is puzzling that they were made in the first place. Some have blamed them on Mersenne, who saw the work through the press. He is supposed to have hastily inferred from the Dedicatory Letter to the Theology Faculty that Descartes intended to prove the immortality of the soul. But in December 1640 Descartes warned Mersenne not to expect a proof of immortality in the *Meditations*. Descartes thought the most he could prove was that the mind is distinct from the body, not subject to die when the body does. Since God is omnipotent, he can always annihilate the mind (Adam and Tannery III, p. 265–266). The title page of the second edition claimed only a proof that mind and body are really distinct, and it dropped any claim to be approved by the learned.

The *Meditations* is a work with multiple agendas. No reasonable interpreter doubts that Descartes wanted to establish the religious conclusions announced on the title page of the second edition. But the First Meditation emphasizes a different aim: establishing something firm and lasting in the sciences. It is that project that has preoccupied most English-language students of Descartes and made the *Meditations* one of the most commonly used texts in modern universities. The project involves more than just validating our reliance on clear and distinct ideas. As Descartes said in a letter to Mersenne (January 28, 1641), he also wanted to accustom people to the foundations of his physics and destroy Aristotelian natural philosophy.

The First Meditation begins by recalling the project of the *Discourse*: ridding ourselves of all past beliefs. Descartes assumed that if a belief survives a thorough attempt to doubt it, and is permissive in what it counts as a valid ground of doubt, it will qualify as indubitable and provide a proper foundation for reconstructing our system of beliefs. If the fact that a belief is indubitable is to make it a proper foundation for a new system of beliefs, that indubitability cannot be a merely psychological mat-

ter. But facts about what we can and cannot believe are relevant to determining what is indubitable. We cannot doubt a belief at will. We must have *some reason* for doubt. That reason need not be probable enough to make the belief improbable. But if, after a thorough search for some reason, we cannot find even a slight reason for doubt, our inability to doubt the proposition is more than just a psychological fact about us.

How are we to proceed? If we had to question each of our beliefs individually, it would be an endless task to doubt them all. Fortunately, many of our beliefs are based on other beliefs. If we shake the foundation, we shake everything that rests on it. Most, if not all, of our beliefs are based on trust in the senses. Descartes actually said, early in the First Meditation, that *all* his past beliefs were. But when Frans Burman questioned him about this, he explained that the “I” who speaks to us in the *Meditations* is a man who is first beginning to philosophize, someone who holds the opinions anyone might hold, if he has not reflected critically on his beliefs. Call this fictional person “the meditator.” Descartes does not endorse all the opinions the meditator expresses, any more than the author of a dialogue endorses all the opinions his characters express. Before the First Meditation is over, reflection will lead the meditator to drop this empiricist assumption, but in the beginning, empiricism rules.

The meditator briefly considers common cases of sense deception as a ground of doubt, but dismisses them because they support doubts only about small or distant objects, not a more general doubt about all material objects. More serious, he thinks, are the skeptical implications of dreaming. Each night, when he falls asleep, he dreams. In those dreams he has experiences just as vivid as his most vivid waking experiences. Or at least if there is a difference between his dreams and his most vivid waking experiences, it is not discernible during the dream. Only afterward, when he wakes up, does he realize that he was dreaming. So it is possible, for all he knows, that he is dreaming *now*, no matter how convincing his present experience seems to be. If this doubt can be raised about *any* sense experience, no matter how vivid, then no belief based on sense experience can be certain. And if all justified beliefs are based on sense experience, then no belief is certain.

That seems to be the conclusion the meditator reaches during the first stage of his reflections. But the *Meditations* are a dialogue within the meditator’s mind, a dialogue between his skeptical side and his dogmatic side. After reflection it occurs to the meditator that perhaps arithmetic and geometry, those sciences that deal with the

simplest and most general objects and care little whether their objects exist in nature, might not be affected by the dream argument. Sense experience is our primary means of knowing what is in nature. But if the mathematical sciences do not require objects actually existing in nature, they may not depend on sense experience. If they do not, they will not be impugned by an argument that shows sense experience to be unreliable. Moreover, it seems impossible that truths so clear should be suspected of falsity.

The meditator then reflects on the implications of a belief he has long held: that there is a God, who can do all things, and who has made him what he is. If there is such a being, it seems he might have created him (the meditator), not only with deceptive perceptions of everything around him (so that he seems to see Earth, a sky, and other extended objects even though there are no such things), but also with mistaken beliefs about even the simplest truths of mathematics—so that it seems evident that two added to three makes five, though this proposition is false. Of course, the meditator also believes that God is supremely good, and that such a being would not want him to be deceived. But the meditator does, after all, make mistakes. Evidently, if the meditator was created by a good God, it is consistent with God’s goodness to permit him sometimes to be deceived. Couldn’t it be consistent with God’s goodness to make him always be deceived? Moreover, dropping the assumption that God created the meditator does not help. The less perfect his cause, the less reason he has to think that his cognitive faculties are not flawed.

The meditator has no answer to these arguments. He concludes that a legitimate doubt can be raised about *all* his former beliefs and that he has powerful (*validas*) and carefully considered (*meditatas*) reasons for these doubts. The reasons are powerful not because of their probability, but because of their scope, because they cast doubt on all kinds of beliefs, sense-based or not. The meditator insists that his former beliefs remain highly probable, more reasonable to believe than to deny. Later he will characterize the doubt based on the possibility of a deceiving God as “slight (*tenuis*) and ... metaphysical.” Many critics have asked how Descartes *knows* that the premises of his skeptical arguments are true. The answer is that he does not, and *need not*, claim to know that. Since the meditator is seeking absolute certainty, the only epistemic requirement for a legitimate ground of doubt is that the doubt not be one that he has compelling reasons to reject.

In the Second Meditation, having resolved to set aside as false anything that admits even the slightest

doubt, Descartes claims to find his Archimedean point, a proposition that resists all attempts to doubt it, on which he can build his revised system of beliefs. His initial certainty is the existence of the self. But the argument for the certainty of his existence takes a different form than it had in the *Discourse*. The famous inference—"I think; therefore, I exist"—does not appear. Instead, the *cogito* paragraph concludes with the words "This proposition, *I am, I exist*, is necessarily true as often as I utter it or conceive it in my mind" (Adam and Tannery VII, p. 25).

This formulation, combined with the absence of any explicit inference and some obscure remarks Descartes makes in the second set of replies, has led some readers to think Descartes is claiming intuitive certainty for the proposition "I exist." But we must remember that in the *Discourse* and the *Meditations* Descartes was writing for readers who had not read the *Regulae*. In neither the *Discourse* nor the *Meditations* does he introduce intuition as a central concept in his epistemology. Moreover, like the *Discourse*, but unlike the *Regulae*, the *Meditations* has raised as yet unresolved doubts about those paradigms of intuitive knowledge, the simplest truths of mathematics.

There is an alternative to seeing the existence of the self as something which, if known at all, must be known either by intuition or by inference from intuitions. As the *cogito* paragraph opens, the meditator is reviewing his situation. He has rejected the existence of all bodies, but perhaps there is something incorporeal whose existence he cannot doubt. God, perhaps? But God does not yet qualify as an indubitable being; at this stage the meditator thinks he himself might be the cause of his thoughts about God. What about himself? Is his existence so bound up with the existence of his body that he cannot exist without it? No. *If he has convinced himself of something (say that there are no bodies), then he must exist*, whether bodies exist or not. Perhaps a supremely powerful deceiver is deceiving him about everything (including his own existence). *But if the deceiver is deceiving him, then he exists*.

The italics here emphasize two *cogito*-like conditionals that each have an antecedent hypothesizing some thought process that the meditator *may* be involved in (convincing himself, being deceived by the deceiver) and a consequent affirming his existence. The meditator does not commit to either of the antecedents. The point is that whatever skeptical hypothesis he entertains, and whether he is responsible for his beliefs or the deceiver is, it follows from that hypothesis that he exists. Descartes hit on a way to justify accepting something as a first principle without incurring reasonable accusations of dogmatism: if the

truth of a proposition follows from any skeptical hypothesis that could validly be invoked to cast doubt on it, then it's permissible to accept that proposition as certain without other argument, specifically, without having to deduce it from some prior certainty and without having to appeal to an infallible faculty of intuition.

Any valid ground of doubt must entail the existence of the doubter. Although valid doubts need to satisfy only a weak epistemic requirement (that we not have compelling reasons to reject them), there is another condition they must also satisfy: They must explain, conjecturally at least, how the person engaged in the search for truth could be mistaken. But if they do that, they must say something of the form "Perhaps, but you could be mistaken because God is deceiving you, or you are dreaming, or you are yourself the source of this thought, etc." The skeptic, if he is rationally, and not dogmatically, skeptical in his attempt to cast doubt on our beliefs, must argue that there is some reason why things seem to us as they do, even though things are not as they seem. As soon as he does that, he concedes that we are thinking, and hence that we exist.

Descartes used the same procedure when he took up the next problem in the Second Meditation: What is this self whose existence the meditator is now certain of? The meditator starts from the beliefs that he assumes a beginner in philosophy would have and asks which of them, if any, can survive radical doubt. The meditator thinks that he is something that has both a body (something with shape and location, occupying space so as to exclude other bodies, perceptible to the senses, and movable by other bodies that come in contact with it) and a soul (a fine substance, like air or fire, infused throughout the body and responsible for nutrition, motion, sensation, and thinking).

Not many of these prereflective beliefs can survive the hypothesis that some supremely powerful malicious being is deceiving him. The meditator has already rejected, until it can be reestablished on firmer ground, the belief that there are bodies. So the self whose existence he is certain of is apparently not something corporeal, nor can it engage in functions requiring the existence of a body. Nutrition and movement must go. At first it seems that sensation too must go, since sensation apparently presupposes the existence of sense organs. Only thought remains. Just as the existence of the self follows from any hypothesis entertained to cast doubt on it, so (trivially) does its thinking. If Descartes's procedure for identifying indubitable first principles is sound, he could have taken "I think" as a first principle and demonstrated "I exist"

from that principle. Perhaps that is why he sometimes gives the appearance of doing that.

To say that the meditator is a thinking being is to attribute a number of different activities to him: that he understands many propositions, affirms some, denies others, and suspends judgment about still others. All this is implicit in the dialogue between his skeptical side and his dogmatic side. And on reflection, even sensation is something whose occurrence he cannot deny. Not having a body, he may not have sense organs, but he cannot deny that it sometimes *seems* to him *as if* he were perceiving something through some organ of the body he thought he had. And such seeming is a purely mental occurrence, immune to skeptical doubt. The skeptic assumes it in his attempt to explain why we had the ill-founded beliefs we had about bodies.

Toward the end of the Second Meditation, Descartes indulges in what looks like a digression. Though the meditator has not yet resolved his doubts about the existence of bodies, he says that he will give in to his natural inclination to believe that he knows bodies (which he can imagine and sense) more distinctly than he knows this mysterious self (which he can neither imagine nor sense). So he decides to examine one particular body, a piece of wax, to see what he knows distinctly in that object. He describes its properties: size, shape, color, hardness, temperature, taste, fragrance, etc. Then he takes the wax near a fire and notes the changes it undergoes in these changed circumstances. All its sensible properties change. What was cold becomes warm; what was hard becomes soft; and so on. But the wax, he says, remains (numerically) the same, in spite of its qualitative changes. No one doubts this. He concludes that the wax is not to be identified with any of its changing sensible properties. What he imagines distinctly in the wax is nothing but an extended something, capable of changing its shape, and capable of change in general.

Descartes draws a number of conclusions from this experiment. First, the wax, and bodies in general, are known, not by the senses or the imagination, but by the mind alone. The wax is capable of changing in many more ways than either the meditator's senses or imagination can encompass. Only the mind can grasp the wax. Second, the mind is better known than the body. Whenever the meditator judges, on the basis of sense evidence, that the wax exists, those sensations do not establish the existence of the wax. But they do establish the existence of the thinking being that judges that the wax exists.

What appears here to be a digression, not necessary to establish the main announced conclusions of the *Med-*

*itations*, does serve Descartes's unannounced purpose of insinuating the foundations of his physics. Just as the middle section of the Second Meditation clarified our prereflective concept of the soul, or mind, paring away the inessential to lay bare the essential property of thought, so the concluding section clarifies our prereflective concept of body. After the wax passage we know not to think of the sensible properties of bodies as essential to them. The only first-order property essential to any body is that it is extended. We also know not to think of bodies as inherently perceptible by the senses.

The wax passage serves another nonobvious purpose. It is characteristic of Descartes's method in the *Meditations* that he does not formally define his central concepts, but lets them emerge in informal ways. One of Descartes's central concepts is that of a clear and distinct idea, which he first mentioned prominently at the beginning of the Third Meditation, where he proposed his criterion of truth: Whatever he perceives clearly and distinctly is true. He did not define "clarity" and "distinctness" until he wrote his *Principles of Philosophy* (and even then the definitions are not very helpful). But the wax passage gives us a paradigm of what it is to acquire a clear and distinct idea. When the meditator begins to reflect on the wax, his idea of it is imperfect and confused. After he considers more attentively what the wax consists in and eliminates the inessential, his idea is clear and distinct.

The Third Meditation illustrates another way in which the process of acquiring clear and distinct ideas can work. When the meditator introduced the idea of God in the First Meditation, he explained the content of that idea by enumerating several attributes that he took God to have, among them that he created the meditator, that he can do all things, that he is supremely good, and that he is a source of truth. The problem the meditator faced was that he was not sure that all these attributes are united in one being. Perhaps he was created by an omnipotent being who is not supremely good and, far from being a source of truth, is a deceiver.

The idea of God is central to both arguments for the existence of God in the Third Meditation. At the heart of those arguments is the contention that the only possible explanation for the meditator's possessing an idea of God is that God does exist and has implanted an idea of himself in the meditator, much as a craftsman might stamp his mark on his work. But what exactly is the content of that idea? Descartes offers three answers to that question in the Third Meditation. The first two involve lists of divine attributes: God is supreme, eternal, infinite, omniscient,

omnipotent, and the creator of all things apart from himself (Adam and Tannery VII, p. 40); God is an infinite substance, independent, supremely intelligent, supremely powerful, and has created the meditator and everything else that exists, if there is anything else (Adam and Tannery VII, p. 45). The French translation of the *Meditations*, which appeared in 1647, adds immutability to both lists.

These varying lists have several notable features: All three include the idea that God is the creator and that he is omnipotent. The two lists in the Third Meditation both omit the attributes that gave trouble in the First Meditation, that God is supremely good and the source of truth. And the Third Meditation lists both include infinity, an attribute that will play an important part in the arguments for God's existence. But no two lists are identical. This highlights a problem to which the Third Meditation will suggest a solution. We cannot adequately explain the content of the idea of God by listing his attributes. We may know where to begin: with his being the creator and being omnipotent. But we do not know where to stop. If God is absolutely infinite, not only are his individual attributes infinite in themselves, he must have infinitely many of them. No finite mind will be able to list them all. And as we learned in the First Meditation, there may be disagreement about some candidates. If God created the meditator and is omnipotent but the meditator makes mistakes and is imperfect in other ways, is God supremely good and a source of truth?

The solution that the Third Meditation proposes is that God is best understood as a supremely perfect and infinite being (Adam and Tannery VI, p. 46), where this implies that he must have *all* perfections and *only* perfections. This formula is a generalization from the various lists of attributes, each of which is a perfection. It is a useful way of summing up those lists, since it covers attributes that may have been omitted, either inadvertently or because of the limitations of the mind compiling the list. But most important, it provides a criterion for deciding what should be on the list and what should not. If an attribute is a perfection, it should be; if it is not, it shouldn't be.

Is there such a perfect being? Descartes first addressed this question in the Third Meditation, mounting two arguments, each starting from the assumption that we have an idea of God of the kind described. In the third set of objections Thomas Hobbes challenged the claim that we have an idea of God. But Descartes replied that Hobbes's challenge depends on confusing ideas with images. Since God is an infinite being, we can, of course, have no image of God. But that does not mean that we

cannot have an idea of him. "Whenever I express something in words and understand what I am saying, it is certain, from this very fact, that there is in me an idea of the thing the words signify" (Adam and Tannery VII, p. 160). If a theist affirms, and an atheist denies, the existence of God, and if they both understand what they are saying, they both have an idea of God.

But how can the mere fact that we have an idea of God lead to a proof of his existence? In the Third Meditation the arguments are causal. They depend first on the general causal maxim that there must be at least as much reality in the total efficient cause as there is in the effect (Adam and Tannery VII, p. 40). It was an axiom of ancient philosophy, which Descartes endorsed, that something cannot come from nothing. A stone that previously did not exist cannot now begin to exist unless it is produced by something in which there exists, "either formally or eminently," whatever is in the stone. Descartes never really explained what the quoted qualification means. It's clear that he did not think that the cause needs to have the same properties as the effect. If it did, then God, who is incorporeal, would not be able to create extended objects. It is also clear that if the cause does not have the same properties, it must have properties "of at least equally great perfection." There cannot be heat in an object not previously hot except from something that is "of an order at least as perfect as is the heat" (Adam and Tannery VII, p. 41). That language clearly does not mean that the cause needs to have heat in it. But it is unclear what restriction the language does place on possible causes.

From this general causal maxim the meditator infers a causal principle applying specifically to ideas: The cause of an idea must contain at least as much formal reality as the idea contains objective reality. If we understood what formal reality is, we would understand what objective reality is, since objective reality can be defined in terms of formal reality. Objective reality is a property of ideas as representative entities that is correlated with the formal reality of their objects. An idea that represents its object as possessing a very high degree of formal reality will have more objective reality than one that represents its object as possessing a lower degree of formal reality. To say that an idea has objective reality is *not* to say that its object exists. All ideas have some degree of objective reality, even though some ideas have non-existent objects. Similarly, all objects have some degree of formal reality, even though some objects do not exist.

Descartes's point is that all ideas have some content, and their content requires causal explanation. In the first

set of replies, he illustrates this with the example of someone who has the idea of a machine with a highly intricate design. The person might have acquired the idea of that machine by observing a real machine with that design. But perhaps there is no such machine. If not, we must seek some other cause for his conception of that object, perhaps in his extensive knowledge of mechanics. If he derived his idea of the machine neither from having observed such a machine nor from his knowledge of mechanics, he may have derived it from someone who had seen such a machine or had the requisite knowledge of mechanics. But whatever the cause, there must be a cause sufficient to produce that effect. The idea of God, as the idea of an infinite being possessing all the perfections that God is supposed to possess, has more objective reality than the idea of a finite substance does. Indeed, it has as much objective reality as it is possible for an idea to have, since its object has as much perfection as it is possible for an object to have.

Stripped to its essentials, the argument is as follows:

- 1) Each idea must have a cause possessing at least as much formal reality as the idea represents its object as having.
- 2) The idea of God represents its object as having the maximum possible formal reality.
- 3) Therefore, the only possible cause of our idea of God is a being that has the maximum possible formal reality (that is, equals all possible perfections).
- 4) Therefore, the idea of God must have God as its cause.
- 5) Therefore, God exists. This argument has generally not been well received by Descartes's readers, partly because of the obscurity of the causal principles involved, and partly because Descartes seems to have precluded himself from ever using such an argument.

The argument appeals to causal principles that Descartes said are known by natural light, a cognitive faculty whose deliverances cannot be doubted in any way. (Adam and Tannery VII, p. 38). As an example of one of the things so known, he gave the proposition: "From the fact that I doubt, it follows that I am." But just before he entered on this argument, he said that until he knew whether God exists and can be a deceiver, he could not be certain of anything (Adam and Tannery VII, p. 36). And he seemed there to regard the possibility of God's deception as a reason for doubting, not only simple truths of mathematics, but also the proposition "If I think that I am something, I am something"—a proposition that would presumably be known by that natural light whose deliverances are beyond doubt. It looks as though, to prove the reliability of the natural light, Descartes needs to construct a proof of the existence of a nondeceiving

God. And to construct that proof, he needs to deploy premises known by the natural light, which he cannot be sure of until he is sure of his conclusion. The reasoning looks circular. The difficulty is known, therefore, as the Cartesian circle.

We will not have the materials to respond to this objection until we have considered the Fourth Meditation. But first we must note briefly that Descartes offers a second causal argument in the Third Meditation, beginning at the top of Adam and Tannery VII, p. 48. The focus of this argument is not on explaining the existence of the meditator's idea of God, but rather the meditator's own existence as a being possessing this idea. This argument has not persuaded many readers either, partly because it involves some of the same conceptual difficulties as the first argument. But it does introduce another restriction on causality, which had interesting consequences.

At one point in the argument the meditator considers the possibility that his existence as a being possessing the idea of God that he has, might be explained by saying that he has always existed, as he does now. This might not seem a plausible hypothesis, since few people are likely to think they have always existed. But Descartes's reason for rejecting it is curious. He replied that each person's life can be divided into countless parts, each completely independent of the others. From the fact that the meditator exists at one moment, it does not follow that he will exist at the next moment. Apparently he will not exist then, unless some cause creates him again at that time. The meditator thus requires a cause to sustain him in existence from one moment to the next, much as he requires a cause to bring him into existence, if he has not always existed. And that cause, of course, must be God.

What is interesting about this position is the assumption that for a cause to explain an effect, the existence of the effect must follow logically from the existence of the cause. The will of an omnipotent being can satisfy this requirement on causality. It is part of the notion of omnipotence that if an omnipotent being wills something, what it wills must occur. But no finite being appears able to satisfy the condition. For any supposed finite cause, it will always be possible for that being to exist without having the effect we suppose it to have. This restriction on causality looks like it will lead quickly to the occasionalist doctrine that no finite being is ever truly a cause, that God is the only real cause of anything that happens, apparent finite causes being merely occasions for his willing things to happen as they do. It is unclear whether Descartes saw that his argument might have these consequences.

At the end of the Third Meditation, having devoted most of his longest meditation to elaborating two complex arguments for the existence of God, Descartes makes a quick argument that God cannot be a deceiver. The God whose existence he has proven is a supremely perfect being, possessing all perfections and no defects. It is manifest by the natural light that all deception involves some defect. So God cannot be a deceiver. Of course, there is the awkward fact, noted in the First Meditation, that God's creatures do sometimes make mistakes. Not until the next meditation will Descartes attempt to reconcile his awareness of that with his conviction that a supremely perfect being created him.

The main line of response to this difficulty in the Fourth Meditation is a variation of a standard approach to the problem of evil: Though God created the meditator as he is, God is not responsible for the meditator's errors, because they arise from the meditator's misusing the free will God has given him. Free will is a good great enough to compensate for whatever evil is involved in the meditator's mistakes. If the meditator exercised his free will properly, he would not make mistakes.

In the Third Meditation, Descartes classified his thoughts into three kinds: ideas, which, though *not* images, are *like* images insofar as they represent their objects as possessing certain properties; volitions or emotions, which involve having an idea of an object and also having some affective attitude toward it (wanting it, disliking it, fearing it, etc.); and judgments, which involve having an idea of an object and affirming or denying something about that object. Only judgments can be true or false. The most common mistake the meditator makes is to judge that things outside him are as his ideas represent them. When they are not, as is often the case, he errs. But error, like any judgment, always involves an act of the will, either affirming something or denying it. The meditator makes judgments he does freely. If he makes a mistake, it is his fault, not God's.

The notion of freedom used here requires some examination. Within one sentence, Descartes suggests two very different conceptions of freedom. The sentence reads as follows:

The will, or freedom of choice ... , consists only in this, that we can do something or not do it (that is, affirm or deny, pursue or flee, the same thing), *or rather*, only in this, that when the intellect proposes something to us for affirmation or denial, pursuit or avoidance, we are so inclined that we do not feel we are determined

to it by any external force. (Adam and Tannery VII, p. 57; emphasis added)

This puzzling sentence presents difficulties both of translation and of interpretation. But what Descartes seems to mean by it is that the first clause (before "or rather") describes one (indeterminist) way we can be free, and the second clause (after "or rather") describes another way we can be free (without assuming indeterminism).

Descartes's view seems to be this: *Much of the time*, when we affirm something, we could have denied it, and when we deny it, we could have affirmed it (or neither affirmed it nor denied it). This will be true under a variety of circumstances: We might have no evidence one way or the other; we might have evidence each way, but the evidence might not favor one way over the other; or the evidence for the proposition might outweigh the evidence against it, perhaps quite strongly, without being conclusive. In all these cases we will have the power to decide either way, and will be free under the first clause of Descartes's definition. This is often called a *liberty of indifference*, though that term has misleading connotations. It may suggest either that we have no evidence one way or the other, or that our evidence one way is no stronger than our evidence the other way. As Descartes conceived this liberty, that will not always be true. In cases where our evidence for a proposition is strong but inconclusive, as is our sense evidence for the existence of material objects, denial or suspension of judgment will be difficult, but not impossible.

But *sometimes*, Descartes thought, we find that we cannot help judging as we do. In the Second Meditation, when the meditator was examining whether there was anything in the world and noticed that it followed from the fact that he was examining this that he existed, he could not but judge that what he understood so clearly was true. He was not aware of any external force compelling him to judge thus. Rather, a great inclination of his will followed from a great light in his intellect. He seemed to be all the more free the less indifferent he was. This is what is sometimes called a *liberty of spontaneity*, a notion that suggests that the absence of external constraint is sufficient for freedom. It is not necessary for our freedom that we have the power to act differently than we do.

Descartes wanted to allow both a liberty of indifference and a liberty of spontaneity. When we do not have clear and distinct ideas, we possess a liberty of indifference. We can judge either way. When we do have clear and distinct ideas, we cannot judge otherwise, but we are still

judging spontaneously, and not under any kind of coercion. The absence of external coercion does not imply that there is no external causation of our judgments. Descartes explicitly allowed that God might be disposing the meditator's innermost thoughts to judge the way he did. That will not diminish his liberty of spontaneity, though it will mean that he no longer has a liberty of indifference.

Some critics have found Descartes's theory of judgment highly implausible. Benedict de Spinoza argued that Descartes was confusing judgments with utterances when he supposed that we might have a liberty of indifference in some of the cases where he claimed it. It is one thing to *say* that one's experiences of the external world might have no more basis than a dream, and quite another to actually *believe* it. The first is easy; the second may well be impossible. Again, is the liberty of indifference that Descartes requires to relieve God of responsibility for our errors compatible with his doctrine that God is continuously creating us at each moment of time? The doctrine of continuous creation seems to make us completely dependent on God; a liberty of indifference seems to make us at least partially independent of God.

For all the time that Descartes spent arguing that we have a liberty of indifference with respect to some ideas, in the final analysis he seems not to have relied on that liberty to reconcile God's goodness with the occurrence of error. At the end of the Fourth Meditation he conceded that God could easily have brought it about that the meditator would never make a mistake without losing his freedom. All God would have to do is to give the meditator clear and distinct ideas about everything he would ever have to make judgments about, or to implant in him a firm resolution to make judgments only about things he perceived clearly and distinctly. In the closing paragraphs of the Fourth Meditation it looks like Descartes's solution to the problem of error does not depend on free will at all, but on the thought that, although the *meditator* might be better if he never made mistakes, it is possible that the *world as a whole* is better for having in it beings who make mistakes. Variety is the spice of the universe.

Nevertheless, the doctrine of judgment in the Fourth Meditation has considerable systematic importance. The method of doubt requires that we suspend judgment about everything we have the slightest reason to doubt, that we withhold our assent from things we do not perceive clearly and distinctly. Moreover, it is arguable that Descartes's vindication of reason depends on our *inability* to refrain from assenting to things we *do* perceive clearly and distinctly. As noted above, when Descartes was

arguing in the Third Meditation that God exists and is not a deceiver, he frequently justified the assumptions of those arguments as things "manifest by the natural light." And it's not clear how, given the arguments of the First Meditation, he can repose confidence in that, or any other, cognitive faculty until he has first determined whether God exists and is a deceiver.

Since the mid-twentieth century, at least, commentators have been reluctant to accuse Descartes of blatant circularity. But there is no consensus about how he escapes the accusation. Here is one try. It is not controversial that Descartes thought that our clear and distinct ideas compel assent when we are attending to them. We may be able to doubt simple propositions of mathematics when we consider them under some general rubric, like "the things which seem most evident to me." But when we are actually focusing on a particular simple proposition of mathematics, we cannot in fact doubt it. It compels our assent. The same is true, Descartes thought, of some metaphysical propositions, such as "So long as I think I am something, I am something," and "If I exist now, then it will not be true at some later time that I never existed."

The arguments for God's existence and nondeception in the Third Meditation are constructed from two kinds of propositions. One kind reports the contents of the meditator's consciousness, specifically, the fact that he has an idea of God. This is a presupposition of the dialogue with the skeptic and amenable to the defense offered above for the propositions "I exist" and "I think." The other kind are general propositions, such as "A cause must have at least as much reality or perfection as its effect," and "Deception is a defect." If we perceive these things clearly and distinctly, we will not be able to doubt them when we attend to them. Descartes may not have thought that they are self-evident, in the sense that they command assent as soon as we understand the terms. But if they do not command assent, then we have not yet perceived them clearly and distinctly. We are confused in some way, perhaps by badly understood experiences that seem to refute the principles.

Suppose that we are able to construct an argument that God exists and is not a deceiver, relying entirely on propositions about contents of our consciousness that we cannot doubt and on general propositions that we perceive clearly and distinctly, which we also cannot doubt when we attend to them. If we perceive all these premises clearly and distinctly, and see equally clearly their connection with the conclusion, we cannot doubt the conclusion.

A skeptic might now say, “I understand that you *cannot* doubt that God exists and is not a deceiver. But that’s just a fact about you. It doesn’t mean the proposition is not worthy of doubt. Perhaps your creator is an omnipotent demon and this conviction of yours is just another of his tricks.” On the interpretation offered here, Descartes would say that once he has a compelling argument to the conclusion that he has been created by a God who is not a deceiver, it is no longer enough to offer the mere supposition that a demon might be deceiving us when we assent to ideas that we cannot in fact doubt. In the First Meditation the hypothesis that an omnipotent creator might deceive us, even about matters most evident to us, constituted a valid ground of doubt, because we had no compelling argument against it. By the end of the Fourth Meditation we do have a compelling argument against it. So it no longer constitutes a valid ground of doubt. The validity of a ground of doubt is situational. What constitutes a valid ground of doubt at one stage of the argument, when we have no compelling argument against it, will no longer be valid when we do have such an argument. Descartes makes this clear in his reply to the seventh set of objections (Adam and Tannery VII, p. 473–474).

It may help to consider the Pyrrhonian skepticism that we find in Montaigne’s *Apology for Raymond Sebond*. The Pyrrhonist advocates what Montaigne calls the principle of equipollence: For every argument in favor of a proposition, there is an equally strong argument against it. Montaigne’s criterion for the strength of an argument is psychological persuasiveness. When someone who holds the principle of equipollence is confronted with a compelling argument that we have been created by a non-deceiving god, he can no longer cast doubt on that conclusion simply by hypothesizing the possibility of deception by an omnipotent being. He must produce an equally strong and compelling argument for the opposite conclusion. Absent such an argument, Descartes is entitled to his conclusion.

There is one other respect in which the situation at the end of the Fourth Meditation is different from the situation at the beginning of the Third Meditation. Now we have a clear and distinct idea of God. At the beginning of the Third Meditation we conceived of God simply as an omnipotent creator who was supposed to be supremely good and is the source of all truth. But we didn’t see any necessary connection between these attributes, and we worried that we might have been created by a being who possessed some of these attributes, but not all of them. By the end of the Fourth Meditation we understand that

what God is, essentially, is a supremely perfect being, who has all the perfections and no defects. Once we have seen this, we see that the hypothesis of an omnipotent deceiver is incoherent. It is not even a hypothesis that we can consider as a possibility.

In the Fifth Meditation, Descartes had two items on his agenda: considering the nature of material things and arguing once more for the existence of God. His most urgent task if he is to recover from his doubts, he said, is to determine whether he can have any certainty about material things. Before he could decide whether such things really exist, he needed to consider what distinct ideas he had of them. He prepared the ground for this consideration in the Second Meditation, where he identified extension as the one first-order property that remains constant in the wax as it changes. There his focus was on a particular body. Here it is on what he calls “continuous quantity ... or the extension of this quantity—or rather, of the thing quantified—in length, breadth and depth” (Adam and Tannery VII, p. 63). So we are to think of geometrical space (continuous quantity) as a material substance extended in three dimensions, of which particular bodies are parts, each possessing its own size, shape, and position, and distinguished from the other parts by their varying motions. (Here again, Descartes is insinuating fundamental propositions of his physics.)

When Descartes reflected on his ideas of extended objects, he realized that he had countless ideas of geometrical objects, objects that may not exist anywhere outside his mind but that nevertheless have a definite nature, “a true and immutable nature,” independent of his mind. He could demonstrate properties of these shapes, even though he might never have observed any shapes of the kind whose properties he was demonstrating. He may have observed triangles; it’s unlikely that he ever observed a chiliagon (a thousand-sided polygon). But he could determine what its properties are, even if there are no chiliagons to observe. Whenever he saw clearly and distinctly that some property belongs to the true and immutable nature of some thing, that property really does belong to that thing. He had a clear and distinct idea of God as a supremely perfect being. He understood that to be supremely perfect, a being must possess all perfections, and that existence is a perfection. He inferred, then, that God must possess the perfection of existence.

This version of the ontological argument depends on a Platonic philosophy of mathematics, which Pierre Gassendi criticized in the fifth set of objections. Gassendi complained first that it seemed to him that it is hard to maintain that there are true and immutable natures apart

from God. He imagined Descartes replying that he was only saying what they say in the schools, that the essences of things are eternal, and that there can be true propositions about them. But Gassendi did not understand how there can be an essence of something—his example is man—if there are no things of that kind. At one point he seemed willing to concede that there is a sense in which “Man is an animal” can be true even if no men exist. But he said that the statement is true only if it is understood conditionally: “If something is a man, it is an animal.” And he gave an analysis of that conditional that makes its truth apparently require the existence of some men:

When man is said to be of such a nature that he cannot exist without being an animal, it is not on that account to be imagined that such a nature is something or is somewhere outside the intellect. The meaning is only that for something to be a man, he must be like the rest of those things to which we give the same name, man, on account of their mutual similarity. (Adam and Tannery VII, p. 320)

Gassendi also questioned whether existence is a perfection: “Existence is not a perfection either in God or in anything else; it is that without which no perfections can be present. ... What does not exist has no perfections or imperfections. ... If a thing lacks existence, we do not say it is imperfect ... but say instead that it is nothing at all” (Adam and Tannery VII, p. 323). Though Gassendi focused on the idea that existence might be a perfection, his reasoning would seem to exclude its being a property of any kind. He treated existence not as something which is predicated of a thing, but as a precondition of any predication.

When Descartes replied, he was puzzled about what category Gassendi wanted to put existence in. Existence seemed to him analogous to omnipotence, something that can be predicated of a thing, and that therefore is a property. But then he rejected Gassendi’s conditional analysis of essential predications. Gassendi’s example, man, was one of the “universals of the dialecticians,” that is, the Scholastic philosophers. Descartes preferred to focus on essences that we understand clearly and distinctly, like those of geometric figures. We cannot understand the latter essences the way the Scholastics and Gassendi did, as based on concepts abstracted from experience of instances of the concept, because there are no instances for us to experience. This is true not only for such unfamiliar figures as chiliagons, but also for such apparently common figures as triangles. The problem is that nothing in our experience strictly satisfies the defini-

tion of a triangle, which requires, among other things, that it be composed of straight lines. The lines we experience turn out, when examined closely, not to be perfectly straight. But we can recognize the figures we experience as approximations of the ideal geometric figures because we have ideas of the ideal figures from another source.

Descartes’s objections to Gassendi’s analysis of essential predication probably go deeper than his opposition to the scholastic theory that our concepts are formed by abstraction from experience. It seems likely that he would reject any conditional analysis of essential predications, even if it was not spelled out in abstractionist terms. Gassendi had complained that the essences Descartes was talking about could not have an immutable and eternal nature apart from God. Descartes replied that he did not claim that the essences of things exist independently of God. He conceived of them rather as depending on the will of God, and as being immutable only because God’s will is immutable. Although Descartes did not explicitly invoke his doctrine of the creation of the eternal truths in the body of the *Meditations* itself –(he *may* have presupposed it in the Third Meditation), he did make it explicit in his replies to objections. (It comes up again in the sixth set of replies.) Reflection on the reasons that may have led Descartes to his doctrine of the creation of the eternal truths may also suggest a reason why he would reject Gassendi’s conditional analysis of essential predications.

One problem that scholastic philosophers faced when they thought about essential predications was that, according to the orthodox theory of universal propositions, they have existential import. “All men are animals” entails that there are men. But if “All men are animals” is a necessary truth, so are its entailments. However, “There are men” is supposed to be a contingent truth, made true at the creation by God’s will. Descartes may have been moved to compare the eternal truths with the laws that a king establishes in his kingdom because a king’s laws depend for their validity not on the existence of violators of those laws, but only on the authority of their source. The king’s prohibition on dueling does not depend on there being any duelists. Descartes may have felt that a conditional analysis of essential predications avoided one problem only to raise another equally difficult problem. On the hypothesis that there are no men, “If anything is a man, it is an animal” is a conditional whose antecedent is false. If this is a material conditional, it is true in such circumstances, as is the conditional “If anything is a man, it is a plant.” If it is a modal conditional, it is unclear what the truth conditions for such conditionals are (if they have any).

Gottfried Wilhelm Leibniz raised an equally serious problem when he argued that Descartes needed to supplement his ontological argument with a proof that the concept of God is consistent. Arguably, that is what Descartes was trying to do, in a limited way, in the Fourth Meditation. That meditation tried to resolve an inconsistency that had threatened his concept of God since the First Meditation: that God was a perfect being who was nonetheless supposed to have created a very imperfect being. But emphasizing human freedom as a solution to that problem, even if it is not Descartes's final solution, only raised the question of whether human freedom is compatible with God's omnipotence, a problem Descartes would address in his *Principles of Philosophy*.

In the Sixth Meditation there are two announced items on the agenda: establishing the existence of bodies and proving that mind and body are distinct. The first step in approaching the latter problem is to recognize (1):

- (1) Whatever I clearly and distinctly understand can be made by God as I understand it.

The thought here seems to be that if I understand something clearly and distinctly, it must be free of contradiction, and that God, being omnipotent, can create anything that does not involve a contradiction. From (1) it follows that (2):

- (2) If I clearly and distinctly conceive myself as a thinking, non-extended thing, then God can create me as a thinking, nonextended thing.

Similarly, (3) also follows from (1):

- (3) If I clearly and distinctly conceive of body as an extended, non-thinking thing, God can create it as an extended, nonthinking thing.

In the Second Meditation Descartes' meditator, in his reasoning, achieved a state in which he satisfied the antecedents of (2) and (3). He had a clear and distinct idea of the wax as an extended thing, to which he did not ascribe any thought, and a clear and distinct idea of himself as a thinking thing, to which he did not ascribe anything corporeal. So he infers (4) and (5):

- (4) God can create me as a thinking thing, apart from my or any other body.  
 (5) God can create my or any other body as an extended thing, apart from me or any other thinking thing.

To show that two things are really distinct, it does not matter what power is required to create them as separate substances. *According to the definition of a real distinction,*

*two things are really distinct if they are substances and it's possible for each to exist without the other.* So this is sufficient to prove that:

- (6) I and my body are really distinct substances.

It is not obvious what is wrong with this argument, though it certainly has not lacked critics.

In the fourth set of objections Antoine Arnauld proposed the following counterexample. An individual might clearly and distinctly perceive that a triangle inscribed in a semicircle is right-angled, but not be aware of the Pythagorean theorem, according to which the square on the hypotenuse of a right-angled triangle must equal the sum of the squares on the other two sides. So he might doubt or deny that a particular triangle inscribed in a semicircle has the Pythagorean property. From Descartes's first assumption (1), he might infer (2'):

- (2') If I clearly and distinctly conceive the triangle inscribed in a semicircle as right-angled, but doubt or deny that this triangle has the Pythagorean property, then God can create a triangle inscribed in a semicircle that does not have that property.

The antecedent of this conditional might well be true, it seems, but the consequent attributes to God a power he cannot have, even if we accept Descartes's doctrine of the creation of the eternal truths. Even if God *could have* created a different nature for triangles, the immutability of his will entails that he *cannot now* create a triangle with a different nature (Adam and Tannery V, p. 160). Descartes replied at length to Arnauld's objection without ever seeming to meet the point. It is not obvious what he should have said to defend himself.

Though Descartes regarded mind and body as substances capable of existing apart from one another, he was also anxious to insist that he is very closely united to his body, "as it were, intermingled with it" (Adam and Tannery VII, p. 81), so that he composes one thing with it. His bodily sensations taught him this: He feels pain when this body is damaged, hunger when it needs food, thirst when it needs drink. He does not feel these sensations when similar things happen to other bodies. So, he said, nature taught him that he is not merely present to his body as a sailor is present to his ship. He thereby rejected what the medievals regarded as the excessive dualism of Plato. Bodily sensations are nothing but confused modes of thinking arising from the union of mind and body. It is not clear that this doctrine of mind-body union is compatible with the doctrine that mind and body are distinct. This was to become a major topic of debate after the publication of the *Meditations*, as we shall see.

Descartes's attempt to prove the existence of bodies has generated not so much debate as dismissal. God, he said, had given him a great propensity to believe that his sensations are caused by material things and no faculty for recognizing any alternative source for them. So Descartes did not see how God could be cleared of the charge of being a deceiver if his sensations were caused by something incorporeal. There must be corporeal things. They may not have all the properties he grasped by sensation, since there is much in those properties that is obscure and confused. But they must have all the properties he understands clearly and distinctly, that is, all the properties that are the subject of pure mathematics.

It is indeed hard to see how a perfectly good God could permit such a massive delusion. But Descartes here has weakened the conditions under which God can be judged to be a deceiver. In the Fourth Meditation, God would have been a deceiver if we had false beliefs that we could not help having. Now God is a deceiver even if we have false beliefs that we can help having, provided we are strongly inclined to believe them and have no way of telling that they are false. Perhaps the proper conclusion from this argument is that it is improbable that our belief in material objects is false. When we are dealing with beliefs that we *could* help having, we probably need to know something about God's purposes before we can decide whether or not he would be a deceiver if we held false beliefs under those circumstances. Descartes did not think that we can know what God's ends are. But probably the main reason the argument has not found much favor is that it does not seem that we should have to accept this complex theistic argument to see the existence of bodies as certain.

We should note an important negative conclusion that Descartes reaches in the Sixth Meditation: Even if we have been created by a nondeceiving God, we have no justification for believing that the things we perceive by the senses have *all* the properties we are inclined to ascribe to them. The properties of which we have confused and obscure ideas—the heat we attribute to hot bodies, the color we attribute to green bodies, and in general what later philosophers were to call “the secondary qualities of things”—these properties, insofar as we think of them as properties of external objects, need not resemble in any way the ideas we have of them. There must be some differences in the things themselves, between a hot object and a cold one, or between a red object and a green one. But so long as there is a systematic correlation between the differences in external objects and the differences in our sensations, we needn't suppose that there is anything

in the objects themselves resembling color or heat. This was one of the fundamental principles of Descartes's physics that he slipped into the *Meditations*.

#### CONTINUED CONTROVERSY (1641–1644)

Even before the publication of the *Meditations* in August 1641, Descartes had begun work on his next major publication, his *Principles of Philosophy* (1644), which he sometimes referred to in the correspondence as his “*summa* of philosophy” or as his “philosophy” or as his “physics.” His aim was to produce “a complete textbook” of his philosophy, combining metaphysics, physics, and biology, in the form of theses, “where, without any excess words, I will just present all my conclusions, with the true premises from which I derive them” (Adam and Tannery III, p. 233). There would be none of the false starts that gave the *Meditations* their dialectical character. When he first began planning this work, he thought of publishing it with a standard textbook of scholastic philosophy on which he would comment. He had selected Eustachius of St. Paul's *Summa philosophiae* for this purpose, but gave up that aspect of the project after Eustachius's death in December 1640. Clearly, he had decided that he could be more open about his anti-Aristotelianism, and could present his cosmology in a way that would escape condemnation.

When the second edition of the *Meditations* appeared in May 1642, it added not only Father Bourdin's objections and Descartes's replies, but also a letter from Descartes to Father Jacques Dinet, a former teacher at La Flèche and now the head of the Jesuit order in France, complaining about his treatment by Bourdin. Descartes had reason to be upset by Bourdin: He was long-winded, sarcastic, and unsympathetic in his interpretation of Descartes's views. Descartes said he showed the acumen of a bricklayer, not a Jesuit priest. And he wrote bad Latin. Though Descartes seems to have had a genuine affection for some members of the Jesuit order and respect for the quality of education the society provided in its schools, he was prone to see conspiracy in its members' actions. He worried that Bourdin's critique was not the opinion of one Jesuit priest, but represented a consensus among the Jesuits. He urged Dinet to read the *Meditations* himself—or if he did not have the time for that, to assign the task to members of the society more competent than Bourdin—and to let him know if they saw problems in his project. Dinet delegated the task to Father Etienne Charlet, formerly the rector at La Flèche and later Dinet's successor as head of the Jesuits in France, who was to

write to Descartes about his works. It appears that Charlet eventually demonstrated his personal good will toward Descartes and his work, but left him uncertain about the attitude of the society as a whole.

Descartes also included in his letter to Dinet an account of a controversy he was embroiled in at the University of Utrecht. In 1641 a follower of his, Henricus Regius, professor of medicine at the University, had engaged in a disputation there in which he presented his version of Cartesian natural philosophy, going further than Descartes judged it wise to go. Regius said that the union of mind and body was an accidental one, rather than substantial, and also denied the existence of substantial forms, those formal aspects of things that in scholastic natural philosophy were supposed to make them the kinds of things they are and explain their characteristic behavior. For these positions Regius came under attack from the rector of the university, Gisbert Voetius, who took the opportunity to hurl a few barbs in Descartes's direction as well.

Regius felt he needed to reply publicly, and Descartes advised him on what to say. Though Descartes thought Regius meant something acceptable when he declared that the union of soul and body was accidental—namely that mind and body are really distinct from one another, each capable of existing without the other—he warned Regius that the Scholastics would interpret this language differently, and that the best thing would be to claim ignorance of scholastic terminology and to say that the disagreement between them was only verbal. Regarding substantial forms, Descartes thought Regius should say that he did not wish to reject them absolutely, and that he meant merely that he had no need to invoke them in his scientific explanations. Saying that fire possesses the form of fire does not help us in any way to understand its ability to burn wood. This was the stance Descartes had taken, leaving it to his readers to draw the conclusion that if substantial forms were explanatorily useless, there was no reason to postulate them.

When Regius published his reply, he only made matters worse. The university condemned the new philosophy and forbade Regius to teach his course on physical problems. “Utrecht University, the first in the world to allow one of its professors to teach Cartesianism, was also the first that forbade its teaching” (Verbeek 1992, p. 19). When Descartes criticized Voetius in his letter to Father Dinet, Voetius responded by arranging for Martin Schoock, a professor at Groningen and a disciple of his, to write a book that accused Descartes, among other things, of atheism and of fathering numerous illegitimate chil-

dren. (Descartes did, in fact, have one illegitimate child, a daughter whom he was quite fond of but who died in 1640, at the age of five.) The full story of the Utrecht affair—which ultimately involved lawsuits for libel, charges of perjury, and a prohibition on any discussion of Descartes, pro or con—is too complex to tell here (for further details, see Verbeek 1992).

#### PRINCIPLES OF PHILOSOPHY (1644)

The *Principles* was Descartes's most systematic work and the one his contemporaries went to for a definitive statement of his philosophy. It consists of four parts, the first dealing with metaphysics and epistemology, the second with general principles of physics, the third with celestial phenomena, and the fourth with terrestrial phenomena. Since Descartes himself preferred the exposition of his metaphysics and epistemology in the *Meditations* to the one he gave in Part I of the *Principles*, and since the science that dominates the remainder of the work is primitive by modern standards, most recent students of Descartes have neglected the *Principles*. Here we must limit ourselves to noting only a few of the many things it adds to what we know from our survey of Descartes's other works.

Among the additions is a metaphor that Descartes used in the Preface to the French translation of 1647: “The whole of philosophy is like a tree, whose roots are metaphysics, whose trunk is physics, and whose branches are all the other sciences, which reduce to three principal sciences, medicine, mechanics and morals” (Adam and Tannery IX-B, p. 14). This passage illustrates Descartes's conception of the close connection among disciplines that we now regard as quite separate, his ambition to found the sciences in metaphysics, and his hope that his foundational work would have practical consequences. Particularly intriguing is his ambition to derive a moral philosophy from his metaphysics and physics. We will see what that led to when we come to his last major work, *The Passions of the Soul*.

One delicate issue the *Principles* raises is the question of the extent of the universe. Copernicus had not claimed that the world was infinite, but later Copernicans, such as Giordano Bruno, did. Though we do not know the specific grounds for the Church's execution of Bruno in 1600, it seems likely that this was one of them. Since Descartes identified matter with (Euclidean) space, it might seem that he too would be committed to the infinity of the physical universe. But in the *Principles* (pt. I, secs. 26–27), he said that he was not. He reserved the term “infinite” for God alone and designated things in which

he could discover no limits—such as the extension of the world and the divisibility of matter—indefinite. Nevertheless, later in the *Principles* (pt. II, sec. 21), he passed from denying knowledge that there are any limits to the extent of the world to affirming knowledge that there are no limits to its extent. When he later began to develop his moral philosophy, he listed, as one of the truths most useful to us, the proposition that we must beware of supposing that there are limits to the extent of the world God created (*Principles*, pt. III, sec. 1). Descartes supposed that an appreciation of the vastness of God's creation would aid us in detaching ourselves from the things of this world (Adam and Tannery IV, p. 292).

Another theologically sensitive issue that Descartes dealt with in Part I is the problem of reconciling human freedom with God's omnipotence (secs. 37–41). Descartes's conception of freedom here seems to be more single-mindedly indeterminist than it was in the *Meditations*. If we are to deserve praise for our actions, we must be in some special way the author of those actions, and not have been determined to so act by our maker. We must have been able to do otherwise. That we have the power to assent or not to assent in many cases is as evident as any first principle, though this is not innate knowledge, but something we learn from what we experience within ourselves. On the other hand, now that we know God, we see that his power is so immense that it would be impious to think we could ever do something he had not foreordained.

Recent discussion of the problem of reconciling human freedom with God's attributes has tended to focus on showing that human freedom is consistent with divine foreknowledge. Descartes was more worried about showing it to be consistent with God's omnipotence. Perhaps Descartes thought that his identification of God's will with his intellect ruled out the possibility that he might foreknow without foreordaining. In any case, the solution that Descartes proposed is that we should maintain both our freedom and God's foreordination, even though we do not see how they could be compatible. God's power is infinite; our intellects are finite. So we should not expect to understand how they can be compatible, and we cannot give up two such certain truths merely because of a defect in our understanding. Had Descartes continued to allow the liberty of spontaneity that he recognized in the Fourth Meditation, it seems that he would not have needed to take this position.

In part II of the *Principles*, Descartes laid the groundwork for a version of Copernicanism that was supposed to avoid the censured claim that Earth moves. In sections

13 and 24 he gave a relativistic account of what we ordinarily mean when we say that a body moves: It changes its place, which is defined as its position relative to other bodies taken to be at rest. We will get different answers to the question of whether something is moving, depending on which other bodies we take as our frame of reference. Suppose that a man is sitting on the stern of a ship headed down river to the sea. We say that he is at rest if we consider his constant relation to the part of the ship where he is sitting. We say that he is moving if we consider his relation to the shore, since he is continually moving away from some parts and toward others. If we think that Earth is rotating on its axis and moving just as much from west to east as the ship is moving from east to west, we say that he is not moving—our frame of reference now being certain bodies in the heavens that we suppose to be motionless. But if we think that there are no such motionless points anywhere in the universe, we will conclude that nothing has a permanent place, except insofar as it is determined by our thought. In part II, section 13, Descartes foreshadowed an argument that, he said, makes it probable that there are no genuinely fixed points in the universe. We get that argument in part III, section 29, where he contended that if we follow ordinary usage, there is no reason to say it is the stars that are at rest rather than Earth.

Descartes seems to reject ordinary usage. In part 2, section 25, he said that if we want to understand motion “according to the truth of the matter,” we ought to define it as “a transfer of one part of matter, or of one body, *from the neighborhood of those bodies immediately touching it, considered as resting, to the neighborhood of other bodies*” (emphasis added). So he treats the immediately surrounding bodies as a privileged reference frame. On this definition, Earth, strictly speaking, is at rest, even though there is admittedly a sense in which it is moving round the Sun. In Descartes's cosmology, it is at rest in relation to the fluid matter immediately surrounding it, which carries it round the Sun, just as a ship, neither driven by the wind nor hindered by an anchor, might be at rest in relation to the water around it, though it is imperceptibly carried out to sea by the tide (pt. III, sec. 26–28). Of course, as Descartes noted, the same thing can be said of all the other planets.

Cartesian scholars have often suspected Descartes of adopting this strict definition of motion simply because he could then claim that in his cosmology the Earth did not move, permitting him to adopt a basically Copernican astronomy without suffering the fate of Galileo. Descartes anticipated that his denial that the Earth moves might be

judged to be “merely verbal,” intended to avoid censure. But he said that a careful reading of his work should remove that suspicion (Adam and Tannery V, p. 550). In any event, it is arguable that he had serious reasons, internal to his philosophy, for wanting to define motion in a way that would escape the relativism he saw in the common conception of motion. Motion is supposed to do a great deal of work in his mechanistic physics. As he said in the *Principles*, “All the variety in matter, all the diversity of its forms, depends on motion” (pt. II, sec. 23). To make that kind of explanatory use of motion, he needed it to be something that really exists in bodies, not something that is in them or not, depending on how you look at them. But his solution to the problem is highly problematic, and not only because it did not in the end protect him from condemnation by the Church. (For more on this complex issue, see Garber 1992, chap. 6.)

We cannot leave this all-too-brief discussion of the *Principles* without noting that at the end Descartes commented on the epistemological status he took his scientific theories to have. He claimed that they are *at least morally certain*, that is, certain enough that it would be reasonable to act on them (or perhaps unreasonable not to act on them), even if they are not absolutely or metaphysically certain (pt. IV, sec. 205). His principles explain so many phenomena that it hardly seems possible that they could be false. And some of his principles, he thought, are absolutely certain, because they are grounded in his certainty that God is supremely good and is not a deceiver (pt. IV, sec. 206). He mentioned mathematical demonstrations, the existence of material things, and “all evident reasonings about material things.” He clearly hoped that his readers would find even more of his conclusions metaphysically certain.

#### ROYAL ADMIRERS, CONTINUING CONFLICTS (1644–1648)

Descartes dedicated his *Principles of Philosophy* to Princess Elisabeth, the daughter of Frederick V (formerly the Elector Palatine and briefly King of Bohemia) and Elisabeth Stuart (sister of Charles I of England). They had begun to correspond in 1643, after Descartes learned that the princess, who was living in exile in the Hague, had read his *Meditations* with approval. She pressed him with acute questions about the relation between mind and body, eliciting some surprising answers. Later their correspondence turned to questions of ethics and psychology, which prompted Descartes to write his last major work, *The Passions of the Soul* (1649), also dedicated to her. Though the extravagant mutual flattery that pervades

their correspondence may be mere courtly etiquette, readers have sometimes wondered if Descartes did not harbor an affection for this sad, lovely, intelligent young woman that might have led to a romance, had not the difference in their ages, social station, and religion made that impossible. In any event, she proved to be a stimulating student.

Elisabeth began their correspondence by raising an issue that was to become central in the subsequent development of Cartesianism: How, in voluntary motion, can the mind, as a nonextended thing, cause its body, an extended thing, to move (Adam and Tannery III, p. 661)? Her paradigm for an intelligible causation of motion—and Descartes’s paradigm too, we might have thought—involves the impact of one body on another, with the cause transmitting some of its motion to the body that begins to move. Impact requires contact, which requires extension in both cause and effect. A nonextended thing cannot have an impact on an extended one.

