## Grammar

- ambiguity in, 6:659–660
- anaphora in, 1:171–175
- Anselm on, 1:218–219
- of appearance, 1:229–231
- behaviorists on, 5:189–190
- in Bernard of Chartres, 1:591
- categorical, 9:356–359
- Chomsky linguistic competence in, 2:244
- cognitive limits and categories in
  - Husserl, 2:81–82
- Condillac on, 8:790–791
- context-free phrase structured, 9:356
- criterion of sentencehood in, 8:804
- existential reference vs.
  - grammatical subject, 1:677
- Hellenistic, 4:302
- history of, Bacon (Roger) on, 1:455
- identity in, 4:567

in Indian philosophy, universals in, 9:580–582

Leibniz on logic and, 5:442

logical form and, 5:508

mass/count distinction in, 6:659–666

mentalists on, 5:189–190

of naming conventions and mass nouns in Chinese, 2:211–212

in natural vs. artificial language, 1:344

negation in, 6:524–525

nondescriptivism and, 6:634

of Pāṇini, 5:410, 7:413–415

philosophy and, 8:770

phrase-structured, 9:355

Platonists on, 5:189

*Port-Royal Grammar*, 8:775

Priestley in, 8:5

propositional types and, 5:507

quality-word relationships, 1:591

in Sanskrit, 7:413

Schleiermacher on, 8:636–637

as sermocinal science, 8:766

in sophism, 8:751–752

speculative, 1:591, 8:770–771

Bernard of Chartres on, 1:590

in medieval logic, 5:432–433

Stoicism's influence on, 9:255

subject and predicate in, 9:285–286

transformational, 9:355–356

universal. *See* Universal grammar

William of Champeaux, 9:767

*Grammar of Science, The* (Pearson), 7:160

Grammarians philosophy, 4:626, 4:631

Bacon and, 8:770, 8:773

of Bentham, 8:792

Condillac on, 8:790–791

imposition and, 8:762

in Middle Ages, 8:770–771

origin of, 8:790

of sophists, 8:751

Grammatical consequences, Leibniz on, 5:442

## Grammatical forms

performative utterances and, 7:199–200

truth and, 7:196

Grammatical relation, coindexing of, 5:509

## Grammatical structure

and logical form, 5:506

phonological form mismatches and, 5:509

transformational grammars and, 5:509

- Mental sentences, Wodeham on, 9:821–822
- Mental state(s)  
 “aboutness” of, 8:81  
 analytical behaviorism on, 1:524  
 in animals, 2:456  
 Armstrong on, 1:286–287  
 vs. automaton states, 3:757  
 Ayer on, 1:437  
 behavior and, 7:447  
 as conceptual connection, 7:54  
 Strawson on, 7:56  
 Berkeley on, 1:586  
 in Buddhist philosophy, 6:253–257  
 causal-functional nature of, 9:16  
 causality of, 6:646–647, 8:192–193  
 in Chinese room argument, 2:238  
 in computationalism, 2:390–391  
 concept of, having, 7:56–57  
 consciousness and, 1:704, 2:449–451, 2:455–456, 4:712  
 contentful, 2:477–478, 8:79–81  
 Dennett on, 2:456  
 description of, 7:52  
 in desire for pleasure, 8:721  
 epistemological content of, 2:478  
 in functionalism, 3:756, 6:645–646, 9:37  
 as functionally discrete internal states, 3:679  
 in higher-order consciousness, 2:454  
 higher-order thought (HOT) theory of, 4:713  
 individuating, 3:760  
 inner processes and outward criteria in, 1:525  
 intentionality and, 3:677, 4:700–701, 4:709, 7:468, 8:81, 9:291  
 in James’s psychology, 4:777–778  
 in law, 7:446–447  
 Lewis (D.) on, 5:314–315  
 in logical behaviorism, 1:534, 9:61  
 materialism and, 6:12–16, 6:646–647  
 nature and, 6:262  
 negative sentences and, 8:804  
 Ockham on, 9:774  
 ontological status of, 1:565  
 of others, personal identity and, 7:221  
 overdetermination of, 2:92  
 ownership of, 1:437  
 physical states and  
 asymmetrical knowledge of, 6:16–17  
 logical connections between, 6:17  
 qualitative vs. contentful, 8:79  
 quantum mechanics and, 5:698  
 Searle on, 8:705–706  
 simulation theory and, 9:36  
 in solipsism, 9:115, 9:118  
 in subjectivity models, 9:292  
 “theory-theory” of, 4:148, 9:36

## CABANIS, PIERRE-JEAN GEORGES

(1757–1808)

Pierre-Jean Georges Cabanis was, with Comte Antoine Louis Claude Destutt de Tracy, the leader of the *Idéologues*. A precocious student of philosophy and of the classics, he chose medicine as a career, but he never practiced. As a protégé of Claude-Adrien Helvétius's widow, he frequented the company of Étienne Bonnot de Condillac, Baron d'Holbach, Benjamin Franklin, and Thomas Jefferson. When Voltaire disparaged his poetry in 1778, Cabanis turned to physiology and philosophy. During the Revolution, he collaborated with Mirabeau on public education and was an intimate of Marquis de Condorcet. Later, he backed the Directory and Napoleon Bonaparte's coup d'état of 18 Brumaire. Although Napoleon made him a senator, Cabanis opposed his tyrannical policies. Bitter and scornful, Napoleon dubbed Cabanis's group "Idéologues." Cabanis wrote on medical practice and

teaching, but his fame and influence derive from one book, *Rapports du physique et du moral de l'homme* (12 memoirs written between 1796 and 1802, published in 1802).

The *Idéologues* (who also included Constantin Volney, Condorcet, Antoine Lavoisier, and Pierre de Laplace) were often scorned in their time, and later, as belated *philosophes* and purveyors of visionary speculations. In the rising tide of metaphysical idealism, their positivistic approach was held in disfavor. They suffered from the influence of the religious revival and the spell exercised by François René de Chateaubriand's *Le génie du Christianisme*, as well as from the popularity of "Illuminist" fads derived from Masonic practices. Their political activity during the Revolution also worked against them, and Napoleon's suppression of their movement left them without an outlet for publication.

Cabanis, like the others, sought a mechanistic explanation of the universe, nature, and human behavior—an approach later continued by Auguste Comte and Hippolyte-Adolphe Taine. Matter alone is real and eternal in its many transitory forms. As Lavoisier had applied analysis to chemistry, so—Cabanis declared—it could be applied to ideas, which could thereby be reduced to the original sensations whence they spring. Self-interest, the

pursuit of happiness and pleasure, and self-preservation are the only motives of action. These notions, already advanced by the eighteenth-century materialists, were systematically developed by Cabanis and Destutt de Tracy. The study of man, they held, must be reduced to physics and physiology. Man must be observed and analyzed like any mineral or vegetable. The medical expert, said Cabanis, should play the part formerly taken by the moralist (an idea that harks back to René Descartes and Julien Offray de La Mettrie). "Physiology, analysis of ideas, and morals are three branches of one science which may be called the science of man." Consequently, Cabanis and his fellow theorists refused to recognize notions not based on phenomena or sensations, that is, not susceptible of exact knowledge and (ultimately, at least) of mathematical notation. An understanding of the "mechanism of language" was considered essential to the understanding of the "mechanism of the intellect" and to the meaning of ideas. Language itself, however, had to be illumined by analysis of the sensations which constitute an idea and by the functioning of the intellect.

In his preface to the *Rapports du physique et du moral de l'homme*, Cabanis insisted that both the moralist and the physician are interested in the whole man; that is, in the physical and the moral, which are inseparable, and incomprehensible taken separately. The moral sciences must be placed on a physical basis. The union of mind and body is the theme of the first "Mémoire." Sensation is the necessary cause of our ideas, feelings, needs, and will. Since sensitivity is the connection between biological life and mind, the mental is only the physical considered from a certain point of view. Cabanis makes a famous comparison between the brain and the stomach: As the latter is a machine for digesting food, so the former is a machine for digesting impressions, by "the secretion of thought." He then develops a genetic analysis of sensations and ideas. There are no causes except those which can act on our senses, no truths except in relation to "the general way of feeling" of human nature, which varies with such positive factors as age, sex, disposition, health, climate, and so on. Thus the state of the abdominal viscera may influence the formation of ideas.

The second "Mémoire" is a "physiological history of sensations." Cabanis defines life as feeling and, following the work of Albrecht von Haller and La Mettrie, discusses the difference between sensitivity and irritability. The latter, he maintains, is only a result of the former, which is the basic biological phenomenon; since both depend on the nerves, they are essentially the same. Voluntary movements come from perceptions, which arise from sensa-

tions. Involuntary movements are caused by the organs' sensitivity, which produces the unconscious (autonomic) impressions that determine many of our ideas and decisions. The action of the nervous system, moreover, is only a specialized application of the laws of physical motion, which are the source of all phenomena. The third "Mémoire" develops a theory of the unconscious. The nervous system is affected by internal changes, that is, by memory and imagination; thus within man exists "another internal man" in constant action, the effects of which are noticeable in dreams. The fourth "Mémoire" explores the influence of age on ideas and "moral affections." The organs, like all else in nature, are in constant motion, and are therefore involved in decomposition and recomposition. Consequently, variations in the cellular tissue produce physical and psychic changes due to chemical action. The fifth "Mémoire" takes up sexual differences. The generative organs are essentially glandular, and their secretions influence the brain and the whole body. Unknown primitive "dispositions" (structures), which cause the embryo to be male or female, are also the cause of sexual differences, both physical and psychic. The fact that women can be forced to reproduction and men only excited to it produces vast differences in habits and mental outlook. What the sexes have in common constitutes human nature.

The sixth "Mémoire" treats the influence of "temperament," that is, the determining effects of the inherited physical constitution. Thus a large heart and lungs produce an energetic character, small ones an intellectual character. Because of heredity, the human race could be improved by hygienic methods. Believing in the inheritance of acquired characteristics and in improvement of species through crossbreeding, Cabanis pleads for a program of eugenics that will do for the human species what human beings have done for dogs and horses. In the seventh "Mémoire" Cabanis explores emotional and mental perturbations caused by diseases. For instance, weakness and irritability of the stomach produce muscular enervation and rapid alternations between excitement and depression. The eighth "Mémoire" discusses such effects of diet, air pressure, humidity and temperature, as excitation and sedation. Cabanis analyzes the effects of different foods and drinks, but his information and conclusions are rather fantastic.

Climate is the subject of the ninth "Mémoire." Man, the most modifiable animal, responds to heat and cold with differences in sexual and physical activity, and consequently in mental and moral habits. The tenth "Mémoire" is the longest. It explores the phenomena of

animal life, including sensitivity, instinct, sympathy, sleep, dreams, and delirium. The forces that cause matter to organize (a natural tendency) are unknown, and will always remain so. Nevertheless these forces are only physical, and life is only organization. Cabanis believed in spontaneous generation. Species have evolved through chance mutations (“fortuitous changes”) and planned mutation (“man’s experimental attempts”), which change the structures of heredity. Cabanis does not, however, develop a general theory of evolution. The eleventh “Mémoire” concerns the influence of the “moral” (mental) on the physical, which is merely the action of the brain on the body. The last “Mémoire,” on “acquired dispositions,” treats the influence of habituation and experience in general.

As a positivist, Cabanis was willing to renounce ultimate explanations. He was interested only in cause and effect on the level of phenomena. Unlike the other Idéologues, he was much influenced by La Mettrie and the man-machine school. He opposed the psychological method of Condillac and the sensationists, which was limited to external sensations. He preferred the physiological approach, which emphasized hereditary dispositions, the state of the organs, dreams, and automatic or unconscious impulses. These factors were more significant for him than experience (sensation) in determining the individual’s behavior; for the tabula rasa concept ignored what the child or adult brings to experience. For the same reason, Condillac’s statue is only an unreal abstraction from the reality of the unified, total, active organism. Cabanis was interested in the moral and social improvement of humankind, which he considered possible through an understanding of physiology—a science that he thought would eventually influence even positive law.

Cabanis and the Idéologues were one moment of a tradition that extends from Epicurus to the contemporary logical positivists (whose interest in linguistic analysis was prefigured by the Idéologues). Cabanis, like the others, has frequently been accused of impoverishing human experience by reducing it to the physical and mechanical level, and by denying the possibility of transcending internal and external sensations. On the other hand, the Idéologues considered man to be his own justification and the master of his own destiny. They had faith in his capacity to progress indefinitely by means of his own resources.

## Bibliography

### WORKS BY CABANIS

The *Oeuvres complètes* (Paris, 1823–1825) of Cabanis was edited by P. J. G. Thurot.

Cabanis, Pierre-Jean Georges. *On the Relations between the Physical and Moral Aspects of Man*, edited by George Mora. Translated by Margaret Duggan Saidi. Baltimore: Johns Hopkins Press, 1981.

### WORKS ON CABANIS

The best study of the Idéologues (although it ignores Cabanis’s connection with La Mettrie and the man-machine outlook) is Emile Cailliet, *La tradition littéraire des Idéologues* (Philadelphia: American Philosophical Society, 1943). ## CAIRD, EDWARD

(1835–1908)

Edward Caird, a leading Scottish Hegelian, was born in Greenock, the fifth of seven boys. His eldest brother, John Caird, became well known as a preacher and theologian, and exercised considerable influence on the young Edward. Educated at Greenock Academy and Glasgow University (with a brief interlude at St. Andrews), Edward Caird went to Balliol College, Oxford, gaining first-class honors in Classical Moderations and in “Greats.” From 1864 to 1866 he was a fellow and tutor of Merton, leaving to take the chair of moral philosophy at Glasgow, which he held until 1893. He then returned to Oxford to succeed Benjamin Jowett as master of Balliol. He resigned because of ill health in 1907, and died the year after.

Caird had a profound influence on his students, who regarded themselves as his disciples and included such distinguished philosophers as Henry Jones, J. H. Muir-

head, J. S. Mackenzie, and John Watson. “The greatest theme of modern philosophy,” Caird held, “is the problem of the relation of the human to the divine” (*The Evolution of Theology in the Greek Philosophers*, 1904). Many of his Glasgow students were destined for the church, and his liberalizing influence on religion was widely transmitted through them beyond the classroom.

Caird’s philosophy was a form of speculative idealism, based on Immanuel Kant but going beyond him. It was essentially a philosophy of reconciliation. The need for philosophy, he held, arises from the apparently irreconcilable opposition between different elements in our spiritual life—between subject and object, religion and science, freedom and determination, reason and desire. Unless we reconcile these antagonisms in a higher unity, we cannot achieve the spiritual harmony without which the highest achievements of humanity are impossible.

Kant, he was convinced, had found the key to the problem, but had failed to grasp the implications of his own doctrine. Caird had first to clear away what he thought was a common misinterpretation of Kant and then to go further along the Kantian road, with G. W. F. Hegel as his guide. Kant had been held, according to Caird, to teach that the material of knowledge is given in sense perception and that the mind then goes to work on it, ordering it by concepts supplied by itself. But, in fact, for Kant there *are* no objects until thought has done its work. Thought enters into the very constitution of experience. And further, the process of knowing is dominated by an “idea of the Reason,” which drives the mind to seek a form of experience in which all differences are seen as elements in a single system.

But instead of insisting that the larger the part played in knowledge by the mind’s synthetic activity, the more adequate that knowledge is, Kant took the view that this activity confines us to appearances and bars us from things-in-themselves. He should have shown, Caird argued, that our knowledge of objects will be imperfect insofar as we fail to recognize that they are only partial aspects of the ideal whole toward which reason points.

Caird’s ethical theory had close affiliations with that of his lifelong friend, T. H. Green. His main problem centered on the opposition of inclination and duty, and his solution lay in establishing the power of human beings to determine their conduct by reference to the self, as a permanent center, as distinct from its relatively isolated and transient desires. A self-conscious being seeks *self*-satisfaction, not just the satisfaction of this or that desire. And in this power of determining conduct by reference to the self lies human freedom.

The principle of evolution, Caird recognized, was of great value in reconciling differences, and in his Gifford Lectures, *The Evolution of Religion* (1891–1892), he traced the development of a single religious principle through its varied manifestations in the main religions of the world.

## CAIRNS, DORION

(1901–1973)

Thomas Dorion Cairns was born on July 4, 1901. His father was a Methodist pastor. Cairns studied phenomenological theory of value with Winthrop Bell at Harvard in 1923 and 1924, used a traveling fellowship to study with Edmund Husserl for two years, returned later for over another year, and received his doctorate with *The Philosophy of Edmund Husserl* in 1933. After temporary positions in New York, Cairns taught psychology as well as philosophy at Rockford College from 1938 to 1950. During World War II, he won a Bronze Star as a prisoner of war interrogator in the Air Corps. He was invited to the New School for Social Research in 1954 by Alfred Schutz, taught there with Aron Gurwitsch during the 1960s, retired in 1969, and died on January 4, 1973. All who heard him considered him a brilliant teacher, but he pub-

lished little. However, his translations of Husserl's *Cartesian Meditations* (1960) and *Formal and Transcendental Logic* (1969) played an important role. His *Conversations with Husserl and Fink* (1976), *Guide for Translating Husserl* (1973), and a dozen essays from his Nachlass have appeared posthumously. The editing of the manuscripts of his New School lecture courses began in 2003.

## SOME RESULTS OF CAIRNS'S INVESTIGATIONS

Cairns's original project was to bring Husserl's earlier work up to the level of *Cartesianische Meditationen* (1931), but from attempting to repeat the investigations, he came to propose at least seven major revisions.

(1) Like many in modern philosophy, Husserl pursued a first philosophy that seeks grounds in consciousness for everything else. Hence, the positive sciences are grounded in a primal science called transcendental phenomenology. This first philosophy is transcendental because it refrains from accepting the intramundane status of consciousness in order to avoid trying to ground the world in part of itself. Cairns always accepted the transcendental *epochē* and agreed with his master that it was Husserl's chief contribution.

Husserl's publications emphasize the theory of science (*Wissenschaftstheorie*), especially the theory of logic, although there are remarks about valuation and action. Cairns revised Husserl so that the goal of phenomenological philosophy became not merely knowledge, but the integration of critically justified willing, valuing, and believing.

(2) There is a considerable shift in emphasis when Cairns follows his revision of Husserl's goal by affording value theory and theoretical ethics as much attention as epistemology within his presentation phenomenological first philosophy.

(3) Although many stop after defining intentionality (which Cairns came to call "intentiveness") as directedness toward objects, Cairns followed Husserl in using the concept of synthesis to make this insight fruitful—for example, a synthesis of intensitive processes constituting an object as self-identical and different from other objects.

Although Husserl saw intensitive more clearly than anybody previously, Cairns believed that Husserl still tended to reify the noema (i.e., the thing-as-intended-to in an intensitive process), which is easy to do if one conceives of intentionality as a relation, whereas intensitive is actually a property.

(4) Husserl held that there were sensuous hyletic data immanent in the stream of consciousness. These moments are themselves not intensitive and no distinction was needed between sensing and *sensa* for Husserl, but for Cairns that distinction must be carefully maintained and *sensa* are transcendent of consciousness.

(5) Cairns held that Husserl left much to be done on the emotions and advanced the account by showing above all how emotion can be critically justified by the evidencing of objects valued in it. By contrast, rationality for most philosophers is wholly a matter of propositions conforming to the norms of logic.

(6) Cairns went beyond Husserl in developing the idea of ethics as a theory of critically justified willing (i.e., a theory of practical reason).

(7) Cairns's most radical revision of Husserl concerns the theory of the other. He objected to the reduction of the sphere of ownness introduced in the latter's Fifth Cartesian Meditation because the procedure described as a suspending acceptance of a noema without a suspending acceptance of the noesis is impossible to perform. Instead, Cairns asserted that a series of noetico-noematic strata of transcendental consciousness must be reflectively suspended through "unbuilding" (*Abbau*). Fields of *sensa* are ultimately reached. Through "building up" (*Aufbau*), one allows founded strata to be motivated once again, and thereby can reflectively observe how the intersubjective world is constituted.

A fundamental distinction for most European and North American philosophers holds between inanimate physical nature and the stratum of animate nature. A course in Indian philosophy with James Houghton Woods at Harvard in 1923 prepared Cairns to recognize that when the sense "animate body" is transferred from one's own body it transfers not to some but to all sensuous objects—rocks, trees, and sky included—and that animism follows. In class, Professor Cairns would say that chairs were rather stupid animals who stood in one place unless moved by somebody else. The distinction between inanimate and animate is then secondary, and may be recast as a distinction between animals with evident organs of sensation and locomotion and those without them. And phenomenology is clearly not merely about human consciousness.

In an era when practically all soi-disant phenomenologists devote themselves entirely to the interpretation of texts, Dorion Cairns is among the few who made a strict distinction between what may be called scholarship, which includes translation as well as interpretation of

texts, and what may be called investigation, which is concerned not with texts, but with the “things themselves” in the signification whereby anything is a “thing.” Like Husserl, Cairns regularly offered methodological reflections: he not only described the things reflectively observed, but also described how he had been able to analyze them, emphasizing reflection, analysis, “seeing,” and description.

Furthermore, Cairns often began by describing the *psychological* phenomenological epochē and reduction—a methodological step whereby consciousness remains intramundane but is abstracted from other mundane things—before contrasting it with the specifically *transcendental philosophical* epochē and reduction that refrains from accepting the intramundaneity of consciousness and makes the grounding of the world and all sciences of it possible. Although investigation, methodology included, predominates overwhelmingly in the writings of Husserl, it may be hoped that the posthumous publications of his arguably closest critical continuer will also help phenomenologists remember what phenomenology is.

## CAJETAN, CARDINAL

(1469–1534)

Cajetan (Tommaso de Vio), the most influential Renaissance Thomist, studied and taught in Italy, early distinguishing himself in teaching, commentaries, and debates as a philosopher and theologian. Rising to the leadership of the Dominican Order and becoming prominent in ecclesiastical politics, he was made cardinal in 1517. In 1518–1519 he disputed with Martin Luther.

Cajetan’s works number more than a hundred titles. His later writing was primarily devoted to biblical exegesis; his primary contributions to Thomistic philosophy and theology are due to his earlier commentaries and treatises, most notably his commentary on St. Thomas Aquinas’s *De Ente et Essentia* (On being and essence, 1495), his treatise *De Nominum Analogia* (On the analogy of names, 1498), and his formidable commentary on Aquinas’s *Summa Theologiae* (1507–1522), which is printed with the pontifical (Leonine) edition of Aquinas’s work. Other significant philosophical works include commentaries on Porphyry’s *Isagoge* and on Aristotle’s *Categories*, *Posterior Analytics*, *De Anima*, *Physics*, and *Metaphysics* (these last two have never been published), and a treatise on economics.

The *De Ente et Essentia* commentary is a sophisticated defense of Aquinas’s metaphysics, loosely organized in question format, clarifying (inter alia) the Thomistic

theses that being is the first object of cognition, that matter is the principle of individuation, and that essence and existence are really distinct in creatures. Sensitively attending to language, the work, with the *Categories* commentary, is also an important source for Cajetan's realist semantics.

*De Nominum Analogia* teaches a threefold classification and hierarchy of analogical signification. *Analogy of inequality* only counts as analogy from the metaphysician's perspective; logically, it is a form of univocation (as *body* is predicated equally of, though realized differently in, plant and stone). *Analogy of attribution* is Aristotle's *pros hen* equivocation; a term naming primarily one thing is extended to others by virtue of their relation to the first, as *healthy* denominates animal (intrinsically, as *subject* of health) and medicine (extrinsically, as *cause* of the animal's health). *Analogy of proportionality* is based not on a relation, but on a similarity of relations (as the body's ocular vision is proportional to the soul's intellectual vision). When proper and not merely metaphorical, denomination here is always intrinsic. Cajetan regards this as the most genuine form, a true mean between univocation and equivocation, and the majority of his treatise explores the implications (for abstraction, judgment, and reasoning) of proportionally similar concepts.

Cajetan's writings are shaped by the polemical context of Renaissance Thomism. Concerned to address the objections of humanists (such as Count Giovanni Pico Della Mirandola, whom he debated in 1495), Italian Averroists, and especially Scotists (foremost Anthony Trombetta, his contemporary at Padua and primary dialectical target of the *De Ente* commentary), Cajetan does not simply repeat formulas from Aquinas, he rearticulates Thomistic ideas in sometimes novel terminology. Despite this, and notwithstanding apparent departures from Aquinas on particular points (e.g., whether the soul's immortality is demonstrable), Cajetan was long regarded as a definitively authoritative expositor of Aquinas. When the twentieth-century Thomistic revival, distinguishing the historical Aquinas from longstanding scholastic traditions, emphasized differences between Cajetan and Aquinas, Étienne Gilson and others criticized Cajetan, especially on the topics of abstraction and existence. On analogy some scholars challenged whether the elements of Cajetan's comprehensive, systematic theory—especially the discussion of extrinsic versus intrinsic denomination, the preference for proportionality, and the threefold classification itself—are warranted from Aquinas's rather more dispersed and occasional reflections on the subject. Whether Cajetan's distinct philo-

sophical vocabulary is a departure from the mind of his master, or a legitimate development of authentic Thomism in light of the innovations of the intervening centuries, remains a question, but the forcefulness of his mind has never been doubted.

## CALDERONI, MARIO

(1879–1914)

Mario Calderoni ranks next to his teacher Giovanni Vailati as an Italian "Peircean pragmatist." He was graduated in law from the University of Pisa in 1901, and later lectured on the theory of values at the universities of Bologna and Florence.

Calderoni engaged in analyses of human behavior. These began with the interpretation of voluntary acts, which he regarded as the only nonmetaphysical problem of free will. In everyday life we all possess as good a criterion as is necessary to distinguish between voluntary and involuntary acts. To find out whether an act is to be called voluntary or not, we must modify the circumstances in which it usually occurs. If it still occurs in any case, we call it "involuntary"; if not, we call it "voluntary." The difference rests on the "plasticity" of voluntary acts, on their liability to modification by certain influences. A voluntary act "is liable not to be performed if the actor ... is given some new information on its consequences." What determines his acting is some expectation, which we can modify "either by changing one of the actor's beliefs by means of persuasion or reasoning, or, so to say artificially, by adding to the consequences the act would bring about if it were performed" (*Scritti*, vol. 2, pp. 25–26.). This criterion would hold good even if it were proved that all our

acts are subject to the principle of causality. In Calderoni's hands, it became an empirical, perfectible tool applied to the analysis of moral and legal responsibility.

In *Disarmonie economiche e disarmonie morali* (Florence, 1906) Calderoni viewed moral life as a "wide market where some men ... make determinate demands on other men who oppose such demands with more or less resistance and claim in their turn ... some sort of reward." Moral acts are judged not according to their total value, but according to their marginal or comparative value. We tend to confer the highest moral value not on common acts but on acts so rare that we would be obliged to repress them if their normal production increased. The moral value of actions is therefore related to their supply.

## CALVIN, JOHN (1509–1564)

John Calvin, the Protestant reformer and theologian, was born at Noyon, France. The son of middle-class parents of considerable local importance, Calvin was early directed toward an ecclesiastical career. From 1523 to 1528 he studied theology in Paris, there becoming acquainted with both the scholastic and humanist trends of his day. When he had achieved the master of arts degree, Calvin, in response to his father's wishes, left Paris to study law at Orléans, finishing his doctorate there by early 1532.

By 1534 Calvin had decisively broken with his Catholic heritage and had joined the Protestant reform movement in France. From this time on, all his efforts were devoted to the cause of the Reformation, and most of the remainder of his life was spent preaching, teaching, and writing in Geneva. He carried on a voluminous correspondence with thinkers and reformers all over Europe, and he had a powerful voice in the political and educational, as well as the ecclesiastical, institutions of Geneva.

Calvin's major work was the *Institutes of the Christian Religion*, first published in 1536 and originally addressed to King Francis I of France in defense of the French Protestants. It was extensively revised several times, and the last edition, published in 1559, provides a systematic presentation of virtually all the lines of thought found in Calvin's other mature works.

## KNOWLEDGE OF GOD AND SELF

"Nearly all the wisdom we possess," wrote Calvin in the opening of the *Institutes*, "consists of two parts: the knowledge of God and of ourselves." The overarching question in the *Institutes* is how we acquire this twofold knowledge, and the answers to this question have proved to be the most influential part of Calvin's thought.

Thomas Aquinas had taught that the theologian should start with God and then consider creatures insofar as they relate to God as their beginning and end. Calvin broke decisively with this approach in claiming that knowledge of God is so interrelated with knowledge of ourselves that the one cannot be had without the other. He taught that when we accurately reflect on ourselves, we realize the excellence of our natural gifts; but we also realize that our exercise of these gifts yields "miserable ruin" and unhappiness, and that "our very being is nothing but subsistence in the one God." Without this realization of our misery and dependence—especially of our misery—none of us comes, or even tries to come, to a knowledge of God. On the other hand, there is also no knowledge of self without a knowledge of God. Without a standard by which to measure ourselves, we invariably yield to pride, overestimating the worth of our natural gifts and overlooking the corruption that has resulted from the exercise of those gifts. Calvin readily allowed that "the philosophers," without knowing God, can give us much accurate and worthwhile information concerning man's faculties and constitution (I, XV). Philosophy, however, cannot yield a true estimate of our worth and condition.

In any discussion of Calvin's views on how we can come to know ourselves and God, it is very important to

understand what he meant by knowing God, for his views on this point are both original and subtle. The Scholastics tended to equate knowing God with knowing truths about God. Calvin invariably regarded this as inadequate. He did not deny, indeed he insisted, that knowing God presupposes knowing *about* God. But in addition to this he always maintained that an essential aspect of our knowledge of God is our acknowledgment of his attitude toward us, especially his attitude of benevolence and love. Again, Calvin never equated acknowledging God's benevolence toward us with believing *that* God is benevolent toward us. Rather, acknowledging God's benevolence presupposes worshiping and obeying him. Thus, as Calvin uses the concept "knowing God," there is no knowledge of God apart from worship of, and obedience to, him. For this reason E. A. Dowey (1952) said that Calvin conceived of knowledge of God as existential. It may be added that Calvin held, as did many of the Scholastics, that what can be known about God is never his nature (*quid est*), but only what he is like (*qualis est*); and more specifically, what he is like toward us.

How is knowledge of God to be achieved? Calvin always held that knowledge of God can, in principle, be achieved by nourishing one's subjective awareness of deity and its will, with reflection on the structure of the objective world.

"There is," he said, "within the human mind, and indeed by natural instinct, an awareness of divinity [*sensus divinitatis*]" (I, iii, 1). Although this concept of a sense of divinity played a significant role in Calvin's thought, he spent little time elucidating it. Apparently he thought of it as yielding a rudimentary conviction of dependence on some Maker, as well as a numinous awareness of the glory and majesty of the Creator. In support of his conviction that this sense is universal in humankind, Calvin frequently quoted Cicero. It is this universally innate sense of divinity in humankind that, according to Calvin, accounts for the universality of religion in human society. It is a seed of religion (*semen religionis*). Religion is intrinsic to human life; it was not "invented by the subtlety and craft of a few to hold the simple folk in thrall" (I, iii, 2).

In Calvin's thought, conscience (*conscientia*), as a subjective mode of revelation, was closely related to the sense of divinity. Conscience too, he said, is part of the native endowment of all men, written "upon the hearts of all." Typically he spoke of it as a sort of knowledge whose object is God's will; or, equivalently, the difference between good and evil, the law of God, or the law of nature. Thus it is by virtue of conscience that man is

aware of his responsibility—aware of the moral demands to which he is subject with respect to God and man. Calvin did not state with any exactitude the actual principles that all men know by virtue of conscience. He did say, however, that "that inward law ... written, even engraved, upon the hearts of all, in a sense asserts the very same things that are to be learned from the [Decalogue]" (II, viii, 1); and he said that what the Decalogue requires is perfect love of God and of our neighbor.

The subjective awareness of divinity and of its will can be supplemented, Calvin taught, by reflecting on the structure of the external world and the pattern of history. "[God has] not only sowed in men's minds that seed of religion of which we have spoken but revealed himself and daily discloses himself in the whole workmanship of the universe. As a consequence, men cannot open their eyes without being compelled to see him" (I, v, 1). At various times Calvin called the universe at large a book, a mirror, and a theater for the display of God's attributes—preeminently for the display of his goodness to us but also of his glory, wisdom, power, and justice. In the course of expounding his view that God can be known through his works, Calvin explicitly opposed the view that God can be known by speculation concerning his essence. It is by nourishing his sense of divinity and his conscience, with the contemplation of God's works, that man can in principle arrive at a knowledge of God.

SIN. It was Calvin's persistent teaching, however, that in fact no one does come to know God in the manner described above. The positive demands placed on all men by God's internal and external revelation are rejected, and this rejection results in an endless series of spurious religions. This resistance to God's demands is what Calvin identified as sin. Thus sin is not primarily ignorance about God; although such ignorance, or blindness, as Calvin often called it, will always be a consequence. Rather, Calvin viewed sin as an active willful opposition to God, as a positive refusal to acknowledge his demands of worship and obedience and as a deliberate alienation from him. Its prime characteristic is perversity, and its root is ordinarily pride and self-love.

Thus, being in sin is just the opposite of knowing God. Calvin, however, was quite willing to allow that a person who does not know God because he refuses to worship and obey him can still know or believe a variety of propositions about God that happen to be true. This explains what has, to so many readers, proved to be such an infuriating feature of Calvin's thought—his insistence, sometimes in adjacent sentences, that the pagans do not

at all know God but are not wholly ignorant of him. For example, Calvin, speaking of man's natural ability to know God, said, "the greatest geniuses are blinder than moles." In the very next sentence he said, "Certainly I do not deny that one can read competent and apt statements about God here and there in the philosophers" (II, ii, 18).

Not only was Calvin insistent that knowing or believing "competent and apt" propositions about God was not sufficient for knowing God; he was also profoundly convinced that man's proud refusal to worship and obey God leads him to resist acknowledging the truth about God. Sin, although primarily a matter of the will, infects man's reason as well. Perversity leads to blindness and distortion. Immediately after saying that the philosophers make competent and apt statements about God, Calvin added, "but these always show a certain giddy imagination... . They [the philosophers] saw things in such a way that their seeing did not direct them to the truth, much less enable them to attain it." Thus the consequence of man's willful alienation from God is not merely that he does not know God but also that his views about God are now so incomplete and distorted that nothing at all can be built on them. This is Calvin's judgment on natural theology.

It must be added that Calvin regarded the effects of sin as far more pervasive than have yet been indicated. Not only does sin disrupt man's relation to God; it thereby spreads corruption throughout the whole of human life. Of course, it does not impair our natural faculties as such. Calvin typically spoke of reason and will as man's chief faculties, and he held that the man in sin may be as intelligent and as capable of making decisions as the man who knows God. The corruption is to be found, rather, in the *use* we make of our native capacities.

Calvin maintained that if we are to state accurately what sin does to man's use of his native talents, we must distinguish between man's supernatural gifts, his abilities concerning heavenly things, and his natural gifts, his abilities concerning earthly things (II, ii, 12–13). The supernatural gifts comprise man's ability to know God, to worship him properly, and to obey him inwardly as well as outwardly. We have, however, been stripped of these gifts. The natural gifts pertain to matters of the present life, such as government, household management, all mechanical skills, and the liberal arts. Concerning these, said Calvin, our abilities have certainly not been destroyed. Not only are ancient law, medicine, and natural philosophy worthy of the highest admiration (II, ii, 15); but man, even in his estrangement from God, retains some sense of the laws that must be obeyed if human society is to be preserved. Man "tends through natural

instinct to foster and preserve society. Consequently, we observe that there exist in all men's minds universal impressions of a certain civic fair dealing and order... . And this is ample proof that in the arrangement of this life no man is without the light of reason" (II, ii, 13). Calvin immediately added, however, that although man's abilities concerning earthly things have not been destroyed, they have been profoundly corrupted. In opposition to what he understood as the teaching of the Greek philosophers, he held that both reason and will have been gravely wounded; the mind "is both weak and plunged into deep darkness. And depravity of the will is all too well known" (II, ii, 12).

If man's natural gifts are to be healed and his supernatural gifts restored, his sin must be overcome; he must come to know God. We have already seen that for this purpose man's conscience, his sense of divinity, and his awareness of God's revelation in the objective world are all inadequate. Thus, if human life was to be renewed, it was necessary that God should choose some special means. This he did by revealing himself with special clarity in the history of the Jewish people, culminating in the life and words of Christ. When God leads man to respond to this revelation with faith, then man again knows God. Indeed, faith, consisting as it does in a clear knowledge about God coupled with proper worship and true obedience, is a certain sort of knowledge of God—that sort which focuses on Christ as interpreted in the Scriptures. Thus, in Calvin's thought there is never a contrast between faith in God and knowledge of God; rather, given man's prior perversity, faith is the only kind of knowledge of God available to men. Also, faith, in Calvin's teaching, is never understood in scholastic fashion as an assent to divinely revealed propositions. Rather, the object of faith is God as revealed in Christ.

## SOCIAL AND POLITICAL TEACHINGS

Calvin's social and political theory has also proved most influential. Man, according to Calvin, is a creature of fellowship, created with tendencies that find their fulfillment in a variety of natural groupings, each concerned with a certain facet of man's life in society. One of these groupings is the church, another the state. Church and state are differentiated primarily by reference to their different tasks. The concern of the church is the spiritual realm, the life of the inner man; the concern of the state is the temporal realm, the regulation of external conduct. In regulating external conduct, the general aim of the state, in Calvin's view, is to insure justice or equity in society at large. This equity has two facets. Obviously the state

must enforce restrictive justice, but Calvin also believed that the state should secure distributive justice, doing its best to eliminate gross inequalities in the material status of its members.

It is the duty of the church to seek the welfare of the state, but equally it is the duty of the state to seek the welfare of the church. Thus, part of the state's duty is to promote piety; and Calvin, along with most of his contemporaries, regarded blasphemy as a civil crime. It was Calvin's view, however, that church and state ought to be structurally independent of each other. Church officials are not, by virtue of their office, to have any official voice in the state; and state officials are not, by virtue of their office, to have any official voice in the church.

Although he thought that the best form of government would vary with circumstances, Calvin quite firmly believed that the ideal government would be a republic in which those of the aristocracy who are competent to rule are elected by the citizenry, and in which power is balanced and diffused among a number of different magistrates. The magistrate has his authority from God. In a sense his authority is God's authority; for magistrates, Calvin said, are ministers of Divine justice, vicegerents of God. Thus the duty of the magistrate is to apply the law of God, implanted on the hearts of all and clarified in the Scriptures, to the affairs of civil society. To what extent and under what circumstances Calvin regarded civil disobedience as justified is a matter of debate. What is clear is that Calvin regarded the law of nature as in some sense a standard by which the decisions of the magistrate are to be judged, and at the same time he regarded revolutions which rip apart the entire fabric of human society as not to be condoned.

## INFLUENCE

Both the theological and social views of Calvin have had an enormous influence throughout history. The Reformed, churches of the Continent and the Presbyterian churches of England adhered fundamentally to his thought, and the dominant theological thought of the American colonies was Calvinistic. In the eighteenth and nineteenth centuries the impact of Calvinism on society and theological thought suffered a decline, but the twentieth century saw a resurgence in Calvin's influence. In the early part of the century in the Netherlands, Abraham Kuyper led a revival of Calvinism in politics and education as well as in theology. And the so-called neoorthodox theology, represented by such figures as Karl Barth and Emil Brunner, not only was accompanied by a renewed interest in the writings of Calvin but also in large meas-

ure marked a return to the main patterns of Calvin's theological thought.

*See also* Barth, Karl; Brunner, Emil; Thomas Aquinas, St.

## Bibliography

The standard edition of Calvin's works is that by J. W. Baum, E. Cunitz, E. Reuss, et al., in the *Corpus Reformatorum*, 59 vols. (Brunswick, Germany, 1863–1900). Most of these were translated by the Calvin Translation Society as *Works*, 48 vols. (Edinburgh: Calvin Translation Society, 1843–1855). An especially fine annotated translation is J. T. McNeill, ed., *Calvin: Institutes of the Christian Religion*, translated by F. L. Battles, 2 vols. (Philadelphia: Fortress Press, 1959). The classic study of Calvin's life is Émile Doumergue, *Jean Calvin; les hommes et les choses de son temps*, 7 vols. (Lausanne: G. Bridel, 1899–1927).

For discussions of the sources of Calvin's thought, see François Wendel, *Calvin: Sources et évolution de sa pensée religieuse* (Paris: Presses Universitaires de France, 1950), translated by Philip Mairet as *Calvin* (New York: Harper & Row, 1963); and Josef Bohatec, *Budé und Calvin* (Graz, Austria, 1940). A good discussion of Calvin's theology as a whole is Wilhelm Niesel, *Die Theologie Calvins* (Munich: C. Kaiser, 1938), translated by Harold Knight as *The Theology of Calvin* (Philadelphia: Westminster Press, 1956). The most adequate discussion of Calvin's views on the knowledge of God is E. A. Dowey, *The Knowledge of God in Calvin's Theology* (New York: Columbia University Press, 1952). Calvin's doctrine of man is treated in Thomas Forsyth Torrance, *Calvin's Doctrine of Man* (London: Lutterworth, 1949). Calvin's social and political thought is well discussed in André Biéler, *La pensée économique et sociale de Calvin* (Geneva: Librairie de l'université, 1959); and Josef Bohatec, *Calvins Lehre von Staat und Kirche* (Breslau: M. and H. Marcus, 1937). The finest survey of the history of Calvinism is J. T. McNeill, *The History and Character of Calvinism* (New York: Oxford University Press, 1954).

*Nicholas Wolterstorff (1967)*

## CALVIN, JOHN [ADDENDUM]

During the past few decades much scholarly work has been done on John Calvin by theologians, historians, and others. Some of this work has recognized the ways in which Calvin, despite his rejection of Scholasticism and his ostensibly purely scriptural approach to theology, does in fact use philosophical argument in his work and does engage implicitly with philosophical issues even in his decisions not to proceed philosophically (see Helm 2004). But the context in which philosophers are most likely to have encountered Calvin's ideas since the early 1980s has been that of so-called Reformed epistemology.

This is an approach to the philosophy of religion pioneered mainly, though not exclusively, by philosophers associated with the Reformed (i.e., Calvinist) tradition. It is noteworthy for combining some of Calvin's ideas on the understanding of God with the antifoundationalism that has become more or less orthodox in the mainstream of secular epistemology since the 1950s and 1960s.

The Reformed epistemologists start with a rejection of evidentialism—the claim that one is only justified in holding a belief if one can provide a rational justification for it. Reformed epistemologists such as Alvin Plantinga and Nicholas Wolterstorff (1983) repudiate evidentialism in epistemology generally, and the epistemology of religion in particular. One cannot refute a skeptic by giving a nonquestion-begging proof of the reality (or even probability) of the external world or of other minds; but there is no rational requirement that one should do so. These beliefs are “properly basic” (Plantinga 1981); one does not form them on the basis of argument and is only rationally required to defend them if good reasons for doubt are given in some particular case. Similarly, according to the Reformed epistemologists, with belief in God.

