There are important ambiguities concerning the means of deduction and definition to be admitted in the development of the theory. Here informal axiomatics always makes use of some general background that can be used in developing the theory but is not itself included in the axiomatization. In modern mathematics this background typically includes logic and arithmetic and usually also analysis and some set theory. For example, in an axiomatic theory concerning objects of a certain kind, one permits oneself very quickly to make statements about sequences and sets of those objects, to introduce concepts defined in terms of the primitives of the theory by means of these general mathematical devices, and to make inferences that turn on laws of arithmetic, analysis, or set theory. Such notions often enter into the statement of the axioms themselves. We shall presently say more about the significance of this procedure.

It might seem natural to require provisionally that the means of deduction and definition be restricted to those of pure logic, for logic is supposed to contain those rules of correct inference which have the highest degree of generality and which must be applied in all sciences. We would then regard an axiomatization as only partial if deductions from it required the use of methods of the special sciences—in particular, branches of mathematics (likewise if, in addition to the primitives, notions other than purely logical ones entered into the definitions). An axiomatic theory would then consist of just those statements that are deducible by purely logical means from a certain limited set of statements and of the statements that can be obtained from these by definitions expressible purely logically in terms of the primitives.

It seems possible that such an axiomatic system was the objective toward which Euclid was striving. He evidently did not intend to allow himself general mathematical notions, such as arithmetical ones, for he included propositions involving such notions among his axioms and undertook to develop some of number theory from the axioms in Books VII–IX. Even some of Euclid's well-

known failures to achieve this degree of rigor—for example, his assuming in his very first proof that two circles with the center of each lying on the circumference of the other will have two points of intersection—might have arisen because he saw them as immediate deductions from the meaning of the concepts involved. Of course, a rigorous theory of definition would require definitions to be given or axioms to be explicitly stated in such a way that such deductions do proceed by mere logic.

A perfectly satisfactory axiomatization in this form certainly was not possible in Euclid's time; it probably had to wait for two developments that did not take place until the late nineteenth century, Frege's discovery and axiomatization of quantification theory and the Dedekind-Peano axiomatization of arithmetic. (Nonetheless, considerable progress was made prior to these developments.)

This remark points to a limitation of the conception we are considering, for it does not give a meaning to the idea of an axiomatization of logic itself, although such axiomatization has played a vital role in modern foundational studies. Appreciation of this point leads to the concept of a formal system, but before we consider this concept let us observe a consequence of the axiomatization of a theory.

**1.2. THE ABSTRACT VIEWPOINT.** Suppose a theory is so completely axiomatized that all concepts of the special theory which are used in statements and deductions are explicitly given as primitives and all special assumptions underlying the proofs are disengaged and either stated among or deduced from the axioms. This means that the validity of the deductions does not at all depend on the actual meaning of the primitive terms of the special theory. It follows that the formal structure determined by the primitive concepts and the axioms can have a more general application than they have in the given special theory, in the sense that we could by any choice of interpretation of the primitive terms obtain a deductive system of hypotheses concerning some subject matter, even though the hypotheses will in many cases be false.

This fact is of crucial importance in the study of axiom systems. We can then think of a *model* of an axiomatic theory as a system of objects and relations that provides references for the primitive terms so that the axioms come out true. We can think of axiomatization as having proceeded with a particular model in mind, but this need not have been the case; at any rate, interest attaches to the study of other possible models. (Although we may, in this discussion, allow means of deduction that

go beyond pure logic, it ought to be the case that if a proposition is deducible from the axioms of the theory, then it must be true in all models of the theory. It might be reasonable to take this as a sufficient condition of deducibility, but if so it seems that the notion of model will have to have a relativity comparable to that of the notion of deducibility.)

For example, suppose we consider absolute geometry—that is, Euclidean geometry without the parallel postulate. Then any model either of Euclidean geometry or of the standard non-Euclidean geometries will be a model of absolute geometry. If the parallel postulate is deducible from the other axioms of Euclidean geometry—that is, from the axioms of absolute geometry—then it must be true in every model of absolute geometry. The construction of models for non-Euclidean geometries showed that this is not the case. We call an axiom of a system independent if it is not deducible from the others. Thus, if the theory obtained by dropping an axiom  $\mathcal{A}$  has a model in which  $\mathcal{A}$  is false, then  $\mathcal{A}$  is independent.

Another possibility, which has been much exploited in modern mathematics, is to replace a system of primitive terms and axioms by what amounts to an explicit definition of a model of the axioms. Thus, suppose Euclidean geometry is formulated with two primitive predicates (following Alfred Tarski in “What Is Elementary Geometry?,” 1959):

$$“\beta(x,y,z),”$$

meaning “ $x$ ,  $y$ , and  $z$  are collinear, and  $y$  lies between  $x$  and  $z$  or  $y = x$  or  $y = z$ ,” and

$$“\delta(x,y,z,w),”$$

meaning “ $x$  is the same distance from  $y$  as  $z$  is from  $w$ .” (The variables here range over points, which in the informal theory must be thought of as a primitive notion.) Then we can define a *Euclidean space* as a triple  $\langle S,B,D \rangle$ , where  $S$  is a set of entities called “points,”  $B$  a ternary relation on  $S$ , and  $D$  a quaternary relation on  $S$ , such that the axioms of Euclidean geometry hold. Then to any theorem proved from these axioms corresponds a statement of the form “Every Euclidean space is such that ...” A number of attempts to characterize mathematical structures axiomatically have led in a similar way to explicit definitions of abstract types of structure. This is regarded, for more than historical reasons, as a fruit of the axiomatic method. The search for an axiomatic basis for a mathematical theory is also the search for a formulation of the arguments in a fashion which will make them more gen-

erally applicable, giving them a generality which can be expressed in the definition of a general type of structure.

1.3. FORMALIZATION. Whereas one development of the axiomatic method tends to the replacement of axioms by definitions, another leads to the conception of a formal system. One result of the axiomatization of a theory was that the meaning of the primitive terms became irrelevant to the deductions. If we carry this abstraction from meaning to its limit, we can cover the case of axiomatizations of logic and resolve once and for all the question of what means of deduction are to be allowed. That is, we put into the construction of an axiom system a complete specification of all the means of inference to be allowed (for example, logic and basic mathematics) in the form both of further axioms and of rules of inference that allow us to infer from statements of certain given forms a statement of another given form. If this is done with utmost rigor, so that use can be made of only as much of the meaning of the terms as is specified in axioms and explicit definitions, then the system is specified simply in terms of the designs of the “linguistic” forms in which it is expressed. “Linguistic” is put in quotation marks because, invariably, much of the language has been replaced by an artificial syntax. We are left with a specification of certain strings of symbols as “axioms” and certain rules, each of which allows us to “infer” a new string from certain prior ones. The strings which we can obtain from axioms by successive application of the rules can be called *theorems*.

A proper explanation of the concept of a formal system requires somewhat more apparatus. The exactness of this procedure requires that the strings of symbols used be constructed out of preassigned material, which we can assume to be a finite list of symbols. Among the strings of these symbols we single out a subclass that we call formulae (or well-formed formulae, wffs), which are those strings to which, in an interpretation, we would give a meaning. (The non-wffs correspond to ungrammatical sentences.) Then a certain class of formulae is singled out as the axioms. The class of theorems can be defined as the closure of the axioms under certain operations; that is, rules of the following form are specified:

$$(R_i). \text{ If } \mathcal{A}_1, \dots, \mathcal{A}_{r_i} \text{ are theorems and } \mathcal{R}_i(\mathcal{A}_1, \dots, \mathcal{A}_{r_i}), \text{ then } \mathcal{B} \text{ is a theorem, where } \mathcal{R}_i \text{ is some relation on strings of the symbols of the system.}$$

So the definition of *theorem* is an inductive definition with the clauses  $(R_i)$  and

every axiom is a theorem.

In this setting we can resolve another ambiguity of our original rough conception of axiomatization. The question arises concerning what conditions a class of statements must satisfy to be appropriate as the axioms of an axiomatic theory. Various epistemological desiderata, such as self-evident truth for the intended model, are put aside once we take the abstract point of view. Another requirement that has been found natural in the past is that both individual axioms and the class of axioms as a whole should have a certain simplicity. What there is in the way of general theory about the simplicity of individual axioms has not played much of a role in investigations of the foundations of mathematics, although much effort has been expended in replacing individual axioms with simpler ones or in finding systems of axioms which have particular advantages of “naturalness” for intended applications.

In order to characterize the important axiom systems which have been used in the past we shall have to place some limitation on the class of axioms. In the traditional cases the class has been finite. However, the formalization of such an axiomatic system can give rise to an infinite system—for example, if we take as axioms all instances of a certain schema.

The limitation which is used instead of a finite class of axioms is based on the fact that the notions of formula, axiom, and theorem are to be syntactically specified. Then the requirement is that there be a mechanical, or effective, procedure for deciding whether a given formula is an axiom and whether a given inference (of a formula from finitely many premises) is correct according to the rules of inference. This requirement is natural in the light of the idea that a proof of a statement in an axiomatic theory should contain all the mathematically significant information needed to show that the statement is indeed assertible in the theory. That would not be the case, it is argued, if something beyond mechanical checking were needed to determine the correctness of the proof. (It should be pointed out, however, that generalizations of the concept of formal system in which this condition is not satisfied are frequently used in mathematical logic.)

The notion of a formal system gives the highest degree of generality, in that there is no element of the symbolism whose interpretation is restricted. Indeed, it permits much of what we might want to say about an axiomatic theory to be formulated without reference to interpretation, since the formulae, axioms, and rules of inference are specified without reference to interpretation, and what is a theorem is then defined, again without such reference. An entire division of the theory of formal

systems—what is usually called syntax—can thus be built up with no more than a heuristic use of interpretation. In particular, the intensional notions—concept, proposition, etc.—relied on so far in the informal exposition can be eliminated.

The concept of a formal system also brings to the formulation of the theory the highest degree of precision, at the cost of a still further idealization in relation to the concrete activities of mathematicians. Furthermore, the concept not only gives a refined formulation to axiomatizations and allows a mathematical study of axiom systems of a more general scope than was possible without it but also makes possible a precise formulation of differences about mathematical methods. Carrying the axiomatic method to this limit makes possible a new approach to a wide variety of questions about the foundations of mathematics.

Inasmuch as axiomatization is a rendering of a theory in a more precise formulation (if not a singling out of some particular aspect of the theory), the axiomatized theory cannot be identified in every respect with what has gone before. It can replace, however, what has gone before and actually has done so in many cases. The passage from axiomatization to formalization is in an important respect more radical than the various stages of informal axiomatization, and we can therefore regard a formalization of a theory as not so much a more precise formulation of the theory as an idealized representation of it. The process of replacing expressions of natural language by artificial symbols, which goes on in all mathematical development, is here carried to an extreme. For example, we lay down by a definition what are “formulae” and “proofs” in the system, whereas informally we rely for the notion of sentences on our more or less unanalyzed linguistic sense, and for proofs we rely on this sense, on mathematical tradition, and on intuitive logic. In particular, formulae and formal proofs are of unbounded length and complexity, without regard to the limits of what we can perceive and understand.

With this goes the fact that the basic general notions with which we operate in formulating and reflecting on theories—sentence, proposition, deduction, axiom, inference, proof, definition—are replaced in the formalized version by specifically defined, more or less simplified and idealized substitutes. In particular, although we “interpret” formalized theories, the relation between a sign or a formal system and its reference in some model is a “dead” correspondence, an aspect of a purely mathematical relation between two systems of objects. This enables one to avoid the intractable problems of how lin-

guistic expressions come to have “meaning” and, with it, reference and is therefore an extremely valuable piece of abstraction. But it is an abstraction; moreover, it does not mean that the informal linguistic and intellectual apparatus disappears altogether, since it will still be used in the setting up and investigation of the formalized theory. In fact, one of the results of formalization is a sharper separation between what is within the theory and what belongs to discourse about it—that is, to the metatheory. If the metatheory is in turn axiomatized and then formalized, the same situation arises at the next-higher level.

The importance of this observation is difficult to assess, but it is relevant to a number of problems we shall discuss later—in particular, attempts to argue from results of mathematical logic to philosophical conclusions.

## §2. EPISTEMOLOGICAL DISCUSSION

**2.1. A PRIORI KNOWLEDGE.** We shall now put the matter of axiomatization and formalization aside and consider mathematics from the point of view of general epistemology. The guiding thread of our discussion will be the fact that a powerful tradition in philosophy has regarded mathematics, or at least a part of it, as a central case of a priori knowledge. This means that reflection on mathematics has been at the center of philosophical discussion of the concept of a priori knowledge.

The characteristics of mathematics which have led to the conclusion that mathematics is a priori are its abstract character and accompanying enormous generality and its great exactitude and certainty, which, indeed, have traditionally been considered absolute. Thus, even before setting forth a developed logical analysis of the concept of number, we find that the effort to interpret “ $2 + 2 = 4$ ” as a hypothesis that can be checked by observation runs into obvious obstacles. It is perhaps not so vital that the statement refers to abstract entities, numbers, which are not the sort of thing we observe. The concept of number certainly does apply to empirically given objects, in the sense that they can be counted and that the numbers thus attributed to them will obey such laws as “ $2 + 2 = 4$ .” Therefore, the proposition could so far be taken as a law concerning such entities. Even then its range of application is so enormous, extending over the entire physical universe, that it seems evident that if it were taken as a hypothesis, it would be stated and used in a more qualified way, at least by critically minded scientists. In other words, the certainty that we attribute to elementary arithmetical propositions would be quite unwarranted if they were laws based on observation. Even in the case of math-

ematical principles to which we do not attribute this degree of certainty, such as the axiom of choice and the continuum hypothesis, the possible “contrary evidence” would arise from the deductive development of the theory involved (in the examples, set theory), not from observation.

Moreover, it seems that we ought to be able to conceive of a possible observation which would be a counterinstance. Although it is perhaps not evident that this is impossible, the ideas that come to mind lead either to descriptions of doubtful intelligibility or to the description of situations where it seems obviously more reasonable to assume some other anomaly (such as miscounting or the perhaps mysterious appearance or disappearance of an object) than to admit an exception to “ $2 + 2 = 4$ .”

Another difficulty is that the concept of number must apply beyond the range of the concrete entities which are accessible to observation; such abstract entities as mathematical objects must be subject to counting, and this seems also to be the case for transcendent entities.

The foregoing considerations could be developed into decisive arguments only with the help of both a more developed formal analysis of number and a more detailed discussion of the relation between arithmetical laws and actual counting and perhaps also of the role of mathematics in empirical science. In any case, they do not tell against another form of the denial that arithmetic is a priori, the view that arithmetical laws are theoretical principles of a very fundamental sort, which we are therefore far more “reluctant to give up” in a particular situation than more everyday beliefs or impressions or even than fundamental theoretical principles in science. Such a view would nonetheless take it to be conceivable that in response to some difficulty in, say, particle physics a new theory might be formulated which modified some part of elementary arithmetic.

**2.2. MATHEMATICS AND LOGIC.** The above considerations show why it is necessary to add technical analysis to the epistemological discussion. We shall take as our guiding thread the attempt to show that mathematics—in particular, arithmetic—is a part of logic. This attempt has led to some of the most important results in the logical analysis of mathematical notions. The view that mathematics can be reduced to logic is one of the principal general views on the foundations of mathematics which we mentioned earlier; it goes generally by the name of logicism, and its classic expression is in the writings of Frege and Russell.

Even if successful, the reduction of mathematics to logic could not by itself give an account of how there can be a priori knowledge in mathematics, for it would only reduce the problem of giving such an account to the corresponding problem with regard to logic. Nonetheless, the a priori character of mathematics has traditionally been found perhaps slightly less certain than that of logic. The obvious fact that one of the primary tasks of mathematics is the deductive development of theories has been found to be one of the most powerful supports of the claim that mathematics is a priori. We can expect that a successful reduction of mathematics to logic will simplify the problem of a priori knowledge, and not only by replacing two problems by one. Logic is more unavoidable: We cannot get anywhere in thinking without using logical words and inferring according to logical rules. This would suggest that logic is in fact more basic than mathematics and more certainly a priori. (It would also suggest that philosophical treatments of logic are more liable to circularity.) Moreover, in the course of history philosophers have invoked sources of evidence for mathematics which are at least apparently special, such as Kant's pure intuition. Thus, a reduction of mathematics to logic might make superfluous certain difficult epistemological theories.

The claims of logicism are based in large part on mathematical work in axiomatics. A number of nineteenth-century investigations showed that the basic notions of analysis—for example, rational, real, and complex number—could be defined, and the basic theorems proved, in terms of the theory of natural numbers and such more general notions as class and function. At the same time, axiomatic work was done in the arithmetic of natural numbers, culminating in the axiomatization of Richard Dedekind (1888) and Peano (1889). The movement toward formalization began somewhat later, with the work of Frege and of the school of Peano.

Thus, the effort to reduce mathematics to logic arose in the context of an increasing systematization and rigor of all pure mathematics, from which emerged the goal of setting up a comprehensive formal system which would represent all of known mathematics with the exception of geometry, insofar as it is a theory of physical space. (But of the writers of that generation only Frege had a strict conception of a formal system.) The goal of logicism would then be a comprehensive formal system with a natural interpretation such that the primitives would be logical concepts and the axioms logical truths.

We shall be guided by Frege's presentation, although he did not go very far in developing mathematics within

his system and of course the system turned out to be inconsistent. Nonetheless, it is already clear from Frege's work how to define the primitives and prove the axioms of a standard axiomatization of arithmetic. We shall begin with some discussions of the notions of number and class, which are crucial for the reduction and for the foundations of mathematics generally.

**2.3. COUNTING AND NUMBER.** In order to be clearer about the concept of number, we might start with the operation of counting. In a simple case of carefully counting a collection of objects, we perhaps look at and point to each one successively, and with each of these directions of the attention we think of or pronounce one of a standard series of symbols (numerals) in its place in a standard ordering of these symbols. We are careful to reach each of these objects once and only once in the process. We thus set up a one-to-one correspondence between the objects and a certain segment of the series of numerals. We say that the number of objects in the collection is \_\_\_\_\_, where the blank is filled by the last numeral of the series.

Before pursuing this matter further, let us examine the series of numerals itself. We have certain initial symbols and rules for constructing further symbols whose application can be iterated indefinitely. We could simplify the situation in actual language and suppose that there is one initial symbol, say “|,” and a generating operation, concatenation of another “|,” so that the numerals will be |, ||, |||, ||||, ···. It is not clear, however, that it is merely a matter of “practical convenience” that ordinary numerals are, in the long run, considerably more condensed: If a string of several million “|’s” were offered as a result of counting, one would have to count them to learn what the number was.

However, it is worth asking whether the pure notion of natural number requires more than the possibility of generating such a string of symbols. By “symbols” do we mean here blobs of ink? Only with certain reservations. The particular blobs which we have produced are not at all essential; if we write others—|, ||, |||, ||||, ···—they will do just as well. In fact, we could have chosen symbols of quite different forms and still have produced something equivalent for our purposes, such as +, ++, +++, ···, or something not consisting of marks on paper at all, such as sounds, which are, of course, actually used. As long as it is capable of representing to us the process of successive generation by which these sequences of symbols are produced, anything will do—any collection of perceptible

objects that can be placed in one-to-one order-preserving correspondence with our first sequence of symbols.

Thus, the blobs of ink serve as the representatives of a quite abstract structure. This abstraction allows us (even on a subordinate level) to disregard some limitations of the blobs besides their particularity and accompanying boundedness to a particular place and time. They are constructed according to a procedure for generating successive ones, and what matters is the structure embodied in the procedure, not any particular limitations that might be encountered in carrying it out. On a sufficiently abstract level we say that we can continue to generate symbols indefinitely, although life is too short, paper and ink run out, the earth perhaps disintegrates, etc.

Here we have already taken the step of introducing abstract entities. In a weak form this could be represented as taking certain abstract equivalence relations between entities (e.g., marks on paper) as criteria of identity for new kinds of entities (e.g., symbols as types or, further, numbers). But we have already reached a point where more is involved, since the abstract entities which are represented by all the marks of a given equivalence class belong to a series which can be continued far beyond any practical possibility of constructing representatives. We can create a “pseudo-concrete” model by appealing to space, time, and theoretical physics, but then we are already depending on abstract mathematical objects. Given that we do think of numerals as referring to numbers, it is natural to introduce the apparatus not only of identity but also of quantification. Certain uses of such quantification, however, will involve still stronger presuppositions than we have uncovered up to now, and we shall discuss these when we consider platonism and constructivism.

**2.4. AXIOMS OF ARITHMETIC.** We have so far taken for granted that the natural numbers are obtained by starting with some initial element 0 and iterating an operation of “successor” or “adding 1.” This is the basis for an especially simple axiomatization of the theory of natural numbers, that of Dedekind and Peano, in which the primitives are “0,” “number” (“ $NNx$ ”), and “successor” (which we shall give as a relation: “ $Sxy$ ” means “ $y$  is successor of  $x$ ”). Then the axioms are

- (1)  $NN0.$
- (2)  $NNx \supset (\exists !y)(Nny \ \& \ Sxy).$
- (3)  $\neg S0x.$

- (4)  $Sxz \ \& \ Syz. \ \supset \ x = y.$
- (5)  $(F)[F0 \ \& \ (x)(y)(Fx \ \& \ Sxy. \ \supset \ Fy) \ . \ \supset \ (x)(NNx \ \supset \ Fx)].$

In (5), “ $(F)$ ” may be read “for all properties  $F$ ,” but for the present we shall not discuss just what this means. We do not need to suppose that precisely what properties there are is determined in advance, but we have to acknowledge that if it is not determined what properties there are, then it may not be determined precisely what natural numbers there are.

We could think of the natural numbers as given by a kind of inductive definition:

- (a)  $NN0.$
- (b) If  $NNx$ , then  $NN(Sx).$
- (c) Nothing is a natural number except by virtue of (a) and (b).

However, in this case we have to suppose that the successor relation is given in such a way that axioms (2), (3), and (4) are evident. We might think of “0” as represented by “|” and the successor function as represented by the addition of another “|” to a string. Then there is apparently an appeal to spatial intuition in regarding these axioms as evident. In that event the induction principle (5) will be in some way a consequence of (c). It could be regarded simply as an interpretation of (c), or one might argue, as Ludwig Wittgenstein apparently did at one time (see Friedrich Waismann, *Introduction to Mathematical Thinking*, Ch. 8), that the meaning of all natural numbers is not given to us by such specifications and our independent concept of “all” and that the induction principle functions as a criterion for a proposition’s being true of all natural numbers.

**2.5. THE CONCEPT OF CLASS (SET).** Before we discuss further the notion of number it is necessary to give some explanation of the notion of class or set. We shall consider two explanations, one suggested by Cantor and one suggested by Frege.

**2.5.1. Frege’s explanation.** Instead of the term *class* or *set*, Frege used the phrase “extension of a concept.” Frege’s usage is based on the tendency to regard the predicates of a language as standing in quantifiable places—

John is a Harvard man.  
Henry is a Harvard man.

$\therefore$  John and Henry have something in common—

and the tendency to derive from general terms abstract singular terms, which are usually explained as referring to properties or attributes.

These two tendencies can be separated. Frege regarded predicates in context as in fact referring, but to concepts, not to objects. Concepts, like the predicates themselves, have argument places; Frege called both predicates and concepts “unsaturated” because only with the argument place filled by an object (in the case of a predicate, a proper name) could they “stand by themselves.” A notation which expresses his conception is that of the second-order predicate calculus, in which the above conclusion might be symbolized (misleadingly) as  $(\exists F)[F(\text{John}) \ \& \ F(\text{Henry})]$ . An expression which is syntactically appropriate for denoting an object cannot denote a concept, and vice versa.

The extension of a concept, then, is simply an object associated with the concept in such a way that if two concepts apply to the same objects, they have the same extension—that is,

$$(6) \quad \hat{x}Fx = \hat{x}Gx. \equiv (x)(Fx \equiv Gx),$$

where  $\hat{x}Fx$  is the extension of the concept  $F$ . This is essentially Frege’s famous axiom V (*Grundgesetze der Arithmetik*, Vol. I, p. 36; Frege’s notion of concept can interpret the quantifiers in our axiom 5).

**2.5.2. Cantor’s explanation.** Cantor characterized a set as “jedes Viele, welches sich als Eines denken lässt, d.h. jeden Inbegriff bestimmter Elemente, welcher durch ein Gesetz zu einem Ganzen verbunden werden kann” (“every many, which can be thought of as one, that is, every totality of definite elements which can be combined into a whole by a law”; *Gesammelte Abhandlungen*, p. 204). “Unter einer ‘Menge’ verstehen wir jede Zusammenfassung  $M$  von bestimmten wohlunterschiedenen Objekten  $m$  unserer Anschauung oder unseres Denkens (welche die ‘Elemente’ von  $M$  genannt werden) zu einem Ganzen” (“By a ‘set’ we understand any collection  $M$  of definite well-distinguished objects of our intuition or thought, which are called the ‘elements’ of  $M$ , into a whole”; p. 282).

It is virtually impossible to explain Cantor’s idea of set without using words of the same general type, only vaguer (“collection,” “multitude,” *Inbegriff*). We can perhaps approach it by mentioning a few ways in which multitudes are thought of as unities: by being thought of by means of a predicate—that is, by being brought under a concept in Frege’s sense—so that Frege’s extensions could perhaps be regarded as sets, or by being in some way brought to the attention at once, even without the inter-

vention of language; in particular, a finite number of objects of perception can constitute a set. That the objects must be “determinate and well-distinguished” means that it must be determinate what the elements are, that identity and difference be well-defined for the elements, and that a set must be determined by its elements.

One is inclined in this connection to think of a set as “composed” of its elements, but this is not essential and might lead to confusion of a set with a spatiotemporal sum, but a portion of space or time (for example, a geometric figure) can be partitioned in a number of ways, so the sets of the parts will be different but the sum will always be the same.

The picture of finite sets can be extended in such a way that one might imagine an “arbitrary” infinite set independent of any predicate. Suppose it is to be a set  $S$  of natural numbers. We go through the natural numbers one by one deciding for each  $n$  whether  $n$  is a member of  $S$  ( $n \in S$ ) or not. Although the determination takes infinitely long, it is determined for each  $n$  whether  $n \in S$ . (Or we might imagine its being done all at once by God.)

**2.5.3. Difficulties in these conceptions.** Both Cantor’s and Frege’s conceptions of sets have difficulties which did not come clearly to the consciousness of logicians and set-theorists until the discovery of the set-theoretical paradoxes, discussed below. We shall merely mention here a source of difficulty. In both theories a set or extension is supposed to be an object, capable of being itself a member of sets. Cannot this give rise to circularities—that is, that a set is formed from or constituted by certain objects, among them itself? (Or, in Frege’s terms, among the objects in the range of the quantifiers on the right side of formula 6 are  $\hat{x}Fx$  and  $\hat{x}Gx$  themselves, so that the identity condition for these objects, which from Frege’s point of view was part of their essence, seems to depend on particular facts about them.)

We shall not say anything at the moment about the particular form the difficulties take or about how to resolve them. We shall continue to use second-order quantification somewhat vaguely; one can interpret the variables as ranging over Frege’s concepts, in most cases over classes or even over intensional entities, as might have been suggested by our original word “property.”

**2.6. FREGE’S ANALYSIS OF NUMBER.** We can now proceed to the main steps of Frege’s argument for the thesis that arithmetic is a part of logic. Frege observed that a necessary and sufficient condition for, say, the number of  $F$ ’s (which we shall write as “ $N_x Fx$ ”) to be the same as the number of  $G$ ’s is that there should be a one-to-one corre-

spondence of the  $F$ 's and the  $G$ 's. (In that case we say they are numerically equivalent.) This criterion, which is quite general—that is, not restricted to the case where there are only finitely many  $F$ 's or  $G$ 's—had already been exploited by Cantor to generalize the notion of cardinal number to infinite classes. It can be justified by our discussion of counting and number, above.

On the basis of a one-to-one correspondence between the  $F$ 's and  $\{1, \dots, n\}$  we are prepared to say that the number of  $F$ 's is  $n$ . But no such correspondence can then exist with  $\{1, \dots, m\}$  for any  $m \neq n$ , and if by the same criterion there are  $n$   $G$ 's, then by composition we can set up a one-to-one correspondence between the  $F$ 's and the  $G$ 's. If there are  $m$   $G$ 's for  $m \neq n$ , we cannot. So we say that there are  $n$   $F$ 's if and only if a one-to-one correspondence exists between the  $F$ 's and  $\{1, \dots, n\}$ , and in that case there are  $n$   $G$ 's if and only if there is a one-to-one correspondence between the  $F$ 's and the  $G$ 's. Writing “there are  $n$   $F$ 's” as “ $(\exists x)_n Fx$ ,” we have that if  $(\exists n)[(\exists x)_n Fx]$ ,

$$(7) N_x Fx = N_x Gx. \equiv \text{the } F\text{'s and the } G\text{'s are numerically equivalent.}$$

Since we have no independent criterion for the case where there are infinitely many  $F$ 's, we take (7) to be true by definition in that case. We then have Frege's criterion.

Frege then defined a relation  $H$  as a one-to-one correspondence of the  $F$ 's and the  $G$ 's if and only if for every  $F$  there is exactly one  $G$  to which it bears the relation  $H$  and vice versa—in symbols,

$$(8) (x)[Fx \supset (\exists!y)(Gy \ \& \ Hxy)] \ \& \ (y)[Gy \supset (\exists!x)(Fx \ \& \ Hxy)],$$

where “ $(\exists!x)(\dots x \dots)$ ” can be defined in first-order logic:

$$(9) “(\exists!x)(\dots x \dots)” \text{ for } “(\exists x)[\dots x \dots \ \& \ (y)(\dots y \dots \supset y = x)]”.$$

Thus, numerical equivalence can be defined by a formula “ $(\exists H)\mathcal{S}(H, F, G)$ ,” where “ $\mathcal{S}(H, F, G)$ ” is an abbreviation for a first-order formula, namely, the expansion of (8) in terms of (9).

The relation of numerical equivalence is an equivalence relation; Frege's idea was, in effect, to define cardinal numbers as the equivalence classes of this relation. This definition, however, requires a powerful use of the notion of extension which is allowed by his axiom (6). In other words,  $N_x Fx$  is to be the extension of the concept concept numerically equivalent to the concept  $F$ —that is, we define

$$(10) \quad “N_x Fx” \text{ for } “\hat{G}(\exists H)\mathcal{S}(H, G, F)”.$$

(In fact, in the *Grundgesetze*, Frege avoided applying the extension operator to a second-order variable by appeal to formula 6:  $G$  can be replaced by its extension. We define “ $\hat{G}\mathcal{S}(G)$ ” as  $\hat{y}(\exists G)[y = \hat{x}Gx \ . \ \mathcal{S}(G)]$ .”)

Formula (10) gives a definition of Cantor's general concept of cardinal number, so we can prove (7); no further use of axiom V is needed for the definition of the natural numbers and the proof of the axioms (1)–(5). We now define Peano's primitives—“0,” “ $Sxy$ ” (“ $y$  is the successor of  $x$ ”), and “ $NNx$ ” (“ $x$  is a natural number”):

$$(11) \quad “0” \text{ for } “N_x(x \neq x),”$$

for then (7) yields  $N_x Fx = 0 \equiv \neg(\exists x)Fx$ .

Intuitively,  $n + 1 = N_x(x = 0 \vee \dots \vee x = n)$ ; this result will be reached if we define “ $Sxy$ ” as follows:

$$(12) “Sxy” \text{ for } “(\exists F)\{y = N_w Fw \ \& \ (\exists z)[Fz \ \& \ N_w(Fw \ \& \ w \neq z) = x]\}”.$$

Intuitively, the number of  $F$ 's is one more than the number of  $G$ 's if there is an  $F$  such that the number of the *rest* of the  $F$ 's is precisely  $N_x Gx$ . Definition (12) implies that in this case  $S(N_x Gx, N_x Fx)$ .

The remaining primitive is defined by an ingenious device (already present in Frege's *Begriffsschrift*), which yields mathematical induction: we want to define “ $NNx$ ” so that something true of 0 and of the successor of anything of which it is true is true of every natural number—that is,

$$(13) F0 \ \& \ (x)(y)(Fx \ \& \ Sxy. \supset Fy) . \supset (x)NNx \supset Fx.$$

But this will be immediate if we define “ $x$  is a natural number” as “ $x$  falls under every concept  $F$  which 0 falls under and which is such that any successor of whatever falls under it also falls under it”—that is,

$$(14) “NNx” \text{ for } “(F)\{F0 \ \& \ (x)(y)(Fx \ \& \ Sxy. \supset Fy) . \supset Fx\}”.$$

To prove the other axioms: (1) is immediate from (14); that  $S$  is one-to-one and that 0 is not the successor of anything follow from (12) together with (7).

2.7. DIFFICULTIES IN LOGICISM. The first difficulty with Frege's construction is certainly the use Frege made of the notion of extension. We have alluded to difficulties with the ideas of set theory; they affected Frege's system through Russell's deduction in 1901 of a contradiction from (6). (For Russell's initial exchange of letters with Frege, see van Heijenoort, 1967). We shall discuss Rus-

sell's paradox and other paradoxes and the difficulties of the concept of class below.

Nonetheless, it turns out that a reasonably secure system of set theory can be developed in any one of a number of ways that are more than sufficient for the definition of Peano's primitives and proof of his axioms. In fact, no part of the axiomatic apparatus of a system of set theory which gives rise to any doubts as to consistency is really necessary for this reduction; we can say that if the development in set theory of a branch of mathematics necessarily involves the stronger and more problematic parts of set theory, this is due to the nature of the branch of mathematics itself, not the reduction to set theory.

This success is not without loss for the development of arithmetic: it seems that in the more natural set-theoretical systems (the theory of types, Zermelo's set theory) no definition of " $N_x Fx$ " can be given with the same appearance of naturalness as in (10). The consequences of Russell's theory of types are more serious: The numbers must be duplicated at each type. What one usually ends up doing is identifying the numbers in a somewhat arbitrary way with a sequence of sets of the required order type.

Given that all this has been done, in what sense is the enterprise a reduction of arithmetic to set theory, and in what sense is it a reduction to logic? To take up the last question first, obviously the construction does not reduce arithmetic to logic unless the principles of the set theory involved can count as logical principles. The notion of class is not very far removed from concepts which played a role in traditional logic; from that point of view it is not at all evident why the first-order predicate calculus, which is already a considerable extension of the traditional formal apparatus, should count as logic and the theory of classes should not.

One difference is that whereas a valid formula of first-order logic will yield a truth if the quantifiers are interpreted to range over any domain of objects whatsoever, and without regard to its cardinal number in particular, set theory involves existence assumptions, so the domain over which the quantifiers range must be large enough to contain representatives for the sets whose existence is implied by the formula in question. In Frege's procedure these assumptions were embodied in the admission as a term of an abstract " $\hat{x}Fx$ " for any predicate " $F$ ," and simple nonparadoxical instances of (6) already require that Frege's universe contain infinitely many objects.

Frege, of course, regarded (6) as a logical principle, a view which was fairly well refuted by its inconsistency. It would be much more reasonable to regard set theory as logic if its existence assumptions all followed from a single general principle, such as (6). But the analysis of the foundations of set theory stimulated by the paradoxes points to the opposite conclusion: Any very definite system of existential postulates will prove incomplete in the sense that it is always possible to construct further existential postulates that are stronger (in the sense of first-order, or even second-order, logic). Moreover, these postulates assume a character not unlike principles of construction, so it is at least as natural to consider them hypothetical and analogical extensions of "constructions in pure intuition" as it is to consider them principles of logic. At any rate, if logic consists of the necessary principles of all coherent reasoning, then it seems evident that the stronger principles of set theory do not have this character; it is far from certain even that the weaker ones have it (perhaps even that all of first-order logic does). This being so, a reduction of arithmetic to set theory does little to increase the security and clarity of the foundations of arithmetic.

**2.8. KANT'S VIEW.** One of the purposes that Frege, Russell, and many later proponents had in mind in seeking to reduce arithmetic to logic was to show that no appeal to sensible intuition was necessary in arithmetic, as had been claimed by such empiricists as John Stuart Mill and by Kant in his theory of a priori intuition. Let us consider whether this purpose has been accomplished. Since Kant's view constitutes an independent effort to explain the a priori character of arithmetic, and since it is part of an extremely influential general philosophy, it deserves special mention.

Kant began by insisting that mathematical judgments (at least the most characteristic ones) were synthetic, rather than analytic. We shall not enter into the question of just what he meant by that. Provided that one remembers that the scope of logic was much narrower for Kant than it is for us, it is plausible to suppose that his claim that mathematical judgments are synthetic implies that the propositions of a mathematical theory cannot be deduced from logical laws and definitions. The case of Kant's principal example, the geometry of space, seems clear, given, for instance, the fact that there are consistent geometrical theories which differ with respect to certain fundamental principles, such as the parallel postulate. (Even here, however, one might claim that the difference in principles corresponds to a difference in the meanings of the primitive terms. In application to real space this

comes down to the question of “conventionalism” in geometry. W. V. Quine is probably right in holding that one cannot, in general, decide the question whether such a difference is merely a difference of meaning.)

The case of arithmetic presents a certain similarity if we deny that set theory is logic. The proofs in the set-theoretic development even of such elementary arithmetical laws as “ $2 + 2 = 4$ ” depend on existential axioms of these theories. However, this does not mean that we can come as close to clearly conceiving the falsity of these principles as we can for the principles of geometry. Although we can easily enough set up a domain in which the existence postulates will fail, it is not clear that this counts as conceiving that the numbers 0, 1, 2, . . . should not exist.

Kant went on to maintain that the evidence of both the principles of geometry and those of arithmetic rested on the “form of our sensible intuition.” In particular, he said that mathematical demonstrations proceeded by “construction of concepts in pure intuition,” and thus they appealed to the form of sensible intuition. Mathematical proof, according to Kant, required the presentation of instances of certain concepts. These instances would not function exactly as particulars, for one would not be entitled to assert anything concerning them which did not follow from the general concept. Nonetheless, conclusions could be drawn which were synthetic, because the construction of the instance would involve not merely the pure concept as of an abstract structure but also its “schematism” in terms of the general structure of our manner of representing objects to ourselves.

Thus, geometric figures would obey the axioms of geometry even though these axioms were not provable by analysis of the concepts. At the same time, the constructions would serve to verify any existence assumptions involved. (Indeed, instead of existential axioms Kant spoke of postulates asserting the possibility of certain constructions.)