Descartes replied by saying that what explains the mind’s power to move the body is its union with the body (Adam and Tannery III, p. 664). The notion of the union of mind and body is a primitive one, like extension and thought, which cannot be explained in terms of anything more fundamental. But Descartes thought that we demonstrate our possession of this notion when we attribute to so-called “real qualities,” like weight, a force that moves bodies toward the center of Earth. Although we have no knowledge of weight, except as a force of a sort that has this effect, we find no difficulty in thinking of it as moving a body, even though we do not think that it does so by actually touching one surface against another. We find this easy to conceive because we experience in ourselves a power to move the body, and we infer that bodies possess qualities that have analogous powers. We call these qualities “real,” meaning thereby that we conceive of them as being really distinct from the body that has them, and hence as a kind of substance. (In fact, as Descartes explained elsewhere, we think of them as a kind of spiritual substance, since we attribute goal-oriented behavior to them.)

Unsatisfied with this explanation, Elisabeth pointed out that real qualities are a disreputable part of scholastic natural philosophy that Cartesian physics aims to replace (Adam and Tannery III, p. 684). Descartes promised to give a proper mechanical explanation of such phenomena as the fall of heavy bodies to Earth, so that it will not be necessary to explain the mind’s power to move the body in terms of occult qualities, powers known only by their effects. Since Elisabeth did not really understand weight,

she could not use its supposed causal powers to help her understand how the soul might act on the body. It would be easier for her, she confessed, to grant extension to the soul than to suppose that an immaterial being has the ability to move and be moved by a material one. In his reply (Adam and Tannery III, p. 694), Descartes gave her permission to do just that: to think of the soul as an extended being! Thinking of the soul as extended is just thinking of it as united to the body. Elisabeth was not satisfied with this reply either, which hardly seems consistent with saying that we have a clear and distinct idea of the mind as a thinking, nonextended substance. But she got no more from Descartes on this subject.

Later their correspondence turned to ethical questions, and Descartes recommended that they discuss Seneca's "De Vita Beata" (On the happy life). Elisabeth's life as a princess in exile was not a happy one. Descartes hoped that reading Seneca would help her overcome her depression. Evidently, he had not read Seneca, or had not read him recently, when he made that suggestion. When he did, he did not find much useful there. But when he made his own recommendations for achieving happiness, they had a distinctly Stoic flavor: We should use our reason to consider without passion the value of all the perfections, both of body and of soul, so that we can always choose the better. We should cultivate a firm and constant resolution to carry out what reason recommends as best without being diverted by our passions. Virtue consists in sticking to this resolution, and virtue, Descartes thought, is the path to contentment. But before long he decided that he needed to examine the passions in more detail, so that he could define them. This led to the first draft of his *Passions of the Soul*, written in the winter of 1645–1646.

While these positive developments were occurring, the controversy with Voetius continued and spread to the University of Leiden, where Jacob Revius, the dean of the Staten college at the University, attacked Descartes, and Adriaan Heereboord, Revius's subdean in the college, defended him. This time the principal issues were not so much Descartes's rejection of key ideas in scholastic philosophy as the positive doctrines of his own philosophy:

- Whether the method of doubt leads to skepticism—a reasonable concern, considering the problems Descartes faced in getting beyond the *cogito*
- Whether Descartes was guilty of blasphemy even to suggest the possibility that God might be a deceiver—not so reasonable, it seems, since Descartes had shown sensitivity to the issue by substituting the demon for God at the end of the First Meditation and had gone on to argue that the

hypothesis of a deceiving God involves a contradiction

- Whether Descartes was guilty of atheism in rejecting the Thomistic versions of the cosmological argument for God's existence and replacing them with less satisfactory arguments of his own—a possibly reasonable concern, though the details of the critic's arguments show a poor understanding of Descartes's conception of an idea of God
- Whether Descartes was guilty of Pelagianism for excessively exalting free will

The principal basis for this last accusation was Descartes's claim, in the Fourth Meditation, that he experienced within himself a freedom of choice so great that he could not conceive of the idea of a greater freedom (Adam and Tannery VII, p. 57). It is above all in virtue of his freedom that he understood how he might have been made in the image of God.

The accusation of Pelagianism had come up in the correspondence with Mersenne as early as 1637 (Adam and Tannery I, p. 366). Descartes was always puzzled by it, since he understood the Pelagian heresy to involve the claim that an individual, using only his own natural powers, without a special act of divine grace, can achieve salvation. He knew that he had never made this claim, and he was happy to reject it when the situation required (Adam and Tannery III, p. 544). Nevertheless, when the curators at the University of Leiden forbade any discussion of Descartes's views, pro or con, and Descartes appealed to them, complaining that he must be permitted to defend himself against misrepresentation, the rector of the University, who was well disposed to Descartes, advised him to drop the appeal. The matter might be brought before an ecclesiastical council, where his opponents would surely win, not because of what he had said about freedom of the will, but "because they believe he is a Jesuit in disguise" (Verbeek 1992, p. 47). This was ironic, in view of the trouble Descartes was having with the Jesuits in France, but it was not the last of the ironies arising from Descartes's ambiguous position on free will, as we shall see later.

These were busy years for Descartes. One matter that occupied him was seeing that his principal Latin works were translated into French, so that they could be read by a broader audience. Various friends did the translations: Louis Charles d'Albert, Duke of Luynes, did the *Meditations*; Claude Clerselier, *Objections and Replies*; and the abbot Claude Picot, the *Principles*. The translations were published in 1647. In each case Descartes is supposed to

have reviewed them, presumably correcting anything he found faulty and occasionally adding text to explain his views more clearly. In principle, this means we might prefer the French translations of his works to the Latin originals. But it is not clear how much weight we can put on the French variations. We cannot know how carefully he reviewed the translations. Substantial variations almost certainly come from his hand. Smaller ones are doubtful. Older translations of Descartes into English blended the Latin and French texts. The now standard translation listed in the bibliography (Cottingham, Stoothoff, Murdoch, and Kenny) properly takes the Latin as the primary text, noting variations in the French.

In 1647 or 1648 Descartes initiated a quarrel with his former follower, Henricus Regius, who had developed positions at odds with Cartesian philosophy. Descartes first criticized Regius in the preface he wrote for the French translation of the *Principles* and later in the short work *Notae in programma quoddam* (Notes on a Program; also known as Comments on a Certain Broad-sheet), published in 1648 and notable for its clarification of Descartes's views on innate ideas. Also in 1648, Descartes sat down for a long interview with a young Dutch theology student named Frans Burman. Burman prepared well for the interview, carefully reading Descartes's published works and asking probing questions about them. His record of Descartes's answers is a valuable source of information about Descartes's views, though sometimes it is not clear that Burman accurately transcribed what Descartes said.

Toward the end of this period, Descartes entered into a correspondence with Queen Christina of Sweden, who was making her court in Stockholm a center for learning. Most of their correspondence was conducted through Pierre-Hector Chanut, the French ambassador, and there is none of the give and take that makes his correspondence with Elisabeth so interesting. But Descartes's relationship with Christina was momentous in other ways, as we shall see.

### THE PASSIONS OF THE SOUL (1649)

*The Passions of the Soul* is Descartes's most serious attempt to provide the moral philosophy promised in the preface to the French edition of the *Principles*. In a prefatory letter, Descartes said that he will treat the passions "only as a natural philosopher," not "as a rhetorician, or even as a moral philosopher." But this is somewhat misleading. Although the work begins with a quick course in Cartesian physiology (secs. 1–16), and broader and narrower definitions of the passions that emphasize their

close connection with the body (secs. 17, 25, 27–29), it ends by making a moral evaluation of the passions that smacks more of Aristotelian moderation than Stoic rigor: The passions are all good in their nature; all we need do is to avoid their excess and misuse (sec. 211). Indeed, all the good and evil of this life depend only on the passions (sec. 212).

In the broad sense, the passions of the soul are perceptions the soul receives from the things they represent (sec. 17). Sometimes the things these perceptions represent are in the soul itself, as when we perceive our volitions, imaginations, etc. (sec. 19). Sometimes the things they represent are either in our body or in some external object that acts on our body. This category includes bodily sensations, sensations of external objects, and passions in the narrow sense. These last are defined as excitations of the soul that, though in fact proximately caused by some movement of the animal spirits, are not perceived as having that proximate cause, but are referred to the soul itself (sec. 27).

Descartes maintained that there are six "simple and primitive" passions: wonder, love, hatred, desire, joy, and sadness (sec. 69). All other passions are either combinations of the primitive passions or particular species of them. Like sensations, the passions help to preserve the mind-body union: Their use "consists in this alone, they dispose the soul to will the things nature tells us are useful and to persist in this volition" (sec. 52). They are nature's way of telling us what is useful to us and what is harmful, motivating us to pursue what is useful and avoid what is harmful. The sensation of fear incites the will to flight; the sensation of boldness incites the will to fight.

The connection between the movements of the animal spirits and the excitations of the soul they cause and sustain is no more perspicuous here than it was in the correspondence with Elisabeth. Descartes identified the locus of interaction as the pineal gland, selected for this role, it seems, because it is the only part of the brain that is not double, and because a slight movement of this gland can greatly alter the movements of the animal spirits and, conversely, a slight movement of the animal spirits can greatly alter the movement of this gland (secs. 31–32). But how a particular movement of the pineal gland can affect the soul and how an action of the soul can move the pineal gland are mysteries shrouded in silence. The connections, apparently, are established "by nature" (secs. 44, 50), that is, we assume, the will of God.

Descartes, it seems, thought that for the most part the regularities God has put in place work well for us. But just as in the Sixth Meditations, our bodily sensations can

sometimes lead us astray, causing us to want drink, say, when drink would be harmful to us, so can our passions sometimes lead us astray. “When we feel the blood stirred up, we should be warned and remember that everything which presents itself to the imagination tends to deceive the soul, and to make the reasons favoring the object of its passion appear much stronger than they are, and the opposing reasons much weaker” (sec. 211). If the passion favors some object that does not require immediate action, we should refrain from making any immediate judgment and distract ourselves with other thoughts, until our blood has cooled. If it incites us to an action requiring immediate action, we should reflect on the reasons that oppose that action, and follow them even if they seem weaker. This, Descartes said, is “the general remedy for all the excesses of the passions, and the easiest to put into practice” (sec. 211). Descartes is not at his best when he is doing moral philosophy.

## DEATH AND CONDEMNATION (1649–1663)

In July 1649, in response to an invitation from Queen Christina, Descartes embarked for Stockholm, where he was to enhance the reputation of her court as an intellectual center and provide the queen with lessons in philosophy. This Swedish adventure did not end happily. When Descartes first arrived in October, his duties were minimal. But by mid-January he was required to give Christina five-hour lessons in philosophy, three mornings a week, beginning at five in the morning. Within two weeks he came down with pneumonia. By February 11, 1650, he had died.

Thirteen years later Descartes’s works were placed on the Catholic Church’s Index of Prohibited Books. For a long time it was unclear what the grounds for this condemnation were, but recently the Archives of the Congregation for the Doctrine of the Faith have been opened, permitting a clearer view of the Church’s reasons and procedures. The Holy Office assigned two outside consultants to read Descartes’s works and report on them: Joannes Tartaglia, to read the *Discourse on Method* (and its essays) and the *Meditations* (with the *Objections and Replies*); and Stephanus Spinula, to read *The Principles of Philosophy* and *The Passions of the Soul*. On the whole, the censors (especially Tartaglia) seem to have done their work carefully, attributing to Descartes only doctrines he actually held, or at least doctrines that might reasonably be inferred from what he wrote.

The censors found much to object to. Some were propositions in Cartesian physics where Descartes knew

he was pushing the bounds of orthodoxy: the denial of substantial forms and real qualities; the doctrine that Earth moves, while the Sun is immobile; the doctrine that the physical universe has no limits. Others were fundamental doctrines of Cartesian epistemology: that the existence of the self as a thinking thing is the first evident truth, from which all other evident truths derive; that we cannot clearly understand what is true unless we know clearly that God exists and cannot deceive us; and that the standard Thomistic versions of the cosmological argument are unsatisfactory ways of proving God’s existence.

Particularly interesting are the objections to two doctrines relating to human freedom: that the soul can easily acquire an absolute power over all its passions; and that freedom of the will does not require freedom from necessity, but only freedom from constraint. The first of these was a proposition that Spinoza also sharply criticized, in the Preface to part V of his *Ethics*. The second was one of five Jansenist propositions that the Church had censured in 1653. So while the Dutch Protestants accused Descartes of Pelagianism, the Catholic Church condemned him for Jansenism, that is, for siding with those within the Church who thought that in their reaction against Lutheran/Calvinist denial of free will the Jesuit theologians had succumbed to Pelagianism. The gate to doctrinal orthodoxy is narrow indeed.

## Bibliography

### WORKS BY DESCARTES

*Discourse on Method, Optics, Geometry, and Meteorology.*

Translated by Paul Olscamp. Indianapolis, IN: Library of Liberal Arts, 1965. The only complete English translation of the scientific essays published with the *Discourse*.

*Oeuvres*. 11 vols., edited by Charles Adam and Paul Tannery.

Paris: J. Vrin, 1974–1986. This is the standard edition of the texts in their original languages. All references to Descartes’s

works in this entry are to volume and page of this edition, cited as “Adam and Tannery.”

*Treatise of Man*. Cambridge, MA: Harvard University Press, 1972. The French text with translation and commentary by Thomas Steele Hall.

*Descartes' Conversation with Burman*. Translated by John Cottingham. Oxford, U.K.: Clarendon Press, 1976.

*Descartes: His Moral Philosophy and Psychology*. Translated by John Blom. New York: New York University Press, 1978. The only English language edition of Descartes's correspondence with Elisabeth that gives her letters to Descartes as well as his replies to her.

*Le monde, ou Traité de la lumière (The World)*. French text with English translation by Michael Mahoney. New York: Abaris, 1979.

*Principles of Philosophy*. Translated by Valentine Rodger Miller and Reese P. Miller. Dordrecht, Netherlands: D. Reidel, 1983. The only complete English translation of this work.

*Philosophical Writings*. 3 vols. Translated by John Cottingham, Robert Stoothoff, Dugald Murdoch, and (in vol. 3), Anthony Kenny. Cambridge, U.K.: Cambridge University Press, 1985–1991. The best comprehensive English language edition. It gives the volume and page numbers of the Adam and Tannery edition in the margins.

*The Passions of the Soul*. Translated by Stephen Voss. Indianapolis, IN: Hackett, 1989.

## DESGABETS, ROBERT

(1610–1678)

Robert Desgabets was a French Benedictine who offered a form of Cartesianism that departs from René Descartes's own account of the nature of substance and of one's knowledge of the self and of the external world. These departures are indicated in the two book-length texts from Desgabets published during his lifetime, but they are explicated most fully in manuscripts published only during the mid-1980s, in a definitive edition of his philosophical writings sponsored by *Studia Cartesiana*.

Desgabets was born in Ancemont in Verdun, a region annexed by France in 1552, to Jean des Gabets and Barbe Richard. He entered the Benedictine order in 1636 and taught philosophy and theology for over a decade at Saint-Evre in Toul. In 1648 he was named the Benedictine procurer general in Paris, and the following year he took up the position of professor of philosophy at Saint-Arnold in Metz. From 1653 to 1657 he served in administrative posts in various Lorraine abbeys. It was during this time that Claude Clerselier attempted to draw him into a defense of Descartes by sending him copies of Descartes's discussion in unpublished correspondence of the Catholic doctrine that the Eucharist involves the "transubstantiation" of bread and wine into Christ's body and blood. Desgabets endorsed Descartes's proposal that such transubstantiation occurs by means of the union of Christ's soul with the matter of the Eucharistic elements. What he added to this proposal was an argument against the possibility of the annihilation of this matter that appeals to the result in his 1654 manuscript "Traité de l'indéfectibilité des creatures," that material substance has an existence that is "indefectible," that is, indestructible and immutable.

In 1658 Desgabets spent a brief time in Paris on official business, and while there he participated in public discussions of Cartesian natural philosophy. He also offered for consideration a brief *Discours* on the transfusion of blood, which the French physician Jean-Baptiste Denis included in his 1668 *Lettre à Sorbière* in part to draw the attention of the English Royal Society to French research in this area.

Following his return to the Lorraine provinces in 1659, Desgabets worked to spread the teaching of Cartesianism in local Benedictine abbeys. In the mid-1660s he also became involved in the controversies in France over Jansenist theology associated most prominently with the convent of Port-Royal. Desgabets took the risky step of

siding with the Jansenists and Port-Royal against the religious and political establishment.

Even so, Desgabets later split with the Port-Royalists on the issue of the Eucharist. One occasion for the rupture was the publication in 1671 of his *Considérations sur l'état présent de la controverse*. Jean Ferrier, the royal confessor, promptly condemned the work to Louis XIV as heretical, and Louis ordered François de Harlay de Champvallon, the archbishop of Paris, to censure it. When Harlay questioned the Port-Royalist solitaires Antoine Arnauld and Pierre Nicole about this text, they denounced it in no uncertain terms. In an audience with Clerselier Harlay also insinuated that Desgabets's tract was responsible for a 1671 decree from Louis to the University of Paris that marked the start of the official campaign against the teaching of Cartesianism in France. Pressure from above led Desgabets's Benedictine superiors to interrogate him the following year and to prohibit him from speaking on the issue of the Eucharist. The effects of the censure were felt even into the mid-eighteenth century, when the Benedictine authorities refused the request of some admirers of Desgabets to publish an edition of his writings.

Despite the 1672 censure, Desgabets subsequently became underprior and then prior of the provincial abbey of Breuil. Moreover, the censure did not bring about the end of his philosophical activity. In 1674 he engaged in correspondence with Nicolas Malebranche after the latter sent him a copy of the first volume of his *Recherche de la vérité*. When Simon Foucher wrote *Critique de la recherche de la vérité* that cast doubt on claims in Malebranche's text that mind and body are distinct substances and that ideas represent external objects, Desgabets composed a Cartesian refutation of Foucher's skeptical position. Desgabets's *Critique de la critique de la recherche de la vérité* appeared in 1675, and like his 1671 *Considérations*, it was published anonymously. Desgabets further defended the fundamental tenets of his *Critique* in a manuscript commentary on the *Meditations*, the 1675 "Supplément à la philosophie de Monsieur Descartes."

In 1677 there was a series of conferences concerning Desgabets's distinctive version of Cartesianism that took place at the chateau of the Cardinal de Retz (Jean-François-Paul de Gondi) in Commercy. Around this same time Retz's secretary, Jean Corbinelli, led a discussion of the results of the conferences at a special meeting of Cartesians in Paris that included Malebranche. Shortly after these discussions, in March 1678, Desgabets died at his home abbey of Breuil, near Commercy.

## MATTER, SUBSTANCE, AND THE COGITO

In commentary published with his 1840 edition of the Commercium conferences, Victor Cousin noted that “if dom Robert, in metaphysics, is a disciple of Descartes revolting against all the principles of his master, he is not so in physics. There he is a faithful Cartesian” (cited in Retz 1887, p. 345). The fidelity to Descartes in physics is indicated in a 1666 letter to Clerselier, in which Desgabets criticized as schismatic the attempt of the French Cartesian Géraud de Cordemoy to introduce a version of Cartesian physics that posits indivisible atoms and the void. Desgabets also argued against the atomist admission of vacua by appealing to Descartes’s claim in the *Principles* that matter by its nature occupies all imaginable space.

However, Desgabets went further than Descartes in connecting the claim that matter fills all space to the conclusion that this matter is “indefectible” since not even God can annihilate any part of it. There may seem to be a similarity here to Descartes’s view in the Synopsis to the *Meditations* that “body taken in general” is incorruptible since it cannot be destroyed by natural means. Still, Descartes argued in the *Meditations* that since creatures have a duration divisible into distinct parts, God can reduce them to nothing at any moment by refraining from conserving them. Desgabets explicitly rejected this line of argument when he charged Descartes with confusing the modes of a substance with the substance itself. In the case of the material world Desgabets allowed that particular bodies can and do go out of existence. However, he claimed that these bodies are merely modes of extended substance that exist only “secundum quid” as particular temporal determinations of that substance. Desgabets insisted that substance itself exists “simpliciter” in a manner that is wholly indivisible, and so not subject to temporal change (1675, p. 77f).

Desgabets’s opposition to Descartes’s view that substance has a divisible temporal duration is a clear case of his revolt “against the principles of the master.” Another such case is provided by his charge that it is a “principal fault” in Descartes that he took the certainty of the cogito argument to show that the existence of the self is better known than and independent of the existence of body. In Descartes this conclusion is supported by the possibility of a hyperbolic doubt of the existence of the material world. In the “Supplément,” however, Desgabets objected to the possibility of such doubt. In the first part of this text he urged that the cogito itself undermines this sort of doubt since it reveals that one’s thoughts bear an essential

connection to bodily motion (1983–1985, p. 5:183f). His argument stresses that reflection on the cogito occurs in a continuous time that is not intrinsic to thought as such but derives from the union of one’s thought with motion. Desgabets relied explicitly here on the traditional Aristotelian definition of time as “the measure of motion.” He also held, with other Cartesians, that the only motion is local motion, and further claimed, in orthodox Cartesian fashion, that local motion itself presupposes the existence of the particular bodies that are in motion.

These various premises help to explain his conclusion that the temporality revealed by reflection on the cogito could not exist if there were no bodies external to mind. This argument is somewhat reminiscent of the later appeal in Immanuel Kant to the temporality of consciousness in his “refutation” of a “problematic idealism” in Descartes that takes consciousness to reveal with certainty only the existence of the self. Whereas Kant emphasized that the existence of “outer things” is required for the determination of the temporal succession of inner experience, Desgabets held that the existence of bodies in motion is required for the presence of the temporal duration of one’s thoughts.

Desgabets’s “Cartesian refutation of idealism,” as one might call it, is connected to his endorsement in his *Critique* of Foucher’s rejection of Malebranche’s orthodox Cartesian claim that one has a “pure intellect” that operates independently of the body. For Desgabets, that all one’s thoughts are temporal reveals that they all involve a union with motion. Since he adopted the traditional view that the soul is united to the body through the senses, he accepted the scholastic maxim *Nihil est in intellectu quod prius non fuerit in sensu* (Nothing is in the intellect that was not first in the senses). Pierre Gassendi also had appealed to this maxim in response to Descartes’s claim that one has a pure intellect, and this resemblance has led some commentators to label Desgabets as a Gassendist. Unlike Gassendi, however, Desgabets was firmly committed to a Cartesian dualism that distinguishes mind as thinking substance from body as extended substance.

## IDEAS, EXTERNAL OBJECTS, AND ETERNAL TRUTHS

In the second part of the “Supplément” Desgabets argued that skepticism concerning the existence of extended substance is overturned by “the most simple, the best known, and the most evident of all principles,” namely, that all simple ideas or conceptions correspond to real objects (1983–1985, p. 6:223). Desgabets took this principle to be linked to the claim that to perceive nothing is not to per-

ceive. He admitted that one can make false judgments about what one perceives. Indeed, he pointed to the scholastic claim that sensible qualities exist in bodies as a paradigmatic example of such a judgment, one that is to be corrected by “the great discovery of M. Descartes” that these qualities exist only in us (1983–1985, p. 5:164f). However, Desgabets’s “intentionality principle,” as commentators have called it, requires that ideas that succeed in representing extramental objects, such as the idea of body, presuppose that their objects actually exist in some sense. The qualification is required by Desgabets’s distinction, which informs his discussion of the indefectibility of matter, between modes and the substances they modify. Desgabets allowed that one can conceive of modes that do not actually exist insofar as one can conceive of them as only possibly modifying an existing substance. In this way the nonexistent modes have a “true possibility” conferred on them by substance. Since substance cannot be conceived through any other feature of created reality, however, the possibility of its existence also cannot be conceived through anything else. Desgabets concluded that one cannot even conceive of a substance that is “purely possible” and does not actually exist. For him, then, the mere fact that one has an idea of extended substance, and so can conceive of it, suffices to show that this substance exists external to mind.

Desgabets admitted “an extreme difference between the thoughts of M. Descartes and mine” concerning the issue of the existence of the external material world, since Descartes allowed for the possibility that extended substance exist not in extramental reality but only “objectively” in one’s mind (1983–1985, 6:223). However, one reason for Desgabets’s extreme opposition derives from his development of Descartes’s doctrine of the creation of the eternal truths. Descartes had introduced this doctrine in 1630 in correspondence with Marin Mersenne, in which he insisted that God’s free and indifferent will is the efficient cause of the eternal truths. Desgabets took this position to indicate that there are no preexisting truths concerning creatures that constrain divine creation. But he also insisted that if eternal truths concerning bodies were grounded in a mental objective reality, then those truths would seem to be as contingent and mutable as one’s mind. In Desgabets’s version of the Cartesian doctrine the truths are grounded rather in an extended substance with an atemporal existence that is completely indefectible. Thus, the necessity and immutability of the relevant truths are assured, even given that God has freely created the indefectible substance that provides the foundation for these truths.

The juxtaposition in Desgabets of a strong voluntarism and a firm commitment to substantial indefectibility is found also in the work of the French Cartesian Pierre-Sylvain Regis, who called Desgabets “one of the greatest metaphysicians of our age.” Regis endorsed Desgabets’s arguments both for the claim that one’s idea of extended substance reveals immediately the extramental existence of that substance and for the conclusion that temporal human thought requires a union with and thus presupposes the existence of bodily motion. In both Desgabets and Regis, then, radical doctrines concerning the indefectibility of substance, the intentionality of ideas, and the union of all human thought with motion constitute an unusual but philosophically sophisticated version of Cartesianism.

## DESTUTT DE TRACY, ANTOINE LOUIS CLAUDE, COMTE (1754–1836)

Comte Antoine Louis Claude Destutt de Tracy, the French philosopher and propounder of the doctrine of Ideology, was born in Paris. Educated at the University of Strasbourg, he entered the army and served later as deputy of the Bourbonnais nobility to the States-General. Despite his noble rank he was a fervent partisan of reform in monarchical government, but by 1792 he had become disgusted with the extremists among the revolutionaries and retired from politics to Auteuil, where he joined the celebrated group of philosopher-scientists that found its center at the home of Madame Helvétius. Among his intimates were Pierre-Jean-Georges Cabanis and Marquis de Condorcet, Comte de Volney and Dominique Joseph Garat. Imprisoned for a year under the Terror, he began to study the works of Étienne Bonnot de Condillac and John Locke, the result of which was his elaboration of the discipline he called Ideology. The group associated with Destutt de Tracy took the name *Idéologues* from his doctrine. They became influential in 1795 in two new institutions, the École Normale and the Institut National, especially in the Second Class of the Institut National.

Ideology, according to Destutt de Tracy, is the analysis of ideas into the sensory elements of which he believed them to be composed. Training in this new science would replace classical logic, and, he maintained, if a man learned how to analyze his ideas, he would then discover which of them were founded in experience and which were groundless. Destutt de Tracy held that Ideology was

a branch of zoology; all ideas had a physiological determinant. The child, with its weak sense organs, has nothing but sensation and memory; the adult, whose sense organs have become strengthened through use, has the powers of judgment and intelligence. It was therefore to be asked what the effect of habit would be on judgment. This question was put to the Second Class of the Institut National on 15 Vendémiaire, An VIII (October 6, 1799). The winning *mémoire* was that of Maine de Biran, at that time a young disciple of the *Idéologues*, and his *Mémoire sur l'habitude* (1802) formed the link between the French epistemological tradition of the eighteenth century and that of the nineteenth-century "spiritualists."

The word *thinking* in the works of Destutt de Tracy means, as it did for René Descartes, all conscious processes. Any immediate apprehension is called "feeling," whether it be sensory, emotional, or intellectual. Even memory and the perception of relations were "felt." But the feelings were not images; they were merely the awareness of whatever content might be before one. Destutt de Tracy called these contents ideas, following Locke. They were of four kinds: sensations, memories, judgments, and desires.

The question that puzzled Destutt de Tracy and, for that matter, most of the philosophers of this period in France was whether all consciousness is passive or whether some is active. If all were passive, then we should have no reason to believe in the existence of an external world. There is, however, according to Destutt de Tracy, one idea that gives us an intimation of a reality beyond ourselves, the idea of touch. When we put pressure upon an object, it resists. We cannot, at the same time, desire both a feeling and its annihilation. The feeling of resistance annihilates the desire to penetrate. Therefore, when we feel resistance, we are forced to conclude that there is a resisting object. In this way an element of activity was introduced into Destutt de Tracy's epistemology, an element that was to form the logical nucleus of the theories of his successors, Maine de Biran and Pierre Laromiguière.

Destutt de Tracy thought that the analysis of general ideas into elementary feelings would destroy the analyzer's faith in many of the teachings of religion. For if an idea could not be found to be either an elementary feeling or to be composed of such, it must be discarded. But many religious ideas cannot be so analyzed and therefore must be discarded.

Although the *Idéologues* had favored Napoleon Bonaparte's coup d'état of 1799, they soon opposed him, and in 1803 Napoleon suppressed the Second Class of the Institut. Destutt de Tracy's antireligious views, which

directly clashed with Napoleon's reestablishment of religion, were a major factor in Napoleon's act of suppression. The soon-to-be emperor, moreover, could not tolerate Destutt de Tracy's view that every man has the power to determine the truth and falsity of his ideas without recourse to authority and that among those ideas are those of right and wrong, both moral and political.

## DETERMINABLES AND DETERMINATES

The terminology of “determinables and determinates” existed in scholastic philosophy, but the modern use of these terms originated with the Cambridge (U.K.) philosopher and logician W. E. Johnson, who revived the terminology in his *Logic* (1921). Johnson said, “I propose to call such terms as colour and shape *determinables* in relation to such terms as red or circular which will be called *determinates*.” Some other determinables are size, weight, age, number, and texture. The terminology has since passed into philosophical currency and is now used to mark both the relation between determinate and determinable qualities and the relation between the corresponding words.

The chief features of this relation that Johnson and his successors have found interesting are:

- (1) It is logically distinct from the relation of genus to species. The denotation of a species term is marked off within the denotation of a genus term by the possession of properties known as differentia. The species is thus to be construed as formed by the conjunction of two logically independent

terms, either of which can, depending on the purposes at hand, be construed as genus or differentia. For example, the species term *man* is defined as the conjunction of the terms *rational* and *animal*. However, the determinate term *red* is not definable by conjoining the determinable term *color* with any other independent term. To put this point another way: Whereas we can say, “All humans are animals which are rational,” no analogous statement can be made beginning, “All red things are colored things which are.” Any term that could fill the gap would have to be synonymous with *red*. Red things do not possess some trait other than their redness that, when conjoined with their coloredness, makes them by definition red. Both the genus-species relation and the determinable-determinate relation are relations of the less specific to the more specific; but in the former case the specification is provided by some property logically independent of the genus, whereas in the latter case the determinate cannot be specified by adding additional independent properties to the determinable.

This characteristic has been emphasized by Johnson, John Cook Wilson, A. Prior, and John R. Searle; and it is

this feature that chiefly justifies the introduction of this terminology as an addition to the traditional arsenal. Attempts have been made—by Searle, for example—to give a rigorous formal definition of the determinable relation utilizing this feature; but it is not clear to what extent they have succeeded.

- (2) Determinates under the same determinable are incompatible. For example, the same object cannot be simultaneously red and green at the same point; and a man six feet tall cannot be simultaneously five feet tall. It might seem that counterexamples could be produced to this point since, for example, an object can be both red and scarlet, and red and scarlet are both determinates of color. However, such counterexamples are easily disposed of on the basis of the fact that scarlet is a shade of red, and hence red is a determinable of scarlet.

We must distinguish the relation in which red stands to scarlet from the relation in which color stands to either red or scarlet. Both are cases of the determinable relation, but they are significantly different. We may think of color terminology as providing us with a hierarchy of terms, many of which will stand in the determinable relation to each other as the specification of shades progresses from the less precise to the more precise. But at the top of the hierarchy stands the term *color*, which we may describe as an absolute determinable of all the other members of the hierarchy, including such lower-order determinables as “red” and their determinates, such as “scarlet.”

Our original point can then be restated by saying that determinates under the same determinable are incompatible unless one of the determinates is a lower-order determinable of the other. In the literature of this subject, the counterexamples are usually avoided by saying that any two exact determinates—for example, exact shades of color—are incompatible. However, it is not clear what *exact* is supposed to mean in this context.

- (3) Absolute determinables play a special role vis-à-vis their determinates. This role may be expressed by saying that, in general, for any determinate term neither that term nor its negation is predicatable of an entity unless the corresponding absolute determinable term is true of that entity. For example, both the sentence “The number seventeen is red” and the sentence “The number seventeen is not red” sound linguistically odd because numbers are not the sort of entities that can be colored. Lacking the appropriate absolute deter-

minable, neither a determinate term nor its negation is true of the entity in question.

To have a convenient formulation of this point, we may say that the predication of any determinate term or its negation of an object *presupposes* that the corresponding absolute determinable term is true of that object. We define presupposition as follows: A term *A* presupposes a term *B* if and only if it is a necessary condition of *A*'s being either true or false of an object *x* that *B* is true of *x*. Thus, in short and in general, determinates presuppose their absolute determinables. No doubt certain qualifications would have to be made to account for the operation of this principle in a natural language. For example, perhaps what is presupposed by *red* is more accurately expressed by *colorable* rather than by *colored*.

Aside from the intrinsic interest of these distinctions, they have proved useful in other areas of philosophy. John Locke's very puzzling discussion of primary and secondary qualities can be illuminated by pointing out that he fails to make sufficient use of the distinction between determinable and determinate qualities. When, for example, he says the primary qualities of a material body are inseparable from it in whatever state it may be, he clearly does not mean that a body must have this or that determinate shape or size as opposed to some other shape or size, but rather that it must have the absolute determinables of the primary qualities: It is a necessary condition of something's being a material object that it have some shape or other, some size or other, and so on.

Again, it is useful to point out that absolute determinables are closely related to categories. The notion of a category (or at least one philosophically important notion of a category) is the notion of a class of objects of which a given term can be significantly predicated. Thus, for example, correlative with the notion of *red* is the notion of things that can significantly be called red; these things are the members of the category associated with *red*. But a necessary condition of something's being a member of the class of things that can be significantly called “red” is that the absolute determinable of *red* must be true of that thing since, as we saw above, determinates presuppose their absolute determinables. Because a category (of the sort we are considering) is always a category relative to a certain term, and because a determinate term presupposes its absolute determinable, the absolute determinables provide a set of necessary conditions for category membership relative to the determinate terms.

Where the absolute determinable provides not only a necessary but also a sufficient condition of predictability of the determinate term, the absolute determinable will

simply denote the members of the category associated with the determinate term. Thus, assuming *colored* (or *colorable*) is the only presupposed term of *red*, the category associated with *red*, and with any other determinate of *color*, is only the class of objects that are (or could be) colored.

## DETERMINABLES AND DETERMINATES [ADDENDUM]

The relation between determinates and determinables has certain interesting formal and modal features. It is controversial whether these features are to be explained in terms of something more basic or whether they are primitive.

Formally speaking, the determinate-determinable relation is transitive, asymmetric, and irreflexive. Because *scarlet* is a determinate of *red* and *red* is a determinate of *color*, *scarlet* is a determinate of *color*. Because *scarlet* is a determinate of *red*, *red* is not a determinate of *scarlet*. And nothing is a determinate of itself.

Modally speaking, three features are worthy of note. First, if anything has some property, *p*, then it also has every property, *q*, of which *p* is a determinate. Thus, of necessity, scarlet things are red and colored. Second, the relation guarantees the exclusion of codeterminates. Nothing can have two determinates under a single determinable (provided the determinates are not themselves determination related). Thus, nothing can be both scarlet and crimson, because both are codeterminates of color. Third, and more controversially, any object with a determinable property must have a property that is a determinate of that property. Furthermore, there must be an exactly determinate property under every determinable.

It may be that the modal and formal structure of the determinate-determinable relation is brute, but two theories suggest otherwise. According to David M. Armstrong (1997), codeterminates under a single determinable are partially identical. Having five grams of mass just consists in having one gram of mass five times over. So, the exclusion relation is neatly explained by appeal to familiar facts about identity. Nothing can be five grams of mass and one gram of mass for the same reason that no room can have exactly one lectern and exactly five lecterns. However, the notion of partial identity for properties, as opposed to individuals, remains unclear.

Sydney Shoemaker (1984, 1998) holds that properties are individuated by the causal powers they bestow on objects that instantiate them. This theory of properties provides a ready explanation of the nature of the determinate-determinable relation: The powers endowed by a determinable property are a proper subset of the powers endowed by a determinate of that property (2001). For example, *scarlet* bestows the power to trigger scarlet detectors as well as red and color detectors. Some of the modal and formal features of the relation are then explicable simply by appeal to set theory, with its transitive, asymmetric, and irreflexive relation of proper subsethood. For example, if anything is scarlet, then it is also red, because if anything has the set of causal powers endowed by *scarlet*, then it has every subset of the causal powers in that set, and one of those subsets corresponds to *red*. The exclusion of codeterminates requires another explanation, however, which appeals to the individuation of powers. If an object were both scarlet and crimson, it would have incompatible causal powers, that is, it would be disposed to act in contradictory ways in the identical circumstances.

This reduction of the determinate-determinable relation would be more satisfying were the causal theory of properties that underwrites it less controversial. Among the more surprising consequences of the theory is that the laws of nature are strictly metaphysically necessary. Moreover, the theory is not perfectly general, but applies only to certain properties. The causal relation itself, along with purely formal properties like self-identity, cannot be correlated with a unique set of powers, but such noncausal properties may nevertheless stand in determinate-determinable relations.

One other characteristic is worthy of note: Determinates and determinables do not compete for causal efficacy. If a scarlet patch sets off a red detector, it is appropriate both to say the detector was triggered by the red and that the detector was triggered by the scarlet. The

overdetermination here is harmless, which raises the possibility that the relation may be appropriated by nonreductive physicalists seeking a way to preserve the causal efficacy of the mental in a physical world; perhaps physical properties are determinates of mental determinables (Yablo 1992).

The fit is not quite right, however. To repeat the point made earlier, the determinate-determinable relation is not the genus-species relation, nor is it merely one of greater and lesser generality. A perfectly determinate shape may be realized in different materials, but the conjunctions of that shape with different types of material do not form further determinates of shape. Likewise, mental properties may still admit multiple physical realizations even if they are perfect determinates of thought (Funkhouser).

## DETERMINISM, A HISTORICAL SURVEY

Determinism is the general philosophical thesis that states that for everything that ever happens there are conditions such that, given them, nothing else could happen. The several versions of this thesis rest upon various alleged connections and interdependencies of things and events, asserting that these hold without exception.

There have been many versions of deterministic theories in the history of philosophy, springing from diverse motives and considerations, some of which overlap considerably. We shall consider these in the order in which

they have been historically significant, together with certain alternative theories that philosophers have proposed. There are five theories of determinism to be considered, which can for convenience be called ethical determinism, logical determinism, theological determinism, physical determinism, and psychological determinism.

### ETHICAL DETERMINISM

**ADVOCATES.** It seemed to Socrates that every man always chooses what seems to him best, that no man can set as the object of his choice something that seems evil or bad to him. Plato had much the same view, arguing that no man who knows what is good can possibly choose anything else. They drew the obvious corollary that wrongdoing or the pursuit of evil must always be either involuntary or the result of ignorance.

A thirsty man, for example, might choose to drink from a certain cup in ignorance of the fact that it contains poison, or, knowing its contents, he might be forced to drink from it. But he could not, knowing that it contained poison and that this would bring upon him a great evil, voluntarily drink from it. Socrates and Plato thought that similar reasoning applies to any choice whatsoever. Hence, the Socratic doctrine that virtue is knowledge and vice ignorance. If one knows the good, he automatically seeks it; if one seeks something else, it can only be because he is pursuing an apparent, but specious, good—in other words, because he is ignorant of what is in fact good. An obvious corollary to this, and one that was drawn by Plato, is that the best commonwealth would be one governed by philosophers—that is, by men who know the good and can intellectually distinguish it from its counterfeits.

It is evident that in this ethical intellectualism, which is so central to Platonism, there is a theory of determinism. Men's voluntary actions are invariably determined by an apparent good; hence, all their actions are determined by this, if by nothing else. Philosophers who have been convinced by this teaching have nevertheless without exception insisted that it enhances rather than debases man's freedom. Freedom, they have maintained, is precisely the determination of the will by what is good. To have one's will or choice determined by what is bad is to be enslaved; to have it determined by something less than the highest good is, to that extent, to be less than perfectly free. Thus, Plato described the wicked tyrant, who pursues what is evil because he is ignorant of the true good, as enslaved and an object of pity.

René Descartes believed that no man who knew his true “end” or highest good could reject it in favor of something less and maintained that man’s freedom consisted precisely in knowing that good and being thereby determined to seek it. St. Thomas Aquinas spoke similarly, with qualifications, concerning man’s knowledge of his true “end” or highest good. Gottfried Wilhelm Leibniz similarly took for granted the fact that God could not possibly be guided by anything except the true good, which he must surely know, and that in creating a world, for example, he therefore could not create any but the best possible world. Still, Leibniz maintained, this is no derogation of God’s freedom; on the contrary, it is the most perfect freedom to have one’s will thus determined.

**OPPONENTS.** Aristotle rejected this theory of ethical determinism, mostly because it conflicts with what he took to be the evident fact of incontinence. It seemed clear to him that sometimes a man’s desires or appetites are in conflict with his reason, precisely in the sense that he desires something bad even while knowing that it is bad, which is the very essence of incontinence. John Locke took the same position. A drunkard, Locke pointed out, well knows that his use of spirits is bad for him, but the mere knowledge of this cannot be depended upon to extinguish his desire for them.

Most contemporary thinkers incline to the same view. The moral and intellectual determination of men’s choices and the consequent impossibility of genuine incontinence are no longer considered a plausible view by very many. Nevertheless, it is not easy to see just what is wrong with it. Surely, men do prefer the better to the worse in some sense—not what is absolutely better, perhaps, but what at least seems better; otherwise, why would any man choose it? It is the very nature of things bad to be shunned, and that is precisely why they are called bad.

Perhaps the real issue here is the more general opposition between rationalism and voluntarism. If one assumes the primacy of man’s reason and supposes his will, or what the Greeks called his appetite, to be naturally subordinate to it, then the Socratic thesis of the determination of the will by the reason is difficult to refute. If, on the other hand, one presupposes the primacy of man’s will or appetite and assumes the intellect to be at least sometimes subordinate to the will, then there is no difficulty in accounting for incontinence. Furthermore, there have been many philosophers—for example, Benedict (Baruch) de Spinoza, Thomas Hobbes, and William James—who have insisted that all it means to describe

something as good is that it is the object of one’s will—that is, of his desire or interest. If this is so, then the Socratic thesis becomes utterly trivial. It amounts to saying nothing more than that the object of a man’s will is always an apparent good—that is, something that is the object of his will. This is certainly true but not significant.

## LOGICAL DETERMINISM

Very early in the development of Western philosophy it occurred to certain thinkers that logic alone suggests that men’s wills are fettered, that nothing is really in their power to alter. This thesis was developed by Diodorus Cronus and others of his school, whom Aristotle sometimes referred to as “the Megarians,” and more importantly by the highly influential school of the Stoics. Such views were associated by the ancients with the idea of fate, an idea that has, however, the same implications as certain forms of determinism with respect to human freedom. Thus, if no man’s destiny is in any degree up to him, if everything that he ever does is something he could never have avoided, then in the clearest sense it is idle to speak of his having a free will. The Stoics thought that the most elementary consideration of logic shows this to be true.

The consideration in question is simply the supposition that every statement whatsoever is true or, if not true, false. This ultimately came to be expressed in the dictum *tertium non datur*, meaning that no third truth-value, besides true and false, can be assigned to any statement. If this is so, then it must hold for statements about the future as well as any others, for statements about individual men’s future actions and even for statements or propositions that are never asserted. It must also, of course, apply to statements believed by the gods. The last idea eventually became very important when the belief in an omniscient and infallible god became theological dogma.

What apparently led certain ancients, such as Chrysippus, Posidonius, and the Stoics generally to take the idea of logical determinism seriously was a consideration of signs, omens, and portents, which were then widely believed in. If there are signs from which it can be discovered what is going to happen, especially what a certain man is going to do at a certain time, and if, moreover, such signs are vouchsafed to men by gods, then it seems that such predictions must unavoidably, in the fullness of time, be fulfilled. Any such prediction that was not fulfilled could not have been true when made, contradicting the supposition that it was true. If such a prediction must be fulfilled, then it seems to follow that it is not within

anyone's power to confute it. The extension of this thought to all actions of all men leads quite naturally to the view that no man's actions are ever free or that nothing any man ever does was ever avoidable, it having always been true that he was going to do whatever he eventually did.

**ARISTOTLE'S OPINION.** A penetrating discussion of this problem is contained in some much disputed passages of Aristotle's *De interpretatione*. Aristotle there considers the question whether every true proposition, asserting that a certain event has occurred at a certain time, was true before the event in question took place and whether every false proposition, asserting that a certain event has occurred at a certain time, was false before the event failed to take place at that time.

Suppose, for example, a naval battle took place yesterday. This would seem to entail that it was already true, prior to yesterday, that it was going to occur. If anyone had said a thousand years earlier that such a battle was going to occur that day, then it would seem that his prediction was true, and if anyone had denied it a thousand years earlier, then the events of that day would have shown him to have been wrong. Aristotle, however, seemed reluctant to make this seemingly obvious inference. He suggested that it is inconsistent with the fact that men sometimes deliberate about whether to make certain things happen and with the belief all men have that it is sometimes up to them whether the events about which they deliberate will occur. If it is true a thousand years before a naval battle occurs that it is going to occur on a certain day, then whether or not anyone actually makes the prediction, it is difficult to see how, when that day arrives, it can still be up to the naval commander whether the battle will occur or what point there could be in anyone's deliberating about whether to precipitate it. The same difficulty arises if one supposes it to have been false a thousand years earlier that a naval battle would later occur. Aristotle therefore seems to suggest that some propositions—namely, those which assert or deny the future occurrence of certain deliberate actions of men or of events which are dependent upon these—are sometimes neither true nor false until the actions have either occurred or failed to occur.

**SUBSEQUENT CONTROVERSY.** This whole question was highly vexing to the early thinkers who followed Aristotle. It was even more troublesome to the Scholastics, many of whom felt bound to affirm the freedom of the human will but also bound to affirm that God knows from the beginning of time everything that will ever hap-

pen in his creation. Most of the Stoics, whose philosophy was highly fatalistic anyway, embraced the view of logical determinism or fatalism, while many of the Epicureans, who from moral considerations had always set themselves against any theories of fatalism, sometimes defended the view that statements about the future need not be either true or false and hence could not be known in advance even by the gods.

Diodorus Cronus was perhaps the most polemical of the early advocates of logical determinism. His fundamental principle, which is obviously a very strong one, was that it always follows from the fact that something *has* happened that it was *going* to happen and, hence, that it was true that it was going to happen before it did happen. Applying this seemingly incontestable dictum, Diodorus concluded that nothing is ever possible except what actually happens, from which it follows that it is never within any man's power to do anything except what he actually does.

Among the problems to which this conclusion gave rise was one called "the idle argument," which states that there is never any point in any man's ever taking any precautions or making any preparations. If, for example, a man is ill, then it follows from Diodorus's principle that he is either going to recover or he is not going to recover. If he is going to recover, then he will recover whether or not he summons a physician; similarly, if he is going to perish, then he will perish whether or not he summons a physician. Hence, there is no point in his summoning a physician in either case because the outcome is already inevitable. The philosopher Chrysippus sought to resolve this evident absurdity by inventing the notion of "condestinate" facts, facts whose truths are dependent upon one another. Thus, it may be true that a man is going to recover from his illness and also true that he is going to recover only if he summons a physician, from which one cannot conclude that he will recover whether or not he summons a physician. The two facts are, in this case, "condestinate."

**CONTEMPORARY ANALYTICAL DISTINCTIONS.** Contemporary philosophers have for the most part tried to resolve the problems of logical determinism by distinguishing between modal concepts, such as necessary, impossible, and so on, and the nonmodal concepts of true and false and by refusing to make certain inferences from one kind of concept to the other. Thus, from the fact that something happens of necessity, it follows that it happens, and from the fact that it is impossible for something to happen, it follows that it does not happen. The

reverse of these inferences cannot be made, however; something might happen without being necessary, and something might fail to happen without being impossible. This permits one to say without contradiction that it is true, without being necessary, or false, without being impossible, that a certain man is going to perform a certain action.

The difficulty that some writers have found in this seemingly obvious solution is that “necessary” and “impossible,” as applied to human actions, do not mean logically necessary and impossible. (As Gilbert Ryle and others have noted, the only things that can be logically necessary or impossible are propositions, not events or actions.) When the ancients described an event or action as necessary, they simply meant that it was unavoidable, and when they described it as impossible, they meant that it was not within the power of an agent to bring it about. This is still what men mean by such locutions. It is surely not obvious how an action can be avoidable on the supposition that it has been true from the beginning of the world that it would be performed by a certain man at a certain time and place, and it is not obvious how it can be within the power of an agent to perform a given action on the supposition that it is eternally false that he will. Still, as critics of this line of thought have forever pointed out, we must take for granted that men are often able to do many things which they never do and to forgo many things which they do all the time. It is perhaps just this that has always been at issue.

Following the suggestions of Aristotle, some contemporary philosophers, such as Charles Hartshorne, have maintained that predictions concerning a man’s future voluntary actions are always false, the truth being expressed only by a statement to the effect that he might and might not perform them. Others have argued that such predictions are neither true nor false when made, though they eventually become either true or false. In this connection Ryle has suggested that “correct” and “incorrect,” as applied to predictions of this sort, are more like verdicts than descriptions and thus convey more the idea of “fulfilled” and “unfulfilled” than of “true” and “false.” It would be always wrong to call a prediction fulfilled as long as it is a prediction, and similarly, Ryle suggests, it is misleading to speak of predictions as having been true. Ryle and others have also noted the error of thinking of predictions as the causes of the events they predict, though essentially the same error was pointed out by St. Augustine and many of the Scholastics, who noted that God’s prescience is never by itself the cause of anything.

Perhaps the most significant upshot of this whole problem, however, has been the considerable contemporary philosophical discussion concerning the status of future things, particularly future contingent or undetermined things. Do they exist “in the future,” awaiting only the lapse of time in order to become present, or do they have the more nebulous status sometimes referred to as possible existence? Ryle has suggested that predictive statements are not true or false in the same way that statements about past things are, precisely because the things to which they ostensibly refer do not have the same determinate existence, and that some descriptive statements therefore cannot make sense until the things ostensibly described really do exist. He thus compares certain predictive statements, such as the statement that a given man is going to cough at a certain future time, with statements about “past” things which might have been but never were—for example, certain automobile accidents that were prevented. All these suggestions have raised some of the most vexatious questions in contemporary metaphysics, and they are very far from being resolved.

#### THEOLOGICAL DETERMINISM

With the development of Christian theology there arose the concept of a God who is, among other things, perfectly good, omniscient, and omnipotent and upon whom, moreover, the entire world and everything in it, down to the minutest detail, are absolutely dependent for existence and character. This idea is obviously loaded with possibilities for deterministic theories, and there have been many philosophers and theologians who have developed them into extensive systems, some of which have formed the basis for theological doctrines having an extremely wide and abiding influence.

**MORAL DETERMINATION OF GOD’S WILL.** If, for example, we consider first the absolute goodness of God, it seems incongruous not only to think of him as choosing or by his action inflicting evil, but equally of his being able to choose, inflict, or even permit evil. Since, moreover, the world is the result of his act of creation, it seems to follow that it is the only world that was ever possible, being of necessity the best that was possible. Many of the Stoics affirmed this conception, identifying the world or “nature” with God or Zeus and also with fate. The world, they thought, is the only possible world, and nothing in it could be different from what it is. It is nevertheless good, and so the aim of a wise man should simply be to find and accept his place in it. Spinoza’s philosophy contains essentially the same idea. In the first book of his *Ethics* he affirms that nothing in nature is contingent, that there is

no free will in God, and, hence, that things could not have been produced by God in any other manner, though Spinoza was led to these conclusions by considerations other than the mere goodness of God.

Perhaps it was Leibniz who tried hardest to reconcile the moral determinism implied by God's absolute goodness with the existence of alternative possibilities. Leibniz distinguished two senses of necessity, which he called absolute and hypothetical. Given the absolute goodness of God, he said, then the world that exists must be the only possible world, because it is of necessity the best possible one. But this is only on the hypothesis that God is good; hence, the exclusive necessity of this world is only hypothetical. In the absolute sense, not taking into account God's goodness, this world is only one of many possible worlds, contrary to what Spinoza maintained. Something is necessary in an absolute sense only if its negation involves a contradiction, and in this sense neither God's acts nor men's are necessary. The actions of men are necessary only in the sense that there is a sufficient reason for them, as for everything else. This is consistent with their being free, considered in themselves, Leibniz thought, since in no absolute sense are they necessary.

It is doubtful, however, whether Leibniz's distinctions supply more than a verbal solution to the problem of theological determinism. One can grant that this must be the only possible world given the hypothesis that it is the creation of an absolutely good creator and thus agree that apart from that hypothesis it is not the only possible world. But as soon as one affirms God's goodness, which traditional theology considered beyond doubt, then it is difficult to see in what sense alternative worlds are still "possible." Leibniz's concept of hypothetical necessity has nevertheless had the most far-reaching significance in the subsequent development of the ideas of determinism and free will, for it became a cornerstone for generations of later philosophers, like David Hume, in their attempted reconciliations of physical and psychological determinism with free will.

**DIVINE OMNISCIENCE AND DETERMINISM.** The omniscience of God has likewise seemed to many thinkers to imply the inevitability of everything that happens. The philosophical arguments involved in this kind of determinism, resting on the idea that all truths are eternal, are essentially the same as those which led Diodorus and others to assert fatalism, but the addition of the premise that there is a being who knows all truths

from the beginning of time gives these arguments an especially powerful appeal to the imagination.

*St. Augustine.* An omniscient being knows everything. St. Augustine and virtually every other theologian who contributed greatly to the development of Christian thought assumed without question that God, as thus conceived, must know in advance every action that every man is ever going to perform, including, of course, every sin he will ever commit. If this is so, then the question arises of how men can behave otherwise than God knows they will—how, for example, a man can forgo those sins that God, when he created the man, knew he would commit. The strongest concise way of expressing this point is to say that (1) if God knows that I shall perform a certain act at a certain time and (2) if I am nevertheless able to forgo that act when the time for performing it arrives, then (3) it follows that I am at least able to confute an item of divine knowledge, whether or not I actually do so. That conclusion, of course, is absurd. The second premise, accordingly, must be false if the first is true.

Carneades, a pre-Christian defender of human self-determination and freedom, maintained that even Apollo could not know in advance what men were going to do. Such a view, however, seemed so inconsistent with the notion of omniscience that hardly any Christian thinker entertained it. St. Augustine, in considering this question independently of the idea of God's power, maintained that God's foreknowledge constitutes no threat whatsoever to man's free will. God, according to St. Augustine, foresees all events because they are going to occur; they do not occur just because he has foreseen them. Thus, he compared God's prescience to a man's memory. The fact that someone remembers an event does not render that event necessary or involuntary, and the same is true with respect to God's foreknowing an event. Again, St. Augustine pointed out, there is no difficulty in the notion of God's foreknowing that someone will be happy, from which one can hardly conclude that such a man must therefore be happy against his will. And whether or not we do anything else voluntarily, it can hardly be denied that we *will* things voluntarily, and this constitutes no reason why God should not know what we are going to will. Many of the other events God foreknows are things that, as God knows, depend upon our wills for their happening, from which it follows that they are both foreknown and willed—that is, voluntary. Most of the apparent difficulties in reconciling divine prescience with human freedom seemed to St. Augustine to evaporate in any case as soon as one comprehends the nature of God's eternity. The distinctions of "before" and "after," which

are essential to the formulation of this kind of theological determinism, have no application to God, according to St. Augustine. His eternity is not an everlastingness but, rather, an existence that is altogether independent of time. God therefore sees the whole of history in a manner similar to that in which we view the present, and from this point of view one is not easily tempted to suppose that God's knowledge imposes any determination on things to come.