This account has been worked out most elaborately by Plantinga (1993). He argues that what is needed to turn true belief into knowledge is warrant, an externalist notion that he explicates in terms of proper function. A belief is warranted if it is formed by the proper functioning of a subject's cognitive apparatus. The internalist notion of justification is given only a secondary role; one is justified in holding a belief if one can defend it against specific claims that it is false or unreasonable. Applying this account to religious belief, Plantinga (2000) draws heavily on Calvin's notion of the *sensus divinitatis*. People have been so created that their minds, when functioning properly, are naturally led to a belief in God. This is not through argument, any more than their belief in other minds or physical objects is formed by argument. The obvious disanalogy is that religious skepticism is a live issue in a way that other forms of skepticism are not. Here, Plantinga turns again to Calvin, to his doctrine of sin and its noetic effects. Those who disbelieve in God (or who have inadequate, confused, or half-hearted beliefs) do so because, ultimately, they are repressing or distorting the operations of the *sensus divinitatis* in themselves. (Plantinga compares this with the error theories of religion advanced by Marxists and Freudians, who argue that religious beliefs are self-deceiving evasions of reality.) This tendency to repression is universal; those who escape from it do so through the operations of divine grace. Calvin is again the main source for Plantinga's account of

how the “internal instigation of the Holy Spirit” is necessary for one to be brought to belief in the specifically Christian doctrines of sin and redemption and thus to a true belief in God, which the sin-damaged *sensus divinitatis* cannot now achieve alone. Hence, Plantinga, while seeing non-Christian religions as evidence of the universality of the *sensus divinitatis*, rejects the idea that they can give their adherents a true or adequate knowledge of God.

It is striking that what is perhaps the most discussed late twentieth/early twenty-first-century development in religious epistemology is so deeply indebted to a theological often thought of as nonphilosophical (although Plantinga's interpretation of Calvin has itself been questioned, for example, see Jeffreys [1997]). Plantinga denies that his account is Calvinist in any narrowly denominational sense, and indeed appeals to St. Thomas Aquinas as well as to Calvin. But as a Catholic commentator notes (Zagzebski 1993), the Reformed epistemologists' characteristic externalism, and their focus on the beliefs of individuals rather than of communities, are both, for better or worse, deeply rooted in the thought and sensibility of the Reformed tradition.

## CAMBRIDGE PLATONISTS

The Cambridge Platonists were a group of seventeenth-century thinkers, associated with Cambridge University, who drew on the neoplatonic tradition and contemporary philosophical developments in order to combat vol-

untarism, materialism, and determinism, and promote a tolerant and inclusive understanding of Christianity.

The core members of this school were active from the late 1630s through the 1680s, and were associated either with Emmanuel or Christ colleges. The central thinkers in the movement were Ralph Cudworth (1617–1688), Henry More (1614–1687), John Smith (1618–1652), and Benjamin Whichcote (1609–1683), their founding figure. Other close associates at Cambridge included Peter Sterry (1613–1672), John Worthington (1618–1680), George Rust (1626–1670), and Nathanael Culverwell (1618–1651). Beyond Cambridge, thinkers with connections to the school include John Norris (1657–1711), Joseph Glanvill (1636–1680), and Anne Conway (1631–1679). Leading latitudinarian divines, including Simon Patrick (1626–1707), John Tillotson (1630–1694), Gilbert Burnet (1643–1715), and Edward Stillingfleet (1635–1699), can also be considered disciples of the Cambridge Platonists.

Although the movement was centered in Emmanuel College, long a stronghold for Calvinistic Puritanism, it constituted a repudiation of what the Cambridge Platonists took to be a central feature of Calvinist thought, its voluntaristic understanding of morality as a creation of the divine will. Against this voluntarism, which the Cambridge Platonists perceived as offering an unacceptable account of God as arbitrary tyrant, they argued for a form of moral realism. Good and evil are “eternal and immutable”; moral distinctions are ontologically real and unchanging. Influenced by Renaissance neoplatonism (and thus interpreting Plato through the lens of Plotinus and later Christian Platonism), the Cambridge Platonists conceived of God as the Good, the form of forms. The goodness that God wills is an expression of God’s own nature. Thus, while what is good is not good by virtue of being willed by God, eternal moral distinctions also do not serve as constraints on God’s will.

The Cambridge Platonists declared themselves opposed to any separation of the realms of reason and faith, of the rational and the spiritual. By this they meant most fundamentally to assert that God’s ways are fair, and in this sense reasonable. Rejecting the doctrine of predestination, they insisted that God’s decrees are not arbitrary or unfathomable but are objectively just. The Cambridge Platonists were staunch defenders both of freedom of the will and freedom of conscience. If God is just in holding us responsible for our actions, then these actions must be up to us and freely chosen. Furthermore, faith is reasonable, and reason must be persuaded; it cannot be forced. On matters that reason cannot determine, the Cambridge

Platonists advocated tolerance of a diversity of opinion. They worked for a policy of broad comprehension in the Church of England, minimizing core doctrines and emphasizing moral truths. Their theology thus resembles that of the Dutch Arminians, although arrived at independently.

Reason served for the Cambridge Platonists, as for so much of Renaissance neoplatonism, as a substantial link between the human and divine natures. Whichcote often wrote of reason as the “candle of the Lord.” Discounting the impact of the Fall on human nature, the Cambridge Platonists were optimistic about the capacity of human persons to know God and eternal moral truths through reason. Human knowledge of various moral goods is a participation in God’s own self-knowledge. Although there is a mystical aspect to the Cambridge Platonists’ assertion that God is present within human persons through reason, they were critical of claims to private communications from God, which they condemned as “enthusiasm.” Despite their emphasis on access to divine truth through reason, the Cambridge Platonists did not seek to undermine the authority of revealed truths. They did, though, tend to blur the boundaries between reason and revelation. So, for instance, they entertained the possibility that Plato’s wisdom derived from Moses or other ancient Hebrews, and thus that pagan wisdom was indebted to revelation. But they also argued that pagan anticipations of revealed doctrines, including the trinity, might have derived from the powers of reason, God within.

If Puritan theology was the target against which the Cambridge Platonist movement took shape, the Platonists (particularly Cudworth and More) soon took on new foes, notably Thomas Hobbes. Like the Calvinists, Hobbes was a voluntarist, who made morality dependent on will. That for Hobbes morality was dependent on the will of the human sovereign rather than the will of God rendered his thought no less problematic in their eyes. Hobbes was also attacked for his materialism, which the Cambridge Platonists regarded as a dangerous form of atheism.

Initially, the Cambridge Platonists perceived René Descartes as a valuable ally against both materialism and the old scholastic Aristotelianism. The Cambridge Platonists were among the first English thinkers to read Descartes, and More carried on an extensive correspondence with him. Like Descartes, the Cambridge Platonists were dualists and they regarded a dualism of spirit and matter as indispensable for their defense of the spiritual realm against materialistic reduction. (More’s friend and

pupil Anne Conway, author of *Principles of the Most Ancient and Modern Philosophy* [1692], parted ways with the Cambridge Platonists on this point, moving in the direction of a metaphysical monism).

The Cambridge Platonists came to think, though, that Descartes carried mechanistic explanations of the natural world too far. Arguing that matter is essentially passive and incapable of accounting for complex and orderly natural phenomena, they argued for a spiritual presence mediating between God and the physical universe. More termed this a *Spirit of Nature* or *Hylarchic Principle*, whereas Cudworth spoke of *Plastic Nature*. The eagerness to demonstrate the reality of immaterial substance reinforced in More and Glanvill a belief in witchcraft and a fascination with purported spiritual phenomena. Once seen as evidence of their credulity and backwardness, this feature of their thought is now understood as a further reflection of their support for the new experimental science. The Cambridge Platonists were familiar not only with the work of Hobbes, Descartes, and Benedict Spinoza, but also with Francis Bacon, Robert Boyle, and the Royal Society.

Whichcote's sermons were published by Anthony Ashley Cooper, third Earl of Shaftesbury. John Locke, Richard Price, and Thomas Reid were also indebted to the Cambridge Platonists, particularly Cudworth. Gottfried Wilhelm von Leibniz read both Cudworth and More, and Pierre Bayle critiqued Cudworth's *Plastic Nature*. Jonathan Edwards, John Wesley, Samuel Taylor Coleridge, and Matthew Arnold all admired the Cambridge Platonists. The lasting significance of the Cambridge Platonists resides in their success in carrying forward the insights of the tradition of Christian Platonism through a creative rapprochement with the philosophical revolution underway during their time. Within the heavily empiricist cast of English philosophy, they introduced a distinctive form of idealism.

## CAMPANELLA, TOMMASO (1568–1639)

Tommaso Campanella, a Renaissance philosopher and scholar, was born at Stilo, in Calabria, Italy. At an early age he entered the Dominican order and devoted himself to the study of philosophy. In 1599 he was arrested by order of the Spanish government on charges of heresy and conspiracy. Although he never confessed to either charge, he was considered to be a dangerous subject and was kept in prison at Naples for twenty-seven years. Released in 1626, he was arrested again and arraigned before the Holy Office in Rome to stand trial for certain suspect propositions found in his works. After regaining his freedom, he spent some time at the Dominican monastery of Minerva in that city. In 1634, fearing further persecution, because of the suspicion that he might be involved in a new conspiracy, he followed the advice of Pope Urban VIII and fled to France, where he was befriended by Cardinal Richelieu and King Louis XIII. He died in the quiet of the Dominican monastery of Rue St. Honoré in Paris.

Campanella wrote a great number of books dealing with subjects ranging from grammar and rhetoric to philosophy and theology, from apologetics to politics, and from medicine to magic and astrology. He conceived of philosophy as an all-embracing science to which all other sciences must be referred as their ultimate source and foundation. No subsidiary science deals with all things as they are, but only as they appear, whereas philosophy, and especially metaphysics, deals with all things as they are and insofar as they are. Philosophy is an inquiry after the truth of both human and divine things, based on the testimony of God, who reveals himself either through the world of created things or by direct teaching. Consequently, nature and the Scriptures are the two codes on which philosophy must be built.

### **EPISTEMOLOGY**

In his actual approach to philosophy, Campanella discussed first the possibility and reality of knowledge, thus anticipating a common trend among later thinkers. He was the first philosopher (antedating René Descartes) to assert the need of positing a universal doubt at the begin-

ning of his system and to state the principle of self-consciousness as the basis of knowledge and certitude. He distinguished between innate and acquired knowledge. Innate knowledge (*notitia innata*) is cognition through self-presence and belongs to the very essence of the soul; acquired knowledge (*notitia illata*) is the soul's cognition of external things. Innate knowledge is superior to, and more certain than, acquired knowledge; for the soul cannot be mistaken about what belongs to its nature. Knowledge of the external world can be obtained either by intuition or by abstraction. By intuition one grasps a thing immediately in its concrete reality, so that nothing of the object escapes the penetrating and all-embracing act of the intellect. By abstraction, one obtains only an indistinct and confused image of a thing. This image is what Campanella called the Aristotelian universal and is the object of both sense and intellect. The Platonic universal, on the contrary, is the idea as the formal cause of a thing and can be grasped exclusively by the intellect.

As to the essence and process of knowledge, Campanella gave a twofold explanation. A first explanation is contained in his early works and developed along the general lines of Bernardino Telesio's system. It represents his empirical approach to knowledge, which he reduced mainly to sensation and explained in terms of partial assimilation of the object known. This assimilation is made by contact between the knower and the sensible species of the object known. These species are neither the intentional species of the Aristotelians nor the corporeal images of Democritus. Although they may assume as many different forms as there are sensations, they are always something material that impinges on the senses and represents to a certain extent the external object.

A second and more advanced explanation of knowledge is what may be called the metaphysical approach from the standpoint of the soul as an essentially knowing nature. Here we meet Campanella's characteristic doctrine that to know is to be (*cognoscere est esse*). In this new approach, knowledge is still called sensation and assimilation, but the assimilation is carried so far as to mean a real transformation of the knower into the object known. This doctrine that to know is "being" or "to be" must not be understood in the idealistic sense of the absolute identity of object and subject. Campanella introduced a distinction between knowledge that a person has of himself in virtue of his own nature and knowledge that a person acquires from outside himself. Campanella called this the distinction between "innate" and "illate" knowledge. Both types of knowledge are said to belong to "being": But the former refers to knowledge of the original being of the

knower, and the latter refers to the knowledge of being that is inferred by reasoning and is formally distinct from the being of the knower. In the first case, knowledge *is* the *esse*; in the second case, it becomes intentionally the *esse* in the possession of the extramental reality.

## METAPHYSICS

For Campanella the object of metaphysics is "being," namely, whatever exists either within or outside our mind. He denied a real distinction between essence and existence in creatures, but admitted a real distinction between essence and extrinsic existence, or that type of existence that corresponds to the particular circumstances and environment wherein an essence happens to be in the physical world. All things, whether spiritual or material, consist ultimately, although in different degrees, of power, knowledge, and love as their transcendental principles. These are called "primalities" and are found in creatures as well as in God, of whom creatures are faint imitations. Whereas God is pure and infinite being, creatures are composites of finite being and infinite nonbeing. Being and nonbeing concur in making up finite things, not as physical components but as metaphysical principles. Just as a creature is essentially and necessarily a particular and limited entity, so it also is essentially and necessarily the nonbeing of all other things and of God himself.

## PSYCHOLOGY

In psychology Campanella accepted the trichotomic theory, according to which man is a composite of three substances, body, spirit, and mind or *mens*. The spirit or sensitive soul is the corporeal principle that animates the body and serves as a link between body and mind. The mind or intellective soul is created and infused by God into the body already organized by the spirit; it is a spiritual substance and the form of the whole man. With the Platonists, Campanella defended the doctrine of a world soul, and developed the theory of universal animation by endowing all things with some kind of sensation.

## PHILOSOPHY OF NATURE

Campanella was greatly influenced by Telesio's *De Rerum Natura*, which he defended against the attacks of G. A. Marta (1559–1628). He conceived of space as a primary and incorporeal substance having the capacity to receive all bodies. Space is the substratum of all things. In this space God placed matter, a body that is formless and inactive but capable of being molded into many forms, just as wax is acted upon by a seal. Matter is not pure

potency, as Aristotle taught, but has a reality of its own distinct from the form. This, in turn, is not a substantial principle of material beings and is only improperly called an act. In short, Campanella dismissed the Aristotelian hylomorphic theory and substituted for it Telesio's naturalistic doctrine of heat and cold as the active principles and matter as the passive principle of all material beings. He also rejected Aristotle's notion of time as measure of movement and claimed that time is not something ideal and subjective, but something real. Time is the successive duration of things having a beginning and an end. Or, more concretely, time is the thing itself considered in its successive duration through change.

## ETHICS

Following Telesio, Campanella taught that man's supreme good consists in self-preservation. However, this must not be understood in a purely egoistic sense, but rather as the conservation of one's existence in God in the next life. Whereas God is his own supreme good and does not look to another being outside himself for his preservation, so that to be and to be happy are for him one and the same thing, man depends entirely on God for his own preservation. God is therefore the supreme good toward which man must direct all his acts and operations.

## POLITICAL THEORY

Campanella advocated a universal monarchy with the pope as its supreme temporal and spiritual ruler. This ambitious but hardly realistic plan is described in the *Monarchia Messiae* (The Messiah's Monarchy) and represented the dream of his entire life. *Civitas Solis* (*The City of the Sun*), on the other hand, contains the scheme of a state modeled after Plato's *Republic* and Sir Thomas More's *Utopia*, where people, who live in the pure order of nature, organize themselves into an ideal society ruled by philosophers and share everything. Many of the ideas expressed in this work have some practical value, inasmuch as they contain the germs of social, political, and educational reforms that would be beneficial to the state. In this respect, Campanella may be considered as an original thinker and a forerunner of various modern theories and practices.

## Bibliography

## CAMPBELL, NORMAN ROBERT (1880–1949)

Norman Robert Campbell, the English physicist and philosopher of science, was educated at Eton. From Eton he went as a scholar to Trinity College, Cambridge, and became a fellow there in 1904. From 1903 to 1910 he also

worked as a research assistant at the Cavendish Laboratory, whose director, the celebrated J. J. Thomson, became the most important inspiration of his scientific work. In 1913 he became an honorary fellow for research in physics at Leeds University, but he left this post after the war and from 1919 to 1944 was a member of the research staff of the General Electric Company.

The writers who seem to have influenced him most are Ernst Mach and Henri Poincaré, apart from classical authors such as William Whewell, John Stuart Mill, and W. S. Jevons. On the other hand, such philosophers as Bertrand Russell and Alfred North Whitehead came too late to have much effect on him; the main outlines of his thought developed during the first decade of the century, and there are only occasional references to their writings.

Campbell exhibited the very rare combination of competence in both physics and philosophy, but while he preferred to think of himself primarily as an experimental physicist, it is as a philosopher of science that he made his mark. This point is brought out in the writings of F. P. Ramsey, R. B. Braithwaite, and Ernest Nagel, although these concentrate largely on the formal parts of Campbell's doctrines and pay scant attention to the more valuable contributions that he made to certain methodological ideas, particularly that of analogy. These philosophical views, shaped by Campbell's actual experiences and ideas as a physicist and expositor of physical theories, were meant to be construed as answers to intellectual pressures and problems that confronted him in the years that saw the rise of the twentieth-century atomic theory on the one hand and relativity and quantum mechanics on the other. In philosophy of science, his most important contributions were in the fields of the logic of theory construction and (to a lesser extent) the principles of physical measurement.

## PHILOSOPHY OF THEORY CONSTRUCTION

Campbell's views were stated in systematic form for the first time in a popular book, *The Principles of Electricity*. Thereafter they were developed, with minor changes of emphasis and greater attention to the nature of "mathematical theories," in *Physics: The Elements*. In contrast with the usual textbook approach, his views were deeply interwoven with, and at times even explicitly discussed in, his more formal scientific treatises.

**CONCEPTS AND IDEAS.** Campbell distinguishes sharply between the laws and theories of a science. In the case of laws, the constituent terms (Campbell calls them con-

cepts) designate entities whose magnitudes may be determined more or less directly by instrumental means; they are not unlike what later came to be called operational concepts. The explanatory part of theories, the hypotheses, involve terms that Campbell calls ideas. These lack the instrumental relations of concepts, for a variety of reasons that Campbell does not always clearly distinguish.

Sometimes the ideas refer to the unobservable infrastructure of a physical system, as in the case of the atoms and electrons of modern electrical theory or, more properly (as Campbell points out), to their adjectival aspects, such as their mass, velocity, and momentum. At other times, the ideas pertain to such interstructural devices as Michael Faraday's lines of force, or the carriers of the transfer of electrical and optical phenomena, such as light waves, light corpuscles (photons) or even the "aether," considered the substantival carrier of electromagnetic energy. (Infrastructural entities are unobservable in a sense different from interstructural ones, but the question is controversial.) A third case in which theories are said to involve unobservables is that of geological and evolutionary theories. And there is yet another case, for Campbell denominates certain notions "ideas" because they involve an amount of idealization and abstraction to which no physical entities could correspond. The most frequent and important cases are those ideas which involve infinitesimals, such as the differential coefficients in James Clerk Maxwell's equations or François Marie Charles Fourier's theory of heat.

It follows from the nature of ideas that the hypotheses in which they occur are not directly testable. Their function consists merely in systematically relating a set of corresponding laws, and, through extensions of the theory, in foreshadowing further laws and experiments. This foreshadowing is sometimes negative, for when the ideas are too narrowly framed, they demand not only extension but also the formulation of additional concepts and theories.

**"DICTIONARY" OF A THEORY.** Since the ideas of the hypotheses lack operational meaning, and since their deductive development can, in the first place, yield only statement forms containing either ideas or combinations of them, it is necessary to add certain rules (a kind of "dictionary") that will coordinate the ideas with those operational concepts which occur in the laws to be explained. Of course, not all ideas need dictionary entries. In the beta-ray theory, for instance, the velocity,  $v$ , of the hypothetical electrons *means* "the quantity that is

defined by the relation  $F = e[X + (v \cdot H)]$ .” This expression, however, is a hypothesis in Campbell’s sense because  $v$  never occurs either alone or in combination in the testable derivations at all.

“MATHEMATICAL” THEORIES. All this provided Campbell with a means of distinguishing so-called mathematical theories from nonmathematical ones. In the former, each and every idea is separately coordinated with a corresponding concept by means of a dictionary entry. It follows that whether a theory is of the mathematical type depends partly on historical accidents: Maxwell’s theory became a mathematical theory only after Heinrich Rudolf Hertz’s experiment had demonstrated the existence of the displacement current.

Nonetheless, ideas so far have no meaning apart from their use in hypotheses and their coordination with concepts. In the mathematical cases this is often forgotten, but in the nonmathematical cases this fact is more difficult to overlook. Because of the lack of independent significance of ideas, Campbell held that a theory is not a real explanation unless certain additional requirements are satisfied. One of his reasons for this view was that it is always possible to construct an indefinite number of hypotheses that would account for a set of laws. In the case of mathematical theories, the additional element of consolidation that Campbell suggests is the regulative feature of simplicity and aesthetic elegance—for instance, through symmetrical arrangements of the parts of a theory. (Thus, it was the introduction of Maxwell’s displacement current into the original equations of André Marie Ampère and Faraday that produced a symmetrical set of equations regarding the relations between the electrical and magnetic phenomena for the case of open circuits.) Furthermore, the hypotheses are not entirely arbitrary because their ideas mirror the corresponding concepts of the laws. There is, according to Campbell, a sort of analogy between ideas and concepts (*Physics: The Elements*, p. 141).

ANALOGY. Analogy plays a more central role in the case of the nonmathematical theories. As we have seen, their ideas frequently cannot be clarified at all by the concepts that occur in the laws. According to Campbell, it is an analogy of the hypotheses and their ideas with corresponding laws and concepts of some testable field of science that imparts the missing element of significance and logical strength to the theory. It follows that analogies are not merely aids to the establishment of theories; “they are an utterly essential part of theories, without which theo-

ries would be completely valueless and unworthy of the name” (ibid., p. 129).

Campbell’s point is that “a theory is not a law” (ibid., p. 130); that hypotheses are, from the nature of the case, never directly testable; and, hence, that their addition to the corpus of scientific knowledge would make no difference to science at all if it were not for some additional features that make the hypotheses significant. He dismisses the fact that they supply a systematic relation between the laws of the theory on the grounds that an infinity of such hypotheses can be constructed.

Campbell’s positive grounds for the necessity of analogies are of various kinds. The fundamental reason is that since hypotheses are not directly testable but are only instruments for deductive development, possessing a purely formal content, they lack the sort of meaning required for genuine explanatory power: Only analogy can supply this. Another ground of a more heuristic nature is that analogies aid in the extension of theories, especially when a new field is grafted onto the dictionary of an existing theory (as when optical conceptions were added to Maxwell’s generalization of the electrical theories of Ampère and Faraday).

As mentioned, however, analogy must be supplemented by additional criteria, which are clearly needed for dealing with mathematical theories. These criteria are largely derived from Campbell’s actual experience with the theories with which he had been dealing in his physical textbooks. In addition to simplicity and aesthetic elegance, there is “simplification in our physical conceptions,” such as was produced by the early theories of Faraday, Thomson, and Hendrik Antoon Lorentz. Campbell insists on the importance of such regulative conceptions precisely because “scientific propositions are [not] capable of direct and irrefutable proof.” An additional criterion is the “anticipative force” of a theory—for instance, the suggestiveness of Faraday’s lines in the direction of the existence of electromagnetic radiation, of a motion that is displaced in time, with a given velocity, in empty space.

Finally, another regulative criterion is that of importance, or depth, of the ideas involved. This is invoked particularly in those cases where analogy is barely a relevant consideration, as in such mathematical theories as Maxwell’s, or Albert Einstein’s special theory of relativity.

## METHODOLOGICAL CONTRIBUTIONS

Campbell’s clear account of the logical structure of a theory, with its hypotheses, laws, and dictionary, offers an

elegant means of formalizing the place of ideas (theoretical concepts) within theories. He emphasizes also the logical gap between hypotheses and laws even in cases where its existence had previously been practically overlooked—the mathematical theories. He uses this fact to question Mach's preference for such theories (called phenomenological by Mach), on the grounds that they employ hypotheses and hypothetical ideas just like any other theory. (Whether this does sufficient justice to the difference between the two types of theories must be left an open question.) The theoretical nature of such substantial entities as atoms and electrons seems to differ from that of lines of force on the one hand and, say, from the entropy functions on the other, in deeper ways not caught by Campbell's criteria of ideas.

The fact that the systematizing power of hypotheses is an insufficient criterion of their truth or explanatory power introduces the remaining feature of Campbell's doctrine—such regulative notions as the existence of a strong analogy, of simplicity, symmetry, anticipative force, and, finally, of importance. The most interesting of these is analogy, which in the end emerges as a metaphysical device in terms of which to formulate the special aspect of those theories that involve unobservables. The “absolute necessity” for an analogy is the result of the emasculation of the semantic power of hypotheses, coupled with the consideration that this emasculation entails the introduction of a special constraint that prevents such hypotheses from being mere arbitrary formulas.

## THEORY OF MEASUREMENT

The second part of *Physics: The Elements* is a detailed discussion of the principles of physical measurement; this, like most of Campbell's ideas, was already contained in embryo in *The Principles of Electricity* (Ch. 2). His interest in measurement is not altogether removed from his main philosophical preoccupations mentioned so far. Just as he was concerned with a clear delineation of laws from theories, he was equally firm in stating the differences as well as the relations between laws and definitions. In *Measurement and Calculation* Campbell defines measurement “as the assignment of numerals to present properties in accordance with ... laws.” Thus, every measurable property must have a definite order; the systems to be measured must be capable of “addition,” but what operation is considered “addition” must be carefully specified in a given situation; and whether the resultant quantities yield consistent measurements is a matter for lawlike experience. Campbell points out that the specification in question is usually tacitly adopted ab initio and is, indeed,

often suggested by theory and the relevant analogy. Hence, he believes that “no new measurable quantity has ever been introduced into physics except as the result of the suggestion of some theory” (*The Principles of Electricity*, p. 41).

## CAMUS, ALBERT

(1913–1960)

Albert Camus, the French novelist and essayist, was born in Mondovi, Algeria, and was educated at the University of Algiers. From 1934 to 1939 he was active writing and producing plays for a theater group he had founded in Algiers. About the same time he began his career as a journalist, and in 1940 he moved to Paris. During the German occupation of France, Camus was active in the resistance movement, and after the liberation of Paris he became the editor of the previously clandestine newspaper *Combat*. His literary fame dates from the publication

in 1942 of his first novel, *L'étranger* (*The Stranger*), and an essay titled *Le mythe de Sisyphe* (*The Myth of Sisyphus*). During the immediate postwar period Camus was deeply involved in political activity, and his name was for a time closely associated with that of Jean-Paul Sartre and with the existentialist movement. In 1947 he published a second major novel, *La peste* (*The Plague*), and, in 1951, *L'homme révolté* (*The Rebel*), an essay on the idea of revolt. The latter book provoked a bitter controversy between Camus and Sartre, which ended with a severance of relations between them. In 1957 Camus was awarded the Nobel Prize for literature. His last major work was *La chute* (*The Fall*), a novel that appeared in 1956. In 1960 Camus was killed in an automobile accident.

Although Camus studied philosophy for a number of years at the University of Algiers, he was not a philosopher in any technical or academic sense. Nevertheless, virtually all his literary work was deeply influenced by philosophical ideas, and in two major essays, *The Myth of Sisyphus* and *The Rebel*, he undertook a more or less systematic exposition and defense of the moral attitudes that had in each case found expression in his novels and plays. *The Myth of Sisyphus* can thus be regarded as in some sense a philosophical commentary on *The Stranger*, and *The Rebel* has clear affinities with *The Plague*. There can be no doubt that there are profound differences between the views set forth in these two essays. Camus's philosophical career was essentially a movement away from the nihilism of *The Myth of Sisyphus* toward the humanism of *The Rebel*. Ideas that had been present in his work from the beginning, in one form or another, were to retain their place there; but he progressively revised his views of their relative importance within the moral life.

Although Camus's name is often associated with contemporary European phenomenology and existentialism, there is no evidence that he was ever deeply influenced by, or very much interested in, the doctrines of Edmund Husserl or Martin Heidegger or even Sartre; and on occasion he expressed himself as having distinct reservations with respect to existentialism as a philosophy. In fact, his philosophical thought was formed on much more traditional models. His deepest interest was in those great figures in the Western philosophical tradition—among them Socrates, Blaise Pascal, Benedict de Spinoza, and Friedrich Nietzsche—whose lives and personalities were all reflected in their philosophizing. If he came, as he did, to reject the exaggerated claims that philosophers have made for human reason and subscribed to many of the criticisms that contemporary existentialists have made of the classical tradition, he continued to regard the

striving of the great thinkers of the past to achieve a total conception of reality and of the human relation to the world as reflecting one of the deepest human aspirations and to view its inevitable failure as marking a crisis in man's relation to himself.

On the other hand, Camus does not appear to have had any theoretical interest in the analysis of philosophical problems. His interest in philosophy was almost exclusively moral in character; when he had come to the conclusion that none of the speculative systems of the past could provide any positive guidance for human life or any guarantee of the validity of human values, he found himself in the situation that he describes in *The Myth of Sisyphus*. This essay is ostensibly a consideration of the problem of suicide, which Camus describes as the only serious philosophical problem. The question he asks is whether it makes any sense to go on living once the meaninglessness of human life is fully understood and assimilated. Camus gives a number of somewhat different formulations of what this meaninglessness or "absurdity" comprises. At bottom, it is the failure of the world to satisfy the human demand that it provide a basis for human values—for our personal ideals and for our judgments of right and wrong.

It is very important for an understanding of Camus's point of view to see how closely he thought ordinary moral attitudes are dependent upon metaphysical belief in some kind of congruence between human values and the nature of reality. The external supports on which the validity of moral distinctions rested in the past were, of course, primarily religious in character; but Camus held, as do many others, that with the decline of religious belief in the modern period a number of secular religions—in particular, Hegelian and Marxist historicism—have attempted to tie values to reality by means of a postulated schedule of historical development that guarantees their eventual realization. In *The Myth of Sisyphus*, Camus presupposes, without very much argument, that none of these interpretations of reality as value-supporting can survive critical scrutiny; the tenability of any purposive or evaluative attitude on the part of human beings—the only moral beings—is thus called into question. It is this isolation of the human being as an evaluative and purposive being in a world that affords no support to such attitudes that Camus calls the absurdity of the human condition.

Camus maintained that suicide cannot be regarded as an adequate response to the experience of absurdity. The reason he gives is that suicide deals with absurdity simply by suppressing one of the two poles—the human

being and the “world”—that together produce the tension described above. Suicide is thus an admission of incapacity, and such an admission is inconsistent with that human pride to which Camus openly appeals. Indeed, he goes so far as to say that “there is nothing equal to the spectacle of human pride.” Only by going on living in the face of their own absurdity can human beings achieve their full stature. For Camus, as for Nietzsche, whose influence at this stage of Camus’s thought is very marked, the conscious espousal of the metaphysical arbitrariness of human purpose and action transforms nihilism from a passive despair into a way of revolting against and transcending the world’s indifference to man.

It is evident that in *The Myth of Sisyphus* Camus believed that absurdity, in the sense of recognition and acceptance of the fact that there are no metaphysically guaranteed directives for conduct, could by itself generate a positive ethic. In particular, the ideal of human fraternity was connected with Camus’s heroic nihilism on the grounds that to accept oneself as the sole guarantor of one’s own values would necessarily involve accepting a principle of respect for other human beings. It is here, however, that Camus encountered a very serious difficulty. He found it necessary to show by means of examples just what the specific implications for conduct of his doctrine of absurdity are and also make it plausible that these implications are consistent with the humanistic ideal to which he as an individual is clearly devoted. In *The Myth of Sisyphus*, however, the specimens that are offered of the mode of life appropriate to the “absurd” man bear only a rather remote affinity to that ideal or, for that matter, to any general social ethic. Camus did not demonstrate satisfactorily either that the kind of life that followed from an acceptance of nihilism bore any clear relation to his own moral ideals or that a life dedicated to these ideals could be adequately motivated by an acceptance of absurdity.

What is clear is that Camus, from the beginning, regarded certain responses to absurdity as morally unacceptable. In his “Letters to a German Friend” (1943–1944), he interpreted Nazism as one reaction to the very nihilistic vision of the world that he himself had come to accept. He then went on to condemn it in the severest terms for its denial of human fraternity. Even at this stage in the development of his thought, Camus insisted that an authentic revolt against the human condition had to be a revolt in the name of the solidarity of man with man.

In the character of Meursault, the “hero” of *The Stranger*, this tension between Camus’s nihilistic vision

and his ethical demands becomes particularly clear. Meursault is presented as a man characterized by the moral equivalent of achromatic vision. Although he is not at all given to philosophical reflection, he views the whole conventional human apparatus of moral distinctions, of justice and of guilt, as a kind of senseless rigmarole with no basis in reality. He stands, in fact, outside the whole moral world in a peculiar state that Camus describes as “innocence,” apparently because in a world that affords no transcendental sanction for human judgments of right and wrong there can be no real guilt. His relationship to his mother and to his mistress are devoid of feeling, and he eventually kills an Arab for no particular reason. But at the very end of the novel, after Meursault, facing execution, has burst into a rage against a priest who tries to persuade him to accept the reality of his guilt and the possibility of redemption, there is a long semipoetic passage in which he declares his love of the world and its sensuous immediacy and speaks tenderly and almost lovingly of his fellow men and of their common fate, which he shares. As a number of critics have noted, there is nothing in the novel that prepares one for this passage. Camus, however, clearly wishes to persuade us that these two aspects of Meursault’s character are not just consistent but intimately related to one another; but again he experienced difficulty in showing how a positive ethic of human fraternity can be generated by a nihilistic attitude toward all values.

There can be little doubt that in the years immediately following the publication of *The Stranger* and *The Myth of Sisyphus* Camus substantially revised his view of the moral significance of value-nihilism. Increasingly, it was the injustice and cruelty of man to man that aroused Camus to action; by comparison with the hideous but remediable evils of human society, the cosmic injustice of the human condition seems to have lost some of its obsessive hold on his mind. Like many of the existentialists, Camus still tried to present these two revolts—the revolt against the human condition and the revolt against human injustice—as essentially continuous with one another. Nevertheless, he came to feel that the relationship between these two revolts had been misconceived and that this misconception was at the heart of twentieth-century totalitarianism, to which he was as resolutely opposed in its communistic as in its Nazi version. Camus gradually came to believe that the reason for the extraordinary miscarriage of the Soviet revolution was that the revolutionary tradition had its roots in a revolt against the human condition as such, and that such a revolt can never lead to human fraternity but leads instead to a new enslavement of man by man. This radical revision of his

earlier views found its full expression in Camus's second main philosophical essay, *The Rebel*.

*The Rebel* begins with a consideration of the problem of murder or, more exactly, with the problem of political justification for the killing of human beings. For Camus, political action is essentially violent revolt, and it thus inescapably raises the question of whether one has the right to take the life of another human being. Camus's answer is that taking a human life is inconsistent with true revolt since, as he now makes clear, that revolt involves the implicit assertion of a supraindividual value, the value of human life. It is not altogether clear how this rejection of violence is to be interpreted, but it is interesting to note the approval that Camus expresses in his play *The Just* (1950) of the Russian terrorist Kaliaev who murders the Grand Duke Serge but insists that he himself pay for his act with his life in order to affirm the moral inadmissibility of murder. In any case, the revolt that Camus still advocates in *The Rebel* is presented there as ethically inspired from its inception. He rejects, however, what he now calls "metaphysical revolt," which he sees as a radical refusal of the human condition as such, resulting either in suicide or in a demonic attempt to depose God and remake the world in the image of man. Its deepest motive is not a love for humankind but a desire to destroy the world as it is. The order it attempts to impose on the new world it constructs is informed by no ethically creative principle because, as Camus now declares, nihilism can yield no such principle. A nightmare state of power for power's sake is the ultimate fruit of metaphysical revolt.

In order to substantiate this thesis, Camus reviews the intellectual history of the past two hundred years and discusses in detail a number of poets, philosophers, and practicing revolutionaries whom he regards as the chief fomentors of metaphysical revolt. Among them are the Marquis de Sade, Max Stirner, Nietzsche, le Comte de Lautréamont, Baron de Saint-Just, and Sergei Nechaiev, to mention only a few. G. W. F. Hegel and Karl Marx are assigned a central role in the construction of a view of history and of the state that exempts man from all moral controls and that proposes as the only valid ideal man's total mastery of his own fate. The two political revolutions that Camus thinks were inspired by the ethos of metaphysical revolt are the French and the Russian, although the Nazi "revolution" represents some of the same tendencies in even purer form. Camus considers none of the modern revolutions that did not eventuate in political terrorism, and he makes no attempt to evaluate or even consider other kinds of explanation of the revolutions that he does discuss. As many critics have

remarked, the apocalyptic character of the historical tableau that he presents is in good part due to a principle of selection that seems to reflect a personal predilection for extreme or crisis situations rather than any objective assessment of the real influence that the representatives of metaphysical revolt may have had on the course of events.

Camus's novel *The Plague*, which appeared four years before *The Rebel*, gives clear indications of his reevaluation of nihilism. The plague that descends on Oran symbolizes not just the Nazi occupation of France or even totalitarianism as a political system but all of the many forms that injustice and inhumanity can assume. A variety of reactions to this "plague" is presented; but it is Dr. Rieux, the organizer of the "sanitation squads" that fight the plague, who represents Camus's ideal of moral action. Rieux is not inspired by any dream of a total conquest of evil. Instead, his conception of himself is modest and limited; throughout the struggle he retains his sense of humanity and his capacity for love and for happiness. The doctor is in fact what many have said Camus aspired to be, a kind of "saint without a God."

If *The Rebel* and *The Plague* represent—as they seem to do—Camus's mature position, it would appear that this position differs from traditional nonreligious humanism mainly by virtue of the terminology of revolt that Camus retained even after he had so thoroughly moralized his conception of revolt as to make most of the normal connotations of that term inapposite. As he himself says in *The Rebel*, the true significance of nihilism is negative; it clears the ground for new construction but by itself provides no principle of action. As such it survives in Camus's view of the moral world mainly as a prophylactic against the kind of mystification, religious or metaphysical, by which a man tries to rid himself of his radical contingency and confer upon himself a cosmic status that makes it easier for him to be a human being. Camus was a pitiless critic of all such forms of shamming, and he was convinced that their general tendency was to enable their practitioners to evade the responsibility that goes with moral self-ownership and to confirm them in their inhumanity to their fellow men. Nihilism would seem, in Camus's final view, to be a kind of immunizing experience, although one with very considerable dangers of its own, by virtue of which one is enabled to grasp the ideal of human fraternity in its pure form without the entanglements of ideology and doctrine by which it has so often been disfigured. Camus's attitude toward life is thus, at bottom, simply a stubborn moral integrity and a deep sympathy with his fellow men, to which the somewhat meretricious rhetoric of revolt adds very little. At

the same time, however, it must be conceded that the absence or unavailability of absolute values, whatever these might be, remains for Camus anything but trivial, and it pervades the atmosphere of the humanistic ethic that he erected in their place.

The work of Camus's last years reinforces one's impression that an essentially nonmetaphysical and strongly moralistic humanism was his final view of life. He drew away more and more from direct political action; his refusal to side unambiguously with the Algerian rebels brought him the bitter reproaches of many former associates, among them Sartre. In 1960 in *Réflexions sur la peine capitale* ("Reflections on the Guillotine"), Camus argued that society does not have the right to put its criminals to death, and one wonders in what circumstances Camus would have regarded war as morally defensible. Finally, in *The Fall*, he seems to have abandoned political and social action entirely in favor of a conception of evil that no longer situates it in unjust social institutions or in the terms on which man is permitted to exist but in the very heart of man himself. The protagonist, Clamence, is a man whose interior corruptness is concealed from the world—and for a long time from himself—by a life of philanthropy and active sympathy for his fellow men. He is, in fact, a sort of monster whose ultimate self-knowledge leads him to create a sense of guilt and unworthiness in others by advertising his own corruption. In this way he again feeds his obsessive need for superiority, which was the real motive of his earlier philanthropy. It is not justifiable to impute the unrelieved pessimism of this novel to Camus personally, or to suggest, as some have, that he had accepted the doctrine of original sin; but there can be little doubt that his treatment of the character of Clamence is indicative of a further shift in the locus of the struggle between good and evil. The shift, broadly speaking, is one that emphasizes our inner complicity with evil and our lack of the kind of innocence that Camus had always claimed for humanity. Whether this strain would have been developed further in Camus's thought if he had lived longer is a question to which there can be no answer.

## CAN

What can be true or can be done varies with the meaning of "can." As far as philosophy is concerned, the important senses of this word ("could," past indicative) fall into five major groups. For convenience these groups, most of which are distinguished in *Webster's Third New Interna-*

*tional Dictionary*, may be singled out as the “can” of ability, of right, of inclination or probability, of opportunity, and of possibility.

#### “CAN” OF ABILITY

The “can” of ability has at least three subsenses: (1) to have the skill—“He can speak five languages or paint life-like portraits”; (2) to have the requisite mental or physical power—“He can solve difficult problems, invent remarkable machines, or foretell the future” or “He can swim a mile or do one hundred push-ups”; (3) to have the requisite strength of character—“He can resist anything but pleasure, pass up a free drink, or bear criticism of his books.”

#### “CAN” OF RIGHT

The “can” of right, which is often used interchangeably with “may,” has at least four subsenses: (1) logically or axiologically can—“Equivalent formulas can be interchanged, *salva veritate*, in any extensional context” or “From this we can reasonably infer ...”; (2) can in virtue of custom, agreement, law, and so on—“One can be prosecuted for saying that” or “An ambulance can disregard traffic lights”; (3) permission-giving “can”—“You can borrow my car if you’d like”; (4) be permitted by conscience or feeling—“I can condone no willful act of destruction” or “I can accept electrocution but not hanging.”

#### “CAN” OF INCLINATION OR PROBABILITY

Examples of the “can” of inclination or probability are “I was so angry that I could have killed him” and “That car could hardly have made a trip across the desert.”

#### “CAN” OF OPPORTUNITY

“He could have played chess had he known how,” “Come in here where we can talk,” and “The traffic was so heavy that I could not cross” illustrate the “can” of opportunity.

#### “CAN” OF POSSIBILITY

The “can” of possibility has at least five subsenses: (1) consistency with knowledge—“For all that I know, Jones could have been the one”; (2) whether it is possible for someone (compare with the “can” of opportunity)—“Can you get away for lunch?” (3) the “can” of physical possibility—“If such-and-such has to happen, then it cannot fail to happen” or “A man, properly equipped, can survive indefinitely in outer space”; (4) the “can” of logi-

cal possibility (compare with the logical or axiological use of the “can” of right)—“Nothing can be red all over and green all over at the same time”; (5) conditional possibility (logical or physical)—“If the conclusion of a valid argument is false, not all of the premises can be true” or “In a deterministic system everything that can occur is necessitated by something else.”

#### CAN AND FREE WILL

Because the field of philosophical perplexity is virtually limitless, any one of the “cans” listed above is a possible source of trouble to the philosopher. Nevertheless, several of them (especially the “cans” of ability, opportunity, and possibility), have proved exceptionally potent in bewitching the philosophical imagination, mainly in connection with the age-old problem of free will. This problem is partly generated by the conviction that a man can be said to perform an action freely only if he did not have to perform it but he could have done something else instead. A conviction of this kind tends to generate a problem because if the metaphysical thesis of determinism is intelligible, tenable, and applicable to human actions, it becomes doubtful whether it is ever true that a man can do anything other than what he does do, at least in one of these three basic senses of “can.”

“CAN” OF ABILITY. How the ability senses of “can” bear on the free will issue has received perhaps the largest share of attention in the recent literature, possibly because questions about a man’s abilities are often so crucially relevant in moral contexts. Yet the decisive points about abilities in this connection are easily stated. In all of the subsenses of the “can” of ability, there is an essential distinction between the possession of an ability and the exercise of that ability. To show that a person lacks an ability is more complicated than to show that he does not exercise it. A failure to perform a certain action implies that a man lacks the corresponding ability only if both he wants, wills, intends, or chooses to perform that action and his failure to perform it occurs in relevantly normal conditions. This fact has tempted philosophers (for instance, P. H. Nowell-Smith) to analyze “He can” (in the sense of ability) as meaning “He will if ... .” Important difficulties with such hypothetical analyses have been pointed out by Austin and others, but it has not been shown that there is anything wrong with the line of thought that prompted these analyses—namely, that our use of “can” in this sense is built on the idea that a man need not do what he can do and that in order to find out what he can do, we must find out what he will do if, in relevantly normal conditions, he wants, wills, intends, and

so forth to do certain things. This line of thought is not, moreover, inconsistent with determinism, since determinism does not imply that if, under appropriate conditions, I wanted and were to try to perform an alternative action, I should certainly fail. On the contrary, it is presumably only because a measure of determinism does hold that my trying, in certain circumstances, to perform a particular action is likely to meet with consistent success.