In the case of arithmetic Kant argued that in order to verify “ $7 + 5 = 12$ ” one must again consider an instance, this time in the form of a set of five objects, and add each one in succession to a given set of seven. It seems that although the five objects may be quite arbitrary, even abstract, they will, if not themselves present to perception, be represented by symbols which are present and which exhibit the same structure. In fact, we find this structure even in the symbolic operations involved in the formal proofs of “ $7 + 5 = 12$ ” either within a set theory or directly from axioms for elementary number theory—or even in the proof of the formula of *first-order* logic

$$(15)(\exists x)_7Fx \ \& \ (\exists x)_5Gx \ \& \ (x)\neg(Fx \cdot Gx) \ \cdot \supset \ (\exists x)_{12}(Fx \vee Gx),$$

which is the key to the proof of “ $7 + 5 = 12$ ” in Frege’s construction. We think of “ $(\exists x)_n(Fx)$ ” expanded as follows:

$$“(\exists x)_0Fx” \text{ for } “\neg(\exists x)Fx”.$$

$$“(\exists x)_{n+1}Fx” \text{ for } “(\exists x)[Fx \ \& \ (\exists y)_n(Fy \ \& \ y \neq x)]”.$$

The arguments for the claim that intuition plays an essential role in mathematics are inevitably subjectivist to a degree, in that they pass from a direct semantical consideration of the statements and of what is required for their truth to a more pragmatic consideration of the operations involved in understanding and verifying them (and perhaps even “using” them, in a broad sense) and to a metalinguistic reflection on formulae and proofs as configurations of symbols. Gottfried Wilhelm Leibniz had already emphasized the essential role of calculation with symbols in mathematics, and to Kant this role became an argument for the dependence of mathematics on sensible intuition.

We can see why the arguments must have this subjectivist character if we notice the complete abstractness of both set theory and arithmetic, which talk of objects in general in terms of logical operations (propositional combination, quantification) which are equally general. Even the specifically mathematical objects (sets and numbers) are subjected by the theory only to certain structural, relational conditions, so that they are not, as it were, individually identified by the theory. The content thus does not suggest any direct sensory verification; indeed, it seems that any proposition which is susceptible of such verification must contain some particular reference to space or time or to objects or properties which by nature occur only in space and time. Although it is Frege’s construction and the development of set-theoretic mathematics which make this fact clear, Kant apparently was aware of it in the case of arithmetic, which he related closely to the pure categories and therefore to logic.

Nevertheless, it does not seem, at least in the light of philosophical and mathematical experience, that we can directly verify these propositions, or even understand them, independently of the senses. Determining the precise nature of the dependence of the operations of the mind in general on the senses is one of the central difficulties of all philosophies. But it is hard to maintain that we understand mathematical structures, or even the general notion of object which underlies them, without at least starting with a sensible representation, so that con-

crete explanations make use both of embodiments of the structures by perceptible objects and of reflection on symbolism. For instance, explanations of the notion of class can either make use of an appeal to language, as Frege's explanation does, or begin with the notion of a group of perceptible objects. (Indeed, it seems that even in the second case an appeal to language is sooner or later indispensable.)

Perhaps more decisive than these rather vague considerations is the fact that we cannot carry on any even fairly elaborate reasoning in mathematics without, as it were, placing ourselves at the mercy of a symbolic representation. Prior to the construction of a proof or calculation we do not know the answer to any substantial mathematical question. That the proof can be constructed, that the calculation turns out as it does, is, as it were, brute fact without which one cannot see any reason for the mathematical state of affairs being what it is. In *Über die Deutlichkeit der Grundsätze der natürlichen Theologie und der Moral*, Kant gave this as his principal reason for asserting that mathematics proceeds by representing concepts in intuition, and in the *Critique of Pure Reason* the idea is again suggested in the discussion of " $7 + 5 = 12$ " and the remarks about "symbolic construction" in algebra.

One might argue that the existence of a natural number  $n$  is verified by actually constructing a sequence of numerals up to that point. Such a construction provides a representation for the numbers up to  $n$ . It is noteworthy that either it or a mental equivalent is necessary for a full and explicit understanding of the concept of the number  $n$ . This gives some plausibility to the view that the possibility of such a representation rests on the "form of our sensible intuition," since everything belonging to the content of the particular realization is nonessential. It is perhaps permissible to speak, as Kant did, of "pure intuition," because we are able to take the symbols as representing or embodying an abstract order. This conception could be extended to the intuitive verification of elementary propositions of the arithmetic of small numbers. If these propositions really are evident in their full generality, and hence are necessary, then this conception gives some insight into the nature of this evidence.

However, the above description already ceases to apply when we pass to the construction, by a general rule, of the sequence of natural numbers and therefore when we consider large numbers, which we must describe in terms of general rules. Besides the "factor of abstraction" signaled in our being able to use sensory representations in thinking about the abstract structures they

embody, there is also a factor of higher generality and the accompanying possibility of iteration, so that the sequence of natural numbers extends far beyond those represented by numerals it is possible actually to construct. Here the sense of the notion of "form of intuition" is less clear. Kant's idea, however, must surely be that the larger numbers are conceived only as an extension of the structures of our actual experience. The fact that the forms in question are, according to Kant, those of space and time means that the abstract extension of the mathematical forms embodied in our experience parallels an extension of the objective world beyond what we actually perceive.

Kant connected arithmetic with time as the form of our inner intuition, although he did not intend by this to deny that there is no direct reference to time in arithmetic. The claim apparently was that to a fully explicit awareness of number goes the successive apprehension of the stages in its construction, so that the structure involved is also represented by a sequence of moments of time. Time thus provides a realization for any number that can be realized in experience at all. Although this view is plausible enough, it does not seem strictly necessary to preserve the connection with time in the necessary extrapolation beyond actual experience. However, thinking of mathematical construction as a process in time is a useful picture for interpreting problems of constructivity (discussed below).

Kant's view enables us to obtain a more accurate picture of the role of intuition in mathematics, but, at least as developed above, it is not really satisfying, because it takes more or less as a fact our ability to place our perceptions in a mathematically defined structure and to see truths about this structure by using perceptible objects to symbolize it. The great attraction of Kantianism comes from the fact that other views seem unable to do any better: Frege, for example, carried the epistemological analysis less far than Kant in spite of his enormously more refined logical technique.

2.9. CONVENTIONALISM. Attempts to avoid dogmatism completely while still affirming the existence of a priori knowledge in mathematics have been made on the basis of conventionalism, the characteristic logical positivist view of a priori knowledge. This view in effect rejects the question of evidence in mathematics: Mathematical statements do not need evidence because they are true by fiat, by virtue of the conventions according to which we specify the meanings of the words occurring in

mathematics. Mathematics is therefore “without factual content” or even “empty.”

Before we proceed to discuss this view we should distinguish it from two others which are associated with logical positivism, the view that mathematical statements are true by virtue of the meanings of the words in them and the view that they are analytic. The doctrine that mathematical statements are true by virtue of the meaning of the words they contain is somewhat vague and is likely to reduce to the doctrine that they are analytic, to conventionalism, or to something compatible with Kantianism or even with some form of direct realism. If there are objective relations of meaning which hold not merely by fiat, then there is as much need in this view for an account of the evidence of our knowledge of them as there is for the evidence of mathematics itself.

The view that mathematics is analytic has generally been associated on one side with logicism and on the other with conventionalism. The definitions of “analytic” that have been given have been such that logical truths were automatically analytic. If the thesis that mathematics is analytic was to say more than the thesis of logicism, the definitions had to be taken as explicating a concept which had a more direct epistemological significance, usually truth by virtue of meanings or truth by convention. (Once this has been done, the connection with logicism seems less important, in spite of the importance that the logical positivists attributed to it. Thus, one may explain the claim that the axioms of set theory are analytic by saying that they are “meaning postulates” in Carnap’s sense, but one could argue equally well that the axioms of number theory are meaning postulates. Logicism was important to the logical positivists for other reasons: the reduction served as a methodological paradigm; it served the “unity of science.”)

That the propositions of mathematics should be true by convention in a strong sense, that one should actually have set up conventions which determine that they should be true, seems possible only for “rational reconstructions” of mathematics by explicit construction of an axiom system and identification of the system with mathematics. If such a procedure could be carried out, there would still be room for discussion of the sense in which it showed that the mathematics practiced by those who are not interested in foundations is true by convention.

The usual conventionalist position appeals to rules specifying that certain propositions are to be true by convention or, more often, to rules of another sort (such as semantical rules of an interpreted formal system), from which it can be deduced that certain statements are true,

the nature of the premises being such that they can be called conventions governing the use of expressions. (For example, the truth of any statement that is a substitution instance of a theorem of the classical propositional calculus can be deduced from the information contained in the truth tables for the propositional connectives. Then if the truth tables are regarded as semantical rules specifying the meanings of the connectives, then the theorems of classical propositional logic thus become true by virtue of these rules.)

In the simplest case—that of simply laying down, by rules or in individual instances, that certain sentences are to be taken as expressing true statements—something more seems to be required to justify this procedure as attributing “truth” to “statements.” No serious philosopher, however, has been content to leave the matter at that.

Nonetheless, the procedure of specifying by rules runs into a difficulty essentially independent of the form of the rules and the manner in which they are interpreted. This difficulty, which was pointed out forcefully by Quine early in his career (in “Truth by Convention”) and is perhaps implicit in remarks by Frege, is that the passage from the general statements which are the actual explicit conventions to the truth by convention of specific statements involves inference. So something essentially logical is not, on the face of it, reduced to convention by the analysis. The inferences will assume properties of generality (for example, the properties of the universal quantifiers) and of the conditional, since the rules will in all probability be of the form of conditionals—for instance, they may say that if a statement satisfies certain conditions, then it is true by convention. In the example that we gave, one needs in addition the laws of contradiction and of excluded middle: Application of the truth tables already supposes that each statement has one, and only one, of the two truth-values.

Quine showed that the attempt to regard the rules by which this inference proceeds as themselves valid by convention leads to an infinite regress. For example, suppose a rule is *modus ponens*: from “ $p$ ” and “ $p \supset q$ ” infer “ $q$ ”. This could be stated as the convention:

- (16) If  $A$  and  $C$  are true and  $C$  is the result of substituting  $A$  for “ $p$ ” and  $B$  for “ $q$ ” in “ $p \supset q$ ”, then  $B$  is to be true.

Now, suppose that for some  $A'$  and  $B'$  we have proved that  $A'$  and  $C'$  are true by convention, where

- (17)  $C'$  is the result of substituting  $A'$  for “ $p$ ” and  $B'$  for “ $q$ ” in “ $p \supset q$ ”.

Then we have also

(18)  $A'$  is true;

(19)  $A' \supset B'$  is true.

Therefore, by (16) and *modus ponens*,  $B'$  is true. However, in order to represent this inference as proceeding according to the convention, it is necessary to make another application of *modus ponens*, and so on.

The above argument would not prevent this form of conventionalism from being applied to further parts of mathematics, particularly to existential axioms. In view of the equivalences between derivability statements in logic and elementary propositions in number theory, as well as the above-mentioned element of brute fact in the existence of a derivation, it is not likely that such an approach will work for elementary number theory. But with the stronger axiom systems for set theory the view is on somewhat firmer ground, in that such axioms are often not justified by appeal to direct evidence and “pragmatic” criteria have played a role in the selection of axioms.

Nonetheless, the procedure also has much in common with the setting up of a hypothetical theory in science, and, indeed, as Alfred North Whitehead and Russell already emphasized, the axioms are subject to a sort of checking by their consequences, since some propositions deducible from them are decidable by more elementary and evident mathematical means. It is not evident that if a system of axioms is replaced by another because its consequences come into conflict with intuitive mathematics, the meaning of “set” has changed and the original axioms can be interpreted according to a previous meaning so as to remain true. Moreover, set theory proceeds on the assumption that the truth-value of statements is determinate in many cases where it is not determined by the axioms—that is, by the conventions.

Quine, in fact, now argues, apparently even in the case of elementary logic, that there is no firm ground for distinguishing between making such principles true by convention and adopting them as hypotheses (“Carnap and Logical Truth”). This is as much an extension of conventionalism to the whole of science as a rejection of it in application to mathematics.

**2.9.1. Wittgenstein’s view.** At this point we must consider the possibility that a priori truths, even the elementary ones, are thought of as true by convention, not in the sense that they may be made so by an explicit convention actually set up but in the sense that the conventions are, as it were, implicit in our practice with the logical and mathematical vocabulary. It might still be argued that the

principles of mathematics are not in that way sufficiently distinguished from the principles of natural science or from other rather deep or fundamental principles that we firmly accept. But this objection could be met by a more detailed descriptive analysis of how logical and mathematical words are used.

However, this type of conventionalism must be careful not to slip into the situation of the more explicit conventionalism of requiring a necessary connection between general intentions and their application in particular statements which is not itself accounted for by the conventions. It appears that the only philosopher who has really faced these challenges has been Ludwig Wittgenstein, in his later period. In connection with Wittgenstein it would probably be better to speak of “agreement” than convention, since the reference to explicit conventions or to “decisions” seems metaphorical, as a picture which is contrasted with that against which he is arguing rather than as a fundamental theoretical concept. It is agreement in our actions—e.g., what we say follows from what—that is essential. We should also be cautious in attributing to Wittgenstein any explanatory theory of logical and mathematical knowledge, in view of his disclaimers of presenting a theory.

Even with these qualifications Wittgenstein’s view seems highly paradoxical, for in order to avoid the above-mentioned pitfall the analysis in terms of agreement must extend even to the connection between general rules and their instances. This seems to be the point of the famous discussion of following a rule in Wittgenstein’s *Philosophical Investigations*. What ultimately determines what is intended in the statement of a rule are facts of the type of what is actually accepted in the course of time as falling under it.

Wittgenstein (I, 185) gave the example of instructing someone in writing down the terms of the sequence of natural numbers 0, 2, 4, . . . ,  $2n$ , . . . . At the start the instructor does not actively think that when the time comes the pupil is to write 1,000, 1,002, 1,004, . . . , rather than 1,000, 1,004, 1,008, . . . . Wittgenstein regarded it as conceivable that the pupil might do the second on the basis of a misunderstanding which we just could not clear up. Moreover, it is, as it were, just a fact of natural history that normally, in such a case, we accept the first and reject the second—indeed, continue in that way ourselves. It appears, further, that the same issue can arise for steps in the sequence which have been written before, since the recognition of symbols as tokens of an already understood type is itself an application of a rule (see I, 214).

Wittgenstein's criticism seems directed particularly against certain psychological ideas associated with platonism and Kantianism. The manner in which the steps of writing numerals are determined by the rule cannot be explained by appealing to one's understanding of the relations of abstract entities expressed in the rule or even to the intentions of the instructor. According to Wittgenstein the criterion of how the pupil does understand the rule lies in the steps which he in fact takes. And what makes them right or wrong is their agreement or disagreement with what we do.

The steps are indeed determined by the rule, in the sense that at each stage there is only one number we accept as correct, and the force of social custom directs us to expand the series in the way we do. But this does not mean that Wittgenstein considered his appeals to custom and training as constituting a fully satisfactory explanation of either the agreement that exists or the fact that we feel "compelled" by the rule, for it is because we are made as we are that we react to custom and training as we do.

The paradoxical nature of Wittgenstein's position can perhaps be brought out by considering the case of a complex mathematical proof which contains steps which no one has thought of before. The proof may lead to a quite unexpected conclusion. Yet each step is recognized by every trained person as necessary, and their combination to form the proof is entirely convincing. (This is, of course, not inevitably the case: proofs as published can be obscure or doubtful and can rest on principles about which there are difficulties.) In spite of the fact that it is in principle possible for an irresolvable disagreement to arise at each point, this does not happen: Irresolvable disputes among mathematicians are only about fundamental principles and about taste. Nonetheless, Wittgenstein, in *Remarks on the Foundations of Mathematics*, used the metaphor of decision in speaking of our acceptance of the proof and spoke of the proof as providing a new criterion for certain concepts; his terminology suggests change of meaning.

The vast extent of the agreement on which mathematics rests seems to have astonished Wittgenstein; indeed, it is hard to understand, on his view, how such agreement is possible and why contradictions arise so seldom. We may be faced here with natural facts, but they are facts which show an extremely regular pattern.

Wittgenstein devoted a good deal of attention in the *Remarks* to discussions of calculation and proof, their relation to mathematical truth, and the ways in which they resemble and differ from experiment. In a number of examples he revealed an outlook which resembles Kant's

in seeing a construction either of figures or of arrangements of formulae or propositions as essential to a proof. To the problem concerning how such a singular construction can serve to establish a universal and necessary proposition Wittgenstein suggested a quite different answer: In accepting the proof we accept the construction as a paradigm for the application of a new concept, so that, in particular, we have new criteria for certain types of judgments. (For example, if we have determined by calculation that  $25 \times 25 = 625$ , then a verification that there are  $25 \times 25$  objects of a certain kind is also accepted as verifying that there are 625.) The same question arises in connection with the possibility of conflict in these criteria as arose in connection with agreement.

We shall close at this point our discussion of the a priori character of mathematics and the attempts to justify and explain it. In the sense that the concepts of mathematics are too general and abstract to refer to anything particular in experience, their a priori character is evident, at any rate after a certain amount of logical analysis of mathematical concepts. The a priori evidence of mathematics, on the other hand, is perhaps not raised, by our discussion, above the level of a somewhat vague conviction. In the case of the more powerful forms of set theory one is probably forced to admit that the evidence is less than certainty and therefore to admit that there is an analogy between the principles involved and the hypotheses of a scientific theory. In the case of arithmetic and elementary logic, however, this conviction can withstand the objections that might be posed, but in view of the difficulties we have discussed in relation to various accounts, it seems still not to have been analyzed adequately.

### §3. PLATONISM AND CONSTRUCTIVISM

The discussion in the preceding section suggests that the problem of evidence in mathematics will appear to differ according to the part of mathematics being emphasized. The form which discussion of these differences has tended to take is a distinction between two broad methodological attitudes in mathematics, which we shall call platonism and constructivism. This section will be devoted to a discussion of these attitudes.

**3.1. PLATONISM.** We begin with platonism because it is the dominant attitude in the practice of modern mathematicians, although upon reflection they often disguise this attitude by taking a formalist position. Platonism is the methodological position that goes with philosophical realism regarding the objects mathematics deals with.

Mathematical objects are treated not only as if their existence is independent of cognitive operations, which is perhaps evident, but also as if the facts concerning them did not involve a relation to the mind or depend in any way on the possibilities of verification, concrete or “in principle.”

This is taken to mean that certain totalities of mathematical objects are well defined, in the sense that propositions defined by quantification over them have definite truth-values. Thus, there is a direct connection between platonism and the law of excluded middle, which gives rise to some of platonism’s differences with constructivism.

It is clear that there is a connection between platonism and set theory. Various degrees of platonism can be described according to what totalities they admit and whether they treat these totalities as themselves mathematical objects. These degrees can be expressed by the acceptance of set-theoretic existence axioms of differing degrees of strength.

The most elementary kind of platonism is that which accepts the totality of natural numbers—i.e., that which applies the law of excluded middle to propositions involving quantification over all natural numbers. Quite elementary propositions in analysis already depend on this law, such as that every sequence of rational numbers either tends to the limit 0 or does not, which is the basis for the assertion that any real number is either equal to 0 or not. We shall see that not even this assertion is immune to constructivist criticism.

What is nowadays called classical analysis advances a step further and accepts the totality of the points of the continuum or, equivalently, the totality of subsets of the natural numbers. The equivalence between these totalities and their importance in mathematics were brought out by the rigorous development and “arithmetization” of analysis in the nineteenth century. We recall that the theories of (positive and negative) integers and rational numbers can be developed from the theory of natural numbers by means of the notion of ordered pair alone and that this notion can in turn be represented in number theory. A general theory of real numbers requires general conceptions of a set or sequence of natural numbers to which those of a set or sequence of rational numbers can be reduced.

Following Paul Bernays (“Sur le platonisme dans les mathématiques”) we can regard the totality of sets of natural numbers on the analogy of the totality of subsets of a finite set. Given, say, the numbers  $1, \dots, n$ , each set is

fixed by  $n$  independent determinations of whether a given number belongs to it or not, and there are  $2^n$  possible ways of determining this. An “arbitrary” subset of the natural numbers is fixed by an infinity of independent determinations fixing for each natural number whether it belongs to the subset or not. Needless to say, this procedure cannot be carried out by a finite intelligence. It envisages the possibility of sets which are not the extensions of any predicates expressed in a language.

**3.1.1. Impredicative definitions.** The strength of the assumption of the totality of arbitrary subsets of the natural numbers becomes clear if we observe that it justifies impredicative definitions, definitions of sets or functions in terms of totalities to which they themselves belong. A predicate of natural numbers involving quantification over all sets of natural numbers will have a well-defined extension, which will be one of the sets in the range of the quantifier.

Such definitions have been criticized as circular (for example, by Henri Poincaré), but they do not seem so if we understand the sets as existing independently of any procedure or linguistic configuration which defines them, for then the definition picks out an object from a preexisting totality. The resistance that impredicative definitions met with arose partly because their acceptance clashes with the expectation that every set should be the extension of a predicate, or at least of a concept of the human mind.

Given any definite (formalized) notation, we can by Cantor’s diagonal method define a set of natural numbers which is not the extension of a predicate in the notation. Thus, no procedure of generating such predicates by continually expanding one’s notation can possibly exhaust the totality. And the idea that every set is the extension of a predicate has little sense if it is assumed that in advance of the specification of notations there is a totality of possible predicates which can be arrived at by some generating procedure.

If the statements of classical analysis are interpreted naively, then quite elementary theorems, such as that every bounded set of real numbers has a least upper bound, require impredicative definitions. Nonetheless, in *Das Kontinuum*, Hermann Weyl proposed to construct analysis on the basis of mere platonism with respect to the natural numbers. He proposed an interpretation under which the least upper bound theorem is true. Later interpretations have preserved more of the statements of classical analysis than Weyl’s, and it is an involved technical question how much of it can be given a natural predicative interpretation (see below).

3.1.2. *Set theory and the paradoxes.* Set theory as developed by Cantor and as embodied in the present standard systems involves a higher degree, or variety of degrees, of platonism. The axiom system of Zermelo and its enlargement by Fraenkel (which is called the Zermelo-Fraenkel system), for example, allows the iteration of the process of forming the set of all subsets of a given set and the collection into a set of what has been obtained by iterated application of this or some other generating procedure. This latter allows the iteration into the transfinite. If we assume we have transfinite ordinal numbers, then we can generate a transfinite succession of “universes”  $U$  as follows: Let  $\mathcal{P}(A)$  be the set of all subsets of the set  $A$ .

$U_0 =$  a certain class, perhaps empty, of “individuals.”

$$U_{\alpha + 1} = \mathcal{P}(U_{\alpha}) \cup U_{\alpha}.$$

$U_{\alpha} =$  the union of all  $U_{\beta}$ , for  $\beta < \alpha$ , if  $\alpha$  is a limit ordinal.

Then for certain ordinals  $\alpha$  the  $U_{\alpha}$  will form models for the different systems of set theory ( $U_{\omega} + \omega$  for Zermelo’s set theory, without Fraenkel’s axiom of replacement).

The paradoxes of set theory imply that we must accept some limitations on forming totalities and on regarding them in turn as mathematical objects—that is, as sets. If, for example, the totality of sets is a well-defined set, then it seems that it will be reasonable to ask of each set  $x$  whether it is a member of itself ( $x \in x$ ) or not and to form  $\hat{x}(x \notin x)$ , the set of all sets which are not members of themselves. This will satisfy

$$(y)[y \in \hat{x}(x \notin x) \equiv y \notin y],$$

which implies

$$\hat{x}(x \notin x) \in \hat{x}(x \notin x) \equiv \hat{x}(x \notin x) \notin \hat{x}(x \notin x).$$

a contradiction. This is Russell’s paradox, the most shocking, because the most elementary, of the paradoxes of set theory.

On the same basis one can ask for the cardinal number of the set of all sets, which we shall call  $S$ . Then  $\mathcal{P}(S)$ , the set of all subsets of  $S$ , will have a cardinal number no greater than that of  $S$ , because  $\mathcal{P}(S) \subseteq S$ . But by Cantor’s theorem the cardinal number of  $\mathcal{P}(S)$  is properly greater than that of  $S$  (Cantor’s paradox, 1895).

If the totality  $O$  of ordinals is a set, then, since it is well-ordered, there will be an ordinal number  $\gamma$  that represents its order type. But then  $O$  will be isomorphic to the set of ordinals less than  $\gamma$ —that is, to a proper initial segment of itself. This is impossible:  $\gamma$  must be the great-

est ordinal, but there is no obstacle to forming  $\gamma + 1$  (Burali-Forti’s paradox, 1897).

These paradoxes do not imply that we have to stop or otherwise limit the process, described above, of generating larger and larger universes. On the contrary, we must never regard the process as having given us “all” sets. The totality of sets, and hence the totality of ordinal numbers, cannot be the terminus of a well-defined generating process, for if it were we could take all of what we had generated so far as a set and continue to generate still larger universes.

Thus, suppose we consider the arguments for the paradoxes applied to a particular  $U_{\alpha}$ , as if it were the universe of all sets. The construction precludes  $x \in x$ , so  $\hat{x}(x \notin x)$  is just  $U_{\alpha}$  itself. But  $U_{\alpha} \notin U_{\alpha}$  and hence is disqualified as a set. The same consideration applies to Cantor’s paradox. Burali-Forti’s paradox is avoided because the passage from  $U_{\alpha}$  to  $U_{\alpha + 1}$  always introduces well-orderings of higher order types. Thus, for no  $\alpha$  can  $U_{\alpha}$  contain “all” ordinals, no matter how the ordinals are construed as sets. (A very natural way of construing them would be such that  $\alpha$  occurs in  $U_{\alpha + 1}$  but not in  $U_{\beta}$  for any  $\beta \leq \alpha$ . But then only for certain ordinals will  $U_{\alpha}$  contain an ordinal for each well-ordered set in  $U_{\alpha}$ .)

For some time after they were first discovered, the paradoxes were viewed with great alarm by many who were concerned with the foundations of mathematics. In retrospect this seems to have been because set theory was still quite unfamiliar; in particular, the distinction between the customary reasonings of set theory and those that led to the paradoxes was not very clear. The opposition that set theory had aroused had not yet died down. However, the marginal character of the paradoxes has seemed more and more evident with time; the systems which were soon devised to cope with the paradoxes (Russell’s theory of types and Zermelo’s set theory, both published in 1908) have proved satisfactory in that they are based on a reasonably clear intuitive idea, and no one today regards it as a serious possibility that they (or the stronger Zermelo-Fraenkel system) will turn out to be inconsistent. This does not mean that the security and clarity of set theory are absolute; in the sequel some of the difficulties will become apparent.

The above-described sequence of universes uses general conceptions of set and ordinal but applies the characteristic move of platonism only one step at a time. It renounces what Bernays calls “absolute platonism,” the assumption of a totality of all mathematical objects which can be treated as itself a customary mathematical object—for example, a set. Such a conception seems def-

initely destroyed by the paradoxes. The totality of sets can be compared with Kant's "Ideas of Reason": it is an "unconditioned" or absolute totality which just for that reason cannot be adequately conceived by the human mind, since the object of a normal conception can always be incorporated in a more inclusive totality. From this point of view there is an analogy between the set-theoretic paradoxes and Kant's mathematical antinomies.

If we assume that every set will appear in one of the  $U_\omega$ , we have a conception which is adequate for all of modern mathematics except, perhaps, the recent theory of categories. The conception is by nature imprecise: there are limitations on our ability to circumscribe both what goes into the power set of a given set and what ordinals there are. It is perhaps unreasonable to apply classical logic to propositions involving quantification over all sets, since such an application seems to presuppose that it is objectively determined what sets (and a fortiori, on this conception, what ordinals) there are. Nonetheless, this additional idealization does not seem to have caused any actual difficulties.

This way of conceiving sets combines two of Russell's early ideas for resolving the paradoxes—the theory of types and the theory of "limitation of size." What are rejected as sets are the most inclusive totalities, such as the entire universe. (Our talking of "totalities" while rejecting them as sets is not incompatible with our conception; as John von Neumann observed, all that is necessary is to prohibit them from belonging to further classes. Von Neumann's observation was the basis for some new set theories, the principal one being that of Bernays and Gödel.) Moreover, the sets are arranged in a transfinite hierarchy: One can assign to each set an ordinal, its type or, as it is now called, rank, which will be the least ordinal greater than the ranks of its members. We have thus a transfinite extension of the cumulative theory of types. But we have dropped the more radical idea from which Russell proceeded: that each variable of a system of set theory should range over objects of a specified type, and that " $x \in y$ " is meaningless unless the range of " $y$ " is of a type one higher than that of " $x$ ," so that, in particular, " $x \in x$ " is meaningless.

**3.1.3. Predicativism.** In the first twenty-five years or so after the discovery of the paradoxes a number of more radical proposals for their elimination were presented. These generally amounted to some further attenuation of platonism. We shall first consider the program of eliminating impredicative definitions, which amounts to a restriction of platonism to the natural numbers. This was the outcome of the general views of Poincaré and Russell.

Russell's original theory, the ramified theory of types, which formed the basis of *Principia Mathematica*, was directed to the elimination of impredicative definitions, which he held to involve a "vicious circle" and to be responsible for the paradoxes. The effect was, however, nullified by his axiom of reducibility.

A greatly simplified version of the ramified theory is as follows: One has variables, each of which is assigned a natural number as its level, and the predicates of identity and membership. The logic is the usual quantification theory, except that in the rules for quantifiers allowance must be made for levels. Since the levels can be cumulative, we could have for the universal quantifiers the following:

$$(20) \quad (x^i)Fx^i \supset Fy^j \text{ if } j \leq i;$$

(21) From " $p \supset Fy^j$ " infer " $p \supset (x^i)Fx^i$ ," where for " $p$ " only something not containing free " $y^j$ " can be substituted.

The axioms are those of identity, extensionality, and the following schema of class existence:

(22) If " $F$ " represents a predicate which does not contain free  $x^{i+1}$ , any free variables of level  $> i + 1$ , or any bound variables of level  $> i$ ,

$$(\exists x^{i+1})(y^i)(y^i \in x^{i+1} \equiv Fy^i).$$

One effect of this axiom is that a predicate involving quantification over objects of level  $n$  need not have an extension of level  $n$ . Therefore, the axiom does not assert the existence of any impredicative classes; in fact, it is compatible with the idea that classes are constructed by the construction of predicates of which they are the extensions.

Russell's actual theory combined that of a hierarchy of levels, applied in this case to "propositional functions," the objects over which the variables of a higher-order logic were to range, with the "no class" theory, the introduction of locutions involving classes by contextual definition in terms of propositional functions. In order to derive classical mathematics, however, he wanted to avoid dividing the classes into levels. This he did by postulating the axiom of reducibility, which asserts that for every propositional function there is a function of the lowest possible level (compatible with the nature of its arguments) extensionally equivalent to it. Russell admitted that this axiom was equivalent to the existence of classes, and he has never been satisfied with it. In effect, it yields even impredicatively defined classes and destroys the effect of the hierarchy of levels.

A formalization of mathematics on the basis of the ramified theory is the most natural formalization if a platonist theory of classes is repudiated but classical logic admitted. The construction of the natural numbers leads to the difficulty that the class quantifier needed to reduce induction to an explicit definition is no longer available. One must either assume the natural numbers or have a hierarchy of different concepts of natural number.

A ramified theory with the natural numbers as individuals and the Peano axioms would be a natural formalization of the mathematics allowed by platonism with respect to the natural numbers. But there is in principle no reason not to extend the hierarchy of levels into the transfinite. The question of the limits of predicative mathematics has become identical with the question of the transfinite ordinals that can be predicatively introduced.

We have said that quite elementary proofs in analysis already require impredicative definitions when naively interpreted. Nonetheless, from recent work it appears that a good deal of classical analysis is susceptible of a natural predicative interpretation, which, however, fails for some theorems. One can, on this basis, give a good approximation to classical analysis, but not to the whole of it. That part of mathematics which depends essentially on still more powerful set theory is completely lost. It seems that it would not be reasonable to insist on this limitation unless there were some quite powerful reason for rejecting platonism. We shall discuss some possible reasons later.

**3.2. CONSTRUCTIVISM.** We shall now consider the complete rejection of platonism, which we shall call constructivism. It is not a product of the situation created by the paradoxes but rather a spirit which has been present in practically the whole history of mathematics. The philosophical ideas on which it is based go back at least to Aristotle's analysis of the notion of infinity (*Physics*, Bk. III). Kant's philosophy of mathematics can be interpreted in a constructivist manner, and constructivist ideas were presented in the nineteenth century—notably by Leopold Kronecker, who was an important forerunner of intuitionism—in opposition to the tendency in mathematics toward set-theoretic ideas, long before the paradoxes of set theory were discovered.

Our presentation of constructivism relies heavily on the “intuitionism” of Brouwer, presented in many publications from 1907 on, but the ideas can also be found to some extent in other critics of platonism, including the French school of Émile Borel, Poincaré, and Henri

Lebesgue, although in their work predicativity played a greater role than constructivity. These writers did not arrive at a very consistent position, but they contributed mathematically important ideas. L. E. J. Brouwer reached and developed a conclusion from which they shrank: that a thoroughgoing constructivism would require the modification of classical analysis and even of classical logic.

**3.2.1. Intuitionism.** Constructivist mathematics would proceed as if the last arbiter of mathematical existence and mathematical truth were the possibilities of construction. “Possibilities of construction” must refer to the idealized possibility of construction mentioned in the last section. Brouwer insisted that mathematical constructions are mental. The possibilities in question derive from our perception of external objects, which is both mental and physical. However, the passage from actuality to possibility and the view of possibility as of much wider scope perhaps have their basis in intentions of the mind—first, in the abstraction from concrete qualities and existence; second, in the abstraction from the limitations on generating sequences. In any case, in constructive mathematics the rules by which infinite sequences are generated are not merely a tool in our knowledge but part of the reality that mathematics is about.

Why this is so can be seen from the problem of assertions about the infinite. We have suggested that the generation of a sequence of symbols is something of which the construction of the natural numbers is an idealization. But “construction” loses its sense if we abstract further from the fact that this is a process in time which is never completed. The infinite in constructivism must be “potential” rather than “actual.” Each individual natural number can be constructed, but there is no construction which contains within itself the whole series of natural numbers. To view the series *sub specie aeternitatis* as nonetheless determined as a whole is just what we are not permitted to do.

Perhaps the idea that arithmetic rests on time as a form of intuition lies behind Brouwer's insistence on constructivity interpreted in this way. One aspect of sensibility from which we do not abstract in passing from concrete perception to its form is its finite character. Thus, whatever one may think of the notion of form of intuition, Brouwer's position is based on a limitation, in principle, on our knowledge: Constructivism is implied by the postulate that no mathematical proposition is true unless we can in a nonmiraculous way know it to be true.

Because of its derivation from his own philosophical account of mathematical intuition Brouwer called his position, and the mathematics which he constructed on

the basis of it, intuitionism. We shall use this name for a species of constructivism which answers closely to Brouwer's ideas.

In spite of the "potential" character of the infinite in mathematics, we shall not renounce assertions about all natural numbers or even, with some reservations, talk of infinite classes. A proposition about all natural numbers can be true only if it is determined to be true by the law according to which the sequence of natural numbers is generated. This Brouwer took to be equivalent to its possessing a proof. Thus, the intensional notions of "law" and "proof" become part of the subject matter of mathematics.

A consideration of existential propositions connects the broad philosophical notion of constructivity with the general mathematical notion. Roughly, a proof in mathematics is said to be constructive if wherever it involves the mention of the existence of something, it provides a method of "finding" or "constructing" that object. It is evident that the constructivist standpoint implies that a mathematical object exists only if it can be constructed; to say that there exists a natural number  $x$  such that  $Fx$  is to say that sooner or later in the generation of the sequence an  $x$  will turn up such that  $Fx$ . If  $x$  depends on a parameter  $y$ , this  $x$  must be determinable from  $y$  on the basis of the laws of the construction of the numbers and of the constructions involved in  $F$ . Proving  $(\exists x)Fx$  means showing how to construct  $x$ , so one can say that the proof is not complete until  $x$  has been exhibited. (But then "proof" is used in an idealized sense.) To prove  $(y)(\exists x)Fxy$  must involve giving a general method for finding  $x$  on the basis of  $y$ .

This point of view leads immediately to a criticism of the basic notions of logic, particularly negation and the law of excluded middle. That " $(x)Fx$ " is true if and only if it can be proved does not mean that " $(x)Fx$ " is a statement about certain entities called proofs in the way in which, on the usual interpretation, it is a statement about the totality of natural numbers. According to Brouwer we can assert " $p$ " only if we have a proof; the hypothesis that  $(x)Fx$  is the hypothesis that we have a proof, and it is a reasonable extrapolation to deny that we can say more about what " $(x)Fx$ " asserts than is said in specifying what is a proof of it. The explanation of " $\neg(x)Fx$ " as " $(x)Fx$  cannot be proved" does not satisfy this condition. Brouwer said instead that a proof of " $\neg p$ " is a construction which obtains an absurdity from the supposition of a proof of " $p$ ."

An immediate consequence of this interpretation is that the law of excluded middle becomes doubtful. Given

a proposition " $p$ ," there is no particular reason to suppose that we shall ever be in possession either of a proof of " $p$ " or of a deduction of an absurdity from " $p$ ." Indeed, if the general statement of the law of excluded middle is taken as a mathematical assertion, a proof of it will have to yield a general method for the solution of all mathematical questions. Brouwer rejected this possibility out of hand.

It is evident that such a point of view will lead to changes in quite basic parts of mathematics. Many instances of the law of excluded middle, where the propositions involved can be shown constructively to be systematically decidable, will be retained. But Brouwer rejected even very elementary instances in classical analysis. Let the sequence  $r_n$  of rational numbers be defined as follows: if there is no  $m \leq n$  such that the  $m$ th,  $(m + 1)$ st,  $(m + 2)$ d terms of the decimal expansion of  $\pi$  are each 7, then  $r_n = 1/2^n$ ; if there is such an  $m$ , then  $r_n = 1/2^k$ , where  $k$  is the least such  $m$ . Then  $r_n$  constructively defines a real number  $r$ . But a proof of either  $r = 0$  or  $r \neq 0$  would tell us whether or not there are three 7's in the decimal expansion of  $\pi$ . Thus, we cannot assert either  $r = 0$  or  $r \neq 0$ .

For a satisfactory constructivist theory of analysis, an analysis is needed of the notion of an arbitrary set or sequence of natural numbers. Brouwer's analysis gives additional distinctiveness to intuitionism. Such a sequence is thought of as generated by a succession of independent determinations or "free choices," which may be restricted by some law. Obviously the succession of choices must be thought of as never being complete. In the absence of a law a statement about a sequence can be true only if it is determined to be true by some finite initial segment of the sequence. The consequence of this is that a function defined for all sequences of natural numbers whose values are integers must be continuous. It also leads to sharper counterexamples to the law of excluded middle: It is absurd that for all sequences  $\alpha$ , either  $(x)(\alpha(x) = 0)$  or  $\neg(x)(\alpha(x) = 0)$ . We can also sharpen the result of the preceding paragraph and state generally that not every real number is equal to or different from 0.

The intuitionist point of view thus leads to a distinctive logic and to a distinctive theory of the foundations of analysis. The latter contains another distinctive principle, the bar theorem, obtained by analyzing the requirement that if a function is defined for all sequences, there must be a constructive proof of this fact. It is roughly equivalent to the proposition that if an ordering is well-founded, transfinite induction holds with respect to it. Nonetheless, intuitionism is far from having shown itself capable of the same rich development as classical mathe-

matics, and it is often very cumbersome. Important as it is in itself, it does not provide a sufficient motive for renouncing platonism.