**SUBSEQUENT VIEWS.** St. Augustine's reflections on this problem have for the most part been followed by subsequent thinkers. St. Thomas Aquinas, for example, similarly emphasized the eternity of God's vision and argued that God's knowledge is not by itself the cause of anything. Boethius, in *The Consolation of Philosophy*, defended the same view, adding numerous analogies to increase the plausibility of his arguments. Thus, he noted, a sign shows that to which it points without thereby producing it. In the same way God knows what will come to pass, but his knowing does not cause anything to happen. Again, a man might at one and the same time see another man walking and the sun rising; yet the man's walking can be voluntary, whereas the sun's rising is not. This, Boethius maintained, is the manner in which God views all things from the perspective of eternity. Boethius was thus led to his famous definition of eternity as "the simultaneous and complete possession of infinite life." In such a conception there is no suggestion of succession in time, and God must thus see all things in a manner similar to that in which we view things spread out in a given moment.

This Augustinian solution to the problem, echoed so often in the subsequent history of thought, has not been without dissenters, however. In the fourteenth century Peter Aureol reaffirmed what he took to be the arguments of Aristotle, maintaining that propositions concerning particular future contingent events, such as men's acts of free will, cannot be either true or false. This would seem to imply, of course, that God cannot foreknow them, but Peter Aureol seemed reluctant to draw that heterodox conclusion. He observed that God's foreknowledge does not make anything true or false and is to that extent consistent with the lack of either truth or falsity in some such propositions. He apparently did not observe that in order to be known by God, a proposition must nevertheless be true when foreknown, since God obviously cannot know something to be true that is in fact neither true nor false. William of Ockham expressed similar doubts but, unlike Peter Aureol, was unwilling to reject either the law of excluded middle or the doctrine of divine omniscience. God, according to William of Ockham, is omniscient and

hence knows all future contingent events. In the case of any disjunction to the effect that a given contingent event either is going to occur at a given time or is not going to occur at that time, God knows which of the mutually inconsistent propositions is true since he is omniscient. It follows that one of them is true and the other one false. But, according to this thinker, no one knows how this is possible, and no philosophical arguments, such as St. Augustine's, can render it really intelligible. Ockham's position thus consisted essentially of simply affirming what he thought was required by both logic and faith and refusing to render either intelligible in terms of the other.

The attempts of St. Augustine and many others to reconcile God's omniscience with the indetermination of men's actions were entirely rejected by the eighteenth-century American theologian Jonathan Edwards, who maintained that divine prescience imposes the same necessity upon things as does predestination, a doctrine that had been taught by St. Augustine. Foreknowledge, Edwards agreed, does not cause those things that are foreknown, but it nonetheless renders them certain and therefore inevitable. Indeed, such foreknowledge could not exist if determinism were not true, for there can be no certainty with respect to any contingent things. To say that things are foreknown with certainty by God and are nevertheless contingent and thus uncertain struck Edwards as an evident absurdity.

Similar doubts are expressed, among contemporary philosophers, by Charles Hartshorne. Hartshorne has defended indeterminism and free will, and defending also the belief in God, he has proposed an exceedingly interesting revision of the idea of omniscience. An omniscient being, according to him, is one who knows everything that it is possible to know. There can, however, be no antecedent truth with respect to particular future free actions of men other than that they might and might not occur. God, accordingly, cannot know whether they will be performed until the time for the performance arrives. He is nevertheless omniscient, since only those things that are inherently unknowable are unknown to him. It is significant and rarely noted that this is precisely the position taken by St. Thomas Aquinas with respect to God's omnipotence. God, according to St. Thomas, is omnipotent not in the sense that he can do anything whatsoever but, rather, that he can do anything that it is possible to do.

**DIVINE POWER AND PREDESTINATION.** It was earlier noted that the three chief sources of theological determinism are God's presumably unlimited goodness, knowledge, and power. It is undoubtedly the third of

these alleged attributes that has been the richest source of such theories. Even St. Augustine, although he defended human freedom on other grounds, felt obliged to relinquish it in the light of his conception of God's power. Thus arose the doctrine of predestination and all the baneful consequences it has wrought in the history of Christendom.

A man's power, St. Augustine thought, is nothing in comparison to that of his maker. Indeed, a man is helpless to do anything except sin unless he is assisted by the power and grace of God—"God worketh in us both to will and to do." Adam, our first ancestor, was, to be sure, free and, hence, free not to sin, but he sinned anyway and thereby cast the entire race of men into a morass of sin from which it is unable to lift itself by its own power. God as well as the blessed are unable to sin, but men are unable to avoid it. Accordingly, no man can be saved by the exercise of his own will, which can lead him only to damnation. He can be saved only by being chosen by God.

The same opinions were promulgated by Martin Luther and John Calvin, particularly in Luther's dispute with Desiderius Erasmus and Calvin's dispute with the Arminians on the issue of man's free will; they formed a considerable part of the theological basis of the Protestant Reformation. Both Luther and Calvin stressed the power, sovereignty, and righteousness of God, subordinating to these the belief in his love and mercy. God, according to Luther, does not merely foreknow what will happen. He foreknows, purposes, and does everything according to his eternal, changeless, and infallible will. To affirm any power or freedom on man's part, particularly any freedom to perform meritorious actions, seemed to both Luther and Calvin to compromise the power of God and even to set men in competition with him. Without God's grace everything we do is evil and therefore determined. It is not within any man's power to do any good thing. Even actions which would otherwise be right and proper, such as acts of charity, are, according to Luther, without merit if not accompanied by faith and prompted by grace. Luther thus compared the human will with the will of a beast of burden, which is ridden by either God or Satan. If ridden by God, it goes where God wills, and if by Satan, where Satan wills; in neither case, however, does it choose the rider. The riders, God and Satan, vie over who shall control it. Such views as these were once, of course, the source of persecutions and upheavals, but they are rarely enunciated with seriousness now, even by theologians, for the idea of divine power no longer has the reality in men's minds that it once had.

## PHYSICAL DETERMINISM

Modern theories of determinism were inspired mainly by the development of physical science, particularly in the seventeenth and eighteenth centuries. Scientists then discovered that the motions of the heavenly bodies were not only regular but also "obeyed" certain laws that could be expressed with mathematical exactness. Gradually, the whole approach to the study of nature, which had been philosophical, speculative, and heavily influenced by Aristotle, gave way to observation, experiment, and the search for laws. The idea slowly took hold that all things in nature, men included, behave according to inviolable and unchanging laws of nature. In the philosophical tradition there was a great deal that made this idea plausible, reasonable, and almost inevitable. Theories of determinism were about as old as philosophy. The rise of physical science only prompted philosophers to revise somewhat the content of deterministic theories to which they were already thoroughly accustomed. They more or less ceased thinking of human actions and other events as determined by moral considerations or by an eternal and immutable God and began thinking of them as determined by eternal and immutable laws of nature.

**THE EPICUREANS.** Of course, this idea was by no means new. The view that everything is composed of matter or, more precisely, of minute and impenetrable atoms or invisible material particles had been elaborated by Leucippus and Democritus before the Christian era and had been perpetuated in the teachings of the Epicureans for centuries. Such a conception of nature gave rise to the idea that if everything that happens is resolvable into the motions and combinations of atoms, then men's behavior, too, must be reducible to and understandable in terms of the motions of atoms. The early atomists assumed that this must be true even of men's thoughts and desires, since, according to them, even the "soul" is composed of atoms. The behavior of atoms, in turn, was thought to be a function of their speed, direction of motion, and sometimes their shapes. Atoms changed the direction of their motion simply by being struck by other atoms. Material bodies arose from the combination of atoms into groups or clusters and perished as a result of their dispersion. The atoms themselves, however, were individually indestructible and indivisible.

The Epicureans who took over this theory of nature were not long in discovering its implications with respect to human freedom. These philosophers were concerned mostly with discovering the means to the attainment of the highest good for man, which they took to be happi-

ness and freedom from pain. It would be idle, however, to work out the means for the attainment of this if men had no freedom to choose those means. If the theory of atomism were true, then it would seem that what became of a man and whether he attained a good life were simply matters of how physical bodies and, ultimately, the atoms of which all bodies are composed behaved, and no man would have any hand in what became of him. The Epicureans accordingly modified the theory by claiming the atoms to have the power of occasional spontaneous motion, which they referred to as the capacity to swerve. Ordinarily, an atom would change its direction only by being driven from its path by impact with another atom, but occasionally, they maintained, an atom alters its path spontaneously, without any cause for this change at all. This enabled the Epicureans to maintain that there is an element of contingency and uncertainty in nature, that not everything is determined by physical laws, and that men can therefore intelligibly be thought of as free to some extent or, in modern terms, as having free will. The Epicureans' opponents never tired of waxing merry with the doctrine of the swerve, however. Indeed, that doctrine did enable the Epicureans to avoid determinism, but there appeared to be nothing else in its favor, and it seemed, moreover, to be plainly irrational.

**HOBBS'S MATERIALISM.** Perhaps the best example of physical determinism in modern philosophy is the system of Thomas Hobbes. His philosophy represents a thoroughgoing attempt to interpret human nature according to the basic presuppositions of the science of bodies—that is, physics—and although it is no longer novel, it is probably fair to say that the generations of thinkers since Hobbes who have shared his aim and purpose have not significantly modified or improved upon his fundamental ideas. Modern materialistic theories differ from Hobbes's basic system only in details and mode of expression and share equally with it such purely philosophical merits and defects as it may possess.

Hobbes denied the existence of any immaterial soul or spirit in men, maintaining, as do some contemporary materialists, such as J. J. C. Smart, that ideas, sensations, and all psychological processes are motions or modifications of matter in the brain. From this it at once follows that human behavior is the behavior of matter and is to be understood according to the same general principles that we apply to matter. The idea that men might be the original sources of their own voluntary motions or that acts of will might arise without causes was rejected as unintelligible; nothing, Hobbes said, "taketh a beginning from itself." Whatever happens, whether in the realm of

human behavior, human thought, or elsewhere is caused and hence causally determined by changes of material particles. Voluntary actions are therefore no less necessitated than anything else.

Hobbes nevertheless insisted that such complete physical determinism is consistent with human liberty, for he defined liberty as simply the absence of external restraint or impediment and, hence, as something that even inanimate things can possess. He said that, properly understood, liberty is simply the "absence of all the impediments to action that are not contained in the nature and intrinsic quality of the agent." Hobbes concluded that any unobstructed moving body can be considered free. The unobstructed water of a flowing stream, for example, descends freely, though it is not at liberty to ascend or to flow across the riverbed. It is part of the "nature and intrinsic quality" of water to flow downward, and it flows freely.

Hobbes interpreted human nature according to such analogies. All voluntary human action, he thought, is caused by the alternate operation of the general motives of desire and aversion, which he took to be similar to, and, indeed, varieties of, physical forces. The proximate or immediate cause of a voluntary motion is an act of the will, but an act of the will is never free in the sense of being uncaused. It is caused by some kind of desire or aversion. Deliberation was described by Hobbes as an alternate succession of contrary appetites, a kind of vacillation between competing impulses, in which the appetites are of such approximately equal force that neither immediately overcomes the other. Deliberation ceases when one of them comes to outweigh and thus to prevail over the other. An "act of will," accordingly, is simply the "last appetite"—that is, the desire or aversion upon which one finally acts. To speak of an agent's act of will as "free" would be equivalent to saying that the agent is able to perform it if he wills to perform it, and this Hobbes dismissed as an "absurd speech." To say a man is free to do a given action means only that he can do it if he wills—that is, that his will or "last appetite" is sufficient to produce that action—but it is obviously nonsense to speak of an act of will itself being free in any such sense. Any other sense of freedom, however, seemed to Hobbes inherently incoherent. It is, for example, a fairly common conception of liberty among the advocates of free will that a free agent is one who, when all things necessary to produce a given action are present, can nevertheless refrain from that action. This, according to Hobbes, is equivalent to saying that conditions might be sufficient to

produce a given effect without that effect's occurring, which is a contradiction.

It is noteworthy that Hobbes, though he claimed all human behavior to be physically determined and necessitated, did not conclude that men are not responsible for their actions. In this his theory represents an important departure from some of his predecessors. The Epicureans took for granted that behavior that is physically determined is unfree, and they therefore denied, in the face of their own presuppositions, that all human behavior is physically determined. But Hobbes maintained that a voluntary act is simply one that is caused by an act of will. It is rendered no less voluntary by the fact that acts of will are caused. Generations of philosophers, while for the most part rejecting Hobbes's materialism, have nevertheless followed him in this and in his conception of liberty. Arthur Schopenhauer, for example, declared it nonsense to ask whether acts of will are free, giving the same reason that Hobbes had given; defined freedom as the absence of impediments and constraints; and, like Hobbes, found no incongruity in speaking of inanimate bodies, such as a flowing stream, as acting freely. In the twentieth century Moritz Schlick, A. J. Ayer, and many others made the point that freedom is not opposed to causation but to constraint. The significance of these ideas is enormous, for they appear to offer the means of once and for all reconciling the apparent opposition between determinism and freedom, thus dissolving the whole problem of free will. Many philosophers are still convinced that this insight is entirely correct and that there really is therefore no problem of free will.

### PSYCHOLOGICAL DETERMINISM

Most philosophers since Socrates, and even those before him, have, unlike Hobbes, distinguished between men's minds and their bodies, taking for granted that men are not just collections of material particles. Descartes distinguished minds and bodies as two entirely distinct substances whose essential properties are utterly different. Most philosophers since have rejected much of Descartes's philosophy but have nevertheless preserved the distinction between minds and bodies. In contemporary philosophy minds and bodies are not often described as distinct substances, but an absolute distinction is nevertheless often drawn between "psychological" predicates and verbs, on the one hand, and "physical" ones, on the other, and this amounts to much the same thing. Because of this, most modern theories of determinism, as applied to human behavior, can suitably be called theories of psychological determinism. Most of these theories are in

complete agreement with Hobbes's concept of free and voluntary behavior as the unconstrained and unimpeded behavior that is caused by an act of will, a motive, or some other inner event. The only significant difference is that acts of will and other inner causes are conceived of as psychological or mental events within the mind of the agent rather than as modifications of matter in his brain.

**CARTESIAN INDETERMINISM.** Descartes stands out in modern philosophy as a defender of free will, which is conceived of as indeterminism with respect to the voluntary operations of the mind. In his *Meditations* he described such freedom as infinite, meaning that no limitation whatsoever is put upon the mind's power of choice. His theory was essentially that willing consists of assenting or dissenting to some conceived object of choice or to some proposition. By the understanding one is enabled to entertain certain propositions, but understanding by itself neither affirms nor denies, neither chooses nor rejects. This role is reserved for the will. Accordingly, human understanding can be of limited scope, as it is, without in any way limiting the freedom of the will. The understanding sometimes represents things in an obscure and confused manner, sometimes even falsely, as in the case of various illusions and deceptions, but it sometimes represents them clearly and distinctly. Intellectual error results from the precipitous use of the will—that is, from assenting to things that are not clearly and distinctly perceived by the understanding. Moral error results from a similar unrestrained use of free will—that is, from men's assenting to or choosing objects that are only speciously good, without a clear and distinct apprehension of their true worth. Thus, error is always avoidable. To know what is true, attain genuine knowledge, and choose rightly, one needs only to confine the assent of the will to what is clearly and distinctly perceived by the understanding as true or good. God cannot therefore be blamed for men's errors. He endowed men with understanding adequate for the perception of truth and with a will that is absolutely unlimited in its freedom to accept what is true and reject what is doubtful or false.

This way of conceiving of the human will has provided what is virtually a standard solution to the problem of moral evil—that is, to the problem of reconciling the occasional turpitude of men with the presumed goodness of their creator—but beyond that hardly any philosophers have agreed with it. Probably no other indeterminist, for example, has described the freedom of the human will as unlimited. The theory was also quickly subjected to criticism on epistemological grounds. With great perception Spinoza, for example, challenged the basic dis-

inction between the understanding and the will. It is quite impossible, Spinoza said, to have a clear and distinct understanding of some truth without at the same time assenting to it. The perception of truth is one and the same thing with the knowledge of it, and one cannot therefore have a true idea without at the same time knowing that he has a true idea.

Much more important, however, were the implications of Descartes's idea of a "free" will, conceived of as a will that is not determined by anything else. It appeared to imply that men's choices are completely random and capricious, utterly mysterious and inexplicable. In fact, this has always been the overwhelming stumbling block for all theories of indeterminism, whether in the Epicurean notion of spontaneous swerves of atoms or Descartes's notion of uncaused assents, dissents, and choices. If such things are really free in the sense of being causally undetermined and if human behavior is to be explained in terms of such things, then human behavior itself would have to be random, capricious, and utterly inexplicable. Since, however, human behavior does not appear to be exactly what these theories suggest, there has always been a powerful incentive to reject indeterminism in favor of some conception of determinism that does not do violence to men's conceptions of liberty.

Innumerable philosophers have thought that this is accomplished in the manner suggested by Hobbes—that is, by conceiving of a voluntary action as one that is caused by such an inner event as volition, motive, desire, choice, or the like; conceiving of an involuntary action as one that is caused by some state or event external to the agent; and then defining a free action not as a causally undetermined one but as one that is not involuntary or constrained. This kind of determinism has been advocated by so many philosophers, including many contemporary writers, that it would be tedious to list them. The basic idea was suggested by Aristotle, although Aristotle did not discuss the problem of free will as such. It was lengthily defended by John Locke, who was, however, aware of some of the difficulties in it, which he never entirely resolved except by enormous equivocations. Probably the most famous classical defense of it was presented by David Hume, who is still thought by many to have solved the problem of free will.

**LOCKE'S THEORY OF LIBERTY.** Locke, like Descartes, distinguished between a man's mind and his body and described both as substances. Changes in a man's body, including voluntary motions, are, he thought, all caused, but the causes are within the mind in the case of volun-

tary motions. Unlike Descartes, however, Locke did not suppose that anything within the mind is causally undetermined, nor did he think it necessary to suppose this in order to preserve the belief in human freedom, which he thought misleading to label "freedom of the will."

Locke defined liberty or freedom as "a power in any agent to do or forbear any particular action, according to this determination or that of the mind, whereby either of them is preferred to the other." One acts freely, then, provided he is acting according to the preference of his own mind, and this is perfectly consistent with his action's being causally determined. It might, for instance, be determined by that very preference. Locke also defined freedom as "being able to act or not to act, according as we shall choose or will," and this again, far from implying that free actions are uncaused, implies that they are caused by the agent's choice or will. In the light of this, Locke, like Hobbes, dismissed the question whether men's wills are free as "improper" or meaningless, like asking whether a man's sleep is swift or whether virtue is square. Liberty, he said, is something that can be possessed only by agents, not by their wills.

That an action can be perfectly voluntary and nevertheless unavoidable was, Locke thought, borne out by clear examples. Suppose, for instance, that a man went to a certain room because there was someone he had a strong desire to see and suppose that while he was there conversing with him, someone secretly bolted the door behind him so that he could not leave. Now, Locke pointed out, his action of remaining in the room, entirely in accordance with his own preference and desire, would not cease to be voluntary just because he could not, unbeknown to him, leave if he wanted to.

One acts voluntarily and freely, then, in doing what one wills, prefers, or chooses. Locke distinguished, however, between desires or preferences and volitions, noting that men can prefer certain things they can by no means will. Thus, a man might prefer to fly than to walk, but he cannot will it. Locke defined a volition as "an act of the mind knowingly exerting that dominion it takes itself to have over any part of the man, by employing it in, or withholding it from, any particular action." Elsewhere he defined a volition as "an act of the mind directing its thought to the production of any action, and thereby exerting its power to produce it." A volition, then, is a psychological act that sometimes figures causally in the production of voluntary motion. It is itself causally determined by the mind, and the mind, in the determination of its volitions, is, Locke thought, causally deter-

mined by the satisfaction of doing or continuing a given action or by feeling uneasy in doing or continuing it.

There is, then, throughout Locke's involved, tortuous, and sometimes equivocating discussion the general presupposition that determinism is true and that indeterminism is irrational and unintelligible. The philosophical problem, as he understood it, is simply that of showing that determinism is compatible with what all men believe concerning human liberty. He seemed to believe that once certain crucial concepts, such as "voluntary," "free," and the like, are rightly defined and understood, the problem of free will would evaporate.

**HUME ON FREEDOM AND NECESSITY.** The defining of the concepts was, in any case, precisely what David Hume set out to do in his celebrated discussion of liberty. According to Hume, all men have always been of the same opinion on this subject, believing both that men are free and that all their actions are causally determined. There is therefore no philosophical problem of free will, and the whole dispute, he thought, has heretofore been purely verbal in character, involving only confusions in the meanings of words.

It was a fundamental point of Hume's philosophy that causation is essentially constant succession, that there is no necessary connection between causes and their effects. Causes, therefore, do not compel the occurrence of their effects; they only precede them. The question of whether human actions are caused, then, is simply the question of whether there is anything with which they are constantly joined. Hume claimed that no one has ever been in any doubt about this. Throughout history certain actions have always been associated with certain motives with the same constancy and regularity that one finds between any causes and their effects. Human actions are caused, then, in the same way that everything else is caused.

Far from concluding from this, however, that no human actions are free, Hume concluded the opposite, for he considered it the very nature of a free action that it springs from the motive of the agent. He therefore defined freedom as being able to act according to the determinations of one's own will—that is, of one's motives—a definition that presupposes that one's free actions are caused. One's actions are not unfree if they are caused but if they are caused by something other than the determinations of one's own will.

Nor does this conception of liberty, according to Hume, vitiate a man's responsibility for what he does. On the contrary, responsibility depends upon the causation

of actions by motives. All laws are based on rewards and punishments and thus rest on the assumption that men's motives can be relied upon to have a regular influence on their behavior. There would be no point in appealing to such motives as fear and hope if nothing could be predicted from their operation. Justice, moreover, requires such an operation of motives, for no man can be a fit object of punishment if his actions are in no way traceable to his motives. Indeed, if one could not rely upon the constant and predictable operation of motives, all intercourse with one's fellows would be hazardous or impossible. One could not even invite a guest to his table with any confidence of not being robbed by him, for the knowledge of his honesty and friendliness would in that case provide no assurance. Sometimes, to be sure, men are robbed or murdered when they had every reason to expect otherwise; however, men are also sometimes destroyed by earthquakes and the like when they had no reason to expect it. No one concludes from this that earthquakes are without any causes. Determinism, then, does not imply that all human behavior is predictable in the most straightforward sense of the term, for many unpredictable things are nevertheless causally determined. A man might not know why his watch has stopped and might not have been able to predict that it was going to stop, but this is only because the cause is hidden from him. He does not suppose that there was no cause at all. Similarly, a normally genial man might on occasion be peevish, but this is only due to some cause—some intestinal disorder, for instance—that is hidden from others and perhaps even from himself.

The important question for Hume, then, was not whether all human actions are causally determined, since all men have always been convinced that they are, or whether any human actions are free, since all men have always been of the same opinion on this, too. It is simply the question of how these two beliefs, so universally shared, can both be true, and Hume found the answer to this in analyzing what is meant by saying that one's action may be caused and also free.

**DETERMINISM AND RESPONSIBILITY.** What is essentially Hume's argument has been repeated by other philosophers and is still vigorously pressed by many of them. There have nevertheless always been doubters who have contended that this is a superficial conception of liberty, that the actions of a causally determined agent can be "free" only in a technical sense that does not at all correspond with the notion of freedom that men in fact have and that moral responsibility requires. A genuinely free action, according to this point of view, is not merely one

that is in keeping with one's preferences, desires, and volitions, but one that is avoidable or, in C. D. Broad's terminology, "substitutable." To say that a given action was free means at least, according to these writers, that the agent could have done otherwise given the very conditions that obtained, not just that he could have done otherwise if something within him had been different. This thought was expressed by Immanuel Kant, who rendered it in the formula "ought implies can." What Kant had in mind was that whenever one rightly judges that a given agent is morally obligated to perform a certain action, he must logically presuppose that the agent can perform it—not just that he can if he wants, prefers, or wills to, but that he can in some absolute sense. This kind of freedom has been aptly called "categorical," as opposed to the "hypothetical" freedom defended by Hume and others, for it is a freedom both to do and to forbear doing a certain action under the same set of conditions.

The difficulty in deterministic theories that all these critics have felt can perhaps be illustrated with an example. Suppose that a given man is often motivated to steal and that in accordance with determinism he always does steal when, prompted by that motive, his efforts to do so meet with no impediment. According to the determinist theory, these actions are then free and voluntary, and he is responsible for them. Suppose further, however, still in keeping with determinism, that he has no control over the occurrence of this motive, that it arises, let us suppose, as a result of an abominable background and deprivation in his youth, that, in short, he is the product of precisely those influences that nourish and perpetuate that motivation. One's inclination may be to say that even given such a background, he did not have to become a thief, but that would not be in keeping with the thesis of determinism. According to that thesis, it was causally determined and, hence, inevitable and unavoidable that he should become whatever he is. It follows from these suppositions, then, that he cannot help being whatever he is and performing just the actions he does perform. We can indeed still say that if he were not the kind of man he is or if he were motivated otherwise than he is or if something had been different, he could then act otherwise than he does; however, any point to ascribing this merely hypothetical kind of freedom to him seems to vanish when we add, as the determinist must, that nothing could have been different, that he could not have been any other kind of man, that he could not have been motivated differently, and that, hence, he could not have acted otherwise than he did.

It was with this sort of thing in mind that Kant, contrary to what he acknowledged to be the requirements of reason, postulated what he called a "causality of freedom" and insisted that the theory of determinism cannot be applied to men. Their freedom, he thought, must be categorical or such that their actions are not entirely determined by factors over which they have no control. The same point was pressed by G. W. Fichte, Thomas Reid, Samuel Clarke, and William James, and among contemporary writers it has been eloquently urged by C. A. Campbell and many others. It was essentially the point that was skillfully made by Henry Mansel in his criticisms of J. S. Mill's determinist theories. Mill defended a theory that was in all basic respects identical with Hume's—that causation is constant conjunction; that men, when acting voluntarily, always act in accordance with their strongest desires or aversions; that justice, morality, and the administration of laws all require such causal determination of behavior, and so on. Mansel argued that when pressed to its ultimate conclusions, this theory did not differ in its consequences from what he called "Asiatic fatalism," or the view that all men are helpless to do anything except what they actually do. Mill denied this by arguing that although one's actions are determined by his will, his will by his desires, his desires by his motives, and his motives by his character, his character is itself amenable to his will. Mill did not, however, succeed in explaining how, according to his theory of determinism, a man's character, which he evidently thought of as the ultimate determinant of his conduct, could be "amenable" to or within the control of his "will," which is merely the expression of his character.

"HARD" AND "SOFT" DETERMINISM. William James is among the relatively few philosophers who, impressed by the kind of argument Mansel directed against determinism, have defended a theory of outright indeterminism or chance. He was, like the Epicureans, led to do so by what he thought were the requirements of morals. Determinism, he said, implies that the world we have is the only possible world and that nothing could have been other than it was; he declared this to be incompatible with the reasonableness of regret and other basic moral sentiments. In the course of his argument he drew a very useful distinction between what he called "hard" and "soft" determinism. By soft determinism he meant all those theories, like those of Hobbes, Hume, and Mill, which affirm that determinism is true and then, by means of what he considered sophisticated and contorted definitions, somehow manage to preserve a semblance of certain moral notions like liberty, responsibility, and so on that, accord-

ing to James, are plainly obliterated by any theory of determinism. Hard determinists, on the other hand, are those who affirm what their theory entails—namely, that no man can help being what he is and doing what he does and that moral distinctions are therefore irrational and ought never to be applied to men or anything else.

There have been relatively few defenders of hard determinism, most philosophers preferring instead to try reconciling determinism with morals. Certain materialist philosophers of the French Enlightenment, such as Baron d'Holbach, are exceptions, for they did maintain that men are only helpless products of an impersonal nature who govern neither themselves nor anything else but are simply carried along to whatever destinies the circumstances of their lives inflict upon them. Arthur Schopenhauer sometimes defended the same thought, emphasizing the irrational forces that govern human behavior. The American lawyer Clarence Darrow applied this hard determinism in courts of law with the most devastating effect, saving many men from the gallows not by pretending they were legally innocent but by the simple and eloquent plea that they could not help being what they were and doing what they had done. Among contemporary philosophers the claim that men are not morally responsible, as an implication of determinism, has been vigorously defended by John Hospers, and many others have pointed out the dubious character of soft determinism. The standard "solution" to the problem of free will, embodied in the writings of Hume, Mill, and many others, is as a result no longer considered to be as obvious as it once was, and a decreasing number of philosophers are now willing to speak blithely of free and voluntary behavior's being caused by motives, desires, volitions, and the like.

**DETERMINISM AND MODERN PSYCHIATRY.** Contemporary psychiatrists are for the most part highly impatient with theories of human freedom, particularly the theories with which philosophers are familiar. Whether all or most human behavior is causally determined is, after all, an empirical question of fact, and psychiatrists profess to know with considerable assurance not only that it is but to some extent what the causal factors are, particularly in cases of deviant behavior. Philosophers have largely been content to speak in general terms of motives, volitions, desires, and the like as the springs of action, but psychiatrists speak of specific unconscious fears, defenses, and hostilities. One finds in their writings, in fact, an extensive and elaborate terminology for the identification and description of hitherto undreamed of forces that are supposed to be the real determinants of

behavior, including certain typical human behavior that both the learned and unlearned have long been accustomed to thinking of as rational, deliberate, and free. Philosophical speculations on the problem of free will have, as a result, come to appear rather superficial to many of those who are familiar with psychiatry.

*Hospers's opinion.* Perhaps no contemporary philosopher has done more toward viewing these problems in the light of modern psychiatry than John Hospers. One can, according to this writer, agree with the philosophers who maintain that freedom is opposed not to causality but to restraint and compulsion and also think of human behavior as being typically caused by human desires and even volitions. He nevertheless advances impressive empirical evidence, drawn from typical cases of the kind long familiar to psychiatry, to show that our very desires, volitions, and even deliberations are the product of unconscious forces, compromises, and defenses that are not only not within our control but whose very existence is usually unsuspected by those—all of us—who are their victims; that they were for the most part implanted in us in our earliest years, to which our memory does not even extend; and that our after-the-fact explanations or reasons for our behavior are mostly illusions and wishful thinking. "It is not," Hospers claims, "as if man's will were standing high and serene above the flux of events that have moulded him; it is itself caught up in this flux, itself carried along on the current." Spinoza compared a man with a conscious stone which thinks it moves freely through the air only because it does not know the cause of its motion, and Baron d'Holbach compared him with a fly riding on a heavy wagon and applauding itself as the driver. Hospers similarly says that a man is "like the hands on the clock, thinking they move freely over the face of the clock," a comparison that is particularly apt in the light of the psychiatrists' claim that the forces that move us lie within us and are normally deeply hidden.

Philosophers almost entirely agree that if a man's behavior is the effect of a neurosis or inner compulsion over which he has no control and of which he usually has no knowledge, then in a significant sense he is not morally responsible, and in any case he certainly is not free. The most common illustration of this is kleptomania. What is philosophically significant about kleptomania is that its victim does act according to his own volition and desire but that the volition and desire are themselves the product of a neurosis. The profound significance of Hospers's view lies in his claim, which with considerable justification he believes is empirically sup-

ported by psychiatry, that virtually all significant behavior is of the same order as kleptomania and other familiar compulsions, having its sources in the unconscious. The issue is accordingly not a philosophical one but an empirical one. It is simply whether, in fact, as Hospers graphically expresses it, “the unconscious is the master of every fate and the captain of every soul.” His defense of this claim is an array of fairly typical cases that are quite well understood by psychiatrists—the compulsive gambler who always plays until he loses, the man who inwardly loves filth and so washes his hands constantly, the mother who lets her child perish of illness on the train because she “must get to her destination,” and so on. In case histories like these, Hospers believes, we can, if we are honest and sophisticated, see our own lives and conduct partially mirrored and perhaps begin to have some inkling of the unconscious, deeply hidden but powerful forces that almost entirely determine what we are and what we do. If Hospers is right and if psychiatrists do actually know what they confidently claim to know—and it would be very rash to suggest that they really do not—then the problem of determinism versus free will is not, as Hume thought, resolved in a way that accommodates both views. It is, rather, solved, and it is solved on the side of hard determinism with all the enormous and, to some minds, shocking implications that theory has for morals and law.

**THE THEORY OF SELF-DETERMINATION.** The great difficulty of indeterminism, as previously noted, is that it seems to imply that a “free” or causally undetermined action is capricious or random. If one’s action is strictly uncaused, then it is difficult to see in what sense it can be within the control of an agent or in any way ascribable to him. The difficulty with determinism, on the other hand, is that it seems to render every action ultimately unavoidable. The implications of determinism do not therefore significantly differ from those of pure fatalism.

It is partly in order to meet both of these difficulties that some philosophers have defended a theory of self-determination or agency. The essential elements of all such theories are that men are the sources or causes of their own actions; that their being the source or cause distinguishes those bodily motions that are actions from those that are not, the latter being caused by something other than themselves; and that free actions are those that an agent performs or produces but that he is not caused by anything else to perform or produce. This theory thus distinguishes “action,” or “agency,” as a basic philosophical category, treating actions as different in kind from

other events and as not in any way describable in terms of the latter.

The theory of self-determination is most fully and clearly set forth by Thomas Reid in his *Essays on the Active Powers of Man*, though he does not call his theory by that name. The basic idea, however, was, according to Cicero’s essay *On Fate*, advocated by Carneades. It has also been defended by G. W. Fichte and Samuel Clarke. Aristotle seems to have had some such conception in mind when he spoke of men and other animals as self-moved, and Kant also seemed to when he ascribed to men a special causality of freedom and distinguished this sharply from ordinary causality. Perhaps its best-known advocate among contemporary philosophers is C. A. Campbell, who ascribes a “creative activity” to “selves”—that is, to minds or persons—and argues that men are capable of originating their own actions in opposition to the inclinations of their characters.

*Carneades on causality and freedom.* Carneades, in trying to resolve the problems begotten by the Epicurean theory of uncaused swerves of atoms, on the one hand, and the fatalism of their opponents, on the other, suggested that the idea of being uncaused is ambiguous, like the idea of something’s being empty. When one describes a vessel as empty, one does not ordinarily mean that it is absolutely empty—that it does not contain even air, for example. One means only that it does not contain oil or wine or whatever one might expect. Similarly, when one says that a man’s action was uncaused, one does not mean that it was without any cause at all but only that it had no antecedent cause. This is compatible with its having been caused by the agent himself. Carneades noted, moreover, that the Epicureans themselves ascribe the power of motion to atoms, giving no account or cause of why they should be in motion other than that it is their nature to move. Why, then, may not men be thought of as having a similar original power of motion without supposing that some antecedent force must set them going? When men act freely, he thought, they are simply the sources of their own behavior, which is therefore caused, though not caused by anything external to themselves. One acts unfreely when one is caused to act as one does by some antecedent and external force. This way of viewing the matter, Carneades suggested, does not imply any fatalism, nor does it imply that a man’s actions are random, like the swerves of the atoms. To say that a man is the cause of his own action does not imply that he was unable to cause any other action, nor does it imply that his action was uncaused.

*Reid's theory.* Reid developed many arguments against determinism, which he sarcastically called “the glorious system of necessity,” but his own positive theory is remarkably similar to that of Carneades. Reid argued that determinism is inconsistent with a whole range of beliefs that are shared by all mankind and maintained that we have far more reason for adhering to these than for affirming any philosophical theory with which they are inconsistent. In particular, he maintained that determinism is incompatible with deliberation, with morality, and with the pursuit of ends. When, for example, a man deliberates about some possible course of action, he assumes that the proposed end, as well as the means to its attainment, is within his power to accept or reject—that is, that it is up to him whether the end shall be sought and if so, how. Without this belief he could not deliberate. The belief itself, however, is incompatible with determinism, for determinism entails that no act that is performed was avoidable and that in this sense it is never up to any man what he does. Again, all men believe that a basic distinction can be made between acts that are blameworthy, praiseworthy, and neither. Determinism, however, implies that every act that is performed is ultimately unavoidable and, hence, that no such basic distinction can be made. Finally, all men believe they can pursue, sometimes over a long period of time, certain ends that they have previously conceived. This implies, however, that their actions in pursuit of such ends are within their own power and control, which is inconsistent with determinism.

Reid therefore defined the liberty or freedom of a moral agent as “a power over the determinations of his own will,” a definition that contrasts interestingly with Hume’s definition of freedom as “a power of acting or not acting according to the determinations of the will.” In rejecting determinism, Reid did not, however, affirm that human actions are uncaused. On the contrary, he maintained that nothing happens without a cause, that everything that changes is changed either by some other thing or by itself. Not all causes, then, are antecedent and external causes. Some things, such as men, are sometimes the causes of their own behavior. Indeed, Reid took this to be the very reason for calling a man an agent—namely, that he is a being who acts, not merely one that is acted upon. To speak of an agent being caused to act by something other than himself was for Reid a contradiction, so that acting and acting freely amount to the same thing, whereas the idea of a necessary agent amounts to a contradiction.

It is evident that Reid employed the concept of causation differently from Hume. A cause, he said, is not merely some change that always accompanies another. It is always something that has the power to produce a change, whether in itself or in something else, and no man can define it beyond this. In fact, he maintained that no man would even understand any philosophical definition of a cause if he did not first have the idea of causation from the awareness of himself as an agent. There is, then, no reason why men may not be the original causes of their own voluntary actions, which is precisely what all men believe themselves to be. This way of viewing the matter permits us to say that determinism, defined as the thesis that everything that happens is the result of some antecedent cause or causes, is false and, further, that nothing occurs without any cause whatsoever. Reid’s philosophy thus overcomes the chief difficulties of both determinism and simple indeterminism. It accomplishes this, however, only by introducing what many philosophers have thought to be an enormous difficulty of its own—namely, understanding how anything can be the cause of its own changes. One is reminded of Hobbes’s dictum, “Nothing taketh a beginning from itself.” Alexander Bain pressed this difficulty in both Reid’s and Samuel Clarke’s philosophies, maintaining that it rendered their claims quite unintelligible, and Patrick Nowell-Smith has made the same point against C. A. Campbell’s similar views. The idea of something’s being self-moved in the sense understood by Carneades, Reid, Clarke, and Campbell is obviously entirely unlike any concept of physics. Accordingly, Nowell-Smith has suggested that it should be understood in the way such physical concepts as self-regulating, self-propelled, self-starting, and the like are understood, thus rendering it less esoteric. It was Reid’s view, however, that this seeming difficulty is only a fact, that all men really do consider themselves to be the causes of their own voluntary actions in a sense in which no inanimate things are ever causes, and that we should be guided in our opinions not by what this or that system of philosophy requires but by what the common sense of mankind universally affirms.

THE “STRONGEST MOTIVE.” It is fairly common to suppose that a man invariably acts—in fact, must act—in response to his “strongest motive” and that voluntary behavior is therefore always causally determined by such motives. Philosophical determinists frequently fall into this line of thought, sometimes substituting “strongest desire” for “strongest motive,” though it is now less common than it once was. It is well illustrated in one of Alexander Bain’s discussions of the free will controversy,

in which he writes that “in the absence of prohibition, [an agent’s] decision follows the strongest motive; being in fact the only test of strength, of motive on the whole.” Again, Bain notes that “any supposition of our acting without adequate motive leads at once to a self-contradiction; for we always judge of strength of motive by the action that prevails” and, further, that the action that follows upon deliberation “testifies which motive has in the end proved the strongest.”

It is to the credit of Thomas Reid, with whose writings Bain was familiar, that he exhibited both the source of the considerable persuasiveness of such reflections as these and at the same time their fallaciousness. The reason this kind of claim has seemed so compelling to so many philosophers is that it has functioned as an analytic statement or one that is rendered true by definition of the concept of a “strongest motive.” As such, it sheds no light whatsoever on any fact of human nature and leaves entirely unanswered the question of whether voluntary actions are really caused.

What, Reid asked, is the test of whether the motive that is strongest is the one acted upon? It is simply the motive that prevails. The claim that a man acts upon his strongest motive therefore means, Reid noted, only that he acts upon that motive upon which he acts, which is hardly a significant philosophical claim. If, however, we apply any other criterion for distinguishing which motive is strongest, then there is nothing at all to suggest that we always act on our strongest motives. On the contrary, it is a fairly common experience to feel strongly motivated to do something from which we nevertheless refrain from purely rational considerations, for example, or perhaps from moral ones. The temptation here, of course, is to say that the fact that one refrains from a given action only shows that some contrary motive is “stronger,” but this indicates that we are again using as our concept of the strongest motive the motive that prevails and saying nothing more than that a man acts upon the motive upon which he acts.

Reid, however, went further than this by denying that motives can be likened to forces and that varying “strengths” can be ascribed to them in the first place. A motive, he said, is not a cause but a rational consideration of a reason. As such, it is something purely abstract, which has “strength” or “weakness” only in the sense of expressing wisdom, prudence, or the opposites. A “conflict of motives” is nothing at all like the conflict of opposing forces, one of which overcomes the other by superior force. It is more to be likened to the conflicting pleas of contending attorneys. One of these can be

“stronger” or have more “force” or “weight” than the other only in the sense that it is more reasonable and persuasive. When, accordingly, we speak of rational or intelligible considerations as having “force,” “weight,” or “strength,” we are not using these notions in the sense they have for physics but as metaphors borrowed from physical nature. It is, Reid thought, largely from mixing these literal and metaphorical meanings that some persons are led into theories of determinism and into supposing that human nature bears a greater resemblance to inanimate bodies than it actually does.

## CONTEMPORARY PROBLEMS

The problems of determinism are still very lively in philosophy and have recently gained powerful momentum from detailed philosophical analyses of peripheral questions. Most current philosophical discussion bearing on the problem of free will is not aimed directly at whether men have free will, but at a whole host of questions that have been begotten by this long controversy. Ludwig Wittgenstein’s reflections have made it evident, for example, that philosophers do not even know what it means to call something an action in the first place or just how some of men’s bodily motions qualify as actions while others do not. It is an elementary distinction that is constantly made by common sense, but philosophers have thus far been unable to analyze it. Obviously, as long as this ignorance prevails, there is little point in discussing whether men’s actions are ever free. Certain recent writers, such as Arthur Danto, have suggested that the concept of an action is basic and unanalyzable and that it corresponds to nothing that is found in physical science. Previous generations of philosophers often took for granted that an action is a bodily motion caused by some such inner episode as a volition, motive, desire, or choice, but these terms are now used with much greater care.

Gilbert Ryle, in his *The Concept of Mind*, declared volitions to be a fabrication of philosophy, corresponding to nothing that has ever existed, and since his devastating critique of this whole notion there has been great reluctance among scholars even to employ the word. The concepts of desire, motive, choice, and kindred notions have been similarly subjected to criticism, so that fewer philosophers are still willing to speak blithely of them as causes. A. I. Melden, for example, maintained that no particular motive can be described at all independently of the action of which it is allegedly the cause and that its connection with an action is therefore a logical one, not, as Hume and so many others supposed, a causal one. Moreover, Melden pointed out that if an action is con-

ceived of as a bodily motion together with its motive in order to distinguish actions from bodily motions that are not actions, then it is plainly impossible to explain any action in terms of its motive, as philosophers were once so ready to do.

The interpretation of statements expressive of human ability as either disguised or incomplete conditional statements has likewise been considerably unsettled by the precise and detailed analyses of J. L. Austin. In his celebrated essay "Ifs and Cans" this writer maintained that statements involving the locution "I can" cannot possibly require, for their complete sense, the addition of some such hypothetical as "if I choose" but are, instead, to be understood in some absolute sense. Accordingly, they do not, as so many philosophers since Hume have supposed, express the idea of a causal condition at all. "I could have if I had chosen," is similarly claimed by Austin to express a past indicative rather than a conditional despite its grammatical form, for it normally expresses the idea of having had an opportunity or ability rather than the idea of a causal connection between one's choice and one's action. In statements involving the locution "I shall if I choose," the word *shall*, according to Austin, is normally expressive of an intention rather than a simple future tense and thus also differs essentially from other conditionals in the future tense. Such painstaking analyses as Austin's, although not pursued with the explicit aim of supporting or disconfirming any theories of determinism or free will, have nevertheless considerably weakened some of the strongest defenses of determinism since so many of them have more or less presupposed that statements expressive of human ability, which are so central to any discussion of free will, are simply disguised statements of causal conditions and thus are not only consistent with, but actually imply, a theory of determinism for the very understanding of them.

The highly refined and critical inquiries of contemporary philosophy have brought into further question the whole concept of the will. Is willing to do something an act, for instance, or not? If it is, then how does it shed any light on the concept of acting? If it is not, then how does an action differ from any other bodily change having an inner psychological cause? Clearly, no difference is marked merely by applying different names to such things. Furthermore, if there are such things as acts of will, do they or do they not require antecedent causes? If not, then why should any action require an antecedent cause? If so, then how are deliberate or willed actions to be distinguished from simple compulsions?

Closely associated with the notion of the will is that of intending. Doing something intentionally is now seldom thought of as merely undergoing some change as the result of an inner intention, intentions currently being thought of more in the manner in which Reid described motives—namely, as reasons and purposes having a rational content. Again, it is fairly common practice among contemporary philosophers to distinguish sharply, as Reid did, between the causes of an action and the reasons for it. If this is a real distinction, then it follows that whether some human acts are reasonable and intelligible is quite independent of whether they are caused, and there is no absurdity in describing an action as both free, in the sense of being avoidable and not the effect of antecedent conditions, and rational. This line of thought has raised anew the whole problem of understanding purposeful behavior. Men often do certain things in order to achieve certain results, and this appears to distinguish human behavior from the behavior of inanimate things in a fundamental way. When philosophers were more eager than they are now to interpret human behavior within the framework of determinism, many of them assumed that purposeful behavior was simply behavior that is caused by purposes, desires, or intentions, but this conception harbors the same difficulties as the volitional conception of action that Ryle, Melden, and others have so severely criticized. If one is acting in acting purposefully and if action can be distinguished from such other bodily behavior as digestion, perspiration, and the like only in terms of concepts like purpose, desire, or intention, then one can hardly explain purposeful activity as action that is caused by one's purpose, desire, or intention. The connection is conceptual rather than causal. Desires, purposes, and intentions are, moreover, desires for this or that, purposes or intentions to do this or that, and their objects or aims may never be realized. Thus, they are what we sometimes call "intentional" concepts, and there seems to be nothing that completely corresponds to them in the realm of physical science. No inanimate thing, for example, can without metaphor be spoken of as behaving as it does in response to its desire for something which perhaps never has and never will exist, and no engineer who spoke in that manner of even the most sophisticated machine would ever suppose that he had thus given a causal explanation of anything.

More and more philosophers are inviting attention to certain fundamental differences between the way men view the past and the future. The future, some have wanted to suggest, is a realm of possibilities in a sense in which the past is not. This idea is at least as old as Aristo-

tle's philosophy, but the renewed interest in whether men's actions might be free in some sense not countenanced by determinism has quickened interest in it. It is, for example, sometimes contended that there is a fundamental difference between finding that something is true and making something become true, a contention that renders the concept of action more fundamental than it was once supposed to be and raises anew the question of what is meant by acting freely.

The question, then, of whether determinism is true or of whether men have free will is no longer regarded as a simple or even a philosophically sophisticated question by many writers. Concealed in it is a vast array of more fundamental questions, the answers to which are largely unknown.

### Bibliography

The literature on determinism and free will is so vast that only a sampling can be given here.

A good though not recent critical history of the controversy is outlined in Alexander Bain's *Mental and Moral Science* (London, 1872), Book IV, Ch. 11. More recent general studies include Sidney Hook, ed., *Determinism and Freedom in the Age of Modern Science* (New York: New York University Press, 1958), which is a collection of papers by contemporary philosophers, and Sidney Morgenbesser and James Walsh, eds., *Free Will* (Englewood Cliffs, NJ: Prentice-Hall, 1962), which brings together carefully selected discussions from classical and modern writers and is intended mainly for students. A widely read but superficial discussion of the problem is contained in D. F. Pears, ed.,

*Freedom and the Will* (New York: St. Martin's Press, 1963), which is in part the transcription of a series of discussions by contemporary philosophers most of whom are connected with Oxford University.

### ETHICAL DETERMINISM

The ethical determinism associated with Plato and Socrates is a theme of Plato's *Protagoras* and *Gorgias*, and certain elements of this theory are treated rather unsatisfactorily in his *Hippias Minor*. Aristotle discusses the theory and related problems in the *Nicomachean Ethics*, Book VII, Ch. 2.

### LOGICAL DETERMINISM

The most frequently cited reference in discussions of logical determinism is the ninth chapter of Aristotle's *De Interpretatione*. Among the many more recent discussions of the problems arising from those passages are A. N. Prior's "Three-Valued Logic and Future Contingents," in *Philosophical Quarterly* 3 (1953): 317–326; R. J. Butler's "Aristotle's Sea Fight and Three-Valued Logic," in *Philosophical Review* 64 (1955): 264–274; G. E. M. Anscombe's "Aristotle and the Sea Battle," in *Mind* 65 (1956): 1–15; Richard Taylor's "The Problem of Future Contingencies," in *Philosophical Review* 66 (1957): 1–28; R. Albritton's "Present Truth and Future Contingency," *ibid.*: 29–46; and C. Strang's "Aristotle and the Sea Battle," in *Mind* 69 (1960): 447–465.

One of the best sources for the ancients' views on both determinism and fatalism and the only source for some of them is Cicero's *De Fato*, translated by H. Rackham for the Loeb Classical Library (London, 1942). The problem of fatalism, conceived of essentially as it was by ancient philosophers, has been extensively discussed in recent literature—for example, in Gilbert Ryle's provocative essay "It Was to Be," which is Ch. 2 of his *Dilemmas* (Cambridge, U.K.: Cambridge University Press, 1954), and by A. J. Ayer, "Fatalism," the concluding chapter of his *The Concept of a Person* (New York: St. Martin's, 1963). Richard Taylor's "Fatalism," in *Philosophical Review* 71 (1962): 56–66, was followed by many critical discussions by various British and American authors in subsequent issues of the same journal and in *Analysis* 23 (1962) and 24 (1963), and in the *Journal of Philosophy* 61 (1964) and 62 (1965).

### THEOLOGICAL DETERMINISM

Leibniz's claim that God could create no world except the best one possible and the implications he drew from this are found in his *Discourse on Metaphysics* and his *Theodicy*. St. Thomas Aquinas's opinions on the moral determination of God's will are set forth in the *Summa Theologiae*, Part I, Q. 19, especially Articles 9 and 10.

The question whether determinism and fatalism follow from the conception of God as an omniscient being has been discussed by countless authors. St. Augustine's views, for example, are reproduced in a selection titled "On Free Will," in Morgenbesser and Walsh, *op. cit.*, and also in *The City of God*, Book XI, Ch. 21. Boethius's famous treatment of the problem is given in *The Consolation of Philosophy*, Book V. St. Thomas Aquinas discusses it in the *Summa Theologiae*, Part I, Q. 14, Article 13. His views and the views of various other Scholastics are given in Frederick Copleston's excellent *History of Philosophy*, Vols. II–III (London, 1950–1953). An extensive defense of theological determinism and

predestination on various grounds is given by Jonathan Edwards in his famous *Freedom of the Will*, edited by P. Ramsey (New Haven, CT: Yale University Press, 1957). Charles Hartshorne's rather novel and perceptive reconciliation of free will with certain theological presuppositions is found in Ch. 3 of his *Man's Vision of God* (Chicago: Willett Clark, 1941). Although some of the foregoing sources raise the question of predestination, this doctrine, developed specifically as an implication of God's power, is more fully developed in St. Augustine's *Treatise on the Predestination of the Saints*, in the Nicene and Post-Nicene Fathers, first series, Vol. V, edited by Philip Schaff (New York, 1902); see also Augustine's *Enchiridion on Faith, Hope and Love*, edited by Henry Paolucci (South Bend, IN: Regnery/Gateway, 1961). Martin Luther's uncompromising denial of human free will is set forth in his polemic with Erasmus, under the title *Discourse on Free Will*, translated by Ernst F. Winter (New York: Ungar, 1961). John Calvin's defense of the same doctrine can be found at the close of the third book of his *Institutes of the Christian Religion*.

#### PHYSICAL DETERMINISM

The materialism of the Epicureans and the manner in which they tried to reconcile this with free will are beautifully exhibited in Lucretius's *On the Nature of Things*; an excellent source for earlier Epicurean arguments is Cicero's *De Fato*. Thomas Hobbes's materialism and arguments in favor of determinism are most fully expressed in *On Human Nature*. A more readily available source of Hobbes's important writings on this question is a paperback book of selections edited by Richard S. Peters, *Body, Man and Citizen* (New York: Collier, 1962). Arthur Schopenhauer, though he was not a materialist, defended a theory very similar to that of Hobbes in his *Essay on the Freedom of the Will*, translated by K. Kolenda (New York: Liberal Arts Press, 1960).

#### PSYCHOLOGICAL DETERMINISM

Most discussions of determinism and free will in modern philosophy have been within the framework of psychological determinism, which assumes that human behavior has its origins in psychological causes of various kinds. Descartes's defense of free will within this context is expressed in the fourth of his *Meditations* and also in *The Principles of Philosophy*, Part I, Sections 32–39. John Locke's extremely vacillating but influential discussion is found in *Essay concerning Human Understanding*, Book II, Ch. 21, where he discussed at length the idea of power. The classic attempt to reconcile determinism and liberty was achieved by David Hume in Section 8 of his *Enquiry concerning Human Understanding*. A defense along similar lines has been given, among numberless others, by C. J. Ducasse, in Ch. 11 of *Nature, Mind and Death* (La Salle, IL: Open Court, 1951). A now famous essay expressing essentially the same view was written by Dickinson Miller under the name R. E. Hobart and titled "Free Will as Involving Determinism and Inconceivable without It," in *Mind* 43 (1934): 1–27. J. S. Mill defended Hume's theory in his *Examination of Sir William Hamilton's Philosophy*, the relevant excerpts from which are reprinted in Morgenbesser and Walsh, op. cit.

Problems of moral responsibility are involved in almost every discussion of determinism and are central to most of them. Immanuel Kant's treatment of the problem and his defense of the idea of a causality of freedom are given in his *Critique*

*of Pure Reason*, under the section "Transcendental Dialectic," particularly in his discussion of the third "antinomy," and, more fully, in his *Critique of Practical Reason*. C. D. Broad's influential and highly elaborate analysis, "Determinism, Indeterminism and Libertarianism," appears in his *Ethics and the History of Philosophy* (London: Routledge, 1952) and has been reprinted in Morgenbesser and Walsh, op. cit. Problems of determinism and responsibility are discussed by several authors in Hook, op. cit., particularly in the essays by Paul Edwards, "Hard and Soft Determinism," and John Hospers, "What Means This Freedom?" Both authors vigorously defend determinism and the claim that determinism and moral responsibility cannot be reconciled with each other.

William James's essay "The Dilemma of Determinism," in which the distinction between hard and soft determinism was first made, is included in almost all of the many collections of his popular essays. Most modern and contemporary writers who have defended deterministic theories have also defended some version of soft determinism, though they have seldom used the term itself. Examples, in addition to most of those already mentioned, are Patrick Nowell-Smith, in the last two chapters of his *Ethics* (Baltimore: Penguin, 1954), and A. J. Ayer, in Ch. 12 of his *Philosophical Essays* (London: Macmillan, 1954).