**“CAN” OF OPPORTUNITY.** Although the truth of determinism does not imply that if a man performs a certain action, he could not (in the sense of the “can” of ability) have done otherwise, it might still be claimed that he would not, under these conditions, have the opportunity to do otherwise and, thus, that he could not do otherwise in the sense of the “can” of opportunity. But this claim is simply false, since in the ordinary sense of “opportunity” one can be said to have the opportunity to do many things that one is not presently doing, whether or not determinism holds. As the examples of the “can” of opportunity indicate, “having the opportunity to do *X*” does not mean anything like “being in a situation in which nothing physically essential for one’s performance of *X* is lacking,” which the claim in question seems to suppose (for more on this point see Taylor, *Metaphysics*). On the contrary, to have the opportunity to do something requires only that one be in a situation such that if, roughly speaking, one wanted to do it, it would be reasonable to expect that one would be successful in doing it if one were able to do it (that is, could do it in the sense of ability). And such a situation would normally be lacking in many things essential, in the required sense, to one’s performing that action. Not only might it lack the essential interest or even ability on one’s own part, but it might also fail to involve the means that one would have to take in order to accomplish that action if it were at all complex—for instance, walking across the room in order to grasp the vase that one “has the opportunity” to break, throwing it toward the floor with sufficient force, and so on.

**“CAN” OF POSSIBILITY.** In spite of all this, it still seems possible to argue that, given determinism, a man cannot do other than what he does do in the sense that any alternative action on his part is physically impossible. A claim of this sort is, however, false if taken literally, since what is physically possible *simpliciter* need be consistent only with the laws of nature, not consistent with the laws of nature *and* certain initial conditions. If, however, the claim is to be taken in a slightly different way—namely,

that it is *conditionally* physically impossible for the man to perform some other action—then it is entirely unexceptionable if the thesis of determinism is tenable and applicable to human actions. The reason for this is simply that the notion of conditional possibility is a technical one, definable by reference to determinism: Roughly, “*A* is conditionally physically possible” is by definition equivalent to “Nothing has happened that physically determines non-*A*.”

Because one is to make sense of “conditional physical possibility” by reference to determinism or something like it, it is clear that the hard-fought question whether determinism rules out human freedom is not the question whether determinism rules out the conditional possibility of a man’s doing other than what he does do. There is, in fact, little that is controversial about the last question; it gets an analytic “Yes.” What is controversial is the question whether the sense of “can” involved in the morally relevant query “Can he do otherwise?” is to be understood as the “can” of conditional possibility. For if, as both libertarians and sophisticated fatalists seem to think, this “can” is of basic moral significance, then free actions are possible only if determinism is false, untenable, or inapplicable to human actions. If, on the other hand, this sense of “can” is *not* the one that does concern us or should concern us when in a moral context we wonder whether a man can do other than what he does do—the opinion of the “reconcilers” of the empiricist tradition—then there is, perhaps, no incompatibility between determinism and human freedom after all.

**NORMATIVE “CAN.”** How is this basic question about the “can” in the morally crucial use of “He can do otherwise” to be resolved? Only a few, admittedly feeble, hints can be given here. First, the idea that this “can” is that of conditional possibility seems extremely dubious, since this sense of the word is pretty clearly a contrived one, not mentioned even in unabridged dictionaries and thus hardly one that, like the “can” of ability and opportunity, is likely to be used in the familiar, everyday, morally compelling assessment of free, responsible actions. Second, the less heavy-handed and therefore far more tempting claim—that it is at any rate naive or unreasonable to describe an action as free if it is conditionally impossible for the agent to have done otherwise—seems very unsatisfactory when it is carefully pressed. For one thing, to think of free actions as differing from unfree ones in being conditionally undetermined is to make the very notion of a free action practically useless, since any question that might arise about the freedom of a given act would presumably then have to be settled by a fairly

hopeless hunt for causes in the jungles of neurology. For another thing, to conceive of free actions in this way is to sever their ties with those complex principles of personal responsibility that incline us to excuse, rather than emphatically condemn, the kindly old parson who (we might imagine) suddenly, spontaneously, and without cause wills to, and does, baptize the infant he is baptizing. The last point really seems to go to the heart of the matter: To conceive of free actions as conditionally physically indeterminate actions is to conceive of them in too naturalistic a way. After all, the very identity of an action—think of promising or murdering—is determined not just by the physical movements involved but also by a complex system of rules, laws, and so forth. Since it is the application of such rule concepts that distinguishes actions involving the same physical movements—murder and defensive or punitive acts—the basic vocabulary of action descriptions is essentially normative to a very large extent. (Actually, the vocabulary of action description is “intentional” in a way in which “scientific” language presumably is not.) Because the “can” in the morally crucial claim “He can do otherwise” plainly belongs to the family of words specifically used in connection with human actions, there is an inescapable force to the claim, made by many contemporary philosophers, that to identify this sense of the word with “conditional physical possibility” is to confuse a practical, largely normative “can” with an aseptic, scientific, theoretical one and thus to misconceive drastically the purpose, point, and import of the familiar, nontechnical statement “His action was done freely.”

## CANTOR, GEORG

(1845–1918)

Georg Cantor, a mathematician who created set theory and a corresponding theory of transfinite numbers, revolutionized mathematics at the end of the nineteenth century with his ideas about the infinite, which were to be of profound significance not only for mathematics but for philosophy and many allied disciplines as well.

He was born on March 3, 1845, in St. Petersburg, Russia, to Georg Woldemar Cantor, a successful merchant and the son of a Jewish businessman from Copenhagen, and Maria Anna Böhm, who came from a family of notable musicians and was a Roman Catholic. But Cantor’s father, raised in a Lutheran mission, was a deeply religious man and passed his own strong convictions on to his son. Later in life, Cantor’s religious beliefs would play a significant role in his steadfast faith in the correctness of his controversial transfinite set theory, just as his mother’s Catholicism may have made him particularly amenable to the substantial correspondence he undertook with Catholic theologians over the nature of the infinite from a theological perspective.

### EARLY MATHEMATICAL STUDIES

Cantor received his doctorate in 1868 from the University of Berlin, where he had studied with Leopold Kronecker, Ernst Eduard Kummer, and Karl Weierstrass. His dissertation was devoted to number theory, as was his *Habilitationschrift*. When Cantor began teaching as an instructor at the University of Halle, among his colleagues there was Eduard Heinrich Heine. Heine had been working on problems related to trigonometric series, and he urged Cantor to take up the challenging problem of whether or not, given an arbitrary function represented by a trigonometric series, the representation was unique. In 1870 Heine had established the uniqueness of such representations for almost-everywhere continuous functions, assuming the uniform convergence of the trigonometric series in question. Cantor succeeded in establishing increasingly general versions of the uniqueness theorem in a series of papers he published between 1870 and 1872, the most remarkable of which showed that even if an infi-

nite number of exceptional points for the representation were allowed, the uniqueness could still be shown if such infinite sets of “exceptional” points were distributed in a particular way. Such sets of exceptional points constituted what Cantor called sets of the first species.

An infinite set of points  $P$  was said to be of the first species if its set of limit points  $P'$  was finite; if not, then  $P'$  must contain an infinite number of points and also have a derived set, the second derived set of  $P$ ,  $P''$ . If for some finite number  $v$  the  $v^{\text{th}}$  derived set  $P^v$  contains only a finite number of points, then its derived set will be empty, that is,  $P^{v+1} = \emptyset$ . It was for such first-species sets that he was able to establish the uniqueness of trigonometric series representations, even though there were an infinite number of exceptional points. Transfinite set theory would arise from Cantor’s later consideration of point sets of the second species, all of whose derived sets were infinite. From these Cantor would eventually generate an endless hierarchy of what he came to call transfinite ordinal, and later their corresponding cardinal, numbers.

## THE REAL NUMBERS

Cantor realized that to define the structure of point sets of the first species unambiguously required a rigorous definition of the real numbers, which he approached in terms of fundamental, convergent sequences of rational numbers in his last paper on trigonometric series of 1872. In the same year Richard Dedekind introduced his own rigorous definition of the real numbers in terms of “Dedekind cuts.” Both approaches are concerned with the continuity of the real numbers in general, a subject that was to haunt Cantor for the rest of his life. In particular, he succeeded in proving just a few years later, in 1874, that the set of all real numbers was in fact nondenumerably infinite, that is, of a distinctly higher order of infinity than denumerably infinite sets like the whole, rational, or algebraic numbers. This fact soon led to the articulation of one of Cantor’s most famous problems: his continuum hypothesis, that the infinite set of real numbers  $R$  is the next higher order of infinite sets following denumerably infinite sets like the set of all natural numbers  $N$ . Cantor became especially interested in the question of whether or not point sets of two and higher dimensions might furnish examples of increasingly infinite orders of infinity, something he answered negatively in 1877. This was another of Cantor’s important early results, his proof (though faulty) of the invariance of dimension; the first correct proof was published by L. E. J. Brouwer in 1911.

Between 1879 and 1883 Cantor wrote a series of articles that culminated in an independently published

monograph devoted to the study of linear point sets, *Grundlagen einer allgemeinen Mannigfaltigkeitslehre: Ein mathematisch-philosophischer Versuch in der Lehre des Unendlichen* (Foundations of a general theory of sets: A mathematico-philosophical investigation into the theory of the infinite). In addition to introducing such concepts as everywhere-dense sets, he showed that whereas everywhere-dense sets were necessarily of the second species, first-species sets could never be everywhere-dense.

## TRANSFINITE NUMBERS

In his series of papers on linear point sets, and in the *Grundlagen*, Cantor introduced his new concept of transfinite numbers. At first, these were limited to the transfinite ordinal numbers that he generated from the point sets of the second species that he had introduced in 1872. Considering the entire sequence of derived sets  $P^v$ , none of which was empty (i.e., every derived set  $P^v$  contained an infinite number of limit points):  $P'$ ,  $P''$ ,  $\dots$ ,  $P^v$ ,  $\dots$ , Cantor defined the intersection of all these sets as  $P^\infty$ . This was an infinite set that in turn led to the next derived set  $P^{\infty+1}$ . If this set were infinite, and in fact every derived set thereafter, this led to an endless hierarchy of further infinite derived sets:  $P'$ ,  $P''$ ,  $\dots$ ,  $P^v$ ,  $\dots$ ,  $P^\infty$ ,  $P^{\infty+1}$ ,  $\dots$ ,  $P^{\infty+v}$ ,  $\dots$ ,  $P^{2\infty}$ ,  $\dots$

At first, Cantor only regarded the superscripts as “infinite symbols,” but early in the 1880s he began to distinguish these indexes as numbers independently of point sets of the second species. By the time he wrote the *Grundlagen* in 1883, these infinite symbols had become transfinite ordinal numbers.

## CONTROVERSY AND CRITICISM

Cantor understood that his new ideas would be controversial, and his work had already met with criticism, especially from Kronecker, his former teacher at the University of Berlin. Cantor was so concerned about the possible objections to his new ideas that he undertook a detailed analysis of the subject historically, which served his strategy in the *Grundlagen* to present a detailed analysis of the foundations of transfinite set theory from both a philosophical and theological perspective. It was in the *Grundlagen* that he made one of his most famous statements, that “the essence of mathematics lies precisely in its freedom” (1996, p. 182). As Cantor later confided to the mathematician David Hilbert, this statement was inspired by the negative criticism Kronecker had made of set theory and was a call for open-mindedness among mathematicians, especially in dealing with new and novel ideas proposed by younger mathematicians. But the

opposition mounted by Kronecker served a useful purpose in stimulating Cantor's own philosophical reaction and his determination to provide the soundest possible foundations, both mathematically and philosophically, for transfinite set theory.

What Cantor did in the *Grundlagen* was to present the transfinite ordinal numbers as a direct extension of the real numbers. But because he generated these infinite real numbers as abstractions from sets of points, he rejected the possibility of there being actually infinitesimal numbers. He also knew that an important property of the transfinite ordinal numbers was their noncommutativity, that is:

$$\begin{aligned} 2+\omega &= (1, 2, a_1, a_2, \dots, a_n, a_{n+1}, \dots) \neq \\ &(a_1, a_2, \dots, a_n, a_{n+1}, \dots, 1, 2) = \omega+2, \\ 2\omega &= (a_1, a_2, a_3, \dots; b_1, b_2, b_3, \dots) \neq \\ &(a_1, b_1, a_2, b_2, a_3, b_3, \dots) = \omega 2. \end{aligned}$$

Such distinctions brought new insights to the differences between finite and infinite sets. For finite sets and their corresponding ordinal numbers, addition and multiplication were commutative; infinite sets were more interesting because their corresponding ordinal numbers and transfinite arithmetic were not commutative. Cantor expected that understanding such differences would not only explain the seemingly paradoxical nature of the infinite but would also answer some of the long-standing objections to the infinite that historically had been so persuasive to mathematicians and philosophers alike.

## TRANSFINITE CARDINALS AND CANTOR'S ALEPHS

Although the *Grundlagen* offered a systematic presentation of Cantor's transfinite ordinal numbers, there was no mention of his best-known innovation: the transfinite cardinal numbers, or alephs. Indeed, nowhere in the *Grundlagen* was there any indication that the power of an infinite set was to be equated with the concept of a transfinite cardinal number, a step he first took in a lecture he delivered at Freiburg in September 1883. Over the next decade he used a number of different notations for transfinite cardinal numbers, but did not decide on a definite symbol until Giulio Vivanti, an Italian mathematician who was writing an introductory monograph on set theory, asked Cantor about notation. Only then did he finally choose the Hebrew aleph for the transfinite cardinal numbers. In "Beiträge zur Begründung der transfiniten Mengenlehre" (Contributions to the founding of

the theory of transfinite numbers) he designated the least transfinite cardinal number as  $\aleph_0$ .

It was also in "Beiträge" that Cantor offered an algebraic interpretation of his continuum hypothesis, based on his proof of 1891 that given any infinite set  $P$ , the set of all its subsets was of a higher power than  $P$ . Since the cardinality of the set of all real numbers could be written as  $2^{\aleph_0}$ , and if  $\aleph_1$  was the next largest cardinal following  $\aleph_0$ , then the continuum hypothesis could now be expressed as  $2^{\aleph_0} = \aleph_1$ . Cantor hoped that with this new algebraic formulation of the hypothesis, he would soon manage to produce a proof that the power of the real numbers was indeed equal to  $\aleph_1$ . He never succeeded in doing so, for reasons that only became apparent in the twentieth century, thanks to the results of Kurt Gödel (who established that the continuum hypothesis was consistent with the basic axioms of Zermelo-Fraenkel set theory) and Paul Cohen (who showed, on the contrary, that the continuum hypothesis was independent of the same axioms), which meant that it was possible to conceive of consistent set theories in which Cantor's continuum hypothesis did not hold.

Cantor's last major publication appeared in two parts in the journal *Mathematische Annalen* in 1895 and 1897. "Beiträge" not only offered a complete account of both his transfinite ordinal and cardinal numbers but also his theory of order types, which investigated in detail the different properties of the sets of natural, rational, and real numbers, respectively. The well-ordered set of integers, taken in their natural order, he designated ( $\omega$ ; the set of rational numbers in their natural order, which were everywhere-dense but not continuous, he designated  $\eta$ ; sets like the real numbers that were continuous he designated by the order-type  $\theta$ . But the result he hoped to achieve in "Beiträge" but failed to produce, namely, proof of his continuum hypothesis, remained illusive.

## CANTOR'S MANIC DEPRESSION

Much has been written about Cantor's unfortunate history of mental illness, which some writers have linked with the heavy criticism of Cantor's transfinite set theory from Kronecker. But recent studies suggest that what Cantor suffered from was manic depression, which would have afflicted him regardless of the controversies surrounding his mathematical work (see Grattan-Guinness 1971, Dauben 1979, Charraud 1994). Whereas the earliest serious breakdown occurred in 1884, as Cantor was encountering his first disappointments in trying to prove the continuum hypothesis (for a detailed account of what happened, see Schoenflies 1927), the manic depression

became more serious as he grew older, and after 1900 he spent increasingly long periods under professional care, often at the Nervenclinic in Halle. Also, following the first attack in 1884, Cantor began to take up interests other than mathematics, including the idea that Francis Bacon was the real author of writings attributed to William Shakespeare and that Joseph of Arimathea was the natural father of Jesus. Cantor also began an extensive correspondence with Catholic theologians, and even wrote to Pope Leo XIII directly, in hopes that a correct understanding of the infinite mathematically, in terms of his transfinite set theory, would help the church avoid making any incorrect pronouncements on the subject, especially where the absolutely infinite nature of God was concerned, which Cantor took to be consistent with but wholly different from the concepts of transfinite set theory.

The mathematician Eric Temple Bell (1986) offers a Freudian analysis of Cantor's relationship with his father, whose initial opposition to Cantor's wish to become a mathematician Bell takes to be the source of his son's later mental problems; more recently, Nathalie Charraud (1994), a French psychoanalyst, examined the records of Cantor's treatment at the neurological clinic in Halle and offers a different, Lacanian assessment of the role Cantor's father played in his son's life. Equally important in understanding Cantor's tenacious defense of his controversial set theory is the role that religion played with respect to the transfinite numbers, which he took to have been communicated to him from God directly. For details of how his religious convictions and periods of manic depression may actually have played important, supportive roles in the battle to establish transfinite set theory as a fundamental part of modern mathematics, see Joseph Warren Dauben (2005).

One final aspect of Cantor's career as a mathematician deserves brief mention, because he was primarily responsible for the creation of the Deutsche Mathematiker-Vereinigung (German Mathematical Society), of which Cantor was elected its first president in 1891. He was also instrumental in promoting the idea of the first International Congresses of Mathematicians, beginning with Zürich in 1897, and then Paris in 1900 (Dauben 1979, pp. 163–165).

## THE PARADOXES OF SET THEORY

To conclude with an assessment of Cantor's significance for philosophy, he was above all responsible for making the infinite a central part of modern mathematics. From the time of the Greeks, Zeno's discovery of the paradoxes

of motion and Aristotle's opposition to the concept of completed infinities (as opposed to the potential infinite) led most mathematicians to avoid using the infinite in their work. Cantor faced the subject head-on and argued that there was nothing inherently contradictory in considering actually infinite collections of point sets or the infinite sets of integers, rational, and real numbers as unified, completed objects of thought. His contemplation of these eventually led to his development of transfinite set theory, transfinite arithmetic, and his fundamental concepts of transfinite ordinal and cardinal numbers. His greatest contribution was understanding the roles these played in establishing a proper foundation for mathematics, which he approached essentially on formalist terms. Consistency, for Cantor, was the only test a new mathematical theory needed to pass before he considered it legitimate as a subject for study and application.

When Cantor himself first realized the contradictions inherent in trying to decide the ordinal number of the set of all transfinite ordinal numbers, or the cardinality of the set of all transfinite cardinal numbers, his solution was to simply ban such "collections" from mathematics, saying they were too large to be considered legitimately as "sets." But as others like Cesare Burali-Forti and Jules Richard began to consider the antinomies of set theory, Bertrand Russell discovered a logical paradox at the heart of set theory involving the set of all sets that are not members of themselves. One solution to this dilemma was advanced by Ernst Zermelo, who sought to axiomatize set theory in such a way that the paradoxes would be excluded. Further developments along such lines were made by Russell and Alfred North Whitehead in their monumental *Principia Mathematica*; alternative axiomatizations were also advanced by Abraham Fraenkel and John von Neumann, among others.

By the end of his life, Cantor was a mathematician honored by the Royal Society with its Copley Medal for his outstanding contributions to mathematics. He was also granted an honorary degree by the University of St. Andrews (Scotland). Today, the highest award conferred by the German Mathematical Society is a medal honoring its first president, Georg Cantor.

## CAPREOLUS, JOHN

(c. 1380–1444)

John Capreolus, a French Dominican theologian, was born in Rodez. He studied at the University of Paris, receiving the magistrate in theology in 1411. Later he taught in Dominican houses of study at Toulouse and Rodez and came to be recognized as the “Leader of the Thomists” (*Princeps Thomistarum*). His chief work is *Defensiones Theologiae D. Thomae* (Defenses of the theology of St. Thomas). This is the first commentary that considers the *Summa Theologiae* more important than Thomas Aquinas’s *Commentary on the Sentences*, a view which has persisted in later Thomism. The *Defensiones* is historically useful for its information on scholastic philosophical controversies of the fourteenth century and the views of John Duns Scotus, John of Ripa, Peter Aureolus, and Durandus of Saint-Pourcain. Capreolus’ contributions to philosophy are in the field of metaphysics. On the then central question of the relation between essence and existence, he taught that they are distinguished as two different beings (an extreme real distinction) and used the terminology of Giles of Rome (*esse essentiae* and *esse existentiae*) to express his position. Capreolus regarded essences as eternal and uncreated entities, not efficiently produced by God but subject only to divine formal causality. On the other hand, he stressed the importance of existence in treating personality (divine and human), teaching that personality is the very subsistence of the act of existing (*esse actualis existentiae*, see *Defensiones*, Vol. V, pp. 105–107). Where other thinkers required some sort of formal or modal constituent of the person, Capreolus demanded nothing more than the act of existing as an intelligent individual nature. He taught that the intrinsic principle that individuates bodies is matter marked by quantity (*materia signata*), as did Thomas, but Capreolus insisted that the quantification must be actual (under definite dimensions) and not indeterminate (*Defensiones*, Vol. III, pp. 200–241).

## CARD, CLAUDIA

(1940–)

Claudia Card, an American philosopher, has published work on a wide range of philosophical topics but is best known for her contributions to ethics and feminist philosophy. Card began her academic career at Harvard University, where she received a PhD for her dissertation on theories of punishment. Currently the Emma Goldman Professor of Philosophy and Senior Fellow at the Institute for Research in Humanities, Card has been a professor of philosophy at the University of Wisconsin at Madison since 1966. Card is also an affiliate professor in women's studies, environmental studies, Jewish studies, and lesbian, gay, bisexual, and transgendered studies. Extraordinarily active in various philosophical societies, Card was named the Distinguished Woman Philosopher of the Year in 1996 by the Eastern Society for Women in Philosophy. The author of numerous scholarly books and journal articles, Card has also given a number of media interviews and served on many editorial boards. Her research interests include feminist philosophy, lesbian ethics, and evil.

Card's work is striking not just for the range of areas of philosophy to which it makes a contribution but also for the connections it draws between them. In ethics Card's work is notable for showing how questions in mainstream moral philosophy are tied to pressing political issues. In *The Unnatural Lottery: Character and Moral Luck* (1996), for example, Card defends the concept of moral luck and explores how a person's opportunity to act morally is affected by such variables as gender, race, social class, and sexual identity. Card asks about the implications of moral luck for attributions of moral responsibility and in the course of her examination discusses the problems faced by survivors of childhood sexual abuse. Another notable feature of Card's contribution to philosophy is her attraction to difficult, troubling, and important questions. Her work on moral luck falls into this category, as does her later work on evil. Card's monograph *The Atrocity Paradigm: A Theory of Evil* (2004) explores the relationship between evil and other con-

cepts/practices such as forgiveness, toleration, and hate. Card asks what distinguishes evils from ordinary wrongs. The theory of evil developed in the book is applied to such practices as war rape and violence against intimates. She also addresses the moral "gray zone," in which persons can occupy the dual role of the victim and the perpetrator of evil.

Within feminist philosophy Card argues that feminism is not a single, unified worldview, but rather a lively debate characterized by the belief that women's subordination is wrong and that one should pay close attention to women's lived experiences. She stresses the importance of enabling women to describe their experiences in their own terms and cautions against the tendency to gloss over the unique experiences of nonwhite and poor women. Card's work urges one to be alert to the dangers of internalized oppression and adaptive preferences, and, in particular, to the ways in which oppression can compromise the integrity of its victims. Under oppressive circumstances victims are often motivated to ease their burdens by collaborating with their oppressors and/or uncritically adopting oppressive practices. In such cases, she contends that the oppressed cannot elude all responsibility; bad luck, for Card, does not necessarily subvert moral culpability and she advises that "[w]e need to be alert to the dangers of becoming what we despise" (1991, p. 26).

Card believes that opposition to real evils, such as, for example, domestic violence, should be given priority to opposition to gender inequalities, such as pay equity for tenured professors. Equality feminism, she says, trivializes the feminist movement and takes attention away from the graver problems that women face. On its own, Card thinks that care ethics is ill equipped to handle real evils. She also impugns care ethics for the way in which it dichotomizes the values of justice and care. Justice, she says, is not only about impartiality and universal principles of fairness, but also about giving people what they deserve, including compassionate, caring responses such as gratitude, trust, loyalty, and forgiveness.

Rejecting the idea that there is an essential lesbian identity, Card believes that there are, nonetheless, some historical commonalities among the experiences of lesbians. In *Lesbian Choices* (1995) Card attempts to articulate a lesbian ethics, understood as a ethics that grows out of the histories and experiences of lesbians and draws on paradigms and archetypes common in lesbian culture.

## CARLYLE, THOMAS

(1795–1881)

Thomas Carlyle, the essayist, historian, and philosopher of culture, was born in Ecclefechan, Scotland, the eldest son of a stern, puritanical stonemason. There can be little doubt that the often-hysterical extravagances of Carlyle's later social doctrines had a direct emotional origin in the Calvinism of his childhood. In 1809 he became a divinity student at Edinburgh University, but he soon stopped attending the university courses and read widely on his own in modern literature. After leaving Edinburgh in 1814, he taught school, at the same time broadening his already impressive span of reading. In addition to imaginative literature and German philosophy, Carlyle's serious interests at this time extended to Voltaire and François Fénelon, as well as to the scientific works of Isaac Newton and Benjamin Franklin. A reading of Edward Gibbon in 1817 immediately precipitated Carlyle's rejection of the Bible as a historical record and gave impetus to his growing interest in history and social institutions.

Convinced that he could never become a minister, he returned to Edinburgh in 1819 and began his literary career as a freelance journalist. The next three years were the most miserable in a generally agonized life. He was unknown; he was socially, ideologically, even stylistically antipathetic to the fashionable literary world. He was also very poor, desperately lonely, and because of his irregular eating habits, almost permanently dyspeptic. Religious doubts quickly darkened into unbelief, and in 1822 he

experienced the spiritual crisis later hieroglyphically recorded in *Sartor Resartus* (1833–1834). Like the hero of *Sartor*, Diogenes Teufelsdröckh, Carlyle found a new (if decidedly secular) faith in the moral efficacy of work: "Doubt of any sort cannot be removed except by Action," extols Teufelsdröckh. Conviction is worthless until it is converted into activity, mere speculation being "endless, formless, a vortex amid vortices." Therefore, one must "Do the Duty which lies nearest thee ... Work while it is called To-day; for the Night cometh wherein no man can work." Here, in a language persuasively familiar to his readers, Carlyle expressed the chief psychotherapeutic discovery of his youth—one which was more widely disseminated in the writings of Thomas Arnold, John Ruskin, John Henry Newman, and particularly the later prophetic Carlyle himself, and was to become a leitmotif of mid-Victorian culture. Soon Carlyle found a role in which his genuine talents could emerge. His translation of Johann Wolfgang von Goethe's *Wilhelm Meister* in 1824 and his *Life of Schiller*, which was published as a book in 1825, established him as the first interpreter of German literature to the British public.

Carlyle's marriage in 1826 to Jane Baillie Welsh, an attractive, high-strung, and unusually intellectual twenty-five-year-old woman, ended his loneliness without in any way soothing the more creative ontological anxieties upon which his work depended. Carlyle's long years of isolated reading now bore fruit in a series of remarkable articles published in the *Great Reviews*.

### LITERARY CRITICISM

Carlyle's early essays, especially "Jean Paul Friedrich Richter" (1827), "The State of German Literature," "Goethe," "Burns" (1828), "Voltaire," and "Novalis" (1829), are masterpieces of literary and ideological exegesis. However, his critical method, which was uncompromisingly didactic even for its day, was much more a criticism of life than any technical analysis of words on a page; in effect, it was essentially romantic criticism. Carlyle viewed literature as a form of self-revelation and literary criticism as a heightened confrontation of personalities engaged in the quest for moral truth. He stressed the primary need for the "transposition of the critic into the author's point of vision," which is the prerequisite of all historical and biographical as well as literary studies. Like Samuel Taylor Coleridge before him, Carlyle recognized Germany as the great contemporary source of spirituality and inwardness. For Carlyle, however, Goethe rather than Immanuel Kant was Germany's spiritual leader. More than any other writer, Goethe tri-

umphed over all doubts and denials and manifested the freedom of belief and activity. In this respect Carlyle believed that there was a significant contrast to be made between Goethe and Voltaire. In the essay “Voltaire,” Carlyle argued that despite Voltaire’s intellectual adroitness, his power of rapid, perspicuous arrangement of scientific and historical data, his humanity, and his universal susceptibility of mind, his real claim to greatness was that he “gave the death-stab to modern superstition.” Such an achievement was, however, too negative: For Carlyle, Voltaire remained essentially a mocker, “the greatest of all Persifleurs,” his chief fault being a terrible lack of earnestness.

This contrast between Voltaire and Goethe—between the pragmatic values of the eighteenth century and those of a new age of belief which was, if not actually beginning, at least imminent—ran through Carlyle’s works in ever-widening applications. Moreover, it is symptomatic of the type of thinker Carlyle was that most of his later ideas were already contained embryonically in his very earliest writings (for example, in his first original publication in 1822 in the *New Edinburgh Review*, which was significantly a critique of Goethe’s *Faust*). Had he stuck to literature and written more about the English classics, Carlyle would today no doubt be placed between Coleridge and Matthew Arnold as one of the major British literary critics of his age. But his interest in literature was only a steppingstone to a more vital concern with history and social diagnosis. He never really methodologically distinguished between criticism, biography, and historical and philosophical analysis. They were all used as media through which the current *crise de conscience* was to be more clearly seen and diagnosed. In this respect Carlyle may be thought of, in his early works, as an amateurish practitioner of *Geisteswissenschaften* (or “human studies”), in roughly the sense given to that term by Wilhelm Dilthey.

### EARLY SOCIAL CRITICISM

“Signs of the Times” (1829), “On History” (1830), and particularly “Characteristics” (1831) were Carlyle’s earliest communications in the self-assumed role of Victorian prophet. The early nineteenth century, he claimed, was a mechanical age, both externally and internally, its chief symptom being an excessive self-consciousness. With its inheritance of the largely negative contributions of the Enlightenment, it was an age of inquiry and doubt rather than of meditation and faith. Outwardly, social mechanization was more prized than individual vitality. Inwardly, morality no longer sprang from belief in a tran-

scendental authority but arose out of prudential feeling grounded on mere calculation of consequences. The most grievous mistake of bourgeois liberalism was its doctrine that social welfare can be promoted solely through external politico-economic legislation, whereas, in truth, all human progress that is genuine (“dynamical”) must emerge from the moral culture of individual men. According to Carlyle, although the present time is thus out of joint, there is nevertheless strong hope for the future. History is a cyclical but progressive (perhaps spiral) unfolding of human capabilities, and borrowing freely from Johann Gottfried Herder and the Saint-Simonians, he affirmed that the modern period is the end of a critical phase. Even as the darkest hour heralds the dawn, so the springtime of organic rebirth is now at hand.

As it happened, Carlyle was not the only British subscriber to this philosophy of history in the early 1830s. J. S. Mill’s papers on “The Spirit of the Age,” which appeared in the *Examiner* for 1831, propounded very similar views. These papers, which immensely impressed Carlyle, led to the formation of his somewhat precarious friendship with Mill. Doubtless the chief obstacle for Mill was Carlyle’s blatantly authoritarian concept of morality and his notorious views on liberty and democracy, three notions that were soon to be dramatically embodied in Carlyle’s theory of the hero.

### THE HERO AND HISTORY

In the *French Revolution* (1837), Carlyle stereoscopically visualized the events between the death of Louis XV and the appointment of Napoleon Bonaparte as commander in chief of the Army of the Interior in 1795 as the accumulated result not so much of economic or social, but of moral and, in the last analysis, theological causes. The French Revolution, he sometimes seemed to suggest, was an upheaval ordained by the Creator to punish the sins of the world. Yet at the same time, and importantly for Carlyle’s anthropomorphic imagination, it was an exhibition of individual personalities (of Honoré Gabriel Riqueti, Comte de Mirabeau, Georges-Jacques Danton, Maximilien-Francois-Marie-Isidore de Robespierre, etc.) in their most intense form. “History,” he had written in 1830, “is the essence of innumerable Biographies.” Biography, which is based on insight into human personality, is the foundation of all historical inquiry; hence, the true history of an age is the biography of its great men. Carlyle’s main interest in history (as in literature) was in the moral psychology of specific individuals who seemed to him endowed with certain admirable traits of character that

he felt to be chronically lacking in the contemporary *Zeitgeist*.

The lectures he delivered in 1840, *On Heroes, Hero Worship, and the Heroic in History*, blended mythology with metaphysics to produce an image of the ideal type of individual needed as the savior of humankind. The hero can take many forms: He can be a god (Odin), a prophet (Muhammad), poet (Dante Alighieri and William Shakespeare), priest (Martin Luther and John Knox), a man of letters (Samuel Johnson, Jean-Jacques Rousseau, Robert Burns), or a political ruler (Oliver Cromwell and Napoleon). In fact the hero can be “what you will, according to the kind of world he finds himself born into”: His ever-varying persona results from the deeper needs of society. He is directed not by the “mechanical” needs of men, but by their “dynamical,” unseen, mystical needs. Thus, all heroes have discerned “truly what the time wanted” and have led it “on the right road thither.” In this sense, the hero is a gift from heaven, or as Carlyle otherwise puts it, a force of nature; his essential quality is “Original Insight” into the “primal reality of things.” Because of the hero’s firm contact with the “great Fact of Existence,” he cannot lie. “He is heartily in *earnest*”; an unconscious sincerity emanates from him turning his acts or utterances into “a kind of ‘revelation’” which the ordinary, unheroic man is morally obliged to recognize and obey. For “all that is *right* includes itself in this of cooperating with the real tendency of the World.” Indeed, the proper feelings of ordinary men toward the heroes of their age are loyalty (which is “akin to religious Faith”), reverence, admiration, and “an obedience which knows no bounds.” Hero worship, Carlyle significantly concludes, is a basic and indestructible tendency of human nature: It is “the one fixed point in modern revolutionary history, otherwise as if bottomless and shoreless.”

As with Friedrich Nietzsche’s *Übermensch*, there was a tendency in the twentieth century to view Carlyle’s theory of the hero far too much in terms of contemporary political experience—that is, to think of the hero as a direct ancestor of fascism. But Carlyle, like Nietzsche, was essentially a philosopher of culture, not a political theorist. The hero concept is best understood as a rather curious and obsessional example of a spiritual phenomenon that reached something of a climax in the nineteenth century, most notably in the thought of Ludwig Feuerbach, Auguste Comte, Karl Marx, and Nietzsche—namely, the uneasy substitution of purely secular objects of veneration for the traditional transcendental one. Worship of God gave way to worship of man and human society.

## AFTER 1840

Beginning with *Chartism* (1839), and more disastrously in *Past and Present* (1843) and the *Latterday Pamphlets* (1850), Carlyle explicitly incorporated the hero concept within the central tenets of his early social criticism to produce not only a renewed attack upon the materialistic spirit of industrial society but also an indictment of political liberty and democracy. Once more he protested against laissez-faire, the irresponsible pursuit of wealth in which “cash payment” has become the “sole nexus” between men, thus displacing the traditional ties of obligation. But social justice, he now paradoxically asserted, can be achieved only through the enforcement of social inequality. Members of the aristocracy and those heroes of the business world, the “Captains of Industry,” must assume their responsibilities as rulers of the masses: Freedom consists in “the right of the ignorant man to be guided by the wiser.” In this instance, as in nearly all of Carlyle’s writing after about 1840, it seems that genuine social criticism was lost sight of in an increasingly pathological obsession with power: Nothing could have been further from the spirit of Mill’s *On Liberty* (1859) and *Representative Government* (1861). In *Oliver Cromwell’s Letters and Speeches, with Elucidations* (1845) and the *History of Frederick the Great* (1858–1865), Carlyle tried to give some historical backing to his by now hopeless moral aberrations for which he ultimately received the Prussian Order of Merit in 1874.

It is impossible to exaggerate Carlyle’s impact, for better and worse, upon all aspects of Victorian culture, ranging from the development of the novel (particularly as evidenced in the work of Charles Dickens), to the formation of social policy. Nietzsche described him as a man constantly misled by a craving for a strong faith that he lacked the necessary capacity to experience. But it was hardly the capacity Carlyle lacked; rather, like Nietzsche himself, he needed something to have faith in. In the absence of his father’s God, he chose what seemed to him the best substitute—the hero.

## Bibliography

### WORKS BY CARLYLE

The Centenary Edition, edited by H. D. Trail, 30 vols. (London, 1896–1899; New York, 1896–1901) is the most complete edition of Carlyle's *Works*. Carlyle's correspondence, most notably with Goethe, Ralph Waldo Emerson, Mill, and John Stirling, is essential reading for anyone interested in Carlyle's thought or, indeed, in nineteenth-century intellectual history in general. See also *Correspondence of Emerson and Carlyle*, edited by J. Slater (New York: Columbia University Press, 1964).

### WORKS ON CARLYLE

To date there exists no full-scale analysis of the whole range of Carlyle's thought. The best short account is given by Ernst Cassirer in *The Myth of the State* (New Haven, CT: Yale University Press, 1946), Chs. 15–16. J. A. Froude, *Thomas Carlyle 1795–1835*, 2 vols. (London: Longmans Green, 1882) and *Thomas Carlyle 1834–1881*, 2 vols. (London: Longmans Green, 1884) are still indispensable. Among the many important specialized studies are B. H. Lehmann, *Carlyle's Theory of the Hero* (Durham, NC: Duke University Press, 1928); C. F. Harrold, *Carlyle and German Thought: 1819–1834* (New Haven, CT: Yale University Press, 1934); René Wellek, "Carlyle and the Philosophy of History," *Philological Quarterly* 23 (1944): 55–76; and G. Holloway, *The Victorian Sage* (London: Macmillan, 1953), Chs. 1–3.

## CARNAP, RUDOLF

(1891–1970)

Rudolf Carnap was the philosophically most articulate member of the Vienna Circle in the 1920s and 1930s, and later of the movement that came to be known in the United States as logical empiricism. During his lifetime, he was respected among analytic philosophers as the proponent of a number of ambitious language projects, especially, in his later years, a system of inductive logic. The philosophical agenda underlying these technical projects, however, remained largely implicit; only disconnected fragments of this agenda, often reduced to superficial slogans, gained some currency. Subsequent generations,

quite reasonably, discarded these fragments with some contempt. The coherent and powerful view that Carnap actually held (and partly articulated), of which the ambitious technical projects were manifestations and illustrations, but not explicit statements, has only begun to be unearthed. As a result, the view of Carnap held during his lifetime and since his death is under revision.

### INFLUENCES AND EARLY AMBITIONS

Carnap was born on May 18, 1891, in the German town of Wuppertal. At this time the region ("Bergisches Land") was known for its pietistical, even mystical, brand of Lutheranism, and the Carnap family was strongly imbued with this local tradition. Carnap's mother's family was more intellectual, in the German tradition of *Bildung*. Carnap's grandfather, Friedrich Wilhelm Dörpfeld, was a leading educational thinker and writer who championed the ideals of Johann Friedrich Herbart. When Carnap was eight, his father died. His mother taught him and his sister at home, following her father's educational program. Teaching was restricted to one hour a day, and the children were encouraged to work out the implications of what they had learned for themselves. His mother also emphasized the arbitrary nature of moral and linguistic conventions.

Carnap's mother was evidently the strongest influence on Carnap's early mental development. In many ways this influence probably derived from the religious and educational views of her father, of whom she wrote a biography. She was herself a highly literate person, at home in the German classics, who took a particular interest in the philosophical and religious writings of Theodor Gustav Fechner, the founder of psychophysics. When Carnap began to doubt the religious doctrines he had been brought up with, he turned first to Fechner's mystical pantheism as a more explicit and detailed version of the worldview embodied in the writings of Johann Wolfgang von Goethe. The ethical and practical convictions associated with the religion of his childhood never changed. Though he abandoned it, first for pantheism, then for atheism, this change was very gradual and took a long time. And it was an entirely doctrinal change; it did not affect his values. The pragmatist streak in educational Herbartianism allowed room for the replacement of its religious props by a scientific humanism of the kind Carnap imbibed from the popular writings of Hermann von Helmholtz, Ernst Haeckel, Wilhelm Ostwald, and others.

Ostwald in particular appears to have been an important early influence. A Nobel Prize-winning chemist, he had sketched in his popular writings a consis-

tent and comprehensive worldview firmly anchored in the nineteenth-century positivist tradition of Auguste Comte and Ernst Mach. His wide-ranging interests also encompassed the German classics, the history of science, visual art, politics, and much else. He was perhaps the archetypal embodiment, during the first decade or so of the new century, of a thoroughly and uncompromisingly “scientific worldview.” He was unusually cosmopolitan for a German of his generation and had traveled widely, including to the United States, where he was instrumental in establishing physical chemistry as a discipline.

Carnap advocated pacifism and internationalism, and campaigned for the use of an international language such as Esperanto, both among scientists and more widely. Many of these aspects appealed to Carnap; he even became an Esperantist in his teens, while still at school. He was especially influenced by Ostwald’s conception of a “system of science” (*System der Wissenschaft*), modeled on Comte’s system of unified science. In this conception, there was no fundamental distinction between human and physical sciences, of the kind that the German idealists and neo-Kantians had advocated. All knowledge was part of a single system, whose basic concepts were those of physics. This system was needed as a blueprint, Ostwald thought, for optimizing the hitherto rather aimless and chaotic output of the scientific disciplines; it would give them coherence and enable them to cooperate.

When Carnap studied at the University of Jena, from 1909, he encountered Gottlob Frege and learned modern logic from him. Though he did not immediately see the wider philosophical applications of Frege’s logic, he was enthused by Frege’s Leibnizian ideal of a universal language that could tie all knowledge together and display its deductive interrelations. Comte and Ostwald, like other nineteenth-century positivists, had been vague about the precise nature of the relations among the various sciences in their proposed “system of science.” In Frege’s logic, Carnap saw a tool for making these relations completely transparent and explicit, and making the “system of science” into something much more than a vague ideal. Logic could serve as a central discipline for bringing order to the rather chaotic and spontaneous growth of knowledge. This “system of science” could thus be a tool for coordinating and *organizing* knowledge-production on a large scale, in just the way Ostwald had envisaged.

But Jena also subjected Carnap to a quite different kind of influence, one much more at odds with anything in his background up to that time: the German Youth Movement (*Jugendbewegung*). This was a Romantic,

back-to-nature rebellion of middle-class German teenagers against the materialistic and socially complacent values of their parents. There was a strong emphasis on a healthy life, especially long walks in the wilderness and avoidance of the “bourgeois” drugs (alcohol, tobacco, caffeine), as well as an idealization of peasant life and the customs of premodern times. The movement took many different local forms. In Jena, the publisher Eugen Diederichs organized the “Sera Circle,” a group of university students and other young people who undertook outings with elaborate, medieval-style costumes and rituals, some improvised and some traditional. The annual midsummer celebration was a high point, when the group, with its banners, costumes, and pageantry walked in procession to a mountain some distance from town, accompanied by horse-drawn carriages. There they built a bonfire, danced, feasted, sang, and jumped over the flames two by two until sunrise. In the years just before the First World War, Carnap became very active in organizing these and similar events.