**3.2.2. *Finitism.*** So far our account of constructivism has been based entirely on Brouwer's intuitionism. However, intuitionism is not the only possible constructivist development of mathematics. Indeed, it makes some quite powerful assumptions of its own. As we have said, the intuitionists make the notions of construction and proof a part of the subject matter of mathematics, and the iteration of logical connectives, especially, renders it possible to make quite elaborate and abstract statements involving construction and proof. Thus, intuitionist mathematics seems to rest not merely upon intuition but upon rather elaborate reflection on the notion of intuitive construction. (It also does not obviously exclude impredicativity, since what counts as a proof of a given proposition can be explained in terms of the general notion of proof.) A constructivist might feel that intuitionism leads from the Scylla of platonist realism to the Charybdis of speculative idealism.

A weaker and more evident constructive mathematics can be constructed on the basis of a distinction between effective operation with forms of spatiotemporal objects and operation with general intensional notions, such as that of proof. Methods based on operation with forms of spatiotemporal objects would approximate to what the mathematician might call elementary combinatorial methods or to the "finitary method" which Hilbert envisaged for proofs of consistency. Formal systems of recursive number theory, in which generality is expressed by free variables and existence by the actual presentation of an instance or (if the object depends on parameters) a function, will accord with this conception if the functions admitted are sufficiently elementary—for example, primitive recursive functions. In such formalisms any formula will express a general statement each instance of which can be checked by computation. For this reason classical logic can be used. Moreover, the concept of free choice sequence can be admitted so that some analysis can be constructed.

The precise limits of this conception are perhaps not clear, although it is evident that some constructive arguments are excluded. The conception does not allow full use of quantifiers but probably does allow a limited use of them.

**3.2.3. *The Hilbert program.*** If one accepts the idea that from a philosophical point of view constructivist conceptions are more satisfactory than platonist conceptions—more evident or more intelligible—one is not

necessarily constrained to abandon classical mathematics. The way is still open to investigating classical mathematics from a constructive point of view, and it may then prove to have an indirect constructive sense and justification.

Such an investigation was the objective of the famous program of Hilbert, which was the third main animating force—with logicism and intuitionism—in foundational research in the period before World War II. The possibility arises first from the fact that classical mathematics can be formalized (though not completely; we shall consider this fact and its implications later). Once it has been formalized, one can in principle drop consideration of the intended meaning of the classical statements and simply consider the combinations of the symbols and formulae themselves. Thus, if the proof of a certain theorem has been formalized in a system  $S$  (say Zermelo-Fraenkel set theory), it is represented as a configuration of symbols constructed according to certain rules. Whether a configuration is a proof can be checked in a very elementary way.

The concepts by which a formal system is described belong, in effect, to finitist mathematics. For example, the consistency of the system is the proposition that no configuration which is a proof will have a last line of a certain form—for example,  $\mathcal{A} \ \& \ \neg\mathcal{A}$ . Nonetheless, although in the mathematical study we abstract from the intended interpretation, this interpretation certainly guides the choice of the questions in which we are interested.

Hilbert sought to establish classical platonist mathematics on a firm foundation by formalizing it and proving the consistency of the resulting formalism by finitist means. The interest of the question of consistency depends on the fact that the formulae of the system represent a system of statements; that is, even if the meanings of the platonist conceptions are highly indeterminate, statements in terms of them are introduced according to an analogy with "real" (i.e., finitist) statements which is intended to preserve at least the notions of truth and falsity and the laws of logic.

In fact, Hilbert had a further motive for his interest in consistency: the fact that platonist mathematics is an extension of an extrapolation from finitist mathematics. Certain elementary combinatorial notions are also embodied in the formalism; formulae involving them express "real statements." Hilbert thought of the other formulae as expressing "ideal statements"—analogous to the ideal elements of projective geometry—introduced to give greater simplicity and integration to the theory. Within the system they have deductive relations to the

real statements. It would be highly undesirable that a formula of the system should be seen by elementary computation to be false and yet be provable. One might hope to prove by metamathematical means that this would not happen. In the central cases a proof of consistency is sufficient to show that it would not. Thus, suppose we extend a quantifier-free recursive number theory by adding quantifiers and perhaps also second-order quantifiers. A proof of the consistency of the resulting system will show that no false numerical formula (stating a recursive relation of particular integers) will be provable. In fact, it will yield a constructive proof of any formula of the original system provable in the extension, in this sense showing the use of “ideal” elements to be eliminable. Since Hilbert it has been pointed out (chiefly by Georg Kreisel) that many further results relevant to the understanding of nonconstructive mathematics from a constructivist point of view can be obtained from consistency proofs.

Hilbert hoped to settle the question of foundations once and for all, which for him meant establishing the platonist methods of set theory on a firm basis. His hope was founded on two expectations: that all of mathematics (at least all of analysis) could be codified in a single formal system and that the consistency of this system could be proved by methods so elementary that no one could question them. He was disappointed of both these expectations as a result of Gödel’s incompleteness theorems (1931). Work on the program has nonetheless continued, with the limitations that one has to work with formalisms which embody only part of the mathematics in question and that the proofs must rely on more abstract, but still constructive, notions; and the work in finitist proof theory has achieved valuable results, some of which will be discussed later.

#### §4. MATHEMATICAL LOGIC

Our remaining considerations on the subjects of the two preceding sections fit best into an independent discussion of mathematical logic as a factor in the study of the foundations of mathematics. Before World War II an important part of the work in logic was directed toward establishing, in the service of some general position such as logicism or intuitionism, a more or less final solution to the problems of foundations. Certain particular results, and probably also a more diffuse evolution of the climate of ideas, have discouraged this aim. Today nearly all work in mathematical logic, even when motivated by philosophical ideas, is nonideological, and everyone

acknowledges that the results of this work are independent of the most general philosophical positions.

Starting from the axiomatic method in a more general sense, mathematical logic has become the general study of the logical structure of axiomatic theories. The topics selected from the great variety of technical developments for discussion here are Gödel’s incompleteness theorems, recursive function theory, developments related to Hilbert’s program, foundations of pure logic, and axiomatic set theory.

#### 4.1. GÖDEL’S INCOMPLETENESS THEOREMS.

Research in mathematical logic took quite new directions as a result of the discovery by Kurt Gödel, in 1930, of his incompleteness theorems. According to the first theorem (as strengthened by J. B. Rosser in 1936) any formalism  $S$  that is sufficiently powerful to express certain basic parts of elementary number theory is incomplete in the following sense: A formula  $\mathcal{A}$  of  $S$  can be found such that if  $S$  is consistent, then neither  $\mathcal{A}$  nor  $\neg\mathcal{A}$  is provable in  $S$ . The conditions are satisfied by very weak systems, such as the first-order theory  $Q$  whose axioms are the Peano axioms for the successor function and the recursion equations for addition and multiplication. (This system is formalized in first-order logic with equality, having successor, addition, and multiplication as primitive function symbols. The axioms are versions of our axioms (1)–(4), recursion equations for addition and multiplication, and an axiom which says that every number not equal to 0 is the successor of something.) They are satisfied by extensions of systems that satisfy them and therefore by the full elementary number theory  $Z$  (the first-order version of the Dedekind-Peano axiomatization, obtained from  $Q$  by adding induction: in place of the second-order axiom (5) one adds all results of substituting a predicate of the formalism for “ $F$ ” in (7), by analysis, and by axiomatic set theories in which number theory can be constructed. They are also satisfied by formalizations of intuitionist theories. Evidently adding further axioms offers no escape from this incompleteness, since the new theories will also satisfy the conditions of the theorem.

One of the conditions necessary for some general statements of the theorem is that which we mentioned earlier, that proofs can be checked mechanically. This must be interpreted more precisely in terms of one of the concepts of recursive function, discussed below.

The technique of Gödel’s proof is of great interest and has since found wide application. It consists of a mapping of the syntax of the theory into the theory itself, through assigning numbers to the symbols and formulae

of the system. Any syntactical relation will then be equivalent to some relation of natural numbers. For the crucial relation “ $\mathcal{P}$  is a proof in  $S$  of the formula  $\mathcal{A}$ ” the corresponding relation  $P(x,a)$  can be expressed in the theory, and certain things about it can be proved in  $S$ . Then the undecidable formula  $\mathcal{A}$  is a formula which has a number  $k$  such that what  $\mathcal{A}$  says (about numbers) is equivalent to the unprovability of the formula number  $k$ , i.e.,  $\mathcal{A}$ . (1) Then if only true formulae are provable,  $\mathcal{A}$  is unprovable. But then  $\mathcal{A}$  is true. Therefore, (2) by the same assumption  $\neg\mathcal{A}$  is also unprovable. This appeal to the notion of truth was replaced in Gödel’s detailed argument by the condition that  $S$  be consistent for (1) and  $\omega$ -consistent for (2). By changing the formula Rosser showed that the assumption of  $\omega$ -consistency could also be replaced by that of consistency.

The proof that if  $S$  is consistent, then  $\mathcal{A}$  is unprovable is finitist. If  $S$  and the mapping of its syntax into  $S$  satisfy some further conditions, the argument can be formalized in  $S$ . This yields the second theorem of Gödel. If  $S$  is consistent, then the formula which, under the above mapping, corresponds to the consistency of  $S$  is unprovable in  $S$ .

The first theorem implies not only that mathematics as a whole cannot be codified in a single formal system but also that the part of mathematics that can be expressed in a specific formal notation cannot be so codified. This fact undermines most attempts at a final solution to the problem of foundations by means of mathematical logic. The second theorem was a blow to the Hilbert program in particular. The methods that the Hilbert school envisaged as finitary could apparently be codified in first-order number theory  $Z$ ; indeed, that they can be so codified seems fairly certain, even though the notion of finitary methods is not completely precise. Therefore, not even the consistency of  $Z$  is provable by finitary means. Moreover, the consistency of stronger and stronger systems requires stronger and stronger methods of proof.

There has been much discussion of the broader philosophical implications of Gödel’s theorem. We shall not enter into the discussion of such questions as whether the theorem shows the falsity of any mechanistic theory of mind. It should be remarked that there are a number of connections between the surpassing of any given formal system by possible means of proof and the inexhaustibility phenomena in the realm of mathematical existence. Gödel’s argument can be viewed as a diagonal argument parallel to that by which Cantor proved that no countable set of sets of natural numbers can exhaust all

such sets. Peano’s axioms are categorical if the range of the quantifiers in the induction axiom (5) includes all classes of natural numbers, but in the context of a formal system one can use only the fact that induction holds for classes definable in the system, of which there are only countably many. In set theory the addition of axioms asserting the existence of very large classes can make decidable previously undecidable arithmetical formulae.

**4.2. RECURSIVE FUNCTION THEORY.** A number of problems in mathematical logic require a mathematically exact formulation of the notion of mechanical or effective procedure. For most purposes this need is met by a concept of which there are various equivalent formulations, arrived at by several writers. The concept of (general) recursive definition, introduced in 1931 by Jacques Herbrand and Gödel, was the first. A function of natural numbers which is computable according to this conception (the “computation” consists of the deduction of an evaluation from defining equations by simple rules) is called a general recursive, or simply a recursive, function. Other formulations are that of  $\lambda$ -definability (Alonzo Church), computability by Turing machine (A. M. Turing), algorithms (A. A. Markov), and different notions of combinatorial system (Emil Post and others).

The concept of recursive definition has proved essential in decision problems. Given a class of mathematical problems defined by some parameter, is there an effective algorithm for solving each problem in the class? As an example consider the tenth problem of Hilbert: Given a polynomial with integral coefficients, is there a general method that tells us whether it has a zero among the integers? If such a question can be resolved in the affirmative, the resolution can generally be reached on the basis of the intuitive conception of an algorithm: If one can invent the procedure, then it is generally clear that the procedure is effective. But to give a negative answer to such a question one needs some idea of the possible effective procedures. The development of recursive function theory has made possible a large number of results asserting the nonexistence of decision procedures for certain classes of problems. This way of interpreting the results depends on a principle known as Church’s thesis, which says that the mathematical conception of an effectively computable function in fact corresponds to the intuitive idea—i.e., that a number-theoretic function is (intuitively) effectively computable if and only if it is recursive.

An important type of decision problem is that concerning provability in formal systems. Given a formal system  $S$ , is there an algorithm for deciding whether a given

formula  $\mathcal{A}$  is a theorem of  $S$ ? If there is, then  $S$  is said to be decidable. Although quite interesting examples of decidable systems exist, the systems to which Gödel's first incompleteness theorem applies are undecidable. In fact, Gödel's type of argument can also be used to prove that first-order logic is undecidable (as by Church in 1936).

Another important aspect of recursive function theory is the classification of sets and functions according to different principles related to recursiveness. One such principle, stated in terms of the complexity of possible definitions by recursive predicates and quantifiers (the Kleene-Mostowski hierarchy), not only is of wide application in logic but is closely related to older topological classifications. One can single out the arithmetical sets (those sets definable from recursive predicates by quantification over natural numbers alone), the hyperarithmetical sets (a certain transfinite extension of the arithmetical hierarchy—in effect, those sets definable in ramified analysis with levels running through the recursive ordinals), and the analytic sets (those sets definable from recursive predicates by quantification over numbers and functions, or sets, of natural numbers). The recursive ordinals, singled out by Church and Kleene, can most readily be characterized as the order types of recursive well-orderings of the natural numbers.

The theory of recursive functions is evidently valuable for explicating different notions of constructivity and for comparing classical and constructive mathematics. A constructive proof of a statement of the form " $(x)(\exists y)Fxy$ " should yield an effective method of obtaining  $y$  from  $x$ . For example, Kleene and his collaborators have shown that any statement provable in formalized intuitionist number theory and analysis has a property called "realizability," which amounts roughly to interpreting " $(x)(\exists y)Fxy$ " as asserting the existence of a recursive function giving  $y$  in terms of  $x$ . Although it is also intuitionistically meaningful, the construction gives a classical interpretation of the intuitionist formalisms. It also allows a sharpening and extension of Brouwer's counterexample technique. Certain classically provable formulas can be shown not to be realizable and therefore not to be provable in the intuitionist formalisms Kleene considers.

A problem arises with regard to the relation between the concept of recursive function and the fundamental concepts concerning constructivity—for instance, the concept of intuitionism. One cannot interpret Church's thesis as explicitly defining "effectively computable function" and therefore as giving the meaning of the intuitionist quantifiers. For by definition a function is general

recursive if there is a set of equations from which for each possible argument one can compute the value of the function for that argument, a statement of the form " $(x)(\exists y)Fxy$ ." If this is interpreted constructively, the proposed definition is circular. The relation between "function constructively proved to be everywhere defined" and "general recursive function" is still not clear. One can ask whether every intuitionistically everywhere-defined number-theoretic function is general recursive or whether every (classically) general recursive function can be proved constructively to be such. Neither question has yet been resolved.

**4.3. DEVELOPMENT OF THE HILBERT PROGRAM.** For the study of constructivity it is also important to study more restricted types of recursive definition that can be seen by definite forms of argument to define functions. This is particularly important for the extended Hilbert program.

Gödel's second incompleteness theorem meant that the consistency even of elementary number theory  $Z$  could not be proved by the methods envisaged by Hilbert. A number of consistency results of the sort envisaged by Hilbert have since been obtained by stronger constructive methods. Gödel and Gentzen proved independently (and finitistically) that if intuitionistic first-order arithmetic is consistent, then so is classical first-order arithmetic. The proofs were based on a quite simple method of translating classical theories into intuitionist theories which is of wide application—for example, to pure logic. One renders an atomic formula  $P$  by  $\neg\neg P$  (in elementary number theory, equivalent to  $P$  itself). If  $\mathcal{A}, \mathcal{B}$  are translated into  $\mathcal{A}^\circ, \mathcal{B}^\circ$ , respectively, then  $\mathcal{A} \vee \mathcal{B}$  is translated by  $\neg\neg(\mathcal{A}^\circ \vee \mathcal{B}^\circ)$ ,  $(\exists x)\mathcal{A}$  by  $\neg\neg(\exists x)\mathcal{A}^\circ$ ,  $\mathcal{A} \supset \mathcal{B}$  by  $\neg(\mathcal{A}^\circ \& \neg\mathcal{B}^\circ)$ ,  $\mathcal{A} \& \mathcal{B}$  by  $\mathcal{A}^\circ \& \mathcal{B}^\circ$ ,  $\neg\mathcal{A}$  by  $\neg\mathcal{A}^\circ$ , and  $(x)\mathcal{A}$  by  $(x)\mathcal{A}^\circ$ . Evidently the translation not only proves relative consistency but also gives each provable formula an intuitionist meaning according to which it is intuitionistically true. If  $\mathcal{A}$  is a quantifier-free formula of number theory, or if it is composed with conjunction, negation, and universal quantification only, then if it is provable in  $Z$ , it is intuitionistically provable. This translation can easily be extended to ramified analysis. Since intuitionistically the consistency of the intuitionist systems follows from their soundness under the intended interpretation, the consistency of the classical systems has been intuitionistically proved.

A sharper result was obtained in 1936 by Gerhard Gentzen. New proofs, with various advantages and refinements, have since been found by several workers.

Gentzen proved the consistency of  $Z$  by adding to finitist arithmetic the assumption that a certain recursive ordering of natural numbers, of order type  $\epsilon_0$  (the least ordinal greater than  $\omega$ ,  $\omega^\omega$ ,  $\omega^{\omega^\omega}$ ,  $\dots$ ), is a well-ordering. This assumption could be proved in intuitionist ramified analysis using set variables only of level 1 but could not in elementary number theory.

Gentzen's result has made it possible to extract further information about the power of elementary number theory. Kreisel obtained information about the relation between elementary number theory and certain quantifier-free arithmetics and also obtained a characterization of the functions which can be proved in  $Z$  to be general recursive.

A corresponding result for ramified analysis for finite levels was obtained by Lorenzen in 1951 and sharpened by Kurt Schütte. It was extended by Schütte to transfinite levels.

On the basis of these results we can say that constructive consistency proofs are available for all of predicative mathematics. In well-defined senses they are the best possible results (for instance, the above-mentioned ordinal  $\epsilon_0$  cannot be replaced by a smaller one). Nonetheless, efforts to give such a proof for impredicative classical analysis, not to speak of axiomatic set theory, have proved fruitless.

Results of quite recent research have shed considerable light on this situation. Clifford Spector (1962) proved the consistency of classical analysis relative to a quantifier-free theory (Gödel 1958) of primitive recursive functionals of arbitrary finite types, enriched by a new schema for defining functionals by "bar recursion." This amounted to generalizing Brouwer's bar theorem to arbitrary finite types. Such generalized bar recursion has not found a constructive justification, but the method has led to consistency proofs by the original bar theorem for subsystems of analysis which are, according to a reasonable criterion, impredicative.

Kreisel (1963) has shown that intuitionist analysis, with the bar theorem and a strong schema of "generalized inductive definitions" included, does not suffice to prove the consistency of classical analysis. Such a proof requires an essential extension of constructive methods beyond the established intuitionist ones.

Solomon Feferman and Schütte have given an analysis of the notion of predicativity according to which established intuitionist methods go beyond predicative ones. According to their conception, inductive definitions

such as that of the class  $O$  of numbers representing the recursive ordinals are impredicative.

What has been the fate of the Hilbert program? Put most broadly, its objective was to secure the foundations of platonist mathematics by a constructive analysis of classical formal systems. The incompleteness phenomena have made it impossible, in dealing with stronger and stronger systems, to avoid the introduction of more and more abstract conceptions into the metamathematics. However interesting the information obtained about the relation between these conceptions and the platonist ones, it is not evident that these conceptions are in all respects more secure. Moreover, in the present state of research it is not certain that strong enough constructive methods can be found even to prove the consistency of classical analysis.

This state of affairs is unfavorable to those methodological views seeking to restrict mathematics to the methods which have the greatest intuitive clarity. It is evident that such methods will not suffice to resolve certain mathematical questions whose content is extremely simple, namely those concerning the truth of certain statements of the form " $(x)Fx$ ," where " $F$ " stands for a primitive recursive predicate of natural numbers. Proponents of the views in question seem forced to admit that even such questions can be objectively undetermined.

**4.4. FOUNDATIONS OF LOGIC.** An important result concerning pure logic obtained in finitist metamathematics is a theorem, or cluster of related theorems—including Herbrand's theorem (1931) and Gentzen's theorem (1934)—to the effect that the proof of a formula of first-order logic can be put into a normal form. In such a normal-form proof the logical complexity of the formulae occurring in the proof is in certain ways limited in relation to the complexity of the conclusion; for instance, no formula can contain more nested quantifiers than the conclusion. The proof is, as it were, without detours, and *modus ponens* is eliminated. As a consequence, a quantifier-free formula deduced from quantifier-free axioms can be proved by propositional logic and substitution, which implies all the consistency results proved by the Hilbert school before the discovery of Gödel's theorem. Gentzen's theorem also applies to intuitionist logic and to other logics, such as modal logics.

These theorems, which are the fundamental theorems of the proof theory of quantification theory, are closely related to the fundamental theorem of its semantics, Gödel's completeness theorem. Every formula not formally refutable has a model—in fact, a model in which

the quantifiers range over natural numbers; i.e., there are denumerably many individuals. This can be strengthened to the following: If  $S$  is any set (finite or infinite) of formulae of first-order logic, it has a denumerable model unless some finite subset of  $S$  is inconsistent—that is, unless the conjunction of the subset's members is formally refutable (Skolem-Löwenheim theorem).

This theorem has some quite startling consequences: in particular, it applies if  $S$  is the set of theorems of some system of set theory. Then if the system is consistent,  $S$  has a denumerable model even though  $S$  may contain a theorem which asserts the existence of nondenumerable sets. That is not a contradiction: If  $n$  represents a nondenumerable set in the model, there will indeed be only countably many  $m$ 's such that  $m \in n$  is true in the model, but the assertion " $n$  is nondenumerable" will be true in the model because the model will not contain an object representing the function that enumerates the objects  $m$  for which  $m \in n$  is true in the model. The model is denumerable only from "outside."

This is an example of a model which is nonstandard in that it differs in some essential way from the intended one. The Skolem-Löwenheim theorem also implies the existence of nonstandard models for systems of number theory. In fact, there is a nonstandard model even for the set  $S$  of all true formulae of elementary arithmetic. The number sequence cannot be characterized up to isomorphism by any countable set of first-order formulae.

The existence of denumerable models of set theory illustrates how essential the platonist conception of set, particularly of the set of subsets of a given set, is to set theory. If there is no more to the platonist conception than is specified in any particular formal system, then apparently the cardinal number of a set cannot be objectively determined. Indeed, the cardinal number of a set depends on what mappings there are and therefore on what sets there are.

The acceptance of this relativity has been urged by many, including Skolem. A fully formalist conception would give rise even to the relativity of the natural numbers themselves.

The completeness theorem and the construction of nonstandard models are fundamental tools in a now rapidly developing branch of logic called model theory. This subject can be viewed as a development of logical semantics, but what is perhaps distinctive about the point of view underlying recent work is that it regards a model of a formal theory as a type of algebraic structure and, in general, that it integrates the semantic study of formal

systems with abstract algebra. Model theory takes mathematical logic a long way from the philosophical issues with which we have been mainly concerned, in particular by taking for granted a strong form of platonism. The leaders of this development have, in fact, emphasized the application of metamathematical methods to problems in ordinary mathematics.

There are other investigations concerning the foundations of pure logic. For example, we have mentioned that there can be no decision procedure for quantification theory. Nonetheless, there is interest in the question of what subclasses of formulae are decidable. As a striking result in this direction we might mention the proof of A. S. Kahr, E. F. Moore, and Hao Wang (1962) that the existence of models of formulae of the form " $(x)(\exists y)(z)M(x,y,z)$ " (or, equivalently, the provability of formulae of the form " $(\exists x)(y)(\exists z)M(x,y,z)$ " where " $M(x,y,z)$ " is an arbitrary quantifier-free formula, is undecidable. The development of appropriate concepts of model and completeness proofs for modal logics and intuitionist logic has come to fruition in recent years. In the case of the completeness of intuitionist logic, the situation is unclear. E. W. Beth (1956) has given a construction of models in terms of which he proves classically the completeness of intuitionist quantification theory. On the other hand, Kreisel has shown that the completeness of intuitionist logic cannot be proved by methods available in present intuitionist formal systems and, indeed, that it is incompatible with the supposition that all constructive functions of natural numbers are recursive.

**4.5. AXIOMATIC SET THEORY.** We shall not undertake here to survey the different axiomatic systems of set theory. We shall, however, mention some developments in the metamathematics of set theory, developments concerning the axiom of choice and Cantor's continuum problem.

The axiom of choice asserts (in one formulation) that for every set  $A$  of nonempty sets no two of which have a common element, there exists a set  $B$  which contains exactly one element from each of the sets in  $A$ . This axiom became prominent when Zermelo used it in 1904 to prove that every set can be well-ordered. Although it was much disputed, it came to be applied more and more, so that entire theories of modern abstract mathematics depend essentially on it. Naturally the question arose whether it was provable or refutable from the other axioms of various systems of set theory. A. A. Fraenkel (1922) showed that it could not be proved from Zermelo's axioms, provided that the axioms allowed individ-

uals—that is, objects which are not sets—in the range of the quantifiers.

The continuum problem appears to be an elementary problem in the arithmetic of cardinal numbers: Is there a cardinal between  $\aleph_0$ , the cardinal of the integers, and  $2^{\aleph_0}$ , that of the continuum; stated otherwise, does the continuum contain subsets of cardinal number different from that of the continuum and that of the integers? If the answer is negative, then  $2^{\aleph_0} = \aleph_1$ , the first cardinal larger than  $\aleph_0$ , and the cardinal of the first noncountable well-ordering. Cantor's conjecture that  $2^{\aleph_0} = \aleph_1$  is called the continuum hypothesis.

Gödel, in 1938, proved that the axiom of choice and a generalization of the continuum hypothesis are consistent with the other axioms. The argument applies to a number of different systems, including the Zermelo-Fraenkel system (ZF). What is proved (finitistically) is that if, say, ZF is consistent, it is likewise consistent with a new axiom, the axiom of constructibility, which implies the axiom of choice and the generalized continuum hypothesis. For the constructible sets, which are the sets obtained by extending the ramified hierarchy of types through all the ordinals, can be proved in the system to satisfy all the axioms plus the axiom of constructibility, which says that every set is constructible. In terms of models, any model of ZF contains a subclass that is a model in which all sets are constructible. The constructible sets are of interest on their own account; Gödel has remarked that the idea behind them is to reduce all impredicativities to one special kind, the existence of large ordinals. However, he does not consider the axiom of constructibility plausible.

Thus, it has been known for some time that the axiom of choice and the continuum hypothesis are not refutable from the other axioms. More recently, Paul J. Cohen proved that they are not provable either. That is, if, say, ZF is consistent, it remains so by adding the negation of the axiom of choice or by adding the axiom of choice and the negation of the continuum hypothesis. Starting from Gödel's ideas, Cohen developed a quite new method for constructing models, which has led very quickly to a large number of further independence results.

The situation with respect to the axiom of choice and the continuum problem raises anew the question of how definite our idea of a set is, whether or not such a question as the continuum problem has an objectively determinate answer. Most mathematicians today find the axiom of choice sufficiently evident. But the continuum hypothesis—perhaps because of its more special character and because of the fact that the analogy of the infinite

to the finite on which the conception of the set of all subsets of a given set is based does not suggest a justification of it—is left much more uncertain by considerations of intuitive evidence or plausibility. The role of the Skolem-Löwenheim theorem in Gödel's and Cohen's constructions might encourage the idea that the continuum hypothesis is in fact undetermined. Gödel himself believes that it is false and hopes that an axiom will be found which is as evident as the axiom of choice and which suffices to refute the continuum hypothesis. At present no one seems to have a good idea of what such an axiom would be like. It would have to be of a different character from the usual strong axioms of infinity, to which the method of Gödel's consistency proof applies.

The question of the continuum hypothesis is thus very close to the general epistemological question concerning platonism. If the general conceptions of set and function are given in some direct way to the mind, if, to echo René Descartes, the idea of the infinite is in one's mind before that of the finite, there is no reason to expect a comparatively simple question like the continuum problem to be unanswerable. If, on the other hand, the platonist conceptions are developed by analogies from the area where we have intuitive evidence, if they are "ideas of reason" which, without having an intuition corresponding to them, are developed to give a "higher unity" which our knowledge cannot obtain otherwise, then it would not be particularly surprising if the nature of sets were left indeterminate in some important respect and, indeed, could be further determined in different, incompatible ways.

## SUPPLEMENT (2005)

The period since 1967 has seen considerable work in all areas of the foundations of mathematics. This is most notable on the mathematical side. These developments will be discussed before turning to philosophical work.

### §5. MATHEMATICAL LOGIC

Of the extensive work since the 1960s, that dealing with formalized axiomatic theories is most central to the foundations of mathematics, although there might now be more debate than earlier about the centrality of the axiomatic method. For some time mathematical logic has been divided into Proof theory, Model theory, Computability (recursion) theory, and Set theory (see the entries on those subjects), although of course there are important interconnections. Model theory and com-

putability theory are more purely mathematical, although their methods are important for the other two areas, and some applications (such as nonstandard analysis) are of foundational interest.

One upshot of work in Proof theory is that strong subsystems of classical analysis (second-order arithmetic) have been analyzed by means that are in some sense constructive but much more powerful and abstract than was envisaged in the early history of the subject. A possibly clearer foundational gain was achieved by another proof-theoretic program, which can trace its roots to Hermann Weyl's (1918) attempt to reconstruct classical analysis predicatively. The work of Harvey Friedman, Stephen Simpson, and others, surveyed in Simpson (1998), showed that many standard theorems of analysis (and of other branches of mathematics) can, if suitably formulated, be proved in weak systems. The method of Reverse mathematics (q.v.) made it possible to calibrate exactly what axiomatic power was needed to prove a particular theorem.

The most striking developments have been in set theory, where Paul Cohen's proof in 1963 of the independence of the axiom of choice and the continuum hypothesis touched off an explosion of research. Cohen's method of forcing proved of wide applicability. In the following years, many more independence results were found in all areas of set theory and its applications. In particular, many classical conjectures were shown both consistent with and independent of the standard axiom system ZFC (or ZF in cases where the axiom of choice sufficed to prove a statement).

This body of work might suggest to a philosopher a vast indeterminacy in the concept of set or of the universe of sets, a random-seeming collection of logical relations among statements independent of ZF or ZFC. However, there is more order than this picture would suggest. The existence of important independent statements would suggest seeking new axioms, and in fact progress has been made by developing the consequences of two kinds of new axioms: strong axioms of infinity (axioms asserting the existence of certain large cardinals) and special cases of the axiom of determinacy.

The large cardinal axioms that have been studied have turned out to be linearly ordered by consistency strength (see §6 of the entry on Set theory), and this has made it possible to determine the consistency strength of other independent statements. In particular this is true of the game-theoretic axiom of determinacy. The assumption PD that the latter holds for projective sets of real numbers (roughly those definable by quantification over

reals) implied solutions to the classical problems of descriptive set theory, the study of these sets. PD (and more) was shown to follow from strong large cardinal axioms.

Although this result left the continuum problem untouched, it did show that a program of investigating new axioms along lines proposed by Kurt Gödel in the 1940s could settle an important class of open problems. The large cardinal axioms implying PD have the desirable feature that their consequences in second-order arithmetic cannot be altered by forcing. W. Hugh Woodin's (2001) approach to the continuum problem (see §6 of the entry on Set theory) aims to extend this result to a higher level. But it is not regarded even by Woodin himself as a definitive solution, and even the question whether the continuum hypothesis has a determinate truth-value remains open.

## §6. APPROACHES TO PHILOSOPHY OF MATHEMATICS

In 1967 philosophy of mathematics was largely ancillary to logic, and discussion centered either on logical results or on the earlier foundational programs that had contributed to the development of mathematical logic. Since then it has become more a subject in its own right. It has been influenced by the general tendencies moving the philosophy of science away from logic. In particular, historical studies have assumed a larger role, and many such studies have been of developments not close to logic.

In the earlier entry, the philosophical problems discussed concern the analysis of basic mathematical concepts (such as natural number) and the identification and justification of mathematical principles. The term *foundations* naturally suggests that focus. But the philosophy of mathematics can and does contain inquiries of other kinds. It has been charged with concerning itself only with elementary mathematics. This charge is not correct; for example, identifying the axioms required for conclusions in set theory is a matter of high-level mathematical research, and in general the justification of axioms is not independent of knowledge of the theories developed from them.

But it is true that an inquiry into basic concepts and principles will be selective in its attention to the elaboration of mathematics in current and earlier research. And one may well seek philosophical understanding of aspects of mathematical practice of a different kind. One influential strand of work of this kind is that inaugurated by Imre Lakatos, particularly in his book *Proofs and Refutations* (1976). Lakatos studied a classic theorem of Leon-

hard Euler (1707–1783) relating the number of vertices, faces, and edges of a polyhedron and brought to light difficulties that had been found with proofs of it over a period of time and the refinements of the statement of the theorem that had resulted. An underlying idea was that mathematical knowledge is more fallible than a certain traditional picture has it, for a different reason from those that might be suggested by difficulties with basic principles. For reasons of space, this sort of inquiry will not be pursued here, but it should be recognized that this strand of philosophy of mathematics has grown relative to the whole since 1967.

## §7. LOGICISM AND THE NEO-FREGEAN PROGRAM

In §2, much attention is paid to the project of reducing arithmetic to logic and the analysis of number. Logicism in its earlier forms has not been revived, but a kind of neologicism has become an active program. It was observed that the axioms of arithmetic could be derived in second-order logic from the criterion (7) in §2.6, with numerical equivalence defined as in (8). (This is briefly sketched after (12), but the most difficult case, the proof that every natural number has a successor, is omitted.) (7) thus formulated has come (misleadingly) to be called Hume's principle (HP). The second-order theory with the number operator  $N_x Fx$  and HP as a nonlogical axiom is called Frege arithmetic (FA). In 1983 Crispin Wright gave the proof that the Dedekind-Peano axioms of second-order arithmetic are provable in FA using Frege's definitions, but this was in essentials proved by Gottlob Frege and has come to be called Frege's theorem. Intuitively, Frege uses the definition of  $N_x Fx$  in terms of extensions only to derive HP, and then the work is done by that principle. Richard G. Heck Jr. showed in 1993 that this was essentially true of Frege's proofs in *Grundgesetze*. Several logicians showed that FA is consistent if second-order arithmetic is.

Wright's neo-Fregean proposal is to take FA as basic arithmetic. It is a logical construction of arithmetic only if the notion of cardinal number is a logical notion and HP is a principle of logic. As a proof that arithmetic is a part of logic the construction seems to be question-begging. Still, it generated a lot of discussion by Wright and others of the status of abstraction principles like HP, which take an equivalence relation of entities of one kind as a criterion of identity for entities of another kind. Wright's initial idea seems to have been that HP is something close to a definition, although it is not an explicit definition and does not meet the usual standard for a

contextual definition, that it should enable the term introduced to be eliminated by paraphrase of contexts in which it occurs. A fatal difficulty for this idea is that HP can be true relative to a domain of individuals only if the domain is infinite. Wright and his collaborators continued to argue that HP is analytic. Others have doubted that a principle that implies the existence of an infinite sequence of objects could be analytic. Another difficulty is that Frege's inconsistent axiom V is an abstraction principle, and other abstraction principles that seem plausible are either inconsistent or can be satisfied only in a finite domain.

The program of axiomatizing parts of mathematics by abstraction principles is of independent logical interest, and work has been done on analysis, and preliminary work on set theory. Kit Fine (2002) carried out an extensive analysis of abstraction principles, to distinguish those that introduce inconsistency from those that do not.

## §8. PLATONISM

Since World War II, the view that classical mathematics is seriously threatened by the known paradoxes or by other unknown ones has virtually disappeared. Platonism as described in §3 has been widely accepted as a mathematical method. Taking the language of classical mathematics at face value, as implying the existence of abstract mathematical objects, even forming uncountable and still larger totalities, and allowing reasoning using both the law of excluded middle and impredicative definitions, is probably a default position among philosophers and logicians. This can be called default platonism. It is in relation to such a view, whether accepting it or rejecting it, that much of the work in the philosophy of mathematics since 1967 has concentrated on ontological problems. How might this position be rejected?

## §9. CONSTRUCTIVISM

In §3.2, platonism is contrasted principally with constructivism. Intuitionism and other forms of constructivism did not accept the reasoning characteristic of classical mathematics, in the case of intuitionism the law of excluded middle.

A significant development in this area is the argument in favor of intuitionist logic based on considerations of the philosophy of language presented by Michael Dummett (1973). This has, however, had more influence on discussions of realism as a general philosophy than on the foundations of mathematics specifically. Important metamathematical work on intuitionistic theories was done especially in the 1960s and 1970s. An important

development is the development of intuitionistic-type theories that are of much greater expressive power than traditional intuitionistic theories. That of Per Martin-Löf (1984) is the most developed. But although intuitionistic logic has proved to have wide application, intuitionism has declined significantly as a general approach to mathematics, competing with classical mathematics. Another constructive approach to mathematics, pioneered by Errett Bishop (1967), has been developed by several mathematicians. Although it has been more active in the last generation than intuitionism, philosophers have been more interested in the latter, perhaps justifiably because what is philosophically interesting about the Bishop approach is shared with intuitionism, and L. E. J. Brouwer and other intuitionists did more to develop philosophical arguments for their position.

#### §10. NOMINALISM

The term *platonism* is also used so that the view contrasts with nominalism. Since 1980 or so that opposition has been more prominent among philosophers, especially in North America. This is perhaps fundamentally due to the great influence of scientific naturalism on all theoretical parts of philosophy.

The traditional way in which nominalism rejects default platonism is by not taking the language of mathematics at face value and seeking to paraphrase it in such a way that commitment to abstract mathematical objects is avoided. Programs of this kind have been pursued especially since the 1980s, but it has proved essential to enlarge traditional nominalist resources in at least one of two ways: allowing points and possibly regions of space-time as physical or allowing modality. It is then possible to reconstruct a considerable amount of classical mathematics, at least if one accepts a controversial thesis of George Boolos (1998) that his reading of the language of monadic second-order logic by means of the English plural does not involve commitment to such entities as sets, classes, concepts, or pluralities. What has been achieved in this sort of reconstruction is surveyed in John P. Burgess and Gideon Rosen, *A Subject with No Object* (1997).

A bolder proposal was made by Hartry H. Field (1980, 1989): Where he parted from default platonism was in rejecting the view that statements of classical mathematics, taken at face value with regard to meaning, are true and even that mathematics aims at truth. He sought to account for the apparent objectivity of mathematics by viewing it instrumentally, as a device for making inferences within scientific theories. The role of truth

is taken over by conservativeness: Given a nominalistic scientific theory  $T$ , a mathematical theory  $M$  is conservative if adding its resources to those of  $T$  does not enable the derivation of conclusions in the language of  $T$  that were not already derivable. This committed him to giving nominalistic versions of scientific theories, and (with the previously mentioned assumption about points and regions of space-time) he was able to give such a version of the Newtonian theory of gravitation. Difficulties stand in the way of carrying out this program for modern physical theories.