The most thoroughgoing defense of the theory of self-determinism was given by Thomas Reid, in his *Essays on the Active Powers of Man*, of which there have been many editions. A contemporary defense of what is essentially the same theory is given by C. A. Campbell, in Ch. 9 of *Selfhood and Godhood* (London, 1957). The same book contains an appendix in which the opinions of Patrick Nowell-Smith are subjected to a most thoroughgoing criticism. A similar concept is defended by Richard Taylor in "Determinism and the Theory of Agency," in Hook, op. cit. The same theory underlies Taylor's "I Can," in *Philosophical Review* 69 (1960): 78–89, reprinted in Morgenbesser and Walsh, op. cit. Another article that indirectly suggests such a view is Arthur Danto's "What We Can Do," in *Journal of Philosophy* 60 (1963): 435–445. Determinism is also attacked at great length in Konstantin Gutberlet, *Die Willensfreiheit und ihre Gegner* (Fulda, Germany, 1893), and in Ch. 9 of M. Maher, *Psychology* (London, 1940). These two works are written from a Catholic point of view.

A. I. Melden's *Free Action* (London, 1961) offers fairly elaborate and penetrating analyses of a wide range of concepts that have always been central to the free will controversy, such as those of wants, motives, actions, and so on; although the author does not try to prove directly that men have free will, he attacks the bases of certain widely held determinist theories. Gilbert Ryle's *The Concept of Mind* (London: Hutchinson, 1949) contains a chapter, "The Will," which amounts to a devastating critique of the idea that voluntary actions are caused by volitions. J. L. Austin's "Ifs and Cans," which is included among his *Philosophical Papers*, edited by J. O. Urmson and G. J. Warnock (London: Oxford University Press, 1962), is a painstaking inquiry into what is meant by saying of an agent that he could have done otherwise; although it is directed at claims made specifically by G. E. Moore and Patrick Nowell-Smith, it actually attacks the foundations of theories that have been widely held for over a century.

A detailed and annotated bibliography of works on determinism and free will can be found in Paul Edwards and Arthur Pap, eds., *A Modern Introduction to Philosophy*, 2nd ed. (New York: Free Press, 1965).

*Richard Taylor (1967)*

## DETERMINISM, THEOLOGICAL

Theological determinism or predestination is the belief that events are determined or necessitated by God. One form of the traditional belief insists that owing to his omnipotence, God controls the occurrence of things. Another form asserts that his omniscience, making possible his foreknowledge of future events, affects the occurrence of such events. There are also nontraditional forms. Throughout the history of Islamic and Jewish philosophy, the debate over predestination was central.

When Islamic philosophy emerged in Baghdad in the ninth century CE, the religious and intellectual circles in the city had been witnessing a heated debate over the issue of predestination (*al-qadar*). There were three main Islamic views at the time: events in the universe, including human actions, are not predestined (*Mu'tazila*); all such events are predestined (*Jabriyya*); some aspects of such events are predestined, whereas others are humanly "acquired" (*Ash'ariyya*). In treating this issue, Muslim philosophers tried to reconcile Greek rationalism with Islam.

Abū Yūsuf al-Kindī (c. 801–873) and Abū'l-Walīd Ibn Rushd (Averroes, 1126–1198) denied predestination. They interpreted the Islamic revelations to assert that God does not, for example, control human actions. They both believed that at the moment God desires or wills something to happen, it happens. However, neither God's power nor his knowledge necessitates that he desire or will everything that happens to happen. If one reads Ibn Rushd carefully, though, one discovers that for him, God determines all events, because his omnipotence means that he fulfills all possibilities. Such fulfillment includes that of the natures of things and the laws that govern them. The conduct of any being is consequent upon its nature and its laws. In some of his writings, Ibn Rushd also stresses that God's knowledge of things is the cause of those things.

Abū al-Naṣr al-Fārābī (870–950) and Abū'Alī al-Husayn ibn Sīnā (Avicenna, 980–1037) adhered to neoplatonic tendencies, according to which everything necessarily follows from God's nature. Even God's nature

itself is necessitated to act in certain ways. There is no room for God's will or choice, let alone the will or choice of any other being. This is despite the fact that al-Fārābī and Ibn Sīnā speak of God's omnipotence and omniscience, and even of human free will. However, they do not use these terms in the traditional sense. "Omnipotence," for example, is the ability to fulfill all possibilities, and omniscience is knowledge of universals.

Abū Ḥāmid al-Ghazālī (1058–1111) attacked such philosophical views in his famous work *The Incoherence of Philosophers* (1184). He considered such ideas non-Islamic and classified some of them, for example, God's inability to know particular events, as heretical. In the absence of such knowledge, reward and punishment, which are essential to Islam, become meaningless, especially in light of the Islamic concept of God's absolute justice.

Reward and punishment did not pose a problem for al-Kindī, because he believed that human beings have free will and that God knows particular events. Therefore, reward and punishment are not in conflict with his justice. The other three philosophers mentioned were not concerned about the issue either. For them, God does not reward and punish people. According to al-Fārābī and Ibn Sīnā, following death, bodies eventually disintegrate and souls become close to or distant from God, based on their degree of knowledge. Their closeness is their reward; their distance is their punishment. Reward and punishment are necessary consequences of the souls' conduct in life. To Ibn Rushd, there is no reward and punishment after death. The bodies disintegrate and the individual souls merge with the universal soul.

Moses Maimonides (1135–1204) asserts the Judaic belief that the human soul is intrinsically free, and agrees with the Greek and Muslim philosophers that matter is the source of natural evil. Thus, he absolves God from moral and natural evil, and justifies reward and punishment for the former, because God does not predetermine human action. However, God can intervene under certain circumstances. Maimonides was criticized by many Jewish thinkers for his rational approach to Judaism, which they feared denies some of its basic ideas, for example, that God wills whatever happens according to his knowledge of the natures of things.

## DETERMINISM AND FREEDOM

Determinism is the family of theories that takes some class of events to be effects of certain causal sequences or chains, more particularly certain sequences of causal circumstances or causally sufficient conditions. One of these theories, universal determinism, associated with much science and philosophy, concerns the class of all events without exception. Another theory concerns physical events. Determinism in a third and important sense is human determinism. It is the theory that our choices and the many other antecedents of our actions, and the actions themselves, are effects of certain causal sequences. Lesser theories, usually associated with Freud and given no philosophical attention to speak of, concern themselves with particular sorts of conscious or otherwise mental causes of choices and actions, notably early sexual desires.

There are various relations between these four determinisms, depending on how they are additionally characterized. The most important relation, perhaps, is that universal determinism entails human determinism. That is not to say, however, that human determinism cannot be asserted, supported, or proved independently of universal determinism.

It is explicit or implicit in any of the above theories that the events in question are effects as more or less standardly conceived. An effect is an event such that an identical event follows every counterpart of the causal circumstance in question, or an event such that because the circumstance occurred, the event was in a stronger sense necessitated or had to happen (Sosa and Tooley 1993). A theory of our choices and actions, in contrast, that has to do with effects so-called—say, for example, effects conceived as events preceded by merely necessary conditions, or events merely made probable by antecedents—would not ordinarily be taken as a determinism. Indeed, weaker ideas of effects have often enough been introduced by philosophers precisely in order to avoid something else explicit or implicit in deter-

minisms—that they may be inconsistent with or pose a challenge to beliefs in human freedom.

### HUMAN DETERMINISM

This entry's concern will be with human determinism. It involves three large problems or enterprises.

The first is the formulation of a conceptually adequate theory. Human determinism has traditionally been thought about without reference to the philosophy of mind. Still, an adequate treatment of it must rest on a theory of the mind that is conceptually adequate: clear, consistent, and something like complete. Also, it must surely be that the theory of the mind, perhaps in what it rejects, say a puzzling power of originating choices, should be consonant with the philosophy of mind generally (Priest 1991, Heil 1998, Lowe 2000, Crane 2001).

The second problem with human determinism is its truth, whether or not this is considered in relation to universal determinism. The third problem is what can be called the human consequences for our existence of a human determinism. Is there in fact the consequence that we are not free? The philosophy of determinism and freedom, except in the philosophy of science and philosophical ruminations by scientists, has mainly concerned itself with this problem of consequences.

If these three problems are not the only ones that have been raised about determinism and freedom (Adler 1958), they have become the main ones (Kane 2002; Campbell, O'Rourke, and Shier 2004; Clarke 1995).

The formulation of a conceptually adequate theory is simple in terms of a truly physicalist or materialist philosophy of mind—one that takes conscious or mental events to have only or nothing but physical properties, however additionally conceived. In this case, human determinism becomes part of physical determinism. However, relatively few philosophies of mind are truly physicalist. Anomalous Monism, to mention one, is fairly typical in denying "nothing-but materialism" (Davidson 1980).

All other determinist theories face considerable problems of formulation. They encounter the problem of actually characterizing their primary subject matter—conscious or mental events. There is also the problem of the psychoneural relation, traditionally called the mind-body problem. If mental events are taken not to be in space, how can they be lawlike correlates or effects or causes? Further difficulties include the avoidance of epiphenomenalism, the nineteenth-century doctrine that actually makes conscious antecedents no part of the causation or explanation of our actions.

It is my view, seemingly now shared with most philosophers of determinism and freedom in the early twenty-first century, that despite these difficulties a conceptually adequate theory of human determinism can be formulated. This used to be doubted (Austin 1961, P. F. Strawson 1968).

Is any theory of human determinism true? A conceptually adequate theory has the support of much ordinary rationality, philosophy, and much science. It is notable that the ordinary philosophy of mind has no indeterminism in it. This most flourishing part of philosophy, much of it concerned with exactly the explanation of behavior, contains nothing at all of origination, an uncaused or uncausing initiation of choices and actions. Contemporary neuroscience, as distinct from philosophizing by retired neuroscientists and the like, plainly proceeds on the assumption of a human determinism. A reading of any of the main textbooks of neuroscience confirms this (Kandel et al. 1991) It is worth remarking, about what was called ordinary rationality, that in the end, which may be a long way down the line, it sits in judgment on science itself. That is to say, first of all, that inconsistency is not an option.

#### DENIALS OF HUMAN DETERMINISM

Despite these considerations, many or most of us do not take human determinism to be true. We deny or more likely doubt it. There may be an explanation of this, as distinct from a ground or justification, in our culture, at any rate European and North American culture.

One familiar ground used for this denial or doubt has been interpretations of quantum theory—applications to the world of the formalism or mathematics in which this part of physics can be said actually to consist. According to these interpretations, there are things at a microlevel of reality that are not effects. These things, well below the level of neural events in the brain, the events of ordinary neuroscience, are taken as made probable by antecedents but not necessitated by them. They are not chance events in the sense of being events of which it is true in advance that they are as likely not to occur as to occur. However, each one is certainly a chance event in that its actual occurrence or existence, no matter the antecedent probability, is such that there exists no causal explanation to be found for it. This is a matter of what is in the world, not our capabilities of knowing it.

Perhaps there is no strong consensus within science as to the truth of such indeterminist interpretations of quantum theory, despite an inclination in that direction. Something of the same sort may be true within physics

itself. It is notable that outstanding treatments of the question in the philosophy of science may be agnostic (Earman 1986, 2004).

Opposition to indeterminism, some of it by philosophers, is strengthened by the fact, too often glossed over, that no satisfactory interpretation of quantum theory's application to reality has ever been achieved, although the theory is now getting on for a century old. It is possible to try to explain an ascendancy of an indeterminist understanding of quantum theory, say among other philosophers who would not tolerate contradiction, obscurity, and mystery elsewhere, by the fact of a cultural and institutional ascendancy of science in general and physics in particular. It is unclear to me why indeterminist interpretations have persisted within physics in the absence of any direct and univocal experimental evidence (Bohm and Hiley 1993, van Fraassen 1991, Bub 1997).

One opposition to the idea that indeterminist interpretations of quantum theory prove or indicate the falsehood of determinism has to do with the supposedly undetermined things. Are they in fact events, which is to say things that happen; perhaps understood as ordinary things having properties at or for a time (Kim 1973)? Determinism has no concern with anything other than events. Numbers or propositions or other abstract objects, for example, are not part of its subject matter of effects. It does not say five is an effect. A reading of accounts of quantum theory quickly establishes that it is not clear that the things denied to be effects, about which there is real and wide disagreement, are indeed things asserted to be effects by a determinism. Some of these have been probabilities, features of a calculation, and waves in abstract mathematical space.

There is another uncertainty about any undetermined microevents, assuming such real events to exist. What is their relation to macroevents, and in particular to the neural events ordinarily taken to be in some intimate connection with such conscious or mental events as choices? Does the microdeterminism issue in macrodeterminism? Does it “translate up”? Or does the microdeterminism, instead, “cancel out” (Weatherford 1982)?

It is difficult indeed to resist the proposition that there is no indication at all of macroindeterminism in the physical world. Taken together with the previous uncertainty about amplification, this appears to issue in a kind of dilemma. Either microindeterminism if it exists does not translate up, in which case it does not matter to the problem with which we are concerned—or, because it would translate up if it existed, and there is no macrodeterminism, it follows that microindeterminism does not exist.

Answers or attitudes with respect to the question of the truth of a determinism do indeed affect responses to the third problem, that of the consequences of human determinism. Someone inclined to the truth of determinism may then be inclined, partly as a result of the further inclination that we have some freedom or others, to the response that we must have a freedom that goes with determinism. Still, the problem of the human consequences of determinism can be considered on its own, as usually it has been by philosophers.

Traditionally those consequences have been taken as having to do with freedom or free will, moral responsibility, and the justification of punishment. The central question is whether determinism is compatible or consistent with free choices and actions, with holding people responsible for and crediting them with responsibility for actions, and with imposing justified punishments on people and rewarding them. Compatibilists, who can be traced back at least to the seventeenth century (Hobbes 1839), answer yes. Incompatibilists, with Hobbes's great adversary in their history, answer no (Bramhall 1844).

The stock in trade of compatibilists has been the conception of freedom as voluntariness. That, in a rudimentary account, is the conception of a free and responsible action as in accordance with the desire of the person in question rather than against his or her desire. It is the conception, they say, that issues in the seemingly indubitable judgment that a man chained to the wall is not free, and that a woman whose life is under real and immediate threat by someone with a gun is not free.

The stock in trade of incompatibilists has been the idea of freedom as origination. This, in a rudimentary account, is the conception of a free action as one that the person was not caused to perform, but which was up to the person or in his or her control. This is the conception, incompatibilists say, that is familiar to all of us in that most common thing in our lives: holding people responsible for things. We hold people responsible only, as we say, when they are not literally caused to do what they do, but have a choice. We take a man to have been free exactly when he could have done otherwise than he did.

## DEALING WITH OBJECTIONS TO HUMAN DETERMINISM

The rudimentary conception of freedom as voluntariness, as well expressed as the absence of ordinary constraint or compulsion, has been enriched in order to deal with objections. One objection was that people in the grip of an addiction are not acting against their own desire for heroin, but nonetheless are not free. A response

in defense of compatibilism has been that voluntariness consists in someone's acting according to a desire that they desire to have. There is the possibility, indeed, of thinking of a hierarchy of desires (Frankfurt 1971).

Other objections, or perhaps the reaction that both the rudimentary and the amended ideas of voluntariness do not do justice to the fullness of our reactions to people in their actions, may call up other developments. A free choice or action, it may be said, is not only in accordance with the desired desire of the agent rather than against it, but grows out of the personality, character, history, and indeed the very being of the person. Who can object, compatibilists ask, to the idea that such a choice or action, so autonomous, is what we take to be a free and responsible one?

The conception of freedom as origination has also been given much attention, again in response to objections, usually about obscurity. It has long been insisted that an originated decision, although not a standard effect, is not merely that. It is not merely a chance or random event. Hobbes's adversary Bramhall in the seventeenth century explained originated choices and actions as owed to the elective power of the rational will. It has become common to try to explain such choices by assigning them to what is called agent causation as against standard causation (Chisholm 1976, O'Connor 1995). Agent causation, whatever else is said of it, does not give rise to effects that had to happen or were necessitated. Other attempts to further clarify origination are in terms of teleology, in particular that the occurrence of choices and actions are somehow explained by their goals (O'Connor 1995), and in terms of a mixture of determined and undetermined events (Kane 1985, 2002), and in terms of reasons rather than causes (Ginet 1990).

It is clear that a determinism can be true and there can still be voluntary choices and actions. There is full compatibility. There is nothing in a theory of determinism that rules out choices and actions being according to someone's desire. Determinism is evidently never the theory that all choices and actions are against the wills of the agents. Compatibilism, indeed, is best seen as based on the proposition that free choices and actions have certain causes, causes somehow internal to rather than external and somehow opposed to the agent.

It is equally clear that if a decent theory of determinism is true, there can be no originated choices and actions. There is clear incompatibility. An originated choice or action, by rudimentary definition, is an event that is in a standard sense uncaused. The question of whether determinism is compatible with freedom has

been the question of whether our freedom consists in voluntariness or origination, not the question of whether determinism is compatible with origination.

### HUME, KANT, AND COMPATIBILISM

To come to the principal arguments of the two traditions of philosophers, Hume was typical of compatibilists in maintaining that anyone who actually thinks of what he or she means in speaking of a free and responsible action will immediately see that it is an unconstrained or uncoerced one—a voluntary one. What is needed is no more than some self-reflection, unconfused by religion or the like (Hume 1955).

Kant, although in fact not an incompatibilist, certainly not an ordinary incompatibilist, was as positive in declaring that to think of one's idea of a free and responsible action is not to think merely of one that was necessitated in a certain way. To go along with Hume and suppose otherwise, he said, is to engage in no more than a little quibbling with words (Kant 1949). With these philosophers, there was already a kind of stalemate about determinism and freedom.

Near the beginning of the twentieth century, it was taken as established, by some, that compatibilism was proved by a simple consideration. If a person acted freely on some occasion, it was true that the person could have acted otherwise. But, it was said, the latter means that the person would have acted differently if he or she had chosen differently, which is consistent with determinism (Moore 1912). By the mid-twentieth century, however, it became clear to some that "could have acted otherwise" is inconsistent with determinism (Austin 1961).

Subsequent twentieth- and indeed twenty-first-century compatibilists, undaunted by the failure of their predecessors to prove it, have somehow stuck to the conviction that our common idea of freedom, our common idea of what is necessary for moral responsibility and right punishment, is voluntariness (Ayer 1973, Magill 1997). One further contention is that the idea of origination, despite the seemingly clear rudimentary description of it, is actually incoherent, and so the field is left to the tolerably clear ideal of voluntariness (G. Strawson 1986).

Another compatibilist argument, widely discussed, begins from a thought experiment about moral responsibility (Frankfurt 1969). What it amounts to is the idea of a person subject to the control of a neuroscientist with some apparatus who will secure that the person will act in a certain way if it happens that the person is not on the way to doing so. Those are the causal facts. Suppose, how-

ever, that the person actually is on the way to and absolutely committed to doing A—wants it, wants to want it, and so on. It remains true, given the neuroscientist in the background, that he cannot do anything else. But it is clear, surely, that he is morally responsible for A. It follows, we are told, that freedom does not require being able to do otherwise than we do in a strong sense—it does not require origination and is not itself origination. Other recent compatibilist argumentation has been the elaboration of the idea of voluntariness by seeing its growth and extent in terms of evolution (Dennett 2003). Our human freedom is favorably contrasted with the lesser freedom of other animals.

Twentieth-century incompatibilists gave much attention to an argument well-developed from its beginning in Kant's philosophy (van Inwagen 1986). Here we have it that a free action is one that is up to us. Suppose now that an action is subject to determinism—the effect of a causal sequence, a series of lawlike connections leading back to some causal circumstance prior to the birth of the agent. Can such an action be up to us? The answer given is that it can only be up to us if the lawlike connections and the first causal circumstance are within our control—which definitely they are not. Hence free actions cannot be effects of certain causal sequences but must be originated.

Given the unbroken history of the philosophical debate on determinism and freedom until recently, must there be a presumption that either compatibilism or incompatibilism is true? Can that respectful attitude survive certain troublesome questions and alternatives?

If you reflect on the compatibilist case of the desiring and committed agent but with the neuroscientist around the corner, or indeed on any of many cases, say the simple one of the man chained to the wall, one thing you must be persuaded of is that there certainly is *an* idea of freedom—voluntariness. Quite as clearly, if you reflect on the incompatibilist case of the agent about whom it is supposed that a causal circumstance before his birth was not up to him, one thing you must allow is that there is *an* idea of freedom such that he does not have it—origination.

Does it follow from either speculation, however, that each of us has *only* the idea of freedom in question? That we all have and use only that single settled idea? That is exactly what is intended by each speculation, exactly what it is supposed to prove.

To ask the question, perhaps, is to become at least worried. Recall the first agent doing what he wants and

responsible although in the toils of the neuroscientist. Is it just the philosophers who can readily think that there still *is* a sense in which he is not free—he cannot do otherwise in a sense of the words inconsistent with determinism? And is it just the philosophers who can readily think of the second agent, who indeed does not have a causal circumstance in the distant past in his control, that there still *is* a clear sense in which his action may indeed be in his control? It may be wholly in accord with his desires and character and his whole existence, not pushed on him by anyone else or anything else or any conflict within him. Do we not have and use both conceptions?

What may lead someone to assent to one of the two speculations, and to either compatibilism or incompatibilism, is of course the proposition that freedom either is or is not compatible with determinism. That is a logical or necessary truth, is it not? Well, it is a truth only on a certain ordinary assumption or presupposition. The presupposition of course is that freedom is one thing, that we in general have only one idea of freedom. Evidently this presupposition needs thinking about, and it has been thought about in additional ways.

### DEFENSES OF COMPATIBILISM

An original defense of compatibilism prepared the way by making more explicit the fact that determinism is not best seen as raising a question of consistency or inconsistency, but rather as affecting attitudes directed at certain facts or propositions having to do with moral responsibility—and also such personal and nonmoral attitudes as gratitude and resentment (P. F. Strawson 1968). Subsequently it was proposed that determinism affects more attitudes than these, including the important attitude to the future that is hope and the important attitude to inquiry and conclusions that is confidence.

It was argued that it is plain that we are all subject to two kinds of hope, one for an open future where all has not been fixed by the past, one for a future in which we get what we want, maybe a whole kind of life. To this attitudinal argument, a behavioral one was subsequently added. What we secure by enacting and benefiting from bills of rights and political liberty is evidently an absence of compulsion. What we punish for in part is an action of which we take it that it could have been otherwise despite the past, and we have the same thought in various personal relations (Honderich 1988, 1993).

Such considerations also bear nearly as sharply on weaker positions to which compatibilists and incompatibilists may be retreating. These positions are that voluntariness is our more important conception of freedom

(Dennett 1984, 2003), the freedom more worth having, or that origination has these recommendations (Kane 1985, 2002).

### THE WIDER DEBATE

The ensuing wider debate—wider than compatibilism and incompatibilism—has included the idea that our being free requires origination but our being responsible requires only voluntariness (Fischer 1994). A different inquiry into what is called autonomy also accepts that we do not have to choose between compatibilism and incompatibilism (Mele 1995). It has been argued, against compatibilism's way of saving our responsibility from determinism, that we must give up our real idea of responsibility (Pereboom 2001). There has been the more radical contention that ascribing freedom and responsibility to people is a matter of attitudes that do not depend on objective facts or propositions at all (Double 1991, 1996).

Against another thought, that of giving up the set of attitudes inconsistent with determinism and taking satisfaction in the set of consistent ones, it has been argued that despite the truth of determinism we must maintain the illusion that we have the power of origination (Smilansky 2000). The thought of giving up the inconsistent attitudes and being satisfied by the others has also been followed by another radical idea. It is that roughly our attitudes to ourselves previously associated with origination can survive acceptance of determinism, and so must be owed to something else entirely different. This could be the nature of our consciousness, or the explanatory nature of certain causal lines of events within sequences of causal circumstances (Honderich 2002).

It is too early to say, but it may be that a consensus is emerging that determinism and freedom can no longer be the protracted and tired battle between compatibilism and incompatibilism. It is not possible to conjecture about the outcome of an alternative discussion.

**Ted Honderich (1996, 2005)**

## DETERMINISM AND INDETERMINISM

Determinism is a rich and varied concept. At an abstract level of analysis, Jordan Howard Sobel (1998) identifies at least ninety varieties of what determinism could be like. When it comes to thinking about what deterministic laws and theories in physical sciences might be like, the situation is much clearer. There is a criterion by which to judge whether a law—expressed as some form of equation—is deterministic. A theory would then be deterministic just in case all its laws taken as a whole were deterministic. In contrast, if a law fails this criterion, then it is indeterministic and any theory whose laws taken as a whole fail this criterion must also be indeterministic. Although it is widely believed that classical physics is deterministic and quantum mechanics is indeterministic, application of this criterion yields some surprises for these standard judgments.

## FRAMEWORK FOR PHYSICAL THEORIES

Laws and theories in physics are formulated in terms of dynamical or evolution equations. These equations are taken to describe the change in time of the relevant variables characterizing the system in question. Additionally, a complete specification of the initial state referred to as the initial conditions for the system and/or a characterization of the boundaries for the system known as the boundary conditions must also be given. A state is taken to be a description of the values of the variables characterizing the system at some time  $t$ . As a simple example of a classical model, consider a cannon firing a ball. The initial conditions would be the initial position and velocity of the ball as it left the mouth of the cannon. The evolution equation plus these initial conditions would then describe the path of the ball.

Much of the analysis of physical systems takes place in what is called state space, an abstract mathematical space composed of the variables required to fully specify the state of a system. Each point in this space then represents a possible state of the system at a particular time  $t$  through the values these variables take on at  $t$ . For example, in many typical dynamical models—constructed to satisfy the laws of a given theory—the position and momentum serve as the coordinates, so the model can be studied in state space by following its trajectory from the initial state  $(q_0, p_0)$  to some final state  $(q_f, p_f)$ . The evolution equations govern the path—the history of state transitions—of the system in state space.

However, note that there are important assumptions being made here. Namely, that a state of a system is characterized by the values of the crucial variables and that a physical state corresponds to a point in state space through these values. This cluster of assumptions can be called the faithful model assumption. This assumption allows one to develop mathematical models for the evolution of these points in state space and such models are taken to represent (perhaps through a complicated relation) the physical systems of interest. In other words, one assumes that one's mathematical models are faithful representations of physical systems and that the state space is a faithful representation of the space of physically genuine possibilities for the system in question. Hence, one has the connection between physical systems and their laws and models, provided the latter are faithful. It then remains to determine whether these laws and models are deterministic or not.

## LAPLACEAN DETERMINISM

Clocks, cannon balls fired from cannons, and the solar system are taken to be paradigm examples of deterministic systems in classical physics. In the practice of physics one is able to give a general and precise description of deterministic systems. For definiteness the focus here is on classical particle mechanics, the inspiration for Pierre Simon Laplace's famous description:

We ought to regard the present state of the universe as the effect of its antecedent state and as the cause of the state that is to follow. An intelligence knowing all the forces acting in nature at a given instant, as well as the momentary positions of all things in the universe, would be able to comprehend in one single formula the motions of the largest bodies as well as the lightest atoms in the world ... to it nothing would be uncertain, the future as well as the past would be present to its eyes. (Translation from Nagel 1961, pp. 281–282)

Given all the forces acting on the particles composing the universe along with their exact positions and momenta, then the future behavior of these particles is, in principle, completely determined.

Two historical remarks are in order here. First, Laplace's primary aim in this famous passage was to contrast the concepts of probability and certainty. Second, Gottfried Wilhelm Leibniz (1924, p. 129) articulated this same notion of inevitability in terms of particle dynamics long before Laplace. Nevertheless, it was the vision that Laplace articulated that has become a paradigm example for determinism in physical theories.

This vision may be articulated in the modern framework as follows. Suppose that the physical state of a system is characterized by the values of the positions and momenta of all the particles composing the system at some time  $t$ . Furthermore, suppose that a physical state corresponds to a point in state space (invoking the faithful model assumption). One can then develop deterministic mathematical models for the evolution of these points in state space. Some have thought that the key feature characterizing this determinism was that given a specification of the initial state of a system and the evolution equations governing its states, in principle it should be possible to predict the behavior of the system for any time (recall Laplace's contrast between certainty and probability). Although *prima facie* plausible, such a condition is neither necessary nor sufficient for a determinis-

tic law because the relationship of predictability to determinism is far too weak and subtle.

Rather, the core feature of determinism is the following condition: “Unique evolution: A given state is always followed (and preceded) by the same history of state transitions.” This condition expresses the Laplacean belief that systems described by classical particle mechanics will repeat their behaviors exactly if the same initial and boundary conditions are specified. For example, the equations of motion for a frictionless pendulum will produce the same solution for the motion as long as the same initial velocity and initial position are chosen. Roughly speaking, the idea is that every time one returns the mathematical model to the same initial state (or any state in the history of state transitions), it will undergo the same history of transitions from state to state and likewise for the target system. In other words, the evolution will be unique given a specification of initial and boundary conditions. Note that as formulated, unique evolution expresses state transitions in both directions (future and past). It can easily be recast to allow for unidirectional state transitions (future only or past only) if desired.

### UNIQUE EVOLUTION

Unique evolution is the core of the Laplacean vision for determinism (it lies at the core of Leibniz’s statement as well). Although a strong requirement, it is important if determinism is to be meaningfully applied to laws and theories. Imagine a typical physical system  $s$  as a film. Satisfying unique evolution means that if the film is started over and over at the same frame (returning the system to the same initial state), then  $s$  will repeat every detail of its total history over and over again and identical copies of the film would produce the same sequence of pictures. So if one always starts *Jurassic Park* at the beginning frame, it plays the same. The tyrannosaurus as antihero always saves the day. No new frames are added to the movie. Furthermore, if one were to start with a different frame, say a frame at the middle of the movie, there is still a unique sequence of frames.

By way of contrast, suppose that returning  $s$  to the same initial state produced a different sequence of state transitions on some of the runs. Consider a system  $s$  to be like a device that spontaneously generates a different sequence of pictures on some occasions when starting from the same initial picture. Imagine further that such a system has the property that simply by choosing to start with any picture normally appearing in the sequence, sometimes the chosen picture is not followed by the usual sequence of pictures. Or imagine that some pictures often

do not appear in the sequence, or that new ones are added from time to time. Such a system would fail to satisfy unique evolution and would not qualify as deterministic.

More formally, one can define unique evolution in the following way. Let  $S$  stand for the collection of all systems sharing the same set  $L$  of physical laws and suppose that  $P$  is the set of relevant physical properties for specifying the time evolution of a system described by  $L$ : A system  $s \in S$  exhibits unique evolution if and only if every system  $s' \in S$  isomorphic to  $s$  with respect to  $P$  undergoes the same evolution as  $s$ .

### TWO CONSTRUALS OF UNIQUE EVOLUTION

Abstracting from the context of physical theories for the moment, unique evolution can be given two construals. The first construal is as a statement of causal determinism, that every event is causally determined by an event taking place at some antecedent time or times. This reading of unique evolution fits nicely with how a number of philosophers conceive of metaphysical, physical, and psychological determinism as theses about the determination of events in causal chains, where there is a flow from cause to effect that may be continuous or have gaps. The second construal of unique evolution is as a statement of difference determinism characterized by William James as “[t]he whole is in each and every part, and welds it with the rest into an absolute unity, an iron block, in which there can be no equivocation or shadow of turning” (1956, p. 150). This reading of unique evolution maintains that a difference at any time requires a difference at every time.

These two construals of unique evolution are different. For example, consider a fast-starting series of causally linked states (Sobel 1998) where every state in the series has an earlier determining cause, but the series itself has no antecedent deterministic cause (its beginning—the first state—is undetermined by prior events or may have a probabilistic cause) and no state in the series occurs before a specified time. The principle that every event has an earlier cause would fail for a fast-starting series as a whole though it would hold for the events within such a series. This would be an example where causal determinism failed, but where difference determinism would still hold.

However, the causal construal of unique evolution is unsatisfactory. Concepts like *event* or *causation* are vague and controversial. One might suggest explicating causal determinism in terms of the laws  $L$  and properties  $P$ , but concepts like *event* and *cause* are not used in most physi-

cal theories (at least not univocally). In contrast, unique evolution fits the idea of difference determinism: any difference between  $s$  and  $s'$  is reflected by different histories of state transitions. This latter construal of unique evolution only requires the normal machinery of the theoretical framework sketched earlier to cash out these differences and so avoids controversies associated with causal determinism.

## DETERMINISM IN CLASSICAL MECHANICS

Most philosophers take classical mechanics to be the archetype of a deterministic theory. *Prima facie* Newton's laws satisfy unique evolution. After all, these are ordinary differential equations and one has uniqueness and existence proofs for them. Furthermore, there is at least some empirical evidence that macroscopic objects behave approximately as these laws describe. Still, there are some surprises and controversy regarding the judgment that classical mechanics is a deterministic theory.

For example, as Keith Hutchinson (1993) notes, if the force function varies as the square root of the velocity, then a specification of the initial position and velocity of a particle does not fix a unique evolution of the particle in state space (indeed, the particle can sit stationary for an arbitrary length of time and then spontaneously begin to move). Hence, such a force law is not deterministic. There are a number of such force functions consistent with Newton's laws, but that fail to satisfy unique evolution. Therefore, the judgment that classical mechanics is a deterministic theory is false.

**NEWTONIAN GRAVITY.** One might think that the set of force functions leading to violations of unique evolution represents an unrealistic set so that all force laws of classical mechanics really are deterministic. However, worries for determinism await one even in the case of point-particles interacting under Isaac Newton's force of gravity, the paradigm case of determinism that Laplace had in mind.

In 1897 the French mathematician Paul Painlevé conjectured that a system of point-particles interacting only under Newton's force of gravity could all accelerate to spatial infinity within a finite time interval. (The source of the energy needed for this acceleration is the infinite potential well associated with the inverse-square law of gravitation.) If particles could disappear to "spatial infinity," then unique evolution would break down because solutions to the equations of motion no longer would be guaranteed to exist. Painlevé's conjecture was

proven by Zhihong Xia (1992) for a system of five point-masses.

Though provocative, these results are not without controversy. For example, there are two interesting possibilities for interpreting the status of these particles that have flown off to spatial infinity. On the one hand, one could say the particles have left the universe and now have some indefinite properties. On the other hand, one could say that the particles no longer exist. Newton's mechanics is silent on this interpretive question. Furthermore, are events such as leaving the universe to be taken as predictions of Newton's gravitational theory of point-particles, or as indications that the theory is breaking down because particle position becomes undefined? Perhaps such behavior is an artifact of a spatially infinite universe. If the universe is finite, particle positions are always bounded and such violations of unique evolution are not possible.

**DIAGNOSIS.** Other failures of unique evolution in classical mechanics can be found in John Earman's (1986) survey. What is one to say, then, about the uniqueness and existence theorems for the equations of motion, the theorems that appear so suggestive of unique evolution? The root problem of these failures to satisfy unique evolution can be traced back to the fact that one's mathematical theorems only guarantee existence and uniqueness locally in time. This means that the equations of motion only have unique solutions for some interval of time. This interval might be short and, as time goes on, the interval of time for which such solutions exist might get shorter or even shrink to zero in such a way that after some period solutions cease to exist. So determinism might hold locally, but this does not guarantee determinism must hold globally.

## DETERMINISM IN SPECIAL AND GENERAL RELATIVITY

Special relativity provides a much more hospitable environment for determinism. This is primarily due to two features of the theory: (1) no process or signal can travel faster than the speed of light, and (2) the space-time structure is static. The first feature rules out unbounded-velocity systems, while the second guarantees there are no singularities in space-time. Given these two features, global existence and uniqueness theorems can be proven for cases like source-free electromagnetic fields so that unique evolution is not violated when appropriate initial data are specified on a space-like hypersurface. Unfortunately, when electromagnetic sources or gravitationally

interacting particles are added to the picture, the status of unique evolution becomes much less clear.

In contrast, general relativity presents problems for guaranteeing unique evolution. For example, there are space-times for which there are no appropriate specifications of initial data on space-like hypersurfaces yielding global existence and uniqueness theorems. In such space-times, unique evolution is easily violated. Furthermore, problems for unique evolution arise from the possibility of naked singularities (singularities not hidden behind an event horizon). One way a singularity might form is from gravitational collapse. The usual model for such a process involves the formation of an event horizon (i.e., a black hole). Although a black hole has a singularity inside the event horizon, outside the horizon at least determinism is okay, provided the space-time supports appropriate specifications of initial data compatible with unique evolution. In contrast, a naked singularity has no event horizon. The problem here is that anything at all could pop out of a naked singularity, violating unique evolution. To date, no general, convincing forms of hypotheses ruling out such singularities have been proven (so-called cosmic censorship hypotheses).

### DETERMINISM IN QUANTUM MECHANICS

In contrast to classical mechanics philosophers often take quantum mechanics to be an indeterministic theory. Nevertheless, so-called pilot-wave theories pioneered by Louis de Broglie and David Bohm are explicitly deterministic while still agreeing with experiments. Roughly speaking, this family of theories treats a quantum system as consisting of both a wave and a particle. The wave evolves deterministically over time according to the Schrödinger equation and determines the motion of the particle. Hence, the particle's motion satisfies unique evolution. This is a perfectly coherent view of quantum mechanics and contrasts strongly with the more orthodox interpretation. The latter takes the wave to evolve deterministically according to Schrödinger's equation and treats particle-like phenomena indeterministically in a measurement process (such processes typically violate unique evolution because the particle system can be in the same state before measurement, but still yield many different outcomes after measurement). Pilot-wave theories show that quantum mechanics need not be indeterministic.

### DETERMINISTIC CHAOS

Some philosophers have thought that the phenomenon of deterministic chaos—the extreme sensitivity of a vari-

ety of classical mechanics systems such that roughly even the smallest change in initial conditions can lead to vastly different evolutions in state space—might actually show that classical mechanics is not deterministic. However, there is no real challenge to unique evolution here as each history of state transitions in state space is still unique to each slightly different initial condition.

Of course, classical chaotic systems are typically considered as if there is no such thing as quantum mechanics. But suppose one considers a combined system such that quantum mechanics is the source of the small changes in initial conditions for one's classical chaotic system? Would such a system fail to satisfy unique evolution? The worry here is that, since there is no known lower limit to the sensitivity of classical chaotic systems, nothing can prevent the possibility of such systems amplifying a slight change in initial conditions due to a quantum event so that the evolution of the classical chaotic system is dramatically different than if the quantum event had not taken place. Indeed, some philosophers argue that unique evolution must fail in such circumstances.

However, such sensitivity arguments depend crucially on how quantum mechanics itself and measurements are interpreted as well as on where the cut is made distinguishing between what is observed and what is doing the observing (e.g., is the classical chaotic system serving as the measuring device for the quantum change in initial conditions?). Although considered abstractly, sensitivity arguments do correctly lead to the conclusion that quantum effects can be amplified by classical chaotic systems; they do not automatically render one's classical plus quantum system indeterministic. Furthermore, applying such arguments to concrete physical systems shows that the amplification process may be severely constrained. For example, investigating the role of quantum effects in the process of chaos in the friction of sliding surfaces indicates that quantum effects might be amplified by chaos to produce a difference in macroscopic behavior only if the fluctuations are large enough to break molecular bonds and are amplified quickly enough.

### BROADER IMPLICATIONS

Finally, what of broader implications of determinism and indeterminism in physical theories? Debates about free will and determinism are one place where the considerations in this entry might be relevant. One of the most discussed topics in this regard is the consequence argument, which may be put informally as follows: If determinism is true, then our acts are consequences of laws and events in

the remote past. But what went on before we were born is not up to us and neither are the laws up to us. Therefore, the consequences of these laws and events—including our present acts—are not up to us. Whether or not the relevant laws satisfy unique evolution is one factor in the evaluation of this argument.

What of broader philosophical thinking about psychological determinism or the thesis that the universe is deterministic? For the former, it looks difficult to make any connection at all. One simply does not have any theories in the behavioral sciences that are amenable to analysis under the criterion of unique evolution. Indeed, attempts to apply the criterion in psychology do not lead to clarification of the crucial issues (Bishop 2002).

With regards to the universe, it has been common practice since the seventeenth century for philosophers to look to their best scientific theories as guides to the truth of determinism. As one has seen, the current best theories in physics are remarkably unclear about the truth of determinism in the physical sciences, so the current guides do not appear to be so helpful. Even if the best theories were clear on the matter of determinism in their province, there is a further problem awaiting their application to metaphysical questions about the universe as a whole. Recall the crucial faithful model assumption. In many contexts this assumption is fairly unproblematic. However, if the system in question is nonlinear—that is to say, has the property that a small change in the state or conditions of the system is not guaranteed to result in a small change in the system's behavior—this assumption faces serious difficulties (indeed, a strongly idealized version of the assumption, the perfect model scenario, is needed but also runs into difficulties regarding drawing conclusions about the systems one is modeling). Since the universe is populated with such systems—indeed, it is likely to be nonlinear itself—one's purchase on applying the best laws and theories to such systems or the universe as a whole to answer the large metaphysical question about determinism is problematic.

## DETERMINISM IN HISTORY

Philosophical reflection upon history has always been impressed by the limited extent to which individuals and groups seem to be able to mold events to their purposes. In the case of some events at least, there seems to be an inexorable necessity—an inevitability or unavoidability—about what happens. The "necessity" of historical events, however, has been asserted by historians and philosophers of history in at least three fundamentally different senses.

### SENSES OF DETERMINISM

**FATE AND PROVIDENCE.** The first sense is the notion that events are "fated" to occur, a notion familiar to Greek as well as Oriental thought. The central concept is of an agency external to the historical process itself, sometimes, but not always, personified, determining events somewhat in the way a human agent may be said to determine, through his will, what happens in a process he monitors and manipulates. It is generally assumed, however, that the means by which fated events are brought about lie outside the mechanism of ordinary causal connection: they are "transcendent." This clears the way for a characteristic expression of fatalism—the assertion that what is fated will occur no matter what we do to try to prevent it. To many critics, such a claim has appeared unintelligible.

For historical events are surely, in some sense at least, constituted by what we do. A revolution, for example, could hardly occur if nobody revolted. The fatalist claim thus looks self-contradictory. What fatalism really denies, however, is the preventive efficacy of anyone's actions prior to the fated event, a refinement that leaves the claim coherent, if unbelievable. Nor is the doctrine necessarily involved in the incoherence of representing prior actions as both within our power to have performed otherwise and, at the same time, fated in their turn. For fatalism, unlike some other forms of historical determinism, has generally been asserted selectively. It is the doctrine that certain things will necessarily come to pass, not that everything happens necessarily.

Many theological philosophies of history are fatalistic in the indicated sense because of the role they assign to the will of God in their accounts. Unlike most of their pagan predecessors, however, these accounts generally make some attempt to rationalize and even to moralize interventions hitherto conceived as arbitrary, and usually also as menacing. In this way a fatalistic conception of history becomes "providential." Theological interpretations, of course, leave little for philosophers to argue about; for the workings of Divine Providence can be discerned only through some extrarational insight or source of revelation. And as G. W. F. Hegel complained about providential theories generally, the overarching purpose or plan is usually conceded, even by those who claim insight into it, to be partly "concealed from our view." Some theological interpretations have tried to meet this sort of objection by identifying the workings of providence, tentatively at least, with certain standing conditions and even with historical laws. A comparison between Reinhold Niebuhr's twentieth-century *Faith and History*, with its confidence in the "providential structure of existence," and Bishop Jacques Bénigne Bossuet's seventeenth-century *Discourse on Universal History*, which still envisages God ruling the course of empire by "decree," is instructive in this connection. Yet even Niebuhr confessed in the end that, to a finite human mind, both the plan and mode of operation of God in history remain mysterious.

**HISTORICAL INEVITABILITY.** Any attempt to make fate or providence immanent in the ordinary processes of history is a move toward a second major conception of the necessity of historical events, one often referred to in contemporary discussion as the doctrine of "historical inevitability." In this conception, the course of history has a necessary overall direction, whether it be attributed to an active but impersonal "force," a *nisus* toward some

ultimate goal, or a “dynamic” law of development. The necessary direction of history has been variously conceived by various philosophers. Thus the Greeks tended to envisage it as cyclical and repetitive, while most philosophers of the Enlightenment found an equally simple but linear pattern of inevitable progress. According to Giambattista Vico, history traces a spiral path as civilization after civilization, each in its own unique way, follows the curve from heroic age to neobarbarism. According to Hegel, the spiral proceeds dialectically toward the actualization of a potential human freedom, each regress contributing to an ultimate spiritual synthesis. Just how deterministic such interpretations of history’s direction were actually intended to be is, in fact, a disputable matter. Almost none assert that every historical event happens necessarily; the claim is usually limited to the main trend or the more significant events. And many speculative theorists do not seem to claim even that much. Oswald Spengler, for example, in his *Decline of the West* left the origin, by contrast with the development, of historical cultures unaccounted for; Hegel’s lectures on the philosophy of history can be interpreted as having held that the stages of freedom succeed each other only with “rational,” and not with “natural” necessity; and Arnold Toynbee’s *Study of History* discovered historical “laws” so accommodating that they appear to be compatible with an almost indefinite number of exceptions.

Yet the discovery of inevitability is generally taken to be a major goal of speculative theories of history. And historians themselves often refer to “underlying tides and currents” (A. L. Rowse) or “great social forces” (E. P. Cheyney) in a way which seems to call for a more literal interpretation than the references they also occasionally let slip to the “fate” or “destiny” of historical individuals. Recent polemical works like K. R. Popper’s *The Poverty of Historicism* (Boston: Beacon, 1957) and Isaiah Berlin’s *Historical Inevitability* (London: Oxford Univ. Press, 1955) certainly assume that the doctrine of inevitability is still a live option for many people. Like fatalism, it is regarded by its critics as morally and politically dangerous. But it has also been subjected to a logical and conceptual critique, the major complaint of which is that insofar as historical inevitability is asserted on empirical grounds, the notion of “necessity” is employed in a way that is scientifically indefensible. According to Popper, inevitability theories confuse genuine laws, which assert conditional and hypothetical necessities, with statements of historical *trends*, which are not necessities, but facts. Laws license prediction whenever the conditions specified in their antecedent clauses are satisfied. The lack of corresponding empirical justification for the social

“prophecies” obtained by merely extrapolating trends is often obscured by the “force” metaphors characteristically used in describing them.

A speculative theorist who wished to claim metaphysical rather than scientific status for his conclusions might perhaps remain unmoved by such considerations. Yet almost all inevitability theorists at some point cite empirical evidence; and in the nineteenth century particularly, such theories were often thought to provide models for social science itself. The belief that the extrapolation of trends is a scientifically respectable procedure, Popper observed, may well be traceable to the fascination that untypical sciences like astronomy have had for philosophers of history. The temptation is to say that if eclipses can be predicted by projecting the observed behavior of the solar system, then revolutions and the like ought similarly to be predictable by projecting the tendencies of the social system. Such reasoning ignores the fact that the cyclical “direction” of the solar system is not just observed; it is explained. And the explanation is in terms of initial conditions obtaining, together with laws of motion that are conditional and hypothetical. The same could be said of the so-called directional law of evolution in biology, which is sometimes cited as a paradigm for linear theories of historical inevitability. No corresponding attempt is usually made to derive the alleged necessity of observed historical trends from more fundamental considerations. For to represent the large-scale pattern as “resultant” in such a way, especially if the relevant initial conditions included individual human actions, might undermine the thesis of unavoidability.

**SCIENTIFIC DETERMINISM.** The notion of explaining historical trends in terms of the operation of scientific laws brings us to a third generic conception of necessity in history, the “scientific” sense. To put it most simply, an event might be said to be determined in this sense if there is some other event or condition or group of them, sometimes called its cause, that is a sufficient condition for its occurrence, the sufficiency residing in the effect’s following the cause in accordance with one or more laws of nature. The general assertion of historical determinism then becomes the assertion that for every historical event there is such a sufficient condition. Whether, in consequence, history manifests a unitary pattern or direction is a further and separate question.

*Race and climate.* Many historical determinists who would claim to be “scientific” in the above sense have gone a step further. Like the inevitability theorists, they have sought a simple clue to the historical process, in this

case in causal factors of a limited range. Typical of such single-factor theories are those that fasten on certain biological or psychological conditions, such as the alleged racial characteristics of certain groups, or on features of the physical environment, such as topography, climate, soil, or natural resources. The writings of Joseph Arthur de Gobineau and of Houston Stewart Chamberlain, with their concept of Aryan superiority, are notorious examples of the first of these, although few serious attempts have been made to write detailed and scholarly histories (rather than propaganda) on their principles. The search for geographical determinants, on the other hand, has a reputable record going back at least to Baron de Montesquieu and Jean Bodin, and it received classic expression in the work of Henry Thomas Buckle in the nineteenth century and of Ellsworth Huntington in the twentieth. Both types of theory, however, oversimplify the diversity of history. It is one thing to point out that civilizations originated in river valleys or that the decline of Rome was accompanied by race-mixing. It is quite another—even if some features of events can properly be ascribed to such factors—to say that all significant historical change is determined by geographical or biological causes.

**Social causes.** Racial and environmental interpretations locate the explanatory factors outside the course of historical events themselves. Social interpretations offer single-factor accounts that seek causes in one kind of historical condition by contrast with others. According to Karl Marx, for example, the explanation of political, religious, legal, and other “ideological” features of a society is to be found in that society’s mode of economic life and in the relations of production that its human elements consequently take up toward each other. In extreme forms of the theory at least, a one-way causal relation is asserted to hold at any time between economic and noneconomic factors, as well as between economic conditions at different times. Such an economic interpretation of history, with its more variable explanatory factor, has a far richer potential than racial or environmental ones for explaining the details of historical change. As with all single-factor theories, however, any attempt to defend its monistic causal claims generally either fails to carry conviction or runs afoul of a basic distinction between sufficient (determining) and merely necessary (conditioning) conditions. Thus, in a crude but revealing lapse, often cited, Friedrich Engels argued that because a man cannot engage in politics, science, religion, and art if he lacks the basic material conditions of life, the latter *determine* the former.

**Multiple-factor theories.** More considered statements of single-factor theories try to provide for a degree of interaction between the chosen factor and others. This leaves the difficult problem of explaining the sense, if any, in which the special factor is the fundamental one. It also leaves the problem—which bedeviled inevitability theories as well—of the relation between large-scale social causes and effects and the actions of participating individuals. “Great man” theories like Thomas Carlyle’s are rightly out of fashion, but it is difficult to deny the historical importance of a Vladimir Lenin or a Napoleon Bonaparte. Georgii Valentinovich Plekhanov’s classical Marxist discussion of this problem, in *The Role of the Individual in History*, adopts the uneasy compromise that individual causes can make a difference to a historical outcome, but only to its less significant features or to its timing. Such legislation as to the “spheres of influence” of various sorts of conditions, all conceded to be necessary, often seems highly arbitrary; and under pressure, single-factor theories tend to develop into “interpretations” only in the sense of directing attention to one factor in historical change that is deemed especially noteworthy, often for pragmatic reasons. The claim that historical events are determined then ceases to have any special connection with the claims made for the chosen factor. It reverts simply to the assertion that for every event there is a sufficient condition, no matter how disparate the causal elements that may sometimes be required to constitute it.

In the broad sense thus indicated, the contention that historical events are all determined may seem quite unproblematic. And when one considers the thoroughly causal language of historical accounts, the contention may seem also to be in accordance with historical practice. It is true that what historians actually call a cause is seldom itself a sufficient condition. But it is generally assumed by determinists that its claim to be a cause depends upon its completing a sufficient set of such conditions, some of which may not have been overtly specified. Yet the assumption of scientific determinism in history has been disputed on a number of grounds, the three set forth below being among the most frequently cited. These arguments have a common feature: all claim that this assumption contradicts others that the historian normally and properly makes. In consequence, the notion is represented as importing an incoherence into historical thinking as a whole.

## OBJECTIONS TO DETERMINISM

**CHANCE.** It has been objected, first, that history is a realm in which events sometimes occur “by chance”—it

being assumed that what happens by chance cannot happen of necessity. Certainly, historians often report what happened in such terms. And chance has been regarded by some of them almost as a principle of historical interpretation. Thus J. B. Bury, in his *Later Roman Empire*, represented the success of the barbarians in penetrating the Roman Empire as due to a succession of coincidences—the “historical surprise” of the onslaught of the Asiatic Huns, which drove the Goths west and south; the lucky blow that killed a Roman emperor when the Goths engaged a Roman army that just happened to be in their way; the untimely death of that emperor’s talented successor before he had arranged for the assimilation of those tribesmen who had settled within the imperial border; the unhappy fact that the two sons who subsequently divided the empire were both incompetent, and so on. Bury’s example does at least afford a strong argument against the notion that history is a *self*-determining system—one of the assumptions of the doctrine of historical inevitability. It illustrates the intrusion of nonhistorical factors into the historical process—an untimely death, for example—Bury’s awareness of which led him to object to any search for what he called “general” causes. Bury’s example makes clearer, too, the inappropriateness of a science like astronomy as a model for social and historical explanation. For the solar system, unlike human society, is virtually isolated from such external influences. This makes it possible for us to make astronomical predictions without taking into account anything but the description of the state of the system itself at any time and to predict accurately for long periods ahead. In history the situation is very different. The sufficient conditions of historical events are seldom to be found in other historical events.

But does the admission of chance, as Bury described it, count against the whole doctrine of historical determinism in the scientific sense? In support of their claim that it must, historical indeterminists sometimes cite parallels in physical inquiry. Modern subatomic physics, for example, whether correctly or not, has often been said to be indeterministic precisely because it regards certain aspects of the behavior of single electrons as matters of chance. Yet it may be questioned whether any of the contingencies, accidents, or unlucky “breaks” mentioned by Bury were matters of chance in the physicist’s sense. For there is no reason to think of any of them as uncaused. What is peculiar about them is that they occur (to use a common phrase) at the intersection of two or more relatively independent causal chains. But there is nothing in such coincidences, determinists will maintain, that enables us to say that what occurs at the “intersections”

could not be deduced from prior statements of conditions and appropriate laws, provided we took all the relevant conditions into account.

In practice, of course, a historian may not be in a position to explain why a given coincidence occurred; at least one relevant chain—the biological one leading to the emperor’s death, for example—may be beyond the scope of his kind of inquiry. What happened may consequently be represented by him as something unforeseen—perhaps even as the intrusion of the “irrational” into the course of events. Here the notion of chance is extended from the paradigm case where an event is said to have no cause at all to one where the cause is simply unknown because nonhistorical.

The notion is commonly extended further (as Bury’s example illustrates) to events whose causes, although not beyond the range of historical inquiry, are beyond the immediate range of the historian’s interests—the appearance of the Huns, for example. This makes it misleading to define “chance event” in history, as some have done, as an event that has historical effects but lacks historical causes. The causes of the invasion of the Huns simply lie outside the story the historian is telling. The judgment that a historical event happened by chance is thus a function of what the historian (and his readers) are concerned about. (This also covers the case where “by chance” seems chiefly to mean “unplanned.”) It follows that, from one standpoint, an event may properly be judged to be a chance occurrence, while from another it clearly could not be: the activities of the Huns, for example, were scarcely a matter of chance from their own standpoint. Speculative philosophers of history, if they aim to take the additional standpoints of God or “History” into account, will obviously have further problems when deciding whether something was a chance occurrence. The issues thus raised are doubtless of considerable interest for a general account of the logic of historical narration. It is difficult to see, however, that they have any important bearing on the acceptability of historical determinism.

NOVELTY. A second consideration often advanced against the determinist assumption is that history is a realm of novelty and that its course must therefore remain not only unforeseen but unforeseeable, even if we take into account the broadest possible range of antecedent conditions. The fact that what the historian discovers is often surprising is thus held to have an objective basis in human creativity, from which periodically there emerge events and conditions with radically novel characteristics. Such “emergence,” it is often claimed,

rules out the possibility of scientific prediction before the event because prediction is necessarily based on laws and theories that relate types of characteristics already known. In this connection it is interesting to note a “proof” offered by Popper that some historical events at least are unpredictable in principle. If we accept the common assumption that some historical events are dependent in part on the growth of human knowledge, Popper pointed out, then it is logically impossible that we should be able to predict them before they occur. For *ex hypothesi*, one of their conditions must remain unknown to us.