For Carnap, the lasting effect of this involvement was to give him the sense that the basic forms of human life are within human control; they do not have to be accepted from tradition or from existing conventions. This attitude of “voluntarism” would prove to be of fundamental importance to Carnap’s philosophy through all its phases. And though the Youth Movement “did not leave any externally visible achievements,” Carnap later wrote, “the spirit that lived in this movement, which was like a religion without dogmas, remained a precious inheritance for everyone who had the good luck to take an active part in it. What remained was more than a mere reminiscence of an enjoyable time; it was rather an indestructible living strength which forever would influence one’s reactions to all practical problems of life” (Carnap 1956/7, pp. B34–B35). Moreover, it was something he missed throughout his subsequent life:

After the war ... the same spirit was still alive in the life of my newly founded family and in the relationships with friends. When I went to Vienna, however, the situation was different. I still preserved the same spirit in my personal attitude, but I missed it painfully in the social life with others. None of the members of the Vienna Circle had taken part in the Youth Movement, and I did not feel myself strong and productive enough to transform single-handedly the group of friends into a living community, sharing the style of life which I wanted. Although I was able to play a leading role in the

philosophical work of the group, I was unable to fulfill the task of a missionary or a prophet. Thus I often felt as perhaps a man might feel who has lived in a strongly religious [and] inspired community and then suddenly finds himself isolated in the Diaspora and feels himself not strong enough to convert the heathen. The same feeling I had in a still greater measure later in America, where the power of traditional social conventions is much stronger than it was in Vienna and where also the number of those who have at least sensed some dissatisfaction with the traditional forms of life is smaller than anywhere on the European continent. (Carnap 1956/7, p. B35)

Into this idyllic dawn of a new world erupted the unheralded disaster of August 1914 and the Great War. Carnap and his Sera friends dutifully enlisted and were not even unwilling combatants, at first. Only when they witnessed the scale of the slaughter did doubts arise. Like Wittgenstein on the eastern front, Carnap participated in many of the bloodiest engagements on the western front. Both young philosophers were profoundly alienated by the culture of the officer corps. Both were wounded and were decorated for bravery. But their reactions could not have been more different. Wittgenstein withdrew into an inner life of mystical contemplation, inspired by Leo Tolstoy. Carnap, in contrast, came to appreciate that it was precisely an over-emphasis on the contemplative life, and a lack of interest in public life, that had made the German intelligentsia complicit in the bloodshed, and had allowed it to stand idly by while the political elites had started a world war. The only answer, he now decided, was active involvement in politics. Accordingly, he joined the anti-war independent socialist party, sent clandestine circular letters to friends with excerpts from the foreign press, and wrote well-informed articles about world government for underground newsletters.

The general conception behind this new commitment was a natural extension of the positivist idea of a “system of science” inherited from Comte and Ostwald, combined with the voluntarism Carnap derived from the Youth Movement. For the human race to survive and avoid disasters like the Great War, Carnap thought, it needed to take its fate into its own hand. Conflicts among nations and classes could not be left to an anarchic state of nature, but had to be subordinated to consciously chosen forms of civic cohabitation. These, of course, required highest-level conceptual planning and organization of knowledge; this too was part of the “politics” Carnap now

regarded himself as involved in. For all the various social functions to work together, it was essential to arrive at a “structure of community” (*Gemeinschaftsgestalt*) that could serve to coordinate them so as “to remove [these tasks] from the realm of chaotic whim and subordinate them to goal-oriented reason” (Carnap 1918, p. 18).

Carnap’s intention immediately after the war was to realize this ambition through teaching and direct political involvement. Before the war he had intended to become a physicist; now his first priority was to obtain the teaching certificate for secondary schools. The papers he wrote to qualify for the certificate show him at work, both within physics itself and in philosophical reflection about the foundations of geometry, on the construction of an Ostwaldian-Comtean “system of science” with Fregean logicist tools. In the course of these projects, he evidently came to realize that his vision of a “system of science” was anything but obvious. Though there had been much talk, among positivists (like Mach) and some systematic philosophers (like Richard Avenarius) of the reducibility of all knowledge to an empirical starting point, much work was still to be done. Like Comte in response to an earlier revolution, Carnap now realized that the reconstruction of society along the lines he had in mind, with its *Gemeinschaftsgestalt* to coordinate all productive activities within it, required the reconstruction of *knowledge* as the first and indispensable step. Though social reform could go ahead meanwhile, it could not be put on a genuinely rational basis until a “system of science” was developed, a conceptual system that was adequate to the scientific and conceptual revolutions of the past decades *and* that afforded a vantage point from which the whole of knowledge could be surveyed and organized, allowing individual claims or theories to be rationally judged. It was to the development of such a conceptual system that Carnap now single-mindedly devoted himself.

## EARLY WRITINGS AND PROJECTS

This change in priorities also brought with it a change in career plans. Carnap now decided to pursue an academic career after all, but was faced with the quandary that the kind of work he planned fell between academic stools. The first project he chose for a dissertation topic was, like his 1920 paper on space and geometry, intended to work out a partial “system of science” for a subrealm of knowledge. This time it was to be an axiomatization of relativistic space-time kinematics, and the question Carnap particularly had in mind was much discussed then: Precisely what is the *empirical content* of general relativity, and precisely what parts of it were conventional? Even

before the war, Carnap had read Henri Poincaré. Now he also encountered the “radical conventionalist” Hugo Dinger, who rejected relativity on the Poincaréan grounds that all the observations involved could be accommodated without giving up Euclidean geometry, whose axioms are much simpler. Carnap disagreed; the simplicity of the system as a whole should be maximized, he said, not just the simplicity of the axioms, though he admitted that this was itself a conventional decision.

However, his proposed project was rejected by the physics department in Jena as too philosophical, and the philosophers thought it was too scientific. So instead, he reworked his 1920 paper on space and geometry, and this was accepted. The result was Carnap’s doctoral dissertation and first philosophical publication, *Der Raum* (Space; 1922). Here too the central question was the status of the empirical basis (*Tatbestand*) within our conceptions of space. The answer, Carnap said, depends on whether we have mathematical, intuitive, or physical space in mind. Formal or mathematical space, Carnap said, can be constructed from logic alone, in the way Bertrand Russell had suggested in *Principles of Mathematics*, and so it has no empirical content. Intuitive space is not constructed in this logicist way, but derives from axioms based on a pure phenomenological essence-perception (*Wesensschau*) of our spatial experience. These axioms concern not the metrical properties of space, as Immanuel Kant had thought, but only its topological properties. Physical space, finally, adds the empirical basis, which, however, as Carnap argued with the aid of an extended example, underdetermines the choice of metrical geometry (it fixes the choice only up to topological assumptions).

During this period, Carnap framed the basic epistemological questions in terms of an “idealistic conception” deriving from the “positivist idealism” of Hans Vaihinger, a neo-Kantian philosopher whose book *The Philosophy of As If* had generated a great deal of discussion after its publication in 1911. Vaihinger took an extreme positivist view of what we actually know: It is only the “chaos” of our immediately present sensations that we can rely on for certain. The “reality” we construct on this basis, whether in science or in everyday life, is not genuine knowledge but a tissue of useful *fictions* that we purposefully invent to get things done in the world and to serve our mental and social needs. These fictions include not just Kant’s synthetic a priori propositions (the axioms of arithmetic, geometry, and mechanics, as well as the principles of causality and of the uniformity of nature), but also, for example, the fictions of religion, of natural jus-

tice and equal citizenship, of free will and moral reasons. This was essentially a pragmatist position, as Vaihinger himself recognized, though he thought William James wrong to make utility a *standard* of truth. There is genuine truth, Vaihinger maintained, however limited in scope, while the fictions, though useful, are *not* true. They are to be judged by practical results, not by cognitive standards.

Carnap sought to pursue his dream of a system of knowledge within the framework of such an “idealistic conception.” He tried various ways of *deducing* aspects of physical “reality” from the “chaos” of experience, even using a makeshift fuzzy logic at one point, but these efforts led nowhere. It seemed impossible to break out of the phenomenal “chaos” convincingly. But amidst all his other projects, the preoccupation with this overall system did not let him go. “I worked on many special problems, always looking for new approaches and improved solutions,” Carnap wrote of this period “But in the background there was always the ultimate aim of the total system of all concepts. I believed that it should be possible, in principle, to give a logical reconstruction of the total system of the world as we know it” (Carnap 1956/7, p. E4).

## THE AUFBAU PROJECT AND VIENNA

In the winter of 1921/1922 Carnap read a book that showed him how to overcome the main obstacle to his project of a “total system of all concepts,” Russell’s *Our Knowledge of the External World as a Field for Scientific Method in Philosophy*. This book gave Carnap the crucial hint that the way to get from the chaos of experience to a “reality” was not by *analysis* of experience, but by *construction*, using what Russell called a “principle of abstraction”: “When a group of objects have that kind of similarity which we are inclined to attribute to possession of a common quality, the principle [of abstraction] shows that membership of the group will serve all the purposes of the supposed common quality, and that therefore, unless some common quality is actually known, the group or class of similar objects may be used to replace the common quality, which need not be assumed to exist” (Russell, pp. 44–45). Experiences could be gathered into equivalence classes. For example, a series of experiences of “red,” at a certain position in the visual field, could be defined as equivalent. For the purposes of constructing a “real” world, this class can be regarded as an object and used in place of the quality. No actual quality, transcending momentary experience, need figure in subsequent steps to a “reality.” The evanescence of “chaotic” experi-

ence is no longer a constraint. The problem of forcing the fluid character of lived experience into the straightjacket of deductive relations disappears.

Russell's principle also solved another problem. According to Vaihinger, the "chaos" of subjective experience has no structure; nothing is "given" but the undifferentiated chaos itself. No distinguishable "elements" present themselves as naturally discrete or isolable from the chaos, available unambiguously in themselves, without calling on externally imposed fictions. A somewhat less extreme version of this holistic starting point had just been articulated by a new school of "Gestalt" psychologists. Russell's principle of abstraction—his method of substituting "logical constructions for inferred entities" (such as qualities)—solved this problem as well. Instead of trying to isolate specific elements within the undifferentiated "chaos," Carnap could obtain the elements he sought by partitioning the entire "chaos" into just two sectors, which he called the "living" and "dead" parts of experience, corresponding essentially to David Hume's "impressions" and "ideas." This one distinction allowed Carnap to arrange experiences into a temporal sequence ("ideas" belong to the past; "impressions" are present), and thus made it possible to identify holistic "temporal cross-sections" of experience, in which the total experience of a given specious present remains intact as a momentary whole.

This chronological sequence of experiential time slices gave Carnap the basic framework he needed for identifying qualities as cross-temporal equivalence classes of particular aspects within certain time slices. The holistic time-slices of experience did not need to be *analyzed*. Rather, qualities and qualitative relations could be *constructed* by defining equivalence classes of sufficiently "similar" experience aspects (e.g., approximations to "red" at certain coordinates of the visual field) across a series of time slices. ("Similarity" could be defined as precisely as needed.) The result of this procedure—with "quality classes" standing in for qualities, and so on—was therefore essentially what empiricists (like Hume, John Stuart Mill, and Mach) had always hoped to achieve by analysis, but it was accomplished *without* analysis. Carnap called it "quasi-analysis." Once qualities had been constructed, physical objects could be constructed as classes of spatial relations among qualities, and the path to a "reality" was clear.

Carnap still followed Vaihinger in distinguishing sharply between the direct, genuine, first-hand knowledge of the "chaos" and the fictive, constructed nature of "reality." But he put the boundary between them in a dif-

ferent place. Phenomenology, Carnap thought, offered an escape route from Vaihinger's completely undifferentiated chaos. It gave certain basic distinctions *within* the chaos (such as that between "living" and "dead" experience) a degree of objectivity. These distinctions, then, were *not* "fictional" but actually extended the range of what could be genuinely *known*, even *without* fictions, just from the "chaos" itself. So Carnap put the boundary between the "chaos" and the fictions further out than Vaihinger had done. But fictions were still needed to get from this immediately known *primary world* (of "chaos" supplied with a minimal, phenomenologically justified structure) to a fictive *secondary world* of "reality"—be it the everyday world of physical objects and forces, the abstract scientific world of fields and space-time coincidences, or some other construction.

Carnap thought at this point that he could show on phenomenological grounds that the primary world was two-dimensional, in all sense modalities. So the stepping-off point from the fixed primary world up to a freely choosable secondary world was located at the point of ascent from two to three dimensions. Within the primary world, the construction proceeded entirely by explicit definition, beginning from the qualities obtained by quasi-analysis. Secondary worlds are not uniquely determined by the one given primary world, so the construction of a secondary world proceeds by optimizing its "fit" to whichever fictions are chosen to guide the construction, subject to the constraint of the primary world.

Regarding the choice among fictions to guide this ascent, Carnap remained as radically pragmatist as Vaihinger. The choice of fictions was entirely a matter of what was practically useful for some purpose. To obtain the scientific secondary world, Carnap suggested, we need adopt only two fictions, corresponding roughly to Kant's categories of cause and substance: (1) a principle of induction or uniformity of nature and (2) a principle of "continuity" (as Mach had called it), the principle that a certain cluster of perceptions grouped into a physical object, say, remains constant while we are not perceiving it if it remains sufficiently similar (by defined standards) before and after the interruption.

It seemed then that the problems facing Carnap's dream of a "total system of all concepts" had been overcome. He could now go public with his grand plan to revolutionize the conceptual framework of knowledge. He immediately wrote up a sketch of the new "total system of all concepts" that he gave the Vaihinger-inspired title *Vom Chaos zur Wirklichkeit* (From the chaos to reality). He organized a conference for the following year (1923) to

discuss it—the first conference of “scientific philosophy.” The participants, who previously had each been working alone, became a like-minded community. Carnap also talked to Hans Reichenbach and others about starting a new journal to propagate the new ethos. The program of “conceptual politics” was well under way.

Carnap continued to work on his “total system of concepts” and in 1928 published *Der logische Aufbau der Welt* (*The Logical Construction of the World*), which became the programmatic bible of the Vienna Circle (Carnap had joined it in 1926, when he became a junior lecturer at the University of Vienna). The *Aufbau* exemplified the Vienna Circle’s goal of “rational reconstruction,” the replacement of vague, informal concepts by precise ones defined within a standard logical language in which all of knowledge could be expressed. The concept rationally reconstructed in the *Aufbau* was that of “empirical content” (or “empirical meaning”), which had long been of central importance for empiricists but had never been made logically precise.

Though the germ of the *Aufbau* is already contained in “From the Chaos to Reality,” there were also some important changes. In the 1922 system, three components had worked somewhat uneasily together: (1) the *basis* of momentary time-slices of total experience, distilled from a chaotic primary world by phenomenological reflection; (2) the *fictions* that guided the construction of a secondary world from the primary world; and (3) the *logic* that connected the constructional steps. As Carnap worked on the system after 1922, these three parts came to seem less compatible with each other. Though he had greatly reduced the number of fictions from Vaihinger’s heterogeneous jumble, the two he had chosen still seemed somewhat ad hoc. And phenomenological reflection, though also a kind of “thought,” did not operate mechanically, without mental assistance, as the logical system of Frege and Russell did. Logic and phenomenology seemed to be fundamentally different kinds of constructional procedure that could not be reduced to each other. If Carnap was to take seriously Russell’s dictum that “logic gives the method of research,” then everything that *could* be done by logic alone *had* to be done by logic alone. Accordingly, by 1925 Carnap gave up the distinction between “primary” and “secondary” worlds (between a single determinate “given” reality and optional constructed “realities”). Instead, he extended the logical construction *downwards* as far as possible to perform the tasks that had previously been left to phenomenology.

This displacement of phenomenology by logic led Carnap to minimize the number of relations required for

the construction. By 1925 the number of basic relations had been reduced to five, and in the published *Aufbau* there is only a *single* basic relation—that of “remembered similarity” of qualitative aspects across temporal slices of experience. Indeed, the imperative to eliminate the subjective element altogether and make the construction *entirely* logical led Carnap to the extreme of suggesting that even this one remaining basic relation might be eliminated if we define it “implicitly,” that is, define it simply as “whatever basic relation leads to our existing body of scientific knowledge” (1928/2003, sec. 153).

Carnap did not, however, give up Vaihinger’s pragmatist orientation. To make the fictions of cause and substance that guided the construction less ad hoc, Carnap suggested that they could be deduced from some “highest principle of constitution,” which might in turn be deducible from “whatever it is that knowledge contributes to the more comprehensive context of life purposes” (1928/2003, sec. 105). And he emphasized that the *Aufbau* construction was not the only possible one, but that quite different approaches might be appropriate for different purposes.

The *Aufbau* construction gave the Vienna Circle a standard by which to judge any statement and determine whether it has meaning. Carnap gave a popular lecture around this time in which he depicted human intellectual history since the Greeks as a struggle between “critical intellect” and “poetic imagination.” In the ancient world, he said, critical intellect had dealt poetic imagination a major blow with its concept of a single, all-encompassing physical space. In response to any mythical creature or entity the imagination might dream up, critical intellect could now ask, “Where is it located in space?” or, “Tell me exactly how I can get there from here.” Imagination took to hiding its goblins and spirits in remote, inaccessible places, but this was only a stopgap. Eventually, imagination struck back more forcefully by inventing *metaphysics*. It hit on the idea of a *nonmaterial* God and other nonmaterial entities. This was plausible, Carnap explained, because we often refer, quite legitimately, to nonmaterial items like numbers, relations, and so on. Many thinking people were taken in. But now, he said, critical intellect has found a tool to combat this maneuver. Just as the ancients had hit upon the idea of an all-encompassing *physical* space, so now we, here in Vienna, have developed a single, all-encompassing *conceptual* space: the *Aufbau* system. This system puts the burden on the poetic imagination to specify exactly how to get to any supposed non-material entity from “here”—from my own immediate experience. This was how the *Aufbau* sys-

tem provided the basis for the Vienna Circle's campaign against metaphysics and traditional obscurantism, and exemplified the circle's project of "rational reconstruction"—the piecemeal replacement of traditional, vague concepts by more precise and useful ones.

## WITTGENSTEIN

When Carnap went to Vienna in 1926, the *Aufbau* was substantially complete. He assumed that its construction of physical objects and theoretical entities would all be of a piece, so that concrete and theoretical objects could also be cashed out again in terms of subjective experience. In 1926 he published the booklet *Physikalische Begriffsbildung* (Physical concept formation), in which he argued for the completely seamless intertranslatability of subjective experiences and the sets of 14-tuples of numbers in which, he said, the world could, against a set of background theories, be exhaustively described.

But on arriving in Vienna, Carnap was confronted with a new influence that disrupted this harmony. The Vienna Circle was just in the process of reading Wittgenstein's *Tractatus Logico-Philosophicus* line by line, and Carnap came to share their appreciation of it. The *Tractatus* solved what historically had been the severest problem for empiricism: its inability to account for mathematics. Frege's critique of empiricist efforts (by Mill, for instance) to found arithmetic on empirical generalizations had convinced members of the circle that a different approach was needed. But they also rejected Frege's and Russell's view that logic and mathematics were essentially like laws of nature, only of much greater generality, governing *everything*. Wittgenstein argued, rather, that logic and mathematics are about *nothing*; they are empty. They convey no information about the world, as they are "tautological" artifacts of the language itself and neither make nor exclude any assertions about anything that is or is not the case.

What gives a sentence meaning, Wittgenstein said, is that it is a logical "picture" of a fact. So all meaningful sentences have to be built up out of "atomic" sentences, picturing simplest facts, by truth-functional connectives. Since the number of observation sentences supporting a physical law can only ever be finite, this meant, to the Vienna Circle, that a *universal* law cannot, strictly speaking, have meaning. So in Wittgenstein's framework, a law could be nothing more than the body of evidence for it. This made theoretical science as it had been done for the past few centuries impossible, and it broke the seamless continuity Carnap had previously assumed between subjective experience and theoretical concepts. This was

bad enough, but Wittgenstein's conception of meaning raised another problem for the circle. The very sentences expressing that conception fell victim to their own consequences. Wittgenstein confirmed this in the final sentences of the *Tractatus*, where he declared his own book meaningless. So although the Vienna Circle regarded the *Tractatus* as indispensable, they also realized that to do the job they relied on it to do, its conception of language would somehow have to be expanded to admit physical laws and metalinguistic "elucidations."

Carnap's first task, in this project, was an attempt to fit *axiomatic* concepts within Wittgenstein's constraints. During his first few years in Vienna, this was his main focus; he worked until 1930 on a large manuscript called *Untersuchungen zur allgemeinen Axiomatik* (Investigations in general axiomatics). Its main point was to show that David Hilbert's use of a "metamathematics" to prove the consistency of merely formal axiom systems, of which most mathematics consists, was ultimately not essential, but that only a single basic language would suffice. In the *Axiomatics*, Carnap takes a "foundation system" of logic, arithmetic, and set theory as the starting point, and stipulates that all axiom systems must be expressed in it; they derive their meaning from being anchored in this absolute system. Where does this "foundation system" itself come from? Carnap gave a preliminary answer in a sketch entitled "Neue Grundlegung der Logik" (New foundation of logic), where he tried to expand the repertoire of what can be regarded as meaningful (and tautological) within Wittgenstein's picture theory by experimenting with arbitrarily long truth tables.

All this effort came to naught in early 1930 when Alfred Tarski visited the Vienna Circle. In private conversations, he convinced Carnap that the single-language approach of the *Axiomatics* did not really capture the metamathematical concepts that Carnap had wanted to account for in a single language. Later that year a young student of Carnap's, Kurt Gödel, showed that arithmetic was incomplete—that it contained sentences that, although true, could not be proved from its axioms. This contradicted one of the central theorems Carnap had arrived at in his *Axiomatics*.

By the end of 1930, then, the program of rational reconstruction had run aground. The efforts to expand Wittgenstein's restrictive conception of language to allow universal laws and axiomatic mathematics had come to nothing. And much of the damage had been done by mathematicians like Alfred Tarski and Kurt Gödel, who were using metalanguages in very precise ways, appar-

ently flouting Wittgenstein's claim that it was impossible to speak about language *in* language. Could the Vienna Circle's program somehow be rescued?

## SYNTAX

On January 21, 1931, Carnap came down with a bad flu. He hardly slept that night. As he lay awake an idea came to him, in a flash, that solved all his problems. The Wittgensteinian conception of meaning went overboard. We can forget about meaning, he realized, at least in our statements *about* the scientific language—our metalinguistic “elucidations.” Though the scientific language itself had empirical meaning (in a way that remained to be clarified—this became the subject of the “protocol sentence debate”), in our elucidations of it we are not talking about anything extralinguistic; we are talking *always and only about language*. In these metalinguistic elucidations, we must be careful not to talk about “facts” or about “things,” but always confine ourselves to talking rather about “sentences” or “thing names.” As Carnap would soon put it, we should in principle restrict ourselves to the “formal mode of speech” (sentences and names) and indulge in the “material mode of speech” (facts and things) only if we are sure we can translate our statements into the formal mode. Carnap adopted the metalinguistic viewpoint of Hilbert, Tarski, and Gödel, and applied this hitherto purely mathematical method to the whole of knowledge. Philosophy itself was to be reconstructed in the formal mode of speech. What remained of philosophy was the metalinguistic “logic of science” (*Wissenschaftslogik*) that could be expressed in the formal mode.

Carnap immediately threw himself into creating the language for the formal mode of speech. Taking his cue from Hilbert's metamathematics, Carnap sought to strip this standard metalanguage of all problematic assumptions. It would consist simply of strings of dots on a page, and the basic laws of arithmetic would arise unambiguously in the metalanguage from the immediately evident patterns of dots (the commutative law, for instance, is immediately evident from the perceptible equivalence of the number of dots counted from the left and from the right). A few months later, when he was preparing to present his new ideas to the Vienna Circle in June of 1931, Carnap found that he could not express certain essential concepts in this limited language, and turned instead to a more usual axiomatized arithmetic. This also had the advantage that, by using Gödel's trick of arithmetizing syntax, Carnap could now express the syntax of the language (its logic) in the language itself. So the syntactic

metalanguage collapses into its object language, and there is after all only one language again.

Though some details still needed working out, Carnap was convinced he had what he needed: a canonical language for the formal mode of speech. This gave him a new and different way of eliminating metaphysics, superceding the previous, Wittgensteinian way. The previous criterion had been a criterion for *meaning*. The new criterion was not. It required that any statement either be straightforwardly factual or be translatable into the formal mode of speech. In other words, an acceptable sentence had to be statable in a “correct” language—the canonical language or an equivalent. Assuming that the kinks in his canonical language could be ironed out, Carnap thought it would be capable of expressing the entire language of physics, as well as its own syntax in a sublanguage. Since the Vienna Circle's “unity-of-science” program held that all knowledge was expressible in the language of physics, Carnap put his canonical language forward as a *universal* language (though not as *the* universal language) for all knowledge. So another way of putting the new criterion was this: An acceptable statement must be expressible in the language of physics. The new ideas of January 1931 flowed into the stream of Carnap's discussions in the circle, particularly with Otto Neurath, to produce this new doctrine of *physicalism*.

But the demands on the “correct” language were exorbitant. Though Carnap had wanted to keep it weak and uncontroversial, it also had to be capable of expressing all the mathematics needed for physics. On the other hand, its arithmetized syntax had to be capable of expressing the basic concept of “analytic truth,” or there would be no way of saying whether a formal-mode statement “holds.” Gödel had shown that provability was not a sufficient criterion for mathematical or logical truth; there are true sentences that are not provable. So a different criterion was needed, one that would identify the logically true sentences solely by means of the formation and transformation rules of the language. Carnap did attempt such a criterion for “analyticity” in the first draft of his syntax book *Logische Syntax der Sprache* (*Logical Syntax of Language*), written between late 1931 and the spring of 1932. He sent the typescript to Gödel, who pointed out that the new criterion was defective, and that it is *impossible* to give a correct definition of analyticity or logical truth in *any* metalanguage that can be faithfully represented in the object language (e.g., by arithmetization). (This is the indefinability of truth we now associate with Tarski.) So it turns out that Carnap's single-language approach will not work after all.

But although Carnap, with Gödel's assistance, would later develop a new definition of analyticity, in a metalanguage, this definition no longer enjoyed the privileged status that one in the *same language* (had it been possible) could have claimed. And indeed, there is no basis for singling out any particular metalanguage as more "suitable" or "natural" than any other. One option may turn out to be more *useful* than another, but there is no basis for privileging one of the many possible candidates as "correct." So the new definition of analyticity hardly seemed to matter any more. Carnap was more impressed with the *language relativity* of any definition of truth or analyticity. The disputes about protocol sentences within the circle merged in his mind with the disputes among intuitionists, logicists, and formalists in the philosophy of mathematics. All these disputes, it suddenly seemed to him in October 1932, really just revolved around the question how to set up the *language*, and there was no right or wrong answer to such questions. He no longer saw any basis for choosing one solution as "correct." One could only try out different ways and see which ones worked better. This new attitude, which completed Carnap's "linguistic turn" and first appeared in his reply to Neurath about protocol sentences in late 1932, received its definitive statement in the "principle of tolerance," enunciated in *Logische Syntax der Sprache* (The Logical Syntax of Language) in 1934.

#### SEMANTICS, LATER PROJECTS, AND THE IDEAL OF EXPLICATION

Carnap's syntax period was characterized by two successive major ideas. The first, from January 1931, had been the rejection of Wittgenstein's picture theory of meaning and its replacement by (a) a sharp distinction between a language (a calculus or purely formal symbol system) and its interpretation, and (b) the requirement that a language be entirely specified by explicit rules. The second major idea, from October 1932, had been the principle of tolerance: No language is inherently definitive or "correct"; there is no logical "reality" for a language to "correspond to." In the published *Logical Syntax of Language*, these two ideas were enmeshed with a third idea: the restriction to the "formal mode of speech" and the avoidance of meaning. But within a year of the book's publication, that third idea was dropped; Carnap accepted Tarski's new semantical accounts of designation and truth. The first two major "syntax" ideas (those of January 1931 and October 1932), however, survived unscathed, though, for the rest of Carnap's career (so it is actually a bit misleading to call them "syntactic"). What

did *not* survive was the overreaction against "meaning" that accompanied the original insight. In distinguishing between a language and its interpretation, Carnap's first response had been to restrict extra-linguistic interpretation to the object language (and there to physicalistic interpretation), and dispense with it entirely in the "elucidatory" metalanguage. But this restriction was loosened when he saw that interpretation could be completely specified by explicit rules (governing satisfaction, designation, and truth).

The remaining thirty-five years of Carnap's career were largely occupied with technical work on a number of not very successful language projects, of which the best known were these: (1) He tried, in a series of semantic works, to develop a general definition of "analyticity" that would distinguish analytic from synthetic sentences in a natural and obvious way. The shortcomings of these successive attempts were pointed out by W. V. O. Quine, and were often taken to undermine other parts of Carnap's view, for example, the principle of tolerance itself. (2) Carnap also tried unsuccessfully to specify a strict logical relation between observation sentences and theoretical sentences. After he abandoned the *Aufbau* effort to construct theories directly from subjective experience, he offered a series of progressively looser definitions of "empirical content" or "empirical reducibility." These attempts were also subjected to searching criticism, above all by C.G. Hempel. The lesson derived from this failure has generally been to abandon the question altogether, instead of confining the pessimism to Carnap's particular approach. (3) The last three decades of Carnap's life were largely devoted to the creation of an inductive logic. This was intended as a tool for practicing scientists, to give them a way of measuring the objective probability of a theory with respect to the available evidence. It was intended to make precise the informal usage, in everyday *and* scientific life, by which the evidence is taken to "make" one hypothesis "more likely" than another. Carnap's proposals attained some currency in the 1950s and 1960s and were considered by R. B. Braithwaite, for instance, to be the most promising route to a fundamental justification of John Maynard Keynes's theory of probability. But with a few exceptions, Carnap's work on probability has not been in the mainstream of discussion since the 1980s.

Even if these language projects are written off as failures, though, this would not discredit the larger vision or ideal of explication and language engineering that guided Carnap after 1935. He devoted little time to making this ideal explicit, so it must be gleaned indirectly from his

approach to the various language projects and from occasional statements, like the famous paper “Empiricism, Semantics, and Ontology” (1950), his replies to critics in the Schilpp volume, as well as unpublished papers and notes.

The basis of this ideal is the utopian conception of highest-level “conceptual politics” that never left him after 1918. He believed that those who are fortunate enough to be able to devote their lives to thought and reflection have a responsibility to devise conceptual frameworks for human knowledge (as a whole) that will maximize the usefulness of that knowledge for the human species—not for some particular use, but for the full spectrum of uses to which humans put knowledge, especially for the purpose of enlightenment, or liberation from unreflective tradition and conformity. In devising such frameworks we are constrained by certain obvious human limitations, but we should not allow ourselves to be overly constrained by the past—the languages handed down to us by our ancestors. Those give us a starting point, certainly, but we should not treat the puzzles and contradictions embedded in natural languages, or in historical languages of philosophy, with any undue reverence. In fact, we should liberate ourselves from them as far as possible when planning new and better frameworks of thought. Certainly our habitual ways of thinking and talking are deeply entrenched, and are hard for us to abandon, but in Carnap’s view this is no reason to be constrained by them when we envision new ones.

In Carnap’s mature conception, there are three levels of language engineering and language study: *Syntax* considers languages in isolation from anything extralinguistic that they might be thought of as indicating; *semantics* considers languages in relation to an extralinguistic world, but still in isolation from the actual uses of those languages by (human or machine) users; and *pragmatics* considers languages in relation to their use contexts and their users. Each of these three (syntax, semantics, pragmatics) can be considered as *engineering* activities (the creation or discussion of new or improved languages) or as *empirical* studies (of existing languages). The engineering activity Carnap called “pure” syntax, semantics, or pragmatics, while the empirical study he called “descriptive” syntax, semantics, or pragmatics. Linguists generally engage in the *descriptive* syntax, semantics, and pragmatics of already existing natural languages, while logicians generally engage in the *pure* syntax and semantics of constructed languages. Among the traditional sectors of philosophy, epistemology and methodology belong to pragmatics, while whatever remains of metaphysics and

ontology belongs to semantics—though this now becomes a matter of *deciding* which entities to make fundamental to a language framework, given existing scientific knowledge, rather than *finding out* what those entities are or might be.

This voluntarist orientation remained fundamental for Carnap. The notion that something beyond the scope of science might actually *be the case* seemed to him a back door to the re-admission of traditional prejudices and conformities of all kinds. Certainly we need to make assumptions, he acknowledged, but we can *decide* on these and spell them out; they are not “out there” for us to *find*. On these grounds he deprecated Quine’s preoccupation with ontology. It makes no sense to talk about “what there is,” Carnap said, without specifying the language framework in which this is asserted; any such claim is intelligible only relatively to a language framework. It makes perfectly good sense to ask, *within* a framework that includes, say, the Zermelo-Frankel axioms for set theory, whether there are infinite numbers. Such “internal” questions have determinate answers. But it makes no sense, *outside* such a framework, to ask “just in general” whether “there are” infinite numbers. Not only is there no determinate answer, but there is no way to give such an “external” question itself any clear meaning. What we *can* ask instead is the *practical* question whether it is better (e.g., for use in science) to choose a linguistic framework that has infinite numbers or one that does not. But this is not a question of ontology or semantics; this is a question of pragmatics, a question of *which language we want*.

The process by which the human species upgrades its messy and imprecise inherited languages to newly built and more precise ones Carnap called *explication*. He acknowledged that this is a piecemeal process, not a revolutionary one. Humanity replaces its concepts a few at a time. Even the people working at the frontier of knowledge have to use a vernacular, a derivative of ordinary language, to discuss the application of the more precise calculi in which they frame their theories. Their vernacular will, of course, be cleaner and more precise than the vernacular of the society at large. In the scientific vernacular, all concepts used are intended in their scientifically rigorous meanings.

But many concepts even in this tidied-up vernacular have no such precise meanings. They may go on being used for generations before they are made precise. The mathematical concept of the derivative of a function, for instance, was put to good use for nearly two centuries before it was given a precise meaning by the work of Cauchy and Weierstrass. Another example Carnap often

cited was the replacement of our vague, subjective, intuitive sense of “hot” and “cold” by the precise, quantitative concept of temperature, which we can define intersubjectively by reference to measurement devices. This concept not only takes the place of the former vague concepts for many purposes; it also gave us many capabilities the vague concepts lacked. For instance, it can provide an outside, objective framework or standard against which to judge subjective feelings; instead of just saying “I feel hot” or “I feel feverish,” I can take my temperature and find out exactly how much higher it is than its ordinary level. So explication also provides a framework of objectivity that enables us to escape from a merely subjective view of the world. But the replacement of the vague, informal worldview by a framework of more objective concepts is iterative and never complete; temperature is not an ultimate constituent of our theory of nature.

Explication, which in Carnap’s view is the main task of conceptual engineering, consists in the *replacement* of a vague concept in need of explication—the *explicandum*—by a more precise one, the *explicatum*. The first step is the *clarification* of the explicandum, the establishment of some basic agreement among those using the vague concept what they mean by it. The next step is a proposal for its replacement, a proposed *explicatum*. This should have the most important uses agreed on in the clarification stage, but need not have all of them. It should, if possible, be expressed in a language framework that makes clear its relation to a wide range of other concepts. Above all, it should be more precise and more useful than the explicandum. The (provisional) acceptance of an explicatum is just its use by the specific community to which it has been proposed and, ultimately, its wider use by the community of those who use the tidied-up scientific vernacular.

Explication differs in one critical respect from the previous Vienna Circle program of “rational reconstruction.” Rational reconstruction was a one-way street; vernacular concepts were to be replaced, piece by piece, with more precise ones. It was assumed that there was a single, definitive logical language in which this reconstruction could be done. But under the new regime of tolerance, there is no longer a single correct language. There is an infinity of possible languages for the community to choose from. Explication is therefore *dialectical*, as Howard Stein, a student of Carnap’s, has pointed out, in a way that rational reconstruction was not. Knowledge has obvious and far-reaching effects on our practical life (more and more so, it seems, as history advances). It can tell us, among other things, about the likely consequences

of various value systems and courses of action, far more than we could have known a few centuries ago. On the other hand, the way we represent our knowledge to ourselves is language-relative. We can only know what we know in a particular language, and the form in which it presents itself to us is relative to that language. The choice *among* languages, though, is not a choice we make *within* a given language framework. It is a practical choice, involving values (as is the choice among explications for a given explicandum, at the local, piecemeal level.). These are *external* questions, in Carnap’s terms. So knowledge and values are in a constant feedback relation to each other, in this dialectical ideal of explication; knowledge shapes values and values shape knowledge.

## Bibliography

### WORKS BY CARNAP

P. A. Schilpp, ed., *The Philosophy of Rudolf Carnap*, Vol. XI in the Library of Living Philosophers (La Salle, IL: Open Court, 1963), is indispensable. This 1,100-page volume contains Carnap’s illuminating intellectual autobiography, 26 critical essays on various aspects of his philosophy, his replies to the critics, and an exhaustive bibliography through 1963. The manuscripts of the original, longer version of the autobiography is held by the Carnap collection of the Young Research Library, UCLA and cited above as “Carnap 1956/7.” Another manuscript item cited above (as “Carnap 1918”) is a newspaper editorial Carnap planned to publish in October 1918; it is held by the Carnap Collection of the Archive of Scientific Philosophy, University of Pittsburgh.

Carnap’s major works include *Der Raum: Ein Beitrag zur Wissenschaftslehre*. Berlin: Reuther & Reichard, 1922; *Physikalische Begriffsbildung*. Karlsruhe, Germany: Braun, 1926; *Der Logische Aufbau der Welt* (1928); English translation by R. George as *The Logical Structure of the World*, 2nd ed. LaSalle, IL: Open Court, 2003; “Überwindung der Metaphysik durch die logische Analyse der Sprache.” *Erkenntnis* 2 (1931–1932): 219–241, translated by Arthur Pap as “The Elimination of Metaphysics through Logical Analysis of Language.” In A. J. Ayer, ed., *Logical Positivism*. Glencoe, IL: Free Press, 1959: 60–81; “Die physikalische Sprache als Universalsprache der Wissenschaft,” in *Erkenntnis* 2 (1931–1932): 432–465, translated by Max Black as *The Unity of Science* (London: Routledge, 1934) *Logische Syntax der Sprache*. Vienna: Springer, 1934, translated by Amethe Smeaton as *Logical Syntax of Language*, 2nd edition. LaSalle, IL: Open Court 2002; “Testability and Meaning.” *Philosophy of Science* 3 (1936): 419–471 and 4 (1937): 1–40; *Foundations of Logic and Mathematics*, Vol. I, no. 3, of *International Encyclopedia of Unified Science*. Chicago: University of Chicago Press, 1939; *Introduction to Semantics*. Cambridge, MA: Harvard University Press, 1942; *Meaning and Necessity: A Study in Semantics and Modal Logic*, 2nd ed. Chicago: University of

Chicago Press, 1956; "Empiricism, Semantics, and Ontology." *Revue internationale de philosophie* 4 (1950), 20–40, reprinted in *Meaning and Necessity*, 2d ed., op. cit., 205–221; *Logical Foundations of Probability*, 2nd edition (Chicago: University of Chicago Press, 1962); and "The Methodological Character of Theoretical Concepts." In Herbert Feigl et al., eds., *Minnesota Studies in the Philosophy of Science*, Vol. I, Minneapolis: University of Minnesota Press, 1956: 38–76; "The Aim of Inductive Logic." In Ernest Nagel, Patrick Suppes, and Alfred Tarski, eds., *Logic, Methodology, and Philosophy of Science*, Stanford, CA: Stanford University Press, 1962: 303–318.

#### WORKS ON CARNAP

The best overview of Carnap's work is the collection of essays *Carnap Brought Home: The View from Jena*, edited by Steve Awodey and Carsten Klein (LaSalle, IL: Open Court, 2004). Also essential is Michael Friedman, *Reconsidering Logical Positivism* (Cambridge, U.K.: Cambridge University Press, 1999), which focuses on the early works. A. W. Carus, *Carnap in Twentieth-Century Thought: Explication as Enlightenment* (Cambridge, U.K.: Cambridge University Press, 2006) cites a range of unpublished sources.

The *Aufbau* was subject to close technical analysis by Nelson Goodman, *The Structure of Appearance*, 3rd ed. Boston, MA: Kluwer, 1977, and from a very different viewpoint, focused on its neo-Kantian origins, by Alan Richardson, *Carnap's Construction of the World: The Aufbau and the Emergence of Logical Empiricism*. Cambridge, U.K.: Cambridge University Press, 1998.

The *Syntax* has attracted a great deal of attention since 1990. Among the most important contributions are Thomas Ricketts, "Carnap's Principle of Tolerance, Empiricism, and Conventionalism." In *Reading Putnam*, edited by P. Clark and B. Hale. Oxford: Blackwell, 1994: 176–200; Warren Goldfarb and Thomas Ricketts, "Carnap and the Philosophy of Mathematics." In *Science and Subjectivity: The Vienna Circle and Twentieth-Century Philosophy*. Berlin: Akademie-Verlag, 1992: 61–78.

The debate between Carnap and Quine has also generated much secondary literature. The classic statements are in the Schilpp volume, as well as Quine's famous "Two Dogmas of Empiricism." Richard Creath has edited their correspondence, together with some very interesting documents, in *Dear Carnap—Dear Van: The Quine-Carnap Correspondence and Related Work*. Berkeley: University of California Press, 1990, with an introduction that gives a lucid overview of the controversy. Important contributions to the debate since then include Howard Stein, "Was Carnap Entirely Wrong, After All?" *Synthese* 93 (1992): 275–295; G.H. Bird, "Carnap and Quine: Internal and External Questions," *Erkenntnis* 42 (1995): 41–64; and Richard Creath "The Linguistic Doctrine and Conventionality: The Main Argument in 'Carnap and Logical Truth,'" In *Logical Empiricism in North America*, edited by Gary L. Hardcastle and Alan Richardson. Minneapolis: University of Minnesota Press, 2003: 234–256.

Among other topics in the vast literature, the posthumously published critique of Carnap by Kurt Gödel ("Is Mathematics Syntax of Language?" in Kurt Gödel, *Collected Works, vol. III: Unpublished Essays and Lectures*, Oxford: Oxford University Press, 1995: 324–363, with an

introductory note by Warren Goldfarb) has aroused much interest; see Goldfarb and Ricketts (above); also Steve Awodey and A.W. Carus, "How Carnap Could Have Replied to Gödel." In Awodey and Klein (above). Finally, Richard Jeffrey addresses a central feature of Carnap's philosophy, in the context of the inductive logic, in his paper on "Carnap's Voluntarism," in *Logic, Methodology, and Philosophy of Science IX*, edited by D. Prawitz, B. Skyrms, and D. Westerståhl. Amsterdam: Elsevier, 1994: 847–866.

A.W. Carus (2005)

## CARNEADES

(214–129/8 BCE)

Carneades became scholar of the Academy (Plato's school) sometime before 155 BCE, when he was sent to Rome along with the leaders of the Stoa and the Peripatos (Aristotle's school) to represent the interests of Athens before the senate. It was during the embassy to Rome that the most notorious episode in his life took place. According to tradition, Carneades delivered public lectures on succeeding days, defending justice on the first and arguing that it is a form of folly on the second day.