#### §11. STRUCTURALISM

Two related intuitions about modern mathematics are widely expressed: that it is the study of (abstract) structures and that mathematical objects have no more of a nature than is expressed by the basic relations of a structure to which they belong. The structuralist view of mathematical objects is a development of the second intuition. Its relation to default platonism is ambiguous. Some versions, which can be called eliminative structuralism, reject one part of that view, taking the language of mathematics at face value, by proposing paraphrases that eliminate reference to mathematical objects or at least to the most typical mathematical objects. Others take the structuralist idea as an explication of what the reference to objects in standard mathematical language amounts to. This noneliminative type of structuralism offers an ontological gloss on default platonism rather than a modification or rejection of it.

A simple case of an eliminative structuralist analysis is a translation of the language of second-order arithmetic into that of pure second-order logic. Suppose  $A$  is a sentence of second-order arithmetic. Since arithmetical operations such as addition and multiplication are second-order definable, it can be assumed that  $A$  contains as only primitives  $N$  (natural number),  $S$  (successor), and  $0$ . The structure of the natural numbers is characterized by a second-order sentence with these primitives, the conjunction  $P$  of these axioms. If  $A$  is provable, the sentence  $P \rightarrow A$  is provable by pure logic. If  $A$  is true, it is valid in the standard semantical sense. One can regard  $P \rightarrow A$  (or the result of replacing  $N, S, 0$  by variables) as a translation of  $A$  that eliminates reference to numbers. The translation has the difficulty that if there is no structure satisfying the axioms, then  $P \rightarrow A$  and  $P \rightarrow \neg A$  are both vacuously true. The translation seems to presuppose that  $P$  is satisfiable.

One version of structuralism would allow sets as basic objects. This would be a natural way of developing

the first intuition, understanding structures as set-theoretic constructs. But a general structuralist view of mathematical objects would naturally aim not to exempt sets from structuralist treatment. At this point modality has been introduced. In the previous example, the assumption that it is possible that there are  $N$ ,  $S$ , and  $0$  satisfying  $P$  is sufficient, since  $P \rightarrow A$  can be strengthened to  $\Box(P \rightarrow A)$ . The modal structuralism of Geoffrey Hellman (1989) is a version of eliminative structuralism relying on this idea. It includes a detailed treatment of set theory. (An approach had been sketched earlier by Hilary Putnam [1967].)

What these constructions accomplish depends on the status of second-order logic, a question that arises also for the neo-Fregean program and for nominalism. Concerning this there has been much debate. Regarding set theory, there is the additional problem that the presupposition of the possibility of the structure is of a structure of such large cardinality that it could not be witnessed by objects that are in any sense concrete or physical, so that the claim of the construction to eliminate reference to mathematical objects can be questioned.

Other versions of structuralism are suggested by remarks of Willard Van Orman Quine (1969) and of some earlier writers. Noneliminative structuralisms have been worked out in some detail by Michael D. Resnik (1997), Stewart Shapiro (1997), and Charles Parsons (1990). Concerning these views, there is debate about the status of structures, as well as about questions about identity.

## §12. ROBUST PLATONISM?

A more robust type of platonism is expressed in Gödel's remark that "the set-theoretical concepts and theorems describe some well-determined reality, in which Cantor's conjecture must be either true or false" (1964, p. 260). Such a view would be supported by whatever general considerations support philosophical realism. But something more is demanded, a certain clarity and unambiguity of set-theoretical concepts and quantification over sets. Gödel wished to argue that the continuum hypothesis (CH) must be either true or false, even though he was unable to determine which. What might reinforce his claims would be a development (such as the work of Woodin [2001]) that determines the truth-value of CH. However, the assumptions of such a result might then be incorporated into a less robust platonist view. Perhaps the greater value of Gödelian realism is as a regulative principle: one is more likely to find answers to mathematical

questions if one assumes at the outset that there are answers to be found.

That decisive philosophical arguments can be given for such a realistic stance is unlikely. An alternative is to say that default platonism applied to mathematics as it develops represents the limit of what one should claim about the determinateness of the reality described by mathematical theories. This would be the application to mathematics of the naturalistic stance recommended by Quine in many writings, but without his privileging of empirical science. Such a view was advanced by Hao Wang (1974) and more recently by Penelope Maddy (1997).

Gödel's confidence in set-theoretic concepts has not been universally shared; in particular Solomon Feferman (1998, 1999) has defended a skeptical view, influenced by the earlier predicativist tradition.

## §13. EPISTEMOLOGICAL PROBLEMS

In the 1967 entry, the epistemological discussion centered on the question whether mathematics can be shown to be *a priori*. It seems that there has been no decisive advance on this question, so others will be concentrated on here.

Paul Benacerraf (1973) raised in rather abstract terms a problem about mathematical knowledge: If default platonism is true, how can one have mathematical knowledge? One response would be to start from the fact that one evidently does have mathematical knowledge and then question the assumptions that generate the problem. One assumption made in Benacerraf's original formulation, the causal theory of knowledge, is relatively easy to reject. To demand a causal relation between objects referred to in a proposition for knowledge of that proposition seems to stack the deck in advance against abstract objects, and the causal theories that were current when he wrote have not stood up well in general epistemology. But one can see the problem in more general terms: Can one give an epistemology for mathematics that is naturalistic? The most fruitful approach might then be to examine actual mathematical knowledge and to consider what sort of explanation of it makes sense and whether it then meets some standard of naturalism.

No explicit program of this kind has been carried far. One place where one might naturally look for naturalistic explanation is psychology, and there has been a considerable amount of research on the development of concepts of number in young children. Although the questions are often framed in terms of the concept of set, it is not clear that that is essential or that ontology is at all

central to the formulation of the problems. It can be argued that mathematical ontology only arises at a more advanced state of the development of mathematical competence than the children investigated have reached.

When one does consider even the mathematics taught in elementary college courses, then what one has to go on is history and the reflection of mathematicians (and sometimes philosophers) on the justification of their claims. That some basic statements and inferences are rationally evident seems an inescapable assumption. Examples would be simple logical inferences and the most elementary axioms of set theory, such as the pairing axiom. It does not mean that this evidence does not get crucial reinforcement from the development of theories based on these evident starting points or that the latter can never be revised in the light of the further development of knowledge. Other assumptions might become evident when an edifice of knowledge has been built up; that might be true of higher-level set-theoretic axioms such as power set and choice. What possible explanations of rational evidence would count as naturalistic is a question that has not been much explored. But now any grounds for holding that no acceptable explanation is possible would have to rely on *a priori* presuppositions.

A less abstract and perhaps more interesting epistemological question arises particularly for higher set theory. It is suggested by the indispensability argument mentioned earlier. Whatever one thinks of rational evidence in general, it is already diminished when one reaches the usual axioms for the mathematics applied in science, as is indicated by the issues about the law of excluded middle raised by Brouwer, and those about impredicativity raised by Poincaré (1908) and Weyl (1918, 1919). However, a long history of successful application convinces one, for example, that the classical mathematics of the continuum is necessary for science and at least as well established as basic physics itself. This is the claim made by the indispensability argument, and it had been suggested earlier by Bertrand Russell and then Gödel that axioms could derive their evident character from the theory they give rise to. Among the applications of mathematics, however, are those within mathematics. Gödel's view apparently was that much of mathematics (including some higher set theory) could be seen to be evident in an *a priori* way, not contaminated by evidence derived from application in empirical science. However, particularly in higher set theory axioms could obtain additional justification through the theories constructed on their basis, and such justification would be possible for stronger axioms, such as the stronger large cardinal

axioms that have been proposed, where a convincing intrinsic justification is not available.

Gödel's view and the indispensability argument have in common that the justification of mathematical axioms can rest at least to a certain degree on their consequences. However, for Gödel this is compatible with the status of mathematics as rational knowledge independent of experience, whereas for the main proponents of the indispensability argument, Quine and Putnam (1971), it is not. The indispensability argument clearly runs out before higher set theory. Empirical science makes no use of it, and indeed it has been argued that from the proof theorist's point of view the mathematical theories that are applied in science are weak.

Since few are satisfied with intrinsic justifications for the strongest axioms of infinity, and little such justification is claimed for determinacy axioms, the accepted solution to the classical problems of descriptive set theory rests on assumptions whose justification depends on the theory they give rise to (see Martin 1998). The same would have to be admitted for any solution to the continuum problem that can be expected in the foreseeable future.

#### §14. HISTORICAL STUDIES

Practically every aspect of the history of the foundations of mathematics has seen some intensive scholarly study in the period since 1967. With respect to Immanuel Kant, a decisive development was Michael Friedman's *Kant and the Exact Sciences* (1992), which integrated Kant's philosophy of mathematics with his philosophy of physics and gave the strongest version of the logical view of the role of intuition in mathematics pioneered by Evert Willem Beth (1959) and Jaakko Hintikka (1974). Younger scholars have followed up Friedman's work, often criticizing aspects of it. In particular they have explored the relation of Kant's thought about mathematics to the mathematics of his own time and earlier and to the philosophy of his immediate predecessors.

One strand of work on Frege, of which Boolos and Heck (see Demopoulos 1995) have been the leaders, has worked out perspicuously the mathematical content of Frege's work, particularly in *Grundgesetze*. Another strand has emphasized his conception of logic and how it differs from our own conception of logic. A third has drawn connections of Frege to nineteenth-century developments in mathematics, particularly geometry.

The foundations of mathematics as an object of special study arose from the revolution in mathematics in

the nineteenth century, particularly developments in its second half: the rigorization of the methods of analysis, the beginning of set theory and of abstract methods, the rise of modern logic, and the role assumed early in the twentieth century by the paradoxes. Every aspect of this development has been the subject of scholarly study. The same holds of later developments such as Russell's logic, Brouwer's intuitionism, the Hilbert program, and the work of the Vienna Circle. Space does not permit describing this work, but in the bibliography selective references have been given.

## Bibliography

### TEXTBOOKS

- Boolos, George, John P. Burgess, and Richard C. Jeffrey. *Computability and Logic*. 4th ed. New York: Cambridge University Press, 2002. The first edition of this book (by Boolos and Jeffrey) was published in 1974.
- Enderton, Herbert B. *A Mathematical Introduction to Logic*. 2nd ed. San Diego: Harcourt/Academic Press, 2001. The first edition of this book was published in 1972.
- George, Alexander, and Daniel J. Velleman. *Philosophies of Mathematics*. Oxford, U.K.: Blackwell, 2002.
- Shapiro, Stewart. *Thinking about Mathematics*. New York: Oxford University Press, 2000.
- Shoenfield, Joseph R. *Mathematical Logic*. Reading, MA: Addison-Wesley, 1967. Reprinted Urbana, IL: Association for Symbolic Logic, 2001.

### COLLECTIONS OF PAPERS

- Benacerraf, Paul, and Hilary Putnam, eds. *Philosophy of Mathematics: Selected Readings*. 2nd ed. (with revised selection). Cambridge, U.K.: Cambridge University Press, 1983.

- Ewald, William, ed. *From Kant to Hilbert: A Source Book in the Foundations of Mathematics*. 2 vols. Oxford, U.K.: Clarendon Press, 1996.
- Gödel, Kurt. *Collected Works*, 5 vols. Edited by Solomon Feferman et al. New York: Oxford University Press, 1986–2003. Vol. I, *Publications 1929–1936*, 1986. Vol. II, *Publications 1938–1974*, 1990. Vol. III, *Unpublished Essays and Lectures*, 1995. Volumes IV and V, *Correspondence*, Oxford: Clarendon Press, 2003.
- Hart, W. D., ed. *The Philosophy of Mathematics*. New York: Oxford University Press, 1996.
- Shapiro, Stewart, ed. *The Oxford Handbook of Philosophy and Mathematics and Logic*. New York: Oxford University Press, 2005.
- Van Heijenoort, Jean, ed. *From Frege to Gödel: A Source Book in Mathematical Logic, 1879–1931*. Cambridge, MA: Harvard University Press, 1967.

### §1. The Axiomatic Method

#### 1.1. Axiomatization

- Beth, Evert Willem. *The Foundations of Mathematics: A Study in the Philosophy of Science*. Amsterdam, Netherlands: North-Holland, 1959. Parts II and III.
- Euclid. *The Thirteen Books of Euclid's Elements*, 3 vols. 2nd ed. Translated by Thomas L. Heath. New York: Dover, 1956. The first edition of this book was published in 1908.

#### 1.2. The abstract viewpoint

- Hilbert, David. *Grundlagen der Geometrie*. 10th ed. Stuttgart, Germany: Teubner, 1968. Translated as *Foundations of Geometry* (Chicago: Open Court, 1971). The first German-language edition of this book was published in 1899.
- Tarski, Alfred. "What Is Elementary Geometry?" In *The Axiomatic Method*, edited by Leon Henkin, Patrick Suppes, and Alfred Tarski. Amsterdam, Netherlands: North-Holland, 1959.

#### 1.3. Formalization

- Church, Alonzo. *Introduction to Mathematical Logic*. Princeton, NJ: Princeton University Press, 1956.
- Hilbert, David, and Paul Bernays. *Grundlagen der Mathematik*, 2 vols. 2nd ed. Berlin: Springer, 1968–1970. The first edition of this book was published in 1934–1939.
- Kleene, Stephen Cole. *Introduction to Metamathematics*. New York: Van Nostrand, 1952.
- Tarski, Alfred. *Introduction to Logic*. New York: Oxford University Press, 1941.

### §2. Epistemological Discussion

#### 2.2 Mathematics and logic

- Frege, Gottlob. *Grundgesetze der Arithmetik*, 2 vols. Hildesheim, Germany: Olms, 1962. Partly translated by Montgomery Furth as *The Basic Laws of Arithmetic: Exposition of the System* (Berkeley: University of California Press, 1964). The first German-language edition of this book was published in 1893. Vol. 2, 1903.
- Frege, Gottlob. *Die Grundlagen der Arithmetik*. Edited by Christian Thiel. Hamburg, Germany: Meiner, 1986. Translated by J. L. Austin as *The Foundations of Arithmetic: A Logico-mathematical Enquiry into the Concept of Number*. 2nd ed. (Oxford, U.K.: Blackwell, 1953). The first German-language edition of this book was published in 1884.

Russell, Bertrand. *Introduction to Mathematical Philosophy*. London: Allen and Unwin, 1919.

Russell, Bertrand. *The Principles of Mathematics*. 2nd ed. London: Allen and Unwin, 1937. The first edition of this book was published in 1903.

Whitehead, A. N., and Bertrand Russell. *Principia Mathematica*, 3 vols. 2nd ed. Cambridge, U.K.: Cambridge University Press, 1925–1927.

#### 2.4. Axioms of arithmetic

Dedekind, Richard. *Was sind und was sollen die Zahlen?* 3rd ed. Braunschweig, Germany: Vieweg, 1911. The first edition of this book was published in 1888. Translation in Ewald.

George and Velleman, above.

Hilbert and Bernays, above.

Kleene, *Introduction*, above.

Peano, Giuseppe. *Arithmetices principia nova methodo exposita*. Turin, Italy: Bocca, 1889. Translation in van Heijenoort.

Waismann, Friedrich. *Introduction to Mathematical Thinking*. New York: Ungar, 1951.

#### 2.5 The concept of class (set)

Benacerraf and Putnam, above. Papers in part IV of 2nd ed. on the concept of set.

Cantor, Georg. *Contributions to the Founding of the Theory of Transfinite Numbers*. Chicago: Open Court, 1915. Translation of papers written from 1895 to 1897.

Cantor, Georg. “Foundations of a General Theory of Manifolds.” In Ewald 1996. (With some other short texts.) Translation of a paper of 1883.

Cantor, Georg. *Gesammelte Abhandlungen*. Edited by Ernst Zermelo. Hildesheim, Germany: Olms, 1962. The first publication of this book was in 1932.

Fraenkel, A. A., Yehoshua Bar-Hillel, and Azriel Lévy. *Foundations of Set Theory*. 2nd ed. Amsterdam: North-Holland, 1973.

Gödel, Kurt. “The Present Situation in the Foundations of Mathematics.” In Gödel 1986–2003, Vol. III, 45–53.

#### 2.6 Frege’s analysis of number

Frege, Gottlob. *Begriffsschrift*. Hildesheim, Germany: Olms, 1964. The first publication of this book was in 1879. Translation in van Heijenoort.

Frege, Gottlob. *The Foundations of Arithmetic*, above.

Frege, Gottlob. *Grundgesetze der Arithmetik*, above.

George and Velleman, chapter 2.

#### 2.7. Difficulties in logicism

Carnap, Rudolf. “Die logizistische Grundlegung der Mathematik.” *Erkenntnis* 2 (1931): 91–105. Translation in Benacerraf and Putnam.

Poincaré, Henri. *Science et méthode*. Paris: Flammarion, 1908. Translated by Francis Maitland as *Science and Method* (New York: Nelson, 1914).

Wittgenstein, Ludwig. *Remarks on the Foundations of Mathematics*. Rev. ed. Translated by G. E. M. Anscombe. Edited by G. H. von Wright, R. Rhees, and G. E. M. Anscombe. Cambridge, MA: MIT Press, 1978.

#### 2.8 Kant’s view

Kant, Immanuel. *Kritik der reinen Vernunft*. Riga, Russia: N.p., 1781. Translated by Paul Guyer and Allen W. Wood as *Critique of Pure Reason* (New York: Cambridge University Press, 1998). See especially Introduction (in 2d ed.),

Transcendental Aesthetic, Axioms of Intuition, and Discipline of Pure Reason in Dogmatic Use.

Kant, Immanuel. “Untersuchung über die Deutlichkeit der Grundsätze der natürlichen Theologie und der Moral” (1764). In *Gesammelte Schriften*, Vol. 2, 272–301. Berlin: G. Reimer, 1902. Translated by David Walford in *Theoretical Philosophy, 1755–1770* (New York: Cambridge University Press, 1992).

#### 2.9 Conventionalism

Carnap, Rudolf. *Logische Syntax der Sprache*. Vienna, Austria: Springer, 1934. Translated as *Logical Syntax of Language* (London: Routledge and Kegan Paul, 1937).

Carnap, Rudolf. *Meaning and Necessity*. 2nd ed. Chicago: University of Chicago Press, 1956.

Gödel, Kurt. “Is Mathematics Syntax of Language?” In Gödel 1986–2003, Vol. III, 334–362. The introduction by Warren Goldfarb (324–334) questions the interpretation of Carnap as a conventionalist.

Quine, W. V. “Carnap and Logical Truth” (1960). In *The Ways of Paradox and Other Essays*. 2nd ed. Cambridge, MA: Harvard University Press, 1976.

Quine, W. V. “Truth by Convention” (1936). In *The Ways of Paradox and Other Essays*. 2nd ed. Cambridge, MA: Harvard University Press, 1976.

Wittgenstein, Ludwig. *Lectures on the Foundations of Mathematics, Cambridge, 1939*. Edited by Cora Diamond. Ithaca, NY: Cornell University Press, 1976.

Wittgenstein, Ludwig. *Philosophical Investigations*. 2nd ed. Translated by G. E. M. Anscombe. Oxford, U.K.: Blackwell, 1958.

Wittgenstein, Ludwig. *Remarks on the Foundations of Mathematics*, above.

### §3. Platonism and Constructivism

#### 3.1. Platonism

Bernays, Paul. “Sur le platonisme dans les mathématiques.” *L’enseignement mathématique* 34 (1935): 52–69. Translation in Benacerraf and Putnam.

Church, Alonzo. “Comparison of Russell’s Solution of the Semantical Antinomies with That of Tarski.” *Journal of Symbolic Logic* 41 (1976), 747–760. Gives a precise formulation of the ramified theory of types, taking account, as §3.1.3 does not, of its intensional aspect.

Feferman, Solomon. “Systems of Predicative Analysis.” *Journal of Symbolic Logic* 29 (1964): 1–30. Part 1 surveys work on predicativity up to 1963.

Gödel, Kurt. “Russell’s Mathematical Logic” (1944). In Gödel 1986–2003, Vol. II, 119–141.

Gödel, Kurt. “What Is Cantor’s Continuum Problem?” (1947, 1964), In Gödel 1986–2003, Vol. II, 254–270.

Russell, Bertrand. “Mathematical Logic as Based on the Theory of Types” (1908). In *Logic and Knowledge: Essays 1901–1950*, edited by Robert Charles Marsh. New York: Macmillan, 1956.

Weyl, Hermann. “Der *circulus vitiosus* in der heutigen Begründung der Analysis.” *Jahresbericht der Deutschen Mathematiker-Vereinigung* 28 (1919): 85–92. Translated as appendix to *The Continuum*.

Weyl, Hermann. *Das Kontinuum*. Leipzig, Germany: Veit, 1918. Translated as *The Continuum* (Kirksville, MO: Thomas Jefferson University Press, 1987).

### §3.2 Constructivism

- Gödel, Kurt. "Über eine bisher noch nicht benützte Erweiterung des finiten Standpunktes." *Dialectica* 12 (1958): 280–287. Translated in Gödel 1986–2003, Vol. II, 240–251. Note also the expanded English version (1972) in the same volume.
- Heyting, Arend. *Intuitionism: An Introduction*. Amsterdam, Netherlands: North-Holland, 1956.
- Hilbert, David. "Die Grundlagen der Mathematik." *Abhandlungen aus dem mathematischen Seminar der Hamburgischen Universität* 6 (1928): 65–85. Translation in van Heijenoort.
- Hilbert, David. "Über das Unendliche." *Mathematische Annalen* 95 (1926): 161–190. Translation in van Heijenoort.
- Hilbert and Bernays, above.
- Tait, W. W. "Finitism." In *The Provenance of Pure Reason*. New York: Oxford University Press, 2005. This article originally appeared in the *Journal of Philosophy* (1981).
- Troelstra, A. S. *Principles of Intuitionism*. Berlin: Springer, 1969.
- Weyl, Hermann. *Philosophy of Mathematics and Natural Science*. Princeton, NJ: Princeton University Press, 1949.

#### 4.1. Gödel's incompleteness theorems

- Gödel, Kurt. "Über formal unentscheidbare Sätze der Principia Mathematica und verwandter Systeme I." *Monatshefte für Mathematik und Physik* 38 (1931): 173–198. Translated in Gödel 1986–2003, Vol. I, 144–195.
- Smullyan, Raymond M. *Gödel's Incompleteness Theorems*. New York: Oxford University Press, 1992.
- Gödel's incompleteness theorem is treated in each of the general works on mathematical logic cited above and in many other works.

#### 4.2. Recursive function theory

- Kleene, *Introduction*, above.
- Rogers, Hartley, Jr. *Theory of Recursive Functions and Effective Computability*. New York: McGraw-Hill, 1967.

#### 4.3. Development of the Hilbert program

- Gentzen, Gerhard. *Collected Papers*. Edited by M. E. Szabo. Amsterdam, Netherlands: North-Holland, 1969.
- Gentzen, Gerhard. "Die Widerspruchsfreiheit der reinen Zahlentheorie." *Mathematische Annalen* 112 (1936): 493–565. Translated in Gentzen 1969.
- Gödel, Kurt. "Zur intuitionistischen Arithmetik und Zahlentheorie." *Ergebnisse eines mathematischen Kolloquiums* 4 (1933): 34–38. Translated in Gödel 1986–2003, Vol. I, 286–295.
- Kreisel, Georg. "Hilbert's Programme." *Dialectica* 12 (1958): 346–372.

## MATHER, COTTON (1663–1728)

Cotton Mather, scholar, clergyman, and author, was the oldest son of Increase Mather, one of the leading figures in the Puritan theocracy in Massachusetts. The younger Mather was so precocious that he entered Harvard College at the age of twelve and was graduated at fifteen. Because he stammered, he felt unqualified to preach and therefore began to study medicine. After a few years, however, he overcame his speech handicap and became the assistant to his father at the Second Church, Boston. Ordained in 1685, he remained in the service of the Second Church for the rest of his life.

Mather was disappointed in many of the major quests of his life. Partly because he associated himself politically with the unpopular royal governor, Sir William Phips, partly because of the diminished prestige of the Puritan clergy, and partly because of his own often unpleasant personal qualities he lost the power to wield significant influence in public affairs. When he greatly desired to succeed his father, who retired in 1701 as president of Harvard College, he was not selected. Convinced that Harvard no longer represented the true Calvinist

faith, he threw himself energetically into the foundation of Yale College, but its presidency was not offered to him until 1721, when he declined the position because of his age.

Mather's intellectual attitudes during his earlier years were extremely narrow, for he moved within the confines of a strict Puritan worldview; later, however, he became more tolerant of the differing beliefs of others. Finally, especially in his *Christian Philosopher* (1721), he moved close to the natural religion characteristic of the Age of Reason. He interpreted the theological doctrine of divine Providence in philosophical terms by asserting that the order of the universe was planned for man's good by an all-wise, all-good God. Man's appreciation of natural Beauty and his application of reason to observations drawn from nature are sufficient to prove the existence and beneficence of God. His scientific communications to the Royal Society of London led to his election as a fellow in 1713, one of the first Americans to be so honored. He was one of the earliest in the colonies to advocate inoculation against smallpox, and he ably defended his position in several pamphlets. The change in his mental attitude thus epitomizes the alteration in the intellectual life that pervaded his milieu.

Nowhere is this duality more apparent than in Mather's involvement in the witchcraft epidemic in Salem. He attempted to make a "scientific" study of the cases, but he came to the conclusion that they could be treated by prayer and fasting. He warned the judges in witchcraft trials to proceed very cautiously against the suspects and to be particularly careful in admitting "spectral evidence," yet in his *Wonders of the Invisible World* (1693) he argued that the verdicts in the Salem trials were justified. By 1700, however, he changed his mind about the fairness of the trials. In regard to the suspicion of witchcraft, as in other respects, Mather stood uneasily between traditional faith and the new scientific outlook.

### **Bibliography**

Mather's most important works (of more than 450 published) are *Magnalia Christi Americana, or the Ecclesiastical History of New England* (London, 1702); *Essays to Do Good* (Boston, 1710; originally titled *Bonifacius*, Boston, 1710); and *Christian Philosopher* (London: E. Matthews, 1721). Kenneth B. Murdock has edited, with introduction and notes, *Selections from Cotton Mather* (New York: Harcourt Brace, 1926; new ed., 1960).

Discussion of Mather may be found in Ralph P. and Louise Boas, *Cotton Mather, Keeper of the Puritan Conscience* (New

York and London: Harper, 1928); Barrett Wendell, *Cotton Mather, the Puritan Priest* (New York: Dodd Mead, 1891; new ed., with introduction by Alan Heimert, New York: Harcourt Brace, 1963); and Otho T. Beall and Richard Shryock, *Cotton Mather, First Significant Figure in American Medicine* (Baltimore: Johns Hopkins Press, 1954).

## MATTER

The term “matter” and its cognates (“material,” “materialist,” “materialistic,” and the like) have played active parts in philosophical debate throughout intellectual history. Natural philosophers have studied material objects and contrasted them with such immaterial agencies as energy and fields of force; metaphysicians and mathematical philosophers have distinguished the material or tangible aspects of things from their formal or intangible aspects, their physical properties from their geometrical ones. Again, the terms “matter” and “material” have played a humble part not only in science but also in moral philosophy and even theology. Matter has thus been placed in opposition to life and mind, soul and spirit, and a preoccupation with worldly pleasures and bodily comforts, as opposed to the “higher” pleasures of the mind, has been condemned as “materialistic” and unworthy of spiritual beings. In thinking about matter, accordingly, the question of how far—if at all—these various distinctions can

actually be justified and reconciled must always be borne in mind.

This question immediately poses a historical problem, for ideas about matter have not been static. On the contrary, they have been subject to continual development, and it is highly doubtful whether one can isolate a single concept of matter shared by, say, Anaximander and Thomas Aquinas, Democritus and René Descartes, Epicurus and Albert Einstein. Thus, for instance, a seventeenth-century philosophical thesis about the relations between mind and matter must be interpreted in relation to seventeenth-century ideas about physics and chemistry. Such a thesis can be transplanted into the intellectual environment of the twentieth century only by taking into account changes in the fundamental concepts of science during the intervening years. We must therefore consider how the concept of matter has been progressively refined and modified in the course of intellectual history.

### GREEK PHILOSOPHY

As far as we can judge from the surviving texts and the testimony of Aristotle, the idea of a constituent or material ingredient (*hyle*) common to things of all kinds was a central concept of the Ionian school of philosophy. The Ionian philosophers, beginning with Thales of Miletus, disagreed about the nature of this common ingredient. Some likened it to water, others to air or breath, others to fire; some insisted that it could have no properties analogous to those of any familiar substance but must be entirely undifferentiated or unlimited. Yet they agreed, at any rate, in their statement of the basic philosophical problem: “What universal, permanent substance underlies the variety and change of the physical world?”

It would be a mistake, however, to think of the Ionians as materialists in the modern sense. As they conceived it, the universal material of things was far from being brute, inorganic, passive, mindless stuff intrinsically devoid of all higher properties or capabilities. Water, for instance, was, for them, not a sterile, inorganic chemical but a fertilizing fluid, and in their system it was quite open to consideration whether the basic stuff of the world might not be provided by either spirit (*pneuma*) or mind (*nous*). At this initial stage in philosophical speculation, indeed, the questions preoccupying philosophers cut across many of the distinctions that later generations were to treat as fundamental.

We first find these distinctions being drawn explicitly and insisted on by the Athenian philosophers, following the examples of Plato and Aristotle. For instance, Plato

and his fellow mathematicians at the Academy explained the properties of homogeneous material substances in one way, those of organized, functional systems in another. Like the Sicilian philosopher Empedocles, they classified material substances into four contrasted states or kinds—solid (earth), aeriform (air), liquid (water), and fiery (fire)—but they added a novel mathematical theory to account for the contrasted properties of these four kinds of substance. Each kind, they supposed, had atoms of a distinct geometrical shape, and they hypothetically identified these shapes with four of the five regular convex solids—tetrahedron, cube, octahedron, and icosahedron—whose mathematical properties had been studied by Plato’s associate Theaetetus. (The fifth solid, the dodecahedron, they associated with the twelve constellations of the outer heavens.) The characteristic properties of organisms, on the other hand, they explained in functional rather than material terms. The form of any bodily organ must be accounted for as reflecting its role in the life of the organism; this form should be thought of as created specifically to perform a particular function as effectively as the available materials permitted.

Aristotle went further. He distinguished sharply between the material substance of which an object was composed and the form imposed on it, and he questioned whether the characteristic properties of any substance or system could be usefully explained in either atomistic or geometrical terms. In order to understand the properties and behavior of any individual object, it was first necessary to recognize it as an object of a particular kind. Each kind of object existing in nature had properties determined by its own special form or essence, so that any universal primary stuff (*hyle*) must be devoid of any particular distinguishing characteristic. For Aristotle and his followers the problem of distinguishing substances became primarily a matter of taxonomy, of qualitative classification, rather than a quantitative, physicochemical problem. Weight, from this point of view, was just one possible quality among others. Aristotle’s views went beyond those of Plato in one other respect that was to have profound implications for cosmology. He drew a clear distinction between the sublunary world, whose objects were composed of the four terrestrial elements—earth, air, fire, and water—and could be created and destroyed, and the superlunary or celestial world of the outer heavens, whose inhabitants were composed of the quintessence (fifth essence) and exempted from change and decay. Of all terrestrial things only the souls of rational beings in any way shared this immutability.

## LATER CLASSICAL AND MEDIEVAL PERIODS

Subsequent philosophers—whether in Hellenistic Alexandria (200 BCE–550 CE), the Islamic centers of learning (650–1150), or the newly founded universities of western Europe (950–1500)—introduced a number of variations into the debate about matter without adding any fundamentally new themes. For both the Stoics and the Epicureans, ideas about matter were closely associated with religious beliefs. Epicurus and his followers—notably, the Roman poet Lucretius—developed the more fragmentary speculations of Democritus and Leucippus about the atomic structure of matter into a complete philosophical system. But the atoms of the Greek philosophers differed from those of nineteenth-century European science in three crucial respects. First, they had an indefinitely large range of sizes and shapes instead of a limited number of fixed forms, one for each chemical “element.” Next, they interacted only by direct contact or impact rather than by exerting forces of attraction or repulsion on one another. And, finally, they existed in special varieties—atoms of magnetism, of life, of mind, and of soul—to explain all sorts of activities—physical, biological, psychological, and even spiritual. The collisions and conjunctions of these atoms were regarded by Epicurus as an autonomous physical process, for his fundamental aim was to attack any belief in external interference by divine agencies in the affairs of the natural world.

The Stoics, such as Zeno of Citium and Chrysippus, rejected atoms in favor of three kinds of continuous physical medium or spirit (*pneuma*) for both scientific and religious purposes. The *pneuma* was an integrative agency, analogous to a field of force, capable of maintaining a stable pattern of properties and behavior in a physical system; in addition, it was capable of existing in separation from the solid and liquid frame of the “body” and could probably be identified with the soul. Instead of rejecting the traditional deities, like the Epicureans, the Stoics reinterpreted them as incorporeal agencies comparable to the *pneuma*. Yet though the Stoics and the Epicureans differed about many things, they agreed that every agency capable of producing physical effects—even the mind—must be regarded as a material body (*soma*). As a result for Lucretius pure mind was composed of very smooth and mobile atoms; for Chrysippus it consisted of undiluted fire.

The alchemical philosophers, for their part, introduced an experimental element into the study of matter. Beginning with the Democritean Bolos of Mendes (c. 200

BCE), going on through Maria the Jewess and Zozimos of Alexandria (second and third centuries CE), the alchemists exploited the traditional craft techniques of the Middle Eastern metallurgists, dyers, and jewelers and attempted to find ways of separating and isolating the essences or spirits in things. In this way they were led to contrast volatile and chemically active substances, such as alcohol and ether (spirits), with solid and passive ones, such as earths and *calces* (bodies). The association of the soul and the body in living creatures was thus treated as analogous to the association of volatile and gaseous with solid and earthy substances in a chemical compound. When freed from this association, incorporeal spirits naturally tended to rise toward the heavens and corporeal bodies to sink to the earth, a fact that apparently harmonized with the traditional Aristotelian contrast between the celestial and terrestrial worlds.

Nevertheless, philosophers and theologians in the strictly orthodox Aristotelian tradition rejected Stoic, Epicurean, and alchemical ideas as being excessively materialistic. In their view the soul was not in any way a subject for chemical or quasi-chemical speculation. The forms or essences of things were not themselves composed of any material stuff, even of the highly tenuous kinds conceived by the Stoics and alchemists. Accordingly, for Thomas Aquinas and the other philosophers of the high Middle Ages, the relation between matter and form was a problem in metaphysics or theology rather than one in natural philosophy.

#### NEW THEORIES: 1550–1750

Thus, the revival of the physical sciences during the Renaissance started from a position in which no single doctrine about the nature of matter was clearly established and generally accepted. All supporters of the new mechanical philosophy were attracted to an atomistic or corpuscular view of matter, but most of them took care to dissociate themselves from the original atomistic doctrines of Democritus and Epicurus, which were still suspected of having atheistical implications. Thus, Johannes Kepler explained the crystalline structure of snowflakes by reference to a geometrical theory of atoms modeled on that of Plato, Galileo Galilei embraced atomism as a physical embodiment for the points of geometry, and Descartes treated all matter as corpuscular in structure, at the same time denying the theoretical possibility of a void or vacuum. All of them regarded such mechanical interactions as collisions as the basic model for physical processes and sought to build up a theory of forces

(dynamics) capable of explaining the established generalizations about the motions of physical objects.

However, attempts to work out an effective and comprehensive system of physical theory without going beyond the categories of atomism inherited from the Greeks encountered a number of difficulties. These sprang ultimately from the dual axiom that any agency capable of producing physical effects must be composed of a corresponding type of material object and that these objects could influence one another only by direct mechanical action, which required that the bodies be in contact. To deny the first half of this axiom implied accepting the notion of nonmaterial physical agencies; to deny the second implied accepting action at a distance. Both these notions were widely rejected as being incompatible with sound natural philosophy.

The immediate outcome of this dual axiom was to commit the advocates of the new mechanical corpuscular philosophy to a proliferation of new kinds of atom—for instance, magnetic, calorific, and frigorific corpuscles—introduced to account for the corresponding physical phenomena of magnetism, heat, cold, and so on. Although some philosophers, including Descartes, saw the possibility of cutting down the types of atoms—for example, by explaining heat as a consequence of the internal agitation of the material atoms composing hot bodies—even Descartes felt bound to accept that light, magnetism, and the like were carried by subtle fluids made up of corpuscles of insensible weight. Matter, he declared, came in three kinds, of which only “third matter” was subject to gravity and thus had any weight.

An indirect but even more profound outcome of the corpuscularian axiom was to support Descartes’s fundamental division between mind and matter as absolutely distinct substances. The least plausible element in traditional atomism had been its psychology. Christian theology had added its own objections to any explanation of mental activity that regarded the mind as composed of atoms, no matter how light or mobile, for this, it was generally agreed, came perilously close to denying the immortality of the soul. The new physical science of the seventeenth and eighteenth centuries accordingly limited its aim. The realm of nature consisted of material bodies interacting mechanically by contact and impact and could be studied by science. The realm of spirit—including, at least, the intellectual activities of human beings—was a distinct and separate object of speculation to which the categories of physical science were not directly relevant. Much of the debate in subsequent epistemology can be traced to this point.

Accordingly, for two hundred years beginning around 1700, the concept of matter kept a central place in physical theory but was set aside as irrelevant to the study of mind. In physics the first major break with traditional ideas came through the work of Sir Isaac Newton. By his theories of dynamics and gravitation, Newton established a sharp distinction between material objects in a strict sense, whose mass conferred on them both inertia and weight, and forces, which were a measure of the way in which material objects interacted rather than a special kind of material thing. In the case of gravity, as he showed in his *Philosophiae Naturalis Principia Mathematica* (1687), these forces had to be supposed capable of acting over distances of many million miles, though Newton himself was inclined to believe that some invisible mechanical link existed by which the sun, for instance, exerted its gravitational action on the planets. In the later editions of his *Opticks* (especially those published after Gottfried Wilhelm Leibniz's death in 1716) he extended this idea to explain other physical phenomena. Electrical, magnetic, and chemical action also, he argued, might prove to be manifestations of forces of attraction and repulsion acting across the spaces between the massive corpuscles of bodies. Thus, the traditional system of atoms and the void was amended to become a theory of material corpuscles interacting by centrally directed forces.

### CLASSICAL PHYSICS

Newton's program for natural philosophy made its way only slowly to begin with, but it met with no grave check until the late nineteenth century. At first, his insistence on mass as the essential property of matter was not found universally convincing. Others continued to regard extension, impenetrability, weight, or the capacity to produce physical effects as the indispensable criterion. As a result, throughout the eighteenth century there was an element of cross-purposes in debates about the corporeal nature of, for example, light and fire. Two developments particularly helped to clarify the intellectual situation and established the Newtonian categories as the basis of physical science. First, Antoine Lavoisier and his followers—notably, John Dalton—demonstrated that the phenomena of chemistry as well as those of physics could be unraveled on the assumption that all genuine material substances possessed mass and were composed of corpuscles or atoms. Second, the mathematical work of Leonhard Euler and his successors transformed Newton's account of forces of attraction and repulsion into the modern theory of fields of force.