Confronted by such an argument, determinists would want to make clear that, as they conceive it, determinism does not entail predictability, even though it has, unfortunately, sometimes been defined in terms of predictability. An event can be determined even though it is not known to be so. Popper himself did not regard the argument cited above as counting against historical determinism; indeed, his own statement of it strongly suggested that the unpredictability of the events in question actually follows from their being determined in a certain way, that is, by a set of conditions that are less than sufficient in the absence of as yet unattained human knowledge. All that is required by the doctrine of determinism, however, is that events *have* sufficient conditions, whether or not they can be known before the fact. It would thus be better, perhaps, to define the notion in terms of explicability rather than predictability. Determinists often point out that the emergent characteristics of natural things can be explained in the scientific sense, although they could not have been predicted before they first emerged. In his “Determinism in History,” Ernest Nagel cited the emergence of the qualities of water out of a combination of hydrogen and oxygen. These are emergent and novel in the sense of not being possessed by the original elements and not being deducible from information about the behavior of these elements in isolation. Yet we have been able to frame laws governing the emergence of these originally novel attributes under specifiable conditions that allow us to deduce and now even to predict the attributes.

A likely reply is that whereas the emergence of the characteristics of water is a recurring, experimentally testable phenomenon, the emergence of novelty in the course of history is not. At least some historical events and conditions, it may be said, are unique and hence not subject to scientific explanation even after the fact. In considering this rejoinder, however, it is important not to misunderstand the claims of scientific determinism. For these do not include the deducibility in principle of the

occurrence of historical events “in all their concrete actuality.” Only events as historians represent them in their narratives are said to be so deducible. And their descriptions of events, it will be argued, are necessarily phrased in terms that apply, although not necessarily in the same combinations, to events at other times and places.

It may of course be doubted that we shall ever actually discover the determining conditions of such historical novelties as Alexander’s use of the phalanx, Caesar Augustus’s imperial policy, or the organization of the medieval church, under descriptions as highly detailed as historians customarily apply to them—a problem scarcely touched by the consideration, advanced by Nagel, that social science has sought, with some measure of success, to discover the conditions under which men act creatively. Yet determinists will regard these as merely “practical” difficulties, not bearing on the basic issue. That issue, they will maintain, is whether the novelties that can be recognized by historical inquiry are such as to rule out their subsumability under laws “in principle.” Unless historians’ knowledge can be said to go beyond any description of such novelties in terms of a unique conjunction of recurring characteristics, the argument from historical novelty will be deemed to have missed its mark.

In fact, this further, and highly debatable claim is one that some historical theorists would be quite prepared to make. They would point out, for example, that we can *listen* to Wolfgang Amadeus Mozart’s music and *read* Isaac Newton’s scientific writings—two examples of creativity cited by Nagel—and, by thus enjoying direct acquaintance with radical historical novelty, discover more than could be conveyed by any description in terms of recurring characteristics. Ordinary historical knowledge of novel military tactics, imperial policies, or institutional organizations, they would maintain, would similarly go beyond what could be expressed without reference, either explicitly or implicitly, to named individuals, groups, or periods. They would consequently represent historical narrative as employing concrete universals—like “Renaissance” or “Gothic”—as well as abstract ones. And since scientific laws can be framed only in terms of abstract universals, they would claim that warranted assertions of novelty expressed in terms of concrete universals do undermine the assumption of determinism.

FREEDOM. A third and even more common argument against accepting a determinist view of historical events turns on the claim that history is a realm not only of chance and novelty but of human freedom. The subject

matter of history, it is sometimes said, is not mere “events” but human “actions,” in a distinctive sense quite familiar to plain men who deliberate and decide what to do. If the historian is not to misrepresent such a subject matter, the argument goes, then he must take seriously the notion of choosing between alternatives. As Johan Huizinga expressed it, in his “Idea of History” (in *The Varieties of History*, edited by Fritz Stern), “the historian must put himself at a point in the past at which the known factors still seem to permit different outcomes. If he speaks of Salamis, then it must be as if the Persians might still win.” In *Historical Inevitability*, Isaiah Berlin gave a further and even more familiar reason for adopting the standpoint of “agency.” “If determinism were true, ...” he wrote, “the notion of human responsibility, as ordinarily understood, would no longer apply.” For an ascription of responsibility requires the assumption that the agent was “in control,” that he could have acted otherwise than he did. Historical accounts, in other words, like the moralistic ones plain men ordinarily give of their own and others’ actions, presuppose “freedom of the will.” And this is held to be incompatible with the assumption of determinism.

Few philosophical problems have been discussed as exhaustively (or as inconclusively) as the problem of freedom of the will, and it is quite impossible in this context to do justice to the subtleties involved. There are, however, two chief ways of handling the present objection. Historical determinists can try to explain away the problem of freedom by arguing that, although moralistic accounts properly regard historical agents as free, the sense in which they must do so is quite compatible with the deterministic assumption. Libertarians, correspondingly, can try to give an account of historic causation that does not rule out an action’s being both caused and undetermined. For historians, either of these ways out of the difficulty would presumably be more acceptable than the outright denial of the legitimacy of either moral appraisal or causal explanation in historical accounts. For, with no obvious sign of strain, historians generally offer both.

The determinist case often turns on the contention that the sense of freedom involved in attributing responsibility to a moral agent is not the “could have done otherwise” of absolute indeterminism; that sense implies only that the agent would have done otherwise if certain antecedents—his circumstances or his character, for example—had been a little different. Indeed, it is often argued that the test of whether the agent is really “in control,” and hence responsible, is whether he acts differently on another occasion when the conditions have been

changed—say, by his having been praised or blamed, rewarded or punished. It is therefore not the agent’s freedom in the sense of his action’s being uncaused that is at stake. The determinist, in arguing this way, conceives himself, furthermore, as accepting, not rejecting, the notion that the moral categories the historian uses are those of the plain man. What is denied is that the “ordinary” sense of “free” is the unconditional “freedom of the will” of the metaphysicians. As for Huizinga’s claim that the historian must think of the agent’s problem as if there were real possibilities open to him, this would be regarded as a purely methodological point. What is brought out thereby is the applicability to actions of a concept of understanding that requires us, quite properly, to view them in relation to what the agents thought about their situations, including any illusions they may have had about them.

Many libertarians might accept the latter contention. But most would surely repudiate the claim that responsibility requires freedom only in a sense compatible with determinism. To ascribe responsibility to a person whose actions necessarily follow from antecedent events, Berlin declared, is “stupid and cruel,” and he meant rationally incoherent, not just foolish. In a sense alleged to be central to our notion of responsibility, such a person could *not* have done otherwise. Must a libertarian who takes such a stand, then, abandon the possibility of explaining actions causally? Some, at least, would say, No, provided we recognize that the term *cause*, when applied to human actions, bears a special sense. Thus, according to R. G. Collingwood, the causes (in a distinctively historical sense) of “the free and deliberate act of a conscious and responsible agent” are to be sought in the agent’s “thought” about his situation, his reasons for deciding to act (*Essay on Metaphysics*). What a libertarian will deny is that any combination of such “rational” causes that excludes the agent’s decision to act—since the latter falls into the historian’s explanandum, not his explanans—is a sufficient condition of his action. Such causes become “effective,” it might be said, only through an agent’s deciding to act upon them. Yet when he does so, reference to them as his “reasons” will explain what he did in the sense of making it understandable. What such reference will not and need not do is explain his action in the sense of showing its performance to be deducible from sufficient antecedent conditions.

It is generally agreed that the conflict between historical determinists and indeterminists cannot be resolved by the offering of proofs or disproofs. Modern scientific determinists, in any case, seldom state their position dog-

matically. According to Nagel, for example, all that can be claimed is that the principle of determinism has “regulative” status as a presupposition of the possibility of scientific inquiry—a principle that must therefore govern the scientific study of history as well. What is particularly interesting about theories of rational causation is the conceptual foundation they offer for denying that the principle of determinism is a necessary presupposition even of seeking explanations when the subject matter is human action: they show at least the conceivability of explanatory inquiry on libertarian principles. It must be conceded, however, that few contemporary philosophers regard indeterminism as an acceptable assumption to carry into historical or social investigation.

### Bibliography

For examples of determinist or near-determinist views of history, see H. T. Buckle, *A History of Civilization in England* (London, 1899) or E. Huntington, *Mainsprings of Civilization* (New York, 1945). The works of various speculative and single-factor theorists mentioned above may also be consulted: Patrick Gardiner's *Theories of History* (Glencoe, IL, 1959) contains relevant extracts from the works of Vico, Hegel, Marx, Plekhanov, Buckle, Tolstoy, Spengler, Toynbee, Croce, and Collingwood. For a contemporary attack on deterministic views, of both the scientific and metaphysical kinds, see Isaiah Berlin, *Historical Inevitability* (London: Oxford University Press, 1954) and the reply offered by E. H. Carr in *What Is History?* (London, 1961). For a moderate defense of the deterministic assumption against such attacks, see Ernest Nagel, “Determinism in History,” *Philosophy and Phenomenological Research* 20 (1960): 291–317. The viability of indeterministic historical and social scientific inquiry is argued for in Alan Donagan, “Social Science and Historical Antinomianism,” *Revue Internationale de Philosophie* 11 (1957): 433–449. The role of the individual in history is discussed in Sidney Hook, *The Hero in History* (New York: John Day, 1943). Johan Huizinga's “Idea of History” is included in English translation in *The Varieties of History*, edited by Fritz Stern, pp. 290–303 (New York: Meridian, 1956). The claim that

historians use “cause” in a special sense is developed by R. G. Collingwood in *An Essay on Metaphysics* (Oxford: Clarendon Press, 1940), which should be read in conjunction with his *The Idea of History* (Oxford: Clarendon Press, 1946).

## DEUSSEN, PAUL

(1845–1919)

Paul Deussen, the German philologist and philosopher, was the son of a Protestant clergyman in the village of Oberdreis in the Westerwald. He received a thorough classical training in the old secondary school of Pforta, where he developed a close friendship with Friedrich Nietzsche. Both Deussen and Nietzsche enrolled in the theological faculty at the University of Bonn, but Nietzsche soon shifted to classical philology and followed his teacher Ritschl to Leipzig. Deussen remained in Bonn for four semesters, then also shifted to classical philology and earned his doctorate at Berlin in 1869 with a dissertation on Plato's *Sophist*. After a brief period of teaching in secondary schools, he became the tutor for a Russian family in Geneva in 1872. There he intensified his study of Sanskrit, began a study of the Indian philosophical classics, and became an enthusiastic follower and interpreter of Arthur Schopenhauer (after having long resisted Nietzsche's enthusiastic endorsements). In 1881 he qualified to lecture in Berlin under Eduard Zeller on the basis of his work *The System of the Vedanta*, and became an extraordinary professor in 1887. Appointed full professor in Kiel in 1889, he retained this post until his retirement.

Deussen's major work, on which he labored for more than twenty years, was the *Universal History of Philosophy*, consisting of two large volumes in six parts. The first volume was devoted to Indian thought and the second to the thought of the West from the Greeks to Schopenhauer, with a section on the philosophy of the Bible.

For Deussen the history of philosophy was a discipline indispensable not only for the understanding of life but for its religious interpretation as well. Its task was to strip off the “mythical vestments” or “hulls” of the various philosophical and religious systems in order to discover the single unified truth that all share.

This unified, permanent truth was made clear in the philosophy of Immanuel Kant as completed by Schopenhauer, but it also embraced insights from the Vedanta, Plato's doctrine of Ideas, and Christian theology. Schopenhauer, Deussen said, had “freed the essentials of

Kant from the weight of traditional misunderstanding” and offered “the completion of a unified doctrine which is grounded in experience, internally coherent in its metaphysics, and which appears, in its practical part, as a Christianity renewed throughout its whole depth on scientific foundations, and which will become, and for the predictable future remain, the foundation of all human scientific and religious thought” (*Geschichte der Philosophie*, Vol. 1, Part 1, p. 22). Rightly understood, Schopenhauer was the *philosophus Christianissimus* (the most Christian philosopher). The affirmation of the will to live is the egoism of our natural existence; its denial is “disinterested righteousness, the love of man, and the willingness to sacrifice for great causes—all great, heroic, overindividual striving and creating” (*Erinnerungen an Friedrich Nietzsche*, p. 105). But the divine, in this synthetic conception, cannot be understood theistically. The highest Being is beyond all personality, and all will eventually confess, “I believe in one living, but not one personal God.”

Deussen was one of the early interpreters of Jakob Boehme (1897). He edited a critical edition of Schopenhauer in fourteen volumes (Munich, 1911), and he founded the Schopenhauer Society and edited its yearbook from 1912 until his death.

### Bibliography

Deussen's chief work was *Allgemeine Geschichte der Philosophie, mit besonderer Berücksichtigung der Religionen*, 2 vols. (Leipzig: F. A. Brockhaus, 1894–1917); Vol. I, Part 2 was translated by A. S. Geden as *The Philosophy of the Upanishads* (Edinburgh: T. and T. Clark, 1908). *Die Elemente der Metaphysik* (Aachen: J. A. Mayer, 1877), was translated by C. M. Duff as *The Elements of Metaphysics* (London, 1894).

Deussen was the first Western philosopher to include Eastern thought in a general history of philosophy in any scientific way. Among his publications in this field are *Das System des Vedanta* (Leipzig: F. A. Brockhaus, 1883), translated by Charles Johnston as *The System of the Vedanta* (Chicago: Open Court, 1912); *Die Sūtra des Vedānta*, translated from the Sanskrit (Leipzig, 1887), translated by H. Woods and C. B. Rumble as *The Sutras of the Vedanta with the Commentary of Cankara* (New York, 1906); *Sechzig Upanishads des Veda*, which he translated from the Sanskrit (Leipzig: F. A. Brockhaus, 1897); *Vier philosophische Texte des Mahābhāratam* (Leipzig: F. A. Brockhaus, 1906); *Bhagavadgītā. Der Gesang des Heiligen* (Leipzig, 1911); and

*Die Geheimenlehre des Veda* (Leipzig: F. A. Brockhaus, 1907–1909).

Three volumes of an autobiographical nature are *Mein Leben* (Leipzig, 1927); *Erinnerungen an Friedrich Nietzsche* (Leipzig: F. A. Brockhaus, 1901); and *Erinnerungen an Indien* (Leipzig: Lipsius and Tischer, 1904). Bound together with the *Erinnerungen an Indien* is a lecture, “On the Philosophy of the Vedanta in Its Relations to Occidental Metaphysics,” delivered and first published in Bombay in 1893.

On Deussen, see “Erinnerungen an Paul Deussen,” which is Vol. 20 of *Jahrbuch der Schopenhauer-Gesellschaft* (1920).

## DEUSTUA, ALEJANDRO O. (1849–1945)

Alejandro O. Deustua, the Peruvian educator, aesthetician, and philosopher, was born in Huancayo. He was a professor at the University of San Marcos, rector of the University, and director of the National Library in Lima. Deustua contributed greatly to the development of Peruvian education at all levels. His philosophical writing was done at an advanced age. It reflected the influence of K. C. F. Krause and Henri Bergson.

Running through the thought of Deustua are the polar ideas of liberty and order. Their interplay extends to a philosophy of civilization, but it is most clear in his major interest, aesthetics. It may be introduced through his definitions of beauty and art. Beauty is “a conciliation of liberty and nature, through the mediation of an ideal order created by the imagination.” Since an internal image is not sufficient, external forms are created by art, which is the “graceful expression of the conciliation between nature and liberty, a conciliation imagined by the artist and translated by means of adequate or expressive forms.”

The element of nature is furnished by human sensibility, including sensation and emotion. Liberty is found in absence of resistance, which in turn allows development from within to take place. It belongs to spirit and is paramount in that function of spirit called imagination, which is defined not as imaginal but as creative. Liberty is manifest only in an order, and it is fully realized only in an order entirely of its own making, an artistic order or harmony. This order is created by the imagination, using sensuous elements and acting in close relation with emotion. Harmony is a unity in variety: aesthetic pleasure is opposed to monotony and to excessive complexity. Types of harmony are symmetry and rhythm. Related to these are an outward order of parts and whole in space, charac-

teristic of classical art, and an inward order of causes or purposes in time, characteristic of romantic art. When liberty is realized in order, the result is grace.

In addition to beauty there are several other types of value, to all of which imagination can contribute in one degree or another. These values may in turn contribute to the aesthetic experience, but they fall below beauty in freedom. Logical truth is characterized by demonstrative necessity. Economic value is subject to the imperative of desire, in contrast to the disinterestedness of aesthetic experience. Although moral value presupposes a free agent, it requires that the will submit to duty and law. Religious revelation and myth are aesthetic in nature; but they demand submission to the divine will. Only in the aesthetic sphere is liberty sovereign, unbound by orders or norms external to it. For this reason, aesthetic value is “the value of values.”

## DEWEY, JOHN (1859–1952)

The American philosopher, educator, and social critic John Dewey was born in Burlington, Vermont. A shy youth, he enjoyed reading books and was a good but not a brilliant student. He entered the University of Vermont in 1875, and although his interest in philosophy and social thought was awakened during his last two years there, he was uncertain about his future career. He taught classics, science, and algebra at a high school in Oil City,

Pennsylvania, from 1879 to 1881 and then returned to Burlington, where he continued to teach. He also arranged for private tutorials in philosophy with his former teacher, H. A. P. Torrey. Encouraged by Torrey and W. T. Harris, the editor of the *Journal of Speculative Philosophy* who accepted Dewey’s first two philosophical articles, Dewey applied for the graduate program at the newly organized Johns Hopkins University. He was twice refused fellowship aid, but he borrowed \$500 from an aunt to begin his professional philosophical career.

The external events of Dewey’s Vermont years were relatively unexciting, and there is very little to indicate that he would become America’s most influential philosopher and educator as well as one of the most outspoken champions of social reform. Yet the New England way of life left a deep imprint on the man and his thought. His modesty, forthrightness, doggedness, deep faith in the workings of the democratic process, and respect for his fellow man are evidenced in almost everything that he did and wrote.

Under the imaginative guidance of Daniel Gilman, the first president of Johns Hopkins, the university had become one of the most exciting centers for intellectual and scholarly activity. Dewey studied with C. S. Peirce, who taught logic, and with G. S. Hall, one of the first experimental psychologists in America. The greatest initial influence on Dewey, however, was G. S. Morris, whose philosophical outlook had been shaped by G. W. F. Hegel and the idealism so much in vogue on the Continent and in England.

Dewey was an eager participant in the controversies stirred up by Hegelianism. He dated his earliest interest in philosophy to a course in physiology that he took during his junior year at the University of Vermont, where he read T. H. Huxley’s text on physiology. Dewey discovered the concept of the organic and developed a sense of the interdependence and interrelated unity of all things. He tells us that subconsciously he desired a world and a life that would have the same properties as had the human organism that Huxley described. In Hegel and the idealists, Dewey discovered the most profound philosophical expression of this emotional and intellectual craving. From this organic perspective, which emphasized process and change, all distinctions are functional and relative to a developing unified whole. The organic perspective could be used to oppose the static and the fixed and to break down the hard and fast dichotomies and dualisms that had plagued philosophy.

Dewey’s writings during his Hegelian period are infused with an evangelical spirit and are as enthusiastic

as they are vague. Whatever issue Dewey considered, he was convinced that once viewed from the perspective of the organic, old problems would dissolve and new insights would emerge. Long after Dewey had drifted away from his early Hegelianism, his outlook was shaped by his intellectual bias for a philosophy based on change, process, and dynamic, organic interaction.

After completing his doctoral studies at Johns Hopkins with a dissertation on the psychology of Immanuel Kant, Dewey joined Morris at the University of Michigan in 1884. He remained there for the next ten years, with the exception of one year (1888) when he was a visiting professor at the University of Minnesota. At Michigan, Dewey worked with G. H. Mead, who later joined Dewey at Chicago. During his years at Michigan, Dewey became dissatisfied with pure speculation and sought ways to make philosophy directly relevant to the practical affairs of men. His political, economic, and social views became increasingly radical. He agreed to edit a new weekly with a socialist orientation, to be called *Thought News*, but it never reached publication. Dewey also became directly involved with public education in Michigan. His scientific interests, especially in the field of psychology, gradually overshadowed his interest in pure speculation. He published several books on theoretical and applied psychology, including *Psychology* (New York, 1887; 3rd rev. ed., 1891), *Applied Psychology* (Boston, 1889), and *The Psychology of Number and Its Applications to Methods of Teaching Arithmetic* (New York, 1895). The latter two books were written with J. A. McLellan.

Dewey's appointment in 1894 as chairman of the department of philosophy, psychology, and education at the University of Chicago provided an ideal opportunity for consolidating his diverse interests. In addition to his academic responsibilities, Dewey actively participated in the life of Hull House, founded by Jane Addams, where he had an opportunity to become directly acquainted with the social and economic problems brought about by urbanization, rapid technological advance, and the influx of immigrant populations. Dewey mixed with workers, union organizers, and political radicals of all sorts. At the university, Dewey assembled a group of sympathetic colleagues who worked closely together. Collectively they published the results of their research in a volume of the Decennial Publications of the University of Chicago titled *Studies in Logical Theory* (Chicago, 1903). William James, to whom the book was dedicated, rightly predicted that the ideas developed in the *Studies* would dominate the American philosophical scene for the next twenty-five years.

Shortly after Dewey arrived in Chicago, he helped found the famous laboratory school, commonly known as the Dewey School, which served as a laboratory for testing and developing his psychological and pedagogic hypotheses. Some of Dewey's earliest and most important books on education were based on lectures delivered at the school: *The School and Society* (Chicago, 1900) and *The Child and the Curriculum* (Chicago, 1902). When Dewey left Chicago for Columbia in 1904 because of increasing friction with the university administration concerning the laboratory school, he had already acquired a national reputation for his philosophical ideas and educational theories. The move to Columbia, where he remained until his retirement in 1930, provided a further opportunity for development, and Dewey soon gained international prominence. Through the Columbia Teachers College, which was a training center for teachers from many countries, Dewey's educational philosophy spread throughout the world.

At the time that Dewey joined the Columbia faculty, the *Journal of Philosophy* was founded by F. J. E. Woodbridge, and it became a forum for the discussion and defense of Dewey's ideas. There is scarcely a volume from the time of its founding until Dewey's death that does not contain an article either by Dewey or about his philosophy. As the journalistic center of the country, New York also provided Dewey with an opportunity to express himself on pressing political and social issues. He became a regular contributor to the *New Republic*. A selection of Dewey's popular essays is collected in *Characters and Events*, 2 vols. (New York, 1929).

Wherever Dewey lectured he had an enormous influence. From 1919 to 1921, he lectured at Tokyo, Beijing, and Nanjing, and his most popular book, *Reconstruction in Philosophy* (New York, 1920), is based on his lectures at the Imperial University of Japan. He also conducted educational surveys of Turkey, Mexico, and Russia. Although he retired from Columbia in 1930, he remained active and wrote prolifically until his death. In 1937, when Dewey was seventy-eight, he traveled to Mexico to head the commission investigating the charges made against Leon Trotsky, during the Moscow trials. After a careful investigation, the commission published its report, *Not Guilty* (New York, 1937). In 1941 Dewey championed the cause of academic freedom when Bertrand Russell—his arch philosophical adversary—had been denied permission to teach at the City College of New York, Dewey collaborated in editing a book of essays protesting the decision.

Although constantly concerned with social and political issues, Dewey continued to work on his more technical philosophical studies. M. H. Thomas's bibliography of his writings comprises more than 150 pages. Dewey's influence extended not only to his colleagues but to leaders in almost every field. The wide effects of his teaching did not depend upon the superficial aspects of its presentation, for Dewey was not a brilliant lecturer or essayist, although he could be extremely eloquent. His writings are frequently turgid, obscure, and lacking in stylistic brilliance. But more than any other American of his time, Dewey expressed the deepest hopes and aspirations of his fellow man. Whether dealing with a technical philosophical issue or with some concrete injustice, he displayed a rare combination of acuteness, good sense, imagination, and wit.

### EXPERIENCE AND NATURE

The key concept in Dewey's philosophy is experience. Although there is a development from an idealistic to a naturalistic analysis of experience and different emphases in his many discussions of the concept, a nevertheless coherent view of experience does emerge. In his early philosophy Dewey was sympathetic to the theory of experience developed by the Hegelians and the nineteenth-century idealists. He thought of experience as a single, dynamic, unified whole in which everything is ultimately interrelated. There are no rigid dichotomies or breaks in experience and nature. All distinctions are functional and play a role in a complex organic system. Dewey also shared the idealists' antipathy to the atomist and subjectivist tendencies in the concept of experience elaborated by the British empiricists. But as Dewey drifted away from his early Hegelian orientation he indicated three major respects in which he rejected the idealistic concept of experience.

First, he charged that the idealists, in their preoccupation with knowledge and knowing, distorted the character of experience. Idealists, Dewey claimed, neglected the noncognitive and nonreflective experiences of doing, suffering, and enjoying that set the context for all knowing and inquiry. Philosophy, especially modern philosophy, had been so concerned with epistemological issues that it mistook all experience as a form of knowing. Such bias inevitably distorts the character of both man's experience and his knowing. Man is primarily a being who acts, suffers, and enjoys. Most of his life consists of experiences that are not primarily reflective. If we are to understand the nature of thought, reflection, inquiry, and their role in human life, we must appreciate their emer-

gence from, and conditioning by, the context of nonreflective experience. There is more to experience, Dewey believed, than is to be found in the writings of the idealists and, indeed, in the writings of most epistemologists.

The second major departure from his early idealism is to be found in Dewey's rejection of the idea of a single unified whole in which everything is ultimately interrelated. In this respect, he displayed an increasing sympathy with the pluralism of the British empiricists. He insisted that life consists of a series of overlapping and interpenetrating experiences, situations, or contexts, each of which has its internal qualitative integrity. The individual experience is the primary unit of life.

The third shift is reflected in Dewey's increasingly naturalistic bias. The Hegelians and the nineteenth-century idealists did have important insights into the organic nature of experience, but they had overgeneralized them into a false cosmic projection. Dewey discovered in the new developing human sciences, especially in what he called the anthropological-biological orientation, a more careful, detailed, scientific articulation of the organic character of experience.

Dewey thought of himself as part of a general movement that was developing a new empiricism based on a new concept of experience, one that combined the strong naturalistic bias of the Greek philosophers with a sensitive appreciation for experimental method as practiced by the sciences. He was sympathetic with what he took to be the Greek view of experience, which considers it as consisting of a fund of social knowledge and skills and as being the means by which man comes into direct contact with a qualitatively rich and variegated nature. But Dewey was just as forceful in pointing out that this view of experience had to be reconstructed in light of the experimental method of the sciences. One of his earliest and clearest discussions of the nature of experience as an organic coordination is to be found in "The Reflex Arc Concept in Psychology" (*Psychological Review*, Vol. 3, 1896).

Dewey's interest in developing a new theory of experience led many critics to question the exact status of experience within nature, and some objectors charged him with excessive anthropomorphism. Sensitive to this type of criticism, Dewey, particularly in *Experience and Nature* (Chicago, 1925; 2nd ed., New York, 1929), attempted to deal with this criticism and to sketch a metaphysics, "the descriptive study of the generic traits of existence."

Nature, according to Dewey, consists of a variety of transactions that can be grouped into three evolutionary plateaus, or levels. Transaction is the technical term that Dewey used to designate the type of action in which the components and elements involved in the action both condition and are conditioned by the entire coordination. The elements of a transaction play a functional role in the developing coordination. The three plateaus of natural transactions are the physicochemical, the psychophysical, and the level of human experience. There are no sharp breaks or discontinuities within nature. But there are distinctive characteristics of the different levels of natural transactions that are reflected in their patterns of behavior and in their consequences. From this perspective, human experience consists of one type of natural transaction, a type that has been the latest to evolve. The distinguishing characteristics of this level of natural transaction are to be located in the type of language, communication, and social living that humans have developed. Experience is all-inclusive in the sense that man is involved in continuous transactions with the whole of nature, and through systematic inquiry he can come to understand the essential characteristics of nature. Some of the more specific areas of Dewey's philosophy can be investigated against this panoramic view of experience and nature.

## ART AND EXPERIENCE

The ideas contained in Dewey's *Art as Experience* (New York, 1934) provided a surprise for many readers. Popular versions of his philosophy had so exaggerated the role of the practical and the instrumental that art and aesthetic experience seemed to have no place in his philosophical outlook. More perceptive commentators realized that Dewey was making explicit a dimension of his view of experience that had always been implicit and essential to an understanding of his philosophy. The meaning and role of art and aesthetic quality are crucial for understanding Dewey's views on logic, education, democracy, ethics, social philosophy, and even technology.

Dewey had persistently claimed that knowing, or more specifically, inquiry, is an art requiring active experimental manipulation and testing. Knowing does not consist of the contemplation of eternal forms, essences, or universals. Dewey argued that the "spectator theory of knowledge," which had plagued philosophy from its beginnings, is mistaken. He also objected to the sharp division between the theoretical sciences and the practical arts that had its explicit source in Aristotle and had influenced so much later philosophy. Dewey maintained

that Aristotle's analysis of the practical disciplines is more fruitful for developing an adequate theory of inquiry than is his description of the theoretical sciences of knowing. Not only is inquiry an art, but all life is, or can be, artistic. The so-called fine arts differ in degree, not in kind, from the rest of life.

Dewey also gave a prominent place to what he called immediacy, pervasive quality, or aesthetic quality. This immediacy is not restricted to a special type of experience but is a distinctive feature of anything that is properly called "*an* experience." The primary unit of life, we have mentioned, is *an* experience, a natural transaction of acting, suffering, enjoying, knowing. It has both temporal development and spatial dimension and can undergo internal change and reconstruction.

But what is it that enables us to speak of an individual experience? Or, by virtue of what does an experience, situation, or context have a unity that enables us to distinguish it from other experiences? Dewey's answer is that everything that is an experience has immediacy or pervasive quality that binds together the complex constituents of the experience. This immediacy or pervasive quality can be directly felt or had. But this qualitative dimension of experience is not to be confused with a subjective feeling that is somehow locked up in the mind of the experienter. Nor is it to be thought of as something that exists independently of any experienter. These qualities that pervade natural transactions are properly predicated of the experience or situation as a whole. Within an experiential transaction we can institute distinctions between what is subjective and what is objective. But such distinctions are relative to, and dependent on, the context in which they are made. An experience or a situation is a whole in virtue of its immediate pervasive qualities, and each occurrence of these qualities is unique. As examples of such pervasive qualities, Dewey mentions the qualities of distress or cheer that mark existent situations, qualities that are unique in their occurrence and inexpressible in words but capable of being directly experienced. Thus, when one directly experiences a frightening situation, it is the situation that is frightening and not merely the experience.

These pervasive, or "tertiary," qualities are what Dewey calls aesthetic qualities. Aesthetic quality is thus an essential characteristic of all experiences. Within an experience, the pervasive quality can guide the development of the experience, and it can also be transformed and enriched as the experience is reconstructed. Aesthetic quality can be funded with new meaning, ideas, and emotions. A situation that is originally indeterminate, slack,

or inchoate can be transformed into one that is determinate, harmonious, and funded with meaning; this type of reconstructed experience Dewey called a consummation. Such experiences are reconstructed by the use of intelligence. For example, when one is confronted with a specific problematic situation that demands resolution, one can reconstruct the situation by locating its problematic features and initiating a course of action that will resolve the situation. Consummations are characteristic of the most mundane practical tasks as well as the most speculative inquiries. The enemies of the aesthetic, Dewey claimed, are not the practical or the intellectual but the diffuse and slack at one extreme and the excessively rigid and fixed at the other. The type of experience that philosophers normally single out as aesthetic is a heightened consummation in which aesthetic qualities dominate.

Dewey viewed human life as a rhythmic movement from experiences qualified by conflict, doubt, and indeterminateness toward experiences qualified by their integrity, harmony, and funded aesthetic quality. We are constantly confronted with problematic and indeterminate situations, and insofar as we use our intelligence to reconstruct these situations successfully we achieve consummations. He was concerned both with delineating the methods by which we could most intelligently resolve the conflicting situations in which we inevitably find ourselves and with advocating the social reforms required so that life for all men would become funded with enriched meaning and increased aesthetic quality.

## LOGIC AND INQUIRY

Early in his career, Dewey started developing a new theory of inquiry, which he called instrumental or experimental logic. Dewey claimed that philosophers had lost touch with the actual methods of inquiry practiced by the experimental sciences. The function of instrumental logic is to study the methods by which we most successfully gain and warrant our knowledge. On the basis of this investigation, instrumental logic could specify regulative principles for the conduct of further inquiry.

The central themes of Dewey's conception of logic were outlined in *Studies in Logical Theory* (Chicago, 1903), applied to education in *How We Think* (Boston, 1910), and further refined in *Essays in Experimental Logic* (Chicago, 1916). Dewey also wrote numerous articles on various aspects of logic, but his most systematic and detailed presentation is in *Logic: The Theory of Inquiry* (New York, 1938), in which he defines inquiry as "*the controlled or directed transformation of an indeterminate situ-*

*ation into one that is so determinate in its constituent distinctions and relations as to convert the elements of the original situation into a unified whole*" (p. 104). By itself, this definition is not sufficient to grasp what Dewey intends. But his meaning can be understood when the definition is interpreted against the background of what we have said about the individual experience or situation and the way in which it is pervaded by a unifying quality.

We find ourselves in situations that are qualified by their indeterminateness or internal conflict. From the perspective of the experiencer or inquirer, we can say that he experiences a "felt difficulty." This is the antecedent condition of inquiry. Insofar as the situation demands some resolution, we must attempt to articulate the problem or problems that are to be solved. Formulating the problems may be a process of successive refinement in the course of the inquiry. The next logical stage is that of suggestion or hypothesis, in which we imaginatively formulate various relevant hypotheses for solving the problem. In some complex inquiries we may have to engage in hypothetico-deductive reasoning in order to refine our hypotheses and to ascertain the logical consequences of the hypothesis or set of hypotheses. Finally, there is the stage of experimental testing in which we seek to confirm or disconfirm the suggested hypotheses. If our inquiry is successful, the original indeterminate situation is transformed into a unified whole. Knowledge may be defined as the objective of inquiry. Knowledge is that which is warranted by the careful use of the norms and methods of inquiry. When "knowledge" is taken as an abstract term related to inquiry in the abstract, it means warranted assertibility. Furthermore, the knowledge gained in a specific inquiry is funded in our experience and serves as the background for further inquiry. By reflecting on this general pattern of inquiry, which can be exhibited in commonsense inquiry as well as the most advanced scientific inquiry, we can bring into focus the distinctive features of Dewey's logic.

First, this pattern of inquiry is intended to be a general schema for all inquiry. But the specific procedures, testing methods, type of evidence, and so on, will vary with different types of inquiry and different kinds of subject matter. Second, a specific inquiry cannot be completely isolated from the context of other inquiries. The rules, procedures, and evidence required for the conduct of any inquiry are derived from other successful inquiries. By studying the types of inquiry that have been most successful in achieving warranted conclusions, we can abstract norms, rules, and procedures for directing further inquiry. These norms may themselves be modified in

the course of further inquiry. Third, all inquiry presupposes a social or public context that is the medium for funding the warranted conclusions and norms for further inquiry. In this respect, Dewey agrees with Peirce's emphasis on the community of inquirers. Inquiry both requires such a community and helps to further the development of this community. Dewey attempted to relate this idea of a community of inquirers to his view of democracy. The essential principle of democracy is that of community; an effective democracy requires the existence of a community of free, courageous, and open-minded inquirers. Fourth, inquiry is essentially a self-corrective process. To conduct a specific inquiry, some knowledge claims, norms, and rules must be taken as fixed, but no knowledge claim, norm, or rule is absolutely fixed; it may be criticized, revised, or abandoned in light of subsequent inquiry and experience.

Dewey's theory of inquiry as an ongoing self-corrective process and his view of knowledge as that which is warranted through inquiry both differ radically from many traditional theories of inquiry and knowledge. Dewey thought of this theory as an alternative to the views of those philosophers who have claimed that there is an epistemological given that is indubitable and known with certainty. According to this epistemological model, some truths are considered to be absolutely certain, indubitable, or incorrigible. They may be considered self-evident, known by rational insight, or directly grasped by the senses. On the basis of this foundation, we then construct the rest of our knowledge. From Dewey's perspective, this general model that has informed many classical theories of knowledge is confused and mistaken. There are no absolute first truths that are given or known with certainty. Furthermore, knowledge neither has nor requires such a foundation in order to be rational. Inquiry and its objective, knowledge, are rational because inquiry is a self-corrective process by which we gradually become clearer about the epistemological status of both our starting points and conclusions. We must continually submit our knowledge claims to the public test of a community of inquirers in order to clarify, refine, and justify them.

## DEMOCRACY AND EDUCATION

Dewey is probably best known for his philosophy of education. This is not a special branch of his philosophy, however, for he claimed that all philosophy can be conceived of as the philosophy of education. And it is certainly true that all the concepts we have discussed inform his thinking about education. He returned again and again to the subject of education, but the essential ele-

ments of his position can be found in *My Pedagogic Creed* (New York, 1897), *The School and Society* (Chicago, 1900), *The Child and the Curriculum* (Chicago, 1902), and especially in his comprehensive statement in *Democracy and Education* (New York, 1916).

It is essential to appreciate the dialectical context in which Dewey developed his educational ideas. He was critical of the excessively rigid and formal approach to education that dominated the practice of most American schools in the latter part of the nineteenth century. He argued that such an approach was based upon a faulty psychology in which the child was thought of as a passive creature upon whom information and knowledge had to be imposed. But Dewey was equally critical of the "new education," which was based on a sentimental idealization of the child. This child-oriented approach advocated that the child himself should pick and choose what he wanted to study. It also was based on a mistaken psychology, which neglected the immaturity of the child's experience. Education is, or ought to be, a continuous reconstruction of experience in which there is a development of immature experience toward experience funded with the skills and habits of intelligence. The slogan "Learn by Doing" was not intended as a credo for anti-intellectualism but, on the contrary, was meant to call attention to the fact that the child is naturally an active, curious, and exploring creature. A properly designed education must be sensitive to this active dimension of life and must guide the child, so that through his participation in different types of experience his creativity and autonomy will be cultivated rather than stifled.

The child is not completely malleable, nor is his natural endowment completely fixed and determinate. Like Aristotle, Dewey believed that the function of education is to encourage those habits and dispositions that constitute intelligence. Dewey placed great stress on creating the proper type of environmental conditions for eliciting and nurturing these habits. His conception of the educational process is therefore closely tied to the prominent role that he assigned to habit in human life. (For a detailed statement of the nature and function of habit, see *Human Nature and Conduct*, New York, 1922.) Education as the continuous reconstruction and growth of experience also develops the moral character of the child. Virtue is taught not by imposing values upon the child but by cultivating fair-mindedness, objectivity, imagination, openness to new experiences, and the courage to change one's mind in the light of further experience.

Dewey also thought of the school as a miniature society; it should not simply mirror the larger society but

should be representative of the essential institutions of this society. The school as an ideal society is the chief means for social reform. In the controlled social environment of the school it is possible to encourage the development of creative individuals who will be able to work effectively to eliminate existing evils and institute reasonable goods. The school, therefore, is the medium for developing the set of habits required for systematic and open inquiry and for reconstructing experience that is funded with greater harmony and aesthetic quality.

Dewey perceived acutely the threat posed by unplanned technological, economic, and political development to the future of democracy. The natural direction of these forces is to increase human alienation and to undermine the shared experience that is so vital for the democratic community. For this reason, Dewey placed so much importance on the function of the school in the democratic community. The school is the most important medium for strengthening and developing a genuine democratic community, and the task of democracy is forever the creation of a freer and more humane experience in which all share and participate.

#### ETHICS AND SOCIAL PHILOSOPHY

In order to understand Dewey's moral philosophy, we must again focus on his concept of the situation. Man is a creature who by nature has values. There are things, states of affairs, and activities that he directly enjoys, prizes, or values. Moral choices and decisions arise only in those situations in which there are competing desires or a conflict of values. The problem that a man then confronts is to decide what he really wants and what course of action he ought to pursue. He cannot appeal to his immediate values to resolve the situation; he must evaluate or appraise the situation and the different courses of action open to him. This process of deliberation that culminates in a decision to act is what Dewey calls "valuation." But how do we engage in this process of valuation? We must analyze the situation as carefully as we can, imaginatively project possible courses of action, and scrutinize the consequences of these actions. Those ends or goods that we choose relative to a concrete situation after careful deliberation are reasonable or desirable goods. Our choices are reasonable to the extent that they reflect our developed habits of intelligence. Choices will be perverse or irrational if they are made on the basis of prejudice and ignorance. Dewey is fully aware that there are always practical limitations to our deliberations, but a person trained to deliberate intelligently will be prepared to act intelligently even in those situations that do not

permit extended deliberation. When we confront new situations we must imagine and strive for new goals. As long as there is human life, there will always be situations in which there are internal conflicts that demand judgment, decision, and action. In this sense, the moral life of man is never completed, and the ends achieved become the means for attaining further ends. But lest we think that man is always striving for something that is to be achieved in the remote future, or never, Dewey emphasized that there are consummations—experiences in which the ends that we strive for are concretely realized.

It should be clear that such a view of man's moral life places a great deal of emphasis on intelligence. Dewey readily admitted his "faith in the power of intelligence to imagine a future which is a projection of the desirable in the present, and to invent the instrumentalities of its realization." It should also be clear that ethics conceived of in this manner blends into social philosophy. Valuation, like all inquiry, presupposes a community of shared experience in which there are common norms and procedures, and intelligent valuation is also a means for making such a community a concrete reality. Here, too, ends and norms are clarified, tested, and modified in light of the cumulative experience of the community. Furthermore, it is the objective of social philosophy to point the way to the development of those conditions that will foster the effective exercise of practical intelligence. The spirit that pervades Dewey's entire philosophy and finds its perfect expression in his social philosophy is that of the reformer or reconstructor, not the revolutionary. Dewey was always skeptical of panaceas and grand solutions for eliminating existing evils and injustices. But he firmly believed that with a realistic scientific knowledge of existing conditions and with a cultivated imagination, men could ameliorate the human condition. To allow ourselves to drift in the course of events or to fail to assume our responsibility for continuous reconstruction of experience inevitably leads to the dehumanization of man.

#### PHILOSOPHY AND CIVILIZATION

Dewey presented a comprehensive and synoptic image of man and the universe. The entire universe consists of a multifarious variety of natural transactions. Man is at once continuous with the rest of nature and exhibits distinctive patterns of behavior that distinguish him from the rest of nature. His experience is also pervaded with qualities that are not reducible to less complex natural transactions. Thus, Dewey attempted to place man within the context of the whole of nature. In addition, Dewey was sensitive to the varieties of human experience. He

sought to delineate the distinctive features of different aspects of experience, ranging from mundane practical experience to the religious dimension of experience. Within the tradition of philosophy Dewey may be characterized as a robust naturalist or a humanistic naturalist. His philosophy is both realistic and optimistic. There will always be conflicts, problems, and competing values within our experience, but with the continuous development of “creative intelligence” men can strive for and realize new ends and goals.

This synoptic view of man and the universe is closely related to Dewey’s conception of the role of philosophy in civilization. Philosophy is dependent on, but should attempt to transcend, the specific culture from which it emerges. The function of philosophy is to effect a junction of the new and the old, to articulate the basic principles and values of a culture, and to reconstruct these into a more coherent and imaginative vision. Philosophy is therefore essentially critical and, as such, will always have work to do. For as the complex of traditions, values, accomplishments, and aspirations that constitute a culture changes, so must philosophy change. Indeed, in pointing the way to new ideals and in showing how these may be effectively realized, philosophy is one of the means for changing a culture. Philosophy is continually faced with the challenge of understanding the meaning of evolving cultures and civilizations and of articulating new projected ideals. The motif of reconstruction that runs throughout Dewey’s investigations dominates his conception of the role of philosophy in civilization. He epitomized the spirit of his entire philosophical endeavor in his “plea for casting off of that intellectual timidity which hampers the wings of imagination, a plea for speculative audacity, for more faith in ideas, sloughing off a cowardly reliance upon those partial ideas to which we are wont to give the name facts.” He fully realized that he was giving philosophy a more modest function than had been given by those who claimed that philosophy reveals an eternal reality. But such modesty is not incompatible with boldness in the maintenance of this function. As Dewey declared, “a combination of such modesty and courage affords the only way I know of in which the philosopher can look his fellow man in the face with frankness and humanity” (*Philosophy and Civilization*, p. 12).

tism; Value and Valuation; Woodbridge, Frederick James Eugene.

### **Bibliography**

The most exhaustive bibliography of John Dewey’s writings is M. H. Thomas’s *John Dewey: A Centennial Bibliography* (Chicago: University of Chicago Press, 1962). This excellent guide includes a comprehensive listing of Dewey’s writings, translations and reviews of his works, and a bibliography of books, articles, and dissertations about Dewey.

A less comprehensive bibliography of Dewey’s writings can also be found in *The Philosophy of John Dewey*, edited by P. A. Schilpp (Evanston, IL: Northwestern University Press, 1939).

The following secondary sources are helpful as general introductions to Dewey’s life and philosophy. Richard J. Bernstein, *John Dewey* (New York: Washington Square Press, 1966) focuses on the concept of experience and nature. George R. Geiger, *John Dewey in Perspective* (New York: Oxford University Press, 1958) stresses the role of aesthetic experience as the key to Dewey’s philosophy. Sidney Hook, *John Dewey: An Intellectual Portrait* (New York: Day, 1939) captures both the spirit and letter of Dewey as a man, social reformer, and philosopher. Robert J. Roth, S.J., *John Dewey and Self-Realization* (Englewood Cliffs, NJ: Prentice-Hall, 1962) shows the importance and meaning of religious experience for Dewey.

*Richard J. Bernstein (1967)*

## DEWEY, JOHN [ADDENDUM]

John Dewey has undergone an extraordinary renaissance of scholarly and public concern with his thought. Dewey (1859–1952) was encyclopedic in both his interests and achievements. The full and startling range of his written reflections is now apparent with the completed publication of his *Works* in a critical edition of thirty-seven volumes. Commentaries and critical interpretations have followed apace.

In the mediated public mind, prior discussion of Dewey’s thought for the most part was devoted to his work on education, both in theory and practice. Unfortunately, these discussions of Dewey’s approach to pedagogy and to schooling as an institution in a democratic society were often disconnected from his metaphysics, aesthetics, and social and political philosophy. This interpretive mishap is now being rectified with the appearance of many perceptive studies of Dewey’s thought, including his previously neglected thoughts on religion and logic.

Fundamentally, John Dewey is an unregenerate philosophical naturalist, one for whom the human jour-

ney is constitutive of its own meaning and is not to be rescued by any transcendent explanations, principles of accountability, or posthumous salvation. Obviously, this position is both liberating and baleful, in that it throws us back on our own human resources, for better and for worse. In effect, we are responsible for our actions, for the course of human history, and we are called upon to navigate between the shoals of supine obeisance and arrogant usurpation. In *A Common Faith* (1934), Dewey warns of the danger to human solidarity when we do not accept this responsibility. “Weak natures take to reverie as a refuge as strong ones do to fanaticism. Those who dissent are mourned over by the first class and converted through the use of force by the second.”

Leaving no philosophical stone unturned, Dewey addresses the pitfalls and possibilities of the human condition from a wide array of vantage points. His central text is *Experience and Nature*, in which he probes the transactions of the human organism with the affairs of nature. These transactions are to be understood and diagnosed as experiential oscillations between the “precarious” and the “stable.” The settings for this trenchant discussion include communication, mind, art, and value. In retrospect, Dewey offered that he should have titled this work *Culture and Nature*, an appropriate reconsideration, for it is helpful to read Dewey as a philosopher of culture, with an eye toward his grasp of human institutions, social, political, and educational.

Since the 1980s the focus of commentaries on the work of Dewey has been directed to his social and political philosophy, particularly his writings between 1927 and 1935, namely, *The Public and Its Problems*, *Individualism Old and New*, and *Liberalism and Social Action*. Although Dewey’s thought was indigenous to American culture, it is nonetheless remarkable that themes found in Marxist and existentialist traditions are present in these writings, cast differently but equally telling. Of special note is the renewed admiration for Dewey’s philosophy of community and his deep grasp of the complex relationships of individuals in communities. For Dewey the irreducible trait of human life is found in the activity of face-to-face communities. Their quality is the sign of how we are faring, humanly. At the end of *Human Nature and Conduct*, he writes a message for his time and for our time as well.

Within the flickering inconsequential acts of separate selves dwells a sense of the whole which claims and dignifies them. In its presence we put off mortality and live in the universal. The life of the community in which we live and have our

being is the fit symbol of this relationship. The acts in which we express our perception of the ties which bind us to others are its only rites and ceremonies.

## Bibliography

### WORKS BY DEWEY

- Works of John Dewey*. Edited by J. A. Boydston. Carbondale: Southern Illinois University Press, 1969–1990. Divided into Early Works (5 vols.), Middle Works (15 vols.), and Later Works (17 vols.). This is a critical edition.
- The Correspondence of John Dewey, 1871–1952*. Edited by Larry A. Hickman. Charlottesville, VA: InteLex Corporation, 1999–2005. Vol. 1 (1871–1918), 1999. Rev. ed. 2001, 2005; Vol. 2 (1919–1939), 2001. Rev. ed. 2005; Vol. 3 (1940–1952), 2005.
- The Essential Dewey*. 2 vols. Edited by Larry A. Hickman and Thomas Alexander. Bloomington: Indiana University Press, 1998.
- The Philosophy of John Dewey*. Edited by J. J. McDermott. Chicago: University of Chicago Press, 1981. Complete selections from Dewey’s major writings.

### WORKS ON DEWEY

- Campbell, J. *Understanding John Dewey*. Chicago: Open Court, 1995. The most intelligent and accurate interpretation of Dewey’s thought overall.
- Hickman, L. A. *John Dewey’s Pragmatic Technology*. Bloomington: Indiana University Press, 1990.
- Hickman, L. A., ed. *Reading Dewey: Interpretations for a Postmodern Generation*. Bloomington: Indiana University Press, 1998.
- Martin, Jay. *The Education of John Dewey—A Biography*. New York: Columbia University Press, 2003.
- Rockefeller, S. C. *John Dewey: Religious Faith and Democratic Humanism*. New York: Columbia University Press, 1991.
- Schilpp, P. A., and L. E. Hahn, eds. *The Philosophy of John Dewey*, 3rd ed. La Salle, IL: Open Court, 1989. Contains a bibliography of Dewey’s publications with entries and corrections until 1989.
- Shook, John R. *Dewey’s Empirical Theory of Knowledge and Reality*. Nashville, TN: Vanderbilt University Press, 2000.
- Sleeper, R. S. *The Necessity of Pragmatism: John Dewey’s Conception of Philosophy*. New Haven, CT: Yale University Press, 1986. An insightful presentation of the relationship between Dewey’s thought and major currents in contemporary philosophy.
- Welchman, J. *Dewey’s Ethical Thought*. Ithaca, NY: Cornell University Press, 1995.
- Westbrook, R. *John Dewey and American Democracy*. Ithaca, NY: Cornell University Press, 1991. A synoptic and especially perceptive book on Dewey’s social thought.

## DIALECTIC

The term *dialectic* originates in the Greek expression for the art of conversation (*διαλεκτική τέχνη*). So far as its great variety of meanings have anything in common, it is perhaps that dialectic is a method of seeking and sometimes arriving at the truth by reasoning, but even this general description, which to fit the variety of cases is so vague as to be valueless, fails to do justice to the Hegelian and Marxist notion of dialectic as a historical process. However, among the more important meanings of the term have been (1) the method of refutation by examining logical consequences, (2) sophistical reasoning, (3) the method of division or repeated logical analysis of genera into species, (4) an investigation of the supremely general abstract notions by some process of reasoning leading up to them from particular cases or hypotheses, (5) logical reasoning or debate using premises that are merely probable or generally accepted, (6) formal logic, (7) the criticism of the logic of illusion, showing the contradictions into which reason falls in trying to go beyond experience to deal with transcendental objects, and (8) the logical development of thought or reality through thesis and antithesis to a synthesis of these opposites. Meaning (2) is notably still current, and the term is often used in a pejorative sense.

In the following discussion the different kinds of dialectic will be elucidated in their historical order.

### SOCRATES AND HIS PREDECESSORS

Dialectic perhaps originated in the fifth century BCE, since Zeno of Elea, the author of the famous paradoxes, was recognized by Aristotle as its inventor (Diogenes Laërtius, *Lives* VIII, 57). Aristotle presumably had Zeno's paradoxes in mind, as they are outstanding examples of dialectic, in the sense of refutation of the hypotheses of opponents by drawing unacceptable consequences from those hypotheses. For example, it is unacceptable that Achilles never overtakes the tortoise; therefore, the hypothesis that leads to this conclusion must be rejected. Insofar as this method relies on the law of formal logic known as *modus tollens* (if  $p$  implies  $q$ , and  $q$  is false, then  $p$  is false), Zeno was a pioneer of logic, but there is no evidence that he could formulate the law itself; it was left to Aristotle later to state explicitly the principles that underlie this kind of dialectic, and thus to create the science of formal logic.

Dialectic as the use of such indirect logical arguments to defeat an opponent seems to have been used by Zeno for serious philosophical purposes, but it later

became, in the hands of the Sophists, a mere instrument for winning a dispute. For example, the Sophist Protagoras claimed that he could "make the worse argument appear the better"; such an aim belongs rather to rhetoric than to logic or philosophy. This degenerate form of dialectic was named "eristic" by Plato (for example, in *Sophist* 231E) and others, from the word *ἔρις* (strife). Eristic came to make deliberate use of invalid argumentation and sophistical tricks, and these were ridiculed by Plato in his dialogue *Euthydemus*, which takes its name from an actual Sophist who appears in it as a user of eristic arguments. Aristotle, too, thought the Sophists worth answering in his book *De Sophisticis Elenchis* (Sophistical refutations), although he sharply distinguished eristic from dialectic, dialectic being for him a respectable activity.

If, however, the lost work of Protagoras did begin, as several subsequent writers attest, with the claim that on every subject two opposite statements (*λόγοι*) could be made, and if the book continued with a content of statement and counterstatement, then Protagoras deserves to be considered the ancestor of the medieval or of the Hegelian dialectic rather than the father of eristic.

Socrates stands in contrast to the Sophists. Unlike them, he professed to be seeking the truth. But he was not above winning the argument, and what is called the *elenchus* was a major element in dialectic as practiced by him, if we are to accept as accurate the presentation of him in Plato's earlier dialogues. The Socratic *elenchus* was perhaps a refined form of the Zenonian paradoxes, a prolonged cross-examination that refutes the opponent's original thesis by getting him to draw from it, by means of a series of questions and answers, a consequence that contradicts it. This is a logically valid procedure, for it corresponds to the logical law "if  $p$  implies not- $p$ , then not- $p$  is true (that is,  $p$  is false)." Dialectic seems to have been, for Socrates, literally the art of discussion, a search for truth by question and answer; but the definition of a concept is the sort of truth that was typically sought by him, and he supplemented his *elenchus* with another technique, later called *epagoge* (*ἐπαγωγή*) by Aristotle. This consisted in leading the opponent on to a generalization by getting him to accept the truth of a series of propositions about particular cases. It may now be seen why, in discussing dialectic, Aristotle says "there are two innovations that may justly be ascribed to Socrates: epagogic arguments and universal definition" (*Metaphysics* M 4, 1078b). For Aristotle had a different conception of dialectic, and since *elenchus* goes back to Zeno, the two features he mentions are the only contributions made by

Socrates to dialectic as Aristotle understood it. The Socratic irony, or pretense not to know anything and not to be conducting a refutation, was a personal feature of Socrates' dialectic and contributed nothing to later developments.