He was renowned in antiquity above all for the argumentative virtuosity that he displayed in the skeptical examination of views of other philosophers. For this he was indebted to the example of Arcesilaus, who had inaugurated the skeptical turn in the Academy in the third century BCE, which saw the examination of other schools' theories, especially the Stoa's, replace the elaboration of its own positive doctrines as the school's principal occupation. By common consent, Carneades brought this practice to its highest level. Until the dissolution of the school, which probably occurred under the scholar Philo of Larissa, who left Athens for Rome in 88 BCE, philosophy in the Academy and among the philosophers in its orbit was dominated by Carneades and his legacy. He also stimulated Stoics such as Antipater of Tarsus to modify and refine their positions.

### CARNEADES AND THE ACADEMY

Like Arcesilaus and Socrates before him, Carneades wrote nothing, but exerted an influence on his students and contemporaries through his teaching and in-person practice of philosophical debate. What is known of him depends ultimately on works written by those who were in a position to observe him, especially Clitomachus, his student and, after an interval, successor as head of the Academy. None of these works have survived, but they

were mined extensively by authors such as Cicero and Sextus Empiricus, whose books are available.

Carneades was credited in antiquity with founding the third or New Academy, which succeeded the second or Middle Academy of Arcesilaus and the old Academy of Plato and his immediate followers. Two new characteristics appear to set Carneades apart from his middle Academic predecessors. Ancient philosophers and modern historians of philosophy have credited him with a less skeptical attitude toward the possibility of well-founded beliefs, if not of certain knowledge. And the evidence shows that he tackled and sometimes defended views about a wider range of issues—not only epistemology, but logic, ethics, natural philosophy, and theology as well. If the first of these is correct, the second comes as no surprise. A moderation of the Academy's skepticism would have opened the way for the suitably circumspect adoption of views in ethics, natural philosophy, and other areas.

Caution is in order, however. The Academics' arguments were in the first instance dialectical. They aimed to deduce conclusions unwelcome to an opponent from assumptions to which that opponent was committed, either because they were already explicitly incorporated in the opponent's theories or because they were for some other reason difficult for the opponent to reject. Without committing their authors to a position themselves, such arguments expose difficulties within the opponent's position and show that the opponent's claims to knowledge were not secure.

Carneades's practice of defending positive views, which at first appears to be a departure from the Academic tradition of dialectical argument, may instead be viewed as a continuation of it by other means. Arguments between the Academy and other schools often reached an impasse. The powerful case brought by the Academics against Stoic epistemology, for instance, elicited a formidable response. If the burden of proof belonged to the Academy, it had not proved its case; the Stoics were not obliged to concede all the premises of the Academy's arguments on pain of self-contradiction. On the other hand, by rejecting those premises, the Stoics often committed themselves to theses that were highly disputable and implausible. And they were not content merely to exhibit the consistency of their theories; they claimed that these theories were true, and that open-minded and intelligent auditors could be persuaded of this.

To this end, the Stoics now argued that the consequences of rejecting their position were unacceptable and that no alternative could do justice to the relevant con-

siderations. If an argument of this kind were successful, the Stoics' opponents would be compelled to reevaluate their doubts. At a minimum, Carneades's positive proposals served to counter arguments of this kind by showing that there remained alternatives that his opponents were not in a position to exclude. Thus, although they were his in the sense of being his creations, Carneades's proposals need not have been his in the sense of expressing his convictions. Some of his theories seem to have been meant only to serve polemical purposes, others were considerably more substantial and deserve to be taken seriously in their own right. It is obvious that some of Carneades's successors did adopt positions of his; it is obvious that some of Carneades's successors adopted some of his theories as their own positions; it is less clear whether Carneades committed himself to these or any other theories.

### CARNEADES'S SKEPTICAL ARGUMENTS

Like his Academic predecessors, Carneades argued for the two epistemological propositions for which ancient skepticism is most famous: that nothing can be known and that one ought therefore to suspend judgment about all matters. Strictly speaking, they argued that there are no cognitive impressions. The cognitive impression (*kataleptikē phantasia*), the Stoics' criterion, is a perceptual impression that arises in conditions that both ensure that it is true and impart to it a clarity and distinctness that belong only to impressions produced in this way. By confining one's assent to cognitive impressions, one can avoid accepting any false perceptual impressions. Because this is a necessary condition for knowledge according to the Stoa, if there are no cognitive impressions, it follows for anyone who accepts Stoic epistemological views that nothing can be known. The Academy made its case by arguing that the special character of clarity and distinctness allegedly peculiar to the cognitive impression was not, in fact, confined to impressions that had arisen in the ideal conditions specified by the Stoa, but could in fact also belong to false impressions, which were therefore indistinguishable from impressions with the required truth-guaranteeing origin.

Carneades probably added to the stock of skeptical arguments that he had inherited, but the contribution to the debate for which he is best known came in response to the Stoics' counterarguments. In answer to their contention that, without cognitive impressions, human beings would be deprived of a basis for rational action as well as the possibility of wisdom, he developed a theory of probable impressions (from *probabilis*, that which

invites approval, Cicero's Latin for the Greek *pithanos*, persuasive). The theory describes how one may discriminate among impressions by checking to see whether an initially persuasive impression agrees with one's other impressions or if there is anything about the conditions in which it arose that casts doubt on it. Depending on the amount of time available and the importance of the matter at issue, one may perform more or fewer such checks. No amount of checking is sufficient to eliminate the possibility of error, but it will be possible to achieve the degrees of confidence required in different circumstances to make rational action and theoretical inquiry possible. The theory is an early instance of fallibilism.

This account of probable impressions is behind the views that Carneades defended about assent. Sources reveal that he sometimes argued that the wise person will withhold assent, but be able to act and inquire by going along with probable impressions in a way that does not amount to assent; whereas on other occasions, Carneades maintained that the wise person will assent and so form opinions, but with the proviso that he may be wrong. The first view, championed by Clitomachus, is the classical skeptical stance that influenced the other ancient school of skeptics, the Pyrrhonists. The second, which was favored by Philo of Larissa among others, gave rise to a form of probabilism, which is the other legacy of the New Academy.

## ETHICS

In ethics Carneades was famous for describing a framework that allegedly classified not only all the views about the goal of life that had been held, but also all those that could be held. He starts with the assumption that practical wisdom must have an object, and one toward which human beings have a natural impulse. He identifies three possibilities: pleasure, freedom from pain, and natural advantages such as health and strength. The principle of virtue is to act with a view to obtaining one of these. There are six simple views, depending on whether the goal is merely to act with a view to obtaining one of the three candidate objects or actually to obtain it. Three further combined views take the goal to be a combination of virtue and actually obtaining the corresponding object. The Stoic position, that virtue is the only good, appears third on the list as the view that the goal is acting with a view to obtaining the natural advantages whether one obtains them or not. At different times Carneades defended the view that the goal is actually to obtain the natural advantages or the view that it is a combination of virtue and pleasure. His aim seems to have been to challenge the Stoics by showing

that the considerations captured by the framework do not all point to their view. Carneades's division influenced his successors and through Cicero the understanding of Hellenistic ethical theory.

Other issues that attracted Carneades's attention include Stoic and Epicurean views about fate and moral responsibility and Stoic theology, against the last of which he used a series of Sorites arguments to show that the Stoics could not consistently set any bounds to the divine, so that on their view everything threatened to become divine.

## CAROLINGIAN RENAISSANCE

The reign of Charlemagne (768–814) ended the long period of cultural decay and intellectual stagnation that had begun over three centuries before with the barbarian invasions of Western Europe. Despite the disintegration of the Carolingian Empire under Charlemagne's successors, the cultural revival that he inspired continued until the Vikings put an end to it, and even then something of the achievement of the eighth and ninth centuries survived to foster the renaissance of the eleventh and twelfth centuries.

The "Carolingian Renaissance" was dominated by two practical interests, ecclesiastical reform and social progress. Since Charlemagne depended on churchmen to implement his educational policy, the religious motives and ecclesiastical achievements—liturgical reform, monastic renewal, advancement of clerical education—inevitably predominated. Literary sensibility and intellectual curiosity were not, however, wholly lacking in the churchmen of the age, and some charming poems and substantial doctrinal treatises remain to testify to their intellectual versatility.

The chief agent, though not the finest mind, of the Carolingian Renaissance was the Englishman Alcuin (735–804). The Irishman John Scotus Erigena (c. 810–c. 877), the Lombard Paul Warnefrid (d. c. 800), the Spaniard Theodulf of Orleans (d. 821), the Frenchman Remigius of Auxerre (d. c. 908), and the German Rabanus Maurus (d. 856) exemplify the cosmopolitan character of the movement.

The centers of the revival were cathedral and monastic schools established by legislation throughout the Frankish dominions. In addition to a theology consisting mainly of traditional biblical exegesis, their curriculum included the seven liberal arts—the trivium of grammar, rhetoric, and logic and the quadrivium of arithmetic, geometry, astronomy, and music. The assimilation of ancient learning was stressed, and little original work was done; the chief forms of academic literature were commentaries and handbooks.

In philosophy the arts curriculum did not go beyond logic. Several scholars are known to have touched on the question of universal ideas, but the issue does not seem to have been widely debated. The Carolingian Renaissance produced very little speculative philosophy; the great exception, the work of Erigena, stands alone both in its systematic character and in its Neoplatonic inspiration.

The few philosophically interesting ideas of the age emerged more or less incidentally in the course of theological reflection and debate.

Perhaps the most important single fragment of philosophical theology to survive from the ninth century is the *Dicta Candidi de Imagine Dei*, attributed to the monk Candidus, schoolmaster at Fulda in 822, which includes the earliest known dialectical demonstration of God's existence by a medieval author. The principle of the proof is the idea of the scale of perfection. Moving from that which simply exists through that which exists and lives and that which exists, lives, and possesses intelligence, the writer argues that the scale would be incomplete without the omnipotent intelligence which is God.

Another small work of some philosophical interest was obviously inspired by consideration of the problem of universals. Fredegisus of Tours (died 834), in his *Epistola de Nihilo et Tenebris*, assumes that every term has some real entity corresponding to it. He concludes that the "nothing" (*nihil*) of the orthodox Christian doctrine of creation "out of nothing" must be conceived as a pre-existent, undifferentiated stuff out of which God created everything, including human souls and bodies. Fredegisus was evidently an early instance of a theological dialectician who found difficulty in reconciling the results of his logical analysis of the meaning of terms with doctrinal orthodoxy; the problem was not widely recognized as urgent until the eleventh century.

The outstanding intellectual issue of the Carolingian Renaissance was unquestionably the problem of predestination. The German monk Gottschalk (d. c. 868) was accused of teaching that from eternity God has infallibly predestined some men to salvation and others to damnation; that God therefore does not in any sense will the salvation of all men; that Christ's atoning sacrifice was offered only for the elect; and that each man's will is irresistibly determined either to good or to evil. The authority of Augustine and of his great disciples Fulgentius of Ruspe and Prosper of Aquitaine was invoked by Gottschalk and others in favor of these ideas. In opposition to this intransigent Augustinianism, Erigena expounded a libertarian doctrine, inspired by Greek thought; others sought a middle way within the Augustinian tradition. The controversy was long and heated, and its terms were not always clearly defined, but it is obvious that the crucial issue was the relation between divine immutability and omnipotence, on the one hand, and human freedom and moral responsibility, on the other. After a series of conflicting synodical decisions, the moderate Augustinians were officially vindicated, but the

debate was to be repeatedly renewed in the later Middle Ages and the Reformation and Counter-Reformation.

A second vigorous controversy of the period had to do with the presence of Christ in the Eucharist. Paschasius Radbertus (d. c. 860), in his *De Corpore et Sanguine Domini*, the first technical elaboration of Eucharistic doctrine in theological history, asserted the identity of the sacramental elements with the historical body of Jesus crucified and glorified. Although he insisted at the same time on the spiritual and mystical manner of Christ's presence, some of his statements could be interpreted in a crudely materialistic sense, and Ratramnus (d. 868), in his *De Corpore et Sanguine Domini*, opposed an ostensibly symbolist doctrine to the realism of Radbertus; owing to vagueness of definition, however, it remains uncertain how far and in precisely what way the two doctrines were incompatible. The debate is significant primarily because it eventually issued in the definition of the dogma of transubstantiation by the Fourth Lateran Council (1215) and in the subtle metaphysical elaboration of that dogma in the theology of Thomas Aquinas.

## CARROLL, LEWIS (1832–1898)

Lewis Carroll is the pen name of Charles Lutwidge Dodgson. The eldest son of a large clerical family, he was born at Daresbury, Cheshire, was educated at Rugby School, and entered Christ Church, Oxford, in 1850. On obtaining first-class honors in mathematics in 1854, he was appointed student and mathematical lecturer of the college, and remained on its foundation until his death. In many ways an archetype of the pernicky bachelor don, Dodgson had a wholly uneventful academic career. Hampered by a stammer, he shone neither as lecturer nor as preacher (he took deacon's orders in 1861). He embroiled himself—often amusingly, although usually without effect—in academic politics, was for a time curator of the college common room, and visited Russia in 1867. His leisure was spent in gallery-going and theatergoing; in photography, at which he was an expert; in the writing of light verse; and in the patronage of an interminable succession of small girls. The last peculiarity has endeared him to psychoanalytical biographers, who would seem, however, to have enriched the literature of nonsense on the subject more often than they have been able to explain it.

Dodgson the mathematician published a number of books and pamphlets, none of any lasting importance. The best known is *Euclid and His Modern Rivals* (London, 1879); the most useful, probably his edition of *Euclid I & II* (London, 1882); and the most original, his contributions to the mathematical theory of voting, to which attention was drawn by D. Black in his *Theory of Committees* (Cambridge, U.K., 1958). Dodgson's mathematical outlook was, in general, conservative and provincial, aiming no higher than the improvement of elementary teaching or routine calculation. His talent found greater scope in the construction of puzzles contained in *A Tangled Tale* (London, 1885) and *Pillow Problems* (London, 1893), which at times show depth as well as ingenuity. The same can be said of his dabbings in symbolic logic, which otherwise make little advance on the work of Augustus De Morgan and John Venn. His *Game of Logic* (London, 1887) and *Symbolic Logic, Part I* (London, 1893) present logic merely as a mental recreation devoted to the solution of syllogistic problems by means of a

square diagram and colored counters. His logical output was completed by nine papers on elementary logic and by two short pieces in *Mind* (n.s., 3, 1894 and n.s., 4, 1895). His influence is to be seen mainly in the attempts of later logicians to imitate the elegant absurdity of his examples. Their failure merely emphasizes the rarity of his own peculiar gift.

Needless to say, that gift finds its happiest exercise in his writings for children. *Alice in Wonderland* (London, 1865), *Through the Looking-Glass* (London, 1871), and *The Hunting of the Snark* (London, 1876) and, to a lesser extent, the two parts of *Sylvie and Bruno* (London, 1889 and 1893), are the only works that keep his name alive—or deserve to do so. Apart from *Pickwick*, and perhaps *Waverley*, they seem also to be the only works of fiction generally known to philosophers, and have been constantly pillaged for quotations. All five are dream narratives or have episodes depicting dreams, whose aberrant logic is responsible for much of their philosophic interest and fun. *Alice in Wonderland* exploits the idea of sudden variations in the size of the heroine; its sequel, the conception of a world in which time, space, and causality are liable to operate in reverse. The characters—a bizarre medley of nursery and proverbial figures, animals (fabulous or otherwise), plants, playing cards, and chessmen—are all much addicted to argument; and their humor, where it does not rely upon puns, is largely a matter of pursuing logical principles to the point of sophistry or absurdity. The frog, who supposes that an unanswered door must have been asking something, is a simple case in point. The King of Hearts and the White King, who both take “nobody” for a person, are victims of the same error and have often been cited as a warning to less venial, because less nonexistent, hypostatizers of the null class.

These books are further remarkable for their echoes—and pre-echoes—of philosophic controversy. Tweedledum and Tweedledee are Berkeleian metaphysicians, and the latter has notions of logic that bespeak the influence of Gottfried Wilhelm Leibniz. Alice herself, on the road to their house, is a step ahead of Gottlob Frege in discovering the difference between *Sinn* and *Bedeutung*. Humpty Dumpty has been taken, on anatomical grounds, for a Hegelian; but his ascription of fixed meaning to proper names and denial of it to general terms, plus his confident philology and shaky mathematics, proclaim him beyond doubt an early, if eccentric, linguistic analyst. The White Knight's reactionary views on the mind-body question give no hint of the metalinguistic virtuosity he later displays in the announcement of his song. The distinctions there enunciated have been formalized by Ernest Nagel in

“Haddocks’ Eyes” (in J. R. Newman, *The World of Mathematics*, New York, 1956, Vol. III, pp. 1886–1890). They would not have troubled the Duchess, another adroit logician, although her primary interest is in morals. Her cat, on the other hand, although adept enough at defying the principle that an attribute must inhere in a substance, offers a regrettably invalid proof of its own madness, as does the pigeon of Alice’s serpentine. The Hatter, March Hare, and Dormouse are sounder reasoners; whatever their troubles with time, they know a fallacy of conversion when they see one, and it is no great wonder that Messrs. Bertrand Russell, George Edward Moore, and John McTaggart, who were supposed to resemble them, should have been known at one time as the “Mad Tea Party of Trinity.”

Not even Nobody, in his senses, would venture to identify that other and more formidable trio, the Queen of Hearts and her chessboard cousins. The former’s principle of government by decapitation scarcely ranks as a political theory; but the White Queen is respected by philosophers both for her abilities in believing the impossible and for her success in proving, for the special case of jam at least, that the future *will* resemble the past, if not the present. The Red Queen is no less celebrated, among physicists, for her anticipations of the theory of relativity. In this, however, she meets competition from the Bellman in the *Snark*, who has been acclaimed, on the strength of his map, as the first general relativist and is, in any case, the undisputed inventor of an interesting three-ply version of the semantic theory of truth ( $\vdash p, \vdash p, \vdash p \equiv “p”$  is true). Of his crew members, the Baker, with his lost identity and Heideggerian premonitions of impending *Ver-nichtung*, has been plausibly represented as a protoexistentialist; but the other protagonists still abide the conjecture of commentators, as do the quest and the quarry itself. The *Snark* has been taken for everything from the Tichborne inheritance to the North Pole, and from a business depression to the atom bomb. F. C. S. Schiller’s interpretation of it in *Mind!* (1901, pp. 87–101) as the Absolute is elaborately argued, and doubtless finds an echo in the *Oxford Dictionary’s* definition of the creature as a “chimerical animal of ill-defined characteristics and potentialities”; but its fondness for bathing machines is not really explained thereby, and the theory founders completely on the Bellman’s explicit assertion, confirmed by the Baker’s uncle, that Snarks are Many and not One. Nobody, it is true, has been more successful than Schiller on this point, and his views have been generally accepted; but the opinions of nonentities have no place in a grave work of learning such as the present, so neither use nor mention of them is appropriate here.

### Bibliography

Apart from the standard *Life and Letters of Lewis Carroll* by his nephew, S. D. Collingwood (London: T.F. Unwin, 1899), the soberest accounts of Carroll’s life are Derek Hudson, *Lewis Carroll* (London: Constable, 1954), and Roger Lancelyn Green, *Story of Lewis Carroll* (New York: Henry Schuman, 1950) and *Lewis Carroll* (London: Bodley Head, 1960).

The least incomplete version of Lewis Carroll’s works is *The Complete Works of Lewis Carroll* (London and New York, 1939). The most philosophical editions are *The Annotated Alice* (New York: C.N. Potter, 1960) and *The Annotated Snark* (New York: Simon and Schuster, 1962), edited by Martin Gardner.

The pioneer work of logical investigation in this field is P. E. B. Jourdain, *The Philosophy of Mr B\*rr\*nd R\*ss\*ll* (Chicago: Open Court, 1918). Further light on the subject may be obtained, inter alia, from R. B. Braithwaite, “Lewis Carroll as Logician,” in *Mathematical Gazette* 16 (1932): 174–178; P. Alexander, “Logic and the Humour of Lewis Carroll,” in *Proceedings of the Leeds Philosophical and Literary Society* 6, Part 8 (1951): 551–566; and, despite some inaccuracies, from W. Weaver, “Lewis Carroll, Mathematician,” in *Scientific American* 194 (4) (1956): 116–128; and R. W. Holmes, “The Philosopher’s *Alice in Wonderland*,” in *Antioch Review* 19 (2) (1959): 133–149.

P. L. Heath (1967)

## CARROLL, LEWIS [ADDENDUM]

The success of the “Alice” books established Charles L. Dodgson’s reputation as a gifted writer of children’s literature. His admirers expected humor in everything he wrote from then on, an attitude that affected the reception of his serious pieces and prevented his work from contributing to the development of their subjects. For example, the more amusing *Euclid and His Modern Rivals* (1879) overshadowed his more important book, *Curiosa Mathematica. Part 1. A New Theory of Parallels* (1888).

Dodgson made significant contributions to linear algebra in *An Elementary Treatise on Determinants* (1867), a book that though marred by odd notation and unusual terminology, contains the first written proof of a standard theorem connecting the rank of a matrix with the existence of solutions to certain linear systems (chap-

ter 4, proposition II). One of his techniques, condensation, was used in an early step of the solution to the alternating sign matrix problem (Bressoud 1999).

In the field of cryptology his five cipher systems, based on the three cipher paradigms of his time (Vigenère, Beaufort, Variant Beaufort) are not well known. These were: Key-Vowel, Matrix, Alphabet, Telegraph, and Memoria Technica. The first two (1858, unpublished) were unbreakable from a practical point of view. The third and fourth (1868) were secure by the standards of his time for ordinary telegrams and mailed postcards. The last (1875), directly tied to word games, was the most literary.

His publications on the theory of voting consisted of four pamphlets, three written between 1873 and 1876, and *The Principles of Parliamentary Representation* (1884). The pamphlets of the 1870s, an outcome of Dodgson's involvement with college and university affairs, reflect his independent rediscovery of Condorcet's cyclical majorities and include the first application of game theory to sophisticated voting. The argument of the 1884 pamphlet, written to influence the outcome of two electoral reforms, a goal it did not accomplish, is based on the zero-sum game. Dodgson was the first to treat formally apportionment (allocating seats to districts) and proportional representation (assigning seats to political parties) together.

Dodgson's contributions to logic have been widely recognized since William Warren Bartley, III's edition of *Lewis Carroll's Symbolic Logic* (1977) which includes the unpublished manuscript of part 2 of Dodgson's *Symbolic Logic*. Dodgson developed a formal logic where he set down intuitively valid rules for making inferences. A comparison of the two parts reveals the progress he made toward an automated approach to the solution of multiple connected syllogistic problems, many being humorous puzzle problems. The most important of his techniques, the method of trees, foreshadowed modern concepts and techniques in automated reasoning that were developed from the 1950s. Dodgson's use of existential import, abandoned in modern logical usage, marred the reception of part 1 of his book. He developed a method of diagrams as a visual proof system for syllogisms that he introduced in *The Game of Logic* (1887). Like his tree test, which is a proof system for soriteses, it is sound and complete. His self similar diagrams (invariant under a change of scale) are capable of handling existential statements and are easily extended to any number of sets using a linear iterative process. In this regard, they are superior to the diagrams described by John Venn in 1880.

## CARTESIANISM

According to one panoramic view of modern philosophy, René Descartes is the father and Cartesianism an inherited characteristic or family trait. With no disparagement intended of this assessment of Descartes's influence, the term *Cartesianism* will be used here in a less contentious way to refer to the multifarious, more or less self-conscious efforts on the part of his contemporaries and immediate successors to supply what they found lacking in his ambitious attempt to reconstitute human knowledge. Three directions of their activities can be distinguished and, corresponding to them, three particular applications of the term *Cartesianism*.

(1) It was evident that Descartes's project of a universal and all-encompassing science of nature was not fully realized. His intended *summa philosophiae, Principia Philosophiae (Principles of Philosophy*, Amsterdam, 1644), lacked the proposed parts on plants and animals and man; and his posthumously published and widely read *Traité de l'homme (Treatise on Man*, Paris, 1664) ended abruptly. Moreover, in his *Discours de la méthode (Discourse on Method*, Leiden, 1637) and in the letter prefacing the French translation of the *Principles* (Paris, 1647), he asked for assistance in carrying out his program for the sciences, suggesting that cooperative endeavor in the acquisition of *expériences* would be necessary to decide among equally possible explanations of the more partic-

ular facets of nature. His early admirers, attracted as much—and often far more—by his physics than by his metaphysics, accepted the invitation, and, working within the framework of his methodological prescriptions and cosmologic theory, distinguished themselves not only from their scholastic opponents of the academic establishment but also from other non-Aristotelian scientists of the time whose work went against views they had inherited. In the seventeenth century, *les cartésiens* were predominantly Descartes’s followers in physics; and the term *Cartesianism* has acquired some of its less favorable associations from its application to this maligned movement in the history of science.

(2) A second line of development can be traced from Descartes’s novel use of the term *idea* in presenting what has sometimes been considered the characteristically Cartesian view that knowledge is attained by way of ideas. These “as it were images of things” (*tanquam rerum imagines, veluti quasdam imagines*), as they were introduced in the *Third Meditation*, were variously described in his works, and a host of questions arose about their origin and nature. “Orthodox” Cartesians differed in their interpretations of Descartes’s answers to these questions, while the more independently minded, accepting the thesis that knowledge is attained by way of ideas, produced deviant answers of great subtlety and originality. Since John Locke and his followers accepted Descartes’s general thesis although they disagreed on the subject of innate ideas, Cartesianism, in a second application of the term, has been taken to cover a considerable domain, including family squabbles among rationalists and empiricists as well as more recent disputes, such as that about the genesis and status of sense data. (It should be noted that this use of “Cartesianism” to refer to the “way of ideas” differs from another use, in which “Cartesianism” and “rationalism” are roughly coextensive and connote a view or views about innate ideas or principles.)

(3) When Descartes was presented with objections to his metaphysics framed in terms of traditional categories and distinctions, a number of thorny problems became apparent; notably, concerning the substantiality and causal efficacy of his seemingly formless and inert corporeal things and concerning the union in man of a body and a soul, or mind, that is alleged to be really distinct from the body. In these sensitive areas, Descartes’s teachings were interpreted and developed in various ways; and those who chose to follow the natural light rather than Descartes came to conclusions far removed from, and incompatible with, his. Yet, because of a common view concerning the distinction of mind and matter, Nicolas

Malebranche and Benedict (Baruch) de Spinoza, as well as some less celebrated metaphysicians, have been called Cartesians; and Cartesianism, in a third acceptance of the term, comprises various monist, pluralist, and occasionalist variations on a common metaphysical theme. Within the limits of this general survey of Descartes’s influence, Cartesianism will be mapped in each of the three general areas to which the term has been applied.

## PHYSICS AND DERIVATIVE SCIENCES

Like Descartes, the Cartesians attracted to his program for the sciences thought of themselves as possessing a powerful method for investigating nature; and, though they disagreed with him and among themselves on particular applications, they accepted a general theory in physics, salient features of which were the laws of motion in Part II of the *Principles*; the theory of vortices in Part III; and the doctrine of subtle matter that underlies explanations of various phenomena, both celestial and terrestrial, in Parts III and IV of the *Principles*. Although Descartes’s laws of motion became increasingly troublesome—Malebranche accepted them at first but was later forced to modify them beyond recognition—the cosmogonic picture of which they were part was altered but not effaced. It was an integral feature of the picture that Earth, like the other planets, was transported in a whirlpool that centered about the sun; and, while Descartes took pains in the *Principles* to distinguish his view from that of Nicolas Copernicus and to point out that, in his view and according to his definitions, Earth, though indeed a planet, was, strictly speaking, at rest, his followers were less concerned to establish a difference. They, too, rejected the possibility of unoccupied space or a vacuum, and claimed that apparently empty spaces—the heavens, the “pores” of bodies, and experimentally produced vacuums—were actually filled with subtle matter. Like Descartes, they made free use of the adaptable particles of subtle matter in their jigsaw-puzzle explanations of the workings of nature. There was some question as to what they conceived the vaunted “true” method to be, as evidenced by Gottfried Wilhelm Leibniz’ skeptical queries. Nonetheless, some general characteristics of their practice were apparent.

Following the rule of evidence in the *Discourse*, they understood Descartes’s injunctions against preconception and precipitancy as condemnations of merely accepted opinion and of idle speculation; and contrary to a popular conception of their apriorism, they were keenly interested in the detailed observation of nature and in experiments, thinking of themselves as countering the

bookish physics of the Scholastics and the wanton practices of alchemists, astrologers, and the like. Lenses, Torricellian tubes, and sundry apparatus were much in evidence; and, like Descartes, many of them took pleasure in anatomical and physiological investigations. To what use they put their observations and experiments is one thing; their cult of *expériences*, another—and an indisputable fact. The requirement of clear and distinct ideas was met in the doctrine that matter is extension and the corollary that change is local motion, or *translatio*. The methodological implications of these complex views were manifold. Negatively, they ruled out explanations involving qualitative entities or “real” qualities, such as light, heat, and weight, in physics, and substantial forms, such as vegetative and sensitive souls, in biology. Also banished were final causes, including natural place, gravitation, and attraction; faculties, virtues, and powers as causes of change; and sensible qualities supposed to inhere in bodies and to be mysteriously purveyed to us by intentional species. Distinctly conceived, bodies were geometrical solids occupying parts of space and were subject to alteration by the crowding, or impact and pressure, of their neighbors. A vacuum, or void, was thought impossible, as were, at least for the “orthodox” Cartesians, indivisible particles or atoms. Sharing corpuscular and mechanistic assumptions with other nonscholastic scientists, they showed the mark of the master in their geometrical notions of—or, as some would have it, their lack of concepts of—mass and force. Quantity of matter was volume; weight was a centripetal reaction in a vortex of bodies of a certain size. Force, as effort or action on the part of bodies, was as suspect as were the powers and virtues of the Scholastics. Distinctly conceived, it was derived from a principle of inertia, and the force of a body in motion was reckoned as the product of mass (volume) and velocity.

**HOLLAND: REGIUS AND CLAUBERG.** During Descartes’s long expatriation in Holland, he made a number of converts to his program for the sciences; and despite outbreaks of official opposition, Cartesianism made an impression on academic life that it did not make in France.

*Regius.* Of special note is Descartes’s sometime friend and disciple Henry de Roy, or Regius (1598–1679), professor of medicine at the University of Utrecht, who typified Cartesian scientists in following the master more or less closely in physics and the derivative sciences while departing from his views in metaphysics. His *Fundamenta Physices* (Amsterdam, 1646), which appeared two years after the *Principles*, recapitulated the physics of

Parts II, III, and IV, to which were added views from the earlier *Meteors* and *Dioptric* and also from unpublished work. Regius’s physics, unlike Descartes’s in the *Principles*, was not represented as derived from metaphysical principles. Moreover, in the concluding chapter on man, adverting to issues concerning the soul, he presented views to which Descartes could only take exception. In the preface to the French translation of the *Principles* (1647), Descartes disowned both the physics and the metaphysics of his disciple; and Regius in turn circulated a defense of his metaphysical theses, arguing for an empiricist view of the origin of ideas and against the necessity of a real distinction of mind and body. Descartes’s reply to Regius, his *Notae in Programma* (1648), contained the prototype of later defenses of innate ideas against empiricist incursions. Innate ideas, he maintained, need not be *actually* present in the mind. Moreover, certain ideas—for example, of God—differ in kind from “adventitious” ideas; and even the latter do not, strictly speaking, come to us from the senses, that is, the sense organs.

*Clauberg.* From Holland, Cartesianism was taken to Germany by Johannes Clauberg, who attempted to explain and defend both Descartes’s physics and his metaphysics. Working out apparent implications of the metaphysics in *De Cognitione Dei et Nostrae ...* (Duisberg, 1656), he too came to hold a deviant view of the relation of mind and body (though not Regius’s), a view linking him with the occasionalists. Clauberg also faced the problem of the relation of traditional logic and Cartesian methodology, and his work in logic anticipated the more famous *Logique, ou L’art de penser* (*Port-Royal Logic*, 1662) of Antoine Arnauld and Pierre Nicole, which was the chief contribution of the Cartesians (Leibniz, of course, excluded) to logic.

**FRANCE: ROHAULT AND RÉGIS.** In France, Cartesianism, though it was not received in the universities and was, in effect, interdicted in 1671, flourished in extracurricular circles. Dissemination of Descartes’s unpublished works and letters was in the hands of his devoted admirer Claude Clerselier (1614–1684), while leadership of his scientific enterprise devolved upon Jacques Rohault.

*Rohault.* The most gifted of the Cartesian scientists, Rohault devised ingenious experiments for his popular weekly meetings and presented the results of his work in his influential *Traité de physique* (Paris, 1671; translated by John Clarke as *System of Natural Philosophy*, London, 1723). Like Regius, he was inclined to separate Descartes’s

physics from his metaphysics; and, in line with this, he developed Descartes's notion of hypothesis or *supposition*, eliminating, however, any qualification to the effect that hypotheses were to be accepted for lack of something better.

*Régis.* Pierre-Sylvain Régis succeeded Rohault as leader of the Cartesian school. In his *Système de philosophie ...* (Paris, 1690), a comprehensive work containing sections on logic, metaphysics, and moral philosophy as well as his extensive physics, he assimilated work that had been done since Descartes's death. The apogee of the Cartesian movement in physics has been set at about the time of Régis's *Système* and of Bernard Le Bovier de Fontenelle's imaginative exploration of the vortices in his *Entretiens sur la pluralité des mondes* (Paris, 1686).

**CRITICAL RECEPTION.** While receiving acclamation, the Cartesians were simultaneously threatened—and eventually discredited—by discoveries, such as that of the finite velocity of light, that contravened crucial parts of their system and by the objections and strictures of Leibniz and of Isaac Newton and his followers. These adverse judgments have been generally accepted. It is commonplace (and true) that Newton showed beyond the shadow of a doubt the incompatibility of the theory of vortices and Johannes Kepler's laws, while Leibniz neatly proved the inconsistency of Descartes's laws of motion with Galileo Galilei's. Citing Leibniz' derogatory characterization of the Cartesians, the not unsympathetic historian Charles Adam has reiterated comments on the paucity of equations in their work and on the uncontrolled play of their imagination in assigning jobs to the ubiquitous particles of subtle matter. His verdict was that Descartes's physics threatened to become as harmful to the progress of science as Aristotle's had been.

Yet, more recently, some less disparaging comments have been made. The picture is considerably brightened when Malebranche and especially Christiaan Huygens (1629–1695) are, by virtue of obvious influences, included among the Cartesians (as in Paul Mouy's [1934] account.) It has also been suggested that the attempted geometrization of physics was premature rather than perverse (Mouy; Max Jammer, *Concepts of Force*, Cambridge, U.K., 1957) and that the unstable and indeterminate particles of the Cartesians, not the billiard-ball atoms of the opposition, were in line with things to come (Geneviève [Rodis-] Lewis, *L'individualité selon Descartes*, Paris, 1950). Nonetheless, Descartes's followers in physics and the derivative sciences, Malebranche and Huygens aside, have not, on the whole, enhanced his reputation.

## THEORY OF KNOWLEDGE

Proposing, in the *Third Meditation*, the term *idea* for those of his thoughts that are the “as it were images of things,” Descartes proceeded to classify ideas according to their apparent origin—as innate or adventitious or made by him. He introduced distinctions bearing on their nature—between formal and material truth or falsity, and between objective and formal reality. Discussions generated by these passages concerned both Descartes's intent and the tenability of the views attributed to him. Four main problems can be distinguished, two relating to the tentative classification of ideas according to origin and two having to do with the distinctions bearing on their nature.

**INNATE IDEAS.** The contratraditional notion of innate ideas—that is, of ideas not derived in some way from the senses but instead having their source in the mind itself—presented an obvious difficulty; namely, how could such an idea, taken to be the form of a thought, exist or preexist in a person's mind if he did not in fact have the thought or indeed never had it? It seemed that Descartes's metaphor of a treasure house in which these ideas were stored needed to be cashed—a process that he attempted and that was carried out in various ways, in the face of some formidable difficulties, by supporters of his doctrine of innate ideas.

**ADVENTITIOUS IDEAS.** It was evident that ideas provisionally classified as adventitious—for instance, of a sound, the sun, or a fire—could not, strictly speaking, come to us from external objects; for, in Descartes's view, there was nothing in the objects or in the sense organs exactly like these ideas, or at least like many of them. Although these ideas could, in some sense, be said to be caused by external objects, they could not, strictly speaking, originate there; and some other cause or source more in keeping with their nature seemed to be necessary. Descartes suggested that the mind had the faculty or power of forming these ideas on the occasion of motions in the brain and that ideas seeming to come to us from without were in fact innate. Both suggestions were explored by his successors.

**MATERIALLY FALSE IDEAS.** Noting that falsity (formal falsity) was to be found in judgments and not in ideas, Descartes added that nonetheless certain ideas—for instance, the idea of cold—might be materially false; that is, if cold were a privation, then the idea of cold, representing a privation or what is not a thing, as if it were a thing would be materially false. The implications to be

drawn from this remark were that, in his view, ideas of sensible qualities—of heat as well as cold, of sounds, colors, and the like—were materially false; and questions arose as to whether the notion of a materially false idea (literally, an idea misrepresenting what is not a thing) made sense, and whether sensations of heat, cold, and the like were, in a strict sense of the term, ideas. Two models seemed to be at work in Descartes's account of sense perception, and a problem bequeathed to his followers was that of specifying the latent distinction between the non-representational and the representational elements—sensations and ideas properly so called—that were supposed to be ingredients of sense experience.

**IDEAS OF EXTENDED THINGS.** There was also a problem concerning ideas of extended things derived from the dual reality—objective and formal—accorded them. As representations, it seemed that they must have something in common with, or be in some respect like, the extended things they represented. Nevertheless, it was taken to follow from their formal reality as modes of thought that they were totally unlike extended things. A dilemma presented itself: Either ideas of extended things were totally unlike extended things, in which case they could not represent them; or, if they were in some respect like extended things, then they could not be accommodated in the mind.

**MALEBRANCHE.** Malebranche, among others, addressed himself to these problems; and, in his elaborate discussions of the nature and origin of ideas and in the numerous polemics to which they gave rise, various answers were surveyed and the major lines of development of Descartes's theory of knowledge were represented. Regarding the problem of materially false ideas and the difficulty concerning ideas of extended things, Malebranche, in the numerous editions of *De la Recherche de la vérité* (first published 1674–1675) and in the *Éclaircissements* added to them, drew a sharp distinction between the perception of heat, color, and the like and the perception of objects as extended. The former consisted in sensations or feelings (*sentiments*), nonrepresentational modifications of the mind conceived on the analogy of feelings of pain, and did not, in his precise use of the term, involve ideas (*idées*). The latter required ideas, which were distinguished from the mind's awareness of them and were not, in his view, modifications of the soul. Approaching the problem of the location or status of these ideas, Malebranche investigated a number of possibilities suggested by Descartes's tripartite classification (adventitious, made by the mind, and innate). Finding

difficulties in the suggested sources, he concluded that ideas of extended things were neither adventitious nor made by the mind nor innate. The arguments against these possibilities served as indirect evidence for his own thesis: that these ideas were (as in a medieval use of the term) archetypes of created things in the Divine Understanding and that the human mind, intimately united with God, perceived created, extended things by way of ideas in him. Because, in this theory, ideas of extended things were not modifications of the human mind, the problem of their existence in an unextended mind did not arise, though, as became evident in the ensuing controversies, there was a related problem about the possibility of their existence in God.

**FOUCHER.** Two of the polemics were especially revealing. In his *Critique de la recherche de la vérité ...* (Paris, 1675) and subsequent writings, Simon Foucher, though he misunderstood parts of Malebranche's tortuous theory, raised problems worthy of serious consideration. First, he urged that, if ideas of extended things had to have something in common with what they represented, they could not be, as he at first wrongly interpreted Malebranche, modifications of the mind or—as Malebranche in fact believed—inhabitants of the divine understanding. Second, granted that ideas of extended things were not modifications of the human mind but were divinely situated, could they be immediately perceived? The basis of the question was that, if immediate perception were tied to Descartes's views about indubitability and the *cogito*, then we could not be immediately aware of anything outside or apart from the mind. Third, he also questioned the distinction (to use Locke's terms) of primary and secondary qualities along lines that were continued by Pierre Bayle and George Berkeley, noting what, in Malebranche's distinction of sensation and idea, seemed to require explanation: that, when we perceive an object, we are aware of one uniform appearance of something having both shape and color. Unfortunately, Malebranche was inclined to dismiss Foucher's criticisms on the ground of misinterpretation, but Dom Robert Desgabets (d. 1678), in his *Critique de la Critique de la recherche de la vérité ...* (Paris, 1675), attempted to defend Cartesian views (though not Malebranche's peculiar versions of them) against this attack.

**ARNAULD.** The most interesting controversy was with Arnauld, who, in *Des Vrayes et des Fausses Idées* (Cologne, 1683), attacked Malebranche's view of ideas as entities distinct from the mind's perception of them by tracing the source of this view to a misconceived analogy with

ocular vision and a confusion of presence in the mind with local presence. For Arnauld, as for Descartes, ideas were modes of thought; and, as Descartes was content to explain the objective presence of objects in the mind as the way they were wont to be there, so Arnauld took it to be the nature of thought or mind, requiring no explanation of the kind Malebranche proffered, to represent objects—near or at a distance, present or absent, real or imaginary. Though Malebranche was not moved by this attempt to impugn his theory as the answer to a pseudo problem, in the course of the controversy he was forced to articulate his view that we perceive extended things in God, not by way of individual archetypes but by way of infinite, intelligible extension, which is the common archetype of all extended things, actual or possible.

**LOCKE AND LEIBNIZ.** A significant event in the annals of the Cartesian theory of knowledge was the publication of Locke's *An Essay concerning Human Understanding* (London, 1690). Locke's attack on innate ideas and principles and Leibniz' defense in his *Nouveaux essais sur l'entendement* (published posthumously, Amsterdam and Leipzig, 1765) are a long story, that cannot be told here. Suffice it to say that, in this division of Cartesianism into empiricism and rationalism, Leibniz used arguments like Descartes's in the *Notae in Programma* and, on this question, represented the orthodox Cartesian point of view.

### METAPHYSICS

The occasionalist, monist, and pluralist developments included in the third application of the term *Cartesianism* were foreshadowed in Descartes's views about corporeal substance.

**OCCASIONALISM.** In the *Principles* (II, 36), maintaining that God was the primary and universal cause of motion, Descartes explained that, when God created matter or extension, he created it with motion and rest; and Descartes implied that, but for God's imparting motion to matter, it would have been motionless and undifferentiated, and that motion and rest, and the resulting differentiation of matter, did not follow necessarily from its nature or essence. He further explained that, in conserving matter from moment to moment, God preserved the same quantity of motion that He originally introduced; and it seemed to follow that God's continuing to impart motion to matter was a necessary condition of the continued existence of motion and that bodies of themselves did not have the power of remaining in motion or of producing motion in other bodies. The conclusion toward which Descartes was drawn was that, although motion

(*translatio*) was a characteristic or mode of bodies, the moving force of bodies was not in bodies themselves but in God. He did not, however, draw this conclusion. In a letter to Henry More, he noted that he was reluctant to discuss the question of the moving force (*vis movens*) of bodies in his published works, for fear that his view might be confused with that of God as *anima mundi*; and the view that he apparently wished to maintain was that, though the moving force of bodies was from God and in a sense was in God, it was also a characteristic or mode of bodies.

The occasionalists, taking the views that matter was inert and that the motion ascribed to bodies was simply change of position, did not hesitate before the conclusion that the force required to move bodies was not in bodies themselves but in the primary and universal Cause of motion, God. According to their conclusion, when a billiard ball that was in motion came in contact with a second ball that was at rest, there was no power or force in the first ball capable of moving the second, and the movement of the second ball required the action of God, who, on the occasion of impact, moved the second ball in accordance with rules that he had established for the motion of bodies. By virtue of the uniformity of God's action, the first ball could be called the cause—the particular or occasional cause—of the second ball's moving; but, without God's action, it was inefficacious, and the primary and universal cause of motion, that is, God, was the effectual cause of the second ball's moving. The occasionalists took it to be true a fortiori that bodies of themselves lacked the power of producing, as in sense perception, changes in the mind; and they offered a number of arguments to show that the mind in turn lacked the power, as in volition, of moving the body. The true cause of both sensations and voluntary movements was God, who instituted laws for the union of mind and body and acted accordingly in particular instances.