After 1800, then, physical scientists went ahead rapidly with the experimental and mathematical work that culminated in the so-called classical physics and chemistry of the late nineteenth century. In this system the agents responsible for physical action were divided into two sharply contrasted categories. On the one hand, there was matter; this consisted of massive atoms that combined to form molecules in accordance with the principles of chemical combination. The mechanical energy associated with the motion of the molecules within any body accounted for its temperature; the fields of force between them explained gravitational, electric, and magnetic attraction and repulsion. On the other hand, there were those agencies—such as light and radiant heat—that apparently lacked both mass and weight and that were transmitted in the form of waves across the empty space between the material atoms. Gravitation apart, these various agencies turned out, as was shown by James Clerk Maxwell's electromagnetic theory of light, to be all of one general kind. By combining the established theories of the electrical and magnetic fields of force into a single mathematical system having the same degree of generality as Newton's dynamics, Maxwell demonstrated that electromagnetic waves would share the known properties of light and radiant heat and would move across space with the same velocity that had actually been measured in the case of light. This interpretation gained greatly in strength when Heinrich Hertz used an intermittent electrical spark to produce artificial electromagnetic waves, the so-called radio waves.

Though devoid of mass, these various forms of radiation nevertheless carried energy. Numerically, the sum total of all forms of energy in any isolated system (like the sum total of the masses of all the material bodies involved) was apparently conserved unchanged throughout all physical and chemical changes. As a result it seemed for several decades that the whole of natural philosophy could successfully be built on the central distinction between matter and energy and on the two independent axioms of the conservation of mass and the conservation of energy. Thus, Newton's program for physical science came close to being finally fulfilled in classical physics and chemistry.

### TWENTIETH-CENTURY RECONSIDERATIONS

This intellectual equilibrium was short-lived. As Sir John Squire put it:

Nature and all her Laws lay hid in Night.  
God said "Let Newton be, and all was Light."

It could not last. The Devil, shouting “Ho! Let Einstein be,” restored the *status quo*.

To do Einstein justice, the difficulties in the classical system that he resolved had been considered residual embarrassments for some time, and many of the conceptual changes for which he argued have since established themselves as indispensable features of physical theory. Still, they did undoubtedly have the effect of blurring the sharp distinctions and tidy certitudes of nineteenth-century science.

The effect of these conceptual changes on our concept of matter has been profound. Physicists have been compelled to reconsider and modify all the fundamental planks in the program enunciated for natural science by the mechanical philosophers of the seventeenth century. To begin with, Einstein displaced the seventeenth-century model of mechanical action as the universal pattern for intelligible physical processes by a new model based on electromagnetic theory. The embarrassments facing physicists in the 1890s arose, he showed, from a mathematical conflict between Maxwell’s theory of electromagnetism and the mechanics of Galileo and Newton. Einstein circumvented these difficulties in his theory of relativity by giving priority to the theory of electromagnetic fields and by amending the principles of Newtonian mechanics to conform to the Maxwellian pattern. As a result the attitudes of a representative late nineteenth-century physicist, such as William Thomson, Lord Kelvin (who declined to accept Maxwell’s theories, declaring that he could embrace a physical explanation of a phenomenon wholeheartedly only if he could make a mechanical model to demonstrate it), have since come to seem excessively narrow.

As a result of this initial change, however, certain other fundamental elements in classical physics have had to be called in question. The absolute distinction between matter and energy, for instance, has gone by the board. It now appears that any quantity of energy ( $E$ ) is in certain respects equivalent to a proportional quantity of mass ( $m = E/c^2$ , where  $c$  is Maxwell’s constant, equal to the measured velocity of electromagnetic radiation); that for theoretical purposes the twin conservation principles of nineteenth-century physics and chemistry should be joined in a single axiom, according to which the sum total of energy and mass (combined according to the formula  $E + mc^2$ ) was conserved in all physical processes; and that in appropriate circumstances a quantity of electromagnetic energy can be transformed into the corresponding quantity of matter or vice versa. This implication was confirmed in the 1930s from a detailed study of individ-

ual actions between atomic nuclei and other particles, and it was dramatically reinforced by the explosion of the first atomic bombs, whose energy was derived from the marginal loss of mass involved in the nuclear fission of such heavy elements as uranium.

Meanwhile, the earlier contrast between matter, which was assumed to exist in discrete atomic units, and radiation, which traveled in the form of continuous waves, was under criticism for quite different reasons. First, Max Planck showed that bodies exchanged light-energy in the form of bundles or wave-packets. Einstein, going further, argued that electromagnetic energy always existed in the form of these photons. Then, in the early 1920s, Louis de Broglie put forward the idea that the subatomic particles into which Niels Bohr and Ernest Rutherford had analyzed the fundamental material units of earlier chemistry might themselves manifest some of the properties of wave-packets. This was confirmed in 1927, when it was shown that a beam of electrons passed through a crystal lattice produced a diffraction pattern just as a beam of light of the corresponding wavelength and velocity would have done. By the 1960s it began to appear that matter-particles might differ from the energy-packets of light or other kinds of radiation only in having part of their energy frozen in the form of inertial mass.

Finally, the theory of quantum mechanics, first formulated between 1926 and 1932 by Werner Heisenberg, Erwin Schrödinger, and P. A. M. Dirac, has radically undercut one last presupposition, which had underlain physical science since the time of Galileo. From 1600 on, the fundamental units of matter—whether called corpuscles, particles, or atoms—had been regarded as intrinsically brute, inert, and passive. They might be constituted in such a way that they are capable of exerting forces on one another by virtue of their relative motions and positions, but one had to seek the ultimate source of this capacity—as of their motion—in God who created them. (This was one point on which Newton, Descartes, and Maxwell all agreed.) Since 1926 the final unit of analysis in physics has ceased to bear any serious resemblance to these inert corpuscles. Instead, the quantum physicists begin with certain wave functions or eigenfunctions, which characterize the activity of, say, an electron or an atom as much as they do its structure and position. Just as mass has ceased to be entirely distinct from energy, so the particles of Newton’s physics have ceased to be absolutely distinct from the forces of attraction and repulsion acting between them. On the contrary, according to the principles of contemporary physical theory,

every kind of fundamental particle—whether of matter or energy—should be associated with a corresponding mode of interaction and force field. Photons, electrons, mesons, nucleons—all these have a dual aspect, being characterized partly by their inertial mass or intrinsic energy and partly by their pattern of interaction with the environment. One outstanding and at present unsettled question is whether the transmission of gravitational forces, from which the whole notion of a field began, also involves the propagation of particles (“gravitons”) at a finite speed. If it proves that “gravitons” do in fact exist and travel at the same speed as photons, this will tie up one of the more notorious loose ends of mid-twentieth-century physics.

### IMPLICATIONS OF NEW THEORIES

Today almost all the axioms of earlier natural philosophy have been qualified, if not abandoned. Mass has ceased to be the essential, unalterable characteristic of all physical objects and now appears to be one variant of the wider category of energy. No longer can any determinate amount of this energy be localized with absolute precision (Heisenberg’s principle), and we are left with a picture of a natural world whose fundamental elements are not so much passive bricks as units of activity. This transformation—as Samuel Sambursky has argued—involves a reaction against the axioms of seventeenth-century physics as radical as the Stoics’ rejection of the atomism of Epicurus. Indeed, Sambursky points out, there is a strong parallel between the two reactions. As in the Stoic theory, physicists today also consider matter essentially active rather than passive and explain its behavior as the outcome of patterns of energy and excitation associated with any given state or condition.

The full implications of this change for our other ideas are beginning to become apparent only now. In biology, at any rate, a considerable change has come about since 1950 by the extension of physical theories about molecular structure into the fields of genetics, embryology, and bacteriology. Here the intimate association of structure and function characteristic of modern subatomic theory is reproduced in the association of specific biological activities with particular configurations (and, thus, eigenfunctions) of the complex molecules involved. The extensions of the new ideas about matter into the theory of organic development and human behavior are still at a speculative stage.

This much can, however, be said. During the centuries that have elapsed since the revival of natural philosophy at the Renaissance, the concept of matter has

changed its character quite fundamentally. In the present state of scientific thought, accordingly, all earlier questions about, for instance, the relation of matter, life, and mind need to be entirely reconsidered. When, for instance, Descartes classified matter and mind as distinct substances, he was putting the concept of mind and mental activities in opposition to a concept of matter as inert extension, a concept that is now discredited. To that extent the extreme dualism of Descartes’s philosophy has been not so much refuted by later science as made irrelevant; its categories no longer fit our situation.

Similarly, other long-standing debates concerning, for example, the reality of the material world or the relation between material objects and our sensations will need to be reappraised in the light of changes in our concept of matter. But this is a task for the future.

### Bibliography

In general, this article follows the argument of Stephen Toulmin and June Goodfield, *The Architecture of Matter* (London: Harper and Row, 1962), in which the development of the concept of matter is fully analyzed but discussed without serious technicalities. For the various periods covered here the reader is referred to the following works.

#### GREEK PHILOSOPHY

S. Sambursky, *The Physical World of the Greeks* (London: Routledge and Paul, 1956), is an outstanding survey for the general reader. W. K. C. Guthrie, *A History of Greek Philosophy*, Vol. 1 (Cambridge, U.K.: Cambridge University Press, 1962), and G. S. Kirk and J. E. Raven, *The Presocratic Philosophers* (Cambridge, U.K.: Cambridge University Press, 1957), are up-to-date scholarly discussions of the Ionian natural philosophers. F. M. Cornford, *Plato’s Cosmology* (London: K. Paul, Trench, Trubner, 1937), is the most convenient existing version of the *Timaeus*, in which Plato’s views about matter are expounded. J. H. Randall Jr., *Aristotle* (New York: Columbia University Press, 1960), provides an illuminating account of that philosopher’s scientific ideas; it is useful for the nonspecialist.

#### LATER CLASSICAL AND MEDIEVAL PERIOD

S. Sambursky’s *The Physics of the Stoics* (London: Routledge and Paul, 1959) and *The Physical World of Late Antiquity* (London, 1962) complete the story begun in his *Physical World of the Greeks* (see above). Cyril Bailey, *The Greek*

*Atomists and Epicurus* (Oxford, 1928), and A. J. Hopkins, *Alchemy, Child of Greek Philosophy* (New York: Columbia University Press, 1934), are scholarly but readable: Both books remain stimulating and full of interest. E. J. Holmyard, *Alchemy* (London, 1957), and A. C. Crombie, *Medieval and Early Modern Science* (Garden City, NY: Doubleday, 1959), are readable popular surveys.

## NEW THEORIES: 1550–1750

H. T. Pledge, *Science since 1500* (London: H. M. Stationery Office, 1939; reprinted, New York: Harper, 1959), and A. R. Hall, *From Galileo to Newton* (London, 1963), are general histories, both of which include useful material on the new theories. Mary B. Hesse, *Forces and Fields* (Edinburgh, 1961); Marie Boas, *Robert Boyle and Seventeenth Century Chemistry* (Cambridge, U.K.: Cambridge University Press, 1958); Hélène Metzger, *Les doctrines chimiques* (Paris, 1923) and *Newton, Stahl, Boerhaave* (Paris: F. Alcan, 1930); I. Bernard Cohen, *Franklin and Newton* (Philadelphia: American Philosophical Society, 1956); and E. J. Dijksterhuis, *The Mechanization of the World Picture*, translated by C. Dikshoorn (Oxford: Clarendon Press, 1961), are scholarly books dealing in a penetrating way with more detailed aspects of the subject.

## CLASSICAL PHYSICS

Edmund Whittaker, *History of the Theories of Aether and Electricity*, 2 vols. (Edinburgh, 1951–1953), and Mary B. Hesse, *Forces and Fields* (see above), are the best specialist surveys. For the general reader Charles C. Gillispie, *The Edge of Objectivity* (Princeton, NJ: Princeton University Press, 1960), N. R. Campbell, *What Is Science?* (London: Methuen, 1921; reprinted, New York: Dover, 1952), Albert Einstein and Leopold Infeld, *The Evolution of Physics* (New York: Simon and Schuster, 1938), and George Gamow, *Biography of Physics* (New York, 1963), may be selected from many others as being particularly useful.

## TWENTIETH-CENTURY RECONSIDERATIONS

A great many books of general interest have been published about the twentieth-century transformation in physical theory. Apart from Einstein and Infeld, op. cit., and Gamow, op. cit., one of especial merit is Banesh Hoffmann, *The Strange Story of the Quantum* (New York: Harper, 1947). Many of the physicists directly involved have written interestingly about the changes—notably, Werner Heisenberg, *Philosophical Problems of Nuclear Science* (London: Faber, 1952). The analogy between Stoic matter theory and wave mechanics is pursued in Sambursky, *The Physics of the Stoics* (see above).

*Stephen E. Toulmin (1967)*

## MATTHEW OF ACQUASPARTA

(c. 1237–1302)

Matthew of Acquasparta, the Italian Franciscan scholastic philosopher and theologian, was born in Acquasparta, near Todi in Umbria, possibly of the illustrious Benivenghi family. In 1254 he entered the Franciscan order, and about 1268 he began studies at the University of Paris, where he was profoundly influenced by Bonaventure's system. Matthew was lector in the Studium Generale at Bologna (at least for the year 1273–1274), and in 1276 he became master in theology at Paris. From 1279 to 1287, he was lector Sacri Palatii in Rome, succeeding John Peckham. He was general of the order from 1287 to 1289. In 1288 he was made cardinal, and in 1291 he was named bishop of Porto and Santa Rufina. Matthew died at Rome, where he is buried in the church of Ara Coeli.

## DOCTRINE

Matthew taught and wrote during the time of conflict between the Augustinian–Franciscan doctrinal tradition and the rising Thomistic Aristotelianism. In this far-reaching controversy he proved himself to be exceptionally well-versed in Augustine's doctrines and in general a faithful follower of Bonaventure. Although he incorporated a few Aristotelian elements, Matthew's system in its entirety shows that he was among the purest adherents of Augustinianism in the last quarter of the thirteenth century. He had a calm, balanced mind, a sober style, and an exact manner of formulating his ideas. In discussion he was generally modest and perceptive. With these qualities he often achieved, at least in his *Quaestiones Disputatae de Fide et de Cognitione*, a level comparable to that of the greatest thinkers of his age.

In his theory of knowledge Matthew taught that our intellect knows the individual object not only by reflection, as St. Thomas Aquinas held, but also by a direct perception, which precedes the formation of an abstract idea. By virtue of this perception, the intellect forms a *species singularis* of the concrete object with all the richness of detail it possesses in reality. In this way the mind prepares for knowledge of the essence of the object. Similarly, the soul knows its own existence and habits not only by reasoning and by reflection but also by a direct and intimate intuition. In *Quaestiones Disputatae de Cognitione*, Matthew presented a personal solution to the controversial question of the activity of the knowing subject. Rejecting the impressionism of Bonaventure and Thomas Aquinas, the innatism of Thomas of York and

Roger Bacon, and the pure activism of William of Auvergne and John Peckham, Matthew defended a semi-activism, not an occasionalism. Whereas according to pure activism the *species intentionalis* is completely (matter and form) caused by the knowing subject, according to Matthew the matter comes from the object, the form from the subject. This opinion, however, was soon contested by Roger Marston as contradicting both Aristotle and Augustine.

Matthew defended the theory of divine illumination almost in the same manner as did Bonaventure. The purely human faculties for knowing the extramental world do not give us either clear understanding or certainty. We need the aid of the divine *rationes aeternae* (divine ideas) to illuminate our mind during the process of knowledge. God is not simply the creator of human intelligence; he also conserves it and concurs in each of its actions. This collaboration of God by means of the divine illumination is possible because man in his mind bears a special likeness to his creator. Our intellect is illumed by the divine light that contains the eternal ideas and is the ground of all created beings. The divine light is not the object itself of our knowledge but the moving principle that leads us to the true knowledge of the created world. Following the Augustinian doctrine, Matthew believed that the object of knowledge never determines the election of the will.

Among Matthew's other philosophical theses, the following are worthy of mention. Matthew, like Bonaventure, rejected the possibility of a creation from eternity; the spiritual beings (souls and angels) are necessarily composed of matter and form, because if they were composed simply of essence and existence (as Thomas Aquinas taught), this would not account for their contingency. Also, the process of coming to existence must be explained by the Augustinian theory of the *rationes seminales*. The "being body" (*esse corporale*) constitutes a plurality of forms. The two elements of the beings, matter and form, are together the cause of individuality. Matthew upheld the Ontological Proof of the existence of God; he also argued that the knowledge of God that we attain through faith is compatible with scientific knowledge. Matthew was particularly interested in problems concerning the relations between the natural order and the supernatural order.

## IMPORTANCE

Matthew is undoubtedly to be ranked among the great scholastic thinkers. His importance, however, lies not so much in the originality of his thought as in the fact that

he is, after Bonaventure, the ideal representative of Augustinianism. The only philosophers that are known to have been directly influenced by him are Roger Marston and Vitalis of Furno.

## Bibliography

### PRIMARY SOURCES

Matthew's most important philosophical works are *Introitus ad S. Scripturam* (1268–1269), in *Bibliotheca Franciscana Scholastica Medii Aevi*, Vol. I (Quaracchi, 1903; 2nd ed., 1957), pp. 3–21; *Introitus ad S. Theologiam* (probably 1271–1272), *ibid.*, pp. 22–33; *Commentarius in I, II, et III Sententiarum* (1271–1272), unedited manuscript at Quaracchi; *Quaestiones Disputatae* (1267–1287), which is almost complete in *Bibliotheca Franciscana Scholastica Medii Aevi*, Vols. I–II, XI, XVII–XVIII (Quaracchi, 1903–1961); *Quaestiones de Anima VI*, in *Archives d'histoire doctrinale et littéraire du moyen âge*, edited by A.-J. Gondras, Vol. XXIV (Paris, 1958), pp. 203–352; *Quaestiones Disputatae de Anima XIII*, edited by A.-J. Gondras, *Études de philosophie médiévale* 50 (1961); VI Quodlibeta, about 90 questions (1276–1279), unedited manuscript at Quaracchi; *Concordantiae Super IV Libros Sententiarum*, unedited manuscript at Quaracchi.

## MAUPERTUIS, PIERRE-LOUIS MOREAU DE (1698–1759)

Pierre-Louis Moreau de Maupertuis, the French scientist and philosopher, was born in Saint-Malo, Brittany. Elected in 1723 to the Académie des Sciences (and to the Royal Society in 1728), he first became known for his work in geometry. The expedition that he led to Lapland in 1736 to measure a degree of meridian near the pole helped finally to prove that Earth was an oblate spheroid. With his early introduction of Newtonian theories into France, Maupertuis became a leading exponent among the *philosophes* of the ideal of experimentalism as opposed to the overly deductive method in science associated with the Cartesian tradition. In 1744 Frederick II of Prussia asked him to reorganize the Berlin Academy of Sciences and later appointed him as its president (1746–1759). The remainder of his career was intimately linked to the activities of this group, and the growth of the academy into an important center of research owed much to his efforts.

### PRINCIPLE OF LEAST ACTION

Maupertuis's famous principle of least action, which contributed signally to the systematization of mechanics, was formulated in "Recherche des loix du mouvement" (1746) as follows: "Whenever any change occurs in nature, the quantity of action employed for this is always the smallest possible"—the "quantity of action" being proportional to the product of the mass of a body and its velocity and the distance traversed. Among the heated controversies provoked by this notion, Samuel Koenig's unfair (although understandable) attribution of it to Gottfried Wilhelm Leibniz brought about a scandalous quarrel and lifelong enmity between Maupertuis and Voltaire. But all this proved irrelevant to the historic value of the principle of least action, which, clarified progressively by the applications it found in the works of Leonhard Euler, Joseph Lagrange, William Hamilton, Hermann Ludwig von Helmholtz, and others, emerged ultimately as a basic concept in the mathematical analysis of dynamic systems.

**COSMOLOGICAL ARGUMENT.** In the *Essai de cosmologie* (1750), Maupertuis's extension of the principle of least action to the much debated problems of theodicy offered a compromise solution between the radical antifinalism of contemporary materialists and the naive finalism of those who saw God's wisdom in every mani-

festation of design in nature, however trivial or self-contradictory. By claiming that an actual mathematical equation showed God's regulation of nature through the parsimony of kinetic means employed in the production of all physical events, Maupertuis succeeded in giving an original and seemingly scientific version of the Cosmological Argument. But his assumption that there is logical necessity as such in the existence of mechanical laws, which was consistent with the example of René Descartes and Leibniz, typified a rationalist attitude that, though prevalent at the time, was already undermined by those who, like David Hume, alleged a merely empirical necessity for physical causation. Although Maupertuis's distrust of metaphysical reasoning led him to present his cosmological argument not as demonstrably certain, but only as the best that the imperfect human intellect was capable of, it remained perhaps less plausible than ingenious, particularly since it was affirmed without sufficient regard either to the epistemological difficulties it incurred or to the possible nontheological interpretations of its underlying minimal concept. Coming late in a current of thought that was to yield before long to new orientations in philosophy, the *Essai de cosmologie* had a limited historical impact. It was, in fact, in a form essentially free of teleological meanings that the principle of least action exercised its considerable influence on the development of physicomathematical science.

### BIOLOGY: THE STRUCTURE OF MATTER

A different science, biology, inspired Maupertuis's next major work (1751), the *Dissertatio Inauguralis Metaphysica de Universali Naturae Systemate* (known also as the *Système de la nature*). Study of the problem of heredity had led Maupertuis to reject, in the *Vénus physique* (1745), the then reigning doctrine of preformation and to favor instead a theory of epigenesis using the law of attraction. But he had subsequently found this theory inadequate and had despaired altogether of accounting mechanistically for the origins and nature of life. In the *Dissertatio Inauguralis*, therefore, he sought to explain the formation of living things by supposing that all the elementary particles of matter are individually endowed in a proportionately elementary degree with "desire, aversion, and memory," by virtue of which they combine to form organic entities.

Such a notion, no less than that of least action, betrays a marked Leibnizian background in Maupertuis's thinking, despite his outspoken criticism of the metaphysics of Leibniz. It is true, nevertheless, that Mauper-

tuis did not assign the metaphysical status of the monads to his “percipient particles” but, rather, presented them as part of a general biological hypothesis; he accounted for the elemental coexistence of physical and psychic properties in nature by reference to a common unknowable substance. Thus, the philosophical basis of his biological theorizing may be described as either an “atomistic dualism” or a “corpuscular psychism,” sustained by a phenomenological accord between matter and its presumed psychic qualities. These ideas were misinterpreted in materialistic terms by Denis Diderot and contributed indirectly to the eventual success of naturalism in biology. Since Maupertuis’s metabiological conception was also intended to explain the structural transformations of the various species by a process of genetic mutation, it merged, in that respect too, with an important current of evolutionist speculation that grew in France after about 1750.

### EPISTEMOLOGY

The views of Maupertuis in epistemology can be judged from a number of his writings. While, like Étienne Bonnot de Condillac and most of the *philosophes*, he agreed with John Locke that sensation is the source of all our knowledge, his position was appreciably more sophisticated, probably because of his encounter with the Berkeleyian critique. If this critique did not quite win him over to subjectivism, he at least became convinced that experience offers no more than the disjointed fragments of a merely phenomenal reality and that the substance presumed to excite in the mind the perceptions that in turn are projected cognitively toward the natural world remains itself beyond objective determination. Maupertuis ascribed even the evidence of mathematics not to any intrinsic veracity of such knowledge but to the fact that it is based on the repetition (*réplicabilité*) of certain simple ideas that consist of identical units and are abstracted from the heterogeneous totality of sensory impressions. In the same spirit, his *Réflexions philosophiques sur l'origine des langues et la signification des mots* (1748) raises the equally crucial question of the linguistic prefigurations of sense experience, from which scientific reasoning is unable completely to escape.

### ETHICS

Maupertuis’s principal excursion into ethics, *Essai de philosophie morale* (1749), tried somewhat overambitiously to reconcile the Stoic, Epicurean, and Christian schools but succeeded only in reaching an eclectic view

characterized by the author’s own pessimism concerning the chances of human felicity. It offered, however, an early instance of the application of arithmetic to the problem of happiness by its attempt to express, in the analogy of statics, the equations of a “hedonistic calculus.”

### IMPORTANCE

Generally, the thought of Maupertuis pursued the aim, shared by many of his contemporaries, of linking philosophy more concretely than in the past with the content of the particular sciences. Instead of presenting an overall logical coherence, his work contributes various philosophical essays reflecting the different points of departure dictated by his primarily scientific interests. The cosmological thesis, speculative biology, and moral opinions of Maupertuis remained largely separate from each other; moreover, Maupertuis himself was often in the curious but historically symptomatic predicament of searching earnestly for metaphysical solutions while disbelieving in their possibility. Having elaborated the principle of least action and the notion of percipient particles of matter in a rather ambiguous zone between metaphysics proper and scientific theory, it is not surprising that he should have suffered much unmerited neglect from historians both of philosophy and of science. But it is now recognized that Maupertuis had a significant, even if secondary, role in the maturing of modern physics and biology alike, as well as in the transition of philosophical thinking from classical metaphysics to the critical position adopted by Immanuel Kant.

## MAXWELL, JAMES CLERK (1831–1879)

James Clerk Maxwell, the British physicist, came from a well-known Scottish family, the Clerks; his father adopted the name Maxwell on inheriting an estate originally belonging to that family. Maxwell was educated at Edinburgh University and the University of Cambridge, becoming a fellow of Trinity College in 1855. In 1856 he won the Adams Prize at Cambridge for an essay in which he demonstrated that the rings of Saturn would be unstable if they were continuously solid or fluid and that they must be composed of discrete and separated parts. Maxwell was professor of natural philosophy at Marischal College in Aberdeen from 1856 to 1860 and professor of natural philosophy and astronomy at King's College in London from 1860 to 1865. His first paper on electromagnetism appeared in 1856; his electromagnetic field theory with the derivation of the velocity of light was first

published in 1861–1862 and in more rigorous form in 1865; and he began work on the kinetic theory of gases in 1860. From 1865 to 1871 Maxwell remained at his country estate in Scotland where he worked on his *Treatise on Electricity and Magnetism*, which summarized the subject and his contributions thereto. In 1871 he became the first occupant of the Cavendish chair of experimental physics at Cambridge, supervised the construction of the Cavendish Laboratory, and later guided the first research done there. During this period he edited the works of Henry Cavendish. During his lifetime Maxwell also did research on color vision, mechanics, and other topics, and although his fame rests on his theoretical achievements, his experimental work was noteworthy.

### THE ELECTROMAGNETIC FIELD

Maxwell's greatest contribution to fundamental physics was his concept of the electromagnetic field, a concept that underwent much modification both in the course of his own researches and at the hands of his successors. In modern terms, a field—such as the electric field—is a condition in the space surrounding charged bodies that determines the force that a unit electric charge would experience if it were placed at any point. In field theory all actions are regarded as transmitted from point to point by the contiguous modification of the field between the points, and the field is regarded as the seat of energy. Contemporary physics is dominated by the field-theoretic viewpoint, whether or not it is reinterpreted in terms of quantum theory.

Maxwell aimed at embodying in mathematical notation the ideas of Michael Faraday and, in particular, Faraday's fruitful concept of lines of force. In this Maxwell was inspired by the work of William Thomson (later Lord Kelvin), who had demonstrated the mathematical analogy between the problems of heat flow and of the distribution of static electricity. Maxwell developed similar analogies in his first paper on the subject, "On Faraday's Lines of Force" (1855–1856), drawing separate analogies for different aspects of electromagnetism: between electrical and fluid currents, and between electric or magnetic lines of force and fluid currents. While suggestive, such an endeavor was of course not a unified theory. "I do not think," he wrote, "that we have any right at present to understand the action of electricity, and I hold that the chief merit of a temporary theory is, that it shall guide experiment, without impeding the progress of the true theory when it appears." The beginning of the paper is of interest as a statement of method; Maxwell points out the pitfalls of commitment to a mathematical formula, in

which case “we entirely lose sight of the phenomena to be explained,” or to a physical hypothesis, the irrelevant parts of which are liable to carry one beyond the truth. He advocates instead the use of physical analogy, “that partial similarity between the laws of one science and those of another which makes each of them illustrate the other.”

In his “On Physical Lines of Force” (1861–1862), Maxwell’s electromagnetic field theory appears for the first time, presented as a deduction from a detailed model of the ether. Magnetic lines of force are represented as molecular (microscopic) vortices in this ether, the matter of the ether whirling around in planes normal to the direction of the lines of force, so that the latter is the direction of the axes of the vortices. Maxwell found that in this fashion he could represent the properties of lines of force needed for magnetostatics, that is, that the lines should tend to contract along their length and repel each other laterally. But how can neighboring vortices spin in the same sense, since their neighboring boundaries move in opposite directions, and how are these motions initiated and communicated through the ether? Maxwell assumed a layer of tiny idle wheels between each pair of vortex cells in the ethereal substance. These wheels can rotate freely, so that a uniform magnetic field is represented by the vortex cells all spinning at the same rate and in the same sense, and the interspersed wheels rotating in place in the opposite sense. The idle wheels can also move from place to place in a conductor, but they are constrained to rolling contact without slipping with the neighboring vortices. The translatory motion of the wheels is identified with the electric current and used to explain the manner in which a magnetic field is created by an electric current (Hans Christian Ørsted’s discovery); it also is used to account for electromagnetic induction. Furthermore, in a dielectric, including the vacuum, the wheels are not free to move in translation, but can only be displaced slightly against the elastic forces of the material of the cells. This action of displacement is the displacement current that forms the new term Maxwell added to previous results, while transforming all of them into his theoretical language. Maxwell then proceeded to calculate the velocity of propagation of transverse waves in his elastic ether. The speed of these waves was proportional to the ratio between the electromagnetic and electrostatic units of charge.

The factor of proportionality between the speed of the waves and the ratio of the units depended in this calculation on the specific model chosen for the ether; the argument showing the two terms to be equal cannot be

regarded as very satisfactory. In “A Dynamical Model of the Electromagnetic Field” (1865), the electromagnetic field equations are presented directly without recourse to the ether model, and the relation between velocity of waves and ratio of electrical units is derived directly from the equations. Since, according to Wilhelm Weber and Friedrich Kohlrausch (1857), the ratio between the units was  $3.11 \times 10^8$  meters/sec., whereas, according to Armand Fizeau, the speed of light was  $3.15 \times 10^8$  meters/sec., Maxwell drew the important conclusion that light consisted of waves in the electromagnetic ether. This finally gained general acceptance when Heinrich Hertz generated electromagnetic waves by electrical means and showed that they had all the properties of light except that they were of much lower frequency, a result of the conditions of generation.

In his later papers Maxwell no longer relied on specific models of the ether. In the *Treatise* he wrote:

The attempt which I then [in “On Physical Lines of Force”] made to imagine a working model of this mechanism must be taken for no more than it really is, a demonstration that mechanism may be imagined capable of producing a connexion mechanically equivalent to the actual connexion of the parts of the electromagnetic field. The problem of determining the mechanism required to establish a given species of connexion between the motions of the parts of a system always admits of an infinite number of solutions.

Nevertheless, he still regarded the underlying phenomena as motions and stresses in the mechanical ether, maintaining that the energy of magnetism “exists in the form of some kind of motion of the matter in every portion of space,” apparently of a vortical character. Maxwell’s views differ from those of the twentieth century in the following ways: The electromagnetic field was not regarded as a separate dynamic entity from matter, that is, a material ether; ordinary matter was treated macroscopically, phenomenologically, rather than from the atomic point of view; and the role of charge in the theory was ambiguous. Late in the nineteenth century H. A. Lorentz combined Maxwell’s field theory with Continental conceptions of atomicity of charge to establish the classical theory of the dualism of matter and field.

#### KINETIC THEORY OF GASES

Also of fundamental importance was Maxwell’s work on the kinetic theory of gases. In deriving the experimental gas laws, previous investigators had made the simplified

assumption that all the gas molecules moved with the same speed. In "Illustrations of the Dynamical Theory of Gases" (1860), Maxwell first derived the equilibrium distribution of the velocities of the molecules: the components of the velocity along a given direction are distributed according to Carl Friedrich Gauss's error law. This paper also contained the startling result, later demonstrated experimentally, that the viscosity (internal friction) of a gas should be independent of its density. Maxwell wrote two other pathfinding papers on the kinetic theory; their main subject was the derivation of the transport coefficients of a gas (coefficients of diffusion, viscosity, and thermal conductivity) and, in the last of them, the discussion of radiometric phenomena.

Maxwell's work on the kinetic theory may be regarded as constituting the first important introduction of statistical reasoning into physics and the first steps in the development of statistical mechanics, later continued by Ludwig Boltzmann and Josiah Gibbs. In statistical mechanics the use of statistics is not a manifestation of any indeterminism in the purported fundamental laws of nature, as it is in quantum physics; rather it is the reflection of our ignorance of the exact motions of the enormous number of molecules in any macroscopic system. The very immensity of this number (there are about  $6 \times 10^{23}$  hydrogen atoms in one gram of hydrogen) and the minuteness of the individual molecules give assurance that in ordinary experiments the measurable properties will be statistical in character and thus will be exactly the properties singled out by a statistical theory.

Maxwell's demon, a hypothetical being that apparently could reverse the tendency of isolated systems toward increase of disorder or entropy and so would violate the second law of thermodynamics, appears in his *Theory of Heat* (London, 1872, pp. 308–309). The thermal equilibration of neighboring vessels containing gas, representing a state of maximum disorder, could be destroyed by a being capable of seeing the individual molecules of the gas who acts so as to let only the faster molecules in one container pass through a small hole into the other, and the slower ones in the latter to pass in the reverse sense. Since the temperature is determined by the mean energy of motion of the molecules, this process would result in the gas in one vessel becoming warmer than that in the other, without any interference from outside the system. The demon has been exorcised by L. Brillouin and others (see Brillouin's *Science and Information Theory*, New York, 1956, Ch. 13). To obtain the information about an approaching molecule that the demon needs in order to decide whether or not to open the hole,

the demon must absorb at least one quantum of light, the energy of which is reasonably greater than the mean energy of the quanta of thermal radiation that are always present. The absorption of this quantum demonstrably leads to a greater increase in entropy in the total system (including the demon) than the decrease obtained by properly manipulating the hole.

### **Bibliography**

The *Scientific Papers of James Clerk Maxwell*, including his semipopular lectures but not the *Treatise* and other books, appear in two volumes edited by W. D. Niven (Cambridge, U.K.: Cambridge University Press, 1890). See in particular his Bradford address, "Molecules," Vol. II, pp. 361–377, in which he expresses most lucidly his religious and metaphysical position. The *Treatise on Electricity and Magnetism*, 3rd ed., edited by J. J. Thomas, was published in 1892 at Oxford. The standard biography is Lewis Campbell and William Garnett, *The Life of James Clerk Maxwell* (London: Macmillan, 1882).

## MCCOSH, JAMES

(1811–1894)

James McCosh, an influential representative of "commonsense realism," was born in southern Ayrshire, Scotland. He was educated at Glasgow and Edinburgh universities. McCosh was licensed for the ministry in 1834 and served as a pastor of the Established Church of Scotland until 1850, when he was appointed professor of logic and metaphysics at Queen's College of Belfast. In 1868 he came to America to serve as president of the College of New Jersey (now Princeton University), a position he held until 1888.

McCosh's philosophical outlook was in its largest features inherited from the "Scottish school" of Thomas Reid, Dugald Stewart, and others. On one side this meant the denial that our beliefs about the external world rest on any dubious inferences, causal or otherwise, from immediately presented ideas. Those beliefs are rather the natural, noninferential accompaniments of sensation,

and their general reliability cannot sensibly be questioned. On another (and for McCosh, more important) side, commonsense philosophy meant apriorism. In *The Intuitions of the Mind, Inductively Investigated* (London and New York, 1860), McCosh undertook to enumerate certain fundamental principles (such as principles of causation and moral good) that belong to the constitution of the mind. Although persons are not necessarily or normally aware of these very general truths, their particular cognitions and judgments are regulated by them. In saying that these principles are to be discovered “inductively” McCosh did not mean that they are inductive generalizations. Certainly one is led to these principles by reflection on experience. But once before the mind, the principles are recognized as self-evidently and necessarily true. McCosh’s realism, unlike that of H. L. Mansel and William Hamilton, was relatively free of the influence of Immanuel Kant. Thus, in *An Examination of Mr. J. S. Mill’s Philosophy* (London and New York, 1866), McCosh defended Hamilton’s intuitional philosophy against Mill’s criticism but took care to disassociate himself from the former’s “agnostic” view that man’s knowledge is limited to the finite.

The most original aspect of McCosh’s philosophy was his effort to accommodate evolution and Christian theism. In one of his earliest works, *The Method of the Divine Government, Physical and Moral* (Edinburgh, 1850), he opposed the view that God’s design exhibits itself entirely in the lawful development of nature. Such a view, he thought, amounted to a denial of divine providence. Divine government proceeds instead by a combination of law and particular, spontaneous interventions. When *The Origin of Species* appeared (1859), McCosh found it natural to identify his “special providences” with Charles Darwin’s “chance variations.” In *Christianity and Positivism* (New York and London, 1871) he argued that evolution, properly understood, is not only compatible with a divine design but in fact magnifies the Designer. Unlike Darwin, McCosh found nothing abhorrent in the notion that God employs the struggle for survival as a technique of creation. He was confident that success in that struggle was a matter of moral rather than physical strength.

McCosh’s writings enjoyed considerable popularity, particularly among the evangelical clergy who found in them a way of dealing with the difficulties raised by science and science-inspired philosophies.

## MCDUGALL, WILLIAM

(1871–1938)

William McDougall, a British-American proponent of hormic psychology, was born in Chadderton, England, the second son of a chemical manufacturer. He was educated at schools in England and Germany, and at Manchester and Cambridge universities, where he received first-class honors in biology. In 1897 he qualified in medicine at St. Thomas’s Hospital, London. While working there with Charles Scott Sherrington, he read William James’s *Principles of Psychology*, and returned to Cambridge to study psychology on a fellowship from St. John’s College. He joined the Cambridge Anthropological Expedition (1899) to Torres Straits, collaborating with W. H. R. Rivers in sensory researches and with Charles Hose in anthropological studies, which resulted in *The Pagan Tribes of Borneo* (London, 1912). He worked at Göttingen with G. E. Müller and subsequently joined the psychology department of University College, London, under James Sully, where he published researches supporting Thomas Young’s theory of color vision against those of H. L. F. von Helmholtz and Ewald Hering (*Mind* 10 [1901]: 52–97, 210–245, 347–382). In London, and in Oxford from 1904 as Wilde reader in mental philosophy, McDougall worked on reflexes, inhibition, and psychophysical relationships. In *Physiological Psychology* (London, 1905) he combined James’s view of instinctive action and emotion as objective and subjective aspects of the excitement of inherited perceptual dispositions with Sherrington’s theory of the nervous system as integrator of reflex and instinctive-impulsive actions. McDougall explained subjectivity and purposiveness through R. H. Lotze’s “psychoneural parallelism,” postulating psychic currents induced in etherlike soul-stuff by neural activity.

McDougall first outlined his hormic psychology in *An Introduction to Social Psychology* (London, 1908). He derived human behavior from instincts, which are innate psychophysical dispositions with specific cognitive, affective, and conative aspects (for example, perception of danger, fear, flight). In adult humans, instincts operate indirectly through socially acquired patterns, the sentiments, in which object(s) and instinct(s) have become enduringly associated. Sentiments increasingly remote from innate instincts are exemplified, for instance, by parental love, family feeling, patriotism. In the growth of character the developing sentiments become hierarchically ranged round a master sentiment (or ruling passion) whose nucleus in a stable character is the self-regarding sentiment.