## PLATO

In the middle dialogues of Plato there occurs a development of the notion of dialectic beyond what we take to be typical of the historical Socrates. Even though Socrates is the protagonist, the views he is portrayed as putting forward are presumably those of Plato. Dialectic is regarded there as the supreme philosophical method, indeed the highest of human arts: it is "the coping-stone, as it were, placed above the sciences" (*Republic* 534E). In the *Cratylus* Plato had described the dialectician as "the man who knows how to ask and answer questions" (390C), and this view of dialectic as question and answer is the Socratic element that forms the single thread running through his altering conceptions of the method. Furthermore, dialectic always had the same subject matter: it sought the unchanging essence of each thing. But the kind of reasoning that Plato regarded as involved in dialectic seems to change: In the middle dialogues it was some kind of operation on hypotheses, whereas in the later ones (for example, *Phaedrus* and *Sophist*) there is, instead, an emphasis on division (*διαίρεσις*) as a method. Division in effect consists of a repeated analysis of genera into species, of more general notions into less general ones, as a way of arriving at a definition when no further division is possible. This process is complemented by the opposite process of synthesis or collection (*συναγωγή*).

Although Plato always spoke of dialectic in an extremely favorable manner, his discussion of it in *Republic* VI–VII marks a high point, as it is there made to be the distinguishing feature in the education of the philosopher-kings and is to be concerned eventually with the supreme Form, that of the Good. It is to reach certainty and overcome the need for hypotheses (*Republic* 511B). But the elevation of the sentiments expressed is matched by suitable vagueness as to the exact process involved, and the interpretation of the few words that are at all precise has been greatly disputed.

It may seem that if dialectic is a process of discussion, then it cannot be of any use for private thought. For Plato, however, there was no difference between the two: "Thought and speech are the same thing, but the silently occurring internal dialogue of the soul with itself has been specially given the name of thought" (*Sophist* 263E; see also *Theaetetus* 189E). However, Plato's most impor-

tant pupil, Aristotle, was already taking a different view of the nature of thought and hence assigning a merely secondary role to dialectic: "Deception occurs to a greater extent when we are investigating with others than by ourselves, for an investigation with someone else is carried on by means of words, but an investigation in one's own mind is carried on quite as much by means of the thing itself" (*De Sophisticis Elenchis* 169a37). Dialectic was no longer to be the method of science.

## ARISTOTLE

The practice of dialectic was probably a major activity in Plato's Academy, to which Aristotle belonged from 367 BCE until Plato's death in 347. Aristotle's *Topics* was apparently intended as an aid to this dialectical debate. It is a handbook for finding arguments to establish or demolish given positions, or *theses*, such as "Every pleasure is good," and while the particular theses used as examples in the *Topics* are no doubt borrowed from the debates in the Academy, the methods provided for dealing with them are completely general, that is, applicable to any thesis of the same form. The *Topics* is therefore the first systematic account of dialectic, and Aristotle indeed boasted that prior to his own treatment of the subject "it did not exist at all" (*De Sophisticis Elenchis* 183b36), and criticized the Sophists for giving teaching that was unsystematic (*ἄτεχνος*). His own trend toward generality and system had the effect that in the *Topics* Aristotle discovered many basic principles of formal logic, including some in the propositional calculus and in the logic of relations, but he hardly reached an explicit formal statement of them. A large part, at least, of this work was written before his discovery of the (categorical) syllogism, a type of argument for which he developed, in his *Analytics*, an elaborate system—the earliest system of formal logic—that superseded dialectic as a theory of demonstration. But even if Aristotle's formal logic developed as an alternative to his dialectic, it may still have arisen out of dialectic in some sense, since it has been argued that he discovered the syllogism as a result of reflection on Plato's method of division.

The distinguishing feature of dialectic for Aristotle was not so much the type of reasoning as the epistemological status of the premises. Reasoning is dialectical if its premises are opinions that are generally accepted by everyone or by the majority or by philosophers; if the premises merely *seem* probable, or if the reasoning is incorrect, then it is "eristic." Aristotelian dialectic is thus quite respectable; it has even been called a "logic of probability," a name that could be misleading because dialectic

tic does not in fact involve inductive reasoning. However, dialectic is not good enough, Aristotle believed, to be a method of acquiring knowledge proper, or science. For that we require demonstration, which is valid reasoning that starts out from true and self-evident premises. The value of dialectic, according to Aristotle, is threefold: It is useful for intellectual training, for discussions with others based on their own premises, and for examining the unprovable first principles of the sciences. “Dialectic, being a process of criticism, contains the path to the principles of all inquiries” (*Topics* 101b3).

### STOICS AND MEDIEVALS

Euclides of Megara (a contemporary of Plato) and his successors in that town were logicians of note, and the Megarian tradition in logic was continued by the Stoics. The Stoic logic was known as dialectic, perhaps because the initiators of their tradition had an interest in the Zenonian paradoxes and related reasoning. Under the headship of Chrysippus, who lived from 280 to 206 BCE, the Stoic school reached its zenith, and it was still going strong four centuries later. A saying is recorded from this period, that “if the gods had dialectic, it would be the dialectic of Chrysippus” (Diogenes Laërtius, *Lives* VII, 180). By “dialectic” the Stoics primarily meant formal logic, in which they particularly developed forms of inference belonging to what we now call the propositional calculus. But they applied the term *dialectic* widely: for them it also included the study of grammatical theory and the consideration of meaning-relations and truth. This widened scope, reflecting the special interests of the early Stoics, remained typical of the school; it was accepted by Cicero and perhaps overemphasized by Seneca, who wrote that dialectic “fell into two parts, meanings and words, that is, things said and expressions by which they are said”—*διαλεκτική in duas partes dividitur, in verba et significationes, id est in res quae dicuntur et vocabula quibus dicuntur* (*Epistulae Morales* 89, 17).

In the Middle Ages “dialectic” continued to be the ordinary name for logic: for example, the first medieval logical treatise was the *Dialectica* of Alcuin. But the word *logica* was also used; in fact, Abelard wrote a *Dialectica* and more than one *Logica*. As the works of Plato and Aristotle became known, the Scholastics took over various conceptions of dialectic, and the medieval disputation, by which university degree examinations were conducted, can be regarded as a remote descendant or revival of the debates in the Platonic Academy. The disputants maintained theses and antitheses, arguing mainly in syllogisms; the most significant difference from

ancient practice was that the class of unacceptable consequences now included those propositions that were inconsistent with divine revelation.

### KANT AND HIS SUCCESSORS

In his *Critique of Pure Reason* (A61, B85) Immanuel Kant asserted rather sweepingly that the actual employment of dialectic among the ancients was always as “the logic of illusion (*Logik des Scheins*).” He explained that he applied the term to logic as a critique of dialectical illusion. He titled the second division of his *Transcendental Logic* “Transcendental Dialectic.” This new kind of dialectic was concerned with exposing the illusion of transcendental judgments, that is, judgments that profess to pass beyond the limits of experience; but the illusion can never, he thought, be dispelled entirely, as it is natural and inevitable.

Although Kant, in his *Transcendental Dialectic*, had set out the antinomies of pure reason as four sets of thesis and antithesis, he did not call his resolution of the antinomies a synthesis. It was his successor Johann Gottlieb Fichte who, in his *Grundlage der gesamten Wissenschaftslehre* (Jena and Leipzig, 1794), first introduced into German philosophy the famed triad of thesis, antithesis, and synthesis. In this he was followed by Friedrich Schelling, but not in fact by G. W. F. Hegel. Fichte did not believe that the antithesis could be deduced from the thesis; nor, on his view did the synthesis achieve anything more than uniting what both thesis and antithesis had established.

### HEGEL AND HIS SUCCESSORS

Hegel is commonly supposed to have presented his doctrines in the form of the triad or three-step (*Dreischnitt*) of thesis, antithesis, and synthesis. This view appears to be mistaken insofar as he did not actually use the terms; and even though he evinced a fondness for triads, neither his dialectic in general nor particular portions of his work can be reduced simply to a triadic pattern of thesis, antithesis, and synthesis. The legend of this triad in Hegel has been bolstered by some English translations that introduce the word *antithesis* where it is not required.

However, there is indeed a Hegelian dialectic, involving the passing over of thoughts or concepts into their opposites and the achievement of a higher unity. But if it is a process that arrives at a higher truth through contradictions, it does not constitute a new conception of dialectic. Hegel actually showed his awareness of the traditional notion by paying tribute to “Plato’s *Parmenides*, probably the greatest masterpiece of ancient dialectic.”

And even the doctrine that dialectic is a world process—not merely a process of thought but also found in history and in the universe as a whole—was not wholly new, but goes back to Heraclitus and the Neoplatonist Proclus. Here again Hegel, with his interest in the history of philosophy, was aware of his predecessors. What seems to be genuinely new in Hegel's view of dialectic is the conception of a necessary movement. Dialectic was said to be “the scientific application of the regularity found in the nature of thought.” The “passing over into the opposite” was seen as a natural consequence of the limited or finite nature of a concept or thing. The contradictions in thought, nature, and society, even though they are not contradictions in formal logic but conceptual inadequacies, were regarded by Hegel as leading, by a kind of necessity, to a further phase of development.

Hegel has had an enormous influence not only on willing disciples but even on thinkers nominally in revolt against him, such as Søren Kierkegaard. One of the most important offshoots of the Hegelian dialectic was the Marxist dialectic, in which, of course, “matter” was substituted for Hegel's “spirit.”

## Bibliography

### GENERAL DISCUSSIONS

For general discussions of dialectic, see Paul Foulquié, *La dialectique* (Paris, 1949); Eduard von Hartmann, *Über die dialektische Methode* (Berlin, 1868; 2nd ed. 1910); Karl Dürr, “Die Entwicklung der Dialektik von Plato bis Hegel.” *Dialectica* 1 (1947); and Jonas Cohn, *Theorie der Dialektik* (Leipzig, 1923).

### SOCRATES AND HIS PREDECESSORS

On Zeno, see H. D. P. Lee, *Zeno of Elea* (Cambridge, U.K., 1936); G. E. L. Owen, “Zeno and the Mathematicians,” in *PAS* 58 (1957–1958): 199–222; and John Burnet, *Early Greek Philosophy* (London, 1892; 4th ed., 1930). For the period before Socrates as a whole, see Burnet's *From Thales to Plato* (London, 1914). For criticisms of the Sophists, see Plato, *Euthydemus*, and Aristotle, *De Sophisticis Elenchis*, translated by W. A. Pickard-Cambridge in *The Works of Aristotle*, Vol. 1 (Oxford, 1928). On this whole phase of dialectic, see the

extremely reliable work of William and Martha Kneale, *The Development of Logic* (Oxford: Clarendon Press, 1962), Ch. 1.

### PLATO

The most helpful book on Plato's use of dialectic is Richard Robinson, *Plato's Earlier Dialectic* (Ithaca, NY: Cornell University Press, 1941; 2nd ed., Oxford: Clarendon Press, 1953), but the word *earlier* occurs in its title because it contains no examination of the methods of division and synthesis that appear in some of Plato's later dialogues. For the original descriptions of the Platonic dialectic, see the Dialogues of Plato, *passim* (in any translation), but above all the *Republic*, Books VI–VII, especially 510–540 in the standard numbering. See also James Adam, *The Republic of Plato*, Vol. II (Cambridge, U.K., 1902; reissued, 1963), pp. 168–179; Richard Lewis Nettleship, *Lectures on the Republic of Plato* (London: Macmillan, 1901), pp. 277–289; Julius Stenzel, *Studien zur Entwicklung der Platonischen Dialektik von Sokrates zu Aristoteles* (Breslau, 1917; 2nd ed., 1931), translated by D. J. Allan as *Plato's Method of Dialectic* (Oxford: Clarendon Press, 1940; reissued, New York: Russell and Russell, 1964); Francis M. Cornford, “Mathematics and Dialectic in the *Republic* VI–VII,” in *Mind* 41 (1932): 37–52, 173–190; R. S. Bluck, “*ὑποθέσεις* in the *Phaedo* and the Platonic Dialectic,” in *Phronesis* 2 (1) (1957): 21–31; D. W. Hamlyn, “The Communion of Forms and the Development of Plato's Logic,” in *Philosophical Quarterly* 5 (1955): 289–302; Georges Rodier, “Les mathématiques et la dialectique dans le système de Platon,” in *Archiv für Geschichte der Philosophie* 15 (1902): 479–490, and his “L'évolution de la dialectique de Platon,” in *Année philosophique* (1905): 49–73; D. S. Mackay, “The Problem of Individuality in Plato's Dialectic,” in *University of California Publications in Philosophy* 20 (1937): 131–154; and Juan A. Nuño Montes, *La dialéctica platónica* (Caracas, 1962).

### ARISTOTLE

For the original account, see Aristotle, *Topica*, translated by W. A. Pickard-Cambridge in *The Works of Aristotle*, Vol. I (Oxford, 1928). The most accessible scholarly discussion of this phase is Ernst Kapp, *Greek Foundations of Traditional Logic* (New York: Columbia Press, 1942). Important treatments of the controversial issues involved are Friedrich Solmsen, *Die Entwicklung der Aristotelischen Logik und Rhetorik* (Berlin, 1929), his “The Discovery of the Syllogism,” in *Philosophical Review* 50 (1941): 410–421, and his “Aristotle's Syllogism and Its Platonic Background,” in *Philosophical Review* 60 (1951): 563–571; and Paul Wilpert, “Aristoteles und die Dialektik,” in *Kant-Studien* 68 (1956): 247–284. There is also Livio Sichirollo, *Giustificazioni della dialettica in Aristotele* (Urbino, 1963).

### STOICS AND MEDIEVALS

For a discussion of Stoic use of dialectic, see Benson Mates, *Stoic Logic* (Berkeley: University of California Press, 1953). For a general account of the medieval phase and references to particular works, see William and Martha Kneale, *op. cit.*, Ch. 4. For the postmedieval rejection of dialectic, see Duane H. Berquist, “Descartes and Dialectics,” in *Laval théologique et philosophique* 20 (2) (1964): 176–204.

## KANT AND HIS SUCCESSORS

Kant and his successors are discussed in Graham H. Bird, *Kant's Theory of Knowledge* (London: Routledge and Paul, 1962); John E. Llewelyn, "Dialectical and Analytical Opposites," in *Kant-Studien* 55 (1964): 171–174; and Richard Kroner, *Von Kant bis Hegel*, 2 vols. (Tübingen, 1921–1924).

## HEGEL AND HIS SUCCESSORS

For general discussions of the Hegelian phase, see K. R. Popper, "What Is Dialectic?," in *Mind* 49 (1940): 403–426, reprinted in Popper's *Conjectures and Refutations* (London: Routledge, 1963); Sidney Hook, "What Is Dialectic?," in *Journal of Philosophy* 26 (1929): 85–99, 113–123, his *From Hegel to Marx* (London, 1936), and his "Dialectic in Social and Historical Inquiry," in *Journal of Philosophy* 36 (1939): 365–378; and Siegfried Marck, *Die Dialektik in der Philosophie der Gegenwart*, 2 vols. (Tübingen, 1929–1931). On dialectic in Hegel, see John M. E. McTaggart, *Studies in the Hegelian Dialectic* (Cambridge, U.K., 1896); G. R. G. Mure, *An Introduction to Hegel* (Oxford: Clarendon Press, 1940); and above all, John N. Findlay, "Some Merits of Hegelianism," in *PAS* 56 (1955–1956): 1–24, and his *Hegel: A Re-examination* (London: Allen and Unwin, 1958), and a valuable chapter by him on Hegel in *A Critical History of Western Philosophy*, edited by D. J. O'Connor (London, 1964). See also Gustav E. Mueller, "The Hegel Legend of Thesis-Antithesis-Synthesis," in *Journal of the History of Ideas* 19 (1958): 411–414; Carl J. Friedrich, "The Power of Negation: Hegel's Dialectic and Totalitarian Ideology," in *A Hegel Symposium*, edited by D. C. Travis (Austin: University of Texas, 1962), pp. 13–35; and Walter Kaufmann, *Hegel* (New York, 1965). On Marx, see Harold B. Acton, *The Illusion of the Epoch: Marxism–Leninism as a Philosophical Creed* (London: Cohen and West, 1955).

*Roland Hall (1967)*

## DIALECTICAL MATERIALISM

Marxism-Leninism is the name given to the form of Marxist theory that was accepted and taught by the Russian and Chinese Communist parties and the Communist parties associated with them. Marxism-Leninism is both a view of the world as a whole and of human society and its development. The view of human society is called historical materialism, the name bestowed upon it by Friedrich Engels. The view of the world as a whole is called dialectical materialism, a title devised by G. V. Plekhanov, the Russian Marxist, and first used by him in an article published in 1891. Marxist-Leninists regard dialectical materialism as the basis of their philosophy and generally begin comprehensive expositions of that philosophy with an account of it. One might say that dialectical materialism constitutes the logic, ontology,

and epistemology of Marxism-Leninism, and historical materialism its ethics, politics, and philosophy of history. Sometimes, however, the term *dialectical materialism* is used for the fundamentals of Marxism-Leninism as a whole. When dialectical materialism is thus conceived, the natural sciences are the working-out of dialectical materialism in the nonhuman sphere and historical materialism its working-out in the sphere of human society. But these slight differences do not affect the content of the theory.

## MARX'S MATERIALISM

Approving references to materialism are prominent in Karl Marx's writings, especially in the early works. In *The Holy Family* (1845), for instance, he argued that one branch of eighteenth-century French materialism developed into natural science and the other branch into socialism and communism. Thus he regarded "the new materialism," as he called it, as a source of the social movement that he believed was destined to revolutionize human life. Materialism, as Marx understood it, was very closely connected with social criticism and social development. One aspect of materialism that Marx supported was its rejection of idealist attempts to undermine and belittle sense experience. He held that there is something dishonest and irresponsible in philosophies which deny that sense experience reveals the existence of an independent material world; hence his view of knowledge was realist, both on philosophical and moral grounds. In taking this view he was much influenced by Ludwig Feuerbach. Like Feuerbach, Marx rejected speculative philosophy, or metaphysics, as we should call it today, on the ground that the truth about the world and society can only be discovered by the use of empirical scientific methods. In a broad sense of the term, therefore, Marx was a positivist, in that he denied the possibility of any knowledge of the world that is not based on sense experience. Hence, Marx's view of the world was naturalistic and opposed to any form of religion or supernaturalism. Again under the influence of Feuerbach, Marx held that belief in God, in an afterlife, and in heaven and hell cannot be rationally justified, but may be explained (indeed, explained away) in terms of the unfulfilled needs and hopes of men whose lives are frustrated by an oppressive social order. Marx held, too, that men are not immaterial souls conjoined with material bodies. In his view, psychophysical dualism is a relic of supernaturalism and must be rejected with it. Marx did not systematically develop this view as part of a philosophical argument but took it as the basis of his view, expressed in *The Holy*

*Family* and in *The German Ideology* (1845–1846), that repression of the instincts and natural desires is bad. Marx, therefore, thought that thinking is inseparable from acting and that scientific advance and practical improvement are in principle bound up with one another. Marx's materialism, therefore, is very wide in scope, combining empiricism, realism, belief in the use of scientific methods pragmatically conceived, rejection of supernaturalism, and rejection of mind-body dualism. Animating these aspects of his view is the conviction that they support and justify the socialist diagnosis of social ills and the prediction that a communist form of society must come.

Marx was very much influenced by the philosophy of G. W. F. Hegel. For example, in *The Holy Family* he borrowed almost verbatim some arguments from Hegel's *Encyclopedia* against abstract and unrealistic thinking, and his earliest, unfinished sketch of his theory of man and society, the so-called *Economic and Philosophical Manuscripts* (1844), was both a critique of political economy and a critique of the philosophy of Hegel. Marx's interest in Hegel continued throughout his life. In a letter to Engels in 1858 Marx wrote that he had been looking at Hegel's *Logic* and would like, if he had time, to write a short work setting out what was wrong and what was valuable in Hegel's method. Later, in the Preface to the second edition of Volume I of *Capital*, Marx referred to "the rational kernel" of Hegel's dialectical method and said that in *Capital* he had "toyed with the use of Hegelian terminology when discussing the theory of value." This sentence does not indicate a very strong attachment to Hegel's dialectic, for "toyed with" (*kokettierte sogar hier und da*) is appropriate to a superficial liaison, and the word *terminology* (*Ausdrucksweise*) might be meant to contrast with the substance of what is being said. But although Marx was as much opposed to the speculative element in Hegelianism as any professed positivist could have been, he was deeply influenced by the Hegelian dialectical method. Jean Hippolyte has shown in his *Études sur Marx et Hegel* (Paris, 1955) how very closely the structure of *Capital* is linked with Marx's earlier, more consciously Hegelian writings, so that some of the Hegelian substance persists, although the Hegelian terminology is less apparent. One important Hegelian legacy is the view that social development takes place through struggle and opposition. Another is that the transition from one important form of society to another is by means of sudden leaps rather than by merely gradual stages. Thus Marx considered that different social laws applied at different historical epochs. Again, Marx shared Hegel's aversion to abstraction and his predilection for

total views, but in this he was at one with Auguste Comte as well as with Hegel. These views of Marx's, however, related to the theory of human society. He showed little inclination to linger over questions of ontology. There is a reference in Volume I of *Capital* to the "law discovered by Hegel in his *Logic*, that at a certain point what have been purely quantitative changes become qualitative," and at this point Marx said that some chemical changes take place in accordance with this law. However, Marx left it to Engels to pursue the matter.

## ENGELS AND DIALECTICAL MATERIALISM

Engels took up the law of quantity and quality in his *Herr Eugen Dühring's Revolution in Science* (1878), generally known as *Anti-Dühring*, which had appeared as a series of articles in the Leipzig *Vorwärts* in 1877. Engels's work was directed against Eugen Dühring, a well-known non-Marxist socialist and publicist, who had vigorously criticized some Hegelian features in Marxist writers as being speculative, metaphysical, and unscientific. Thus Engels, like Marx, felt called upon to defend the Hegelianism of his youth, although, again like Marx, he claimed to have purged it of its speculative and idealist elements. In the Preface to the second edition of *Anti-Dühring* (1885) Engels stated that he had read the whole of the manuscript to Marx before it was printed and that Chapter 10 of Part II (on economics and its history) had been written by Marx himself and abridged by Engels. This chapter has no direct relevance to dialectical materialism and thus has some significance as an indication of Marx's own interests.

**PHILOSOPHY OF NATURE.** Engels apologized in a general way in the preface to the second edition of *Anti-Dühring* for inadequacies in his knowledge of theoretical natural science, although he retracted nothing. He also spoke with approval of "the old philosophy of nature." By this he meant a philosophical examination of the phenomena of the natural world claiming to be more fundamental and general in scope than the particular researches of individual men of science. Such inquiries were more frequent at a time when the term *philosopher* was applied to philosophers and scientists alike and the role of the natural scientist was less definitely specified than it became in the nineteenth and twentieth centuries. Engels alluded to Hegel's contributions to the philosophy of nature in the second main triad of the *Encyclopedia* and called attention in particular to Section 270 in which Hegel criticized Isaac Newton's theory of forces. Hegel,

like Johann Wolfgang von Goethe and Friedrich Schelling (and William Blake), was highly critical of Newton's cosmological theories, and Engels believed that Hegel, at any rate, was being justified by subsequent researches. It should be noted, therefore, that Engels had no objection to the practice of philosophizing about the nature of the physical world but, on the contrary, was consciously reviving an older, and apparently abandoned, intellectual tradition. By doing this, he introduced into the Marxist theory of nature one of its most characteristic features: the claim that the specialized sciences of nature need to be supplemented by a unified philosophy of nature and that as they develop, the natural sciences are constantly verifying the views first propounded by Hegel in his *Logic* and in his *Encyclopedia*.

From 1873 onward Engels had been studying the natural sciences with a view to writing a comprehensive work on the dialectical characteristics of the material world. Part of what he did was incorporated into *Anti-Dühring*, but much of his more detailed work remained unpublished until 1925, when an edition of the surviving manuscripts was published by the Marx-Engels Institute in Moscow under the title *Dialectics of Nature*. This edition was found to be faulty in various ways, and corrected versions were subsequently published and translated. The work contains, inter alia, an essay on electricity (a subject much favored by Schelling and other romantics), in which Engels says that the basic thought of Hegel and Michael Faraday is the same; an attack on parapsychology as "the shallowest empiricism" and a proposal that it be rejected outright on general grounds of theory; notes on infinite series and infinite numbers, which he takes to prove that the world is both infinite and contradictory; and sketches for an attack on Ludwig Büchner and other nonsocialist, nondialectical materialists popular during the second half of the nineteenth century. Engels's criticism of Büchner is particularly interesting since, among a series of passages probably intended to document *Anti-Dühring*, there is a quotation from Büchner's *Kraft und Stoff* in which, while attacking supernaturalism and idealist philosophy, Büchner wrote: "It is needless to observe that our expositions have nothing in common with the conceptions of the old 'philosophy of nature.' The singular attempts to construe nature out of philosophy instead of from observation have failed, and brought the adherents of that school into such discredit that the name 'philosopher of nature' has become a bye-word and a nickname." Engels regarded this as an "attack on philosophy" and accused Büchner of "shallow materialist popularisation." Engels made his own attitude quite clear by appending passages from Hegel's "Philosophy of Nature."

ENGELS ON MARXIST MATERIALISM. After Marx's death in 1883 Engels was occupied in editing the unpublished parts of *Capital*, but in 1886, in some articles that appeared in the Social Democratic journal *Die Neue Zeit*, he turned his attention once more to fundamental philosophical issues. These articles were published in 1888 in book form under the title *Ludwig Feuerbach and the Outcome of Classical German Philosophy*. In this work Engels set out to explain what sort of materialism Marxist materialism is and to show how it is related to the Hegelian philosophy. Engels renewed his support for the dialectical structure of Hegel's philosophy, although, of course, he rejected its idealist aspects. There is an account of Engels's epistemology, in which a pragmatistic point of view is emphasized.

*Mind and matter.* According to the argument of *Ludwig Feuerbach* there are two and only two fundamental but opposing philosophical alternatives: idealism, according to which mind is primary in the universe and matter is created by, or dependent upon, mind; and materialism, according to which matter is the primary being and mind the subordinate and dependent feature of the world. It will be seen that in stating this view Engels extended the term *idealism* beyond its usual philosophical meaning to comprise not only such views as George Berkeley's immaterialism and Hegel's absolute idealism but also any form of theism. Thus, in Engels's classification, St. Thomas Aquinas and René Descartes would both be regarded as idealists because they both held that an immaterial deity created the material world. It should be noted that in this view mind is held to be secondary but not nonexistent. Engels took the widely held natural-scientific point of view that there was once a time when only matter existed and that mind evolved from it and must remain dependent upon it. He did not hold the theory of reductive materialism, according to which mind is just a form of matter.

*Knowledge and perception.* In *Ludwig Feuerbach* Engels also gave a brief account of knowledge and sense perception. He considered that in sense perception the material things in the neighborhood of the percipient's body are somehow "reflected" in his brain "as feelings, instinct, thoughts, volitions." Engels recognized that the theory that in perception the immediate object of awareness is a "reflection" could lead to agnosticism or idealism, for a skeptic could question whether we can ever know of the existence of material things at all if all that we directly apprehend are reflections of them. This, indeed, is a line of thought that Berkeley developed in criticizing John Locke's theory that it is ideas, not physical things, that are directly apprehended. Engels's answer was that

what must dispel any such doubts is “practice, viz. experiment and industry.” His discussion is vague, but he appears to have thought that skeptical doubts about the existence of material things are rendered untenable by a consideration of what we do to and with things. A skeptic’s or idealist’s practice belies his theories. Furthermore, Engels held that the truth of scientific theories about the material world is established by the power they give men to manufacture new substances and things and to bring the forces of nature under human control. “If we are able to prove the correctness of our conception of a natural process by making it ourselves, bringing it into being out of its conditions and using it for our own purposes into the bargain, then there is an end of the Kantian incomprehensible ‘thing-in-itself’” (*Ludwig Feuerbach*, pp. 32–33). Engels appears to have conflated the problem of our perception of the external world with the problem of how scientific laws are established, but it is clear that he believed that the notion of practice can help to solve them both. In the Preface to *Ludwig Feuerbach* Engels printed for the first time, under the title *Theses on Feuerbach*, some jottings made by Marx in 1845. The doctrine of the philosophical importance of practice is stated in these theses, particularly in the first, second, fifth, and eleventh. One of the things that Marx appears to have been asserting in them is that perception is a deed or activity of the perceiving corporeal man and not merely a passivity of an immaterial mind. In 1892, in the introduction to some chapters from *Anti-Dühring* published separately under the title *Socialism: Utopian and Scientific*, Engels developed this view, arguing that perception is a more or less successful action on the world.

**Attack on “vulgar materialists.”** Another feature of Engels’s materialism is its opposition to the theories of those whom he called in *Ludwig Feuerbach* “vulgarising pedlars,” and who, in later Marxist philosophy, are called “vulgar materialists.” These were a group of German writers and lecturers, of whom Büchner was one, who argued that materialism was the inevitable consequence of natural science in general and of physiology in particular. Engels objected that they wasted too much time arguing that God does not exist. He also objected that they identified thought with brain processes. Furthermore, they failed to recognize the social, indeed the socialist, implications of materialism. But primarily he objected that theirs was a mechanical materialism. A consideration of this objection brings us to a central feature of Engels’s dialectical materialism.

By mechanical materialism Engels meant the type of materialism current in the eighteenth century, when the

most highly developed natural science was mechanics. According to this view, all the most complex phenomena of nature, including life and mind, can be reduced to the arrangement and rearrangement of material particles. The most complex beings can be nothing but arrangements of the ultimate simple ones, so that chemical combination, life, mind, and thought are no more than increasingly elaborate applications of mechanical principles. According to Engels, in saying that everything is reducible to the interaction of forces, the vulgar materialists were anachronistically upholding this eighteenth-century view, whereas the natural sciences of the nineteenth century, in developing chemistry and biology, went beyond those of the eighteenth century. In merely mechanical mixtures the original components remain side by side with each other, but in chemical combinations new substances result from the joining of their ingredients. The theory of biological evolution showed that new forms of life have emerged from the simpler forms, not merely more complex ones.

Mechanical materialism itself is a form of what Engels, following Hegel, called the “metaphysical” attitude of thought. Engels’s source in Hegel is the phrase “the former metaphysics,” by which Hegel referred to the philosophical method used by Christian Wolff and others in the eighteenth century in trying to prove important truths about the world and the human soul by the use of definitions and axioms and allegedly strict deductions. Engels agreed with Hegel that this quasi-mathematical method was inappropriate in philosophy and added that it was inappropriate in science too. In *Anti-Dühring* Engels said that in the metaphysical mode of thinking, “things and their mental images, ideas” are regarded as isolated and fixed; things either exist or do not exist; and positive and negative exclude one another. But this, he held, is to overlook the changefulness and interconnections of things. Collecting distinct items of information and neglecting the aspect of process helped natural science to get started but was only a preliminary stage toward grasping the world in all its interconnections, processes, beginnings and endings, and contradictions. Mechanical materialism is a fruit of metaphysical thinking. Metaphysical thinking was, in the Hegelian philosophy, and then in the writings of Marx, superseded by dialectical thinking; and this was, in Engels’s view, another way of saying that mechanical materialism must be superseded by dialectical materialism. Engels believed that nineteenth-century biology and chemistry had developed along lines that Hegel had foreseen and required. In particular, he referred to passages in Hegel’s *Logic* and *Encyclopedia* according to which a fuller under-

standing is gained when the category of mechanism is left behind and replaced by the higher categories of life. In Hegel's "Philosophy of Nature," to which Engels's *Dialectics of Nature* so often refers, the mechanical forms are succeeded by physical ones that include "chemical process" and electrical phenomena, and these by "the organic." It is this sequence that provided the framework for Engels's philosophy of nature.

*Engels on dialectics.* Since dialectical thinking is, in Engels's view, opposed to metaphysical thinking, it is thinking that attempts to grasp things in their interrelationships and in the totality to which they belong, in the process of change, of being born and of dying, in their conflicts and contradictions. Furthermore, it is thinking that recognizes the emergence of novelty and that sees such emergences as sudden, even catastrophic. Dialectical thinking, he also held, was becoming more and more apparent as the natural sciences progressed. Scientific discoverers were dialecticians without knowing it.

**CONTRADICTIONS IN NATURE.** In *Anti-Dühring* Engels expounded his dialectical philosophy of nature in some detail. Dühring had criticized the Hegelian elements of Marx's thought. In particular he had argued that contradiction is a logical relationship and that it is absurd to suppose that it can be a relationship between things or events in the natural world. In Part I, Chapter 12 of *Anti-Dühring* Engels endeavored to defend the dialectical theory against this objection. First, he said that the view that there could be no contradictions in nature rests upon the assumption of "the former metaphysics" that things are "static and lifeless." Then he argued that when we consider things in movement and in their effects upon one another, the dialectical view has to be adopted. "Movement itself," he wrote, "is a contradiction: even simple mechanical change of place can only come about through a body at one and the same moment of time being both in one place and in another place, being in one and the same place and also not in it. And the continuous assertion and simultaneous solution of this contradiction is precisely what motion is." Engels also maintained that what is true of mechanical change of place is "even more true of the higher forms of motion of matter, and especially of organic life and its development." Engels had argued in Part I, Chapter 8 that in absorbing and excreting nutriment living matter at each moment is "itself and at the same time something else." Engels also held that there are real contradictions in "higher mathematics," where straight lines and curves may be identical. (He probably had in mind Section 119 of Hegel's *Encyclope-*

*dia.*) Similarly, Engels said that the square root of minus one is not only a contradiction but "a real absurdity."

Engels's claim that movement is in itself contradictory is based on a passage from Hegel's *Science of Logic* in which it is argued that it is not sufficient, if something is to move, for it to be *here-now* and then, after that, *there-then*, for this would merely be for it to be at rest first in the one place and then in the other. For it to move, Hegel concluded, a body must be "here and not here in the same now" and must "be and yet not be in the same here" (*Science of Logic*, Book II, Sec. 1, Ch. 2, C). Hegel was discussing Zeno, who had argued that since movement is contradictory, what is real cannot move. Hegel in this passage accepted Zeno's arguments that movement is contradictory, but unlike Zeno concluded that since there is movement, movement "is an existing contradiction." Hegel's views on contradiction are difficult to understand and have been interpreted in various ways. If intended to argue that contradictory propositions could both be true, that "both  $p$  and not- $p$ ," then he was wrong and so was Engels in following him. For it can be proved that from any pair of contradictory propositions any conclusion we like can be deduced and hence that if contradictories are true, *anything* can be true. In this logical sense the term *contradiction* has its appropriate use in thought or discourse, as Dühring had argued. In saying that something both is and is not in the same place at the same time, that it is true both that it is in  $P$  at time  $t$  and that it is not in  $P$  at time  $t$ , the whole negating force of the word *not* is lost. Either, then, Hegel's philosophy has no value or he must have meant by "contradiction" something different from what formal logicians mean by it. It is likely enough that it is the second alternative that is correct. In attacking Dühring, Engels seems to have committed himself to the first alternative. He adopted a speculative, nonempirical thesis, for whereas movement is something that can be observed in natural things and events, contradiction is not observable in them. What Engels did in his argument about contradiction in the nature of things was to provide one of Zeno's paradoxes with a merely verbal, and indeed absurd, "solution."

It appears that Engels's doctrine on this matter is now being reinterpreted or abandoned. This process began with an article on Zeno's paradoxes by the famous Polish logician Casimir Ajdukiewicz. When this article appeared in Poland in 1948, dialectical materialists were forced to take account of his arguments. In order to do so they granted that "contradiction" does not mean "logical contradiction" when applied to what exists in nature. This view is adopted by the Russian authors of *The Fun-*

*damentals of Marxism-Leninism: Manual* (English translation, Moscow, no date, but later than 1960), who write: “Contradictions due to incorrect thinking should not be confused with objective contradictions existing in objective things. Although the word ‘contradiction’ is the same in both cases, it means different things” (pp. 99–100).

**QUANTITY AND QUALITY.** Another dialectical law of nature that Engels made much of in his *Anti-Dühring* is that according to which certain of the changes in nature take place suddenly and abruptly rather than by gradual accretion. The simplest instances of this sort of change are the changes of water into ice as its temperature is lowered to the freezing point and into steam as its temperature is raised to the boiling point. The ice and steam do not come into existence gradually and *pari passu* with the gradual lowering and raising of the temperature, but appear all at once as soon as the freezing or boiling point has been reached. Other examples of the principle were given by Engels: the sudden transformation of one chemical substance into another in the course of chemical combination; the melting points of metals; the transformation of mechanical motion into heat; the necessity for a sum of money to exceed a certain amount before it can become capital; the fact, reported by Napoleon, that whereas two Mamelukes were more than a match for three Frenchmen, a thousand Frenchmen were more than a match for fifteen hundred Mamelukes. One very general idea in all this is that gradual alterations in the quantity of something are not necessarily accompanied by a merely gradual alteration in its characteristics. Apart from this, Engels had in mind the evolutionary scheme of development from simpler forms of matter, like gases, to more distinctive and varied forms, like the many kinds of solids, plants, and animals. This development is not a mere rearrangement of otherwise unchanging particles or elements but is the emergence of new features out of the old, even though the later qualities could not have emerged unless the earlier and simpler ones had first existed. The emerged qualities, however, are not reducible to those from which they have emerged. The point at which changes in a single quality transform it into a new one Engels called a “nodal line.” He also said that there is a “leap” from one quality to another.

Once again Engels was following Hegel very closely. The account in *Anti-Dühring* is based upon Sec. 108 of the *Encyclopedia* and Book I, Division 3, Chapter 2, *B* of the *Science of Logic*, where Hegel discussed the category of “measure.” In these passages Hegel tried to show the part played by proportion in the constitution of things. He gave the examples of water turning, at critical points or

nodal lines, into ice or steam, and of chemical combinations and constant proportions, which Engels and Marx repeated later. He also instanced birth and death, the acquisition of new properties by numbers as the series of natural numbers develops, and the acquisition of new features by the notes of a musical scale. He gave a moral example, based on Aristotle, of slight changes that turn virtues into vices, carelessness into crime, and so on. He even gave a political example, borrowed from Baron de Montesquieu, of the relation of a type of constitution to the population of a state. In the *Encyclopedia* Hegel also referred to the ancient Greek puzzles about the point at which a man becomes bald or at which a number of grains of wheat become a heap. Interesting as these examples are, they are extremely disparate. The grains of wheat example is partly a question of how many grains we shall *call* a heap, and this is to some extent a matter of decision. The concepts of a heap or of baldness are rather vague. The examples of a series of gradual physical changes succeeded by a total transformation of quality are clearly of interest to Engels because of the analogy to revolutionary social change by contrast with gradual alteration. Undoubtedly the social examples had impressed Hegel, who had called attention to the gradual steps that lead up to an explosive revolutionary break in the Preface to the *Phenomenology of Mind*, where he wrote: “This gradual disintegration which did not alter the general look and aspect of the whole is interrupted by the sunrise which, in a single flash, brings to view the form and structure of the new world.”

In itself, whether there are or are not nodal lines and constant proportions in the physical world would seem to have no logical connection with the way in which the social order changes, unless, indeed, it is held that human society really is, or is reducible to, physical events—and this is in conflict with Engels’s general rejection of reductive materialism. If, then, this law is not an expression of a view that is inconsistent with Engel’s main view, it would seem to serve an almost animistic purpose. Sudden revolutionary change, he seems to be suggesting, is a fundamental character of the universe as a whole, so that when we urge revolution, we have the universe behind us. That the view at any rate serves this purpose may be seen from Joseph Stalin’s subsequent impatience with it. When socialism is established, it is natural for the socialist leaders not to wish to think in terms of their own disappearance and of the emergence of still further social revolutions. Hence, Stalin, in his famous article on linguistics, wrote scornfully of “comrades who have an infatuation for explosions.”

**INTERPENETRATION OF OPPOSITES.** In addition to the law of transformation of quantity into quality, Engels mentioned two other laws of dialectics, the law of the interpenetration of opposites and the law of the negation of the negation. The first of these laws was already touched upon in the exposition of the theory of contradictions in nature and of the deficiencies of the metaphysical point of view. Although Engels mentioned it in the *Dialectics of Nature*, he did not discuss it as such, and in *Anti-Dühring* his emphasis was on the other two laws, to each of which he devoted a chapter. The law of the interpenetration of opposites (which was later called the law of the unity and struggle of opposites) seems to have been intended to provide an explanation of why there is any change or development at all. An idea behind it is that in the absence of all tension everything would remain exactly as it is, since there would be nothing to provoke any change. Change takes place because the world does not consist of isolated, self-sufficient, independent particulars, but of opposing forces overcoming or being overcome. Contradiction, or opposition, is in this view the motive force both of natural and of human history.

**NEGATION OF THE NEGATION.** The law of the negation of the negation was more specifically emphasized by Engels. He was able to quote from a passage in Marx's *Capital* in which it is said that when, as a result of competition between capitalists, the few remaining giant capitalist enterprises find themselves confronted by a poverty-stricken proletariat, the latter will rise and expropriate the former, the expropriators will be expropriated. "Capitalist production," wrote Marx, "begets, with the inexorability of a Law of Nature, its own negation. It is the negation of the negation." According to Engels in *Anti-Dühring*, the law of the negation of the negation is "an extremely general—and for this reason extremely comprehensive and important—law of development of nature, history and thought, a law which ... holds good in the animal and plant kingdoms, in geology, in mathematics, in history and in philosophy." The law is illustrated, according to Engels, by every case in which a plant has seeds that germinate and result in the growth of further plants. "But what is the normal life-process of this plant? It grows, flowers, is fertilised and finally once more produces grains of barley, and as soon as these have ripened the stalk dies, is in its turn negated. As a result of this negation of the negation we have once again the original grain of barley, but not as a single unit, but ten, twenty or thirty fold" (*Anti-Dühring*, p. 152). One idea in this very famous passage is that out of what looks like death and destruction there arises something better and more vari-

ous. (Engels in fact wrote of "qualitatively better seeds which produce more beautiful flowers.")

In his early book *The Poverty of Philosophy* (1847) Marx had quoted the Latin phrase *mors immortalis*, that is, "deathless death," and Engels similarly regarded progress as taking place through continual destruction and amplified renewal. What holds for plants obviously holds for animals. Geology illustrates the law, too, for it describes "a series of negated negations, a series arising from the successive shattering of old and depositing of new rock formations." The same law appears in mathematics.  $A$  is negated by  $-A$ , and "if we negate that negation by multiplying  $-A$  by  $-A$  we get  $A^2$ , i.e., the original positive magnitude but at a higher degree, raised to its second power" (*Anti-Dühring*, p. 153). Engels even found the law operating in the history of philosophy. In early philosophy, he held, there is a simple, natural form of materialism according to which matter is the source of everything. This form of materialism was negated by idealism, which rightly showed that mind is not the same as matter, but wrongly held that matter is dependent upon mind. In its turn, idealism is negated by "modern materialism, the negation of the negation," which contains in itself two thousand years of philosophical development. Engels believed that in "modern materialism," that is, dialectical materialism, philosophy as previously understood is destroyed and yet preserved in the positive sciences.

This law, like the law of the transformation of quantity into quality, draws together some extremely disparate types of being. Is it likely, indeed, does it make sense to say, that the same principle is exemplified in a rule for operating on algebraical symbols and in the relationship of natural materialism, idealism, and dialectical materialism? One instance of the law that has given rise to much discussion is that of the grain of barley. What is it that negates what, and what is comprised in the negation of the negation? This problem was discussed by the Russian Marxist G. V. Plekhanov in his *The Development of the Monist View of History* (1895), in which he defended Engels's view against the criticisms of another Russian, N. K. Mikhailovskii, who had made fun of the idea that, as he put it, "oats grow according to Hegel." In his account of Engels's argument, Mikhailovskii took it that it is the stalk which negates the seed, and Plekhanov accused him of misquotation and asserted that it is the whole plant which does the negating. Plekhanov argued further that Engels's account of this botanical negation of the negation was supported by an authoritative textbook of botany, Philippe Van Tieghem's *Traité de botanique* (Paris,

1891), which had recently appeared. The whole discussion is entertaining but ludicrous. For the main difficulty about the law of the negation of the negation is that it can be made to fit almost anything by carefully choosing what are to count as the negating terms. The prime interest in the law is that it is intended to give support to the view that human progress is by means of destruction that leads to better things.

**ENGELS'S PHILOSOPHICAL LEGACY.** Engels was deeply interested in the advances of the sciences and believed that as a result of them nineteenth-century materialism had to be very different from earlier types of materialism. But Engels was drawn in two different directions. On the one hand, he sought to establish a naturalistic, scientific view of the world, and this led him in the same direction as the positivists. On the other hand, he was attracted by Hegel's dialectical method and by the romantic dream of a philosophy of nature, and this led him to regard the positivist outlook as thin and unadventurous. Like Marx, he deplored the conservative social tendencies of Auguste Comte and considered Hegel by far the better philosopher. Nevertheless, Engels did adopt one important positivist thesis, the thesis that knowledge of the world can be obtained only by the methods of the special sciences, so that all that can survive of philosophy is logic and the philosophy of the sciences. Thus, at the beginning of *Anti-Dühring* he wrote: "What still independently survives of all former philosophy is the science of thought and its laws—formal logic and dialectics. Everything else is merged in the positive science of nature and history." It should be noted that Engels here used the very adjective "positive" that had been formerly used by Comte de Saint-Simon and Comte. Although the positivists said nothing of "dialectics," Engels's point of approach from Hegelianism to positivism was his claim that the positive sciences make use of the dialectical method. But Engels, as we have seen, searched the sciences for examples of the dialectic and so applied his terms that he could not fail to find them there. This association of a positivist view of philosophy with what positivists would describe as a "metaphysical" view of the sciences was to remain a permanent feature of dialectical materialism.

Engels also bequeathed a problem about the nature of logic. Was formal logic disproved or rendered nugatory by the dialectical logic that was coming to fruition in the nineteenth century? In holding that there are existent contradictions Engels seemed willing to go against formal logic, but he also thought that formal logic would remain as a part of philosophy alongside dialectics. His position was complicated by the fact that in *Dialectics of Nature* he

criticized formal logic as being "metaphysical" in the Hegelian sense already considered. As a result, controversy among exponents of dialectical materialism about the status of formal logic—by which they generally mean traditional Aristotelian logic—has been constantly renewed.

## LENIN'S CONTRIBUTIONS

Lenin's great political achievements, as well as his deep philosophical interest, secured a respectful acceptance for his own philosophical views. And there is some appropriateness in the fact that Lenin's name, rather than Engels's, accompanies that of Marx in the name of the whole doctrine of Marxism-Leninism, since Lenin absorbed and reemphasized Engels's views before superseding him as a founding father.

Lenin's main contributions to dialectical materialism are the doctrine of *partiinost* ("party spirit" or "partisan-ship"), his elaborations of the Marxist theory of knowledge and of matter, and his renewed emphasis upon dialectics.

"PARTIINOST." Lenin briefly formulated the doctrine of *partiinost* as early as 1895, in the course of a controversy with the nonorthodox Marxist reformer Peter B. Struve, who had said that philosophical views were not a matter of controversy between parties but could be shared by members of opposing parties. Lenin wrote that *partiinost* is included in materialism and that no genuine adherent of materialism could remain uncommitted to the proletarian cause. In this particular context Lenin seems to have been thinking primarily of historical materialism; it is clear from his later writings, however, that he thought that the Marxist should never approach philosophical theories with detachment but should adopt or reject them in the light of their effects on the attainment of socialism. There are several points to be noted in Lenin's view. In the first place he held that dialectical materialism is not merely a theory but a form of action for the establishment of socialism. Thus, a dialectical materialist is necessarily a socialist, and his view of the world is inseparable from his efforts to promote the proletarian cause. In the second place, Lenin held that a socialist intellectual cannot be indifferent to philosophical matters. He is not a complete socialist unless he is a materialist, and a materialist of the right kind. Hence, the leaders of the socialist movement must always be on the alert to protect its doctrines against contamination by philosophical idealism. (This last is a doctrine that Stalin strictly enforced.) A fourth point on which Lenin laid great stress is that ide-

alism is fundamentally supernaturalistic, however tenuous the connection between certain forms of it and religion may appear to be on the surface. In attacking idealism, wherever and however it appears in the socialist literature, what is really being attacked is religion and the antisocialist class forces that uphold it.

The doctrine of *partiinost* derives from Marx's and Engels's theory of ideologies. Ideologies, in their view, are systems of ideas whose function is to defend and to justify the class interests of those who believe in them and teach them, and philosophical systems are ideologies in this sense. Bourgeois ideologies serve to promote bourgeois interests, and the way to criticize them is not primarily by intellectual refutation—this will have little or no effect as long as bourgeois class interests remain—but by unmasking the motives behind them. This view is supported by the Marxist doctrine of the unity of theory and practice. In writing a philosophical book a man is taking part in the social struggle, and in a society divided into classes he is of necessity promoting or endeavoring to promote some class attitude. Lenin considered that Marxists, who understand what is going on in the ideological sphere, should do deliberately and consciously what is so often done unknowingly. This attitude was powerfully expressed in his *Materialism and Empirio-Criticism* (1909). Lenin thought that certain members of the Russian Social Democratic party were spreading what were essentially idealist philosophical views, and he set out to put them right. These Marxists (false Marxists, as Lenin thought) were adopting, under the title of empiriocriticism, the phenomenalist theories of Ernst Mach and Richard Avenarius. In doing so, according to Lenin, they were adopting a cryptoidealist philosophy that could weaken the Marxist movement by dissipating its materialism. “Marx and Engels,” wrote Lenin, “were partisans in philosophy from start to finish; they were able to detect the deviations from materialism and concessions to idealism and fideism in each and every ‘new tendency’” (p. 352). Thus, *Materialism and Empirio-Criticism* was largely a diatribe intended to crush a view held to be dangerous to the party.

**KNOWLEDGE AND MATTER.** Lenin's *Materialism and Empirio-Criticism* is not only a partisan polemic but also the book in which Lenin expounded his views about knowledge and the nature of matter. It was pointed out above that some Russian social democrats had taken up ideas from the writings of Mach and Avenarius. Mach and Avenarius had tried to put forward as consistently empiricist a view as possible. Mach sought to eliminate from physics all notions that were not capable of direct or

indirect verification in sense experience, and Avenarius sought for the terms in which the simplest and most economical explanations can be given. They both concluded that fundamentally the statements of science are statements of what people do experience or will experience and that scientific laws state how such experiences are correlated with one another. To the most elementary of these experiences Mach gave the name “sensations,” and empiriocriticism amounted to phenomenalism, the view that material things are actual or possible sensations. Mach's theory of scientific knowledge is not unlike that of the idealist philosopher George Berkeley, who also sought to eliminate from the body of scientific knowledge any conceptions that could not be referred to sensations, or “ideas” (as he called sensations). Mach recognized the similarity between his view of science and that of Berkeley but pointed out that his view differed from Berkeley's in that he did not hold, as Berkeley did, that sensations were produced by God.

Lenin made the most of the fact that Mach's phenomenalist theory had affinities with that of Berkeley. Berkeley, Lenin said, was honest about his religious aims, whereas “in our time these very same thoughts on the ‘economical’ elimination of ‘matter’ from philosophy are enveloped in a much more artful form.” Lenin objected that these phenomenalist views run counter to our everyday practice, in which we come across material things and act upon them. We might call this the argument from common sense. He also objected that the theory that the material world is an orderly correlation of sensations is incompatible with the well-established scientific theory that there was once a time when matter existed but beings capable of having sensations did not. Berkeley, if he had known of this argument, could have countered it by saying that God could somehow have experienced the material world. If Mach had taken this course, Lenin claimed, he would have revealed his idealism.

Having rejected idealism and phenomenalism, Lenin had to give his own account of the material world and of our knowledge of it. He adopted Engels's theory that in perception material objects are “reflected” in the percipient and produce “copies” there. From this it would seem that the material world is much as we see and hear it to be, and Lenin seems to have emphasized this. Plekhanov, following Herrmann von Helmholtz, had argued that sensations are not exact copies of objects outside us but that they possess the same structure and might more accurately be termed “symbols” or “hieroglyphs.” Lenin claimed, however, that Helmholtz's view undermines its

materialist basis, “for signs or symbols may quite possibly indicate imaginary objects, and everybody is familiar with the existence of such signs and symbols” (p. 239). Lenin did not see that a similar objection applies to “copies” or “reflections” as well, for unless we have independent knowledge of that from which the copy is made, we cannot know that it is a copy. Furthermore, Lenin held (*Materialism and Empirio-Criticism*, Ch. 5, Sec. 7) both that sensations copy what is in the physical world and that what is in the physical world is shown by science to be very different from what it appears to be. Thus, he wrote that sensations of red reflect “ether vibrations” of one frequency and sensations of blue, “ether vibrations” of another frequency, but he did not say how sensations can copy or be like the vibrations. Elsewhere he said that it is “beyond doubt that an image cannot wholly resemble the model” and went on to say that “the image inevitably and of necessity implies the objective reality of what it ‘images’” (p. 240). By putting “images” in quotation marks, he seems to have been denying its literal force, and by saying that the images “cannot wholly resemble the model,” he raised doubts about what it was he really meant to assert.

The basic thing that Lenin wanted to say about the nature of matter was that it exists objectively and independently; therefore, he actually defined matter as “that which, acting upon our sense-organs, produces sensations.” This would apply to Berkeley’s God as well as to material objects. Still, Lenin called this his “philosophical” account of matter, contrasting it with the “scientific” conception of matter, which changes as scientific knowledge advances. In Lenin’s view, the philosophical conception of matter remains unaffected as the scientific view of it changes from atomist theories to theories of electromagnetism. In *Materialism and Empirio-Criticism* Lenin argued, probably correctly, that the electromagnetic theory of matter is no less materialistic than atomic theories. Indeed, he held that it is in closer accord with dialectical materialism. “Modern physics is in travail,” he wrote, “it is giving birth to dialectical materialism” (pp. 323–324). Like Engels, he was attracted to theories of matter that “dissolve” the rigid substances and hard atoms of the older views. He believed that such theories were substituting dialectical concepts for metaphysical and mechanistic ones.

**DIALECTICS.** In 1894, in *What the “Friends of the People” Are*, Lenin quoted approvingly from Engels’s *Anti-Dühring*. In *Materialism and Empirio-Criticism* he frequently referred to dialectics, without, however, making it the center of his discussion. But while he was in exile in

Switzerland during World War I, he renewed his study of philosophy, particularly of its dialectical aspects. His *Philosophical Notebooks* (first published in 1933) show the wide extent of his reading during those years, particularly his detailed study of Hegel’s *Science of Logic*, in which he noted some germs of historical materialism. Lenin’s reading of this book led him to conclude that it was not so much opposed to materialist modes of thought as had previously been supposed. On the one hand, Lenin approved of the Marxist commonplace that Hegel’s system is materialism turned upside down. On the other hand he wrote that in the final chapter of the *Science of Logic*, on the Absolute Idea, there is scarcely a mention of God and that “it contains almost nothing that is specifically *idealism*, but has for its main subject the dialectical method” (*Collected Works*, Moscow, 1961, Vol. 38, p. 234). It is apparent from Lenin’s notes that his respect for the *Science of Logic* increased as he read it. Not only did he conclude that it transcended idealism but also that idealism itself has virtues. Two notes in particular may be referred to. Among his comments on Hegel’s *Lectures on the History of Philosophy* he said: “Intelligent idealism is closer to intelligent materialism than stupid materialism” (p. 276). And at the end of a short paper titled “On the Question of Dialectics,” written in 1915, he wrote that idealism “is a *sterile flower* undoubtedly, but a sterile flower that grows on the living tree of living, fertile, genuine, powerful, omnipotent, objective, absolute human knowledge” (*Philosophical Notebooks*, p. 363). Many of Lenin’s jottings in his *Notebooks* are of this character, in marked contrast to the rancorous anti-idealism of *Materialism and Empirio-Criticism*, in which any approach toward idealism is regarded as treachery. Perhaps it is of significance that the one thesis common to Berkeley and Lenin is the thesis that nothing is substantial that is not active.