The originators of the occasionalist movement were Louis de La Forge and Géraud de Cordemoy.

*La Forge.* In the *Traité de l'esprit de l'homme* (Paris, 1666), La Forge represented himself as continuing work that Descartes had left unfinished in his *Treatise on Man* and undertook to explain and develop the notion of a mind or soul distinct from, yet united to, the body. Facing problems concerning the possibility of the body acting on the mind and vice versa, he noted that these problems were not isolated and that there was a related problem concerning the possibility of one body acting on another. In his discussion of these problems, La Forge did not deny that bodies acted on one another or on the mind, or that

the mind acted on the body; on the contrary, he insisted that God in his omnipotence could delegate the power of acting to created things. Yet, distinguishing two senses of “cause,” he denied that created things were unambiguously the causes of the effects attributed to them and called them the “occasional” or “equivocal” causes.

**Cordemoy.** In *Le discernement du corps et de l'âme* (Paris, 1666), Cordemoy, unlike La Forge, was not concerned with presenting views necessarily in harmony with Descartes's, and he denied outright the action of bodies on one another or on the mind and the action of the human mind on the body. In his formally presented proof that God was the true cause of the movement of bodies, he made use of principles that Descartes would have accepted but drew conclusions from them that it would be safe to say would have greatly disturbed Descartes. Descartes had written of a motion in the brain as giving occasion (*donnera occasion*) to the soul to have a certain sensation or thought, and Cordemoy may have had these passages in mind in employing the expression *cause occasionnelle* to refer to what, as in the case of a motion in the brain, might be thought to be the true cause of an event. But, unlike Descartes, he denied that the occasion or occasional cause was, strictly speaking, the cause of the event and maintained that the true cause was God.

**Geulincx.** Arnold Geulincx apparently developed his version of occasionalism independently of La Forge and Cordemoy. Illustrating the lack of causal relation between mind and body, he used the analogy of synchronized clocks, which was later taken up by Leibniz; and, to prove a lack of genuine causation, he made use of the principle that nothing can be done unless there is knowledge on the part of the putative agent or cause of how it is done.

**Malebranche.** Malebranche, the most celebrated of the occasionalists, was familiar with the work of Cordemoy and adapted, for his own purposes and with great originality, the theory of causation he found in Cordemoy. He added powerful arguments, extended the view to cover volitions not pertaining to bodily movements (such as the volition to form an idea), and presented it as an integral part of his theocentric vision of the universe.

**MONISM AND PLURALISM.** It has been argued that the dualisms and pluralism found in Descartes's statements about substance—of uncreated and created substance, corporeal and spiritual substance, and individual substances—contradicted his own definitions and principles and that Spinoza's doctrine of the unity of substance was the consistent and pure form of Cartesianism. It has also been maintained that Spinoza's monism and Leibniz' plu-

ralism were the opposite poles to which philosophers accepting a notion of substance like that of Descartes were inescapably driven. Discussions of these views and of Spinoza's and Leibniz's metaphysics of substance is beyond the limits of this article, though it need hardly be added that the historical and logical relations of Descartes's assertions about substance and those of Spinoza and Leibniz have figured importantly in discussions of Cartesianism and that the essence of Cartesianism has sometimes been located in a common notion of, or presupposition about, substantiality.

It may be noted, however, that Descartes's assertions about corporeal substance also gave rise to conflicting theories among less renowned students of his metaphysics. On the one side, Geulincx, following Descartes's inclination to think of particular bodies as portions of a common stuff or substance, contended that “body itself” (*corpus ipsum*) was primary and substantial and that particular bodies were limitations or modes of corporeal substance. On the other side, Cordemoy, sharing Descartes's inclination to think of particular bodies as objects really distinct from one another, came to the unorthodox conclusion that body in general, or matter, was an aggregate and that the parts of which it was composed were indivisible extended substances, or atoms.

## CARTESIANISM [ADDENDUM]

Apparently, it was the Cambridge Platonist Henry More who introduced the term *Cartesianism*—from the Latin *Cartesius*—into the English language. The term itself now denotes either the views of René Descartes or the various defenses and developments of these views in the writings of les cartésiens, an eclectic group of seventeenth- and eighteenth-century European intellectuals.

### SCIENCE AND THEOLOGY

Descartes is perhaps best known in the early twenty-first century both for his epistemological “method of doubt” and for his metaphysical doctrine of mind-body dualism. However, he was known in the early modern period primarily for his attempt to systematically displace explanations of natural phenomena, deriving from the work of Aristotle, that were then predominant in both Catholic and Protestant schools on the Continent. In *Principles of Philosophy* (1644) Descartes proposed as an alternative for Aristotelian explanations in terms of prime matter, substantial forms, and final causality his own more austere explanations in terms of extension, its modifications, and purely mechanistic laws. There were other critics of the Aristotelianism of the schools, most notably Pierre Gassendi and the Gassendists. Nevertheless, Descartes’s

followers proved to be more adept than the Gassendists at packaging the new mechanistic science. Even so, it is understandable that Cartesian science is not as prominent today given the decisive refutation of Descartes’s particular brand of physics in the work of More’s greatest student, Isaac Newton.

Theological issues also dominated discussions of Descartes’s system in earlier centuries in a way that they no longer do today. Such issues were of immediate practical concern to Descartes himself, who encountered fierce theological resistance not only in France but also in the United Provinces (now Holland), where he lived for most of his adult life. He failed in his attempt to infiltrate the Catholic universities in France at least partly because Aristotelian traditionalists saw his system as a threat to the Catholic dogma of the miraculous conversion in the Eucharist of the substance of bread and wine into the body and blood of Christ.

Descartes did fare somewhat better in the Calvinist United Provinces, where his writings received an audience in the academy during his residence there. Even in this region, however, orthodox Calvinists urged that his insistence on the real distinction between mind and body conflicts with the Aristotelian position that the soul bears a natural relation to a certain body in virtue of being its substantial form. These critics emphasized the threat that his system posed to Christian doctrines such as the resurrection of the body and the unity of the incarnated Christ. Moreover, before and after Descartes’s death critics attempted to gain an advantage over Cartesianism by linking it to heterodox theological views. In the United Provinces the connection was typically to the doctrinally tolerant Dutch Remonstrant Calvinists, who deviated from Reformed Orthodoxy in insisting on one’s freedom to accept or reject divine grace. After his death, however, Descartes was linked in France to a different group, the rigoristic French Jansenists, who set themselves in opposition to a Jesuit theology that emphasizes the dependence of one’s salvation on the activity of one’s undetermined free will. That the Jansenists were linked to Descartes bespeaks the influence of Antoine Arnauld, who was a prominent defender of both Cartesianism and Jansenism.

### CARTESIANISM AND AUGUSTINIANISM

There was a strong inclination among French Cartesians to counter theological objections by invoking the authority of St. Augustine. There were roughly two general approaches, which were reflected in the distinction of the

scholar Henri Gouhier (1978) between “Cartesianism augustinized” and “Augustinianism cartesianized.” The augustinized Cartesians, including Claude Clerselier, Descartes’s literary executor, and the physician Louis de la Forge, were concerned to bolster Cartesian natural philosophy by stressing the ways in which Descartes’s proofs of the existence of God and of the immateriality of mind complement Augustinian spiritualism. The defense of a cartesianized theology was pursued with disastrous consequences by the Benedictine Robert Desgabets, whose development of Descartes’s account of the Eucharist provided the impetus for the official censorship of Cartesianism in France two decades after Descartes’s death.

The cartesianized Augustinians tended to emphasize not Descartes’s infrequent forays into theology, but his more common insistence that theological issues are outside of his jurisdiction insofar as their treatment requires recourse to revelation. This insistence allowed theologians such as Arnauld to appeal to Descartes to safeguard against Jesuit intrusion a “positive” or dogmatic theology devoted to providing a philosophical explication (or, for critics of the Jesuits, misrepresentation) of Augustinian views on matters of faith. Dutch Cartesians also attempted to insulate Cartesian philosophy from theology, though for them the concern was less to promote Augustinian purity in theology than to honor the distinction of the disciplines in the universities. This interest in making Descartes fit for the schools also explains the emphasis in the work of these Cartesians on the similarities between Aristotle and Descartes. It is this “scholasticized” Cartesianism that was exported from the United Provinces to Germany soon after Descartes’s death by Dutch-trained Cartesians such as Johannes Clauberg.

#### MALEBRANCHE AND HIS CRITICS

The reception of Descartes was conditioned by the work of Nicolas Malebranche, a member of the Oratory in Paris. Malebranche attempted with other French Cartesians to link Descartes to Augustine. In Malebranche’s case the result was a synthesis that stressed the dependence of creatures on God’s rational activity. His system included the view, anticipated in the work of La Forge and others, that bodies serve as the noncausal occasion for God to distribute motion by means of the most economical laws. Malebranche further extended this sort of view to theology, arguing that God distributes grace in accord with simple general laws.

Malebranche’s theological views upset Arnauld, his former ally, who took them to be an illustration of the dangers of philosophical incursions into theology.

Nonetheless, the opening salvo in his protracted and increasingly bitter dispute with Malebranche was his critique of Malebranche’s philosophical doctrine that “we see all things in God,” that is, that one knows the bodies one sees through the idea of extension in God that represents them. Arnauld appealed to Descartes in defense of the alternative position that representative ideas are merely modes of one’s soul. The French Cartesian Pierre-Sylvain Régis, who had earlier published a popularization of Cartesianism in his *System of Philosophy* (1690), defended Arnauld’s account of ideas in a polemical exchange with Malebranche during the mid-1690s. Unlike Arnauld, however, but like Desgabets, whom he admired, Régis challenged Malebranche’s claim that eternal essences that serve as the ground for eternal truths are identical to uncreated ideas in the divine reason. As Malebranche himself recognized, such a claim undermines Descartes’s doctrine of the creation of the eternal truths. Régis and Desgabets were both concerned to defend this doctrine by claiming that eternal truths concerning creatures derive not from uncreated ideas in God, but from features of the world that God created with complete indifference.

## CARTWRIGHT, NANCY

(1944–)

Nancy Cartwright, as of 2005, held several academic positions, including professor of philosophy in the Department of Philosophy, Logic, and Scientific Method at the London School of Economics (since 1991); director of the LSE Centre for Philosophy of Natural and Social Science (since 1993); and professor of philosophy in the Department of Philosophy at the University of California at San Diego (since 1998). She had also served on the faculty at the University of Maryland (1971–1973) and Stanford University (1973–1991). She is the recipient of a MacArthur Fellowship and is a Fellow of the British Academy.

Cartwright first became widely known for the radical thesis, presented in her landmark 1983 collection of essays *How the Laws of Physics Lie*, that the fundamental laws of physics did not state truths about the world. The thesis is radical because philosophers have generally assumed that there is some set of underlying physical laws which, ultimately, describe all natural events. This is probably still a majority opinion among philosophers of science, though a much more controversial one than when Cartwright wrote these essays. At the same time she also proposed (along with Ian Hacking) a cautious realism about theoretical entities, which did not depend on people's ability to formulate true laws about them.

Cartwright's argument is based on a distinction between phenomenological and theoretical—or fundamental—laws. Phenomenological laws are, unsurprisingly, the laws that apply to actually observable phenomena. Their application is generally tightly circumscribed by detailed specification of the situations to which they apply. While fundamental laws may play an essential role in the formulation of phenomenological laws, the former are not themselves true. This is because they abstract from all the detailed *ceteris paribus* conditions that give phenomenological laws a chance, at least, of being true within their specific domains.

In her most recent book, *The Dappled World* (1999), Cartwright continues her attack on fundamentalism, the idea—from realism—that there is one unique set of laws applying to everything. The attack on fundamentalism, however, is now more uncompromising, as she has become increasingly skeptical about the usefulness of fundamental laws for deriving phenomenological laws. At the same time, a positive theme that she has developed throughout her career is increasingly emphasized: The conception of science not as searching for laws at all, but as constructing models. For models, the question of truth

does not arise. They may more or less adequately represent parts of reality, and they may be more or less useful in providing understanding, explanation, and prediction.

Another theme more strongly emphasized in the later book is the disunity of science. Whereas a majority of philosophers of science accept a disunified science in the sense that laws in different domains are not reducible to laws of a more fundamental science, a majority of these philosophers see this as a consequence only of practical problems of complexity or the limited cognitive capacities of humans. Cartwright, on the other hand, is a leading advocate of a more radical position: that the autonomy of theories is indicative of what there is to know about the world. The world itself does not have a unitary underlying lawlike pattern. Its nomological structure is dappled.

The other related topic to which Cartwright has been among the most prominent contributors is the nature of causality. The decentering of fundamental laws from the vision of science naturally engenders skepticism about the Humean program of reducing causes to instances of laws. A project introduced in her first book—and developed in detail in her 1989 work, *Nature's Capacities and their Measurement*—is that an understanding of causality in terms of laws should be replaced with one in terms of capacities. In parallel with the emphasis on models, this move contributes to doubts as to whether laws are needed at all. The central thesis of this book is that science cannot be understood without assuming real capacities in the world. As is well known, Hume argued that positing capacities violated a proper empiricism. Cartwright, a committed empiricist, insists that capacities are as empirically accessible as laws and more specifically, that their measurement is a defining activity of science. In a further anti-Humean move, she argues that singular rather than generic causes are fundamental. A paradigm for Cartwright of causal knowledge is that aspirins have the capacity to cure headaches. Yet the canonical evidence for this claim is that on some specific occasions an aspirin actually does cure a headache.

This also connects to a central topic of her earliest work: probabilistic causality. This topic arises because capacities are to be thought of as being displayed only under specific circumstances, so that the relation between a capacity and its exercise is typically probabilistic. Conversely, Cartwright explores the question whether probabilistic relations can provide evidence for causes. Her answer is that they can, but only on the assumption that the effects are indications of real capacities in objects.

This entry has described some main themes from Cartwright's work in fairly abstract terms, but it should be

emphasized that she has been a leader of the move to focus philosophy of science on detailed examination of exemplary cases of scientific work. For the earlier part of her career most of this work was addressed to physics. From the late 1980s she increasingly switched her attention to examples from economics, and is now a leading figure in the philosophy of economics. Perhaps surprisingly to those who see the sciences as hierarchically arranged with physics secure at the top of the heap, Cartwright finds many themes in common to physics and economics. A central idea linking the two is her interest in machines, which can also be seen as concrete instantiations of models. A paradigm from her earlier work is the laser. The moral of this example is that the laser concretely embodies the *ceteris paribus* clauses emphasized in her critical discussion of fundamental laws by a range of actual mechanisms that ensure the proper conditions for the exercising of the crucial capacity—in this case the capacity for inversion in a population of atoms. Central to Cartwright's work on economics is the idea of a socioeconomic machine. As an example, she considers the mechanism by which a central bank increases the money supply. Like the laser, this does not reflect a law of nature, but a capacity of a certain kind of money, under properly controlled conditions, to have an important economic effect.

Cartwright claims as a philosophical hero Otto Neurath, a founding member of the Vienna Circle. Her admiration is of his commitment to seeing in science the capacity to change the world. A concern with the social impact of science and philosophy of science, while often beneath the surface, has been discernible in much of Cartwright's work.

## CARUS, CARL GUSTAV (1789–1869)

Carl Gustav Carus, a German physician, biologist, and philosopher, was born in Leipzig and studied chemistry

and then medicine at the University of Leipzig. In 1811 he became the first person to lecture there on comparative anatomy. Two years later he became director of the military hospital at Pfaffendorf and, in 1814, professor of medicine at the medical college of the University of Dresden, where he remained to the end of his life. He was appointed royal physician in 1827 and privy councilor in 1862.

Carus was widely known for his work in physiology, psychology, and philosophy, and was one of the first to do experimental work in comparative osteology, insect anatomy, and zootomy. He is also remembered as a landscape painter and art critic. He was influenced by Aristotle, Plato, Friedrich Wilhelm Joseph von Schelling, and Johann Wolfgang von Goethe, about whom Carus wrote several works, the most important of which is *Goethe dessen seine Bedeutung für unsere und die kommende Zeit* (Vienna, 1863). Carus's philosophical writings were more or less forgotten until the German philosopher and psychologist, Ludwig Klages, resurrected them.

Carus's philosophy was essentially Aristotelian in that it followed the unfolding or elaboration of an idea in experience from an unorganized multiplicity to an organized unity. This universal, unfolding unity or developing multiplicity within unity Carus called God. God, or the Divine, is not a being analogous to human intelligence; rather, it is the ground of being revealed through becoming, through the infinitely numerous and infinitely varying beings or organisms that come into being through the Divine in space and time.

Carus called his theory of a divine or creative force "entheism." The unknown Divine is revealed in nature through organization, structure, and organic unity. As the ground of being, it is outside space and time, unchanging, and eternal. As thought or insight, it is the God-idea of religion, found everywhere in life and the cosmos. As life, it is the sphere, the basic form taken by living cells and the heavenly stars. As matter, it is the ether exfoliating in infinitely varied things.

According to Carus, the body cannot be separated from the soul. Both are soul, but we speak of "body" when some unknown part of the soul affects the known part; and we speak of "soul" when the known part affects the unknown part.

Carus's metaphysics, and his important contribution to psychology, is a theory of movement from unconsciousness to consciousness and back again. Whatever understanding we can have of life and the human spirit hinges upon observation of how universal unconscious-

ness, the unknown Divine, becomes conscious. Universal unconsciousness is not teleological in itself; it achieves purpose only as it becomes conscious through conscious individuals. Consciousness is not more permanent than things; it is a moment between past and future. As a moment, it can maintain itself only through sleep or a return to the unknown.

## CARUS, PAUL

(1852–1919)

Paul Carus, a philosopher and monist, was born at Ilsenburg, Germany, and died in La Salle, Illinois. After receiving his Ph.D. at Tübingen, in 1876, and completing his military service, he taught in Dresden. Censure of religious views he had expressed in pamphlets led him to leave Germany for England. He then went to New York, where in 1885 he published *Monism and Meliorism*. This book aroused the interest of a German chemist in La Salle, Illinois, Edward Carl Hegeler, who had started a periodical, the *Open Court*. He invited Carus to take over the editorship. In 1888 another and more technical journal, the *Monist*, was founded, and Carus became its editor. Carus also published a series of philosophical classics, edited by leading professors of philosophy, which are still widely used in classrooms. The Carus family operated the Open Court Publishing Company until 1996. Open Court publishes the volumes of the Carus Lectures, which are given at meetings of the American Philosophical

Association. The *Monist* was revived in 1962 under the editorship of Eugene Freeman.

For the *Monist*, Carus chose articles on the history and philosophy of religion, archaeology, biblical criticism, and especially the philosophy of science, both philosophy for the scientifically minded and philosophy about the sciences. He invited contributions from France and Germany and arranged for their translation. Important articles by Bertrand Russell, Ernst Mach, David Hilbert, Jules Henri Poincaré, John Dewey, and Charles Sanders Peirce appeared in the *Monist*. Carus frequently published articles of his own in criticism of his contributors, but the debates seem not so much to have modified his own monistic philosophy as to have led him to explain in detail how it differed from other monisms, such as Ernst Haeckel's.

Monism, for Carus, was the doctrine that all the things that are—however varied, diverse, and independent of each other they may appear to be—are somehow one. What makes them one are certain eternal laws that reside in things and are discovered, not created, by the investigator. These laws of nature are asserted to be dependent on a single law, which Carus identified with God.

Carus viewed his metaphysics as a speculative generalization from the view of mathematics that he had learned from Hermann Grassmann, his teacher at the Stettin Gymnasium. Alfred North Whitehead, too, acknowledged the influence of Grassmann, in his *Universal Algebra*. Some of the similarities between the metaphysics of Carus and Whitehead may have resulted from this common influence.

Carus can be called a realist inasmuch as he rejected the notion that the laws of nature depend on the mind of the investigator. In this he found himself in opposition to the Kantians. Nor did he hold to a materialism. Rather, he insisted that every part of the world is both material (acting in accord with the laws of matter) and spiritual (acting in accord with the laws of mind). The characteristic of mind, or spirit, is the ability to mirror the world. Thus Carus was also a realist in his account of knowing. In ethics he held that the worth of any part of the world depends on the degree to which it knows—that is, mirrors—the whole. This is achieved through greater and greater knowledge of the laws of nature. Hence, devotion to knowledge is the way to greater goodness. Prayer is recommended as a means of changing the will of the man who prays so that he can mirror the one law in his actions.

## CASO, ANTONIO

(1883–1946)

Antonio Caso, a Mexican philosopher and diplomat, was born in Mexico City in 1883 and died there in 1946. He was a professor of philosophy at the National University of Mexico, rector of that institution, lecturer at the Colegio Nacional, and ambassador to several South American nations. He wrote voluminously over a period of three decades and had great influence as a teacher. For his sources he turned especially to Henri Bergson but also to Immanuel Kant, Arthur Schopenhauer, and Edmund Husserl.

The metaphysics of Caso emphasizes process, freedom, life, and spirit. He conceived of reality as a fluent dynamism whose operations and forms are unified organically. The subject-predicate bias of traditional logic distorts reality by its apparatus of static terms related as in a closed machine. Modern science has more insight with its realization that even the physical world eludes a rigorous determinism. The individual particle has a factor of spontaneity; law is only statistical, applying to groups by virtue of the mutual compensation of individual irregularities. By the same token, living process has a unique character that cannot be reduced to the terms of physics and chemistry but stimulates and directs the material vehicle. A conscious living being discovers its own freedom in the simple act of willing a bodily movement: freedom coincides with causation from within. Consciousness is not passively derived from more primitive conditions by laws of association and evolution. On the contrary, the pure ego projects its own structures upon the data of raw feeling, thus supplying the objects of

mature experience and the principles underlying those of association and evolution.

The ethics of Caso is concerned with two triads: that of things, individuals, and persons, and that of economy, disinterest, and love. Things are merely physical, are deficient in unity, are divisible, and are not subjects of value. Individuals are living beings that are indivisible but can be substituted for each other. The value of the merely biological is economy, found in egocentricity and utility and illustrated in nutrition, growth, reproduction, tool making, and death. Beyond individuals are persons, which add the character of spirit to life. Persons are capable of both disinterest and love. Disinterest suspends the mechanisms of selfishness and usefulness in the act of contemplation; love identifies the self with another in sympathy and service and is at its noblest in self-sacrifice. Persons are unique; they play a role as creators of values in society, and in them freedom is most advanced and responsible. Their interplay defines human culture, the enemies of which are individualism and totalitarianism; both are forms of egoism and of economic value. The error of totalitarian philosophy is to transfer the notion of the absolute from a universal principle of existence, where it is justified, to the state, where it does not exist. This philosophy has its source in Thomas Hobbes; it should not be imputed to G. W. F. Hegel, who placed art, religion, and philosophy above the state.

Caso's aesthetics begins with the concept of a surplus of energy, or vital excess, that is the basis of play, art, and the spirit of sacrifice. Art is distinguished from play and from the spirit of sacrifice by disinterest. In addition to the suspension of selfishness and usefulness, disinterest implies abstraction from questions of reality and goodness of the object contemplated. Disinterest preserves art from any possibility of immorality, which requires an interested attitude. It is associated with the intuitive nature of the aesthetic experience, since absorption in the object as an end favors appreciation of its full individuality. The nonconceptual nature of the experience is reconciled with the claim of universality, after the manner of Kant. The experience, however, does not terminate with an image within the mind. The conative tendency of psychic states leads to empathy, or projection of the state upon the outer world. Aesthetic empathy differs from the projection mentioned earlier in that it is emotional and concrete rather than logical and formal, and from that empathy and religious empathy in that it is disinterested. But natural objects do not readily satisfy the aesthetic need. Aesthetic empathy therefore leads to expression, or the creation of works of art, in which are consummated

the empathic tendency and disinterested intuition. In his account of intuition and expression, Caso claimed to follow Benedetto Croce, but he did not do so without wavering.

## CASSIRER, ERNST (1874–1945)

Ernst Cassirer, the German neo-Kantian philosopher, was born in Breslau, Silesia. He studied at the universities of Berlin, Leipzig, Heidelberg, and Marburg and taught first at Berlin. From 1919 to 1933 he was professor of philosophy at Hamburg University; and he served as rector from 1930 to 1933. Cassirer, who was Jewish, resigned his post in 1933 and left Germany. He taught at Oxford from 1933 to 1935, at Göteborg, Sweden from 1935 to 1941, and at Yale from 1941 to 1944. He died in New York City while a visiting professor at Columbia University.

Cassirer was both a prolific historian of philosophy and an original philosopher. His philosophy is in many important respects a development and modification of Immanuel Kant's critical philosophy, idealistic in outlook and transcendental in method. Like Kant, he holds that

the objective world results from the application of a priori principles to a manifold that can be apprehended only as differentiated and ordered by them. His method is transcendental in the sense that he investigates not so much the objects of knowledge and belief as the manner in which these objects come to be known or are constituted in consciousness. His work has to some extent also been influenced by G. W. F. Hegel and, of his own contemporaries, by his teacher Hermann Cohen and by Edmund Husserl.

Cassirer differs from Kant mainly in holding that the principles by which the manifold of experience receives its structure are not static, but developing; and that their field of application is wider than Kant supposed. Kant, according to Cassirer, assumed that the science and mathematics of his day admitted of no philosophically relevant alternatives, and therefore he conceived the synthetic a priori principles of the understanding to be unchangeable. He could not foresee the development of non-Euclidean geometry, of the modern axiomatic method, of the theory of relativity, or of quantum mechanics. Also, in Kant's day many areas of human culture had not yet been subjected to scientific investigation: There existed in particular no developed science of language and no scientific treatment of religion and myth. The idea of the humanities or moral sciences (*Geisteswissenschaften*) arose only in the nineteenth century. Cassirer's professed aim was to extend Kant's static critique of reason, that is, his critique of the organizing principles of natural science and morality, into a dynamic critique of culture, that is, of the organizing principles of the human mind in all its aspects. This aim is apparent in all his works, especially in his magnum opus, *Die Philosophie der symbolischen Formen*.

### THE NATURE OF SYMBOLIC REPRESENTATION

A fundamental problem for the Kantian philosophy had been to understand the conceptualization of experience, in particular the relation between concepts and that to which they apply. For Cassirer, conceptualization, that is, the apprehension of the manifold of experience as instantiating general notions or as perceptual matter exhibiting a conceptual structure, is merely a special case of what he calls "symbolization," "symbolic representation," or simply "representation." Symbolic representation, according to Cassirer, is the essential function of human consciousness and is cardinal to our understanding not only of the structure of science, but also of myth and religion, of language, of art, and of history. Man is a symbolizing animal.

Symbolization creates, and exhibits within our consciousness, connections between perceptual signs and their significance or meaning. It is the nature of symbolic representation in general to constitute, or bring into being, a totality that both transcends the perceptual sign and provides a context for it. The unity of sign and signified allows for distinction in thought, but not in fact—just as color and extension are separable in thought but not in fact. The given always shows itself as a totality, one part of which functions as a representative of the rest. This basic self-differentiation of every content of consciousness is given a more enduring structure by the use of artificial signs that, as it were, articulate the stream of consciousness and impose patterns on it. The artificial signs or symbols, like the Kantian concepts and categories, do not mirror an objective world, but are constitutive of it. Scientific symbols constitute, or bring about, only one kind of objective world—the world of science. Mythical pictures constitute the reality of myths and religion; the words of ordinary language constitute the reality of common sense.

To the three symbolic systems that articulate three types of reality under different “symbolic forms” there correspond three modes of the one function of symbolic representation. The first and most primitive of these modes Cassirer calls the “expression function” (*Ausdrucksfunktion*). In the world it constitutes, the primitive world of myth, the sign and its significance merge into each other. The difference between them exists, but is not consciously noted. The thunder by which a primitive god shows his anger is not merely an external sign that the god is angry. It is the god’s anger. In the same way, in ordinary perception we often not merely associate a smile with a kind intention, but also perceive a kindly smile.

The second mode of symbolic representation is “intuition function” (*Anschauungsfunktion*), which by the use of ordinary natural languages constitutes the world of common sense. The intuition function differentiates our perceptual world into spatially and temporally related material objects or substances that become the bearers of properties, the more permanent properties being apprehended as distinctive of the various kinds of substance, the less permanent being apprehended as accidental. Aristotle’s philosophy represents, according to Cassirer, a prescientific stage of thinking about objects, based on the predominance of symbolic representation in the mode of the intuition function.

The third mode of symbolic representation, the “conceptual function” (*reine Bedeutungsfunktion*) constitutes the world of science, which is a system of relations

as opposed to a system of substances with attributes. The particular, in this mode, is not subsumed under a universal but rather under a principle of ordering, which relates particulars to each other in ordered structures that, Cassirer seems to hold, are always serial in nature. He finds the prototype of this kind of symbolization in the works of Richard Dedekind, Giuseppe Peano, Gottlob Frege, and their successors.

The transcendental inquiry into the nature and function of symbolic representation is supported by a wealth of illustrations taken from the history of philosophy, the natural sciences, general linguistics, anthropology, and the humanities. Symbolic representation as a fundamental and logically primitive function must be seen at work in order to be understood. The philosophical analysis of symbolic representation can hardly do more than point out that in any symbolic representation two moments, the symbol and the symbolized, are united into an essential unity yet stand in polar relationship to each other. It has been objected that this analysis, by identifying a unity with an opposition of two different moments, results in a contradiction. Cassirer’s answer to this objection, and to accusations that his professedly Kantian position is really Hegelian, is that his philosophy is not intended as a logic or a metaphysics, but as a phenomenology of consciousness.

## PHILOSOPHY OF CULTURE

The highly general character of Cassirer’s analysis of symbolic representation gives flexibility to a philosophy of culture. It does not force the variety of the ever-changing contents and structure of culture into rigid and artificial molds. But the very generality of Cassirer’s conception makes it, perhaps, too easy to fit it to any situation and comparably difficult to test. It also makes it difficult to place the conclusions of Cassirer’s special investigations in order of importance. The order here followed is in the main that of the summary given at the end of his *Essay on Man*, itself a synopsis of his *Philosophie der symbolischen Formen*.

Cassirer holds that the polarity that he finds in the relation between symbol and significance or meaning continually expresses itself in two opposing tendencies, a tendency toward stabilization and a tendency toward the breaking up of permanent symbolic patterns. In myth and the primitive religions the conservative tendency is stronger. Mythological explanation explains patterns of the present in terms of origins in a remote past—a type of explanation still regarded in the Platonic dialogues as containing important elements of truth. The more

advanced religions exhibit the opposing evolutionary tendency at work. This is mainly the result of conceiving forces in nature as individuals and persons, and of the consequent emergence of the notion of morality as being rooted in personal responsibility.

In natural languages, through which the common-sense world of substances in public space and time is constituted, the conservative tendency shows itself in the rules to which a language must conform if communication is to be possible. The evolutionary tendency, which is equally essential, works through phonetic and semantic change. The psychology of the processes by which children acquire their language shows important similarities to the development of a language through succeeding generations in a community.

In the arts, the tendency toward new patterns, which has its source in the originality of the individual artist, predominates over the tendency to preserve a tradition. Yet traditional forms can never be entirely discarded, since this would imply the breakdown of communication, making art, which is a cultural and social phenomenon, impossible. The polarity in artistic creation is mirrored in the history of aesthetic theories. Theories of art as based on imitation and as based on inspiration have in one way or another continuously arisen in opposition to each other. Cassirer's own view of the nature of art is largely influenced by Kant's *Critique of Judgment*, in which the essence of artistic creation and aesthetic experience is held to lie in the interplay of the understanding, which imposes rules, and of the free imagination, which can never be completely subsumed under determinate concepts.

In science the stabilizing and objective tendency predominates over that toward change and subjective innovation. Cassirer's philosophy of science is recognizably Kantian, although Kant's absolute a priori is replaced in it by a relative a priori. Scientific theories contain, apart from empirical concepts and propositions, concepts that are a priori and propositions that are synthetic a priori with respect to a given theoretical system. This idea has proved both fruitful and influential and has been further developed by, among others, Arthur Pap, at one time a pupil of Cassirer. Relative a priori concepts and propositions are hardly distinguishable from the theoretical concepts and propositions admitted by logical positivist philosophers of science when it appeared that their original positions were not wholly tenable.

Cassirer regards language, art, religion, and science as aspects in a continuous development that although it is not predictable in advance, does show an organic unity.

Every aspect expresses the fundamental function of symbolic representation in human consciousness and the power of man to build an "ideal" or symbolic world of his own, which is human culture. Cassirer's work depends to a very great extent on the illustrative power of his detailed analyses. For this reason it is difficult to do it justice in a brief survey, especially since philosophical disagreement with his critical idealism is quite compatible with a deep appreciation of his informed scholarship and his sensitive judgment as to what is and what is not important in the various symbolic and conceptual systems that he has investigated.

## Bibliography

### SELECTED WORKS BY CASSIRER

#### Theoretical

*Substanzbegriff und Funktionsbegriff*. Berlin: Cassirer, 1910.

*Zur Einsteinschen Relativitätstheorie*. Berlin: Cassirer, 1921.

These two works have been translated in one volume as *Substance and Function and Einstein's Theory of Relativity*. Chicago: Open Court, 1923; reprinted New York, 1953.

*Philosophie der Symbolischen Formen*. 3 vols. Berlin: Cassirer, 1923, 1925, 1929. *Index*, Berlin, 1931. Translated by Ralph Manheim as *Philosophy of Symbolic Forms*. 3 vols. New Haven, CT: Yale University Press, 1953, 1955, 1957.

*Symbol, Myth, and Culture: Essays and Lectures of Ernst Cassirer, 1935–1945*, edited by Donald Phillip Verene. New Haven, CT: Yale University Press, 1979.

*Zur Logik der Kulturwissenschaften*. Göteborg: Göteborgs Höskolas Årsskrift 47, 1942. Translated by S. G. Lofts as *The Logic of the Humanities*, New Haven, CT: Yale, 2001.

*An Essay on Man*. New Haven, CT: Yale University Press, 1944.

#### Historical

*Leibniz's System in seinen wissenschaftlichen Grundlagen*. Marburg: Elwert, 1902.

*Das Erkenntnisproblem in der Philosophie und Wissenschaft der neueren Zeit*. 3 vols. Berlin: Cassirer, 1906, 1907, 1920. Vol. 4 translated by W. H. Woglom and C. W. Hendel as *The Problem of Knowledge*. New Haven, CT: Yale University Press, 1950.

*Freiheit und Form, Studien zur deutschen Geistesgeschichte*. Berlin: Cassirer, 1916.

*Kants Leben und Lehre*. Vol. XI of *Immanuel Kant's Werke*, edited by Ernst Cassirer and Hermann Cohen. Berlin: Cassirer, 1918.

*Individuum und Kosmos in der Philosophie der Renaissance*. Leipzig: Teubner, 1927. Translated by Mario Domandi as *The Individual and the Cosmos in Renaissance Philosophy*. New York: Harper, 1964.

*Die Platonische Renaissance in England und die Schule von Cambridge.* Leipzig: Teubner, 1932. Translated by F. C. A. Koelln and James P. Pettegrove as *The Platonic Renaissance in England.* Austin: University of Texas Press, 1953.

*Die Philosophie der Aufklärung.* Tübingen: Mohr, 1932. Translated by F. C. A. Koelln and James P. Pettegrove as *The Philosophy of the Enlightenment.* Princeton, NJ: Princeton University Press, 1951.

## CATEGORICAL IMPERATIVE

Immanuel Kant (1724–1804) introduced the term “categorical imperative” to characterize the fundamental principle of morality as it presents itself to beings. The principle is categorical, or unconditional, because it is valid for all humans, indeed, for all rational beings, independently of any particular desires or aims they may have. It presents itself as an imperative precisely because human beings have desires and aims that can be incompatible with the unconditional demands of the principle of morality and thus those demands often present themselves as obligations and constraints. Hence the propositional content of the fundamental principle of morality is identical for all rational beings, but its coloration as an imperative is distinctively human. For Kant, since there is

a single fundamental principle of morality, there is, properly speaking, only a single categorical imperative, although more specific moral duties and obligations derivable from it are themselves unconditionally valid for any agent in the situation in which they arise. Kant contrasts the categorical imperative with “hypothetical imperatives,” which express only the necessity of adopting certain means to achieve certain ends that are themselves merely conditional. Hypothetical imperatives can also present themselves to us as constraints, because we are not always sufficiently rational even to accept willingly the means to ends that we have willingly adopted, but in the case of hypothetical imperatives, we are not under any moral constraint to adopt the ends concerned.

Kant anticipated his mature distinction between categorical and hypothetical imperatives in his *Inquiry concerning the Distinctness of the Principles of Natural Theology and Morality* of 1764. There he wrote, “Every *ought* expresses a necessity of the action and is capable of two meanings. ... Either I ought to do something (as a *means*) if I want something else (as an *end*), or I *ought immediately* to do something else (as an *end*) and make it actual.” He argued that the former do not really express obligations at all; rather, they express only “recommendations to adopt a suitable procedure, if one wish[es] to attain a given end.” Genuine obligations, by contrast, are “subordinated to an end which is necessary in itself.” Kant’s examples of ends that might be necessary in themselves were advancing the greatest total perfection and acting in accord with the will of God (Kant 1764; in Kant 1900, 2: 298; in Kant 1992, p. 272). The first of these is the ultimate end of morality according to Christian Wolff (1679–1754) and Alexander Baumgarten (1714–1762), and the latter the ultimate end of morality according to their Pietist opponent Christian August Crusius (1715–1775). In his *Anweisung, vernünftig zu leben* (Guide to living rationally; 1744/1964), Crusius himself anticipated the distinction that Kant made in the *Inquiry* by contrasting duties of prudence, which are grounded “only in certain ends already desired by us,” with true obligations, which are grounded in “moral necessity” lying “in a law and in our owing fulfillment of it,” and ultimately, in the case of “the obligation of virtue, or true obligation in a narrower sense,” in divine law (§161). A widespread account of Kant’s development of his mature conception of the categorical imperative is that he moved from the idea of an unconditional obligation grounded in a necessary end to the idea of an unconditional obligation that does not depend on any end whatever. Below, that will turn out to be misleading.

Kant first published his mature account of the categorical imperative in his *Groundwork for the Metaphysics of Morals* (1785). There Kant distinguished the categorical imperative from two kinds of hypothetical imperatives, namely, hypothetical imperatives of skill, which simply prescribe practically necessary means to realize entirely optional ends, and the hypothetical imperative of prudence, which prescribes means to an end that all human beings have as a matter of fact, namely happiness. Kant described the imperatives of skill as “problematic” (debatable, since the ends are optional) and the imperative of prudence as “assertoric” (impelled by the goal of happiness). Because the end of happiness is universal but not obligatory and because it is also indeterminate what will actually make anyone happy, the imperative of prudence can give rise only to “counsels of prudence.” Finally, Kant stated, “There is one imperative that, without being based upon and having as its condition any other purpose to be attained by certain conduct, commands this conduct immediately. ... It has to do not with the matter of the action and what is to result from it, but with the form and principle from which the action itself follows” (Kant 1785; in Kant 1900, 4:415–416; in Kant 1996, pp. 68–69). This is the categorical imperative, which is apodictic (certain).

In the *Groundwork*, Kant gave his first official formulation of the categorical imperative and the one to which he most frequently refers in subsequent works. This is that one “must act only in accordance with that maxim through which you can at the same time will that it become a universal law” (Kant 1785; in Kant 1900, 4:421; in Kant 1996, p. 73). He reached this formulation by different routes in the first and second sections of the book. In the first section, he began with the claim that only a good will is of unconditional value, and then argued that a good will is demonstrated in acting from the motive of duty, where “duty is the necessity of an action from respect for law” (Kant 1785; in Kant 1900, 4:400; in Kant 1996, p. 55), rather than in acting from any inclination toward a particular end or object. The good will having thereby been deprived of any inclination to realize it with action, nothing is left as its principle “but the conformity of actions as such with universal law” (Kant 1785; in Kant 1900, 4:402; in Kant 1996, p. 56).

In the second section, Kant argued that the formula of universal law follows from the very concept of the categorical imperative, since once it is stipulated that such an imperative “contains no condition to which it would be limited, nothing is left with which the maxim of action is to conform but the universality of a law as such” (Kant

1785; in Kant 1900, 4:420–421; in Kant 1996, p. 73). In his *Critique of Practical Reason* of 1788 (1996), Kant derives a similar formulation of the categorical imperative from the initial premises that any practical law must be necessary, but that any objective for action is empirical and contingent—a circumstance that leaves only the form of a law to furnish content for the categorical imperative (theorem III, Kant 1788, in Kant 1900, 5:27; in Kant 1996, p. 160).

In the *Groundwork*, Kant offers four further formulations of the categorical imperative. The first of these is “Act as if your maxim were to become by your will a universal law of nature” (Kant 1785; in Kant 1900, 4:421; in Kant 1996, p. 73), where a maxim is a proposal to perform a certain type of action for a certain end. H. J. Paton (1947) held that this introduces a teleological conception of nature into Kant’s argument, and this is true in Kant’s first illustration of how the imperative yields a prohibition of suicide. But since all that Kant explicitly meant by a law of nature is a law that is uniformly followed, this formulation, like the initial one, requires only that you consider whether you could act on your proposed maxim if in fact everyone else were also to act on it. In the second formulation, Kant said that “a possible categorical imperative” needs a ground in “something *the existence of which in itself* has an absolute worth, something which *as an end in itself* could be a ground of determinate laws,” and stated that this ground is “the human being and in general every rational being” (Kant 1785; in Kant 1900, 4:428; in Kant 1997, p. 78). This leads Kant to reformulate the imperative as follows: “So act that you use humanity, whether in your own person or in the person of any other, always as an end and never merely as a means” (Kant 1785; in Kant 1900, 4:429; in Kant 1996, p. 80). By “humanity” Kant meant just the capacity to set and pursue ends (Kant 1785; in Kant 1900, 4:437; in Kant 1996, p. 86; Kant 1797; in Kant 1900, 6:387, 392; in Kant 1996, pp. 518, 522), so this requirement means that the human capacity to set and pursue ends should itself always be an end and never merely a means. Kant interpreted this requirement in turn to mean that the categorical imperative requires that you act only for ends that others can accept or even adopt for themselves. Third, Kant reformulated the imperative as “the principle of a human will as a will giving universal laws through all its maxims” (Kant 1785; in Kant 1900, 4:432; in Kant 1996, p. 82), which requires that any maxim be part of a universally acceptable *system* of maxims. Finally, he formulated the imperative as the requirement that “all maxims from one’s own lawgiving are to harmonize into a possible kingdom of ends” (Kant 1785; in Kant 1900, 4:436; in Kant 1996, p. 86), which is “a

whole both of rational beings as ends in themselves and of the ends of his own that each may set himself” (Kant 1785; in Kant 1900, 4:433; in Kant 1996, p. 83).

This formulation makes explicit that to treat everyone as an end involves not only acting only on universally acceptable maxims but also allowing and promoting the individual ends of each insofar as doing so is consistent with treating all as ends in themselves. This sequence of formulations thus shows that the normative force of the categorical imperative is grounded on recognition of a necessary end, thus that the distance between Kant’s mature formulation and his initial formulation of twenty years earlier is not as great as it initially seems, and that far from proscribing actions in behalf of particular, contingent ends, the categorical imperative prescribes such actions to the extent that such ends are freely chosen and are consistent with universal law. This is the foundation for Kant’s doctrine of duties.