In *Body and Mind* (London, 1911), subtitled *A History and Defense of Animism*, McDougall reviewed psychophysical theories. To explain heredity and evolution, memory and learning, the “body-memory” of growth and repair, and parapsychological evidences of personal survival, he now discarded Lotzean parallelism, and declared himself, unfashionably, a dualist, interactionist, vitalist, animist, and Lamarckian.

In World War I McDougall enlisted as a French army ambulance driver but was drafted into the Royal Army Medical Corps. His command of a British shellshock unit provided the limited clinical material for his *Abnormal Psychology* (see below). In 1920 he became professor of psychology at Harvard, and in 1927 professor of psychology at Duke University. His American period was one of immense literary productivity. *The Group Mind* (New York, 1920) essayed to complete McDougall’s social psychology by applying the hormic theory to “national mind and character.” It was a work of subjective sociopolitical criticism rather than of objective scientific psychology, and resembled his many books of polemic and propaganda on national and international policy, from *Is America Safe for Democracy?* (New York, 1921) to *World Chaos* (London and New York, 1931). In these he advocated racial eugenics, a subsidized intellectual aristocracy, and a world air police, to defend the finest (explicitly North European–American) type of civilization.

In *An Outline of Psychology* (New York and London, 1923), *An Outline of Abnormal Psychology* (New York and London, 1926), and *Character and the Conduct of Life* (New York and London, 1927), McDougall elaborated his theory of personality built from sentiments that are powered by instincts, themselves channels of biological purposive energy (horme). The self-regarding sentiment governs conduct according to guidelines formed through

identifications with admired persons or abstract ideals. Within the self-regarding sentiment, moral sentiments (conscience) control crude instinctive impulses, and thus, in McDougall’s view, individual free will is truly exercised. The ordered hierarchy of sentiments completes the integration of personality. In *Abnormal Psychology*, McDougall reproached both Sigmund Freud and Carl Jung for neglecting the integration of personality—at that time Freud’s “superego” and Jung’s “self” were not yet formulated.

McDougall’s theory still had to explain the occurrence of autonomous complexes apparently outside the hierarchy, and of dissociated activities and “multiple” personalities. Rejecting Freud’s determinism, McDougall considered these unconscious mental functions purposive and goal-seeking. He then combined his personality theory with a revised view of body-mind relationships in an elaborate monadic theory based upon that of Gottfried Wilhelm Leibniz. Every personality is integrated as a converging hierarchy of monads, each “potentially a thinking striving self, endowed with true memory.” A supreme monad “which each of us calls ‘myself’” exercises control by telepathic communication through the hierarchy. Failure of integration allows pathological conflicts, automatism in sleep or hypnosis, or even revolt of a subordinate monad as a dissociated personality.

McDougall left open the question whether monads might be perceptible through the senses, and he considered the monadic theory to be consistent with either a monistic or a dualistic psychophysical theory. To reconcile a presumably purposive mind with an apparently causally determined body, he suggested that there might be two types of monad, one goal-seeking and the other cause-following, that were somehow interconnected, or one single series of monads with two aspects, causalistic and finalistic. Thus McDougall reconciled his theory both with causal-mechanistic schemes of neurophysiological levels (Sherrington) and with more purposive views, neurological (Henry Head, *Studies in Neurology*, London, 1920) and psychological (hormism). However, he too hastily equated biological purpose (horme) with individual goal-seeking will, and acquired self-control with the capacity for choice and responsibility in conduct.

Once a noted experimental physiologist, McDougall later based hormic psychology increasingly upon his purposivist metaphysical beliefs, little upon verifiable observation or experiment. His great experimental work at Duke was designed to test Chevalier de Lamarck’s hypothesis of evolution by inheritance of acquired char-

acteristics. Eventually, after ten years and twenty-three animal generations, McDougall reported an apparently inherited facilitation of learning in laboratory rats. Subsequent workers have not confirmed his results.

A lucid and persuasive writer, McDougall wielded great if temporary influence, and guided many English-reading students toward dynamic, biological, and social psychology. His weaknesses were his fondness for intellectual and verbal solutions to empirical problems, and his temptation to premature systematization. Admiration tinges the epigram that, had the Creator but paused to consult William McDougall, there had been no need of redemption.

## MCDOWELL, JOHN

(1942–)

John McDowell, a professor of philosophy at the University of Pittsburgh, was born in Boksburg, South Africa. After receiving his bachelor's from the University College of Rhodesia and Nyasaland he was awarded a Rhodes scholarship to New College, Oxford, where he earned a second bachelor's in 1965 and a master's in 1969. In 1966

he became a fellow of University College, Oxford, where he remained until he joined the faculty at the University of Pittsburgh in 1986. McDowell is a fellow of both the British Academy and the American Academy of Arts and Sciences.

With the rise of modern science there emerged a view of the world that is radically different from that of everyday life, a view sometimes described as "the view from nowhere." This new view was made possible, McDowell argues, by a new clarity regarding natural scientific understanding. Modern natural science explains things not by giving reasons to show that they are somehow better that way but by subsuming them under discoverable physical laws; it understands things by locating them within the realm of law as it contrasts with what Wilfrid Sellars calls the space of reasons. Because modern scientific understanding focuses on explanation by appeal to (physical) laws rather than to reasons, the world as revealed in the view from nowhere is "disenchanted," empty of meaning and value, indeed, of all distinctively human significance. One of the most pervasive themes in McDowell's work (whether in the philosophy of language, the philosophy of mind, metaphysics, epistemology, or ethics) is that philosophers since René Descartes have mistakenly assumed that respectable philosophy must begin with the view from nowhere, and thereby with a conception of nature as the realm of law, rather than with the everyday view from here and its much richer conception of nature.

Consider an ordinary sign, say a stop sign. In day-to-day life one knows how to follow such a sign. But how, the philosopher asks, can one follow the rule expressed by the sign given that what is presented is itself a mere thing, merely a piece of painted metal? It can seem natural to answer that the sign expresses a rule, tells one how to go on, only under an interpretation, that independent of an interpretation of that bit of matter as a stop sign, the sign just stands there. But this cannot be right, McDowell argues following Ludwig Wittgenstein, because any interpretation—say an utterance of the sound *stop*—will be similarly inert unless provided with an interpretation. The right response is to reject the assumption that what is presented is a mere thing. One can learn to conceive the sign as a mere thing independent of all human concerns, just as one can learn to conceive nature in a way that is independent of sensory experience. (One can learn to take the view from nowhere.)

But that capacity is essentially late; it cannot be understood except against the backdrop of one's everyday ability to follow rules such as that expressed in a stop sign.

Indeed, thinking of a sign as a mere thing is itself a matter of rule-following: from the perspective afforded by the view from nowhere, the sign tells one how it is to be thought, namely, as a particular bit of stuff shaped in a certain way. Although the view from nowhere involves pure cognition rather than bodily action, one needs in that case as well the notion of going on in light of a conception of correctness, of thinking one way rather than another on the basis of an understanding of the thing about which one thinks.

Knowing how to follow a rule is at least in some cases a perceptual skill, the ability to see an expression of the rule (e.g., a stop sign) as telling one how to go on. In his masterwork *Mind and World* (1994) McDowell argues more generally that experience, conceived as the capacity to take in manifest facts (e.g., to see that things are thus and so), is an essential component in any adequate conception of cognition. According to his diagnosis the modern unquestioned assumption that natural scientific understanding is the only acceptable mode of access to nature leads philosophers to begin with the mistaken idea that the space of reasons within which thought operates is dualistically opposed to nature. As a result, modern philosophy falls into an oscillation between two equally unsatisfactory conceptions of cognition: on the one hand, an empty coherentism that eschews the notion of experience altogether, and on the other hand, what Sellars calls the “Myth of the Given,” the idea that brute impacts of the sort described in physics might provide a perceiver with reasons for belief.

Rejecting the assumption that generates the oscillation, McDowell urges that what is needed instead is the Kantian conception of experience as inextricably involving both sensibility and understanding. Because experience so conceived is at once passive, that is, receptivity in operation, and conceptually articulated, it can serve rationally to constrain one’s thought about what is the case, and thereby to explain the empirical contentfulness of thought. As McDowell also argues, the capacity for experience so conceived is essentially second nature; it is acquired only in the course of one’s acculturation into natural language, where natural language is itself to be understood as a repository of tradition, the embodiment of the possibility of an orientation to the world.

In his writings on ethics McDowell argues that modern philosophers have a fundamentally distorted conception of practical reason grounded in their scientific understanding of nature and that this conception has blinded them to the insights of the ancient Greeks. The capacity to act virtuously, he argues following Aristotle,

essentially involves the capacity to take in objective moral facts, where this latter capacity—like the capacity to take in nonmoral facts—is acquired in the course of one’s acculturation. It follows that the rationality, and so the desirability, of a life of virtue cannot be established from the outside, independent of how a virtuous person sees things. Critical reflection in ethics, as in any other domain, is Neurathian, possible only from within the tradition one inherits.

Although mostly written in the form of essays, McDowell’s work systematically addresses many of the deepest philosophical perplexities that can arise on reflection about human being in the world and the nature and place of language in human life. His writings provide a diagnosis and a cure for the ills of modernity, and a rich, subtle, and profoundly moral vision of what it is to be human.

## MCGILVARY, EVANDER BRADLEY

(1864–1953)

Evander Bradley McGilvary, an American realist philosopher, was born in Bangkok, Siam. He received his B.A. from Davidson College in 1884, his M.A. from Princeton in 1888, and his Ph.D. from the University of California in 1897. He was appointed assistant professor of philosophy in California and then Sage professor of ethics at Cornell (1899–1905). From 1905 to 1924 he was professor of philosophy and head of the department at the University of Wisconsin, and in the year 1912–1913 he was the president of the American Philosophical Association. He was the Howison lecturer in 1927, the Mills lecturer in 1928, and the Carus lecturer in 1939.

### PHILOSOPHICAL ORIENTATION

McGilvary's "first impulse" toward philosophy was a reaction against the theology in which he was schooled. He came under the Hegelian influence of George Howison at California, and his writings from 1897 to 1903 reflect this influence. But McGilvary, like other Hegelians of his time, eventually found Hegelianism unacceptable. From the start McGilvary held the view that every part of the world is what it is by virtue of its organic relation to every other part. And when he broke with Hegelianism, he took with him this theory of relations and the characteristically Hegelian view that two antagonistic ideas always suggest a third that synthesizes the truth of each.

Realist philosophers in America during the first two decades of the twentieth century were struggling to formulate an epistemology that would do justice both to those elements in experience that are clearly in the objective world and to those dependent upon the experiencing organism. Taking William James's thesis that "the world is as it is experienced," the non-Hegelian new realists developed a monistic realism, but it always threatened to become panobjectivism. In reaction the critical realists set forth a dualistic realism that always threatened to become pansubjectivism. In his "perspective realism" McGilvary sought to combine the truth of new realism with the truth of critical realism. He, too, took James's thesis as his starting point and sought to combine epistemological monism with epistemological dualism and the theory of external relations with the theory of internal relations. McGilvary's synthesis of the objective and the relative—like John Dewey's and A. N. Whitehead's—was dubbed "objective relativism" by A. E. Murphy.

To effect the synthesis of monism and dualism, McGilvary developed his theory of perspectives. It is summarized in the first three postulates of perspective realism: (1) "In our sense-experience there is presented to us in part the real world in which we all in common live"; (2) "Every particular in the world ... is what it is only because of its context"; (3) "In the world of nature any 'thing' at any time is, and is nothing but, the totality of the relational characters, experienced or not experienced, that the 'thing' has at that time in whatever relations it has at that time to other 'things.'" McGilvary first hinted at such a theory in 1907, but he did not systematically state it until twenty years later, and in 1939 it became the core of his Carus lectures, *Toward a Perspective Realism*. This work is the key to understanding McGilvary's philosophy, and it grew out of his early thinking about the nature of consciousness.

### THE NATURE OF CONSCIOUSNESS

McGilvary believed that the question of the precise nature of consciousness was the fundamental question of philosophy. Like other realists, he agreed with James that consciousness is a relation. Since it was his view that things are what they are only in their relations to other things, he could not agree with realists who claimed that this relation was external. Consciousness, he held, is that relation by which anything becomes an experience. It is a unique kind of "togetherness" of, or between, things. It is neither a spatial nor temporal togetherness, nor is it any other distinguishable relation. The peculiar relation of feeling binds external objects together into an experiential unity we call "consciousness," "awareness," or "experiencing."

McGilvary thought this togetherness may have been what Immanuel Kant meant by the synthetic unity of apperception. It has a unique center of reference in the body of the experiencing organism. This centering gives to the relation of togetherness a character and coloring all its own. Hence, consciousness exists in individualized instances, like other relations, yet each instance produces an individuality generically different from that of any other individualized relation. Each instance is its own kind of betweenness.

As he developed this theory, McGilvary increasingly described consciousness in terms of perspectives. In addition to the familiar perceptual perspectives of space and time, he said, consciousness is characterized by intellectual, moral, and aesthetic perspectives. All these perspectives have both a physical and an "epiphysical," a dynamic and an "epidynamic," causal and noncausal quality. The

most distinctive characteristic of these perspectives is the absence of energy transaction between their station point (the organism) and objects in the perspective. The peculiar “epidynamic” relatedness of a perspective does not “go over” to the object or do anything to it. Yet it does “go over” in the way any other relation “goes over” from one term to another. It is a conditioning relatedness that is not itself a cause of the physical existence of its objects, nor is it itself an object in the relation complex. Thus, a perspective (seeing, for example) is not an act of the organism on its object. If it were, it would be difficult to understand how an organism can see now what antedates the seeing, such as a star that may have exploded aeons ago. Like the verb “to relate,” the verb “to see” does not name an act performed on the objects seen, any more than “having” a grandfather is an act performed on him. Physical objects become a field of vision when light from them stimulates an organism through its eyes, just as grandparents become grandparents only when a grandchild is born.

The organism, then, is a condition of vision, and as such it is not one of the members or terms in the relationship, just as common parents are a condition for the relationship of brotherhood but are not members in that relationship. Seeing the star that no longer exists is no more difficult for McGilvary to explain than how being an ancestor of a president of the United States is a quality that comes to belong to persons who die before the event that permits ascribing that characteristic to them. In the same way the perspective realist can hold that the physical object that initiated the series of physical conditions that ended in a perception of attributes occupying the position of that object still does not have those attributes. These attributes, however, can be considered part of the real world resulting from a real and natural relation between the organism and external objects. Not all physical qualities, then, are causally conditioned. Sense qualities, for example, can be considered part of their object but are not causally related to the organism that senses them.

It is the same for McGilvary with memory or knowledge of the past. The pastness of an event is not independent of all external standpoints. The pastness of consciousness is *retrospective*, a particular kind of perspectivity, but not *retroactive*. Consciousness also is prospective, another kind of perspectivity, but not active on the future. This is the “epiphysical” or “epidynamic” quality of the consciousness relation that distinguishes it from other physical, dynamic, causal relations that act on their objects. Perspectives do not exist if that means being

in space and time. Nor do they subsist. The being of a perspective is its being between—“inter-sistence,” McGilvary called it—and each perspective is its own kind of “inter-sistence.”

But it is not clear whether McGilvary thought that each perspective is an instance of consciousness and whether perspectives go to make up what we call consciousness. Nor does he show us how to distinguish between what the organism contributes to the perspective, as its station point, and what is there independent of the organism. At times he said nothing is there independent of the organism, for the organism is the necessary condition of any perspective. But when Dewey said that the logical forms of our knowledge cannot be read back into nature (because they come into being only when inquiry is instituted and are only modes of operating upon subject matter), McGilvary disagreed. He argued that any logical form that serves to solve a problematic situation serves that purpose because it is actually the form of the subject matter under investigation, not of the subject matter as it was immediately experienced when inquiry started but as successful inquiry shows the subject matter to have been in the natural world.

It is doubtful, then, that McGilvary, like the other objective relativists, was any more successful than other realists in doing justice to the objective and the relative found in experience.

McGilvary’s few articles on ethics present familiar positions, but none of them is developed systematically, nor did McGilvary apply his perspective realism beyond epistemological and ontological problems.

## MCTAGGART, JOHN MCTAGGART ELLIS (1866–1925)

John McTaggart Ellis McTaggart, a British metaphysician, was born in London, the son of Francis and Caroline Ellis. (His father later took the name McTaggart to fulfill a condition for inheriting a bequest.) He attended school at Clifton and went on to Trinity College, Cambridge, where he took first-class honors in the moral science tripos in 1888. He was made a fellow of Trinity in 1891. The next year he paid a visit to New Zealand, where his widowed mother lived, and there he met Margaret Elizabeth Bird, whom he married in 1899, during a second visit to New Zealand. Thereafter he resided at Cambridge. Active in the affairs of his college and the university, he was a busy and successful teacher from 1897 until he retired in 1923. He died suddenly in January 1925.

McTaggart’s philosophy is a peculiar and quite personal variety of Hegelian idealism. Ultimate reality, he held, is spiritual: It consists entirely of individual minds and their contents. He understood this in a way that excludes space, time, and material objects from reality. What appear to us as being these things are really minds and parts of the contents of minds, but we “misperceive” these entities in a systematic way, and this misperception is the source of the whole apparent universe. Despite the

unreality of time, McTaggart argued, there is an important sense in which it is true to say that individual persons are immortal, and that they are reincarnated in a succession of (apparent) bodies. He also held that in reality persons stand in relations either of direct perception, and consequently love, or of indirect perception, and consequently affection, to one another. Love is, indeed, the basically real emotional state. There is, however, no God in this heavenly city, for McTaggart did not think there is any reason to believe that there is or even can be an overarching mind that includes individual minds like ours but is still in some sense an individual mind itself. McTaggart was, in addition, a determinist, though he held that determinism is not incompatible with the existence of valid judgments of moral obligation.

On these basic points McTaggart never changed his mind. He argued in support of them both in his early writings on G. W. F. Hegel and in his great systematic work, *The Nature of Existence*. The main difference between his earlier and his later work is that in the former the arguments are dialectical in a Hegelian manner, whereas in the latter they are more straightforwardly deductive.

#### WRITINGS ON HEGEL

McTaggart’s commentaries on Hegel are all more or less critical of Hegel, and none is entirely reliable as pure exegesis. Two deal primarily with Hegelian methodology. The essays on the dialectic defend Hegel’s method against what McTaggart took to be common misunderstandings and criticisms and offer an account of the way in which the Absolute Idea works to move thought from stage to stage. The *Commentary on Hegel’s Logic* is a detailed and very careful examination of the validity of each step in the logical development of the categories. McTaggart frequently found Hegel to be mistaken or confused about his transitions and in some cases offered alternative modes of development.

The essays on cosmology are among McTaggart’s most interesting work. He here discussed, more fully than anywhere else, a number of concrete topics—such as the moral criterion, sin, the organic nature of society, and the relations between Christianity and Hegelianism—in the light of his metaphysical position. He brought out his differences, not only with Hegel, but with many of the British Hegelians as well. And in the concluding chapter he presented with great clarity and power what is essentially his mature view of the relations between selves in ultimate reality.

### SOME DOGMAS OF RELIGION

In *Some Dogmas of Religion* McTaggart examined, in a careful but nontechnical manner, a number of dogmas that are especially relevant to Christianity. (By *dogma* he meant “proposition having metaphysical significance.”) He argued that dogmas of some sort are essential to any religion and that we must have reasoned proof of a dogma before we can be justified in believing in it. Then, without claiming to give conclusive arguments (for these would involve a whole metaphysical system) he argued in favor of immortality, preexistence, and determinism, criticized the belief in a personal and omnipotent God, and attacked some of the arguments that have been alleged to support this belief. Finally, he tried to show that there is much less connection than is frequently held to be between the truth of theism and improved chances for personal happiness.

### NATURE OF EXISTENCE

McTaggart’s metaphysical system is presented in two parts. In the first, contained in Volume I of *The Nature of Existence*, he gave an extended argument to show that whatever exists must be of a certain nature and must, therefore, satisfy a certain requirement, to be explained below. In the second part, occupying Volume II, he examined various types of entities that our present experience shows us as existing to determine whether these entities can satisfy the requirement; he attempted to account for the apparent existence of those entities that do not really exist; and he evaluated the practical importance of the results he had thus reached.

The argument of Volume I is almost entirely a priori. McTaggart appealed to experience for only two propositions: that something exists, and that what exists has parts. His argument proceeds through the following stages: First, McTaggart offered a proof of the principle of the Identity of Indiscernibles. Second, he argued that every substance must have a “sufficient description,” that is, a description that uniquely identifies the substance and contains no reference to substances that are only identified (as by pointing or by the use of purely referring expressions), not described.

He next moved to the assertion that every substance, without exception, must be divisible into parts that are themselves substances, and hence into parts within parts to infinity. The crucial argument is then presented. The principle that every substance must have a sufficient description together with the principle that every substance is infinitely divisible into further substances would entail a contradiction unless the substances in question

were such that from the nature of any existing substance there follow sufficient descriptions of all of its parts within parts to infinity. This can occur, McTaggart showed, if the substance stands in a certain extremely complex relation to its parts, which he called the relation of “Determining Correspondence”; it can occur, he held, in no other way. Hence, whatever exists—and we know that something does exist—must satisfy the conditions necessary for it to stand in Determining Correspondence relations to its parts.

In Volume II McTaggart denied the existence of material objects, space, judgments, inferences, sense data, and certain other mental contents, on the ground that entities of these types cannot satisfy the conditions required for them to stand in Determining Correspondence relations. His denial of the existence of time, however, rests on a quite different argument. This argument is McTaggart’s most widely discussed contribution to philosophy. Briefly, it is as follows: Temporal positions and events may be ordered either as earlier-later or as past-present-future. Ordered the first way, they form what McTaggart called a *B-series*; ordered the second way they form an *A-series*. In the first stage of the argument McTaggart tried to show that the *A-series* characteristics “past,” “present,” and “future” are essential to the existence of time. He assumed it to be admitted that change is essential to time, and he argued that unless the *A-series* characteristics can change, nothing can change. The *B-series* characteristics cannot change, for if an event is ever earlier than another, it is always earlier; and neither can the other characteristics of events change, for if it is ever true that an event is, for instance, the death of a queen, then it is always true that this event is the death of a queen. Hence, without the *A-series* there cannot be time, and in the second stage of the argument McTaggart tried to show that a vicious infinite regress is involved in affirming the existence of a series ordered by *A-series* characteristics. Each member of such a series must have all the *A-series* characteristics, he said, but those characteristics are incompatible. If we try to remove the contradiction by saying that each member possesses all the characteristics *at different times*, we are presupposing the existence of different moments of time at which the *A-series* characteristics are possessed. But each of these moments, to be temporal, must itself possess all of the *A-series* characteristics, which, again, is impossible; the attempt to relieve this contradiction by appeal to yet another set of moments only gives rise to another set of contradictions, and so on.

McTaggart's complicated and difficult account of the relations between appearance and reality centers on the concept of a *C*-series, analogous to the *B*-series in having its members related by an asymmetrical and transitive relation, but timeless. The model for the *C*-series relationship is the concept of "inclusion," and the terms that are included in and inclusive of each other are perceptions, that is, parts of spirits. McTaggart argued that reality must be structured so as to form a set of related inclusion series that, however, are misperceived as temporal series. He drew the further conclusion that time had a first moment and will have a last moment.

McTaggart went on to discuss the question of the value of the universe, both in its prefinal stages and at the stage when the appearance of time has ceased. Taking both "good" and "evil" to stand for simple, unanalyzable characteristics, and arguing that only what is spiritual can have value, he found that in the prefinal stages the relative proportions of good and evil will fluctuate considerably, though we can be confident that on the whole the proportion of good will steadily increase. In the final stage we will exist in a "timeless and endless state of love" far more profound and powerful than anything we now have any inkling of. We shall, McTaggart said, "know nothing but our beloved, those they love, and ourselves as loving them," and this will be our ultimate and unshakable satisfaction. If McTaggart's metaphysics thus concludes with a vision that he himself was not unwilling to call mystical, it is at least a vision that springs from one of the most brilliantly conceived and carefully executed attempts any philosopher has ever produced to grasp the nature of reality in purely rational terms.

## MEAD, GEORGE HERBERT (1863–1931)

George Herbert Mead, the American pragmatist philosopher, was born in South Hadley, Massachusetts. He received his BA from Oberlin College in 1883 and did graduate work at Harvard in 1887–1888, where he studied under Josiah Royce and William James. From 1888 to

1891 he studied psychology and philosophy in Europe. He was married in 1891 and in the same year was appointed instructor at the University of Michigan. In 1892 he joined the staff of the University of Chicago and later became chairman of its philosophy department.

A major figure in American pragmatism, Mead has also had a large influence on psychologists and social scientists. Many thinkers, including Alfred North Whitehead and John Dewey, regarded Mead as a creative mind of the first magnitude. He published relatively few papers, however, and died before he was able to develop his many original ideas into an integrated philosophy. Large segments of his books were collated from his unfinished manuscripts and from his students' notes and hence are repetitious, unsystematic, and difficult.

Mead's main philosophic themes may be classified as follows: (1) the emergence of mind and self from the communication process between organisms (often termed his "social behaviorism"), discussed in *Mind, Self and Society*; (2) the psychological genesis of scientific categories in purposeful acts, discussed in *The Philosophy of the Act*; and (3) the social conception of nature and the location of reality in the present, discussed in *The Philosophy of the Present*.

## SOCIAL BEHAVIORISM

Mead's thought stemmed from the impact of Darwinism on nineteenth-century ideas. Man was regarded as an organism functioning in accordance with natural laws. This approach opposed traditional philosophy and theology and sought to understand human nature by the methods of experimental science. The theory of evolution also gave impetus to the conception of the universe as a process rather than as a set of fixed, unalterable essences that remain invariant over time. In psychology the process concept was expressed in functionalism, which sought to comprehend all mental phenomena not as structures, traits, or attributes of the mind but as relations between the organism and its environment. These ideas were taken up by behavioristic psychology, which dismissed introspection as unscientific and confined itself to experimental data, particularly the responses of organisms to stimuli under varying conditions.

Mead challenged many of the crudities of behaviorism. In rejecting introspection, this school tended to regard it as a nonexistent phenomenon, since it could not be studied experimentally. Mead's social behaviorism sought to widen behaviorism to include the introspectively observed phenomena of consciousness. For Mead stimulus and response are meaningful only when viewed

as aspects of communication; they cannot be studied in abstraction from the social process in which actions occur. Furthermore, organisms do not merely respond mechanically and passively to stimuli. Rather, the individual purposefully selects its stimuli. Mead here opposed associationism; the organism is a dynamic, forceful agent, not a mute receptacle for ideas that are later associated. For Mead organism and environment mutually determine each other. Mind emerges from this reciprocal determination.

Mead's naturalistic conception of introspection was based on the viewpoint that an idea is the early, inner stage in an ongoing act directed toward an environmental goal. The mistake of the behaviorists was to study merely one part of the complete act, the last, overt stage, thereby ignoring the initial phase of the act, which occurs privately, within the organism.

According to Mead actions occur within a communicative process. The initial phase of the overt stage of an act constitutes a gesture. A gesture is a preparatory movement that enables other individuals to become aware of the intentions of the given organism. The rudimentary situation is a conversation of gestures, in which a gesture on the part of the first individual evokes a preparatory movement on the part of the second, and the gesture of the second organism in turn calls out a response in the first person. On this level no communication occurs. Neither organism is aware of the effect of its own gestures upon the other; the gestures are nonsignificant. For communication to take place, each organism must have knowledge of how the other individual will respond to his own ongoing act. Here the gestures are significant symbols.

Communication is also based on the fact that actions are organized temporally. The consequences of behavior (final phases of the act) are present in imagery during the early phases of the action and control the nature of the developing movement. There are usually several alternative ways of completing a movement that has been started. Since the final phases of the act control the ongoing movement, the organism can select one of these alternative ways of conjoining means with the end. In this manner rational conduct is possible. Where organisms use significant symbols, the role of the other individual controls the ongoing act. In advance of our completion of a social action, we anticipate the response of the other individual. Since our behavior is temporally organized, the imported role of the other may cause us to select a course of action that is different from what we originally intended.

Mind is the ability of an organism to take the role of the other toward its own developing behavior. Reflexivity, the ability of a person to reflect upon himself, is the necessary condition for the emergence of mind within the social process. With reflexivity the social act is imported within the individual and serves to alter the person's ongoing acts. A complete social act can be carried out internally without external movements necessarily occurring. Mead denotes the internalized role of the other as the "me." Each organism has an "I," which is a capacity for spontaneity. The "I" is expressed when the individual alters his ongoing response or creates a new response to the "me." Individuality and originality arise from the inner conversation between the "I" and the imported role of the other. An inner forum comes to exist, consisting of a dialogue between the "I" and the "me." This inner rehearsal of projected actions constitutes introspection, or thinking.

In the organized group situation, such as is exemplified in games, the individual learns to take into himself the entire social organization which now exerts internal control over his ongoing acts. The "generalized other" is the group's attitudes imported into the individual. It is here that social institutions enter into an individual's thinking as a determinative factor and cause him to develop a complete self. Now the inner forum becomes an inner dialogue between the person and the group.

The religious experience occurs in situations where each person becomes closely identified with the other members of the group. In common efforts, such as in teamwork, where a sense of closeness develops among everyone involved, a feeling of exaltation arises. Here Mead refers to a "fusion" of the "I" and the "me."

Mead's social psychology is similar to the psychoanalytic theories of Sigmund Freud and Harry Stack Sullivan in that it conceives personality as arising from the internalization of the roles of other persons and relates inner conflict to the tension between the spontaneous forces of the person and the introjected demands of society. The temporal organization of the act, stressed by Mead, is also a key concept in automatic control machinery and digital computers, where the later stages of a process feed back upon the earlier phases, modifying the ongoing process.

## PHILOSOPHY OF SCIENCE

Mead sought to find the psychological origin of science in the efforts of individuals to attain power over their environment. The notion of a physical object arises out of manipulatory experience. Perception is coordinated with

the ongoing act: When we approach a thing we wish to manipulate, the imagery of handling that thing is present in the distance perception. Here again there is a temporal organization of the act, in that the later phase of the action, the contact experience, is present in the earlier stage when we are merely perceiving the distant object. Perception involves the readiness of the organism to manipulate the thing when the intervening distance has been traversed. The reality of a thing is in the consummatory phase of the act, the contact experience, and this reality is present in the experience of perceiving that thing at a distance.

There is a social relation to inanimate objects, for the organism takes the role of things that it manipulates directly or that it manipulates indirectly in perception. For example, in taking (introjecting or imitating) the resistant role of a solid object, an individual obtains cognition of what is "inside" nonliving things. Historically, the concept of the physical object arose from an animistic conception of the universe.

Contact experience includes experiences of position, balance, and support, and these are used by the organism when it creates its conceptions of the physical world. Our scientific concepts of space, time, and mass are abstracted from manipulatory experience. Such concepts as that of the electron are also derived from manipulation. In developing a science we construct hypothetical objects in order to assist ourselves in controlling nature. The conception of the present as a distinct unit of experience, rather than as a process of becoming and disappearing, is a scientific fiction devised to facilitate exact measurement. In the scientific worldview immediate experience is replaced by theoretical constructs. The ultimate in experience, however, is the manipulation and contact at the completion of an act.

## COSMOLOGY

*The Philosophy of the Present* develops the conception that reality always exists in a present. However, as it is experienced, the present involves both the past and the future. A process in nature is not a succession of instantaneous presents or a sequence of spatial points. Instead there is both spatial and temporal duration, or continuity.

The developing action is the basis of existence. It is true that as we look back the present is determined by the past. But each new present, as it passes into the next present, is a unique emergent. A new future also arises as the result of the emerging present. Hence, we are always reconstructing our pasts and restructuring our future.

Novelty stretches out in both directions from the present perspective.

Every object in the universe is seen from the perspective of a particular individual. What is seen from one person's perspective may be different from that which is seen by another individual. Mead was not solipsistic, however, for although a person sees nature only from his own perspective, he is able to import within himself the perspectives of others. Reality is the integration of different perspectives. Mead made use of the theory of relativity to project his theory of sociality and mind into nature. Sociality is the ability to be in more than one system at a time, to take more than one perspective simultaneously. This phenomenon occurs in emergence, for here an object in the process of becoming something new passes from one system to another, and in the passage is in two systems at the same time. During this transition, or transmutation, the emergent entity exists on two levels of nature concomitantly.

Mead's philosophy has been compared with that of Martin Buber. Although their approaches stem from different traditions, both thinkers have a social conception of nature and conceive of the self as arising from a social matrix. Certain affinities between Mead and Edmund Husserl have been suggested, in that the mind's reflexive examination of itself is an effort to describe the constitution and foundation of experience.

## MEANING

What is it for a sentence—or a substantial expression, such as a word or phrase—to have a particular “meaning” in a given language? While it is widely agreed that the meaning of a sentence, phrase, or word must have something to do with the way that the expression is used by speakers of the language, it is not at all obvious how to move from that vague idea to a precise answer to our question. One problem is that utterances of a given sentence might be used to convey all manner of messages,

many of which would be far removed from what we intuitively regard as the literal linguistic meaning of the sentence. Any account of meaning in terms of use must find a way to avoid having every innovative or idiosyncratic feature of use registered as an aspect of meaning. There are two ideas about linguistic meaning that might help with this problem. One is the idea that linguistic meaning is a matter of convention. The other is the idea that linguistic meaning is compositional; that is, the linguistic meaning of a sentence depends in a systematic way on the meanings of the words and phrases from which the sentence is constructed.

### LINGUISTIC MEANING IS CONVENTIONAL

To define the meaning of a sentence as the message or messages that the sentence is, or can be, used to convey is inadequate, because too inclusive. In order to exclude the innovative or idiosyncratic features of language use, we might reach for the notion of a rule of language: What it is for a sentence to mean that *p* is for there to be a rule saying that the sentence is to be used (or may be used) to convey the message that *p*. However, if a rule is something that is formulated explicitly (in language), then the proposal may just reintroduce the notion of linguistic meaning; and that would be unsatisfactory if the project is to define or analyze the notion of linguistic meaning in other terms. So, instead of the notion of an explicitly formulated rule we can make use of the notion of a convention, defined as a rationally self-perpetuating regularity (Lewis, 1969). The resulting proposal is that what it is for a sentence *S* to mean that *p* in the language of a given population is for there to be a convention in that population to use utterances of *S* to convey the message that *p*.

### LINGUISTIC MEANING IS COMPOSITIONAL

The term *theory of meaning* can be applied to two very different kinds of theory. On the one hand, there are semantic theories that specify the meanings of the expressions of some particular language; on the other hand, there are metasemantic theories that analyze or explain the notion of meaning. We should expect the idea that meaning is compositional to be reflected in semantic theories. The way in which the meanings of sentences depend on the meanings of words and phrases should be revealed in a semantic theory by having the meaning specifications for whole sentences derived logically from more basic principles that specify the meanings of words and phrases.

Many features of the messages conveyed by the use of a sentence will not be seen simply as the results of contributions to meaning made by the words in the sentence—contributions that would be repeated in other sentences—but rather as the products of interaction between the meaning of the sentence and other background assumptions. (The study of this interaction is called pragmatics. See Davis, 1991.) It is true, for example, that a letter of reference that says only, “Mr. X’s command of English is excellent, and his attendance at tutorials has been regular” is likely to convey the message that Mr. X is not a talented philosopher (Grice, 1975). But this message is not the logical product of the meanings of the words and phrases used. Rather, the letter writer is able to convey that message by relying on shared assumptions about what information would be relevant in the circumstances. (See Grice’s early [1961] proposals about pragmatics.)

### TWO APPROACHES TO THE STUDY OF MEANING

These ideas, that meaning is conventional and compositional, can be seen at work in two important approaches to the study of linguistic meaning, on which this article focuses. One is Herbert Paul Grice’s program for analyzing the concept of literal linguistic meaning in terms of psychological notions such as belief and intention (Grice, 1989). The other is Donald Davidson’s project of illuminating the notion of meaning by considering how to construct compositional semantic theories for natural languages (Davidson, 1984).

#### GRICE’S ANALYTICAL PROGRAM

The Gricean analytical program can be regarded as having two stages (for overviews, see Avramides, 1989; Neale, 1992). The first stage aims to characterize a concept of speaker’s meaning that corresponds, roughly, to the idea of conveying, or attempting to convey, a particular message (Grice, 1957, and other papers, 1989). The second stage then aims to use the concept of speaker’s meaning, along with the notion of a convention, to build an analysis of literal linguistic meaning. (In fact, Grice himself did not introduce the notion of convention, but used a slightly different idea. See Grice, 1989; Lewis, 1969, 1975; Schiffer, 1972.)

The basic idea of the first stage of the program is that an agent who is attempting to convey a message—perhaps the message that it is time for tea—makes an utterance (which might or might not be linguistic in nature) with the intention that the hearer should come to believe

that it is time for tea and should believe it, at least in part, in virtue of recognizing that this is what the utterer intends him or her to believe. The analysis of speaker's meaning was refined and complicated in the face of counterexamples (Grice, 1989; Strawson, 1964; Schiffer, 1972), but it retained the crucial feature of not itself importing the notion of literal meaning. This feature is shared by the analysis of convention as a rationally self-perpetuating regularity, and so the prospects are good that the analysis of meaning resulting from Grice's program can meet the requirement of noncircularity.

**PROBLEMS WITH GRICE'S PROGRAM.** Grice's program does, however, face a number of serious objections. One problem concerns the application of the program to sentences that are never used at all—perhaps because they are too long or too implausible. Clearly, the Gricean analysis of literal meaning cannot be applied directly to these sentences. If we want to say that there is, nevertheless, a fact of the matter as to what unused sentences mean, then we seem bound to appeal to the meanings of the words and phrases from which unused sentences are built. But now we come to the most serious problem for the program, namely, how to analyze the notion of meaning as it applies to subsentential expressions.

Parties to a convention know what the relevant regularity is, and their belief that they and others have conformed to the regularity in the past gives them a reason to continue conforming to it. Thus, the Gricean program involves crediting speakers of a language with knowledge about regularities of use. While this is plausible in the case of the use of complete sentences, it is problematic when we move to subsentential expressions. Words and phrases are used in complete sentences, and they make a systematic contribution to the meanings of the sentences in which they occur. Regularities of use for words and phrases are regularities of contribution to the messages that sentences are used to convey. But spelling out in detail how words and phrases (and ways of putting them together) contribute to the meanings of complete sentences is a highly nontrivial project. So, it is not plausible that every speaker of a language knows what these regularities of contribution are.

The problem for the Gricean program is that it seems bound to attribute to ordinary language users knowledge that they do not really have. It may be that we can deal with this problem by invoking some notion of tacit (Chomsky, 1986) or implicit (Dummett, 1991, 1993) knowledge (Loar, 1981). But the dominant consensus—and the view of one of the most authoritative exponents

of Grice's program (Schiffer, 1987)—is that the project of analyzing literal meaning in terms of intentions and beliefs cannot be completed.