#### MAO ZEDONG (MAO TSE-TUNG)

Mao Zedong’s writings on dialectical materialism are referred to here mainly because of the political eminence of their author. Apart from his poems, his writings are mostly on political subjects, and his chief excursions into philosophy are two short articles written in 1937, “On Practice” and “On Contradiction.” It has been suggested that Mao has introduced an empiricist element into dialectical materialism, but this is not borne out by a study of these two writings. In the first, it is true, Mao stated that knowledge begins with sense perception in practical contexts, passes on to rational knowledge, which enables the world to be “molded” for human purposes,

and then leads to more rational knowledge at a higher level. It is not clear from the article whether the author was thinking of induction or of the testing of hypotheses or of both. But it is clear that, in Mao's view, in passing to this higher level "a leap" is made. In thus utilizing the law of the transformation of quantity into quality Mao was asserting that certain sorts of rational knowledge are different in kind from sense knowledge, and this can hardly be described as empiricism.

In "On Contradiction" Mao Zedong argued that in a contradiction each contradictory aspect "finds the presupposition of its existence in the other aspect and both aspects co-exist in one entity." As examples of this he mentioned life and death, above and below, misfortune and good fortune, landlords and tenant-peasants, bourgeoisie and proletariat, imperialists and colonies. He also argued that "each of the two contradictory aspects, according to given conditions tends to transform itself into the other," and as examples of this he cited the revolutionary proletariat becoming the rulers instead of the ruled, peace and war, landlords becoming landless tenants and landless tenants becoming smallholders.

It is easy to see the incongruities in both sets of examples. The opposition between life and death, for instance, is different from those between above and below and misfortune and good fortune, for there is nothing intermediate between life and death, whereas between above and below there is the relation of being at the same level and between good and bad fortune there is the condition of having neither the one nor the other. As to the second set of examples, the transformation of revolutionaries into rulers is not a logical transformation, but something that sometimes happens and sometimes does not. The example of peace and war is trivial. Mao wrote: "War and peace transform themselves into each other. War is transformed into peace; for example, the First World War was transformed into the postwar peace.... Why? Because in a class society such contradictory things as war and peace are characterised by identity under certain conditions." We know, of course, that wars end and that peace is often followed by war, but nothing is added to this by saying that a contradictory aspect transforms itself into its opposite, as if peace were one entity and war another. These writings of Mao Zedong's are, in fact, mainly concerned with immediate practical issues and contribute little to the philosophy from which they derive. It was in Soviet Russia that dialectical materialism was most fully elaborated after Lenin died.

## WORKS BY NON-MARXISTS

Acton, H. B. *The Illusion of the Epoch: Marxism-Leninism as a Philosophical Creed*. London, 1955.

Acton, H. B. “Karl Marx’s Materialism.” *Revue internationale de philosophie* nos. 45–46 (1958): 265–277.

Bochenski, J. M. *Der sowjetrussische dialektische Materialismus (Diamat)*. Bern and Munich, 1950. Translated by Nicolas Sollohub as *Soviet Russian Dialectical Materialism*. Dordrecht, Netherlands, 1963.

Hook, Sidney. *Reason, Social Myths, and Democracy*. New York: John Day, 1950. Contains an excellent discussion of Engels’s dialectical laws.

Joravsky, David. *Soviet Marxism and Natural Science*. London, 1961. Important on “mechanism” and the relation of dialectical materialism to positivism.

Jordan, Z. A. *Philosophy and Ideology. The Development of Philosophy and Marxism-Leninism in Poland since the Second World War*. Dordrecht, Netherlands, 1963.

Paul, G. A. “Lenin’s Theory of Perception.” *Analysis* 5 (1938): 65–73.

Wetter, Gustav. *Der dialektische Materialismus: seine Geschichte und seine Systeme in der Sowjetunion*. Vienna and Freiburg, 1953. Translated by Peter Heath from the fourth German edition as *Dialectical Materialism. A Historical and Systematic Survey of Philosophy in the Soviet Union*. London, 1958. Discusses Marx, Engels, Plekhanov, Lenin, and later Soviet writers.

**H. B. Acton (1967)**

## DIALECTICAL MATERIALISM [ADDENDUM]

The term *dialectical materialism*, commonly used to describe the philosophy of Karl Marx, is suggested by certain statements of Marx, but was not a term that he himself used. In the afterward to the second German edition of *Capital*, Marx says, “My dialectic method is not only

different from the Hegelian, but is its direct opposite” (1996a, p. 1:19). For Georg Wilhelm Friedrich Hegel, the Idea is an independent power, a “demiurge,” for which the real world is an external, phenomenal form. For Marx, “the ideal is nothing else than the material world reflected by the human mind, and translated into forms of thought” (19).

## SPECIES BEING

Marx does not here directly call his method “materialist,” however. In his early *Economic and Philosophic Manuscripts of 1844* he rejects the antithesis of materialism and idealism as terms usually applied to separate individuals, for a social ontology of the human being. The human being is a *species being*—that is, a being that is not just a member of a species, as are individual animals, but one that takes the life of the species as an object of concern. The animal “is one with its life activity,” whereas the human being “makes his life activity itself the object of this will and of his consciousness” (1996b, p. 3:276). (No doubt Marx, in his disparagement of individualism as animalistic, underestimated the extent to which such animals as gorillas, chimps, whales, and so on create real communities comparable to those of humans.) Rather than take human consciousness as a given, and then relate it in some way to the body, Marx explains human consciousness as the result of the way in which human individuals relate to their species. “[I]t is only because he is a species-being that he is a conscious being” (276). So he concludes in general terms that go beyond the opposition of materialism and idealism that “just as society itself produces *man as man*, so is society produced by him.... Thus *society* is the complete unity of man with nature—the true resurrection of nature—the accomplished naturalism of man and the accomplished humanism of nature” (278).

In his first thesis on (Ludwig Andreas) Feuerbach, Marx says that for “all previous materialism” things are regarded as objects of contemplation, and so the active side of human practice “was set forth abstractly by idealism” (1996d, p. 5:3). In the third thesis he rejects “the materialist doctrine that men are products of circumstances and upbringing.” Instead, he asserts “the coincidence of the changing of circumstances and of human activity or self-change,” which is “revolutionary practice” (4). The problem with Feuerbach’s materialism is that he conceives of the individual in isolation, and of the species as only “an inner, mute, general character which unites the many individuals *in a natural way*,” whereas “the essence of man is no abstraction inherent in each single

individual. In its reality it is the ensemble of the social relations” (4).

Language is the initial form of human species consciousness. Language is not primarily a mode of expressing the brain activity of the separate individual, but a vehicle of the social intercourse or species being that constitutes distinctively human consciousness. “[L]anguage is practical, real consciousness that exists for other men as well, and only therefore does it also exist for me” (1996c, p. 3:44). While consciousness presupposes the activity of the brain, it exists primarily outside of the individual’s head in the linguistic interchange between human beings. Language-mediated consciousness is the direct presence of the species to the individual while at the same time the individual is always creatively reproducing the species in new forms. “Consciousness is, therefore, from the very beginning a social product, and remains so as long as men exist at all” (44). In distinguishing such socially mediated human consciousness from animal consciousness Marx supposes a nonreductivist, emergentist, or “dialectical” materialist conception of the relation of conscious activity to the brain. Brain activity is nature presupposed by human social activity but then dialectically transformed and uplifted or “resurrected” by it. This is Hegel’s dialectical sublation (*aufhebung*).

#### LABOR AND THE CUNNING OF REASON

This relational conception of the human individual is given specific expression in the different historical forms of social existence and in terms of different levels of analysis within these social forms. At the most basic level, and within every social form of existence, socially related individuals transform the natural world and “humanize” it through “labor.” In *Capital* Marx again compares human conscious activity with that of animals, “[W]hat distinguishes the worst architect from the best of bees is this, that the architect raises his structure in imagination before he erects it in reality” (1996a, p. 35:188). Thus, the idea, purpose, or goal has primacy in relation to the materials of labor. Marx approvingly cites Hegel’s own idealist analysis of the labor process in his *Logic of Hegel*, where he writes, “Reason is just as cunning as she is powerful. Her cunning consists principally in her mediating activity, which, by causing objects to act and re-act on each other in accordance with their own nature, in this way, without any direct interference in the process, carries out reason’s intentions” (1968, 350). Thus, Marx directly incorporates Hegel’s demiurge, the Idea, into his analysis of human labor. There are certainly material things or

complexes of things, tools, and materials involved in the labor process. But thanks to the “cunning of Reason,” those ideal constructions of language that constitute the presence of the species to the individual, the human agent powerfully channels the forces of nature in ways that lead to the intended goal.

Human activity is mediated by historically evolved systems of tools, material and ideal, spiritual, or cultural. While consciousness is extended through language and other means of communication (such as books, newspapers, and the Internet), practical activity on the natural environment is not merely the activity of the physical body, but of the body extended by tools. Naturalism and reductive materialism abstracts the human individual from his or her intrinsic connection to humanly produced tools and reduces the individual to the naked body alone. The human being for Marx is not “the naked ape” (Morris 1967) but the ape who wears clothes and extends his or her natural existence by humanly produced organs of thought and action existing outside of the biological organism. These organs of thought and action constitute the presence to the individual of the being of the species and are in turn objects for the individual’s creative and transformative thought and action.

#### ALIENATION OF SPECIES BEING

Whereas in other social systems the social connections tying individuals to one another are evident on the surface of social life—as in the direct communal relations in early societies, or as the personal relations of master and slave, lord and serf—in capitalism the social relations are hidden, while the seemingly separate individual comes to the forefront of empirical awareness. Here is the historical basis of those separate, abstract individuals of both idealist and materialist philosophies that Marx attributes to the alienation of human individuals from one another. In capitalism the social relations that essentially underlie the activity of individuals take the specific existential form of separate individuals exchanging their products and labor in the market. In appearance individuals confront other individuals existing outside of them, competing with them, and serving as means to the achievement of their goals, as they are to the others. In essence there is a holistic system of division of labor that makes possible the highly specific activities of each individual and requires their interdependence. It is this underlying social interdependence that constitutes the reality of communism that progressively emerges in specific ways within the womb of capitalism. Marx’s employment of the dialectical categories of essence and existence, or reality

and appearance, reflects his adoption of Hegel's dialectical logic.

### FETISHISM OF THE COMMODITY

The product of labor in this context has a dual nature. It is an individual object of some kind that can be described in its own terms: an automobile or a software program embodying the current state of technology and specific skills of the workers who produced it. At the same time it has an economic value that cannot be explained by its material qualities and that enables it to be equated somehow with a qualitatively different object:

A commodity is therefore a mysterious thing, simply because in it the social character of men's labour appears to them as an objective character stamped upon the product of that labour; because the relation of the producers to the sum total of their own labour is presented to them as a social relation, existing not between themselves, but between the products of their labour. (Marx 1996a, pp. 35:82–83)

Materialists and idealists battle interminably over the explanation of this and other mysteries of philosophy because they preserve the standpoint of the independent, separate individual that gives rise to them. Behind the mystery of economic value is the social nature of human labor, the fact that each product embodies a certain proportion of the combined labor of society. Because the people whose interdependent labor is responsible for the product have organized themselves as separate, disconnected individuals, their underlying social connection takes the form of a mysterious, nonmaterial property of their products. In the value form of the commodity spirit and matter confront one another as irreducible opposites: for the "value-relation between the products of labour ... [has] absolutely no connection with their physical properties and with the material relations arising therefrom" (Marx 1996a, p. 5:83). Consequently, "[t]here it is a definite social relation between men, that assumes, in their eyes, the fantastic form of a relation between things" (83).

This complex relationship produces the "fetishism" (Marx 1996a, p. 5:83) of the products of labor when they become commodities. The combined power of human beings appears before them as an external power ruling over them—the market and the quasi-omnipotent power of money. The mystery of the nonmaterial characteristics of the product can ultimately be explained in one of two ways: (1) As the expression of the social relations between the producers, seen in essentially cooperative activities that belie the capitalist form of private ownership. This is

the kind of social-historical and dialectical "materialism" that Marx espouses. (2) Or it can be approached by reference to "the mist-enveloped regions of the religious world," in which "the productions of the human brain appear as independent beings endowed with life, and entering into relation both with one another and the human race" (83). Marx thought that Hegel's idealism, for all its advances over previous materialism, did not escape this religious, other-worldly, appearance of alienated human activity.

## DIALECTIC IN ISLAMIC AND JEWISH PHILOSOPHY

In these closely related traditions dialectic is primarily associated with the science of *kalām*, commonly translated as "theology," but literally meaning "word," "speech," or "discussion." *Kalām* began in the eighth century as an intellectual defense of Islam against external critics and quickly developed into an internal debate over doctrinal issues concerning the legitimacy of political authority, the necessary conditions of religious belief, predestination and free will, the ontological status of the Qur'ān, and the relation of God's attributes to His essential Unity. *Kalām* was subsequently appropriated by Arabic-speaking Jews living in the Islamic realm, who shared some of its concerns and employed its distinctive techniques and formulas in the defense and systematic explanation of their own faith.

*Kalām* in general is marked by its dual reliance on revelation and reason. The *kalām* theologians, or *mutakallimūn*, took scripture as their primary data but

employed rational argumentation to produce the most robust and coherent interpretations thereof. This distinguished them on the one hand from traditionalists and literalists who saw logical disputation and interpretation as leading to heresy, and on the other hand from the Greek-influenced Islamicate philosophers, or *falāsifa*, who were more fully committed to the demands of reason and thus wary of their theological brethren's residual dogmatism. *Kalām*'s method of reasoning and argumentation was dialectical in at least two respects. The first recalls the Aristotelian concept of dialectic, insofar as the *mutakallimūn* based their arguments on merely probable or generally accepted beliefs—specifically, the revealed truths of Islam or Judaism—rather than rationally self-evident first principles or premises that necessitated consent. The *falāsifa*, who appropriated Aristotle's hierarchical distinction between dialectic and demonstration, considered this approach insufficiently rigorous. While their own adoption of the demonstrative syllogism held out the prospect of certitude, they saw the *mutakallimūn* as hobbled by the questionable epistemic status of their faith-based premises. However, the *falāsifa* did not reject dialectic altogether. They generally recognized its value as a propaedeutic for honing intellectual skills, as well as a tool for communicating crucial truths to those unequipped for philosophical discourse. The *mutakallimūn*, for their part, remained dubious about the philosophers' claims to apodictic certainty.

The second sense in which *kalām* was dialectical recalls certain aspects of the Socratic method. First, it was dialogical: It typically took a question and answer form, in effect presupposing the existence of an intellectual adversary to drive the discourse forward. Its method was thus parasitic: The *mutakallimūn* tended to establish their own conclusions indirectly, by teasing out inconsistencies or internal contradictions in the opponent's position. This strategy often involved the use of dilemmas, where the adversary would find himself trapped between two unacceptable consequences that could be avoided only by adopting the questioner's position. The *mutakallimūn* commonly fashioned their arguments with an eye to the specific concerns, presuppositions, and methods of their opponents as well, advancing internal critiques of their adversaries to refute them on their own terms. Ironically, their assault on the *falāsifa* in the eleventh and twelfth centuries, which effectively brought an end to the classical period of Islamic philosophy, required the instrumental adoption of Aristotelian logic, specifically, the demonstrative syllogism.

Although the presence of dialectical methods within the Islamic and Jewish traditions is often attributed directly to Greek influences, a number of contemporary scholars and historical figures have made the case that versions of these argumentative strategies in fact predate exposure to Christian, Greek, or Syriac sources.

## DIDEROT, DENIS

(1713–1784)

Denis Diderot, the French encyclopedist, philosopher, satirist, dramatist, novelist, and literary and art critic, was the most versatile thinker of his times and a key figure in the advancement of Enlightenment philosophy.

### LIFE

Born in Langres, son of a master cutler, Diderot was a brilliant student in the local Jesuit schools. He was sent to college in Paris and received his master's degree at the age of nineteen. Afterward, he refused to adopt a regular profession and, when his allowance was cut off, lived for many years in poverty and obscurity. His great ambition was to acquire knowledge. In this he was eminently successful, for he emerged from this period of self-education with an excellent command of mathematics and considerable proficiency in the Greek, Italian, and English languages. He first came into public notice as a translator of English works—a history of Greece, the earl of Shaftesbury's *Inquiry concerning Virtue and Merit* (1745), and Robert James's *Medicinal Dictionary* (1746–1748). He was secretly married in 1743; and his wife bore him a number of children, all of whom died in childhood except a daughter, Angélique, who lived to perpetuate the memory of her distinguished father.

In 1746 he published his first original work, the bold and controversial *Pensées philosophiques*. In that year, too, he became associated with the *Encyclopédie*, the greatest publishing venture of the century, of which he soon became editor-in-chief, with the aid of Jean Le Rond d'Alembert for the mathematical parts. This enterprise was his chief occupation and source of income until 1772. The boldness of his thought, in spite of the dexterity with which he attempted to conceal it, met almost instant opposition, resulting in the seizure of manuscripts, censorship, and temporary suppression. Only a man of Diderot's indomitable courage and determination could have brought the project to a successful conclusion.

In 1749, while manuscripts for the *Encyclopédie* were being prepared for the printer, Diderot published his *Lettre sur les aveugles* (Letter on the blind), in which he questioned the existence of purpose or design in the universe. For this and other suspect works he was seized by the police and spent a few uncomfortable months in the prison of Vincennes. His reputation in his parish as a materialistic atheist was catching up with him. The subsequent *Lettre sur les sourds et muets* (Letter on the deaf and dumb; 1751), equally original, was mild enough to

escape persecution. His *Pensées sur l'interprétation de la nature* (Thoughts on the interpretation of nature; 1754) was both a plea for strict adherence to the scientific method and an exposition of results of that method, including definite evidence in support of evolutionary transformism.

After the official suspension of the *Encyclopédie* in 1759, Diderot prudently withheld his most important philosophical works for the use of posterity. The *Rêve de d'Alembert* (D'Alembert's dream), written in 1769, and the *Réfutation de l'ouvrage d'Helvétius* (Refutation of Helvétius) first became public in the nineteenth century. *Le neveu de Rameau* (*Rameau's nephew*), a scathing satire of eighteenth-century society, and the novels *La religieuse* (The nun) and *Jacques le Fataliste* (*Jacques the Fatalist*), which saw the light of day only after the French Revolution, as well as various short stories and dialogues, were all of ethical import. Two bourgeois dramas, *Le fils naturel* (The natural son; 1754) and *Le père de famille* (The father of the family; 1758), accompanied by critical essays, could, however, be safely published, though the *Paradoxe sur le comédien* (The Paradox of the actor), important for its aesthetic insights, was withheld. Diderot's *Salons*, replete with brilliant criticism of art and literature, were also published posthumously, although in manuscript copy they formed an important part of Friedrich Grimm's *Correspondance littéraire*, written only for foreign consumption. Diderot knew that his ideas were too advanced for his own generation, but he maintained the conviction that he would some day be appreciated at his true value.

When, in 1772, his long labors on the *Encyclopédie* were ended, Diderot set off for St. Petersburg by way of Holland and spent some months in 1773 in intimate conversations with Catherine the Great. Persuaded of his merit through Grimm, she had not only paid in advance for his library (he desperately needed the money as a dowry for his daughter) but also gave him a salary as its custodian until his death. Baron d'Holbach's *System of Nature* (1770), frankly atheistic and materialistic, had sharply drawn the line between atheism and deism, and both Catherine and Frederick II took the side of the less revolutionary Voltaire. Since Diderot supported Holbach in this controversy, his political *Observations* on Catherine's plan to recodify Russian law were deemed too radical and suppressed by his royal patron.

Returning to France in 1774, Diderot spent the remaining years of his life in semiretirement, enjoying at least a semblance of domestic felicity. His letters to his mistress, Sophie Volland, form, next to Voltaire's, the

most interesting correspondence of the century. His final work, the *Essai sur les règnes de Claude et Néron* (Essay on the reigns of Claudius and Nero; 1778–1782), was a eulogy of Stoic virtue, as illustrated by Seneca, and also a reply to charges of treachery and immorality made against Diderot in the *Confessions* of Jean-Jacques Rousseau, his former friend and coworker.

Diderot died in Paris six years after Voltaire and Rousseau, with whose names his is inextricably linked as a leader of the French Enlightenment.

## GENERAL PHILOSOPHICAL ATTITUDES

Diderot's philosophy was remarkably undogmatic. He advocated the open mind and believed that doubt was the beginning of wisdom and often its end; he continually questioned his own theories and conclusions, developed extreme theses, or paradoxes, in ethics and aesthetics, and decided that "our true opinions are those to which we return the most often." Nevertheless, after passing briefly through a period of deistic belief (a deist, he finally concluded, was a man who had not lived long enough—or wisely enough—to become an atheist), he became an unabashed and enthusiastic materialist and developed a theory of materialism much less vulnerable than that of his forebears. His main contribution was a philosophy of science that looked far into the future and upon which his aesthetic and ethical theories were firmly and inseparably founded.

**SENSATIONALISM.** Like Voltaire, Rousseau, and Étienne Bonnot de Condillac, Diderot was early preoccupied with the theory of sensationalism. At weekly dinners with the latter two, John Locke's psychology was thoroughly discussed. Between Diderot and Condillac influence was undoubtedly mutual. But Condillac, having taken holy orders and being therefore more circumspect, worked out a more systematic and more abstract philosophy and left it to Diderot to direct French sensationalism into definitely materialistic channels.

Diderot's philosophical thought was clarified by his constant distrust of abstractions. Abstractions, he declared in *Rêve de d'Alembert*, are linguistic signs, which are useful in speeding up discourse and upon which the abstract sciences are built; but as symbols emptied of their ideas, they are obstacles to clear thinking. Those who use abstractions must have constant recourse to examples, thus giving them perceptibility and physical reality. The mind is nothing but the brain functioning;

the will is the latest impulse of desire and aversion. The naming of things is purely conventional.

Diderot's early philosophical publications were especially concerned with problems of communication. His empirical mind could not be satisfied with speculative studies, such as Condillac's theoretical experiment of endowing a statue with one sense at a time. He chose rather to study the actual cases of individuals deprived of the sense of sight or the sense of hearing. His *Lettre sur les aveugles* (1749) dealt first with case histories and the problems of "reading" through touch, illustrated by the methods of Nicholas Saunderson, the blind professor of mathematics at Oxford. This first truly scientific study of blindness led to Diderot's imprisonment. The passage that provoked the authorities was an imaginary deathbed conversation, in which the blind professor, unable to appreciate the alleged perfection of the order and beauties of nature, expressed his consequent doubts as to the existence of an intelligent God. The treatise on the deaf and dumb, two years later, was also based on scientific observation, but proceeded to discuss aesthetic theories, especially the importance of gesture to communication. In his later posthumous works, sensationalism played an important role in the development of his materialistic monism.

**EMPIRICISM.** As early as 1748, in the libertine novel *Les bijoux indiscrets* (The indiscreet toys), Diderot showed himself a pronounced empiricist, a firm believer in the efficacy of the scientific method. In an important chapter of that work, Experience (the word meant both observed fact and experiment) figures first as a growing child, who discovers with the aid of a pendulum the velocity of a falling body, calculates the weight of the atmosphere with a tube of mercury, and with prism in hand, decomposes light. The child visibly grows to colossal stature and, like a Samson, crumbles the pillars of the Portico of Hypotheses.

Diderot's *Pensées sur l'interprétation de la nature*, taking its title and inspiration from Francis Bacon, again extolled the experimental method above purely rationalistic theory. Following the work of Pierre-Louis Moreau de Maupertuis and Comte de Buffon—and especially in studying Louis Daubenton's anatomical comparison of the foot of the horse and the hand of man—Diderot arrived at principles of transformism and natural selection that were to influence greatly his mature philosophy. He surmised that "there had never been but one animal, prototype, through differentiation, of all other animals."

The dawning of the age of biological science, he believed, would usher in the great discoveries of the future.

**IMAGINATION.** Observation and the classification of natural phenomena was the first and essential step, but the great scientist must perceive relationships and form hypotheses, subject to experimental verification. Diderot closely associated the poetic imagination with the scientific, both in theory and practice. This theory is clearly expounded in the first of the three “conversations” of *Rêve de d’Alembert*. This section discusses the role of analogy, which is merely the working out of the rule of three by the feeling instrument that is man. To the genius, whether poet or scientist, will come the sudden perception of a new relationship, resulting in poetic metaphor or useful hypothesis.

**STYLE.** Diderot’s own mind worked in sudden flashes of perception. His best philosophical works are random or loosely associated thoughts or observations—or dreams. His satirical narrative, *Rameau’s Nephew*, and his novel, *Jacques the Fatalist*, are apparently loosely constructed, much given to dialogue, with digressions and intercalated stories after the manner of Laurence Sterne. They follow the pattern of general conversation, in which one idea gives birth to another, and so on, until the thread is difficult to retrace. The theory of associationism was firmly based, however, on his theories of sensationalism and memory (to be discussed below).

**SCIENTIFIC BACKGROUND.** Diderot’s inquisitive and encyclopedic mind equipped him admirably to comprehend the great advances that the sciences were making in the middle of the century. From mathematics he turned to chemistry and for three years studied assiduously under Guillaume-Francois Rouelle, forerunner of Antoine Lavoisier. He was well acquainted with the work of the Dutch biologists Nikolaas Hartsoeker and Bernard Nieuwentyt, who laid the foundations for the still unknown science of genetics. He was familiar with Abraham Trembley’s experiments with the freshwater polyp, and with Joseph Needham’s discovery of Infusoria, in apparent proof of the theory of spontaneous generation. These experiments influenced his development of the concepts of the sensitivity of matter and the essential identity of its organic and inorganic forms.

As translator of Robert James’s *Medicinal Dictionary*, Diderot was well informed in the science of medicine. Characteristically, he sought (in vain), before writing his *Lettre sur les aveugles*, to be admitted to an operation for cataract, and he consorted with doctors, many of whom

were contributors to the *Encyclopédie*. While in prison at Vincennes, the recently published first three volumes of Buffon’s *Natural History* received his careful scrutiny, and from all possible sources he collected case histories of injuries to, and surgical operations on, the brain.

By 1769, when he composed *Rêve de d’Alembert*, Diderot was adequately prepared to develop an original philosophy of science, a monistic theory that has been described as naturalistic humanism and dynamic, or “energetic,” materialism, which far surpassed the mechanistic theories of his forebears, from Lucretius to Julien Offray de La Mettrie, and foreshadowed Charles Darwin. In this work, first published in 1830, Diderot showed himself at once a great and an imaginative philosopher and writer. In its pages, his mature philosophy, presented fantastically but seriously, was best illustrated.

#### MATERIALISM—MATTER IN MOTION

Diderot adopted the Heraclitean theory of flux. The universe, for him, was a single physical system, obeying the immutable laws that René Descartes assigned to matter in motion; it was dynamic or “becoming,” rather than static or created. Unlike Descartes, however, Diderot followed John Toland in believing that motion was not added but was essential to matter. He gave the idealistic monad of Gottfried Wilhelm Leibniz a positive content. Diderot maintained that not only are bodies affected by external force but that the atom contains internal forces, a form of kinetic or potential energy. All things carry with them their opposites; being and not-being are part of every whole. “Living,” he wrote, “I act and react as a mass; dead, I act and react in the form of molecules. Birth, life, decay, are merely changes of form.” No knowledge was gained, no solution reached, in postulating a Creator or supernatural agency to account for material phenomena. All change, including the transformation of the universe from chaos to order, was to be explained by the interaction of the elementary material particles. What man perceives as order is simply his apprehension of the laws of motion as enacted by material bodies.

**SENSITIVITY OF MATTER.** An additional and very important hypothesis upon which Diderot’s construction was built was the sensitivity of all matter, both inorganic and organic. By postulating both motion and sensitivity as inherent in matter, he felt that the entire range of natural phenomena (both physical and mental) and the full variety of experience could be adequately explained. All that nature contains is the product of matter in motion,

subject to the processes of fermentation produced by heat; through eons of time growth, increasing complexity, and specialization have occurred.

Diderot believed that there were no inexplicable gulfs between the various kingdoms. The known facts concerning the inorganic, the organic, plant, animal, and man, were like islands jutting out of a sea of ignorance. As the waters receded through scientific investigation, the missing links would be discovered. "How d'Alembert differs from a cow," he admitted, "I cannot quite understand. But some day science will explain." He nevertheless attempted to trace the development of his friend, from the earth mold to mathematician, from the unconscious through the subconscious to the conscious life.

### BIOLOGY AND EVOLUTION

During Diderot's lifetime the biological sciences were in their infancy. The scope and profundity of his insights are therefore all the more amazing. When scientific facts failed him, he had recourse to hypotheses that he was convinced would some day be verified. It was in consideration of this conviction that he presented his mature philosophy as a dream, a dream that, with the passage of time, can truly be called prophetic.

The crucial problem that confronted Diderot was to account for the emergence and behavior of the living individual. The coordinated behavior and continuous identity that characterize the organism seemed to transcend any possible organization of discrete material particles. It was difficult to see how merely contiguous material parts could form an organic whole capable of a unified and purposeful response to its environment. Traditionally, the existence of unique species and individuals was explained by recourse to supernatural design and metaphysical essence.

Contemporary science offered Diderot a choice between preformation, a Lucretian theory accepted at times by La Mettrie, and epigenesis, which explained organic formation in terms of juxtaposition and contiguity. Diderot rejected preformation, and in support of epigenesis he developed the concept of molecular combinations endowed with specialized functions and organic unity. In *Rêve de d'Alembert*, Diderot employed the image of a swarm of bees in an attempt to bridge the gap between contiguity and continuity in the production of a whole that is qualitatively unique and different from the sum of its parts. He pointed out that although the swarm consists simply of numerous separate individuals in physical contact, it does, as a whole, possess the characteristic of purposeful, unified behavior that is associ-

ated with the individual organism. It is possible to mistake the swarm of thousands of bees for a single animal. The unity of the organism is derived from the life of the whole, and Diderot thus affirmed the continuity of the kingdoms and refuted the metaphysical principle of essences. A half century later the discovery of the organic cell and the principles of cell division confirmed his views.

Diderot found support for his theories in the embryological ideas that he had gathered from his reading, especially of Albrecht von Haller's *Elements of Physiology*, and from Dr. Bordeu, his friend and the protagonist in the conversations of *Rêve de d'Alembert*. In the conversation with d'Alembert, which gives rise to the dream, Diderot attempts briefly to trace d'Alembert from the parental "germs." He then describes how, under the influence of heat, the chicken develops within the egg. Excluding all animistic hypotheses, he declares that this development "overthrows all the schools of theology; ... from inert matter, organized in a certain way and impregnated with other inert matter, and given heat and motion, there results the faculty of sensation, life, memory, consciousness, passion, and thought."

**HEREDITY.** Diderot's conviction of the importance of hereditary factors constitutes the main argument of his refutation of Claude-Adrien Helvétius's work *On the Mind*, in which education and law, purely environmental factors, were proposed exclusively as causes of the development of a moral society. Diderot agreed with Bordeu ("organs produce needs, and reciprocally, needs produce organs") on the Lamarckian principle of the inheritability of acquired characteristics. Moreover, he clearly stated his belief that the individual recapitulates the history of the race and that certain hereditary factors may crop up after many generations.

To explain how parental factors are inherited (cells and genes were as yet unknown), Diderot resorted to a hypothesis of organic development through a network or bundle of threads (or fibers or filaments), which strongly suggested the nervous system. Any interference with the fibers produced abnormalities, or "monsters." (He was one of the first to seek to understand the normal through the abnormal, both in embryology and psychology.) In his careful description, in *Rêve de d'Alembert*, of the embryological differentiation between the male and female sex organs, he was led to surmise that man is perhaps the "monster" of the woman, and vice versa. His theories clearly foreshadow not only the phenomena of recessive genes but also the fundamental role of chromo-

somes. One of his chief arguments against design in the universe was nature's prolific production of "monsters," most of which were too ill adapted to their environment to survive. Their elimination was the closest he came to the principle of natural selection.

### MATTER AND THOUGHT

Diderot believed that once it is granted that sensitivity is a property of matter and that matter thereby develops increasing complexity and specialization, it then follows that thought can best be understood as a property of that highly complex and specified material organ, the brain. He accepted Bordeu's theory of the individual life of the various bodily organs. All were linked, however, through the nervous system to the central organ, which, depending upon circumstances and temperaments, exerted more or less control over them. Personal identity, the unified self, was thus assured by the nervous system, and the brain played the role of both organ and organist.

MEMORY. Self-awareness, however, depends entirely on the remembering function of the human brain. Quite characteristically, Diderot assigned a neural mechanism to Locke's theory of the association of ideas. In his investigations of the physical substrata of memory, he read all he could find on the anatomy of the brain and injuries to the brain and consulted doctors and specialists in brain surgery. A number of case histories were reported in *Rêve de d'Alembert*. In the preliminary conversation with d'Alembert, however, he used La Mettrie's metaphor of vibrating strings and harmonic intervals to explain the association of images and memory, the passage from sense perceptions to comparisons, reflection, judgment, and thought. Memory furnishes the continuity in time, the personal history that is fundamental to self-consciousness and personal identity. In Diderot's mind, memory was corporeal, and the self had only material reality. He thus attempted to give psychology a scientific, physiological basis, which was further developed in the nineteenth and twentieth centuries.

In the midst of notes taken mostly from his reading and published later as the *Éléments de physiologie*, Diderot included an eloquent passage in support of his theory: "I am inclined to believe that all we have seen, known, perceived, or heard—even the trees of a great forest ... all concerts we have ever heard—exists within us and unknown to us." He could still see in his waking hours the forests of Westphalia, and could review them when dreaming—as brilliantly colored as if they were in a painting. Moreover, "the sound of a voice, the presence of

an object ... and behold, an object recalled—more than that, a whole stretch of my past—and I am plunged again into pleasure, regret, or affliction."

DREAMS AND GENIUS. The concept of the greater or lesser control exerted by the central organ over the other organs of the body was applied by Diderot not only to dreams but also to the phenomenon of genius. In sleep, control is relaxed and anarchy reigns. A random recall in the central organ may then be referred to the subordinate organ, or the procedure may be reversed, from organ to brain. In dreams, random combinations may be formed and dragons created. Only personal past experience is available, however, for such imaginings. The one impossible dream is that the dreamer is someone else.

Applied to genius, the explanation of which was of great concern to Diderot and an important aspect of *Rameau's Nephew*, the concept of central control ran into difficulties. In the early *Pensées philosophiques*, in opposition to Blaise Pascal, he championed the strong emotions as the chief source of the good, the true, and the beautiful. Later, his acquaintance with David Garrick led him to write a paradox on the acting profession, in which he claimed that the great actor, with complete command of his emotions, makes his audience laugh or weep by coolly calculated gesture and intonation; he must register the emotions, but not feel them at the same time. In *Rêve de d'Alembert* he explained that dominating control by the center produced wise and good men but that genius was the result of the strongest emotions under almost complete control, a theory that could be illustrated by the horseman, Hippolytus, in firm command of the most spirited horses that Greece produced. In Diderot's hands, genius was not a mere talent produced, as Helvétius had claimed, by education and chance, but a psychophysiological phenomenon, and in that respect akin, when central control is lost, to madness.

### ETHICS

The fundamental principles of Diderot's ethics may be found most readily in *Rêve de d'Alembert*. Will and liberty (free will) he described as senseless terms, abstractions that obscured the facts. The will of the waking man is the same as that of the dreamer: "the latest impulse of desire and aversion, the last result of all that one has been from birth to the actual moment." "There is only one cause ... and that is a physical cause." But Diderot clearly distinguished between fatalism and determinism. Man is not, like the lower animals, a prey to the bombardment of the senses. The self, the brain with its properties of memory

and imagination, intervenes between the external stimulus and the act.

Diderot was tempted, but refrained from writing a treatise on ethics. Many critics have attributed this failure to the moral dilemma posed by his determinist convictions. It is more probably that he felt his ideas were too advanced for the age and society in which he lived. Moral problems were foremost in his mind throughout his career. A letter of 1756 stated clearly his deterministic beliefs. Heredity played a dominant role, for some, happily, are endowed with moral or socially acceptable propensities, while others, unfortunately, are not. Moral monsters must be eliminated, but in general, man is modifiable. *Rameau's Nephew* is, among other things, the story of the dilemmas that confront moral man in an immoral society, in which honesty is not necessarily the best policy.

Diderot's imaginary *Supplément au voyage de Bougainville* (1796) describes and extols the primitive customs of Tahiti. Unlike Rousseau's, Diderot's "primitivism" was not a plea for a return to a less civilized society. Not nature or natural law, but the fundamental laws of nature, were uppermost in Diderot's mind. The conventions of modern society, it seemed to him, unnecessarily restricted the basic biological needs of man. Before Sigmund Freud, he sensed the dangers of sexual repression, a theme developed in the final section of *Rêve de d'Alembert* and fundamental to his novel *La religieuse*. Celibacy, in his view, led too often to mental or sexual aberration. He ended his Tahitian tale, however, with the admonition that, though we should try to change bad, or "unnatural," laws, we must obey the laws that our society has imposed.

Diderot frankly admitted his enjoyment of sensual pleasures—books, women, pictures, friends, and toasting his toes before a fire. But in the preface of *Le père de famille*, addressed to the princess of Nassau, he declared that "he who prefers a voluptuous sensation to the conscience of a good act is a vile man." He felt certain that through education and knowledge we could recognize what was good, and that virtue, or beneficence, was the one and only path to happiness. There are intimations in his works of a belief that the good and wise man, in a corrupt society, should at times rise above a bad law, a theme illustrated in his last play, *Est-il bon? Est-il méchant?*

Toward the end of his life, in his praise of Seneca, he extolled the Stoic concept of virtue as its own reward. He summed up his natural, humanistic ethics in a brief pronouncement: "There is only one virtue, justice; one duty,

to be happy; one corollary, neither to overesteem life nor fear death."

## AESTHETICS

In the theory and practice of the arts dependent on the imagination—literature, music, and the fine arts—Diderot also introduced innovations. His approach to the theory of Beauty was through the perception of relationships and the arts of communication. An unusual perception of relationships, through analogy and associative memory, was the mark of the genius, whether scientist or poet. The artist first experiences an emotional or aesthetic stimulus strong enough to fire his imagination. A second moment of enthusiasm, which comes from the ability to communicate his vision through his special technique, sounds, colors, lines, or words, is essential, however.

His *Encyclopédie* article "Beau" (1751) gave evidence of a thorough acquaintance with French and English aestheticians. That same year he launched out on his own in his *Lettre sur les sourds et muets*. Here he discussed the importance of gesture and expression in communication. The great actor is one who paints in gestures what he expresses in words, just as the great poet paints in sounds and rhythms what he means in words. Likewise, the beauty of a painting depends on its inner rhythm and structure. The sublime in painting and poetry is derived from the emotions imparted through the harmonies of sound and color, the wedding of sense and sound. Poetry, he declared, is therefore essentially untranslatable.

**ART AND MORALITY.** A strong moralistic tone pervaded Diderot's aesthetic theories and criticism. The painter must have morals as well as perspective. The bourgeois drama, a genre that he originated and illustrated, though not very successfully, should compete with the law in persuading us to love virtue and hate vice.

There was more than a touch of sentimentality in the art criticisms of the *Salons*, which he wrote biennially from 1759 to 1781. For a period, the bourgeois pathos of Jean-Baptiste Greuze held a strong appeal for him. A notable connoisseur of the arts, he was not, however, fooled. He recognized the masterly compositions of François Boucher, but condemned his allegorical subjects and depiction of the loves of the gods. Pierre Teilhard de Chardin's use of color, he knew, was far superior to that of Greuze, though his subject matter was too often "ignoble." Yet Teilhard de Chardin taught him that painting was not, as the classical theorists long held, the imitation of beautiful nature. He stood in awed amazement before

Teilhard de Chardin's painting of the skate and called it magic.

**CRITICISM.** Diderot created modern art criticism as a literary art. The *Salons*, especially of 1765 and 1767, still make fascinating reading and contain the best of his literary criticism. That he was himself a great writer is now at last being generally recognized. First and foremost, he was a master of dialogue; written for the ear, his dialogues are artistic transpositions of reality. His dislike of abstractions made him an early champion of realism. He never ceased to admire Molière and Jean Racine—and William Shakespeare—but believed that the theater was destined to follow new paths. His romantic spirit was revealed by his advocacy of strong emotions and his streak of sentimentality. He therefore foreshadowed the romantic-realistic revolt against classicism, delayed in France until the nineteenth century by the political revolution.

Diderot's trinity was truth, goodness, and beauty. In his aesthetic order, first place was given to that which was both useful and agreeable; second, to the merely useful; and third, to the purely agreeable. Since the essence of the arts was not subject matter, but the perception and communication of relationships, he felt it was advantageous to add a moral subject, the useful, to technical beauty.

## SOCIETY AND POLITICS

Diderot made his *Encyclopédie* a major weapon for upsetting the social and political institutions of the Old Regime. In the first volume his article "Autorité politique" boldly proclaimed, before Rousseau's *Contrat social*, that sovereignty resided in the people, who alone should determine how and to whom it should be delegated. There, too, appeared the first discussion of the "general will." In an often vain effort to evade censorship, he chose out-of-the-way places, sometimes seemingly harmless definitions of terms, to point out the danger that lay before both the state and the church unless they were strictly separated.

In his *Observations* on the instructions of Catherine II to her deputies in the recodification of Russian law, he was even more forthright: "The only true sovereign is the nation," he wrote; "there can be no true legislator except the people." He also chided Catherine for submitting political institutions to religious sanction: "Religion is a support that in the end almost always ruins the edifice." He did not hesitate to call her a tyrant and refuted her arguments in favor of benevolent despotism. Her suppression of his manuscript was so thorough that parts of it were coming to be known only in the twentieth century.

*Rameau's Nephew* was a sweeping satire of French eighteenth-century society, especially of the often ignorant and very wealthy general tax collectors, who, with their hordes of parasites, were a menace to the development of the arts, as well as powerful enemies of the *Encyclopédie*. In a dialogue with Diderot, the parasitic nephew of the great Jean-Philippe Rameau defended his debasement and moral corruption, quite shocking to his moralistic interlocutor, as the only means of satisfying the pangs of hunger in a thoroughly corrupt society. Throughout Diderot's works—in his dramas, his short stories and novels, in his art and literary criticism, as well as in his social and political theories—his sympathies were with the Third Estate.

Because he was forced to withhold his best and most forthright works for publication by future generations, the growth of Diderot's fame has been a very slow process. Rousseau declared that it would take two centuries for the realization that he was the great genius of his century. His first enthusiasts were also men of genius, Johann Wolfgang von Goethe, Honoré de Balzac, Charles-Pierre Baudelaire, and Victor Hugo.

It can hardly be a cause for wonder that Diderot is receiving special attention in Marxist societies and that many excellent editions and translations have come from Marxist presses. Yet it was to the scientist and philosopher in Friedrich Engels, rather than the social economist, that Diderot's work most greatly appealed. His philosophical determinism was in no sense economic determinism; his sturdy bourgeois qualities give small comfort to Marxist sociology; and his views of the importance of hereditary traits are in sharp opposition to behavioristic theory. He would seem to qualify most readily as a naturalistic humanist.

## Bibliography

### WORKS BY DIDEROT

- Oeuvres complètes*. 20 vols, edited by J. Assézat and M. Tourneux. Paris: Garnier, 1875–1877.
- Oeuvres*, edited by A. Billy. Paris, 1935. Essential works in one volume.
- Correspondance*, edited by G. Roth. Paris, 1955–.
- Le rêve de d'Alembert*, edited by Jean Varloot. Paris, 1962.
- English Translations**
- Diderot's Early Philosophical Works*. Translated and edited by Margaret Jourdain. Chicago and London: Open Court, 1916.
- Dialogues*. Translated and edited by Francis Birrell. New York: Brentano, 1927.
- Diderot, Interpreter of Nature; Selected Writings*. Translated and edited by Jean Stewart and Jonathan Kemp. London: Lawrence and Wishart, 1937. Best translations of *Rêve de d'Alembert*, etc.
- Rameau's Nephew and Other Works*. Translated by Jacques Barzun and Ralph H. Bowen. Garden City, NY: Doubleday, 1956.
- Jacques the Fatalist and His Master*. Translated by J. Robert Loy. New York: New York University Press, 1959 and 1961.
- Selected Writings*. Translated and edited by Lester G. Crocker. New York: Macmillan, 1966.
- Diderot: Political Writings*, edited by John Hope Mason and Robert Wokler. New York: Cambridge University Press, 1992.

### WORKS ON DIDEROT

## DIKĒ

*Dikē* is the old Greek word for "law, justice." By the fourth century BCE it was largely replaced by its cognate *dikaioσynē*, Plato's cardinal virtue, justice.

In early Greece (Homer, Hesiod), *dikē* ranges in meaning from a specific claim by one party to a dispute, to a judgment or settlement, or to the personified force or goddess Justice/Law. In Homer's *Iliad*, the trial scene on Achilles's shield (18.497–508) depicts the elders (as judges) in a competition to see who can propose the straightest *dikē* (the best judgment/settlement). In Hesiod's *Works and Days* animals eat one another, but Zeus gave humans *dikē*—law, judicial process—which is far better (276–280), and *Dikē* sits beside her father Zeus and punishes those who corrupt the judicial process with crooked *dikē* (256–262).

The sixth-century lawgiver Solon promotes *dikē*—law-abiding conduct—as part of a general program of *eunomia* (good order, law and order). He also speaks of his legislation as providing a straight *dikē* (judicial process) for every Athenian. For the fifth-century thinker Heraclitus, *dikē* becomes a cosmic force of order and balance. Heraclitus's *dikē* is not static, however, but—as in a lawsuit—a balance of opposing forces, so that, as he says paradoxically, *dikē* is *eris* (strife).

Fifth-century tragedians regularly see *dikē* as a cosmic force, justice, largely in the sense of punishment or retribution. All the characters in Aeschylus's *Oresteia* claim to seek *dikē*—justice—primarily in the sense of punishment or revenge for previous wrongs, though in some passages the chorus suggest a larger sense of justice as cosmic and social order. Plato's *Protagoras* pictures the sophist Protagoras telling a story in which the gods give *dikē*, law or justice, together with *aidōs* (respect) to all humans; he concludes from this that *dikē* is necessary for the survival of human society.

Through the fifth century, *dikē* in all its meanings—from judicial process to cosmic force—remains something external to human beings. Not until the fourth century does Plato make justice a personal virtue of individuals, and then it is no longer *dikē* but *dikaiosynē* (see especially *Republic*, Book IV).

## DILTHEY, WILHELM

(1833–1911)

The German philosopher and historian Wilhelm Dilthey was born in Biebrich on the Rhine, the son of the preacher to the Duke of Nassau. He studied theology and philosophy in Heidelberg and Berlin and combined both of these interests in his early work on the ethical and hermeneutical writings of Friedrich Schleiermacher. Dilthey's first major publication, a volume on the life of Schleiermacher, appeared in 1870 while he was teaching in Kiel. In 1871, Dilthey received a professorship in Breslau (now Wrocław, Poland). It was around this time that he met Count Yorck of Wartenburg, and their friendship produced an intellectual correspondence about the nature of life and the meaning of history that has inspired thinkers such as Martin Heidegger and Hans-Georg Gadamer. In 1882, Dilthey was called back to Berlin to fill the chair that George Wilhelm Friedrich Hegel had once held. The University of Berlin and the Prussian Academy would be the locus of his world for almost thirty years, until his death in 1911. This is the period in which he published most of his writings about the human sciences (*Geisteswissenschaften*), a covering term for both the humanities and social sciences. These writings consider how the human sciences contribute to the understanding of life and history.

### CRITIQUE OF HISTORICAL REASON

Dilthey saw his overall project as a Critique of Historical Reason examining the conditions that make possible the respective cognitive results of the natural and the human sciences. Although influenced by both Immanuel Kant and Hegel, he rejected the transcendental and formal limits of the former and the metaphysical absolutes of the latter. His task was to translate the insights of idealism into a more open empirical approach to what it means to experience reality.

Although the natural sciences are about nature and the human sciences about history, this does not justify hypostatizing history as a spiritual domain separate from nature. The spiritual life of human beings is conditioned—but not determined by—natural processes. Even

when human beings set themselves free purposes, the realization of these purposes requires that the laws of nature be obeyed. In Book 1 of his *Introduction to the Human Sciences* (1883), Dilthey grants the human sciences a relative cognitive independence from the natural sciences. Yet he assigns the human sciences a greater reflective scope in that they express more aspects of human experience. They not only ascertain what is—do the natural sciences—but also make value judgments, establish goals, and prescribe rules.

For the human sciences, theory is always framed by practical considerations instigated by historical life. Therefore, philosophical reflection about their conditions of possibility makes it necessary to regress behind the logical and epistemological foundations of the natural sciences to establish the more encompassing life-nexus of all human experience. This reflective turn initiated in Book 2 of the *Introduction to the Human Sciences* and worked out in the posthumously published drafts for Book 4, shows the human sciences to have an important advantage over the natural sciences in that they preserve some of the intuitive access to the reality of experience as it is lived. The natural sciences merely construct a phenomenal or ideal world that abstracts from the overall nexus of life so that human beings stand as impartial intellectual observers of this abstractly represented nature.

By contrast, the world that is formed by the human sciences is the historical-social reality in which human beings participate. It is a fuller world that is accessible not merely as conceptually mediated cognition (*Erkenntnis*), but also as immediate knowledge (*Wissen*) found in lived experience. Conceptual cognition is representational and objectifying. Lived experience provides a prerepresentational self-presence that involves a direct knowing. Any state of consciousness is implicitly present to itself in what Dilthey calls “reflexive awareness” (*Innewerden*). This does not require an explicit consciousness of being conscious—such an act of self-consciousness would be more than reflexive, namely, reflective. At the basic level of reflexive awareness there is not yet a self as an object of reflection.

According to Dilthey, there is no self underlying consciousness. Instead, the self arises out of consciousness as the correlate of the world. Within the nexus of consciousness as a function of life, reflection can differentiate between facts of inner perception and facts of outer perception, thereby producing a distinction between self and world. This world is not a product of an inference, but is felt primarily through resistance to the practical impulses of the will. Rather than grounding the objectivity of the

world on a transcendental “I think,” Dilthey claims that its reality is given in the reflexive awareness of the relation between efficacy and resistance involved in willing. Through this expanded reflexive awareness, the life-nexus in which the self participates discloses things and other selves that can resist its will. These modes of reflexive awareness are as basic to Dilthey’s theory of hermeneutical understanding (*Verstehen*) as the transcendental and empirical ego were to Kant’s theory of intellectual understanding (*Verstand*). Whereas Kant sought an explanative mode of understanding for natural phenomena by deriving them from the most general laws of scientific cognition, Dilthey seeks to understand the meaning of things in terms of their own inherent context. Hermeneutical understanding provides a kind of situated understanding that receives its bearings from the reflexive awareness of lived or prescientific experience.

## DESCRIPTION AND STRUCTURAL UNDERSTANDING

In 1894, Dilthey published another important work, the *Ideas for a Descriptive and Analytic Psychology* (Dilthey 1977). Here he works out the implications of his philosophical views about lived experience for psychology as a human science. Hitherto, psychology had been treated as a kind of natural science that synthetically constructs mental phenomena from atomistic elements such as sense-data by using hypothetical laws of association. This assumes that psychic life comes in discrete states that must be connected. Dilthey argues, however, that psychic life presents itself as a continuum in which states are already connected. It is the task of psychology to attempt to describe this general nexus of psychic life and to analyze specific states on its basis.

Dilthey’s descriptive and analytic psychology has three main parts. The first delineates the general structural systems of consciousness that can be differentiated at the levels of cognition, feeling, and volition. The cognitive system relates the acts of perception, imagination, and memory on the basis of which we conceptually represent the world. The felt and instinctual aspects of consciousness can be related to form a distinct structural system whereby we coordinate the value of things. A volitional structural system functions to link and rank the purposes we set. A cross-sectional analysis of any lived experience will manifest aspects of each of these three functional structures. Indeed, the structural systems manifest a degree of interdependence belying the traditional hierarchical assumption that the cognitive level is fundamental and that feeling and willing merely respond

to what has been perceived. Thus we do not perceive impressions of sense unless there is a felt interest in them and the will is stirred enough to attend to them.

The second main part of psychology as a human science traces the development of psychic life. It examines how psychic structures are defined and articulated over time. Here Dilthey stresses the importance of treating each phase in the teleological development of a psychic life-course as having its own inherent worth. Every phase has its immanent purposiveness and is to be treated as a kind of epoch. Although an epochal phase may contribute to its successor, it should never be treated as a mere means. The values of childhood, for example, should never be sacrificed for the goals of adulthood.

The third, concluding part of Dilthey's descriptive and analytic psychology integrates these structural and developmental approaches by showing how an acquired psychic nexus is gradually produced and informs future experiences. The acquired psychic nexus becomes the individualized framework according to which each self tends to specify its own experiences. It provides a historicized apperceptive mass that influences what will be perceived. It is like an implicit worldview that can regulate further experiences and actions.

Dilthey initially formulated his conception of the acquired psychic nexus as part of an effort to understand artistic creativity. In his 1887 essay "The Imagination of the Poet: Elements for a Poetics" (Dilthey 1985), Dilthey argues that what distinguishes artists from other human beings is the capacity to articulate their acquired psychic nexus in typical ways. In ordinary life, our experience and behavior reflect contingent local conditions as well as our acquired psychic nexus. Playwrights and novelists can establish fictional contexts that limit the extent to which characters will be distracted by local contingencies. By more adequately reflecting the acquired psychic nexus of their creators, the actions of fictional characters can also address more general aspects of life. The literary imagination produces typical situations and characters that help focus the meaning of human existence. Individuals manifest creativity when the perspective that informs their acquired psychic nexus becomes more than regulative, but constitutively typical.

The self-givenness of reflexive awareness and the self-presence of lived experience provide an implicit kind of understanding of life that psychological description and literary expression can make explicit. The inherent connectedness of consciousness renders it unnecessary to introduce hypothetical explanative links into the foundation of psychology. On this basis, Dilthey claims that the

natural sciences are mainly about causal explanation and the human sciences about description and structural understanding. But this contrast is not absolute. Sometimes natural sciences must be content with description and interpretation, and sometimes human sciences cannot rely on general descriptions to account for significant details and must appeal to hypotheses. The difference is that the natural sciences tend to begin with explanative hypotheses, whereas the human sciences may end up with explanative hypotheses.

## HERMENEUTICS

Unlike the natural sciences, the human sciences do not abstract from ordinary life, but analyze it. Analysis is compatible with understanding because, unlike abstraction, it need not isolate things from their overall context. The hermeneutical task of analysis is to enable us to recognize the whole in its parts and the parts in the whole. There is always this circularity in coordinating parts and wholes when reading a text. Hermeneutics as a human science reflects on what it means to apply the art of exegesis from texts to the experience of life in general.

The essay "The Rise of Hermeneutics," published in 1900 (Dilthey 1996), represents an important phase in Dilthey's development. Here he begins to sketch out a position that would define his final work. While he does not abandon the project of describing and analyzing lived experience, he came to view description and analysis as limited in their ability to capture the full meaning of life. The inner connectedness of our own experiences may provide a kind of self-understoodness or self-evidentness (*Selbstverständlichkeit*), but we do not achieve real self-understanding (*Selbstverständnis*) until we have manifested ourselves objectively. To truly understand ourselves is to be able to see ourselves as others see us.