G. W. F. Hegel famously charged that Kant’s categorical imperative is an “empty formalism,” that is, that it either presupposes some already accepted particular end or else licenses any action that anyone is willing to universalize. This is clearly false, since the imperative requires consistency between any maxim on which you are proposing to act and the universalization of that maxim. Moreover, as the analysis above shows, universalization includes the requirement that your maxim be universally acceptable. This means that it is not enough that *you* be willing for your maxim to be universalized; everyone must be willing. More recent authors, including Marcus G. Singer (1971), Onora O’Neill (1975, 1989), and Allen Wood (1999), have considered cases in which clearly permissible maxims seem to fail the test of universalizability while clearly impermissible maxims seem to pass it. This shows that considerable care is needed in properly formulating maxims to be tested by the categorical imperative. John Rawls (2000) has interpreted the categorical imperative as yielding a “CI-procedure,” which can be directly applied to individual maxims or proposals of action, while Barbara Herman (1993) has argued that it rather yields “rules of moral salience,” that is, general factors of moral relevance that need to be considered in undertaking any particular action. The latter seems closer to Kant’s own use of “categorical imperative” in the *Metaphysics of Morals* (1797) to yield general categories of duty, although Kant himself sometimes interpreted the requirement of being universalizable to apply to very specific types of action, as in his notorious argument of 1798 that lying is always wrong, no matter what the circumstances.

In addition to these questions about the interpretation and application of the categorical imperative, it has been criticized from a number of other points of view. Philippa Foot (1972/1978) has argued that categorical form is not sufficient to show that a requirement is moral, since rules of etiquette are also stated in categorical form. She concluded that both etiquette and morality, in spite of their categorical form, are really systems of hypothetical imperatives, to be adopted only if one wants to be regarded as polite or moral respectively. Bernard Williams (1985) accepted the categorical imperative as formulating the demands of morality, but raised questions about whether these demands are “overriding,” that is, whether one’s own personal projects and goals must always be sacrificed to the demands of morality in cases of conflict between them. R. M. Hare (1971) likewise accepted that moral principles have the form of categorical imperatives, or universal prescriptions, while raising the question of whether such prescriptions must always be accepted. These latter objections suggest that Kant was correct to use the concept of the categorical imperative to characterize the demands of morality, but that there is room to debate both whether he correctly identified the ground of any possible categorical imperative and whether morality itself is overriding.

## CATEGORIES

Philosophical categories are classes, genera, or types supposed to mark necessary divisions within our conceptual scheme, divisions that we must recognize if we are to make literal sense in our discourse about the world. To say that two entities belong to different categories is to say that they have literally nothing in common, that we cannot apply the same descriptive terms to both unless we speak metaphorically or equivocally.

### ARISTOTELIAN THEORY

The word *category* was first used as a technical term in philosophy by Aristotle. In his short treatise called *Categories*, he held that every uncombined expression signifies (denotes, refers to) one or more things falling in at least one of the following ten classes: substance, quantity, quality, relation, place, time, posture, state, action, and passion. By “uncombined expression” Aristotle meant an expression considered apart from its combination with other expressions in a sentence, and he intended his account to apply only to those expressions we now call

“descriptive” and “nonlogical.” Logical expressions, such as “not,” “or,” “some,” and “every,” are excluded; these were called by medieval philosophers “syncategorematic,” to distinguish them from the categorematic expressions covered by Aristotle’s account of categories.

Each of the ten classes of entities signified constitutes a category, or genus, of entities, and each categorematic expression is said to be an expression in the category constituted by the class of entities it signifies. The nouns “plant” and “animal,” for example, signify kinds of substances and are said to be expressions in the category of substance; the nouns “color” and “justice” signify kinds of qualities and are said to be expressions in the category of quality. On the other hand, the adjectives “colored” and “just” signify, respectively, colored and just things (substances) and also connote (consignify) the qualities color and justice. Aristotle labeled such expressions “derivative terms” or “paronyms” and held that instead of signifying substances simply, as expressions in the category of substance do, they signify substances derivatively by connoting accidents of substances.

Although Aristotle implied that his ten categories constitute the ten highest genera of entities and hence the only true genera—the only genera that cannot be taken as species of higher genera—he also implied that it is not essential to his theory that the categories be exactly ten in number or even that they be mutually exclusive and exhaustive. Categories are listed in various of Aristotle’s writings, but the list usually stops short of ten without indication that categories have been omitted. He explicitly stated that no absurdity would result if the same items were included in both the category of quality and that of relation. He remarked that the expressions “rare,” “dense,” “rough,” and “smooth” do not signify qualities, since they apply to a substance with reference to a quality it possesses, yet he did not specify in which category or categories these expressions are included. Despite these indications that his theory of categories is not entirely complete, medieval philosophers generally wrote as though Aristotle’s list of ten provided a final, exhaustive enumeration of the highest genera of being.

What is essential to Aristotle’s theory of categories is that substances be properly distinguished from accidents and essential predication from accidental predication. Any entity, regardless of the category in which it is included, can be an entity referred to by the subject term of an essential predication. “Man is an animal.” “Red is a color.” “Four is a number.” “A year is twelve months.” The subject terms denote entities that fall, respectively, in the categories of substance, quality, quantity, and time, and

the predication in each case is essential. On the other hand, only entities in the category of substance can be entities referred to by subject terms of accidental predication. There is no such thing as an accident of an accident; accidents happen to substances and not to other accidents. “Red is darker than orange” does not assert something that happens to be, but need not be, true of red; it asserts what is essentially true of red, something that red must always be if it is to remain the color red. “Red is John’s favorite color” does not assert anything that may happen to be true of red; rather, it asserts something that may happen to be true of John. To undergo change through time while remaining numerically one and the same thing is what principally distinguishes substances from entities in other categories. If John ceases to regard red as his favorite color, we say not that red has changed while remaining the same color but that John has changed while remaining the same person.

Categorematic expressions, for Aristotle, are technically “predicates,” but they are not “predicates” in a sense that keeps them from serving as subject terms in essential predication. The minor term of an Aristotelian “scientific syllogism” occurs only as a subject, though Aristotle gave no examples in which it is a proper name. He regarded the ultimate subject terms in demonstration as common names marking species that are not further divided. Such expressions are still “predicates” in that like more generic terms they are applied to individuals in answer to the question What is it? But proper names are in a class by themselves; they are applied only in answer to the question Who? or Which? and are not “predicates” at all. Yet if proper names are thus not categorematic expressions, they are still fundamental to Aristotle’s theory of categories. Without proper names there are no names for the subjects of accidental as distinct from essential predication. Man as such is an animal—“man” names every person indifferently if it names any, and the question of naming which one (or ones) does not arise. But only some man (or men) is (are) snub-nosed, and until the question Which? is answered by a proper name the subject of the accidental predication remains unnamed.

CATEGORY-MISTAKES. If we ask what, according to Aristotle’s theory, would be the sort of thing often called today a “category-mistake,” we must distinguish a mistake that violates what is essential to the theory from a mistake that violates a particular category-difference marked by the theory. Only a mistake of the first kind is strictly a category-mistake. Mistakes of the second kind form a subclass of equivocations. In his *Topics* (107a3–17), Aristotle listed as one example of equivocation the sentence

“The musical note and knife are sharp.” That “sharp” is here used equivocally is shown by the fact that a musical note and a knife belong to different categories. A musical note is a kind of sound, and sounds are qualities. (Aristotle argued in *On the Soul*, 420a25–28, that we speak of the sound of a body as we speak of the color of a body.) A knife is a kind of substance, and one who believes that “sharp” applies in the same sense to musical notes and to knives may be said to have made the category-mistake of confusing a quality and a substance. Yet an appeal to category-differences is not necessary to expose the equivocation, and many equivocations cannot be exposed in this way because there is no violation of a category-difference. Aristotle claimed that the equivocal use of “sharp” in the example is also exposed by the fact (among others) that musical notes and knives are not compared with respect to their sharpness. Two notes may be equally sharp, or two knives, but not a note and a knife. Again, two flavors are equally sharp, but not a flavor and a note or a flavor and a knife. The equivocation in “The flavor and note are sharp” is exposed, although since flavors and sounds are both qualities there is no violation of a category-difference.

The appearance of absurdity produced by an equivocation can always be removed and literal meaning restored by distinction between the different senses of the crucial words. But with a genuine category-mistake there is no literal meaning to restore. In a passage in his *Posterior Analytics* (83a30–33), where he was discussing features of essential and accidental predication, Aristotle remarked that Plato’s forms can be dismissed as mere sound without sense. The point is illustrated by a sentence like “The color white is white.” The sentence may seem to make sense if one claims that since the color white is the standard by which we judge things to be white, it is itself white. But the sense is only apparent, because whatever is white remains numerically one and the same object even if its color changes. Such an object cannot be the quality, that is, the color white itself, as we then have the absurdity that the color white changes its color. Plato’s theory of forms, as Aristotle interpreted it, makes the mistake of confusing accidental with essential predication. “The color white is the color white” is not an accidental but a trivially true essential predication; it is clearly not what is intended by the Platonic assertion that the color white is white. But the latter is just as absurd as the assertion that sitting sits.

Except in the passage in the *Posterior Analytics*, Aristotle did not refer to Plato’s forms as mere sound without sense. Plato’s theory has certain affinities with Aristotle’s

metaphysical account of substance as a composite of form and matter, and in his *Metaphysics*, Aristotle criticized Plato’s forms, not as sound without sense, but as entities that fail to do the job they should, since they cannot be formal causes (991a11; 1033b26) and lead to an infinite regress (the third-man argument: 990b17). His criticism of the theory of forms receives attention in the history of philosophy mainly in this context of form, matter, and substance, and the passage in the *Posterior Analytics* that dismisses the forms as sound without sense is generally passed over or dismissed as a result of more than usual hostility toward Platonists. Yet apart from hostility, Aristotle was required by his theory to regard a sentence like “The color white is white” strictly as a category-mistake.

### KANTIAN THEORY

Aristotle’s theory dominated discussion of categories until the work of Immanuel Kant, where we find a radically new conception of a category. Kant professed in his theory of categories to have achieved what Aristotle had tried but failed to achieve in such a theory. Instead of beginning with uncombined expressions, Aristotle should have started with expressions of statements or judgments. Every statement is universal, particular, or singular in quantity; affirmative, negative, or infinite in quality; categorical, hypothetical, or disjunctive in the relation of its parts; and problematic, assertoric, or apodictic in modality (*Critique of Pure Reason*, “Transcendental Analytic,” I, 2–3). Each of these twelve ways in which judgments are classified in logic corresponds to a function of the understanding indispensable to the formation of judgments, and each such function yields a category, or pure concept of the understanding, in one of the four major divisions of categories: quantity, quality, relation, and modality. The function, for example, of relating subject to predicate in a categorical judgment yields the relational category of substance and accident, and the function of relating antecedent to consequent in a hypothetical judgment yields the relational category of cause and effect.

Kant’s conception of substance leads to important departures from Aristotle in the treatment of common names and paronyms. Whether an expression serves as a common name or as a paronym depends on its function in a given statement and not on its signification as an uncombined expression. “Stone,” for example, serves as a common name of the substance in which a change occurs in “The stone grows warm,” but it serves to specify a kind of change that occurs in a substance in “The sand

becomes stone.” In the second case “stone” serves as a paronym; it connotes certain properties, such as hardness and solidity, and denotes any substance, such as a certain amount of sand, that acquires these properties. For Aristotle the change from sand to stone is substantial change, or coming to be, rather than alteration; for Kant substantial change is impossible because substance is related to accident as that which undergoes alteration is related to that which becomes and ceases to be. A substance is altered when one of its accidents ceases to be and is followed by another accident, so accidents, not substances, become and cease to be.

With Kant’s theory there are no ordinary equivocations that can be exposed as category-mistakes, since categories are pure (formal), as opposed to empirical, concepts. “Substance” and “quality,” in Aristotle’s theory, are the highest generic terms that apply, respectively, to knives and sounds, so the equivocation in “The knife and musical note are sharp” can be exposed as a confusion of a substance and a quality. In Kant’s theory, by contrast, generic terms represent empirical concepts, and an equivocation that confuses genera, as “The knife and musical note are sharp” confuses bodies and sounds, is not a category-mistake but a confusion of empirical concepts. One makes a category-mistake—violates what is essential to Kant’s theory—by misapplying a category rather than by mistaking the category in which an entity belongs. The important point is that Kant’s categories apply only to phenomena or appearances, not to entities or things in themselves. Every appearance can be judged according to every category and cannot be said to belong properly in one category rather than another. An appearance of red, for example, has extensive magnitude equal to a spatial area and is hence a quantity; it has intensive magnitude as a sensation with a certain degree of intensity and is hence a quality; it is related to further appearances as accident is to substance and effect to cause; and in relation to other appearances it is possible, actual, or necessary.

In Aristotle’s theory, on the contrary, a redness is properly an accident in the category of quality; it exists in a substance from which it may be separated in thought but not in being. The extensive magnitude comprising a spatial area is a quantity of the substance and not of the redness; the intensity of the sensation of redness is a quality of the perceiving subject. Questions concerning the cause or the possibility, actuality, and necessity of the redness can be answered only by references to the substance that is said to be red. When the color is separated in thought from the substance the resulting abstract entity, the color red, can be characterized essentially (red, for

example, is darker than orange), but to take it as an entity that itself has accidents is to make the category-mistake of confusing a quality with a substance.

To say that the color red is red is, for Kant, to misapply the relational category of substance and accident. Categories can be applied correctly only to phenomena, and in the case of a relational category both terms of the relation must be phenomena. The phrase “the color red” stands for the concept under which appearances of red are subsumed and not for an appearance that may be related to an appearance of red as substance to accident. This sort of category-mistake needs little attention since with Kant’s theory there is no compelling tendency of the human mind to confuse a concept with its instances. But there is a natural tendency to make the mistake of applying categories to what are technically, for Kant, ideas and ideals; the former give rise to antinomies of pure reason and the latter to fallacious proofs of God’s existence. Platonism in the form that gains a hold on men’s minds is the mistake of applying the category of existence to ideals, not the mistake of confusing a concept with its instances. Along with antinomies and fallacious proofs of God, Kant argued for a third kind of category-mistake, a mistake that occurs when categories are misapplied in judgments about a thinking substance; the result is a set of equivocations giving rise to what Kant called “paralogisms of pure reason.” These three kinds of category-mistakes are to be exposed not as sound without sense but as illusions to which the human mind is naturally prone.

## POST-KANTIAN THEORIES

Although Kant’s theory of categories marks the single most important development in the subject since Aristotle, his list of twelve categories never acquired anything like the dominant role once held by Aristotle’s list of ten. Kant’s influence has been to change the conception of how a list of categories should be formed, rather than to provide the list itself. Instead of looking for the highest genera of being, the most universal kinds of entities, one should look for the most universal forms of understanding presupposed in the formation of judgments. The strong influence of Kant is evident in the theories of categories of such philosophers as G. W. F. Hegel, Edmund Husserl, and Charles Sanders Peirce.

Peirce’s theory is closely connected with his contributions to logic, but his conception of what constitutes a category is sufficiently Kantian to distinguish his theory radically from the theory usually associated with the development of modern logic.

**THEORY OF TYPES.** Bertrand Russell originally devised his theory of types as a means of avoiding a contradiction he had discovered in Gottlob Frege's logic, but the theory has profound implications for philosophy in general, and under its influence "category" has come to be used frequently as a synonym for "logical type."

As the theory of types is presented in *Principia Mathematica*, its cardinal principle (called by Russell the "vicious-circle principle") is that whatever involves all of a collection must not be one of the collection. The class of white objects, for example, includes (and hence involves) all white objects, and to say that this class is itself a white object is to violate the principle and to utter nonsense. The set of entities consisting of all white objects and the class of white objects is for Russell an "illegitimate totality," a set that "has no total" in the sense that no significant statement can be made about all its members. The purpose of the theory of types is to provide a theoretical basis for breaking up such a set into legitimate totalities. A totality is legitimate when and only when all its members belong to the same logical type, and two entities are of different logical types when and only when their inclusion in the same class yields an illegitimate totality. Whenever an entity involves all the members of a given class its logical type is said to be higher than the type of the members of this class. Logical types thus form an infinite hierarchy with individuals at the lowest level, or zero type, classes of individuals at the next level, then classes of classes, and so on. Since to every class there corresponds a defining property of that class, there is an equivalent hierarchy of logical types with individuals again at the lowest level, but with properties of individuals next, then properties of properties of individuals, and so on. "X is a member of the class of white objects" is equivalent to "X is white," and the two sentences "The class of white objects is a white object" and "The color white is white" are equally expressions of a type-mistake or category-mistake and are equally nonsensical.

The theory of types, if true, gets rid of the contradiction Russell wanted to avoid. This contradiction arises when the class of all classes that are not members of themselves is said to be or not to be a member of itself. According to the theory of types the attempt to make either assertion violates the vicious-circle principle and results in nonsense. But if this way of avoiding the contradiction is to be satisfactory, there must be reasons for accepting the theory of types other than the fact that if it is accepted the contradiction it was designed to avoid is avoided. Efforts to find such reasons have carried investigations concerning the theory of types from the sphere of

technical issues in mathematical logic into the sphere of philosophical issues in a theory of categories. Developments in both spheres have often proceeded independently, and even though technical work in mathematical logic has developed alternatives to the theory of types (especially to the theory as first stated by Russell), the fact that the theory is not needed to avoid the original contradiction is not in itself conclusive evidence that the theory has nothing to be said for it as a theory of categories.

Russell offered in support of the theory of types the fact that it outlaws not only conditions giving rise to the paradox concerning class membership but also those giving rise to an indefinite number of other paradoxes of self-reference, including the ancient paradox of the liar. But alternative ways of avoiding these other paradoxes have been developed. More serious than its nonuniqueness as a consistent solution to the problems it was designed to avoid is a difficulty intrinsic to the theory itself. Even if the theory is true, there seems to be no way to state it without contradiction. The word *type* illustrates the point. In stating the theory one uses this word, which is itself a particular entity, with reference to all entities, so one entity is made to involve the collection of all entities. Russell tried to cope with the difficulty by proposing that a difference in logical type be taken as a difference in syntactical function rather than a difference in the totalities to which two entities may be legitimately assigned. Instead of saying that the color white and a table are of different logical types because the latter but not the former can be included in the class of all white objects without forming an illegitimate totality, we may say that the phrases "the color white" and "a table" belong to different logical types because the latter but not the former yields a significant statement when it replaces X in the sentence-form "X is white."

Reference to linguistic expressions rather than entities avoids a vicious-circle fallacy because the hierarchy of types asserted by the theory then includes only the totality of expressions within a given language, not the totality of all entities. But any given statement of the theory must be in a metalanguage whose expressions are not included in the totality of expressions covered by the statement. While the theory can thus never be applied to the language in which it is itself stated, it can always in principle be restated in a further language (a meta-metalanguage) so that it applies to the language in which it was originally stated as well as the language to which it originally applied. Universal application of the theory is thus possible in principle by proceeding up an infinite hierarchy of languages, while the application of the theory to each

particular language asserts the existence of an infinite hierarchy of types of syntactical functions within that language. But in neither case is there the simple assertion that the class of all entities comprises an infinite hierarchy of logical types.

The conception of logical type as syntactical function is much easier to maintain when the expressions typed are those of an artificial language, such as a logical calculus, rather than those of a natural language, such as English. Generalization about the totality of expressions in an artificial language is easy because this totality is generated by the rules one must lay down if one is to construct an artificial language in a clear and definite sense. But such relativity to the rules of an artificial language makes it impossible to maintain all that was originally claimed for the theory of types. Russell was originally understood as claiming to have *discovered* that what appears to be stated by sentences like “The color white is white” and “The class of white objects is a white object” is simply nonsense. But then it seems that the most one can say is that Russell *constructed* an artificial language (a calculus or formalism) in which the translations of these English sentences are not well-formed formulas. The mere construction of such a language is clearly not the same as the discovery that in point of logic certain apparent statements are really nonsense. The case against Russell’s original claim is all the more damaging in view of the fact that formalisms have since been constructed in which translations of certain sentences that are nonsense according to the theory of types are well-formed formulas, and the contradiction the theory of types was designed to avoid does not appear. Enlarging the notion of logical type to include semantic as well as syntactical function does not change the picture. Semantic rules for an artificial language are necessary if one is to do certain things with the language, but these rules, like syntactical rules, are stipulated in the construction of the formalism; addition of such rules in no way furthers the claim to having discovered that certain sentences are nonsense rather than having constructed a language in which they become nonsense.

#### CATEGORIES AS DISCOVERED IN A NATURAL LANGUAGE

The claim to discovery is essential to a theory of categories, and the claim may still be made if types are found among the expressions of a natural language rather than imposed on the expressions of an artificial language. Instead of beginning with the vicious-circle principle as defining a condition we must impose on any language if

we want to make sense, we may begin with expressions in the natural language we ordinarily use—expressions with which we assume we make sense, if we make sense at all—and try to determine what differences in type our making sense requires us to recognize in these expressions. This sort of approach is taken by Gilbert Ryle in *The Concept of Mind*, where he considers expressions we use in talking about mental powers and operations and argues that certain of these expressions cannot belong to the same type or category as others. Ryle’s test for a category-difference is a case where one of two expressions cannot replace the other without turning the literal meaning of a sentence into an absurdity. To begin with an obvious case, when “the man” in “The man is in bed” is replaced by “Saturday” the result is clearly an absurd sentence if taken literally. Less obvious cases often go undetected by philosophers and remain a source of philosophical confusion. “He scanned the hedgerow carefully” becomes absurd when “saw” replaces “scanned,” although the absurdity disappears when the adverb is omitted. Failure to note that “to see” belongs in the category of “achievement” verbs while “to scan” is a “task” or “search” verb has misled philosophers to posit a mental activity corresponding to seeing that is analogous to the genuine activity of scanning.

For Ryle categories are indefinitely numerous and unordered. The totality of categories is not in principle an infinite hierarchy of types; categories provide no architectonic such as Kant’s fourfold division of triads; and there is no distinction setting off one category from all the others as basic regardless of their number, as Aristotle’s distinction between substance and accident. There are thus no mistakes that are strictly category-mistakes rather than ordinary equivocations or absurdities. Ryle explains in his article “Categories” that he uses “absurdity” rather than “nonsense” because he wants to distinguish a category-mistake from mere sound without sense. According to Ryle, a category-mistake is not a meaningless noise but a remark that is somehow out of place when its literal meaning is taken seriously; many jokes, he observes, are in fact “type-pranks.”

#### WHAT IS A THEORY OF CATEGORIES?

The above observations suggest that Ryle has no *theory* of categories at all—no principles by which categories can be determined and ordered. Yet he seems unwilling to give up all claims to a theory of categories. He is especially concerned with countering the impression that category-differences are on a par with differences created by a particular set of linguistic rules. In his article “Categories” he

considers briefly the question What are types of? He suggests that instead of saying absurdities result from an improper coupling of linguistic expressions, it is more correct to say that they result from an improper coupling of what the expressions signify. But one must be wary of saying that types are types of the *significata* of expressions. A phrase like “*significata* of expressions” can never be used univocally, because such use presupposes that all *significata* are of the same type. Ryle claims we can get along without an expression that purports to specify what types are types of, since the functions of such an expression are “purely stenographic”; if we want an expression performing these functions, he suggests “proposition-factor” but cautions that to ask what proposition-factors are like is ridiculous since the phrase “proposition-factor” has all possible type-ambiguities.

Ryle seems hardly to have advanced the question of the status of a theory of categories beyond the point where Russell left it. It appears to be just as difficult to establish category-differences by appeal solely to ordinary language as to establish them by appeal solely to an artificial language. J. J. C. Smart points out, in “A Note on Categories,” that with Ryle’s test of a category-difference we are led to make very implausible (if not absurd) claims about category-differences. When, for example, “table” replaces “chair” in “The seat of the chair is hard,” the result seems clearly an absurd sentence. Yet if “table” and “chair” do not belong in the same category, what words do? If the phrase “category-difference” is to have anything like the force it has had from Aristotle to Russell, the claim to having discovered that “table” and “chair” are expressions in different categories is itself absurd. Though Ryle may not want to make the claim, he cannot avoid it and maintain his test of a category-difference.

Yet Ryle, whatever his intentions, may be said to have established the negative point that absurdity alone is never a sufficient test of a category-mistake. Aristotle, Kant, and Russell each began with metaphysical or logical principles that purport to set limits of literal sense; a violation of these principles results either in sound without sense or in intellectual illusion, and in both cases in more than simple absurdity. Ryle appears to want the advantages of a theory of categories and at the same time to avoid the embarrassment of having to defend its principles. Such a theory promises to rid philosophy of many fallacious arguments and contradictions, but the promise is worthless if the principles of the theory are no more tenable than the arguments and contradictions it sweeps away. Aristotle’s metaphysics of substance and accident, Kant’s transcendental logic, and Russell’s elevation of the

vicious-circle principle have proved as philosophically debatable as Platonic forms, proofs for the existence of God, and paradoxes of self-reference. It is comforting to believe that such debatable principles can be discarded and that the forms, proofs, and paradoxes can be exposed as category-mistakes by appeal to nothing more than what a man of common sense will recognize as an absurdity in his own ordinary language. But unfortunately our common use of “absurdity” covers too much. One can hardly hope to rid philosophy of Platonic forms with no more argument than the claim that saying the color white is white is like saying the seat of a table is hard.

Ryle also calls attention to another negative point about a theory of categories. The theory cannot have a subject matter in the usual sense. We cannot generalize about all proposition-factors, all entities, or all of whatever it is types are said to be types of as we generalize about, for example, all bodies or all biological organisms. We may say that every proposition-factor is of some type, but we cannot say what it is like regardless of its type as we can say what every body or biological organism is like regardless of its type. Since everything we can talk about is a proposition-factor, we have nothing with which they can be contrasted; we do, however, have things with which to contrast bodies and biological organisms. Ryle sees this point as forcing us to accept a phrase like “proposition-factor” as merely a kind of dummy expression we may use to preserve the ordinary grammar of “type” and “category,” although the important thing is not to preserve the grammar but to avoid the error of thinking we can preserve it with other than a dummy expression. If we take “proposition-factor” as a metalinguistic expression applying to factors in a particular language, we succeed in preserving the grammar without a dummy expression, but only at the price of making categories relative to a particular set of linguistic rules. The use of a dummy expression is at least consistent with the claim (which Ryle seems to want to make) that a recognition of absurdity is not relative to the rules of a particular language. We may be said to recognize, regardless of our language, the absurdity of saying that the seat of a table is hard or that the color white is white, although we are unable to give criteria of absurdity.

Aristotle tried to cope with the subject-matter problem by holding that while we cannot generalize about all entities as we can about all bodies or all biological organisms (“being is not a genus,” as he put it), we can have a science of being because there is one primary type of being—substance—and every other type exists, by being

an accident of substance. Although we have, then, nothing with which to contrast all beings, we can contrast substances with accidents, and the science of substance is the science of being *qua* being in that conditions for the being of substance are conditions for the being of everything else. A theory of categories may thus be founded on the principle that substances alone can have accidents and all categories other than substance are categories of accidents. For Kant categories do not distinguish beings or entities but a priori forms of understanding, and, unlike Aristotle's beings or Ryle's proposition-factors, these forms comprise not everything we can talk about but only necessary conditions for judgments about objects of experience. The forms stand in sharp contrast with other objects of discourse and constitute a single subject matter belonging to the science of transcendental logic.

Neither Aristotle's nor Kant's theory of categories seems immune to the objection that its subject matter is created rather than discovered. Aristotle's pronouncements about substance and accident and Kant's about forms of understanding each provide principles that yield a scheme of categories, but one may ask whether the pronouncements are anything more than rules for the construction of a certain kind of language—whether the construction of an Aristotelian metaphysics or that of a Kantian transcendental logic provides a theory of categories with anything more than an artificial language within which certain category-differences are established. An answer to this question is proposed by P. F. Strawson in his *Individuals*. Strawson suggests that theories of metaphysics have tended to be either descriptive or revisionary. A metaphysics is descriptive insofar as it yields a scheme of categories that describes the conceptual scheme we actually presuppose in ordinary language. A theory becomes revisionary to the extent that it leads to a departure from our ordinary scheme. Strawson cites the metaphysical theories of Aristotle and Kant as descriptive, those of René Descartes, Gottfried Wilhelm Leibniz, and George Berkeley as revisionary. While all five philosophers construct special languages, only Aristotle and Kant do so in a way that results in a scheme of categories that describes the conceptual scheme of our ordinary language.

But if in this sense Aristotle and Kant in their theories of categories describe rather than create a subject matter, what they describe is not what they claim as their subject matter. Strawson professes in his own theory of categories to describe the conceptual scheme of our ordinary language, but he does not profess to give principles of being *qua* being or a transcendental deduction of pure

concepts of the understanding. If Aristotle and Kant to some extent describe the scheme Strawson sets out to describe, this achievement was certainly not their primary objective, and since they differ radically at crucial points, as in their views of alteration and substantial change, they can hardly be said in any case to describe the same scheme. One must say, rather, that each offers metaphysical or transcendental hypotheses that purport to account for and establish the necessity of the conceptual scheme underlying common sense. One may of course accept much of what they say in description of their schemes as true of what one takes to be our commonsense scheme and yet reject their hypotheses. With the rejection there is no need to defend the hypotheses' claims to a metaphysical or transcendental subject matter, but one then needs to explain how our commonsense scheme is subject matter for description. A description of common features in the grammars of Indo-European languages is not exactly what Strawson means by a description of the conceptual scheme of our ordinary language. But it can hardly be said that his efforts to distinguish the two descriptions are entirely successful. In some of his arguments he seems to appeal to metaphysical hypotheses of his own and hence to have a theory accounting for, and not simply a description of, the conceptual scheme he claims as his subject matter. In other arguments he seems, like Ryle, to make an ultimate appeal to our commonsense recognition of absurdity.

The construction of a theory of categories as descriptive metaphysics differs, according to Strawson, from what has come to be called philosophical, or logical, or conceptual analysis. But the difference is not "in kind of intention, but only in scope and generality." Strawson describes philosophical analysis as relying on "a close examination of the actual use of words," and while this is "the best, and indeed the only sure, way in philosophy," what it can yield is not of sufficient scope and generality "to meet the full metaphysical demand for understanding." But Strawson does not elaborate the demand and gives no criterion for deciding when philosophical analysis must give way to descriptive metaphysics. He sometimes implies that we may pass imperceptibly from one to the other, and this may be the case if to do descriptive metaphysics is simply to articulate what is presupposed in a given philosophical analysis. But it can hardly be the case if descriptive metaphysics, unlike philosophical analysis, has its own peculiar subject matter—being *qua* being, pure concepts of the understanding, our commonsense conceptual scheme, or whatever. Philosophical analysis is clarification of thought about a given subject matter, and to articulate the presuppositions of a given

analysis is not to analyze a new subject matter but only to push the original analysis as far as we can. In the end we may arrive at distinctions that agree with what philosophers from Aristotle to Strawson have called “category-differences,” and there is no harm in using the label if we mean only that the distinctions are ultimate in the analysis we have given and not also that they have to be supported by a hypothesis about a special subject matter. We can hardly make the additional claim without passing beyond the point where we can hope for help from philosophical analysis.

## HISTORICAL NOTES

**STOICS AND NEOPLATONISTS.** In place of Aristotle’s ten categories the Greek Stoics substituted four “most generic” notions or concepts: substratum, or subject; quality, or essential attribute; state, or accidental condition; and relation. The Stoic view, as well as the Aristotelian doctrine, was criticized by the Neoplatonist Plotinus. In his *Sixth Ennead* Plotinus argued that the ultimate categories are neither the Aristotelian ten nor the Stoic four but correspond to the five “kinds” listed in Plato’s *Sophist*: being, rest, motion, identity, and difference. The central point for Plotinus was that different categories apply to the intelligible and sensible worlds, the ultimate categories applying only to the former. Plotinus’s views on categories figured prominently in medieval discussions only as they were considerably modified by his pupil Porphyry. In Porphyry’s short commentary on Aristotle’s *Categories*, generally known as the *Isagoge* (*Εἰσαγωγή*, “Introduction”), he accepted Aristotle’s list of ten but raised Plotinian questions about the way they exist. He noted that categories are genera and asked whether genera and species subsist (exist outside the understanding) or are in the naked understanding alone; whether, if they subsist, they are corporeal or incorporeal; and finally, whether they are separated from sensibles or reside in sensibles. He remarked that these questions are too deep for an introductory treatise, and we have no record of how he thought they should be answered.

**BOETHIUS.** Boethius translated the *Isagoge* into Latin, along with Aristotle’s *Categories* and *On Interpretation*. He also wrote a commentary on the *Isagoge*, offering answers to Porphyry’s unanswered questions, and thus began a tradition, which persisted throughout the medieval period, of accepting Porphyry’s questions as presenting the fundamental issues for any account of categories. Since genera and species appear most prominently as genera and species of substances, the issues

centered first of all in the signification of common nouns taken as names of kinds of substances. The medieval “problem of universals” thus arose from Porphyry’s questions about Aristotle’s categories, and prominent medieval philosophers, such as Peter Abelard, Thomas Aquinas, John Duns Scotus, and William of Ockham, are known as conceptualists, realists, or nominalists because of their answers to these questions. The important point for a history of theories of categories is that the discussion of the problem of universals by major figures in medieval philosophy occurred within an unquestioned framework provided by Aristotle’s theory of categories—in particular, within a framework that presupposed the basic Aristotelian interrelation of substance and accident and essential and accidental predication.

**LOCKE AND HUME.** The Aristotelian framework broke down in modern pre-Kantian philosophy. Signs of the breakdown were evident in Thomas Hobbes and Descartes, but its full force appeared in John Locke and David Hume. With Locke’s account of substance as an “unknown something” underlying appearances, essential predication in the category of substance becomes impossible, and the signification of common nouns supposed to name kinds of substances can be fixed only by “nominal essences,” by conventional factors, rather than by Ockham’s “natural signs in the soul.” Essential predication, and hence necessary truth, remains possible only when the subjects are things of our own creation (“mixed modes”) and not when they are substances in the real world.

The full consequences of Locke’s departure from an Aristotelian framework were drawn by Hume. If it is impossible to know what something in the real world necessarily (essentially) is, it is also impossible to know that any one thing in the real world is necessarily connected with another or that any state of a thing at one time is necessarily connected with its state at another time. In other words, not only substance but also causality—an equally if not more fundamental notion (though not recognized as a category by Aristotle)—is made a matter of habit and custom. The stage was set for Kant to answer Hume with a radically new theory of categories.

**HEGEL.** Despite the radical differences between Kantian and Aristotelian categories, two basic points of similarity remain: (1) Categories provide form but not content for cognitive discourse about the world and thus serve to distinguish what we can meaningfully say in such discourse from what we may seem to say when we make category-mistakes or misapply categories. (2) Categories presup-

pose the substance-accident (subject-predicate) form basic to Aristotelian logic. Hegel's philosophy retains neither of these points of similarity, although he adopted the Kantian view that the clue to a system of categories is to be found in logic. But instead of turning to logic as a study of forms of reasoning without regard for content, Hegel turned to logic as a dialectical process in which form and content are inseparable. The essential nature of this process is seen not in the forms under which subject and predicate are brought together in the premises of reasoning to make affirmative, negative, disjunctive, hypothetical, and other types of judgment but in the basic stages through which the process itself repeatedly moves. These stages Hegel called "thesis," "antithesis," and "synthesis," and he took them as interrelating the basic ideas, notions, or principles of reason, which he also called "categories." This interrelation of categories constitutes both Hegel's system of philosophy and what he held to be the "system of reality." The categories, then, are many, and their exact number cannot be determined until the system of reality is fully articulated. Hegel thus marked the beginning of a tradition in modern philosophy, in which "category" means simply any basic notion, concept, or principle in a system of philosophy.

This use of "category" is standard not only among Hegel's progeny of absolute idealists but also among metaphysicians generally, who dissociate themselves from analytical philosophy. The use remains even when there is no vestige of Hegel's threefold pattern of thesis, antithesis, and synthesis as a means of ordering the principles of speculative philosophy. The categorial scheme in Alfred North Whitehead's *Process and Reality*, for example, is readily understood as dealing with the sort of notions Hegel called "categories" but hardly with categories in the Aristotelian-Kantian sense of setting limits of cognitive meaning, a sense that still survives in analytical philosophy.

PEIRCE. The collapse of Kant's theory of categories is inevitable, according to Peirce, as logic advances beyond the subject-predicate form recognized by Aristotle. So long as statements like "John gave the book to Mary" are not seen as possessing a logical form fundamentally different from and coordinate with the simple subject-predicate form of statements like "John is tall," categories are determined by what may be taken as different forms of this one-subject-one-predicate relation. Aristotle and Kant analyzed the forms differently, but the relation analyzed was the same. With the development of logic beyond Aristotle (a development to which Peirce made significant contributions), statements like "John gave the

book to Mary" are recognized as statements with three-place predicates ( $x$  gave  $y$  to  $z$ ) and are different in logical form from statements with one-place predicates ( $x$  is tall). Peirce claimed to have demonstrated in his "logic of relatives" that although one-place, two-place, and three-place predicates are basically different in logical form, predicates with more than three places have no features of logical form not already found in three-place predicates.

The demonstration remains one of the more questionable parts of his logic, but Peirce accepted it as proof that in formal logic there are but three fundamentally different types of predicates and hence that there are but three categories. He sometimes referred to his categories as the "monad," the "dyad," and the "polyad," but he preferred the more general expressions "firstness," "secondness," and "thirdness." As genera (or modes) of being, the categories are designated as "pure possibility," "actual existence," and "real generality." A pure possibility stands by itself, determined by nothing but conditions of internal consistency; what actually exists stands in relation to other existences and to some extent both determines and is determined by them; a true generalization is a representation related to other representations, to actually existing things, and to pure possibilities. In his philosophical cosmology Peirce had three universes corresponding to the three modes of being, and in his semeiotic theory, or theory of signs, he developed an extensive classification of signs, with the main divisions triadic, each triad comprising a firstness, a secondness, and a thirdness. Although Peirce's categories thus function architectonically somewhat as Hegel's thesis, antithesis, and synthesis, they serve, as Hegel's triad does not, to set limits of cognitive meaning. Though Peirce did not use the phrase "category-mistake," he said repeatedly in his later writings that nominalism, which he regarded as the great error in the history of philosophy, arises from the failure to recognize real generality as a mode of being distinct from actual existence. In arguing that universals have no actual existence, the nominalist has failed to see that to ask in the first place whether they have such existence is a category-mistake. In his final years Peirce labored to show that the pragmatic criterion of meaning, which he propounded early in his career, is not only consistent with but actually necessitated by his theory of categories.

HUSSERL. The role of categories in setting limits of cognitive meaning figures prominently in the philosophy of Husserl. To determine "primitive forms" or "pure categories" of meaning is the first task of a "pure philosophical grammar." The fundamental form is that of propositional meaning, and other primitive forms, such

as the nominal and adjectival, are forms of meaning that belong to constituents of a proposition. After determining these pure categories of meaning, pure logical grammar turns to primitive forms or categories of the composition and modification of meaning (forms such as those exhibited by propositional connectives and modal expressions). In addition to a pure logical grammar, Husserl held, there are a pure logic of consistency (noncontradiction) and a pure logic of truth. The picture is further complicated in that pure logic may be taken as giving rise to a formal ontology and, again, developed into a transcendental logic. A full account of categories requires the full development of logic in all its phases, and in this respect Husserl's view of categories seems reminiscent of Hegel. But at no point (even in formal ontology) did categories cease for Husserl to be purely formal and become inseparable from content. Husserl was careful to distinguish the kinds of nonsense precluded by his categories from nonsense of content (*inhaltlich Unsinn*). A phrase like "if-then is round" is nonsense because it violates a category-difference, a condition of meaningfulness established by logic alone; a phrase like "the seat of the table is hard" violates no such condition, and its nonsense arises from a material, not a formal (logical), incompatibility. While at times Husserl's language may suggest what Rudolf Carnap and others have since called "syntactical categories," it should be noted that Husserl had nothing like Carnap's technical distinction between syntax and semantics and that the "syntactical categories" of Husserl's pure logical grammar are in Carnap's sense neither purely syntactical nor semantical.

**FREGE AND WITTGENSTEIN.** In their philosophies of mathematics and logic both Peirce and Husserl remained close enough to Kant not to accord set theory the fundamental role it has come to play in logic and the foundations of mathematics. Frege, although he did not present any of his views under the heading "a theory of categories," did far more than Peirce or Husserl to shape the discussion of categories in the twentieth century. Frege analyzed sense and reference, concept and object (notions fundamental to Peirce's and Husserl's theories of categories) in a way that permitted him to take set theory as basic in mathematics and to define cardinal numbers as classes of classes. Russell's efforts to cope with the contradictory notion of the class of all classes not members of themselves (a notion one seems forced to admit with Frege's analysis) produced the theory of types.

The conclusion suggested by the difficulties encountered in the theory of types, that categories as setting limits of cognitive meaning are not proper subject matter for

a theory, was first advanced by Ludwig Wittgenstein. In his early work, *Tractatus Logico-philosophicus*, Wittgenstein spoke of the limits of cognitive meaning as the ineffable, as what can be shown but not said. In his later writings he repudiated the suggestion that the limits constitute an ineffable subject matter, something to be unveiled but not articulated as a theory by philosophical analysis. Nevertheless, with the assumption of such subject matter philosophical clarity is to be achieved by the construction of an ideal language, a language is stripped of all superfluous symbolism and is hence unable to give the illusion of transcending the ineffable limits of cognitive meaning. But if this assumption is itself an illusion, as Wittgenstein later held, if we can no more show than we can state the limits of *all* language, then philosophical clarity can be achieved only piecemeal, context by context; there is no short cut via an ideal language. And a fortiori there is no universal scheme of categories to be unveiled, let alone to be established by a theory. Wittgenstein's influence may be seen in the hesitation of Ryle, Strawson, and other present-day analytical philosophers to claim that categories should (or can) have the absolute universality claimed in theories of categories from Aristotle's to the theory of types.

## CATTANEO, CARLO (1801–1869)

Carlo Cattaneo is possibly the most interesting Italian philosopher of the nineteenth century, and was a distinguished scholar in history, economics, linguistics, and geography. Born in Milan, he received a law degree from the University of Pavia, where for some years afterward he taught Latin and the humanities. In 1839 he founded the journal *Il Politecnico*, which he described as "a monthly repertory of studies applied to culture and social prosperity." Cattaneo led the 1848 Milanese insurrection against Austrian rule, the story of which he related in a masterly booklet, *L'insurrezione di Milano nel 1848* (in *Scritti storici e geografici*, Vol. IV, Florence, 1957; first published in French in Paris, 1848). When the first Italian war of independence ended in failure, in 1849, Cattaneo went into exile, first in Paris and then in Lugano, Switzerland, where for several years he taught philosophy in the local lyceum. Although he was appointed a deputy to the Italian parliament in 1860, he refused to enter the parliament house in order not to have to swear allegiance to the king. He continued to spend most of his time at Lugano, where he edited a new series of *Il Politecnico* from 1860 to 1863, the first series having been suspended in 1844.

The main influence on Cattaneo was the Lombard Enlightenment philosophy espoused by his teacher G. D. Romagnosi, which was interested in scientific inquiry as related to the well-being of society and concerned with progressive government—facets visible in the work of Alessandro Volta and Cesare Beccaria. Cattaneo blended this inheritance with reflection on his own research in fields other than philosophy but generally disregarded philosophical tradition. He developed an original though unsystematic body of ideas that can best be described as an empirical, scientifically minded phenomenology of history or a nonidealistic historicism. The contemporary reader may catch a Marxian ring or occasionally find a

resemblance to such thinkers as Wilhelm Dilthey, G. H. Mead, and John Dewey.