#### DAVIDSON AND TRUTH-CONDITIONAL SEMANTICS

Any metasemantic theory can be used to provide conditions of adequacy on semantic theories. Thus, consider the Gricean metasemantic proposal:

Sentence *S* means that *p* in the language of population *G* if and only if (iff) there is a convention in *G* to use utterances of *S* to convey the message that *p*.

And suppose that a semantic theory for a particular language *L* delivers as one of its meaning specifications:

Sentence *S*<sub>1</sub> means (in *L*) that wombats seldom sneeze.

Then, according to the metasemantic proposal, one necessary condition for the correctness of the semantic theory is that there should be a convention in the population of *L*-speakers to use utterances of *S*<sub>1</sub> to convey the message that wombats seldom sneeze.

This kind of transposition can be carried out in the opposite direction too. Any condition of adequacy on semantic theories can be reconfigured as a partial elucidation of the concept of meaning—or of whatever other concept plays a key role in the semantic theory—and a great deal of philosophical work on the concept of meaning proceeds by considering constraints on semantic theories. Davidson's work (1984) provides an important example of this approach.

**THE TRUTH-CONDITIONAL FORMAT.** As we introduced the notion, a semantic theory is a theory that tells us what expressions mean. It is natural to suppose, then, that the key concept used in a semantic theory will be the concept of meaning, and that the format of the meaning specifications for sentences will be either:

The meaning of sentence *S* = *m*

or else:

Sentence *S* means that *p*

according as meanings are or are not regarded as entities. But Davidson (1967) rejects both these formats, and argues instead for the truth-conditional format:

Sentence *S* is true if and only if *p*.

His argument comes in two steps.

The first step is intended to rule out the idea that, to each word, each phrase, and each sentence, there should be assigned some entity as its meaning. This step proceeds by showing that, under certain assumptions about the assignment of entities, all true sentences would be assigned the same entity. (The argument that is used here is sometimes called the Frege argument.) Clearly, no such assignment of entities could be an assignment of meanings, since not all true sentences have the same meaning. However, it is possible to resist this first step by arguing that an assignment of meanings would not conform to the assumptions that are needed to make the Frege argument work.

Even though the first step is controversial, the second step in Davidson's argument remains important for anyone who begins by favoring the format:

Sentence S means that *p*.

We said that, given the compositionality of meaning, we should expect that, in a semantic theory, the meaning specifications for whole sentences will be derived from more basic principles that specify the meanings of words and phrases. But Davidson points out that the logical properties of the “means that *p*” construction raise problems for the formal derivation of meaning specifications for sentences. In contrast, the truth-conditional format is logically well understood. And from the work of Alfred Tarski on certain formal languages (1944, 1956) we can carry over methods for deriving truth-condition specifications for sentences from axioms that assign semantic properties to words and phrases.

**CONDITIONS OF ADEQUACY.** If what a semantic theory tells us about each sentence of a language is to be cast in the truth conditional format:

Sentence S is true if and only if *p*

then what are the conditions of adequacy on semantic theories? We have already seen an adequacy condition on the internal structure of a semantic theory; namely, that it should reveal how the truth conditions of complete sentences depend on the semantic properties of words and phrases. But what conditions must the truth condition specifications themselves meet, in order to be correct?

Tarski imposed, in effect, the condition that the sentence that fills the “*p*” place should translate (or else be the very same sentence as) the sentence S. (This is Tarski's Convention T [1956].) This condition of adequacy can be transposed into a partial elucidation of the concept of

truth in terms of the concept of translation. The concept of translation is sufficiently closely related to the concept of meaning that we can move from here to a partial elucidation of truth in terms of meaning:

If a sentence S means that *p* then S is true iff *p*.

But we cannot shed any light on the concept of meaning itself without bringing in extra resources.

The key notion that Davidson introduces is that of “interpretation.” We imagine using the deliverances of a semantic theory to help interpret the linguistic behavior of speakers. For these purposes, we can abstract away from the details of the format, and use deliverances in the schematic form:

Sentence S \_\_\_\_\_ *p*

to license the redescription of utterances of a sentence S as linguistic acts of saying or asserting that *p*. Now, by providing a way of understanding speakers' specifically linguistic behavior, a semantic theory can play a part in the project of interpreting, or making sense of, them. So, any constraints on the project of overall interpretation of people can be reconfigured as partial elucidations of the key concepts used in semantic theories.

Two suggestions for overarching constraints on interpretation emerge from Davidson's work. One possible constraint is that speakers should be so interpreted that what they say and believe about the world turns out to be by and large correct. This is the “principle of charity” (Davidson, 1967, 1973). The other possible constraint—widely reckoned to be more plausible—is that speakers should be so interpreted that what they say and believe about the world turns out to be by and large reasonable or intelligible. This is sometimes called the “principle of humanity” (see Wiggins, 1980).

In the imagined project of interpretation, the deliverances of a semantic theory are used in schematic form. For these purposes, at least, it does not matter whether the semantic theory uses the “means that *p*” format or the “is true if and only if *p*” format. So we can, if we wish, say that the constraints on interpretation shed light on the concept of meaning and thence—by way of the connection between meaning and truth—on the concept of truth.

## MEANING AND USE

We began from the vague idea that meaning has something to do with use, and have focused on two approaches to the study of meaning, both of which lay stress upon

such notions as conveying the message that *p*, saying that *p*, and asserting that *p*. Both approaches take the basic way of specifying the meaning of a sentence to involve a “that *p*” clause, and both permit the straightforward connection between meaning and truth. However, there are other ways to develop the idea of a link between meaning and use. For example, we might regard knowing the meaning of a sentence as knowing how to use it appropriately. Or we might say that knowing the meaning of a sentence is knowing under what circumstances a speaker would be warranted in using the sentence to make an assertion. Many of these ways of linking meaning with use do not lead to specifications of meaning by way of a “that *p*” clause, and so do not support the direct transfer of elucidation from the concept of meaning to the concept of truth. It is to metasemantic theories of this kind that the term “use theory of meaning” is usually applied. Use theories of meaning are often coupled with the claim that there is nothing substantive to be said about the concept of truth (see Field, 1994; Horwich, 1990, 1995).

## MEASUREMENT AND MEASUREMENT THEORY

Metrology in general and measurement theory in particular, have grown from various roots into fields of great diversity in the natural and social sciences, engineering, commerce, and medicine. Informally, and in its widest empirical sense, a measurement of a property, exhibited by stereotype objects in variable degrees or amounts, is an objective process of assigning numbers to the objects in such a way that the order-structure of the numbers faithfully reflects that of degrees or amounts of the measured property. Measuring instruments with pointers and calibrated scales for reading are the basic empirical means by which numerical assignments are realized. Abstractly, a particular way of assigning numbers as measures of extents of a property in objects is called a *quantity scale*. In the natural sciences, the results of measurement on a quantity scale are expressed in the form of denominate numbers, each comprised of a numerical value (magnitude) and a physical unit. Nominalists support the view that the results of measurement are not denominate numbers but numerals and perhaps other symbols.

### CLASSICAL TEMPERATURE MEASUREMENT

To illustrate this morass of preliminary definitions, consider classical temperature measurement. Temperature is a local thermodynamic property of physical substances,

linked to the transfer of thermal energy (heat) between them. From the standpoint of statistical mechanics, heat in a physical substance is a macroscopic manifestation of the random motion of the constitutive atoms or molecules. An increase of temperature in the substance matches the increase of rate of molecular motion, so that temperature can be rigorously conceived as a measure of the kinetic energy of molecules.

It is important to emphasize that classical temperature measurement does not depend on any of these deep underlying physical theories. In 1592 Galileo Galilei was able to measure temperature in a theory-independent way, using the contraction of air that drew water up a calibrated tube. Approximately a century later, Daniel G. Fahrenheit invented the mercury-in-glass thermometer, again without understanding energy conservation laws that were discovered and firmly established only after 1850. These remarks, however, are not all that obvious and must be taken with a grain of salt. Precise construction of thermometers and their calibration certainly relies on theories of heat and the correct representation of (freezing and boiling) reference points. Immediately a foundational question arises: Is measurement theory-laden? The answer to this question is subtle and depends on how measurement is modeled. Because modeling of numerical quantification of measurable properties makes no commitments to and assumptions about quantitative laws and substantive scientific theories, a straight answer must be in the negative. However, measurement theory addresses many issues that go well beyond the construction of quantity scales, including prominent relationships among quantity scales of measurable properties, studied by well-established scientific theories.

From the inception of quantifying temperature and other variable properties, the concept of measurement has proved to be a steady source of methodological difficulties. For example, it would be false to conclude that today it was twice as warm as yesterday because today the local temperature at noon was balmy ninety degrees and it was only forty-five degrees yesterday. The inference may appear correct because on the Fahrenheit scale indeed there is  $90^{\circ}\text{F} = 2 \times 45^{\circ}\text{F}$ . But to the opposite effect, a meteorologist equipped with a Celsius thermometer observed at the same site that the temperature today was  $32.2^{\circ}\text{C}$  and it was  $7.2^{\circ}\text{C}$  yesterday, inferring that today's temperature was approximately 4.6 times higher than yesterday. Based on the familiar conversion formula  $b^{\circ}\text{C} = 5/9(a^{\circ}\text{F} - 32)$  from Fahrenheit to the Celsius scale, the meteorologist quickly obtains the equalities  $32.2^{\circ}\text{C} = 90^{\circ}\text{F}$  and  $7.2^{\circ}\text{C} = 25^{\circ}\text{F}$ , further corroborating that today's

temperature on the Celsius scale is not twice as high as it was yesterday. Simple physical experiments show that it is not meaningful to make scale-independent comparative statements of the form above —“yesterday was  $n$  times as warm as today,” if the temperature is measured traditionally on an *interval* scale (including Celsius, Fahrenheit, Reaumur, and Rankine) in the sense of Stanley Smith Stevens (1960) and the definition recalled below. Science has little use for observational statements whose truth depends on the choice of quantity scales. In all cases of quantitative observation, the main interest is in those measurement data that are invariant under scale transformations. Louis Narens discusses many other examples of a similar nature in his *Theory of Meaningfulness* (2002).

A performance of any empirical observation is usually a complex activity that is impossible and (fortunately) unnecessary to report completely. The structure of a measurement-based observation that an experimenter is able to extract and analyze formally with some success is best captured by a measurement model. For example, in the simplest and best-known physical situation of temperature measurement, the experimenter assumes that the temperature-bearing entities (e.g., substances in vessels) can, at least conceptually, be identified and distinguished one from another, and then appropriately labeled or described. As common in other branches of mathematics, the experimenter next conceives of collecting such labels or mathematical descriptions of substances into a set, to be called a *measurement domain* and denoted  $M$ . Because this domain furnishes a mathematical basis for modeling the scale structure of measurable properties, care must be exercised in its selection. To simplify the preceding pedantic language in what follows the discussion will often refer to  $M$  as a domain of substances, objects, or events, when in actuality we mean a set of their mathematical labels or descriptions.

Galileo and Fahrenheit were able to order effectively many substances at given time instances in accordance with their exhibited degrees of the temperature property, here denoted  $t$ , without recourse to any antecedently established thermodynamical theories. This suggests that the scaling model of temperature measurement should be based on a designated comparative relation  $\leq_t$ , where the associated atomic formula “ $x \leq_t y$ ” is meant to express that substance  $y$  is at least as warm as substance  $x$ , for all substances  $x$  and  $y$  belonging to the underlying domain  $M$ .

## THE MEASUREMENT MODEL

The resulting deceptively simple *measurement model*, commonly symbolized by the ordered pair  $(M, \leq_t)$ , captures the ordering of substances with respect to degrees of their temperature property  $t$  at a specified time instant. It should be clear that a similar model can be used to characterize the comparison of substances with respect to their mass property. In many measurement-theoretic applications, the foregoing comparative relation  $\leq_t$ , henceforth abbreviated to  $\leq$ , enjoys the following pair of measurability properties for all elements  $x$  and  $y$  in the given domain  $M$ :

- (i) *Transitivity*: If  $x \leq y$  and  $y \leq z$ , then  $x \leq z$ .
- (ii) *Connectedness*:  $x \leq y$  or  $y \leq x$ .

We associate with every comparative relation  $\leq$  a canonical *indiscernibility* equivalence relation  $\approx$ , defined by

$$x \approx y \text{ iff } x \leq y \text{ and } y \leq x$$

for all  $x$  and  $y$  in  $M$ . Here the notation “iff” is a standard abbreviation for “if, and only if.” Under the foregoing intended interpretation, the atomic formula “ $x \approx y$ ” encodes the fact that substances  $x$  and  $y$  have the same degree of temperature. It should be obvious that the relation  $\approx$  partitions the domain  $M$  into equivalence classes of substances, where each class contains precisely those substances whose degrees of temperature coincide.

At this point we may ask: What are measurement models good for and how do we know that they are adequate? In measurement theory, measurement models have four basic functions: upholding *numerical representation*, specifying the *uniqueness* of representation, and capturing quantitative and qualitative *meaningfulness*.

**REPRESENTATIONAL ROLE OF MEASUREMENT MODELS.** In their *representational* role, measurement models provide a mathematical basis for numerical quantification of extents, degrees, or amounts of measurable properties of objects. For example, in the case of temperature measurement, the possibility of numerical quantification of the variable temperature property  $t$  comes down to the existence of a *quantity scale*, rendered precise by a real-valued function, denoted  $\Phi: M \rightarrow \mathbb{R}$ , that assigns to each substance  $x$  in  $M$  a unique real number  $\Phi(x)$  in  $\mathbb{R}$  (interpreted as the degree of temperature of substance  $x$ ) in such a way that the numerical order in the host field  $(\mathbb{R}, \leq)$  of real numbers agrees with the comparative relation  $\leq$  specified in the measurement model. Formally, we have the order-embedding representational condition

$$x \leq y \text{ iff } \Phi(x) \leq \Phi(y)$$

for all  $x, y$  in  $M$ . In general, there is no guarantee that an order-embedding function  $\Phi$  exists. A major task of representational measurement theory is to find a body of empirically meaningful constraints—constraining the structure of  $(M, \leq)$ , usually called the *representation axioms*, such that they are necessary and sufficient for the existence of a quantity scale (order-embedding function)  $\Phi$ . The preceding transitivity and connectedness properties are usually included in the collection of representation axioms, but generally they are not sufficient for the existence of a quantity scale. In essence, this is the way the experimenter expects to achieve a theoretically justified passage from qualitative observations ( $x$  is  $t$ -er than  $y$ ) to quantitative data that may be processed further by various computational and statistical means. It should be clear that the foregoing low-complexity measurement model is totally ineffective in characterizing the measurement of television violence, unemployment, and many other highly complicated attributes studied in the social sciences.

Not surprisingly, quantity scales (if they exist) are seldom unique. We have already seen that two arbitrary temperature measurement scales  $\Phi': M \rightarrow \mathbb{R}$  (e.g., for Celsius degrees) and  $\Phi: M \rightarrow \mathbb{R}$  (e.g., for Fahrenheit degrees) are always linked via functional composition of the form  $\Phi'(x) = f(\Phi(x))$  for all substances  $x$ , where  $f: \mathbb{R} \rightarrow \mathbb{R}$  is an affine (positive linear) *permissible transformation*, specified by  $f(r) = ar + b$  with  $a > 0$  for all real numbers  $r$ . From the standpoint of algebra, the totality of permissible transformations between temperature quantity scales forms a numerical affine group. In general, a property is said to be measured on an *interval* scale provided that its family of permissible transformations is the affine group. Along similar lines, a property is measured on a *ratio* scale just in case its family of permissible transformations is the similarity group of all functions  $f: \mathbb{R} \rightarrow \mathbb{R}$ , specified by  $f(r) = ar$  with  $a > 0$  for all real numbers  $r$ . So the apparent relativism and arbitrariness in the choice of measurement methods and accompanying quantity scales are factored out by invoking pertinent scale-transformations. In addition to guaranteeing the existence of a quantity scale, representation axioms specify the correct group of permissible transformations between scales. Thus if the experimenter intends to draw conclusions about objective temperature values, he or she must consider the associated affine group of scale-transformations and ensure that they preserve all numerical relationships of interest.

**DETECTION OF MEANINGLESS OBSERVATIONAL STATEMENTS.** Measurement models are instrumental in detecting meaningless observational statements; meaningfulness has long been a favorite of measurement theorists. We begin with the simplest characterization. Given a binary numerical relation  $\rho$  on the real line  $\mathbb{R}$ , we say that  $\rho$  is *quantitatively meaningful* for the measurement model  $(M, \leq)$  just in case for all quantity scales  $\Phi', \Phi: M \rightarrow \mathbb{R}$  the equivalence

$$\Phi'(x) \rho \Phi'(y) \text{ iff } \Phi(x) \rho \Phi(y)$$

holds for all elements  $x$  and  $y$  in  $M$ . It is easily seen that this definition automatically generalizes to  $n$ -place relations. For example, for any pair of temperature scales  $\Phi'$  (e.g., Celsius) and  $\Phi$  (e.g., Fahrenheit) the equivalence

$$\Phi'(x) - \Phi'(y) < \Phi'(z) - \Phi'(w) \text{ iff } \Phi(x) - \Phi(y) < \Phi(z) - \Phi(w)$$

holds for all substances  $x, y, z$ , and  $w$ . The concept of quantitative meaningfulness is extremely useful in determining the applicability of statistical concepts (including sample averages and standard deviation) in the world of measurement data.

There is a closely related concept of qualitative meaningfulness that is based on the notion of automorphism. Recall that an order-embedding map  $\alpha: M \rightarrow M$  of the domain of a measurement model  $(M, \leq)$  to itself is called a measurement automorphism precisely when it is one-to-one and onto. Briefly, a binary relation  $\rho$  on the measurement domain  $M$  is said to be qualitatively meaningful for the model  $(M, \leq)$  provided that for each measurement automorphism  $\alpha: M \rightarrow M$  and for all  $x$  and  $y$  in  $M$  the equivalence

$$x \rho y \text{ iff } \alpha(x) \rho \alpha(y)$$

holds. Less formally, a binary relation  $\rho$  on  $M$  is measurement-theoretically meaningful for  $(M, \leq)$  if the exact identity of  $\rho$ -related objects is irrelevant. The only thing that matters is that the objects in  $M$  possess the measured property in equal amounts. In general, quantitative and qualitative meaningfulness are not coextensive. The notion of qualitative meaningfulness is important in delineating the class of model-definable relations. It is easy to check that the omnipresent indiscernibility relation  $\approx$  is qualitatively meaningful for  $(M, \leq)$ .

**REPRESENTATION AXIOMS.** Finally, in addition to securing a quantity scale and its uniqueness (up to permissible transformations), representation axioms of a measurement model can also be viewed as capturing the

overall *empirical content* under consideration, encountered in testing the measurement model's adequacy. In this context, measurement axioms are usually classified into *rationality* (design) axioms (including transitivity)—assumed to be automatically true under the intended interpretation; *structural* (technical) axioms (e.g., the Archimedean axiom), crucial in establishing powerful representation theorems; and various testable *empirical* axioms, characterizing (often in a highly idealized way) specific measurement methods.

To appreciate the striking simplicity of measurement models, it is important to realize that these models represent the observational structure of a measurable property in such a way that most of the empirical detail of the actual observation is ignored. Here the experimenter is interested only in a basic abstraction that is based on comparisons of extents of given measurable properties, sufficient for a suitable order-preserving numerical quantification.

## REPRESENTATIONAL THEORY OF MEASUREMENT

Measurement theory in general (as a branch of applied mathematics) and representational measurement theory in particular, are mainly based on work summarized in *Foundations of Measurement* (vol. 1, 1971) by David Krantz and others; *Foundations of Measurement* (vol. 2, 1989) by Patrick Suppes and others; and in *Foundations of Measurement* (vol. 3, 1990) by Duncan Luce and others. These authors use a model-theoretic (semantic) conception of empirical theories. In brief, instead of conceiving measurement theory as a deductively organized body of empirical claims, the semantic conception views a theory as a way of specifying a class of set-theoretic relational structures that represents various aspects of reality. The principal objectives of measurement theory are the study of set-based models of measurable properties of empirical objects, maps between them, and the representation of measurement models in terms of convenient numerical structures, with special regards to the relationships between the latter and affiliated quantitative theories of empirical objects.

Representational measurement theory studies many species of measurement models. In his *Physics: The Elements*, Norman Campbell (1920) noted that in modeling *extensive* properties (including, e.g., length, area, volume, mass, and electric charge), the above specified order-theoretic measurement model  $(M, \leq)$  has a powerful algebraic enrichment, typically symbolized by  $(M, \leq, \circ)$ , where  $\circ$  is a binary composition operation on  $M$ , satisfy-

ing the following partially testable empirical conditions for all  $x, y, z$ , and  $w$  in  $M$ :

- (i) *Commutativity*:  $x \circ y \approx y \circ x$ .
- (ii) *Associativity*:  $(x \circ y) \circ z \approx x \circ (y \circ z)$ .
- (iii) *Monotonicity*:  $x \leq y$  iff  $x \circ z \leq y \circ z$ .
- (iv) *Positivity*:  $x \leq x \circ y$  and not  $x \circ y \approx x$ .
- (v) *Strongly Archimedeaness*: If  $x \leq y$  and not  $x \approx y$ , then for any  $z$  and  $w$  there exists a positive integer  $n$  such that  $n \bullet x \circ z \leq n \bullet y \circ w$ , where  $n \bullet x$  is defined inductively by setting  $1 \bullet x = x$  and  $(n + 1) \bullet x \approx n \bullet x \circ x$ .

In the case of length measurement, the measurement domain  $M$  consists of suitable and to some extent idealized length-bearing entities (e.g., straight, rigid rods) that can be properly identified and distinguished one from another. Because length measurement is modeled within a classical framework, relativistic reminders that length is not an intrinsic property of rods but something relational—relative to inertial reference frames—will not be of concern.

To measure length in a basic way, independently of any application of laws, the experimenter *operationalizes* the comparative “at least as long as” relation  $\leq$  by placing two rods side by side in a straight line, with one end of the rods coinciding, and observing which one extends at the other end. In this manner the experimenter has an effective way of determining whether the relational formula “ $x \leq y$ ” holds for virtually any pair of rods  $x$  and  $y$  in  $M$ . Of course if rod  $x$  is a physical part of rod  $y$  or is equal to  $y$ , then the validity of “ $x \leq y$ ” is accepted by default. The composition  $x \circ y$  of rods  $x$  and  $y$  is understood to be the rod obtained by the operation of placing rods  $x$  and  $y$  end to end in a straight line. Thus we take the abutted combination of rods  $x$  and  $y$  to be the whole composite rod  $x \circ y$ .

We know from David H. Krantz and others (1971, p. 73) that the representation axioms above are necessary and sufficient for the existence of a real-valued, order-embedding, additive scale function  $\Phi: M \rightarrow \mathbb{R}$ , satisfying the representational condition

$$\Phi(x \circ y) = \Phi(x) + \Phi(y)$$

for all  $x, y$  in  $M$ . We see that the representation axioms not only justify a numerical quantification of amounts or extents of measurable properties, they capture the structure of the associated extensive measurement process itself.

In his basic concepts of measurement Brian Ellis (1966) addresses the question whether the preceding interpretation of composition operation  $\circ$  is intrinsic to physical measurement of length or is perhaps just a convenient convention. Ellis points out that the representation axioms listed above remain valid even if the experimenter uses an orthogonal concatenation of rods. Specifically, this time the composite rod  $x \circ y$  is obtained somewhat artificially as a rod formed by the hypotenuse of the right triangle, whose sides are the rods  $x$  and  $y$ . Thus here the experimenter is abutting  $x$  and  $y$  perpendicularly rather than along a straight line. Not surprisingly, because the operational peculiarities of respective compositions in a straight line versus orthogonally are not visible in the representation axioms, the corresponding enriched measurement models  $(M, \leq, \circ)$  and  $(M, \leq, \circ')$  are measurement-theoretically indiscernible. Ellis holds a conventionalist view of measurement, in the sense that measurable properties do not exist independently of their methods of measurement.

The technical problem of “ $x \circ x$ ” is circumvented by using an unlimited supply of copies of  $x$  (so that  $x \circ x \approx x \circ y$ , where  $x \approx y$ ) or by passing to a partial composition operation. Ontological objections against using models with infinitely many objects are obvious. Another problem is whether the comparative relation  $\leq$  and composition  $\circ$  of a measurement model  $(M, \leq, \circ)$  are directly observable. Scientific realists in particular argue that in general the representation axioms treat the empirical structures of measurement models as something decisively theoretical.

There are several ways to develop a general theory of *derived* measurement. In some ways the most natural place to start is with the notion of fundamental measurement, covered earlier. A measurable property is said to be *fundamental* or *basic* provided that its measurement does not depend on the measurement of anything else. Simply, a measurement theorist starts with a measurement model  $(M, \leq, \circ)$  of a basic property together with the characterizing representation axioms and then proves the existence and uniqueness of the quantity scale. No other measurement models are needed.

In contrast, a *derived* measurable property is measured in terms of other previously established quantity scales and measurement models. A classical example in physics is density, measured as a ratio of separate measurements of mass and volume. To avoid conceptual confusion, it is not suggested that a fundamental measurement of density is impossible. When mass and volume are known, there are offsetting advantages to working

with a derived notion of density. Another question is whether any measurement is truly basic.

## A BRIEF HISTORY OF MEASURING DEVICES

It is invariably difficult to trace the origins of measurement devices. Weights and measures were among the earliest tools, invented and used in primitive societies. Ancient measurements of length were based on the use of parts of the human body (e.g., the length of a foot, the span of a hand, and the breath of a thumb). Time was measured by water clocks, hourglasses, and sundials.

The earliest weights were based on objects frequently weighed (e.g., seeds, beans, and grains). Comparisons of capacities of containers were performed indirectly by filling gourds and vessels with plant seeds—which were later counted—and water. These *qualitative* measurement methods, used in conjunction with crude balance scales, formed a basis of early commerce. There was an enormous proliferation of local and national measurement systems and units (e.g., Egyptian around 3000 BCE; Babylonian around 1700 BCE; Greek in 500 BCE; and Roman around 100 BCE). Romans adapted the Greek system that was later adopted with local variations throughout Europe as the Roman Empire spread. As these methods of associating numbers with physical objects were growing, it became possible to compare the objects *abstractly* by comparing the associated numbers and to combine them by manipulating numbers. In the presence of standardized units accepted by the whole community it became possible to replace accidental comparatives of the form “five times the width of my finger” with more universal but still unit-dependent “3.75 inches.”

In England in the early thirteenth century, measures and weights (strongly influenced by the Roman system) quickly evolved along the lines of strict standardization. In France, standardization of measures and weights came several centuries later. In 1670 Gabriel Mouton, a French priest, proposed the establishment of a decimalized metrology of weights and measures. The unit of length that was finally decided on was one ten-millionth part of a meridional quadrant of the earth. Weight of a cubic decimeter of distilled water at maximum density temperature of 4°C was adopted as the kilogram. (During the second half of the twentieth century there was a shift away from standards based on particular artifacts toward standards based on stable quantum properties of systems.) The adoption of the metric system in France and generally in Europe was slow and difficult, until the Inter-

national Bureau of Weights and Measures, formed in 1875, recommended the universal adoption of the MKS metric system in European countries that was subsequently signed in seventeen states. In the modern SI (Système International d’Unites) version of the metric system, there are seven base units (length, mass, time, temperature, electric charge, luminous intensity, and phase angle) from which all other units of measurement are derived.

One impressive feature of modern science is the rapidity with which new measuring instruments are being developed. For example, in the case of time measurement, and starting from imprecise ancient water clocks and hourglasses, people in the Middle Ages built town clocks (maintained by hand) to display local time. In 1656 Christian Huyghens built the first accurate pendulum clock; less than a century later John Harrison presented the first nautical chronometer. In 1928 Joseph Horton and Warren Morrison built the first quartz crystal oscillator clock. And finally, in 1950, Harold Lyons developed an atomic clock based on the quantum mechanical vibrations of the ammonia molecule. Cesium atomic clocks measure time with an accuracy of  $10^{-15}$  seconds.

Experimental science has progressed thanks in great part to the speedy development of highly accurate measuring devices in nearly all branches of science, engineering, and medicine. The symbiotic relationship between theoretical research and measurement methodology continues to be a fundamental factor in the development of science. Philosophically, measurement is important because it provides empirical foundations for the construction of quantitative scientific theories, necessary for reliable prediction and explanation of vast categories of empirical phenomena.

## MEDICAL ETHICS

A basis for medical ethics can be found in the Hippocratic oath. These ethics, in sum, emphasize that doctors should keep confidences, soothe their patients' suffering, and not overstep their medical abilities. The limitations of physicians set the limits of the code. With fewer limits, there are more issues to discuss: surrogate motherhood; allocation of expensive but lifesaving modalities; an emphasis on privacy and autonomy and an evaluation of the medical system itself. A caveat is necessary. The discussion of medical ethics that follows is based on the present day American system of medical practice. While much of the ethics and ethos of medicine crosses cultures, other issues may not. For example, particular questions concerning paternalism especially related to truth telling are often culture specific. Also, the American legal system, at least according to some, encourages malpractice suits against physicians leading to interesting questions about how best to practice medicine.

A standard set of topics in medical ethics are: abortion, euthanasia, confidentiality, truth telling, medico-legal jurisprudence, genetics and medicine, allocation, experimentation and informed consent, suffering, and guilt. Each area can be associated with a basic question.

Issues in medical ethics tend to arise not from questions about moral theory but from practical and clinical concerns. Failure to take this fact into account can lead to analyses that bear little resemblance to principles or rules that can be applied in clinical practice. One important difference between typical questions that arise from

moral theory and those that arise in medical contexts is the lack of disinterest that one usually finds in medical contexts where a disinterested perspective is probably unrealistic. One cannot be disinterested in a beautiful but possibly battered infant. One cannot be disinterested in the pain and suffering of a terminally ill patient in virtually unmitigatable pain who asks to be allowed to die. But even if disinterested, a physician need not, therefore, be uninterested or uncaring. Indeed, physicians almost always have emotional investment in cases such as these. Whether they should or should not is another issue (a question that concerns medical education and human nature), but they do.

Even so, the moral principles appealed to are traditional ones. Do not cause pain unnecessarily. Keep promises and tell the truth, except when obvious harm will result from doing so. Do not interfere with the lives of people unless they ask for this sort of help. Do not be so selfish that the good of others is never considered. Thus, despite the glittering high technology of the modern day hospital, the dramatic emergency room, the life and death feeling of the neonatal intensive care unit, the vulnerability often felt in the examining room, medical ethics is still ethics. What follows is a description of some central issues in medical ethics.

### PATERNALISM AND THE GEORGETOWN MANTRA

To say that *A* acts paternalistically toward *B* involves five beliefs on the part of *A* about the action aimed at *B*: (1) It is done for the good of *B*; (2) *A* is qualified to perform the act; (3) the action violates a specifiable moral rule; (4) the most important factor is the good of *B*; (5) *B* believes that no outside help is needed. Justifying a paternalistic action requires that it be clear that *B* would be irrational not to want the action forced and that *A* be willing to accept as a general rule something such as, "In all cases like this, a paternalistic action is allowable" (see Bernard Gert's and Charles Culver's *The Justification of Paternalism*; for an overview of the issue see the entry under *paternalism* in the Stanford Encyclopedia of Philosophy, available from <http://plato.stanford.edu/entries/paternalism/>).

The four part approach to medical ethics, often referred to (after the home of its proponents) as the Georgetown mantra suggests that all medical ethics decisions can be seen from the standpoint of playing off autonomy, beneficence, non-maleficence, and justice one against the other with the goal being, in each case, to get just the right balance. The four parts represent principles: respect persons rights to decide for themselves; help those

in need; avoid harming others; fair treatment, given what is owed. The mantra, popularized in *The Principles of Bioethics* by Tom Beauchamp and James Childress, was presented as a midlevel set of principles between theory, from which they were derivable, and practice. Whether using an approach based on the four principles overemphasized the application of principles to the detriment of, and need for, an overarching theoretical approach, is an ongoing debate, one especially relevant to the pedagogy of medical ethics (see Koppelman [1999]).

Because physicians make ethical decisions to some extent based on their medical school courses in medical ethics, pedagogy has always played an important role in medical ethics. Initially, most medical ethics courses were based on extrapolations from an analytic approach to ethics. There are at least two other approaches. One stresses phenomenology, the other stresses the view that patients are best understood in terms of their unfolding stories or narratives thus diminishing the role of analytic type approaches to medical ethics. The use of literature in teaching medical ethics is a natural consequence of seeing medical ethics in this manner. This essay shall discuss neither the narrative approach to medical ethics, the phenomenological approach, nor the pedagogy of medical training (on the narrative approach, see Howard Brody's *Stories of Sickness* and A.H. Hawkins's *Literature, Medical Ethics, and Epiphanic Knowledge*; for the phenomenological approach, see Zaner [1981]); for pedagogy, see the journal, *Academic Medicine*; for a critique of some uses of literature as well as a defense of an analytic approach to medical ethics, see Zucker [2006]).

## THE DOCTOR-PATIENT RELATIONSHIP

The issue of paternalism is closely related to questions about the norms governing the doctor-patient relationship. Different models have been proposed to characterize this relationship. Most are based on some version of a contract and so rights are important. The business model: Here the patient gives up rights (privacy, for example) and money. For this, the patient receives service (health care). The engineering model: the doctor as a mechanic. Just as one leaves an automobile with the mechanic after trying to describe the problem, the patient tells the mechanic-physician what seems to be wrong and, in effect, leaves. Here, once the physician knows the problem, the patient is treated more like an automobile and less like a person. The patient trades the right to be treated like a person for a tune-up from the doctor—in the hope that this is the best route to running smoothly.

The priest to supplicant model: The doctor has access to important information to which the patient has no access. On this model, getting better is like having one's soul saved by a priest. Staying within the church requires that you follow the rituals required of you by the priest. Getting better requires that you follow the doctor's instructions. On this view, self-help programs would be discouraged. On the collegial model, the stress is on the partnership between the physician and patient. They are partners with a common goal: the health of the patient. On this model, each side trusts the other; each has confidence in the other. The physician suggests treatment, the patient agrees or says why not, so that a compromise can be reached.

The covenant model is not based on a contract. It stresses the dedication of the physician to the goals of medicine. Among the highest of these goals are eliminating disease and alleviating pain. The covenant model focuses on trust, concern, and sympathy. It emphasizes the caring relationship. To many, the appeal to such ideals characterizes the medical profession.

These medical models are ambiguous in the following sense. Are they descriptive or normative? These models are not meant to be an exact replica of reality. Rather, each is, to some extent, heuristic; meant to highlight an aspect of doctor-patient relations making them easier to analyze (on doctor patient models, see E. J. and L. L. Emanuel's *Four Models of the Physician-Patient Relationship*).

## ABORTION

The ethical questions concerning abortion have to do with the justification of killing in a medical context. The first line of defense permitting abortion is the claim that what is killed is not the sort of thing that is (or should be) protected by traditional rules against killing. A second line of defense is seeing abortion as a help to the pregnant woman who wants the abortion. It is even possible to see abortion as a help to a fetus whose life, if not aborted, would be one of pain, degeneration, and death (e.g., infants with Tay-Sachs disease). A third line of defense views abortion as a public health issue. That is, history shows that some pregnant women will seek abortions. If abortions were illegal or very difficult to get, only the rich would be able to get safe abortions. This would be unfair as well as pose health risks to the poor. In a situation, where abortion is contemplated as an option, the question from medicine's standpoint, whether explicit or implicit, is: What is the moral status of a fetus (see entry on "Abortion")?

## EUTHANASIA

There are situations where a physician might be asked (desire) to let a patient die, might be asked (desire) to help a patient to die, or might be asked (desire) to outright kill a patient. The usual reasons are unmitigatable pain (except through rendering the patient unconscious); irrevocable loss of meaningful consciousness (permanent vegetative state); irrevocable loss of some ability held so dear to the patient that death is preferable (see entry on “Euthanasia”).

While it may be rational to prefer death to constant, unremitting pain, it still may be unethical for a physician to allow such a patient to die (by withdrawing or never starting life-sustaining therapy) when that patient can be kept alive. It should be noted that sometimes, the pain referred to is not so much the pain of physiology gone awry as it is the emotional distress caused by the loss of quality of life. That is, a return to baseline may not be possible and, to some people, a new and restricted life is not worth living.

The blunter version of the euthanasia question is: Should a physician kill a patient under any of these circumstances even with the permission of the patient, even where the patient begs to be killed or allowed to die? Writing a prescription for a lethal drug dose and giving it to a patient knowing that it will be used to commit suicide is considered physician assisted suicide. Some consider it a violation of medical ethics. Even if care is taken in establishing the legal and moral rules for physician assisted suicide, this can still be seen as irrelevant to the ethical evaluation. Appeal to the medical tradition does not support assisted suicide as a legitimate form of practice but there is no reason to think that tradition must be obeyed, that no new traditions can be initiated. The clearest example of traditions changing is the shift toward autonomy and consent in medicine—paternalism certainly had been the rule.

It has been argued that medicine has no room at all for intentional killing or letting patients die (see Thomasma and Pellegrino [1993]). The argument can be supported by religion but it need not be. The argument can be based on the nature of the medical profession and what most patients come to expect from physicians. The argument—by no means an uncontested one—is that letting physicians kill patients (or allowing physicians to let patients die) would erode patients’ trust that nothing will be done to them that is not in their best interests. The argument goes on to claim that allowing physicians to kill some patients will create nagging suspicion: Will I be next?

The profession of medicine is dedicated to preserving life and make it better. Therefore, medicine should not aim at ending life. Here there is a clash between individual patient rights and physician rights to discharge what may be seen as the obligations of the profession.

The Council on Ethical and Judicial Affairs of the American Medical Association (AMA) updated its Do Not Resuscitate (DNR) guidelines to include two reasons for withholding Cardio-Pulmonary Resuscitation (CPR): (1) The action would be medically futile; (2) the patient has requested no CPR. The guidelines also suggest that physicians talk to their patients about the possibilities of cardiac arrest and the need for CPR. The idea is to have an informed patient taking an active part in the decision-making. Physicians—the AMA guidelines say—are obligated to honor the wishes of the patient (or named surrogate) except where it is clear to the physician that the CPR would be futile. The definition of *futile* is: (a) unlikely to restore cardiac or respiratory function; or (b) unlikely to achieve stated patient goals.

The guidelines allow the physician to enter DNR in the record because of futility but only if the patient or surrogate is fully informed. *Fully* includes explaining why and what the alternatives are if the patient still wants CPR. Of course, sometimes it is not the patient who wants everything done. Sometimes, it is a family member.

Part (b) of the AMA suggested definition of futility (viz., not likely to achieve stated patient goals) would allow for a patient to demand CPR for just a few hours more of life when that, but only that, was likely to occur. This can be seen as counterproductive in that it is a waste of resources and offers false hope to patients (Lo [1991] offers a standard defense of this view). Judging a hope false on allocation grounds may well beg a question against the role of autonomy in medical practice.