One of the most revealing ways in which we manifest ourselves is through linguistic expression and communication. But Dilthey defines hermeneutics as the theory of interpreting *all* human manifestations, including actions that are not intended to communicate. The range of objectifications needing interpretation is broad. It includes impersonal theoretical judgments, abstract mathematical formulas, concrete poetic expressions of lived experience, personal correspondence, journal entries, works of art, historical monuments and archives, and political deeds and their aftereffects. They are important because only that which is publicly accessible and has been objectified in a common medium can produce determinate meaning.

The work that best articulates this hermeneutical approach to the human sciences is *The Formation of the Historical World in the Human Sciences* (1910). This most mature formulation of Dilthey's Critique of Historical Reason revisits many of the themes of the *Introduction to the Human Sciences*. The human sciences form the historical world, not by producing it, but by giving it a multifaceted discursive shape. Determinate meaning will never be found by confronting the course of history monolithically. The human sciences can give a cognitive form to various strands of history that we knowingly participate in. They allow use to analyze the overall stream of history and direct it, as it were, into a variety of structural systems in which selected currents can be examined for specific interacting forces.

Some of these historical structures had already been identified in the *Introduction to the Human Sciences* as cultural and social organizational systems. Cultural systems were conceived as purposive systems that bring individuals together to achieve certain voluntary goals. These purposive systems are not limited to the goals of high culture—the sciences, the arts, and religion—for they also include economic and social cooperation. Dilthey distinguished these cultural systems from institutional structures which make up the external organization of society. Institutions such as families, tribes, and nation-states are also interactive, but not primarily voluntary. We do not choose our parental family but are born into it. One of the advances of *The Formation of the Historical World* is that all these historical structures are no longer subsumed under the concept of “purposive system.” Dilthey introduces the covering term “productive system” (*Wirkungszusammenhang*) to capture the ways in which the forces of historical life can become structurally organized. The efficacy of history is to be understood in terms of productivity before any causal or teleological account is given. The carriers of history, whether they be individuals, cultures, institutions, or communities, can all be considered as productive systems capable of exerting influence, and in some cases, realizing purposes. Each productive system of history should be approached as being centered in itself.

Individuals too are productive systems when they appropriate new impressions into their acquired psychic nexus: They cognize the present on the basis of past evaluations and future goals. The productivity of the psychic nexus lies in the ways the cognitive, evaluative, and volitional aspects of experience interact. As productive systems, individuals are centered in themselves, but far from self-sufficient. They are also dependent on other more

inclusive productive systems. In the *Introduction to the Human Sciences*, Dilthey was unwilling to conceive these larger systems as subjects or carriers of history. In *The Formation of the Historical World* he qualifies his opposition to transpersonal subjects by treating them as logical rather than real subjects—they are now considered co-carriers of history. Although individuals cooperate in terms of cultural systems and other encompassing productive systems, they never engage more than a part of themselves to any of such systems and therefore cannot be defined by them. Yet the engagement can become so intensive that an individual can put his or her stamp on its mode of productivity. As a consequence, more than the agreed-upon functions of a cultural system will be achieved. For instance, in relation to the classical conventions established by Joseph Haydn (1732–1809) and Wolfgang Amadeus Mozart (1756–1791), a composer such as Ludwig van Beethoven (1770–1827) charts a new course. As a consequence, more than the expected purposes of the system will be achieved. In addition to accommodating new purposes, productive systems provide a meaning framework for expressing a variety of human values.

Dilthey states that he is not offering a philosophy of history that would establish a final purpose of human history. This is because he does not find any justification for the belief that there is a law of overall historical development. Yet there is good reason to think that there can be lawlike development within specific productive systems. Dilthey's theory of history is meant to provide the critical tools to articulate history into the productive systems that can provide an orderly understanding of history. Today, Dilthey's approach would be considered a philosophy of history of the critical rather than of the more traditional speculative kind.

## THE CATEGORIES OF THE HUMAN SCIENCES

Whereas Kant's *Critique of Pure Reason* defined the categories or fundamental concepts of the natural sciences, Dilthey set out to explicate the categories of the human sciences. He distinguishes between formal and real categories. Formal categories relate to all experience, whether it be prescientific or scientific. They arise from elementary operations of thought such as comparing, differentiating, and relating that bring out what is inherent in experience. The formal categories of unity and plurality, identity and difference are shared by the natural and human sciences.

Real categories organize the content of experience more concretely. The natural and human sciences both organize their subject matter in terms of formal part-whole relations and locate them in space and time. In temporal location we can see a transition from the formal to the real. For the natural sciences, time is an infinite form that unfolds uniformly. For the human sciences, time is a finite structure that projects the future based on what is remembered from the past. The time of the human sciences is a lived reality and can be articulated in ways that allow us to understand historical development and the productive force of cultural systems.

Causality is a real category of the natural sciences. While Dilthey does not rule out its applicability to the events that are recounted in human history, he makes it clear that for the understanding of history, the Aristotelian categories “of agency and suffering, of action and reaction” are more appropriate (Dilthey 2002, p. 219). They express how human beings experience the productive force of the historical world and allow them to conceive purposiveness as an agency that stems from within and causality as a force coming from without.

Among the real categories that are distinctive for the human sciences, the three most important are value, purpose, and meaning. From the perspective of value, life is judged as a multiplicity of prized moments that can be juxtaposed. From the perspective of purpose, everything in a life-course tends to be subordinated to some future moment. According to Dilthey, the category of meaning can overcome the juxtaposition and subordination of value and purpose. Meaning articulates the connectedness of life on the basis of the relation between past and present. It is the main category of historical thought and is assigned to memory.

We resort to memory when we orient our experience to the past. On the private level, Dilthey had articulated meaning in terms of the workings of the acquired psychic nexus. At the public level, Dilthey now explicates meaning in terms of Hegel’s concept of “objective spirit.” Objective spirit stands for what the spirit of the past has left behind in the present and has preserved in objective form. It is the most basic framework for orienting us to the past. Objective spirit is the tradition-based sphere of commonality in which we grow up. The language we inherit, the conventions adopted, and the customs learned are all aspects of objective spirit that shape our childhood experiences. “Everything in which spirit has objectified itself contains something that is common to the I and the Thou. Every square planted with trees, every room in which chairs are arranged, is understandable to

us from childhood because human tendencies to set goals, produce order and define values in common have assigned [them] a place...” (Dilthey 2002, p. 229).

Objective spirit represents the initial framework of reference for elementary understanding, not unlike the way a dictionary serves as our first resource when a word in a sentence is not understood. Objective spirit is the common historical medium by which we orient elementary understanding. But when problems arise in understanding that a common reference cannot resolve, we must resort to what Dilthey calls “higher understanding.” Higher understanding attempts to account for cases when the normal convergence between an expression and the meaning it expresses is lacking. Instead of merely appealing to objective spirit as the common background for locating meaning, higher understanding can consider more specialized contexts to determine meaning. Thus, if an unclear sentence is uttered by an economist we can consult professional handbooks. Similarly, social circumstances, industrial conditions, and market forces can be considered when some economic claim is not fully intelligible.

Although higher understanding often concentrates on more restricted productive systems as focal contexts, it will at the same time seek to extract more general results. The universality aimed at by higher understanding may be in the form of an inductive generalization or it may be that of a larger context. Thus the attempt to understand a line of poetry in relation to the poem as a whole is also an act of higher understanding. Here again the attempt is to move from common meaning to universal significance. The important breakthrough for Dilthey is that he no longer requires the understanding of human products to be related back to the psyches of their producers. Although the possibility of referring a work of art to its creator is not ruled out, it is far from being the primary source of its understanding. Indeed, a great work of art can take on a life of its own and can become itself a productive nexus generating an ever deeper meaning over time, as Gadamer has also argued.

Historical understanding, however, requires the move from universality back to individuality. It is appropriate for higher understanding to turn into what Dilthey calls a “re-experiencing,” where individual contributions to the productivity of life do count. To re-experience meaning is not to reproduce the state of mind of an author, but to understand an author better than he understood himself. This is achieved by the contextualizing and structural explication of life-situations made possible by the human sciences.

## REFLECTION ON LIFE

It is never enough to consider an individual life by itself. As Dilthey writes: "The limit of biography lies in the fact that general movements find their point of transition in individuals" (Dilthey 2002, p. 269). Drawing on his own struggles to complete a second volume of the life of Schleiermacher, Dilthey concludes that a biographer cannot fulfill his task without also having broached universal questions about life and history. Notwithstanding the problematic status of biography, Dilthey considers autobiography an especially instructive mode of history because here "the work of historical narrative is already half done by life itself" (Dilthey 2002, p. 222). The narrative produced is never a simple copy of an actual life-course, but a retrospective judgment that depends on the way an individual reflects on his or her life. Here history is not just a human science but has reflective philosophical import.

In the later writings Dilthey often speaks of anthropological reflection as crucial for obtaining a unity of perspective on life. The sciences are radically pluralistic and cannot provide a comprehensive outlook or worldview (*Weltanschauung*). A worldview is not merely a cognitive picture of the world. It goes deeper in expressing a specific stance (*Stellung*) toward concrete life-concerns (*Lebensbezüge*) as well as to life as a whole. An individual's stance toward life can develop into a reflective worldview on the basis of certain more general moods (*Stimmungen*). These moods are more than states of mind; they orient us to the world in ways that anticipate what Heidegger says about moods as modes of attunement in *Being and Time*.

Worldviews have been articulated in literary, religious, and philosophical works. Philosophers have conceptualized worldviews metaphysically. Dilthey analyzes three main types of such metaphysical formulations: naturalism, the idealism of freedom, and objective idealism. Naturalism as found in Democritus, Thomas Hobbes, and others reduces everything to what can be cognized and is pluralistic in structure; the idealism of freedom as found in Plato, Kant, and others insists on the irreducibility of the will and is dualistic; objective idealism as found in Heraclitus, Gottfried Wilhelm Leibniz, and Hegel affirms reality as the embodiment of a harmonious set of values and is monistic. The three types of metaphysical worldviews are incommensurable in that each is reductive in some way. No metaphysical formulation can have more than relative success. But this conclusion does not make Dilthey a relativist, for he rejects all metaphysics as speculative. Metaphysical systems attempt to

arrive at universal determinations that transcend experience. All that is humanly possible is to probe reality on the basis of life-experience and to seek a more limited reflective universality.

The influence of Dilthey's thought and writings is manifold. Husserl considered Dilthey's *Ideas for a Descriptive and Analytic Psychology* (Dilthey 1977) a genial anticipation of his own phenomenological psychology and credits a meeting with Dilthey as leading to his interest in questions concerning understanding in the human sciences. Heidegger's lecture courses from 1919 through 1925 are filled with declarations of Dilthey's importance for understanding history and make extensive use of such Diltheyan terms as "life-nexus" and "life-concern." Max Weber applies Dilthey's distinction between explanation and understanding to sociology and extends Dilthey's reflections on typicality to his theory of ideal types. Herbert Marcuse's early work on Hegel is indebted to Dilthey's highly original approach to Hegel in his *Jugendgeschichte Hegels*. Georg Lukács's Marxist counterpart to this is *Der junge Hegel*.

Dilthey's work continues to play a significant role in the development of hermeneutics. While critical of the Schleiermacher-Dilthey tradition, Gadamer's hermeneutics represents an extension of Dilthey's effort to relate interpretation to the productivity and efficacy (*Wirkung*) of history. In France, the underlying influence of Dilthey's views on understanding and objective spirit can be seen in the writings of Raymond Aron, Jean-Paul Sartre, Lucien Goldmann, and Paul Ricoeur. In Spain, Ortega y Gasset had called Dilthey the most important philosopher of the second half of the nineteenth century, with the result that Dilthey was widely translated into Spanish before any other language. Now extensive translations into English, French, Italian, Chinese, Japanese, and Russian are also becoming available.

**Bibliography**

## WORKS BY DILTHEY

*Briefwechsel zwischen Wilhelm Dilthey und dem Grafen Paul Yorck von Wartenburg, 1877–1897*. Halle (Saale), Germany: M. Niemeyer, 1922. Famous correspondence about the nature of life and history.

*Descriptive Psychology and Historical Understanding*. Translated by Richard M. Zaner and Kenneth L. Heiges, with an introduction by Rudolf A. Makkreel. The Hague: Martinus Nijhof, 1977.

*Dilthey's Philosophy of Existence*. Translated by William Kluback and Martin Weinbaum. New York: Bookman Associates, 1957. Mainly about the theory of worldviews.

*Das Erlebnis und die Dichtung: Lessing, Goethe, Novalis, Hölderlin*. Leipzig, Germany: Teubner, 1922. Influential literary essays, two of which are translated in *Poetry and Experience*.

*Essence of Philosophy*. Translated by Steven A. Emery and William T. Emery. Chapel Hill: University of North Carolina Press, 1954.

*Gesammelte Schriften*, edited by Karlfried Gründer and Frithjof Rodi. 24 vols. Göttingen, Germany: Vandenhoeck & Ruprecht, 1914–2004.

*Selected Works*, edited by Rudolf A. Makkreel and Frithjof Rodi. Vol. 1, *Introduction to the Human Sciences* (1989). Vol. 3, *The Formation of the Historical World in the Human Sciences* (2002). Vol. 4, *Hermeneutics and the Study of History* (1996). Vol. 5, *Poetry and Experience* (1985). Princeton, NJ: Princeton University Press.

#### WORKS ON DILTHEY

de Mul, Jos. *The Tragedy of Finitude: Dilthey's Hermeneutics of Life*. Translated by Tony Burrett. New Haven, CT: Yale University Press, 2004. A reconstruction of Dilthey's ontology of life, highlighting the interpretive character of human existence, contingency, and narrativity.

Ermarth, Michael. *Wilhelm Dilthey: The Critique of Historical Reason*. Chicago: University of Chicago Press, 1978. A comprehensive account of Dilthey's thought with a good historical background.

Makkreel, Rudolf A. *Dilthey: Philosopher of the Human Studies*. Princeton, NJ: Princeton University Press, 1975, 1992. A developmental examination of Dilthey's philosophy that focuses on its relation to Kant's first and third Critiques and highlights the role of reflection and judgment in historical understanding.

Makkreel, Rudolf A., and John D. Scanlon, eds. *Dilthey and Phenomenology*. Washington, DC: Center for Advanced Research in Phenomenology and University Press of America, 1987. Exploration of Dilthey's relation to phenomenology by ten international scholars.

Owensby, Jacob. *Dilthey and the Narrative of History*. Ithaca, NY: Cornell University Press, 1994. A topical study focusing on Books 4–6 of the *Introduction to the Human Sciences*.

*Revue Internationale de Philosophie* 57 (4) (2003). Issue featuring a collection of essays edited by Rudolf Makkreel, including essays by Jean Grondin, Hans Ineichen, Matthias Jung, Makkreel, Sylvie Mesure, Jos de Mul, Tom Rockmore, and Frithjof Rodi.

Rodi, Frithjof, ed. *Dilthey-Jahrbuch für Philosophie und Geschichte der Geisteswissenschaften*. Vandenhoeck & Ruprecht, 1983–2000. Many volumes have special themes such as the relation between Dilthey and the early Heidegger.

Rodi, Frithjof, and Hans-Ulrich Lessing, eds. *Materialien zur Philosophie Wilhelm Diltheys*. Frankfurt am Main: Suhrkamp, 1984. A collection of classical essays on Dilthey by such thinkers as Scheler, Landgrebe, Bollnow, Plessner, Marcuse, Misch, Habermas, and Gadamer.

## DINGLER, HUGO

(1881–1954)

Hugo Dingler, the German philosopher of science, was the most important representative of Continental operationalism, as distinguished from the operationalism of the American physicist P. W. Bridgman. Dingler was also a main contributor to *Grundlagenforschung* (research on the foundations of the exact sciences). After studying under such teachers as David Hilbert, Edmund Husserl, Felix Klein, Hermann Minkowski, Wilhelm Röntgen, and Woldemar Voigt at the universities of Erlangen, Munich, and Göttingen, Dingler received a Ph.D. in mathematics, physics, and astronomy in 1906 and became *Privatdozent* in 1912. He was appointed professor at the University of Munich in 1920 and at the Technische Hochschule in Darmstadt in 1932. In 1934 he was dismissed on charges of philosemitism. He later resumed teaching but soon rebelled again against the political situation, and eventually he was put under the continuous watch of a Gestapo agent “who unfortunately”—as Dingler told the present writer—“was not gifted for philosophy and did not profit from my compulsory daily lessons.” Such difficulties in the German political situation during Dingler's life contributed to the lack of awareness of his work, despite his some twenty books and seventy essays in exceptionally clear German. Perhaps a more decisive factor was Dingler's independence of all the main schools and trends in contemporary philosophy of science—positivism and empiricism, Neo-Kantianism, phenomenology, intuitionism, and formalism.

From the juvenile *Grundlinien einer Kritik und exakten Theorie der Wissenschaften, insbesondere der mathematischen* (Essentials of a critique and rigorous theory of the sciences, especially of the mathematical ones; Munich, 1907) to the posthumous *Die Ergreifung des Wirklichen* (The grasping of reality; Munich, 1955), Dingler's main concern was to give a new answer to the Kantian question “How is exact science possible?” He regarded arithmetic, analysis, geometry, and mechanics as the exact sciences par excellence; he called them “mental” (*geistige*), meaning that they cannot be derived from experience and must be synthesized operationally from a few univocal ideas used as “building stones” (*Bausteine*). In this way

scientific inquiry was to be made continuous with everyday life and viewed in terms of practical activity. The operational reconstruction of the foundations of science was to abolish the field of foundations as an independent territory open to philosophical disagreement or mystification. Dingler came to consider the given itself, as expressed in protocol, or basic, sentences, as a highly complicated kind of result.

To prevent any residues of previous theories from entering into the operational reconstruction, we must start from a “zero situation” in which we suppose only that the world is “simply there” and that we can operate on it. This is a methodological principle, not a metaphysical denial of reality: it is a voluntary suspension of rational processes which can be brought about at any moment. After 1907, under Husserl’s influence, Dingler labeled the zero situation “the standpoint of freedom from presuppositions.” In 1942 he described it as *das Unberührte*, the intact or untouched—“that which has not yet been operated upon.”

The first univocal step out of the zero situation consists in entertaining an idea in which the sheer relation of difference (with equality and similarity as its special cases) is present, and is applied (*anwendet*) only once, as in the idea “something distinct without further specification,” that is, the idea of an entity as distinguished from all the rest, as standing out from a background. This idea is not the description of anything existing in the world but rather is the first requirement for any such description. All we can say about it is that it is present and limited; we can then specify it as constant or variable, and in either case we can also give special attention to its limits. In this way we reach a purely qualitative fourfold scheme which precedes the concepts of number, space, and time. To this scheme correspond four rules of operation, which afford the starting points of the exact sciences: (1) something distinct without further specification, and constant, for arithmetic; (2) the same, but variable, for analysis (more generally for the doctrine of time and variables); (3) the same, but constant, considered with respect to its limits, for geometry; and (4) the same, but variable, considered with respect to its limits, for kinematics and mechanics.

By means of complications of this basic scheme Dingler was able to operationally derive and prove the axioms of the exact sciences and to construct their whole fabric. This painstaking and original construction is to be found chiefly in *Philosophie der Logik und Arithmetik* (1931), *Die Grundlagen der Geometrie* (1933), *Die Methode der*

*Physik* (1938), and *Lehrbuch der exakten Naturwissenschaften* (1944).

## Bibliography

### WORKS BY DINGLER

#### Works on “Grundlagenforschung”

*Philosophie der Logik und Arithmetik*. Munich, 1931.

*Geschichte der Naturphilosophie*. Berlin, 1932. A history of the development of the idea of *Grundlagenforschung* in experimental science.

*Die Grundlagen der Geometrie*. Stuttgart, 1933.

*Die Methode der Physik*. Munich, 1938.

*Lehrbuch der exakten Naturwissenschaften*. Berlin, 1944. Only thirty copies printed. Parts reprinted with Italian translation and a commentary by Enrico Albani in *Methodos* 7 (1955): 277–287, and 8 (1956): 29–30, 122–137, 191–199.

#### Other Works

*Metaphysik als Wissenschaft und der Primat der Philosophie*. Munich, 1926.

*Das System*. Munich, 1933.

*Das Handeln im Sinne des höchsten Zieles*. Munich, 1935.

*Von der Tierseele zur Menschenseele*. Leipzig, 1941.

*Grundriss der methodischen Philosophie*. Füssen, 1949. A crystal-clear summary of Dingler’s main views, but of lower technical quality than his main treatises.

#### Essays

“Methodik statt Erkenntnistheorie und Wissenschaftslehre.” *Kant-Studien* 41 (1936): 346–379.

“Über die letzte Wurzel der exakten Naturwissenschaften.” *Zeitschrift für die gesamte Naturwissenschaft* 8 (1942): 49–70.

“Das Unberührte. Die Definition des unmittelbar Gegebenen.” *Zeitschrift für die gesamte Naturwissenschaft* 8 (1942): 209–224.

“Die philosophische Begründung des Deszendenztheorie.” In *Die Evolution der Organismen*, edited by Gerhard Hebener. Jena, Germany, 1943.

## DIODORUS CRONUS

(b. 4th century BCE)

Diodorus Cronus was born in Iasus, a port town in Caria (a region in the southwestern part of Asia Minor). He inherited his nickname 'Cronus' (old foggy) from his teacher Apollonius. All else that is known about his life must be inferred from anecdotal evidence, connecting him to Athens, where Zeno of Citium studied dialectic with him (cf. Diogenes Laertius 7.25), and to Alexandria, where he is acquainted with the physician Herophilus (cf. Sextus Empiricus, *Pyrrh. Hypotyp.* 2. 245) and where Callimachus mentions him in one of his *Epigrams* (cf. Diogenes Laertius 2.111) suggesting that Diodorus was known in the town. He may have died in Alexandria, some time after 290 BCE.

Since our sources attribute no writings to him, he probably left nothing written. Yet the reports on him show that he was an extremely influential figure in the generation that saw the founding of the Hellenistic schools of philosophy. He belonged to a philosophical sect known as the Dialecticians; these Dialecticians were a school distinct from the Megarians. The name Dialecticians was not, as assumed in the older literature, another name for the Megarians (Sedley 1977). In physics, Diodorus was an atomist; he is said to have called atoms "partless" (Sextus Empiricus, *Adv. Math.* 9.363). One consequence of his atomism is that there are, according to him, no objects that move, only objects that have moved (Sextus Empiricus, *Adv. Math.* 9.363).

Diodorus's greatest impact was in the field of logic where, together with his pupil Philo the Dialectician, he seems to have laid the foundations of propositional logic. With Philo, he engaged in a controversy about the truthcriteria for the conditional; Philo favored a truth-functional analysis of the conditional, claiming that the conditional is true if and only if it is not the case that its antecedent is true and its consequent false (cf. Sextus Empiricus, *Adv. Math.* 8.113–114), Diodorus gave a different account: According to him, a conditional is true if and only if it was not possible and is not possible that its antecedent is true and its consequent false (cf. Sextus Empiricus, *Adv. Math.* 8.115–117).

Diodorus's reputation as a logician, even to the present day, derives from his Master Argument, mentioned by several authors but reported explicitly only in Epictetus (cf. Epictetus, *Diss.* 2.19.1–5). Diodorus claimed that the following three propositions are incompatible: (1) Every past truth is necessary, (2) nothing impossible follows from what is possible, and (3) there is something possi-

ble that neither is nor will be true. Diodorus used (1) and (2) to argue for the falsity of (3), hence for a notion of possibility that defines the possible as that which is or will be true. Here again we find him contradicted by Philo, who defines the possible as that which, by the intrinsic nature of the proposition, is receptive of truth (cf. Boethius, *De interpretatione* ii, 234,10–235, 9). The Master Argument became a bone of contention for Hellenistic logicians; it is still a matter of controversy how exactly Diodorus thought he could deduce the falsity of (3) from (1) and (2).

### Bibliography

#### TESTIMONIA

The testimonia on Diodorus are now conveniently brought together in Volume 1 of G. Giannantoni's *Socratis et Socraticorum reliquiae* (Naples: Bibliopolis, 1990, pp. 414–435). Yet notice that in the account of the Master Argument in Epictetus, a line has been omitted from the text in Giannantoni's collection, so that only the first of the three propositions is quoted in full. The testimonia on Diodorus can also be found in K. Döring, *Die Megariker* (Amsterdam: Grüner, 1972).

## DIOGENES LAERTIUS

(c. 200 CE)

Diogenes Laertius is the author of *Compendium of the Lives and Opinions of Philosophers*, the only general book on philosophers and their philosophy that has been transmitted from classical antiquity. Diogenes is known from this work only—nothing is known about his life—and his date can only be fixed by the dates of the latest personalities mentioned in his text (second century CE), and because he seems to have written prior to the rise of Neoplatonism (c. 250 CE). His work was dedicated to a woman interested in Platonism (bk. 3 § 47).

Diogenes's work belongs to a type of ancient literature (often called *Diadocha* or *Successions*) in which accounts of the lives of philosophers were arranged as series of biographies so that teacher and student followed one another within each major philosophical school.

Diogenes's text is divided into ten sections, or "books":

1: Introduction and various "wise men," including Thales.

(2–7: *The Ionian Tradition*)

2: The Ionian physicists, Socrates, and the minor Socratic schools down to the early third century BCE.

3: Plato.

4: The Academy down to Clitomachus (late second century BCE).

5: Aristotle and the Peripatetics down to Lyco (late third century BCE).

6: Antisthenes and the Cynics down to the end of the third century BCE.

7: Zeno and the Stoics down to at least Chrysippus (late third century BCE), and in the missing end of the book perhaps even down to the first century CE.

(8–10: *The Italic Tradition*)

8: Pythagoras and his early successors; Empedocles.

9: Heraclitus; the Eleatics; the Atomists, Protagoras and Diogenes of Apollonia; Pyrrho.

10: Epicurus.

Diogenes's book is basically a compilation of excerpts from numerous sources; in the biographical sections he often tells which sources he is using, whereas the philosophical sections contain few such references.

The book is also uneven. Some lives contain nothing but anecdotes and aphorisms, whereas others are mainly doxographical reports; some have long, detailed sections on philosophy, whereas others have short, superficial sections. Diogenes is unlikely to have read many philosophical works. However, in book 10 he has preserved four long, original writings by Epicurus, which constitute the most important evidence for Epicurus's philosophy from before the period of Cicero. However, his many references to his predecessors give an impression of the Hellenistic tradition of philosophical biography. Because Diogenes seems to have had a predilection for old documents, he has preserved the testaments of four peripatetics and a number of book catalogs.

Most of Diogenes's biographies include a number of items such as birth, parents, name, appearance, relationship to other philosophers, travels, lifestyle, and circumstances of death, yet they are presented in no particular order. The dominating element in the biographies is the use of anecdotes. In antiquity it was impossible to find documentary evidence concerning a deceased person, unless that person was a famous public figure or had left written works. Often literary works were exploited without regard to the fact that the content of a fictional work is unlikely to apply to the life of its author. Therefore, Diogenes's factual information must be viewed with some skepticism: Notice that most of his dates are taken from a Hellenistic poem.

Diogenes's biographies may have been written with less artistic skill than, for example, Plutarch's; however, they are not unlike other ancient accounts of the lives of philosophers.

Diogenes devotes much space to present the doctrines of the major philosophical schools: Book 3, § 48–109, is a general introduction to the study of the *Corpus Platonicum*; as an account of Plato's philosophy it may be inadequate, but it resembles other Platonic writings of the second century CE. The section on Aristotelian philosophy (bk. 5, § 28–34) is far less satisfying, but all three parts seem to go back to the Hellenistic period. Book 7, § 38–160, is the most comprehensive account of Stoic philosophy from antiquity, the section on logic is especially important. The survey of the Skeptic tropes (bk. 9, § 79–105) is shorter than in Sextus Empiricus but otherwise comparable. The three Epicurean letters and his forty "Principal Doctrines" in book 10 are crucial to what is known about Epicurus; when Diogenes places these aphorisms at the end of his book, he indicates that he considers them a culmination of philosophical wisdom.

For the pre-Socratic philosophers, Diogenes has used a “doxographical” source similar to other accounts in late antiquity; ultimately, it derives from Aristotle and Theophrastus. In the case of Pythagoras, Diogenes presents two excerpts from Aristotle and from Alexander Polyhistor (first century BCE), thus presenting a much earlier expression of Pythagoreanism than is found in other sources from late antiquity.

Diogenes was no philosopher, but he has preserved much of philosophical significance. He seems to have had no influence in antiquity, but since Walter Burley’s *On the Life and Manners of the Philosophers* (early fourteenth century), the Latin translation by Ambrosius Traversarius (1432), and the *editio princeps* of the Greek text in 1533, Diogenes has been the most important single source for the lives and often for the doctrines of ancient philosophers. Until around 1800, Diogenes was the main model for historiography of philosophy.

## DIOGENES OF APOLLONIA

(5th century BCE)

Diogenes of Apollonia was a Greek philosopher belonging to the last generation of the pre-Socratics (fl. around

440–430 BCE.) His native town was either Apollonia on Crete or, more probably, Apollonia on the Pontus. Nothing is known for certain about his life. It has been debated whether he wrote only one book called, in English, *On Nature* or, as Simplicius reported (in *On Aristotle’s “Physics”* 151, 20), four (*On Nature, Meteorology, On the Nature of Man, Against the Sophists*). All the existing fragments seem to come from *On Nature*. His work had an effect in Athenian intellectual life toward the end of the fifth century BCE, and his influence is detectable also in some treatises of the Hippocratic corpus and in the Stoic doctrine of *pneuma* (literally breath; in Stoic philosophy, the mixture of the two active elements, fire and air, and the sustaining cause of all bodies.)

His philosophy was termed “eclectic” already by Theophrastus, and most modern commentators agree with this assessment. Theophrastus listed Anaxagoras, Leucippus, and Anaximenes as the main influences on Diogenes, and to this list we should certainly add Heraclitus. Diogenes’ philosophical doctrine has three prominent aspects: his monism, the teleological traits in his cosmology, and his theory of cognition. Most of the pre-Socratic philosophers working after Parmenides adopted a pluralist ontology. Diogenes, on the contrary, returned to the monism of his Ionian predecessors. He argued that if the proper nature of apparently different types of matter were not the same, then these different types of matter could not causally interact with one another, and we could not explain such phenomena as the nutrition and growth of living organisms, in which apparently different types of matter transform into each other. Therefore, the four elements and the other types of matter of our world must have differentiated from the same primordial stuff, must retain their underlying identity, and must ultimately return to what they differentiated from (Diels and Kranz [DK], B2). Apparent things exist for a limited time, whereas the basic stuff is “an eternal and deathless body” (DK, B7). Yet it is not a passive substrate, but is “strong” and determines how things are formed from it and return to it (DK, B8, B7). Because it is active and eternal, it can also be considered a god.

Diogenes continued by arguing that the basic stuff must be intelligent. He wrote, “For without intelligence it could not have been divided up in such a way as to hold the measures of all things, of winter and summer and night and day and rains and winds and nice weather, along with the rest, which, if one is willing to consider them intelligently, one will find disposed in the finest possible way” (DK, B3). Scholars have disagreed how thorough Diogenes’ teleology, as expressed in this frag-

ment, is. According to Willy Theiler, Diogenes is a full-blown teleologist and the immediate source of the teleological views that Xenophon ascribed to Socrates in his *Memorabilia*. Others have doubted that Diogenes' conception is original and that it is genuinely teleological. Diogenes' argument certainly differs from later, explicitly teleological views in that it remains unclear whether the action of the intelligent principle is directed at some well-defined goal or goals. It also differs from classic statements of the argument from design, with which it has sometimes been associated, in that Diogenes did not argue for the existence of an intelligent causal principle, but sought to show that the ultimate causal principle, the existence of which he established on independent grounds, must also be intelligent.

Diogenes identified the bearer of intelligence with air. He argued that because humans and animals live by breathing, air must be what brings life and intelligence to them (DK, B4). If so, the air, which inheres in, and steers, all things, must be the intelligent causal principle at the cosmic level too. Moreover, the qualitative differences of air explain the differences between species and individuals (DK, B5).

Diogenes' most original contribution was a detailed description of the system of veins, which originate in the head and through which blood and air to all parts of the body. Sensation is produced when air from the outside acts on the air in the sense organs which then reaches the head through the veins. The quality of the air and the veins determine the sharpness of perception. Air mixed with blood produces thought, and we feel pleasure when the appropriate mixture of air and blood pervades the whole body.

## DIOGENES OF SINOPE

(4th century BCE)

Diogenes of Sinope, who lived in the fourth century BCE, was the prototype of the Cynics, who probably were so called from Diogenes' Greek nickname, the Dog (*kuon*; adjective form, *kunikos*). Tradition held that on coming to Athens in exile, he was influenced by Antisthenes' teaching; Diogenes' ascetic distortion of Socratic temperance gives some point to Plato's supposed remark that he was a "Socrates gone mad."

It is not easy to recover the philosopher from, on the one hand, the lurid fog of anecdotal tradition that represents the stunts of an eccentric tramp at Athens and Corinth defacing conventional human standards—as he or his father, Hicesias, was supposed to have defaced in some way the currency of Sinope—or, on the other, the idealized legend that grew after his death. But doxographic traces (for example, Diogenes Laërtius, VI.70–73) and, indeed, the tradition as a whole presuppose a serious teacher who, in disillusioned protest against a corrupt society and hostile world, advocated happiness as self-realization and self-mastery in an inner spiritual freedom from all wants except the bare natural minimum; and who, in a bitter crusade against the corrupting influence of pleasure, desire, and luxury, extolled the drastic painful effort involved in the mental and physical training for the achievement of a natural and inviolable self-sufficiency.

The anecdotes illustrate Diogenes' philosophy in action. Since for Diogenes virtue was revealed in practice and not in theoretical analysis or argument, the stories of, for example, his embracing statues in winter and his peering with a lantern in daytime for a human being, the tales of his fearless biting repartee and criticism of notables such as Alexander, however embroidered or apocryphal, correctly reflect his pointed teaching methods, which encouraged the development of a new didactic form, the *chreia*, or moral epigram. Some exaggeration here is due to the "dog-cynic" shamelessness pedagogically employed to discount convention, and some is no doubt inherent in the uncompromising extremes of Diogenes' doctrines.

He is credited with tragedies illustrating the human predicament and with a *Republic*, which influenced Zeno the Stoic, that was notorious for its scandalous attack on convention. His famous remark that he was a citizen of the world is more probably antinational than international, for he was concerned with the individual rather than the community. Diogenes sought to make any man king, not of others, but of himself, through autonomy of

will, and his own life was his main philosophical demonstration to this end.

## DISCOURSE ETHICS

“Discourse ethics” refers to an approach to moral theory developed by Jürgen Habermas. It is a reconstruction of Immanuel Kant’s idea of practical reason that turns on a reformulation of his categorical imperative: Rather than prescribing to others as valid norms that I can will to be universal laws, I must submit norms to others for purposes of discursively testing their putative universality. “Only those norms may claim to be valid that could meet with the approval of all those affected in their capacity as participants in practical discourse” (Habermas, 1990, p. 66). Normative validity, construed as rational acceptability, is thus tied to argumentation processes governed by a principle of universalization: “For a norm to be valid, the consequences and side effects of its general observance for the satisfaction of each person’s particular interests must be acceptable to all” (p. 197). Furthermore, by requiring that perspective taking be general and reciprocal, discourse ethics builds a moment of empathy or

“ideal role-taking” into the procedure of practical argumentation.

Like Kant, Habermas distinguishes the types of practical reasoning and the corresponding types of “ought” connected with questions concerning what is pragmatically expedient, ethically prudent, or morally right. Calculations of rational choice furnish recommendations relevant to the pursuit of contingent purposes in the light of given preference. When serious questions of value arise, deliberation on who one is and wants to be yields insight into the good life. If issues of justice are involved, fair and impartial consideration of conflicting interests is required to judge what is right or just. Again like Kant, Habermas regards questions of the last type, rather than specifically ethical questions, to be the proper domain of theory. (Thus, discourse ethics might properly be called discourse morality.) This is not to deny that ethical discourse is rational or that it exhibits general structures of its own; but the irreducible pluralism of modern life means that questions of self-understanding, self-realization, and the good life do not admit of universal answers. In Habermas’s view, that does not preclude a general theory of a narrower sort, namely a theory of justice. Accordingly, the aim of his discourse ethics is solely to reconstruct the moral point of view from which questions of right can be fairly and impartially adjudicated.

By linking discourse ethics to the theory of communicative action, Habermas means to show that our basic moral intuitions are rooted in something deeper and more universal than particularities of our tradition, namely in the intuitive grasp of the normative presuppositions of social interaction possessed by competent social actors in any society. Members of our species become individuals in and through being socialized into networks of reciprocal social relations. The mutual vulnerability that this interdependence brings with it calls for guarantees of mutual consideration to preserve both the integrity of individual persons and the web of their interpersonal relations. In discourse ethics respect for the individual is built into the freedom of each participant in discourse to accept or reject the reasons offered as justifications for norms, and concern for the common good is built into the requirement that each participant take into account the needs, interests, and feelings of all others affected by the norm in question. Hence, the actual practice of moral discourse depends on forms of socialization and social reproduction that foster the requisite capacities and motivation.

## DISPOSITIONAL THEORIES

*See Response-Dependence Theories*

## DISTANT PEOPLES AND FUTURE GENERATIONS

Only recently have philosophers begun to discuss the question of whether we can meaningfully speak of distant peoples and future generations as having rights against us or of our having corresponding obligations to them. Answering this question with respect to distant peoples is much easier than answering it with respect to future generations. Few philosophers have thought that the mere fact that people are at a distance from us precludes our having any obligations to them or their having any rights against us. Some philosophers, however, have argued that our ignorance of the specific membership of the class of distant peoples does rule out these moral relationships. Yet this cannot be right, given that in other contexts we recognize obligations to indeterminate classes of people, such as a police officer's obligation to help people in distress or the obligation of food producers not to harm those who consume their products.

Of course, before distant peoples can be said to have rights against us, we must be capable of acting across the distance that separates us. Yet as long as this condition is met—as it typically is for people living in most technologically advanced societies—it would certainly seem possible for distant peoples to have rights against us and us corresponding obligations to them.

By contrast, answering the above question with respect to future generations raises more difficult issues. One concerns whether it is logically coherent to speak of future generations as having rights now. Of course, no one who finds talk about rights to be generally meaningful should question whether we can coherently claim that future generations *will* have rights at some point in the

future (specifically, when they come into existence and are no longer future generations). But what is questioned, since it is of considerable practical significance, is whether we can coherently claim that future generations have rights now when they do not yet exist.

Let us suppose, for example, that we continue to use up Earth's resources at present or even greater rates, and as a result, it turns out that future generations will face widespread famine, depleted resources, insufficient new technology to handle the crisis, and a drastic decline in the quality of life for nearly everyone. If this were to happen, could persons living in the twenty-second century legitimately claim that we in the twenty-first century violated their rights by not restraining our consumption of the world's resources? Surely it would be odd to say that we violated their rights more than one hundred years before they existed. But what exactly is the oddness?

Is it that future generations generally have no way of claiming their rights against existing generations? While this does make the recognition and enforcement of rights much more difficult (future generations would need strong advocates in the existing generations), it does not make it impossible for such rights to exist. After all, the recognition and enforcement of the rights of distant peoples is also a difficult task, but obviously such rights can exist.

Perhaps what troubles us is that future generations do not exist when their rights are said to demand action. But how else could persons have a right to benefit from the effects our actions will have in the distant future if they did not exist just when those effects would be felt? Our contemporaries cannot legitimately make the same demand, for they will not be around to experience those effects. Only future generations could have a right that the effects our actions will have in the distant future contribute to their well-being. Nor need we assume that, for persons to have rights, they must exist when their rights demand action. Thus, to say that future generations have rights against existing generations, we can simply mean that there are enforceable requirements upon existing generations that would benefit future generations or prevent harm to them.

Most likely what really bothers us is that we cannot know for sure what effects our actions will have on future generations. For example, we may, at some cost to ourselves, conserve resources that will be valueless to future generations who may develop different technologies. Or, because we regard them as useless, we may destroy or deplete resources that future generations will find to be essential to their well-being. Nevertheless, we should not

allow such possibilities to blind us to the necessity of a social policy in this regard. After all, whatever we do will have its effect on future generations. The best approach, therefore, is to use the knowledge we have and assume that future generations will also require those basic resources we now find to be valuable. If it turns out that future generations require different resources to meet their basic needs, at least we will not be to blame for acting on the basis of the knowledge we have.

Assuming then that we can meaningfully speak of distant peoples and future generations as having rights against us and us corresponding obligations to them, the crucial question that remains is exactly what rights they have against us and what obligations we have to them. While the answer to this question obviously depends on a substantial social and political theory, the expectation is that the rights and obligations that morally bind us to distant peoples and future generations will be quite similar to those that morally bind us to near people and existing generations.

## DIVINE COMMAND THEORIES OF ETHICS

The general perspective on ethics known as theological voluntarism usually appears in philosophical discussions in the specific form of divine command theories. As its title suggests, theological voluntarism is the view that ethics depends, at least in part, on God's will. In divine command theories the dependency is spelled out in terms of commands by God that express the divine will. The Hebrew Bible portrays God as establishing norms for human conduct by giving commands. Though some of them pertain exclusively to the regulation of religious rituals, others such as the prohibitions of murder and theft

clearly have ethical content. Since the Hebrew Bible counts as authoritative scripture for all three of the major monotheistic religions, divine command theories are a live option within Jewish, Christian, and Islamic traditions.

As the historical research of Janine M. Idziak (1979) shows, many Christian thinkers have exercised this option. St. Augustine, St. Bernard of Clairvaux, St. Thomas Aquinas, and St. Andrew of Neufchateau claimed that divine commands determine the ethical status of particular actions when they dealt with issues in biblical exegesis. John Duns Scotus and William of Ockham endorsed divine command theories. Both Martin Luther and John Calvin advocated an ethics of divine commands. John Locke and William Paley are among the modern philosophers who argued for divine command theories. Søren Kierkegaard's *Works of Love* (1847/1995) contains a divine command theory. In short, over a period of many centuries divine command ethics has attracted support from major figures in both Catholic and Protestant branches of Christianity.

A strong cumulative case for the importance of God's will in ethics can be constructed from within a Christian worldview. As Kierkegaard emphasized, a central element in such a case comes from the Christian New Testament. It is a striking feature of its distinctive ethics of love (*agape*) that love is commanded. In Matthew's Gospel the command is stated in response to a lawyer's query. Jesus says, "You shall love the Lord your God with your whole heart, with your whole soul, and with all your mind. This is the greatest and the first commandment. The second is like it: You shall love your neighbor as yourself" (Matthew 22:37–39). Similar commands are endorsed or stated by Jesus in the other three Gospels. If Jesus is God the son, as traditional Christians believe, such commands derive from and express the will of God. Thus, the ethics of agapeistic love advocated in the New Testament can plausibly be interpreted as having its source in a divine command.

During the final third of the twentieth century a revival of interest in divine command ethics took place among philosophers of religion. Most of the philosophers who wrote on the subject in this period understood divine command theories to be accounts of the realm of moral deontology. This domain of ethics studies topics related to duty; its main concepts are requirement (obligation), permission (rightness), and prohibition (wrongness). Edward R. Wierenga (1989) proposes a causal divine command theory according to which by commanding actions God brings it about that they are oblig-

atory and by forbidding actions God brings it about that they are wrong. Robert Merrihew Adams (1999) advocates a theory in which an action's being obligatory consists in its being commanded by God and an action's being wrong consists in its being contrary to a divine command. Stated in general terms, the principle of obligation of a divine command theory of the type favored by these philosophers asserts that actions are obligatory if and only if, and just because, they are commanded by God. And the principle of wrongness of such a theory claims that actions are wrong if and only if, and just because, they are prohibited by God.

Adams argues that divine commands do not account for ethical goodness and related axiological characteristics. In his theistic Platonism God plays the role of the Form of the Good; God is the paradigm or standard of goodness. Other things are good in virtue of bearing a relation of resemblance to God. For Adams (1999), ethical goodness thus depends on God, but not on God's will or commands.

Philosophers who contribute to the revival of divine command ethics devote a good deal of time and energy to defending divine command theories against criticism. Perhaps the most famous objection has roots that trace back to a question Socrates raises in the *Euthyphro*. Altering it a bit to allow for the difference between Greek polytheism and monotheism, one may imagine a Socratic gadfly asking: Does God command truth-telling because it is obligatory, or is truth-telling obligatory because God commands it? No matter which way questions of this sort are answered, a difficulty for divine command ethics emerges.

If one supposes that God commands truth-telling because it is obligatory, one contradicts the claim of divine command theorists that truth-telling is obligatory because it is commanded by God. In other words, this response forces one to conclude that the obligatoriness of truth-telling is independent of God's commands. But if one insists that truth-telling is obligatory because God commands it, which is what divine command theorists are committed to doing, then one must confront a difficulty that was eloquently formulated by Ralph Cudworth in *A Treatise concerning Eternal and Immutable Morality* (1731/1976). As he notes, divine command theorists are committed to the view that lying rather than truth-telling would be obligatory if it were commanded by God.

However, divine command theorists can accept Cudworth's (1731/1976) point with equanimity if they embed their divine command account of moral deontology in an axiological theory that, like the theistic Platonism

espoused by Adams, makes ethical goodness independent of God's will and commands. Understood in this way, goodness is determined by God's immutable nature and character; it is a matter of who and what God is. God's essential nature, which is paradigmatic of goodness, will then constrain what God can command. Hence, it is open to divine command theorists to hold that it is impossible for God to command lying and so is impossible for lying to be obligatory. This view is consistent with granting that lying would be obligatory if, *per impossible*, God were to command it.

Certain forms of divine command ethics can be shown to stand up well under philosophical scrutiny. Divine command accounts of obligation and wrongness deserve to be regarded as respectable options in ethical theory if the larger theistic worldviews of which they are components are themselves philosophically defensible.

## DŌGEN

(1200–1253)

## MAJOR WORKS OF DŌGEN

Dōgen was the founder of Sōtō Zen Buddhism and helped introduce to medieval Japan many features of Chan Buddhist theory and practice that developed during the Song dynasty in China. His major works include the *Shōbōgenzō* (Treasury of the true dharma-eye), a collection of sermons composed in vernacular Japanese from 1231 until the end of his life; the *Shōbōgenzō Zui-monki* (Miscellaneous talks), another collection of vernacular sermons compiled from 1234 until 1238; the *Eiheī Kōroku* (Recorded sayings at Eihei Temple), a collection of sermons in Chinese compiled from 1236 to 1252; the *Fukanzazengi* (Universal recommendation for Zazen practice), a concise summary of his views on meditation composed in 1233; and the *Eiheī Shingi* (Monastic rules at Eihei Temple), a collection of six essays dealing with monastic rules and regulations composed from 1237 to 1249.

Dōgen is often referred to as the leading philosopher in Japanese history. His writings on many Buddhist topics reflect an approach to religious experience based on a more philosophically oriented level of analysis than is found in the writings of most thinkers in Zen, which is known as a “special transmission outside the scriptures, without reliance on words and letters.” Dōgen has been a major influence on modern Japanese philosophy, especially representatives of the Kyoto School such as Nishida Kitarō, Nishitani Keiji, and Abe Masao, and has been compared with a wide range of classical and modern Western philosophers and religious thinkers ranging from Aristotle and St. Thomas Aquinas to Martin Heidegger, Friedrich Nietzsche, and Jacques Derrida.

## DŌGEN'S LIFE AND TEACHINGS

Some of Dōgen's major philosophical ideas emphasize that philosophy of religion must reflect personal experience of transient existence based on an awareness that the ultimate reality of the universal Buddha-nature is not beyond but is conditioned by impermanence. Impermanent reality is characterized by a fundamental unity of being-time (*uji*) in that all beings occur as temporal manifestations and time is manifested through each aspect of existence. Dōgen maintains that religious practice, or training, and spiritual realization, or the attainment of enlightenment, occur simultaneously and are inseparable in the experience of liberation known as “the casting off

of body-mind” (*shinjin datsuraku*) that is achieved through the methods of zazen meditation and kōan interpretation, which are equally conducive to realization. He also stresses that the naturalist dimension of being-time and impermanence-Buddha-nature is expressible through poetry and aesthetics, but reminds that karmic causality or moral conditioning and retribution are inherent to, rather than outside of, the attainment of enlightenment.

Much of Dōgen's emphasis on impermanence is based on his own experiences. According to the traditional accounts Dōgen was born into an aristocratic family at a time when Japan was beginning to be plagued by repeated civil warfare. He experienced profound sorrow at an early age as his father and mother died by the time he was seven. It is said that when Dōgen saw the smoke rising from incense and vanishing during his mother's funeral, he was deeply moved by an awareness of the inevitability of death and the pervasiveness of ephemeral reality.

The orphaned Dōgen decided to renounce secular life in pursuit of the Buddhist dharma. At first, he studied on Mount Hiei outside the capital city of Kyoto in the dominant Japanese Tendai church, in which the central doctrine was an affirmation of “original enlightenment” (*hongaku*) or the inherent potentiality of all beings to attain the primordial Buddha-nature. However, at the age of thirteen Dōgen had a fundamental “doubt” about the doctrine of original enlightenment: If everyone is already enlightened in that they possess the Buddha-nature, he thought, then what is the need for sustained meditative practice as required by the Buddha's teaching?

Unable to resolve this doubt in Japan, Dōgen traveled to China, where the contemplative path of Zen had become the dominant movement. At first, Dōgen was disappointed in the laxity of the Chinese Chan monks, who failed to inspire him. Then, on the verge of returning to Japan unfulfilled, he met the teacher Rujing, who insisted on an unrelenting approach to meditation. Under the guidance of his new mentor Dōgen attained an awakening experience of the casting off of body-mind, or a continuing process of liberation from all intellectual and volitional attachments, which signified the resolution of his doubt about the necessity of continuously renewed training.

Before his breakthrough experience Dōgen apparently presumed the conventional dichotomies between past, present, and future, now and then, life and death, impermanence and nirvana, time and eternity, and finitude and Buddha-nature. He thought that human beings

were bound to a realm of death and impermanence and that enlightenment was beyond this realm. However, in casting off body-mind he realized that a single moment encompasses the unity of practice and attainment, so that practice is not before—nor does it lead up to—enlightenment and enlightenment is not a teleological goal reached only at the end of practice. Rather, as Dōgen writes in the *Shōbōgenzō*, “[p]ractice and realization are identical. Because one’s present practice is practice in realization, one’s initial negotiation of the Way in itself is the whole of original realization.... As it is already realization in practice, realization is endless; as it is practice in realization, practice in beginningless” (Dōgen, *Dōgen Zenji Zenshū*, vol. 2, pp. 546–547).

On returning to Japan, in 1233 Dōgen established the Sōtō sect at Kōshōji temple in the Kyoto area, but because of sectarian disputes with Tendai and other Zen factions he eventually moved in 1243 to the remote, pristine mountains of Echizen (now Fukui) Province, where Eihei temple was constructed. According to Dōgen’s writings of the late period, every action generates a retributive consequence, and only authentic repentance and acknowledgment of one’s guilt can offset the effects of evil karma. Still, by emphasizing the moment-to-moment cause-and-effect process of karmic retribution—which is inseparable from nirvana as part of the Bodhisattva’s commitment to compassion—Dōgen is consistent with his earlier philosophy of being-time.

A central feature of aesthetic realization is Dōgen’s use of poetic language, especially elaborate metaphors and philosophical wordplay, to convey emotional fulfillment that enhances rather than opposes the enlightenment experience of detachment from worldly, materialistic concerns. One of Dōgen’s most eloquent poems was written near the end of his life as he returned from Echizen to the capital city for medical care. Making the journey to see Kyoto for the first time in ten years, but for what would prove to be the last time, Dōgen wrote in the five-line, thirty-one-syllable *waka* form:

Like a blade of grass,  
My frail body  
Treading the path to Kyoto,  
Seeming to wander  
Amid the cloudy mist on the mountain path.

(Heine 1989, p. 85)

## DOGMA

The Greek word of which “dogma” is a transliteration means “that which seems good.” It was applied by Greek authors to the decrees of public authorities and to the tenets of various philosophical schools. In English the word can be used for any fixed and firmly held belief on any subject, but it usually suggests that the belief is a condition, or at least a sign, of belonging to either a secular or (more frequently) a religious group. The word can also imply that the belief rests on a special—often divine—authority; that any member of the group who attenuates or changes the belief is thereby a “heretic”; and that heresy is a moral, and perhaps also legal, offense that merits the strongest condemnation (and perhaps also punishment).

The clearest example of religious dogma in ancient philosophy comes from Plato. In the *Republic* (376eff.) he lays down two “ways in which God is to be spoken of” (*tupoi theologias*). The first is that God is good and the

cause of good alone; the second is that God is true and incapable of change. In the *Laws* (887E–888D) he actually uses “dogma” to mean a correct “belief” about the gods. Everyone must believe that the gods are concerned with human affairs and that they cannot be appeased by sacrifice. Those who reject these beliefs must be duly punished by the state.

The primary sense of “dogma” is the one it has acquired in Christianity. Other religions have their distinctive tenets, but Christianity alone deserves attention on three grounds. First, its dogmas are far more numerous and complex than those of other faiths: Judaism requires only the recitation of the *Shema*, and Islam requires only assent to the *Kalima*. (Both these short creeds affirm the unity of God.) Second, Christian dogma has had many important points of contact with Western secular philosophy. Third, Christian theologians have given to the word *dogma* itself a technical, precise significance. (There is nothing that can properly be called dogma in the religions of the East. The eightfold path of Buddhism is a nontheistic way of salvation, not a creed. In Hinduism there are many divergent views of God and the Absolute, but none of them is “orthodox.”)

All the main Christian bodies are agreed that dogma is essentially the formulation of belief on the basis of the Scriptures. God revealed himself both in the events to which the Bible testifies and in the biblical interpretation of them. The role of dogma is to express the meaning of this revelation in conceptual terms.

All would also agree that dogma does not add to the revelation that was complete with the apostles. Dogma merely makes explicit what is implicit in apostolic teaching. Hence, St. Vincent of Lérins affirms that the development of dogma is an “advance” (*profectus*), not a change (*permutatio*). Although a dogma can always be restated in a form that is either more exact per se or more comprehensible to a particular audience, its substance is immutable.

This point is clearly made by Hans Küng in his important book on the second Vatican Council, *The Council and Reunion* (London, 1961). On the one hand, “dogmatic definitions express the truth with infallible accuracy and are in this sense unalterable (as against Modernism)” (p. 163). On the other hand, “one and the same truth of faith can always be expressed in a still more complete, more adequate, better formula” (p. 163).

All Christian bodies, finally, would agree that the *ultimate* object of assent is not any statement about God, but God himself. Furthermore, dogmas do not render

God intelligible; they symbolize a mystery that surpasses understanding. Therefore, we cannot assent to them without the gift of faith.

However, Christians differ in their views on both the number of and the authority for dogmatic definitions. Roman Catholic theologians hold that the definitions given by twenty ecumenical councils of the church are inerrant. They further hold that the pope alone, when he speaks *ex cathedra*, is infallible in matters of faith and morals. Finally, they hold that a dogma (for example, the dogma of the Immaculate Conception) can be justified as a logical “development” even though it lacks any scriptural support.

Non-Roman Christians oppose these claims. The Orthodox church holds that only seven councils are ecumenical and inerrant. Both Martin Luther and the Anglican reformers said that all councils are capable of error. All Protestants and Anglicans agree in denying both the infallibility of the pope and the validity of dogmas that are not explicitly supported by the Bible.

From the beginning, dogma has been stated through the terms of secular philosophy. One need mention only the use made of “substance” and “relation” in the doctrine of the Trinity. Such philosophical expressions were required both to make the faith intelligible and to safeguard it against heresy. Even those Protestants who reject scholastic terminology are forced to substitute other concepts (for example, those of existentialism).