For Cattaneo the philosopher's task consists in clarifying objective current historical problems rather than subjective difficulties. There is no single problem to be made the center of systematic speculation, nor any logical or genetic "first truth" on which the chain of deductive reasoning may be hung. There is instead a plurality, itself subject to change, of well-determined and interrelated problems. There are no final solutions to problems, but only a body of perfectible solutions, which are discovered not by absolute reason but by general human reasonableness. Logic is the theory of scientific research; in philosophy, too, the experimental method, which unites men, must supersede metaphysics, whose continuous veerings divided men.

We know in order to act. The aim of all intellectual endeavor is to change the face of Earth for the good of humankind: Both nature and society must be "transformed" by man-invented techniques. Insofar as he brings about a knowledge that is public and beneficial, the philosopher is "a craftsman" who works "for the common people"—"we are all workmen if we supply something useful to mankind." To such philosophy Cattaneo contrasted "the philosophy of the schools," whose "ontological hammer" generated "a hidden, priestly wisdom scorning the common people," drawing on "fantastic hypotheses and imaginary intuitions," and "consuming itself in the repetition of empty formulae"—with the result of "throwing wide-open an immeasurable gap between doctrine and fact about man." In saying such things Cattaneo had in mind particularly Antonio Rosmini-Serbati, who was then trying to reconcile philosophical Catholicism with the subjectivism of modern philosophy.

For Cattaneo thought is social action, and it must be studied in the various human activities. There is no essence of thought to be reached directly. To become acquainted with his own nature, man must not recede into himself but rather must go out into the world to collect information. A complete science of thought amounts to knowledge of all that mankind has produced. By "mankind" Cattaneo meant empirical men in their finite world; while professing to be a follower of Giambattista Vico (who was at the time almost unknown), he was highly critical of Vico's oversimplified principles of interpretation, especially of the notion of historical cycles ("Su la *Scienza nova* del Vico," 1839; "Considerazioni sul principio della filosofia," 1844).

Cattaneo intended the phenomenology of history to overcome in a new way the traditional opposition of appearance and reality. What appears to us is what there is—all the reality we can or must cope with—and we cannot reach it outside the social development of humankind (see especially "Un invito alli amatori della filosofia," 1857). This must be construed methodologically, according to what Cattaneo labeled the "psychology of associated minds." The "solitude of the new-born in front of *things*" is a philosophical myth. "Even sensation is from the beginnings a social fact," and "whatever idea one comes to conceive is never the operation of a solitary mind but rather of several associated minds." (*Psicologia delle menti associate*, 1859–1863, unpublished; quotations taken from *Scritti filosofici*, Vol. II, p. 14; Vol. I, p. 448; Vol. II, p. 16). To help us understand the varieties of human history, a social psychology supported by scientific method must replace individual psychology as connected with that "lobby of theology" which was "[René] Descartes' solitude of consciousness."

## Bibliography

### ADDITIONAL WORKS BY CATTANEO

In addition to the essays mentioned in the article, Cattaneo's main philosophical work consists of studies on Romagnosi, Tommaso Campanella, Wilhelm von Humboldt, and others, the forewords to the annual volumes of *Il Politecnico*, and the lectures (*Lezioni*) delivered at the Lugano Lyceum on cosmology, psychology, ideology (see the pages on categories and language), logic, and law and morals. Students of Cattaneo's philosophy, however, should take into account also many of his writings in other fields.

There are several anthologies of Cattaneo's papers, especially the philosophical ones, the best being those edited by Gaetano Salvemini (Milan, 1922) and Franco Alessio (Florence, 1957). A complete edition of Cattaneo's works, divided into five sections according to subject matter, appeared in 1956 in Florence; the philosophical section, edited by N. Bobbio, comprises three volumes.

### WORKS ON CATTANEO

On Cattaneo's life, see the Salvemini introduction. On his historical position, see Mario Fubini, *Il romanticismo italiano* (Bari: Laterza, 1953), passim. On his thought, see the introductions by Alessio and Bobbio, and also Bruno Brunello, *Cattaneo* (Turin, 1925); Alessandro Levi, *Il positivismo politico di Carlo Cattaneo* (Bari: G. Laterza & figli, 1928); and Luigi Ambrosoli, *La formazione di Carlo Cattaneo* (Milan: R. Ricciardi, 1959).

## CAUSAL APPROACHES TO THE DIRECTION OF TIME

What account is to be given temporal priority and of the direction of time? One natural view is that no account is needed (Oaklander 2004), a position that can be defended by arguing, first, that one immediately perceives

the succession of events (Bergson 1912), and second, that if one can immediately see that events stand in the relation of temporal priority, then the concept of that relation is primitive and unanalyzable.

There are, however, important objections to this view and to the supporting argument. As regards the latter, the question arises whether perception of change does not turn out, on closer scrutiny, to involve not only a momentary visual state but also short-term memories of immediately preceding visual states. If so, then the acquisition of a belief that something is moving or changing will involve inference, and succession will not be something immediately perceived.

As regards the view itself, one problem is that temporal priority is a relation with certain properties: It is impossible for an event to be earlier than itself; if A is earlier than B, B cannot be earlier than A; and if A is earlier than B, and B earlier than C, then A must be earlier than C. If the concept of the earlier than relation is analytically basic, then no account can be given of these necessary truths: they will have to be treated as synthetic *a priori*. By contrast, if the idea of temporal priority is analyzable, then it should be possible to show that these necessary truths are analytic.

One can assume, then, that the concept of temporal priority must be analyzable. What are the possibilities? The answer is that three main types of accounts have been offered. First, philosophers who favor a tensed account of the nature of time often maintain that the tensed properties of pastness, presentness, and future are basic properties and that the tenseless temporal relations of simultaneity and temporal priority are to be analyzed in terms of those tensed properties (e.g., Broad 1933, Sellars 1962, Prior 1967). According to this view, then, the direction of time logically supervenes on the tensed properties of events.

A second approach holds that if events stand in the relation of temporal priority, and if time has a direction, then such facts must be reducible to properties and relations recognized by physics. The idea, accordingly, is to analyze the relation of temporal priority and the direction of time in terms of such things as the direction of increase in entropy, the direction of the expansion of the universe, or the direction of irreversible processes (e.g., Popper 1956; Grünbaum 1971, 1973; Sklar 1974).

A third possibility is a causal approach. Here the idea is, first, that causal processes involve a direction, and, second, that causal facts are more basic than temporal facts,

with the result that the direction of time can be analyzed in terms of the direction of causation.

How do these three alternatives fare? As regards the first, there are two crucial objections. First, it is clear that the relation of temporal priority cannot be analyzed in terms of the tensed properties of pastness, presentness, and futurity alone, since one event may be earlier than another, though both have the same tensed property of pastness. One needs, then, to introduce additional tensed concepts, such as those of one event's being more past than, and more future than, another. These latter, however, are not plausible candidates for primitive concepts, since then one would be unable to explain, for example, why event *A*'s being more future than event *B* entails that *A* is future and *B* is future. However, if one attempts to analyze those concepts, the natural way of doing so is in terms of the concept of the past, and the concept of the future, with the concept of temporal priority. Such analyses, however, will make the analysis of temporal priority in terms of tensed concepts implicitly circular.

Second, even the concept of futurity itself is not a plausible candidate for a basic concept, since it is plausible that it is concepts that pick out immediately given properties and relations that are analytically basic, and the concept of the future does not pick out a property of events that can be immediately perceived. However, if the concept of the future must be analyzed, how is this to be done except in terms of the idea of the present with the idea of temporal priority? So, once again, the attempt to analyze the relation of temporal priority in terms of tensed concepts can be seen to be circular.

In the case of the second approach—which involves analyzing temporal priority in terms of specialized scientific concepts, such as those of entropy and the expansion of the universe—there are also two main objections. First, most proposals for a scientific analysis of temporal priority entail that it is possible that the universe might undergo a temporal reversal. For the universe, rather than expanding forever, may stop expanding, and then begin contracting. Moreover, if this were to happen, entropy would at some point stop increasing and begin decreasing. The direction of time cannot be analyzed, therefore, in terms of the direction of increase in entropy or in terms of the direction of the expansion of the universe, since such analyses entail the unacceptable consequence that the resulting contraction of the universe would be earlier than the time at which the universe stopped expanding.

Second, there are logically possible worlds that contain temporally ordered events, but no increase in

entropy or expansion of the universe. Consider, for example, two uncharged particles rotating endlessly about one another due to gravitational attraction. Accordingly, the concept of temporal priority cannot be analyzed in terms of such scientific concepts.

The conclusion, therefore, is that the first two approaches to the analysis of the concept of temporal priority appear unsatisfactory. If this is so, one is left with the third alternative—that of analyzing temporal priority in causal terms.

### A CAUSAL THEORY OF THE DIRECTION OF TIME AND TEMPORAL PRIORITY

The idea of analyzing the concept of temporal priority in causal terms is not a recent development, since it dates back at least to Gottfried Wilhelm Leibniz (1715/1969) and Immanuel Kant (1781/1961). In more recent years it was advanced by the mathematician Alfred A. Robb (1914, 1921), and by philosophers such as Henryk Mehlberg (1935, 1937), Hans Reichenbach (1956), D. H. Mellor (1981, 1995, 1998), and Michael Tooley (1987, 1997), among others.

Before setting out a causal theory, it will be best to address an initial objection, the thrust of which is that it may well be, as many philosophers and scientists believe (e.g., Lewis 1976), that backward causation is logically possible, and, if this is so, how can the direction of time be defined in terms of the direction of causation?

One response, adopted by some advocates of a causal approach (Mellor 1981, 1995, 1998; Tooley 1987, 1997), is to argue that backward causation is not logically possible. However, a different response is available. For if one considers, for example, Dr. No traveling backward in time, then it is natural to say that the temporal ordering of events inside his time machine is opposite to the temporal ordering of events outside of it. If so, then in a world where there is backward causation, one needs the concept of the local direction of time, which can be defined in terms of the direction of causal processes in that region. One could then go on to introduce the idea of the overall direction of the universe, defined, as David Lewis (1976, 1979) suggests, in terms of the direction of most causal processes.

How can temporal priority be analyzed in causal terms? A natural starting point is the following postulate:

(*P*) If *A* causes *B*, then *A* is earlier than *B*.

This gives one a sufficient condition for one event's being earlier than another, but it does not provide a necessary condition. So how can one arrive at necessary and sufficient conditions for one event's being earlier than another?

To arrive at an answer, consider the following two plausible claims:

- (Q) If  $A$  is earlier than  $B$ , and  $B$  is simultaneous with  $C$ , then  $A$  is earlier than  $C$ .
- (R) If  $A$  is simultaneous with  $B$ , and  $B$  is earlier than  $C$ , then  $A$  is earlier than  $C$ .

These two postulates, with (P), then entail two further, more comprehensive propositions relating causation to temporal priority:

- (S) If  $A$  causes  $B$ , and  $B$  is simultaneous with  $C$ , then  $A$  is earlier than  $C$ ;
- (T) If  $A$  is simultaneous with  $B$ , and  $B$  causes  $C$ , then  $A$  is earlier than  $C$ .

However, in addition, these two conditions, in conjunction with the fact that temporal priority is a transitive relation, entail another, much more encompassing condition:

- (U) If  $\{A_1, A_2, \dots, A_i, \dots, A_{n-1}, A_n\}$  is a set of  $n$  instantaneous events such that, for every  $i < n$ , either  $A_i$  causes  $A_{i+1}$ , or  $A_i$  is simultaneous with  $A_{i+1}$ , and if, in addition, there is some  $i < n$  such that  $A_i$  causes  $A_{i+1}$ , then  $A_1$  is earlier than  $A_n$ .

Principle  $U$ , entailing, as it does, principles  $R$ ,  $S$ , and  $T$ , and more as well, is a comprehensive principle relating causation to temporal priority, and that it follows from the conjunction of the noncausal principles  $Q$  and  $R$  with the modest claim involved in  $P$  shows how powerful principle  $P$  is.

Principle  $U$ , of course, still gives one only a sufficient condition for one event's being earlier than another. The idea now, however, is that the sufficient condition that is given by  $U$  is also a necessary condition. If this is right, then the relation of temporal priority can be analyzed as follows:

$A$  is earlier than  $B$

means the same as

For some number  $n$ , there is a set of  $n$  instantaneous events  $\{A_1, A_2, \dots, A_i, \dots, A_{n-1}, A_n\}$  such that, first,  $A$  is identical with  $A_1$ , and  $B$  is identical with  $A_n$ ;

second, for every  $i < n$ , either  $A_i$  causes  $A_{i+1}$ , or  $A_i$  is simultaneous with  $A_{i+1}$ ; and,

third, there is some  $i < n$  such that  $A_i$  causes  $A_{i+1}$ .

This proposed analysis does, of course, involve a temporal notion—namely, that of simultaneity. However, that will be an objection to the analysis only if the concept of simultaneity itself has to be analyzed in terms of temporal priority. The latter, however, does not seem likely, since it would seem possible for there to be a world that consists of a single moment, containing states of affairs all of which are simultaneous with each other.

### OBJECTIONS TO A CAUSAL ACCOUNT

Causal analyses of temporal priority are exposed to a number of objections, many of them advanced by J. J. C. Smart (1971). Among the most important are the following. First, given that the laws of physics do not, with one possible exception, involve any asymmetry, is it possible to explain causal priority without appealing to temporal priority? Second, it is surely logically possible for there to be events that have temporal location, but that have neither causes nor effects. However, this would seem to be ruled out by a causal analysis of temporal priority. Third, is it not also logically possible for there to be moments of time at which no events take place—perhaps because the world contains gappy causal laws? But then there would be no way of ordering that moment relative to other moments. Finally, and even more dramatically, is it not logically possible for there to be a spatiotemporal world that contains no events at all? But then there would be no causal relations, and so, according to a causal theory of temporal priority, no ordering of times in such a world.

With regard to the first objection, the answer is that most present-day analyses of causation offer accounts of the direction of causation that do not involve any appeal to temporal priority (Lewis 1973; Tooley 1987, 1997; Mellor 1995). As regards the second objection, it does not tell against the account set out earlier, since an event that does not itself enter into any causal relations may have temporal location by being simultaneous with an event that does enter into causal relations.

The third and fourth objections are more threatening. One way of responding to these objections is by appealing to possible events and causal relations. Here the idea is, in the case of the third objection, that if the world had been different at certain times, there would have been events when, as things stand, there are no events, and that it is those possible causal relations that make it the case that the time when no events occur has a temporal loca-

tion. Similarly, in the case of the totally empty spatiotemporal world, if there had been events at some times, these would have caused events at other times, and it is those possible causal relations that serve to order moments of time.

The problem with this sort of response is that if temporal order is to be analyzed causally, it seems clear, especially in the case of the totally empty world, that there are no truth makers for counterfactuals concerning such possible events. A different response, however, is available (Tooley 1987, 1997). The basic idea is that if one adopts a realist conception of space-time, then the continued existence of space-time is itself something that requires explanation if it is not to be a cosmic accident. However, what sort of explanation is possible, other than one according to which regions of space-time themselves causally give rise to other regions of space-time? If such immanent causal connections between spatiotemporal regions are possible, then the temporal ordering of different moments of time can, on a causal theory, be given by those causal relations, rather than only by causal relations between events in space-time.

## CAUSAL CLOSURE OF THE PHYSICAL DOMAIN

The thesis that physics is causally closed asserts that:

Every physical effect has a sufficient immediate physical cause, insofar as it has a sufficient immediate cause at all.

If this thesis is true, it distinguishes physics from all other subject domains. The biological realm is not causally closed, for example, because biological effects often have nonbiological causes, as when the impact of a meteorite precipitated the extinction of the dinosaurs. Again, meteorology is not causally closed: The burning of carbon fuels—a nonmeteorological event—is causing global warming. Nor, importantly, is the mental realm causally closed: A mental pain can be caused by sitting on a physical thumbtack, and a train of thought can be interrupted by a loud noise.

Physics, by contrast, does seem to be causally closed. If one considers any physical effect, then there will arguably always be some prior physical cause: People expect to be able to account for physical effects without leaving the physical realm itself. In particular, this seems to hold even for physical effects that take place within the bodies of conscious beings. When the muscle fibers in a person's arm contract, this is presumably due to electrochemical activity in the nerves, which is due to prior physical activity in the person's motor cortex, and so on. In principle, it would seem possible to account for this entire sequence solely in terms of the resources offered by physics itself, and without making any essential appeal to any other subject matter.

At first pass, the causal closure of physics is solely a claim about how things go within physics itself. It does not assert that everything is physical, only that everything physical that has a cause has a physical cause. As such, it does not rule out realms of reality that are distinct from the physical realm. It is entirely consistent with the causal closure of physics itself; there should be nonphysical realms that operate independently. The closure of the physical says only that *within the physical realm* every physical effect has a physical cause.

Even so, the causal closure of the physical does give rise to a powerful argument for reducing many prima facie nonphysical realms to physics: It suggests that *anything that has a causal impact on the physical realm* must itself be physical. The reason is that the causal closure of the physical seems to leave no room for anything nonphysical to make a causal difference to the physical realm,

because it specifies that every physical effect already has a physical cause.

Intuitively, of course, people take it that many prima facie nonphysical events, such as biological, meteorological, and mental events, do have physical effects. A burrowing animal can dig a hole in the ground; a hurricane can destroy houses; one's current thoughts can give rise to patterns on a computer screen. However, the causal closure of the physical says that these effects already have physical causes. So it seems that the only way to respect the causal efficacy of realms such as the biological, meteorological, and mental is to conclude that they are not distinct from the physical after all. If one wants to maintain that the animal's burrowing, the hurricane, and a person's thoughts have physical effects, then apparently there is a need to identify these processes with the physical causes that their physical effects are already known to have.

Note that this line of reasoning only argues for a reduction to physics of those realms that *do* have physical effects. The causal closure of the physical provides no argument against the possibility of nonphysical realms that lack any physical effects. For example, it is arguable that mathematical, moral, and modal facts have no physical effects. If this is right, then the causal closure of the physical offers no reason to collapse these realms into the physical. (Of course, there may be other arguments against the possibility of such nonphysical realms of reality, such as their epistemological inaccessibility, but that is a different matter.)

The remainder of this entry contains three sections: First, a discussion of the evidence for the causal closure of physics from a historical perspective; second, a consideration of how the thesis can be made properly precise; and finally, an examination of the details of the argument that causal closure implies physicalism about the mental and similar realms.

### A HISTORICAL PERSPECTIVE ON THE EVIDENCE FOR THE CAUSAL CLOSURE OF PHYSICS

Why should one believe the causal closure of physics (which for the moment shall be regarded as the simple claim that every physical effect has a sufficient physical cause)? If this thesis is true, it is not an a priori matter, but something that follows from the findings of science. But exactly which findings? What part of science, if any, argues that physical is causally closed?

At first sight it may seem that causal closure follows from the presence of conservation laws in physics: If there are laws specifying that important physical quantities stay constant over time, does not this show that the later values of physical quantities must be determined by earlier values? However, it depends what conservation laws one has. Not just any set of physical conservation laws rule out the possibility of nonphysical causes for physical effects.

Thus consider Descartes's early seventeenth-century physics. This was based on the conservation of *amount of motion*, which Descartes took to be the product of the masses of all bodies by their scalar *speeds*. (So amount of motion is different from momentum, which is the product of mass by vectorial *velocity*: A car going round a bend at a constant speed conserves amount of motion but not momentum.) As Leibniz observed, Descartes's conservation of amount of motion alone leaves plenty of room for nonphysical causes to intrude on the physical realm. In particular, if mental causes (operating in the pineal gland?) cause particles of matter to change their direction (but not their speed), this would not in any way violate the conservation of amount of motion.

Descartes's physics might allow an independent mind to affect the brain, but Descartes's physics is wrong, as Leibniz further observed. Leibniz himself replaced Descartes's law of the conservation of "motion" with the two modern laws of conservation of (vectorial) momentum and of (scalar) kinetic energy, and thereby arrived at what are now regarded as the correct laws governing impacts. Leibniz's physics, unlike Descartes's, did indeed imply that the later values of all physical quantities are determined by their earlier values, and therewith the causal closure of the physical. However, Leibniz did not draw the modern physicalist conclusion that the mind must therefore be identical to the brain. Because it seemed incontrovertible to him that mind and brain must be ontologically separate, he instead inferred from the causal closure of physical that the mind in fact has no causal impact on the physical world. (It only appears to do so because of the "preestablished harmony" with which God has arranged both the mental and physical worlds.)

Whereas Leibniz's physics implies the causal closure of the physical, this is not true of the Newtonian system of physics that replaced it at the end of the seventeenth century. The crucial difference is that, where Leibniz upheld the central principle of the "mechanical philosophy" and maintained that all changes of velocity are due to impacts between material particles, Newton allowed

that accelerations can also be caused by disembodied forces, such as the force of gravity. Moreover, Newton's system was open-ended about the range of different forces that existed. In addition to gravity, Newton and his followers came to recognize magnetic forces, chemical forces, and forces of adhesion—and indeed vital and mental forces, which arose specifically in living bodies and sentient beings. If one counts vital and mental forces as nonphysical (and this point will be revisited in the next section), then the admission of such forces undermines the causal closure of the physical. For it means that physical effects, in the form of accelerations of particles of matter, will sometimes be due to the operation of nonphysical vital or mental causes.

Newtonian physics has its own conservation principles, but unlike Leibniz's they do not uphold the causal closure of the physical. Crucially, Newton's physics differs from Leibniz's in the way the conservation of energy must be understood. The existence of Newtonian forces means that Leibniz's conservation of kinetic energy no longer holds true; for example, two bodies receding from each other will slow down due to their mutual gravitational attraction, and so lose kinetic energy. Newtonian conservation additionally needs the notion of *potential* energy: the latent energy stored when bodies are "in tension" in force fields, as when two receding gravitating bodies cease to move apart and are about to accelerate together again. The notion of potential energy was not prominent in early Newtonian physics, but by the middle of the nineteenth century physicists concluded that all forces operated so as to conserve the *sum* of potential and kinetic energy—any loss of kinetic energy would mean a rise in potential energy, and vice versa.

This emergence of the modern version of the "conservation of energy" placed strong restrictions on what kinds of forces can exist, but it by no means ruled out vital and mental forces. Provided that the fields of these forces stored in latent form any losses of kinetic energy they occasioned (consider by way of comparison the notion of "nervous energy"), their presence would be perfectly consistent with the conservation of kinetic plus potential energy. True, the conservation of kinetic plus potential energy did apparently imply that all forces must be governed by deterministic force laws (otherwise what would ensure that they always paid back any kinetic energy they borrowed?), and this greatly exercised many Victorian thinkers, especially given that nothing in early Newtonian physics had ruled out spontaneously arising mental forces. But, even so, the Newtonian conservation

of energy did not stop *deterministic* vital and mental forces affecting the physical realm.

Nevertheless, during the late nineteenth and twentieth centuries an increasing number of scientists have come to doubt the existence of vital and mental forces. The most significant evidence seems to have come from physiology and molecular biology, rather than from physics itself. During this period a great deal has come to be known about the workings of biological systems (including brains), and there has been no indication that anything other than basic physical forces are needed to account for their operation. In particular the twentieth century has seen an explosion of knowledge about processes occurring within cells, and here too there is no evidence that this involves anything other than familiar physical chemistry. The result has been that the overwhelming majority of scientists now reject vital and mental forces, and accept the causal closure of the physical realm.

### THE CAUSAL CLOSURE THESIS REFINED

Much recent discussion of the causal closure thesis has revolved around the question of exactly how “physical” should be understood in the claim that every physical effect has a physical cause. As Carl Hempel originally observed, advocates of the causal closure thesis seem to face a dilemma. On the one hand, they can equate “physical” with the category of phenomena recognized by *current* physical theory. But then it seems implausible that “physics” in this sense is closed; past form suggests strongly that physics will in time come to posit various new fundamental causal categories. Alternatively, advocates of causal closure might wish to equate “physical” with the ontology of some ideal *future* physics. But then it is hard to see how the causal closure of the “physical” could have any current philosophical significance, given that people are as yet ignorant of exactly what this “physical” includes.

However, this dilemma is by no means inescapable. True, neither current physics nor ideal future physics gives us a suitable notion of “physics” for framing the causal closure thesis. But this does not mean there are not other suitable notions of “physics.” Indeed there are arguably a number of *different* ways of understanding “physics” that will yield a well-evidenced and contentful causal closure thesis.

For a start, one could simply define *physical* as “neither essentially mental nor biological.” This understanding of “physical” was in effect assumed at the end of the

last section, in the argument that the nonexistence of vital or mental forces establishes the causal closure of physics. Note that nothing in that argument assumed a definitive list of fundamental physical categories; rather the thought was simply that this list would *not* include any *sui generis* mental or vital entities. This is a relatively inclusive understanding of “physical”; it counts as a “physical” cause anything that is not mental or vital, and to this extent renders the causal closure of the physical a relatively weak thesis. But even so it remains a thesis of much philosophical interest, because it still argues that any mental or vital causes of physical effects must be identical to causes that can be identified without using mental or vital categories.

A rather stronger reading of “physical” would take it to cover any categories of the *same general kind as are recognized by current physical theory*. Now the list of fundamental “physical” categories will be taken to include not just anything nonvital or nonmental, but more specifically only items that display the same kind of spatio-temporal pervasiveness and simple mathematical characterizability as those assumed in contemporary physics. Again, there seems good reason to suppose that “physics” in this sense is casually closed, and therefore that anything that in this sense has “physical” effects must itself be “physical.”

Finally, and even more specifically, there is the option of equating “physical” with *microscopic*. Modern physical theory characteristically operates at a level of microscopic spatiotemporal detail. Correspondingly, it is plausible that every microscopic effect can be accounted for by (a combination) of microscopic causes. This version of the causal closure thesis thus argues that anything that has microscopic effects must itself be identical to (a combination) of microscopic causes.

The remainder of this section deals with some complications in the formulation of the causal closure thesis. In the version of the thesis at the beginning of this article, every physical effect was referred to as having a “sufficient immediate physical cause,” rather than just having “a physical cause.” This was to ensure that the physical realm is genuinely causally closed. The specification that the physical cause be “sufficient” is needed to ensure that it causes the physical effect by itself, and not solely in virtue of its conjunction with some *sui generis* nonphysical cause—such a mixed cause would obviously violate the causal closure of physics. Again, the requirement that the physical cause be “immediate” is needed to ensure that it not produce the physical effect only via some intermedi-

any nonphysical cause—such nonphysical intermediaries would again violate the causal closure of physics.

The earlier formulation of the causal closure thesis also specifies that every physical effect has a sufficient immediate physical cause “insofar as it has a sufficient immediate cause at all.” The reason for this latter qualification is to accommodate the indeterminism of modern quantum mechanics, which states that certain physical effects are random, without any sufficient determining cause. It remains the case, however, that according to quantum mechanics these random physical effects still have their *probabilities* fixed by sufficient immediate physical causes. And this in itself will sustain the argument that anything that affects the physical realm must itself be physical. At first sight it may seem that quantum indeterminism creates room for nonphysical causes (determinations of the will, perhaps) to exert a downward influence on the physical realm, by influencing whether or not certain random physical events occur. But this in itself would violate the causal closure of the physical, understood now as including the claim that the *probabilities* of underdetermined quantum physical events are fixed by sufficient immediate physical causes. For, if a nonphysical cause influences whether or not random physical events occur, it must presumably make a difference to the probabilities of those events, and this itself will contradict the thesis that those probabilities are already fixed by sufficient physical causes.

### THE ARGUMENT FROM CAUSAL CLOSURE TO PHYSICALISM

What follows now is a closer look at the argument that moves from the causal closure of the physical to the conclusion that anything with a physical effect must itself be physical. The focus will be on the case of *mental* causes of physical effects, but most of the points made will apply to items with physical effects generally.

Recall the point that the argument gets no grip on realms that have no physical effects. As mentioned earlier, Leibniz used this point to evade physicalism about the mental by holding that the mental and physical realms are causally insulated from each other, albeit unfolding in “preestablished harmony.” Contemporary philosophers who share Leibniz’s conviction that mental states cannot possibly be physical tend to adopt a somewhat different ploy. Instead of denying any causal contact between conscious mind and brain, they allow that brain processes cause conscious mental effects but deny that these conscious states then have any converse influence on the physical realm. The contemporary philosophers of mind

Frank Jackson and David Chalmers have both argued in favor of this “epiphenomenalist” position (Jackson 1982, Chalmers 1996). By viewing conscious states as “causal danglers” that exert no independent influence on the physical realm, they avoid any conflict with the thought that the causal closure leaves no room for anything nonphysical to make a difference to physical effects.

Perhaps there is another loophole in the argument from causal closure. In effect, this argument holds that a nonphysical mind cannot have physical effects because then those effects would have too many sufficient causes—both a nonphysical mental cause and the physical cause guaranteed by causal closure. However, such overdetermination of effects by two sufficient causes is not unknown. Imagine a case of a man who is simultaneously shot and struck by lightning, where either cause would have sufficed for his death on its own. Why should the physical effects of mental causes not similarly be overdetermined by two independent causes?

However, it is not clear that this is a good comparison. Overdetermination by distinct causes occasionally occurs by chance. But if a nonphysical mind has physical effects, then causal closure means that overdetermination of those effects will be routine. This calls for some explanation of why the two independent causes—mental and physical—should always be found together. If the two causes really are distinct, then will not some mechanism be needed to ensure that a sufficient physical cause is in place whenever a mental cause has a physical effect? However, no plausible such mechanism suggests itself.

So the possibility of overdetermination by both physical and mental causes does not support a distinct mental realm in the face of the causal closure of physics. However, there is another sense in which the causal closure of physics does leave it open that all behavioral effects may have both a physical cause and a nonidentical mental cause.

It has been a common theme in much recent physicalist philosophy of mind that mental properties are not *type-identical* to physical properties: many physicalist philosophers of mind are persuaded that, because beings with different physical constitutions can share mental properties such as pain, mental properties must be functional properties that are variably (or multiply) realized by physical properties, or disjunctions of physical properties, or some other kind of property that is metaphysically fixed by (supervenes on) physical properties, but not strictly identifiable with them.

Now, to the extent that causes involve properties, this denial of type-identity for mental and physical properties means that the mental and physical causes of behavioral effects cannot be strictly identical. However, this kind of double causation does not amount to the kind of overdetermination by distinct causes that was argued to be unacceptable above. As long as mental causes supervene metaphysically on physical causes, they are not fully distinct from them, and there is already a built-in explanation for why there should always also be a physical cause (as required by the causal closure of the physical) whenever a mental cause produces a behavioral effect. The denial of type identity creates some space between mental and physical causes, but not so much as to render it mysterious that they are always found hand in hand.

## CAUSAL OR CONDITIONAL OR EXPLANATORY-RELATION ACCOUNTS

Edmund Gettier attacked the traditional analysis of knowledge by showing that inferring a true belief from a false but justified belief produces a justified true belief that does not qualify as knowledge. Subsequent analyses of knowledge were motivated in large part by the wish to avoid examples of the type Gettier used. One way to do so is to insist that a belief must be connected in some proper way to the fact that makes it true in order for it to count as knowledge. In Gettier's examples beliefs are only accidentally true since there are no proper connections between them and the facts that make them true. Analyses that require such connections may either retain or drop the justification condition from the traditional analysis. Without it they are thoroughly externalist analyses since they require only that a belief be externally con-

nected with the fact that makes it true, not that the subject be able to specify this connection.

One intuitive way to specify the proper connection is to say that it is "causal": The fact that makes a belief true must help cause the belief in the subject if the subject is to have knowledge. When this causal relation holds, the truth of the belief is nonaccidental. The causal analysis of knowledge therefore excludes standard Gettier-type cases, but it seems on reflection to be both too weak and too strong: too strong in that knowledge of universal propositions, mathematical truths, and logical connections seems to be ruled out if these cannot enter into causal relations; too weak in allowing knowledge when a subject cannot distinguish a fact that causes her belief from relevant alternatives. Suppose, for example, that a subject *S* cannot tell red expanses from green ones but believes that there is a red expanse before her whenever either a red or a green expanse is there. Then, on an occasion in which a red expanse is before *S* the usual sort of perceptual causal connection will hold, but knowledge that the expanse is red will be lacking.

A different way to specify the necessary connection that handles the sort of case just cited is provided by the "conditional" account. According to this account, *S* knows that *p* only if *S* would not believe that *p* if *p* were not true. In close possible worlds in which *p* is not true, it must be the case that *S* does not believe it. This rules out the case of the red and green expanses since, in a close world in which the expanse is not red but green, *S* continues to believe it is red. A further condition required by this account is that in close worlds in which *p* continues to be true but other things change, *S* continues to believe that *p*.

The conditional account handles both Gettier's cases and those that require the distinction of relevant alternatives. But once again there are examples that seem to show it both too weak and too strong. That the first condition is too strong can be shown by a variation on the color expanse example. Suppose that *S* cannot tell red from green but is very good at detecting blue. Then, on the basis of seeing a blue expanse *S* can come to know that there is not a green expanse before her. But if this proposition were false (if there were a green expanse before her), she would still believe it true (she would think she was seeing red). That the second condition is too strong seems clear from the case of a very old person whose mental capacities are still intact but soon will fail him. That there are close worlds in which he does not continue to believe as he does now by exercising those

capacities does not mean that he cannot know various facts now through their exercise.

That these conditions are too weak can perhaps be shown by cases in which someone intentionally induces a Gettier-type belief in *S*. In this case, if the belief were not true, it would not have been induced in *S*, and yet *S* does not know. Such a case might or might not be ruled out by the second condition, depending on how it is specified and on how the second condition is interpreted. But there are other cases that seem more certainly to indicate that the conditions are too weak. If *S* steadfastly believes every mathematical proposition that she entertains, then the conditions will be met, but she will not know all the true mathematical propositions that she entertains.

An analysis of knowledge should not only accommodate various intuitions regarding examples; it should also be useful to the normative epistemologist in reconstructing the structure of knowledge and addressing skeptical challenges. The conditional account, as interpreted by its main proponent, Robert Nozick (1981), has interesting implications regarding skepticism. According to it, I can know various ordinary perceptual truths, such as that I am seated before a fire, even though I cannot know that there is no Cartesian demon always deceiving me. This is because in the closest possible worlds in which I am not before the fire, I do not believe that I am (I am somewhere else with different perceptual evidence). But in the closest world in which there is a Cartesian demon, I do not believe there is one (since all my perceptual evidence remains the same). These implications are welcome to Nozick but are troubling to other philosophers. My knowledge of being before the fire depends on the demon world not being among the closest in which I am not before the fire. But, according to the conditional account, I cannot know that this last clause is true. Hence, I cannot show that my knowledge that I sit before the fire is actual, as opposed to merely being possible, and it seems that I ultimately lack grounds for being convinced that this is so. Furthermore, implications regarding more specific claims to knowledge and skeptical possibilities are counterintuitive as well. For example, according to this account I cannot know that my son is not a robot brilliantly constructed by aliens, although I can know that I do not have a brilliantly constructed robot son.

A third way of specifying the required connection that makes beliefs true is to describe it as “explanatory.” If *S* knows that *p*, then the fact that *p* must help to explain *S*’s belief. To see whether this account handles the sorts of cases cited, we would need to define the notion of explanation being used here. One way to do so is in terms of a

certain notion of probability: Roughly, *p* explains *q* if the probability of *q* given *p* is higher than the probability of *q* in the relevant reference class (reflecting relevant alternatives); put another way, if the ratio of (close) possible worlds in which *q* is true is higher in the worlds in which *p* obtains than in the relevant contrasting set of worlds. Given this interpretation, the analysis handles the perceptual discrimination case. In it *S* does not know there is a red expanse before him because its being red does not raise the probability of his belief that it is relative to those possible worlds in which this belief is based on its being green. The analysis also allows knowledge in the variation that defeats the conditional account. In it *S* knows that there is not a green expanse before her since the fact that the expanse is not green (i.e., it is blue) explains her belief that it is not green. Since the account must allow explanatory chains, it can be interpreted so as to include knowledge of mathematical propositions, which do not enter into causal relations. In the usual case in which *S* has mathematical knowledge that *p* her belief must be explanatorily linked to *p* via some proof. The truth of *p* makes a proof possible, and the ratio of close worlds in which *S* believes *p* must be higher in worlds in which there is a proof than in the overall set of worlds.

The explanatory account needs to be filled out further if it is to accommodate cases involving intentionally produced beliefs resembling Gettier’s examples since in such cases the fact that *p* helps to explain why the belief that *p* is induced in *S*. As an externalist account, it would also need to provide defense for the claim that *S* can know that *p* even when, from his point of view, he has no good reasons for believing *p*. The analysis does suggest an approach to answering the skeptic different from that suggested by the conditional account. A proponent of this analysis would answer the skeptic by showing that nonskeptical theses provide better explanations of our ordinary beliefs than do skeptical theses.

## CAUSATION: METAPHYSICAL ISSUES

Causal concepts have surely been present from the time that language began, since the vast majority of action verbs involve the idea of causally affecting something. Thus, in the case of transitive verbs of action, there is the idea of causally affecting something external to one—one finds food, builds a shelter, sows seed, catches fish, and so on—while in the case of intransitive verbs, or at least those describing physical actions, it is very plausible that they involve the idea of causally affecting one's own body—as one walks, runs, jumps, hunts, and so on.

It was not long after the very beginning of philosophy in ancient Greece that serious reflection concerning the nature of causation arose, with Aristotle's famous discussion of causation in Book 2 of his *Physics*. The result was Aristotle's doctrine of four types (or, perhaps, aspects) of causes—material, formal, efficient, and final—an account that was immensely influential for about two thousand years.

What was not realized at any point during this time, however—perhaps because of the sense of familiarity with the idea of causation occasioned by the almost ubiquitous presence of causal concepts in even the most rudimentary parts of language—is that the concept of causation gives rise to very serious, puzzling, and difficult philosophical questions. Thus it was only many centuries after Aristotle, with David Hume and his famous discussions of the relation of cause and effect (1739–1740 and 1748), that philosophers realized that the idea of causation was by no means simple and straightforward.

Why did Hume see what so many thoughtful philosophers before him had not? The reason, it would seem, was that Hume held—as did the other British empiricists, John Locke and Bishop (George) Berkeley—that while some concepts can be analyzed in terms of other concepts, in the end analysis must terminate in ideas that apply to things in virtue of objects' having properties and standing in relations that can be immediately given in experience. Hume therefore asked whether the relation of causation was one that could be given in immediate experience. His conclusion was that it could

not. The question for Hume, accordingly, was how the concept of causation could be analyzed in terms of ideas that do pick out properties and relations that are given in experience, and once this question was in view, Hume was able to show that arriving at a satisfactory answer was a very difficult matter.

## FUNDAMENTAL ISSUES AND ALTERNATIVE VIEWS

One of the central issues in the philosophy of causation concerns, then, this Humean problem: Is the concept of causation basic and unanalyzable, or, on the contrary, does it stand in need of analysis? If it does need to be analyzed, how can this be done?

Many different answers have been offered to these questions. But the various approaches can be divided up into four general types: direct realism, Humean reductionism, non-Humean reductionism, and indirect, or theoretical-term, realism.

This fourfold division, in turn, rests upon the following three distinctions: first, that between reductionism and realism; second, that between Humean and non-Humean states of affairs; and, third, that between states that are immediately observable and those that are not. Let us, then, consider each of these distinctions in turn, starting with that between reductionism and realism.

**REALISM VERSUS REDUCTIONISM.** The realism-versus-reductionism distinction in this area arises in connection with both causal laws, and causal relations between states of affairs, and gives rise to a number of related theses. In the case of causal relations between states of affairs, a thesis that is essential to reductionism is this:

### *Basic Reductionism with respect to causal relations.*

Any two worlds that agree both with respect to all of the non-causal properties of, and relations between, particulars, and with respect to all causal laws, must also agree with respect to all of the causal relations between states of affairs. Causal relations are, then, logically supervenient upon the totality of instances of non-causal properties and relations, together with causal laws.

But while this thesis is an essential part of a reductionist view of causation, it is not sufficient. The reason is that this thesis can be combined with a view of causal laws according to which they obtain in virtue of atomic, and therefore irreducible, facts. What is needed, then, is a reductionist thesis concerning causal laws, and here there are two important possibilities:

**Strong Reductionism with respect to causal laws.** Any two worlds that agree with respect to all of the non-causal properties of, and relations between, particulars, must also agree with respect to causal laws. Causal laws are, then, logically supervenient upon the totality of instances of non-causal properties and relations.

**Moderate Reductionism with respect to causal laws.** Any two worlds that agree both with respect to all of the non-causal properties of, and relations between, particulars, and with respect to all laws of nature, must also agree with respect to causal laws. Causal laws are, then, logically supervenient upon the totality of instances of non-causal properties and relations, together with laws of nature.

What lies behind this strong reductionism versus moderate reductionism distinction? The answer is that while most philosophers who are reductionists with regard to causation tend to identify laws of nature with certain cosmic regularities, it is possible to be a reductionist with regard to causation while holding that laws are more than certain cosmic regularities: One might hold, for example, that laws of nature are second-order relations between universals. Such a reductionist would reject Strong Reductionism with regard to causal laws, while accepting Moderate Reductionism.

Each of these two reductionist theses concerning causal laws then entails, in conjunction with the Basic Reductionist thesis concerning causal relations, a corresponding thesis concerning causal relations between states of affairs:

**Strong Reductionism with respect to causal relations.** Any two worlds that agree with respect to all of the non-causal properties of, and relations between, particulars, must also agree with respect to all of the causal relations between states of affairs. Causal relations are, in short, logically supervenient upon the totality of instances of non-causal properties and relations.

**Moderate Reductionism with respect to causal relations.** Any two worlds that agree both with respect to all of the non-causal properties of, and relations between, particulars, and with respect to all laws of nature, must also agree with respect to all of the causal relations between states of affairs. Causal relations are, then, logically supervenient upon the totality of instances of non-causal properties and relations, together with laws of nature.

To be a reductionist with regard to causation, then, is to accept the Basic Reductionist thesis with respect to causal relations, and either the Strong or the Moderate Reductionist thesis with respect to causal laws. This then

commits one either to the Strong Reductionist thesis or the Moderate Reductionist thesis with respect to causal relations.

A realist with regard to causation, correspondingly, is one who rejects either the Basic Reductionist thesis concerning causal relations, or else both the Strong and the Moderate Reductionist theses with regard to causal laws, or all of these.

#### HUMEAN VERSUS NON-HUMEAN REDUCTIONISM.

In addition to the gulf between reductionism and realism, there are also very important divides within both reductionism and realism. In the case of reductionism, the crucial division involves a distinction between what may be called Humean and non-Humean states of affairs. So let us now turn to that distinction.

Different authors offer different characterizations of what a Humean state of affairs is. The basic idea, however, is that Humean states of affairs are ones that consist of particulars having properties and standing in relations, where the properties and relations in question are, in some sense, immediately observable. The idea of being immediately observable can then be interpreted in different ways. A very restrictive interpretation would be one where immediate observation is equated with direct acquaintance, so that only properties and relations that are the objects of Hume's simple ideas—that is, properties and relations that can be immediately given in experience—are classified as immediately observable. Alternatively, one could construe the idea of immediate observation more broadly, so that any properties and relations that can be directly or noninferentially perceived would count as immediately observable.

What would be an example of a non-Humean state of affairs? One type would be any state of affairs that involves a dispositional property or power, since even if, for example, one sees something in the process of dissolving in water, an inference is involved if one is to arrive at the conclusion that the object is such that it is disposed to dissolve when it is in water, since its dissolving on the occasion in question could be a pure accident, or could be caused entirely by some external force, rather than being due to an intrinsic property of the object itself. So an inference is involved, and therefore the water-solubility of an object cannot be an object of direct perception.

Some twentieth-century approaches to causation attempt to analyze causation in terms of powers and propensities. Such approaches are reductionist, but not of a Humean sort.