## CONFIDENTIALITY AND TRUTH TELLING

Confidentiality goes hand-in-hand with privacy and truth telling. During a visit, a physician may ask personal questions such as “Are you sexually active?” Physicians expect truthful answers. Truthfulness is insured by the tacit understanding that answers will be kept private and used only to help the patient. Where the clear well-being of a third party (or parties) is jeopardized by keeping a confidence, there is at least the presumption that the confidence can be violated (on this, see *Tarasoff v. The Regents of the State of California*). Contagious diseases are just one kind of example. People with seizure disorders and drivers of public vehicles who have high blood pressure

would not have their driver licenses suspended if physicians never reported this information. These sorts of cases bring up a related question.

Should a physician be put in a situation where privacy and confidentiality are likely to be compromised? Physicians working for industry or for government can be in a situation where they are expected to reveal what would otherwise be kept confidential. In cases like these, what counts as a confidence is determined by the sort of physician one is. Physicians doing health exams for insurance companies or school boards cannot keep certain conditions private. Physicians working for factories are expected to identify malingerers. Should these be seen as violations of confidentiality? Do they undercut the very professionalism of the physician? A true malingerer does hurt everybody by collecting undeserved benefits. But should it be the role of any physician to protect the economic interest of a company and its workers?

Physicians who work for the armed services or as team physicians in organized sports can find themselves in the odd situation of patching someone up in order to have that person go back into battle or back onto the playing field only to risk more injury. Some physicians in the armed forces may find themselves as consultants to interrogators. The justification here is that in this capacity the physicians are behavioral scientists and therefore freed of their usual ethical obligations because those obligations are based on clinical medicine (see Bloche and Marks [2005] for an analysis of this type situation). Are such physicians in conflict with the higher goals implicit in the covenant view of the doctor-patient relationship? Put another way, is the covenant view of the doctor-patient relation, even if meant merely as normative, a realistic normative picture? What are realistic values for the medical profession? This question is the crux of medical ethics.

“Should physicians ever not tell the truth?” is a question related to the justification of paternalism. The usual context for questioning the necessity of truth telling is along the lines of withholding some information that the physician knows the patient (or a third party) would like to know (e.g., your son has a sexually transmitted disease [STD]); or deflecting a question such as “What do you think it is, doctor?” because the doctor thinks the answer is not one that the patient really wants to hear. Where truth telling and confidentiality conflict, confidentiality almost always will take precedence. Whether it should, is another question. The nondirective counseling favored by most genetic counselors may sometimes be open to being interpreted as withholding truthful replies.

## MEDICO-LEGAL JURISPRUDENCE

There is no issue in medical ethics that does not have a legal version of it—a case brought to court. The theory behind most decisions is personal injury law. In medical malpractice, one must show damage that was caused by care that was less than standard.

There have been many cases that can be considered to be landmarks. *Tarasoff v. The Regents of the State of California*, decided in 1976, found that a psychiatrist was negligent in not warning a third party that she might be at risk from a patient. This decision changed the form of consent in psychiatry and clinical psychology limiting the confidentiality that can be offered a patient in therapy. Less dramatic but almost as far reaching is *Helling v. Carey*, which helped determine standards of care against which to judge physicians; on surrogate motherhood; *in the Matter of Baby M*; on abortion, *Roe v. Wade*; on brain death and persistent vegetative state, *In the Matter of Karen Quinlan, An Alleged Incompetent* and *Cruzan v. Director, Mo. Health Department*; on privacy, *Griswold v. Connecticut*; on informed consent, *Canterbury v. Spence*.

Medical malpractice has an allocation aspect to it. Some specialties are sued much more than others. The usual reasons cited are the high-risk patients seen and the high expectations of many of these patients (here is an overlap of consent and malpractice; appropriate consent should include a realistic statement of expected outcomes). Rather than continue paying for high malpractice coverage to insurers and rather than risk what they take to be unfair assaults on their integrity, specialists will retire early or relocate to areas with low malpractice rates. Legislation proposed to limit awards in malpractice cases can be seen as trying to limit suits filed. But such legislation can also be viewed as aiding insurance companies who cover physicians (as well as aiding less than fully competent physicians).

## GENETICS AND MEDICINE (GENOMIC MEDICINE)

Until the recent successes of the human genome project, issues in medical genetics revolved around genetic counseling and a what now might be termed proto-genetic engineering. Patients, sometimes referred to as clients in the genetic counseling context, almost always ask: Why did this happen to me? Should I have another child? What do you think this is? Directive counseling would answer these questions explicitly, sometimes before they were asked. Nondirective counseling deflected them as best as possible. The justification for the nondirective approach is that any directive counseling smacked of paternalism,

at the least, and eugenics, the attempt to change the gene pool through selective breeding of humans, at the worst. The nondirective approach grew out of the fact that advances in genetics that made genetic counseling a viable specialty coincided with the connection made between the eugenics movement in the United States and the use of eugenics in Nazi Germany. Eugenics is implicit in any directed program of genetic counseling and prenatal diagnosis along with selective abortion, thus the preference for nondirective counseling (negative eugenics weeds out unwanted genetically controlled traits; positive eugenics encourages the proliferation of desired genetically controlled traits).

The major question connected to genetics via the Human Genome Project is in what ways would we like to be better—and just how much better? And not just for us, for our progeny. Talk about what the good life is and even how best to reach it has a long history. But now there is promise that it is attainable via genetic engineering, that we will be able to choose or redesign our genes so that we will have more control over our ability to live the good life. Nurture plays a role but having the possibility of controlling the raw material of nature gives us a head start on nurture. We can be taller, shorter, thinner, more muscular, more musical, more mathematical, and so on. Again, even a head start is better than the level playing field—if these are our goals. John Rawls proposed that because what he termed *natural assets* are not distributed according to moral worth, a principle of redress was needed as a way to compensate people slighted by the natural lottery. Such a principle of redress would have to be implicit in the control over the natural lottery (on this whole topic, see Buchanan, Brock, and Daniels [2000] as well as Rawls [1971]).

Cloning humans, cloning stem cells, methods for prenatal genetic selection (including genetically engineering our progeny) raise issues that reflect those from abortion, euthanasia, privacy, and allocation. Answering: “What sort of person do we want our child to be?” or “What sort of people do we want in general and how much should we spend to get them?” are variations of age-old ethical issues. If some genetic changes are actually crucial to what we are as humans, then there are issues of defining personhood involved.

## ALLOCATION

Allocation issues are divided into microallocation (who gets what) and macroallocation (how should health care itself be distributed). These two questions straddle the line between economics, social and political philosophy,

and ethics. The question is one of a proper distribution of goods, where some baseline version of health is a minimal good and maximum health is the maximum good. Any decision of how to distribute these goods will also determine in part what we take the profession of medicine to be. Given that resources—time and money, as well as organs, fetal tissue, hospitals, operating rooms, and so on—are limited, it is difficult to decide how to distribute health care in a just manner. Why should some people get more and better health care than others? It certainly does happen. Is it because of planning or is it just the luck of the draw? Should something as important as health care be left to luck? The question is how to deal with the reality and the necessity.

Daniel Callahan (2000) has argued that many of our worst allocation problems are traceable to what he terms the research agenda of medicine, an agenda to cure everything to extend life as a goal in and of itself. Daniel Callahan thinks medicine should have another major goal. He offers three alternative principles. First, research should focus on premature death, ones before sixty-five, according to the U.S. government. Callahan gives a looser formulation. He says: “[any death is premature if it occurs] before a person has lived long enough to experience a typical range of human possibilities and aspirations: to work, to learn, to love, to procreate, and to see one’s children grow up and become independent adults” (Callahan 2000, p. 654).

Second, research should aim at reducing poor quality of life at the last stages of life. Third, clinicians should be persuaded that helping a patient to a peaceful death is just as important as fighting for life to the end, against all odds. Callahan says that as ideals, helping a patient to a peaceful death and fighting for life against all odds are of equal value because, in the end, we all die. It is here that this perspective on allocation overlaps euthanasia issues.

A program of allocation based on autonomy and tolerance in a *laissez-faire* driven economy, where economics plays an important role in health care means some people will get less health care and suffer for it. In such situations, one would be forced to say (after H.T. Engelhardt in his Shattuck Lecture of 1984) that this is unfortunate but not unfair. If, however, justice demands more of an equitable distribution of needed goods, and health is one such good, then the unfortunate begins to blend into the unfair.

The lifeboat offers an interesting model for both macro and micro allocation. How many lifeboats should any ship carry? In a crowded lifeboat, should anyone have to go overboard to save the majority? What is the best

strategy for saving the majority, for getting the most moral result? How is such a decision to be made? Should there be prearranged rules, should there be deviations allowed (many toddlers aboard, no sailors), should the rules be made during times of stress (a storm, rising seas)? For a lifeboat case, see *United States v. Holmes*.

### FREE AND INFORMED CONSENT IN CLINICAL AND EXPERIMENTAL MEDICINE

The gold standard for medical experimentation is the randomized, double-blind, and placebo controlled experiment with a statistically predetermined cutoff point. There is no such thing in clinical studies or in science in general as definitive results, *per se*. All results are definitive enough, against a background of assumptions and goals. Design and ethics go together. A poorly designed experiment will waste resources and, where there is risk, will put subjects at risk for no good reason. Consent is an ethically necessary part of any experiment. The consent must be free and informed. Subjects cannot be under so much emotional or physical pressure that they feel that they must consent. They must believe it when told that their deciding not to enter a study will not affect their treatment. This freedom from felt coercion overlaps the informed in free and informed consent because it is unlikely that someone under the previously mentioned stresses would (or could) fully understand the information given. The benefit from an experiment must at least promise some gain to the subject or future patients proportional to whatever is the risk of harm. The gain may be limited only to the knowledge that one has helped some future people.

To highlight some issues, consider work done by Dr. Saul Krugman at Willowbrook. Many children at the Willowbrook State School in New York developed hepatitis because of poor sanitary conditions. Newly admitted children were separated from other children, kept in clean quarters but fed the virus collected from infected children. Careful follow-up on these children revealed that there were two strains of hepatitis, one more communicable than the other. In defense of the experiment, it was pointed out that children were likely to get hepatitis anyway and that as subjects they received better care than they would otherwise. Parents had given consent but the reward for consent was immediate admission instead of a long wait (Munson 2003). Willowbrook exemplifies clashes between a physician's obligations to society—clean up Willowbrook; obligation to patients—find a cure or preventive for hepatitis; obligation to science—

find out more about hepatitis, even if a cure is not imminent. It also highlights consent issues. How can one get truly free and informed consent for these subjects or their parents? Recent experiments utilizing genetic therapy have been halted because of excess morbidity and deaths. In these instances, there was great risk, but taking the risk was the only route to possible freedom from disease.

Free and informed consent is part of any clinical encounter as well. The principles insuring free and informed consent for subjects also apply to patients in everyday clinical situations. Patients must be treated with up-to-date therapies that are aimed specifically at their condition. Treating a contagious disease affects others but does not affect the principle that it is the patient in front of the physician who ought to be the target for therapy. Patients must be told what they are asked to accept as therapy and why. They must believe that they can ask questions as well as ask for a second opinion without jeopardizing their treatment. And, of course, risk in therapy must be proportional to gain. An often overlooked point is that some patients do not want much, if any, information. In such cases, doctors have to gauge just how little information they can safely (medically and legally) refrain from giving verbally (where consent forms are needed, information is written, and the question would be how carefully and explicitly the material should be explained to the patient).

### PAIN AND SUFFERING

Sometimes, medicine can do no more than to alleviate pain. Sometimes, physicians cannot even diagnose the underlying problem. But if they can relieve pain, they have discharged what might be called a minimum obligation. This is the sort of obligation that is captured in the old saying "Above all, do no harm." Sometimes the only way to pursue this end is by listening to a patient ask, and ruminate on, the Jobian question, "Why is this happening to me?" Perhaps this aspect of medical ethics is the one that takes it furthest from traditional philosophy.

## MEDIEVAL AND EARLY CHRISTIAN PHILOSOPHY

In addition to the general article *Medieval Philosophy*, the Encyclopedia features the following articles having discussions of early Christian and medieval schools and movements: *Apologists*; *Augustinianism*; *Averroism*; *Byzantine Philosophy*; *Carolingian Renaissance*; *Chartres, School of*; *Gnosticism*; *Ockhamism*; *Patristic Philosophy*; *Saint Victor, School of*; *Scotism*; and *Thomism*. Particular aspects of early Christian and medieval thought are discussed in the Encyclopedia's general entries, including *Ethics, History of*; *Islamic Philosophy*; *Jewish Philosophy*; *Logic, History of*; *Metaphysics, History of*; *Mysticism, History of*; *Semantics, History of*; and *Universals, A Historical Survey*. See also *Christianity, Illumination*; and *Liber de Causis*. See "Medieval Philosophy" and "Christianity" in the index for entries on important figures in this area.

## MEDIEVAL PHILOSOPHY

"Medieval philosophy" began with the African Christian Augustine of Hippo (354–430), whose life and writings reflected the unsettled state of the declining Roman Empire long before the commencement of the Middle Ages proper. His rich and many-sided works display the Platonic otherworldliness of his theories of knowledge and world history. According to Augustine's vision, the true cosmic plan unfolds in the history of the City of God, and the local accidents of the Earthly City are of little account in comparison. Correspondingly, true wisdom and virtue are obtainable only in the light of the Christian faith and by the prevenience of divine grace; human nature, grossly corrupted since the Fall, is in need of a correspondingly complete divine remaking. Whereas for Plato and Aristotle the fulfillment of human capacities required the possession of a high degree of sophisticated intelligence, for Augustine such fulfillment depended on rightness of the will and the affections. These two features, a radical view of the transforming power of grace and a voluntaristic accent, may be regarded as the kernel of Augustinianism, at least insofar as it affected subsequent thought. The tremendous influence of Augustine on medieval thought is matched by that of Ancius Manlius Severinus Boethius, whose grandiose plan was to transmit to the Latin West the works of Plato and Aristotle—a plan rudely cut short by his execution in 524. However, he accomplished the translation of Aristotle's logical

works into Latin; his commentaries on some of them, and on the Neoplatonist Porphyry's introduction (*Isagoge*) to the *Categories* of Aristotle, were immensely influential in shaping the technical Latin vocabulary and turns of expression that prevailed in the Middle Ages, so much so that any appreciation of medieval thought must inevitably be inadequate without a thorough acquaintance with Boethius's logical output.

The intervention of the Dark Ages presented Western scholars with a gigantic task of rethinking and reconstruction. During these centuries of insecurity and uprootedness there was little intellectual endeavor, apart from the exceptional work of the Neoplatonist John Scotus Erigena in the ninth century. The logical, theological, and classical inheritance slumbered insecurely within the libraries of threatened Western monasteries. When Anselm of Canterbury (1033–1109) began to exploit Boethian logic in order to render his Christian faith intelligible, he had no immediate predecessor who in any way approached his stature as a thinker. Author of the *Ontological Argument* and fully alive to the power of linguistic analysis as a tool for clarifying conceptual problems, Anselm was the father of Scholasticism. Working within an Augustinian framework, Anselm and other logical theologians of the eleventh and twelfth centuries attempted to bring into order and coherence the body of doctrine to which they were committed by Holy Writ, dogmatic pronouncements, and the works of earlier authoritative church writers. The formidable dimensions of the enterprise were well known to them, as is shown in the lists of clashing antitheses made explicit in the *Sic et Non* (For and Against) of the ill-fated logician Peter Abelard (1079–1142). A systematic collection of authoritative opinions, the *Sentences*, upon which all subsequent medieval thinkers exercised their logical and philosophical ingenuity in the form of commentary, was compiled by Peter Lombard (c. 1095–1160).

While the Latin West, employing a predominantly logical Aristotelianism, was engaged in the tasks described above, as well as in controversy on the topic of universals, the more advanced Islamic civilization spreading from the Middle East possessed the whole body of Aristotle's works. These received development, commentary, and a Neoplatonic flavor at the hands of a series of subtle thinkers, among whom were al-Fārābī (c. 873–950), Avicenna (980–1037), and Averroes (c. 1126–c. 1198). From about the middle of the twelfth century on, Latin translations of their works became available; and through these, as well as through translation directly

from the Greek, Western thinkers eventually knew all of Aristotle's writings.

The Jewish philosophers Solomon ben Judah ibn Gabirol (c. 1021–1058 or 1070) and Moses Maimonides (1135–1204) also contributed to the intellectual ferment of the thirteenth century, which was accompanied by the establishment of universities within which members of the recently founded orders of Dominican and Franciscan friars were soon competing with secular masters for professorships. Generally speaking, the Dominicans, following the lead of Thomas Aquinas (c. 1224–1274), attempted to assimilate Aristotle by adopting a framework within which divine grace was seen as completing and fulfilling human nature, rather than dramatically abrogating it in the Augustinian manner. Consequently, the Thomistic tradition represented a separation, at least in principle, of philosophy from theology and a more optimistic view of human nature, society, and the civil state, coupled with opposition to those Latin Averroists who were prepared to compartmentalize their thought to the extent of claiming that on certain points philosophy (Aristotle, as interpreted by Averroes) demonstrated conclusions incompatible with their personal Christianity. Those who preferred to remain within the Augustinian stream, especially St. Bonaventure (c. 1217–1274), John Duns Scotus (c. 1266–1308), and William of Ockham (c. 1285–1349), nevertheless increasingly absorbed elements of the new Aristotelianism. Concerned as they were with the sense in which theology could be a science (a form of knowing), Duns Scotus and William of Ockham evinced a tendency to bring epistemological considerations more to the forefront of their work.

## NATURE OF SCHOLASTICISM

**ARISTOTELIAN EMPIRICISM: MATTER, FORM, AND SUBSTANCE.** Medieval philosophy and logic are aspects of an effort to resolve conceptual puzzles (often, but not always, theologically inspired) and to underpin such resolutions with a satisfactory theory of how things are and why they are as they are. The dominant theory, although subjected to multiple variations and modifications during the medieval period, was basically Aristotelian and therefore involved an ultraempiricist effort (not always successful) to resist the abrogation of the pretheoretical commonsense aspect of the world by the theoretical. Before the consideration of any theory, whether scientific or metaphysical, human beings are inevitably confronted with a world populated by a multiplicity of diverse kinds and sorts of beings that are subject to generation, change, and death. These diverse beings are understood to the

extent that “why?” questions about them or their kinds can be answered; they are the objects of evaluation insofar as they or their qualities, quantities, states, or relations are characterized as good, bad, and so on.

In accordance with the nonabrogatory policy, a technical vocabulary is required such that the pretheoretical picture does not forfeit its basic sense by relativization to a more fundamental theory that demands radical revision of that picture. For example, an ultraempiricist account of how things are must always leave place for the attribution of a literal (and not merely metaphorical) sense to questions regarding the “makings” of sense objects, states of affairs, or processes. The term *matter* represents an attempt to guarantee such a literal sense—it is the general reply to the always sensible question (in the context mentioned) “What is it made out of?” The detailed replies to such questions—“wood,” “stone,” “bones and flesh,” “clay,” “cloth,” and so forth—all mention makings or materials out of which something is made, physical antecedents that are among the necessary conditions of a thing's being.

In the same context, however, explanations of why things are as they are can be given by reference to the kinds or sorts to which those things belong; for example, “Horses are self-moving because they are animals, and all animals are self-moving.” Here a feature of a particular sort of being (horse) is explained by reference to its general kind (animal), and it is the notion of “form” (with its alternative medieval vocabulary, “nature,” “essence,” “quiddity”) that represents a reminder of the fact that things fall into distinguishable sorts (species) that can in turn be subsumed under broader kinds (genera). Since truistic explanations can be given in terms of sorts and kinds, the form or essence is said to be the principle of the intelligibility, or explanation-worthiness, of things; and such general definitions as “Man is rational animal” are said to hold true in regard to the formal aspect of things. Whether or not the definitions are true of things in a scientific sense is of little import to the philosophical notion of form: Its point is to ensure the nonabrogation, by a general theory of how things are, of the pretheoretical picture of the diversity of things; realization of this point may lie behind Aquinas's agnosticism concerning the scientific value of such formal definitions.

It is plain that the replies to questions about the makings (*matter*) of things still involve a formal aspect, since not only are explanations in terms of the definitions of wood, stone, and the other sorts of material mentioned still possible, but it is also possible sensibly to ask what the wood or stone is made out of, or what “stuff” endures

when wine becomes vinegar. In order to do justice to such possibilities—and to the pretheoretical conviction that in processes of change the successive sorts that occur are not totally new creations but rather a sequence of diverse activations of a common substratum—the notion of “prime” matter is employed; this is matter as mere substratum, totally devoid of any formal aspect. Prime matter was viewed schematically, by a kind of extrapolation, as pure susceptibility upon which the various formal actualities supervene, and was said to be by some medievals the principle of individuation, whereby form, the principle of intelligibility and generality, is concretized to the particularity of the various individual “this-es” that belong to a given sort. Thus, one might say that a horse is an *equinizing* of prime matter, a stone is a *petrifying* of prime matter, and so on; this use of verblike nouns helps to bring out the fact that form is act, or actuality, as opposed to the mere susceptibility of prime matter. These verblike nouns are constant, since it never makes sense to say of a horse, for example, that it is more horse or less horse (using “more” and “less” in a non-quantitative sense). Some actualizations, however, are variable, such as whiteness; one can say of a white object that it is (or becomes) more white or less white.

The real correlates of certain of the constant actualizations are called substances, objects that are pretheoretically recognized as being constantly what they are over the whole span of their existence. A horse does not become a horse, and on ceasing to be a horse, it simply ceases to be, whereas a white object can be something that becomes white in varying degrees and may cease to be white, but it is not on that account said to cease to exist. When adjectival terms such as *white* are used to denote subjects in sentences, such as “A white thing is coming down the road,” it always makes sense (although in many instances it may be superfluous) to ask a question like “What is the thing that is white and is coming down the road?” This is true because such terms leave open the possibility of asking a question regarding the nature of the “something else” (*aliquid aliud*, as Aquinas has it) that is qualified (in this instance by the whiteness). When the “something else” is a substance, such as “horse,” the possibility of a further question having a similar sense, but with the substance name in place of the adjective, vanishes. For example, one would not ask, “What is the thing that is a horse and is coming down the road?” Thus, this notion of substance is unlike that with which John Locke was concerned; for him it did make sense, even when a substantial sentence subject had been used, to carry on with requests for information about what he called a “something besides.”

TECHNICAL LANGUAGE, MEANING, AND UNIVERSALS. Much of medieval philosophical and logical discourse involved the endowment of old words with new senses, as part of the artificialization of natural language that is characteristic of the Schoolmen, who, according to Locke, “covered their ignorance with a curious and inexplicable web of perplexed words.” The Scholastics were in fact to some extent aware of the exigencies of discourse of this sort, which constitutes a kind of halfway house between the sort of philosophy that is careful to use only a completely jargon-free natural language, and the sort that is prepared to use the resources of some totally artificial language (such as those of modern symbolic logic) as a set of coordinates whereby sense and senselessness may be distinguished. When discussing the technical sense of “in” in sentences such as “Qualities inhere *in* substances,” Boethius had distinguished no fewer than nine ways in which the word *in* could be used. It was clear to him that the *man* of the technical sentence “Man is a species” does not play the same role as does the name *man* in “Socrates is a man”; if it did, then one should be able to use these two sentences as premises whence “Socrates is a species” (which is false or nonsensical) could be inferred.

How, then, are such terms as *man*, *animal*, *genus*, and *species*, as they occur in sentences like “Man is a species” and “Animal is a genus,” to be understood? These are sentences of a sort that must occur in the discussion of the principles of those definitions described as efforts to do justice to the formal aspect of things. Interpretation of such sentences as consisting of two names joined by *is* naturally leads to the question, transmitted by Boethius when commenting on Porphyry, of what the things are that these names name. Are the things named by such specific or generic names extramental entities additional to individual human beings and animals? An affirmative answer represents one medieval form of the option for a “realist” position in the problem of universals, and throughout the period thinkers were divided on this topic. Certain early medieval antirealists, such as Roscelin and Garland the Computist, developed a solution that had been suggested by Boethius: Words such as *species* and *genus*, said Boethius, may be interpreted as “names of names” (*nominum nomina*), so that “Man is a species” should be analyzed as “‘Man’ is a species,” with *species* naming the word *man* and indicating that it is predicable specifically of many individuals. Herein lies one of the roots of the logical doctrine developed during the thirteenth and fourteenth centuries, the doctrine of *suppositio*.

Roscelin and Garland went further than Boethius and regarded *man* in “Man is a species” not as a mentioned name (a mentioned significant utterance) but as a mere utterance (*vox*) undergoing mention; thus St. Anselm accused Roscelin of having reduced universals to the “breath of an utterance” (*flatus vocis*). Other antirealists, observing that this extreme nominalism (as it is usually called) failed to account for the success of language as a representation of the formal aspect of things, adopted an intermediate position, according to which the universal is a natural (as opposed to a merely conventional) mental sign, or concept; such a position was designed to secure the objective reference of the universal while avoiding commitment to the plethora of extra entities demanded by realism. Abelard, Aquinas, and Ockham may be credited with having held, each in his own way, a doctrine of this type.

**EXTENT OF THE ARTIFICIALIZATION OF LANGUAGE.** There are several facets of the general medieval concern with the study of meaning. In the writings of Anselm of Canterbury, for example, there is an immensely powerful and pervasive realization that the overt, apparent, or grammatical form of an utterance need not show its implicit, true, or logical form—a realization whose revival has been most prominently reinitiated in our own age by Bertrand Russell. Again and again Anselm’s writings contain the contrast between forms of speech that are allowed by the loose texture of ordinary language (*usus loquendi*) and the forms to which a strict attention to the exact sense (*significatio per se*) commits one; the loose texture is methodically explored, and the results of this exploration are applied to the elucidation of difficulties raised by forms of speech found in Holy Writ and ordinary language. In their technical explanations Anselm and his successors felt compelled to make innovations that violated the grammar of the natural language (Latin) in which they wrote; for instance, in expressing the objective counterparts of assertions concerning the meaning of adjectival (as opposed to substantival) words, Anselm used the novel formula “Literate is literacy,” which in its Latin version (*Grammaticus est grammatica*) is about as full of scandals, from the point of view of ordinary Latin grammar, as any three-word sentence could be.

Naturally the classicists of the time, like their counterparts of the sixteenth century, took alarm at these monstrous impurities of language; a classicist rearguard action is shown in the *Metalogicon* of John of Salisbury (c. 1115–1180), who at one point explicitly argues against mixtures of abstract and concrete of the kind put forth by

Anselm. A better-known example of this technical development, resulting in nonsense in respect to ordinary language, is found in Aquinas’s assertion that a man *is* neither his humanity nor his existence, whereas God *is* both his essence (divinity) and his existence; these claims involve a like mixture of concrete and abstract nouns that in nontechnical speech just cannot be connected by the same “is” (or “is not”).

**BREAKDOWN OF COMMUNICATION.** The semiartificial language of the Scholastics was excessively clumsy, and, in the absence of the precise definitional control that goes with a totally artificial language, required for its tolerably safe employment an intuitive power extending beyond the ordinary; even when this has been achieved, the history of the period demonstrates that there is no guarantee that communication will be maintained. For example, skill in the use of such language probably reached its peak in the writings of Duns Scotus, the Subtle Doctor. He rejected the theory that matter is the principle of individuation on the grounds that this attribution leaves the individual lacking in total intelligibility and even makes problematic the possibility of an omniscient being’s (God’s) radical understanding of the individual object. He therefore posited that individuation is performed not by a material, but by a formal, principle; for example, by “Socrateity” in respect of the individual Socrates, and in general by the “thisness” (*haecceitas*) appropriate to each individual “this.” We have already observed the connection between form and intelligibility presupposed in this operation, an operation that raises a further phase of the universals controversy and at the same time exemplifies the breakdown in communication.

Ockham criticized the Scotist thing-centered formal distinction (*distinctio formalis a parte rei*) alleged to hold between the universal nature in question (humanity in the case of a human being) and the individuating formal principle (Socrateity) that makes the individual into *this* individual. Ockham was at a loss to see how this distinction could be thing-centered (*a parte rei*) and yet not commit its proponent to the admission of extra entities (humanity, Socrateity) over and above, and distinct from, individuals, in spite of the fact that the existence of universals as extra entities of this sort was denied by Scotus.

It has already been suggested that form may be best expressed by means of verblike nouns (*equinizing, petri-fying*); hence, the abstract nouns often used to express formal principles could be viewed as being more verblike than namelike—a position taken by Aquinas from Boethius and apparently recognized by other Scholastics.

If this view is accepted, then the statement that the Socrateity of Socrates is distinct from his humanity may be interpreted, using appropriate verblike forms, as asserting that *Socratizing* is not identical with *humanizing*, an analysis that yields a true thing-centered distinction and yet does not send one on a vain search for extra named entities over and above the man Socrates; this offers at least one way in which the Scotist contention may be consistently understood.

But Ockham assumed, in effect, that any distinction that holds in respect of things (a “real” distinction) can only be like that which holds between, for example, Socrates and Plato and that is expressed by a sentence such as “Socrates is not Plato,” wherein “Socrates” and “Plato” are names (as opposed to the verblike *Socratizing* and *humanizing*). When, therefore, Ockham encountered the further Scotist tenet that although a thing-centered formal distinction holds between Socrateity and humanity (for example), it is nevertheless not the case that a real distinction holds between the two, he assumed that “Socrateity” and “humanity” could be treated in the same way as such names as Socrates, Plato, Cicero, and Tully, and that even as the negation of a real distinction between Tully and Cicero amounts to a statement of their real identity as the same individual object, so also the denial of a real distinction between Socrateity and humanity amounts to a statement of real identity of this sort. In point of fact, however, once the verblike nature of the form-expressing words *Socrateity* and *humanity* has been grasped, it becomes clear that a denial of a real distinction between Socrateity and humanity should be understood as the rejection of any attempt to treat those form expressions as though they were pure names. The whole weight of Ockham’s subsequent attack, aimed as it was at the consequence that the Scotists were in such contexts stating the denial of a real identity (one framed in terms of names, as opposed to verbs) is therefore totally misplaced.

The same blindness, combined with the theological premise that God is omnipotent, and hence can effect anything that does not involve a contradiction, also played havoc with other distinctions patiently established by earlier thinkers. For example, the distinction between essence and existence, some of whose associated theses were described above as embodying novel uses of words, was attacked on the grounds that the essence of a thing (a man’s humanity) and its existence are (if a *real* distinction holds between them) two things distinct in the way that Socrates and Plato are two distinct things. In consequence, the Ockhamists considered themselves licensed

to assert that the admission of a *real* distinction between essence and existence has as a consequence the possibility of God’s omnipotence producing something’s essence without at the same time producing its existence, or vice versa, however, this is patently absurd, and therefore (they concluded) there is no real distinction between essence and existence.

In the presence of such misplaced criticism it is obvious that scholastic thought could have been better expressed in a fully artificial language, armed with precise definitions and a greater capacity for generating and identifying new parts of speech than that of the semiartificial language that was used.

REACTION AGAINST TECHNICAL ARTIFICIALIZATION. Although the artificialization of natural language for the expression of technical truths beyond the capacity of natural language proceeded apace from the time of Anselm, the final major philosophical reaction, brought about by communication difficulties, was in the opposite direction. Ockham’s attitude to the contrast between ordinary and technical discourse was the polar opposite of Anselm’s attitude at the opening of the period. For Anselm, accounts of meaning could and did call for the use of, or have as consequences, technical assertions that were either nonsense from the point of view of ordinary usage, or at least involved radical departures therefrom—and his successors were similarly venturesome.

Ockham, although likewise constantly conscious of the contrast between ordinary speech and the technical forms of speech used by his predecessors, nevertheless placed propriety of expression on the side of ordinary speech, and not on the technical side, except in those instances where the novel locutions of his forerunners could be explained away or disarmed as mere stylistic ornament. His lists of sentences that are false if taken literally (*de virtute sermonis*) because words are not therein used properly (*secundum proprietatem sermonis*) are catalogs of the sort of technical assertions that for Anselm and following thinkers had been a necessary consequence of the special requirements of logical and philosophical discourse, and that for them enshrined propriety to a degree to which the looseness of ordinary speech could not aspire. This reversal of attitude, symptomatic of the breakdown of communication in terms of semiartificial language, did not, of course, immediately prevail, it was combated at great length, for instance, by John Wyclyf (c. 1320–1384). Nevertheless, Ockham’s attitude, reinforced by Renaissance philology, ultimately triumphed and was represented in the strictures of Locke on “the frivolous

use of uncouth, affected, and unintelligible terms” that made philosophy “unfit or incapable to be brought into well-bred company and polite conversation.”

**ETHICS AND POLITICS.** Augustine’s severe view of the effects of the Fall of man resulted in a largely negative view of the civil state. He held that save in the ideal case of a Christian commonwealth, earthly states are merely coercive institutions that would not exist had man not fallen, and serve simply to issue punishments and remedies for the corruption of human nature. Correspondingly, divine grace is seen by Augustine as playing a dramatically elevating part in the reformation and reordination of the will. However, the thirteenth-century revival of full Aristotelianism, coupled with the Thomist view of grace as a completion rather than an abrogation of nature, allowed that civil subordination was natural to man, would exist even if the Fall had not taken place, and hence could not be written off as an extraneous penal imposition; the state possesses a positive value in its own right.

Aquinas’s enormously detailed philosophical anthropology constituted the foundation of his version of Aristotelian humanist ethics and politics, to which he attempted to give a Christian completion; it cited the perfection and fulfillment of human nature in the intellect rather than in the will: Accordingly, he viewed law as essentially a rule of right reason, rather than as a species of will-based command. This doctrine was in conflict with the teachings of the Augustinian voluntarists such as Ockham, whose view has endured through Thomas Hobbes and John Austin down to modern times. Aquinas’s system of rationally based natural law as a measure of the value of human actions in general, and of human law in particular, was in opposition to the absolutist tendencies evident in the coalescence of revived Roman law with Augustinianism, which were to come to final fruition in the sovereign nation-state of our own era. The distinction between the righteous prince (who remains within the bounds of the law) and the tyrant (who puts himself above the law) had been trenchantly enunciated by John of Salisbury, was supported by the non-Roman medieval legal tradition, and clearly presupposes limits to the powers of the chief legal authority.

It is clear that Aquinas’s natural-law theory supports this limiting attitude and justifies resistance to tyranny; he was therefore faced with the task of coming to terms with those features of Roman law (to be emphasized in the Renaissance) according to which the prince is above the laws. This he did by distinguishing between the coer-

cive power (*vis coactiva*) and the directive, or rationally qualifying, power (*vis directiva*) of law: In respect of the first the prince is above the law, but in respect of the second he is voluntarily subject to it. In his theory of law Aquinas directly influenced Richard Hooker, to whom Locke admitted his indebtedness.

It is in connection with Aquinas’s defense of the right of resistance, as well as in his *prima facie* puzzling assertions on the relation of the papacy to civil power, that we may best see how he attempted to resolve the perennial problem of the relation between political principle and political fact through the use of exceptive (*nisi forte* ...) clauses. Instead of rigidly carrying through principle to the bitter end and at all costs, without any regard for concrete or historical facts (in the manner, one might say, of Plato in the *Republic*), Aquinas suggested that the most rational course would be to make appropriate accommodations with local conditions, if necessary by recourse to empirically based anticipation of the results of political action. For example, it follows from natural law that tyranny may rightly be resisted by force; this justification of rebellion may be acted upon, said Aquinas, except perhaps (*nisi forte*) when the facts of the case make it plain that the revolution will generate worse evils than the tyranny that it is designed to displace. Again, in religious matters he declared that the ecclesiastical power is to be obeyed rather than the civil, and in civil matters the lay power is to be obeyed rather than the ecclesiastical, except perhaps (*nisi forte*) in the special case of the two powers’ being amalgamated in one person, such as the Roman pontiff.

Commentators discussing this last example, and not armed with a realization of the significance of its exceptive (*nisi forte*) structure, have inferred from it that Aquinas here committed himself to an extreme papalist position that would endow the pope with the fullness of spiritual and temporal power. However, once the significance of that structure has been gathered from the many other available textual examples, the conclusion may be drawn that Aquinas taught the separation of these powers as a matter of principle, yet he also observed the local fact that insofar as the pope is a temporal ruler of papal territory, he, exceptionally, holds both spiritual and temporal power. A like adaptability may be seen in Aquinas’s concession that the secondary precepts of natural law are mutable in accordance with changing historical conditions and in his recommendation that laws should be tailored to fit the type of population for which they are intended; to attempt to legislate a people into full virtue is futile.

Augustinianism in general, and the Augustinian theory of law as essentially will-based command, received impetus and encouragement from the archbishop of Paris's condemnation in 1277 of certain Aristotelian theses of Arabic philosophical complexion, a condemnation that also bore upon some Thomist positions. The tendency of Averroism had been toward a pantheism that diminished the freedom of God in the act of creation. Aquinas's claim that moral evaluation consists of rational assessments based upon the intrinsic nature of the cases in question was also susceptible of being interpreted as constituting a restriction on divine omnipotence. Accordingly, Duns Scotus and Ockham, in varying degrees, claimed that the rules governing the attribution of Tightness or wrongness to human actions were contingent in relation to the absolute power of God; the consequent contingency of connection between deed and merit has caused some historians to assume that in Augustinian thought one may find the basis of Martin Luther's doctrine of justification by faith alone, as well as a source for the legal aspects of the Hobbesian theory of sovereignty.

**SCIENCE AND PHILOSOPHY.** Although the nonabrogatory policy of medieval philosophy outlined above served well enough to ensure that philosophers took seriously the fully human realm of reasons, purposes, hopes, and so forth, thus avoiding the split between the thinker as a human being and the thinker as a philosopher, the extrapolation of that policy's attendant ultraempiricism to sciences such as physics and cosmology tended to a greater or lesser extent to inhibit their development as practical tools. A prime and early example of such ultraempiricist inhibition is to be found in the refusal of the second-century astronomer Ptolemy to consider a sun-centered planetary system because it so obviously is at variance with things as we find them to be, a refusal that was espoused by most but not all medieval philosophers. On this point Ptolemy was in agreement with the physics-based cosmology of Aristotle, but in general he represented a rival tradition, that of the mathematicians, who were usually regarded by the medievals as devisers of ingenious fictions that served merely to "save the observed appearances." Mathematical theories were accordingly believed to lack the necessity attributable to the vast and coherent background of Aristotelian physics and metaphysics, and this attitude prevailed until the time of Galileo Galilei.

However, there was some support for the development of mathematical physics, insofar as it relies on thought experiments as opposed to exact experiment, in the very competent medieval enlargements on a point

whose root lay ultimately in Aristotle's *Categories*; there, when attempting to differentiate between substances (such as man, tree, stone) and qualities (such as whiteness, roundness, hardness), Aristotle pointed out that the latter are susceptible of degree, while the former are not. To this remote starting point much of modern mechanics owes its origin, for through speculation on the various kinds, rates, and degrees of "intension" and "remission" of qualities, the ideas of constant motion and acceleration and deceleration (uniform or nonuniform), and their relations to time and distance were thoroughly explored by fourteenth-century philosophers, such as those of Merton College, Oxford. Nicholas Oresme (c. 1325–1382) related these aspects of motion to their graphical expressions and anticipated infinitesimal calculus and coordinate geometry. Herein lies the starting point of certain segments of Galileo's mechanics.

## MEDITATION IN INDIAN PHILOSOPHY

Meditation as a distinct practice in Indian philosophy appears in a variety of texts from the third century before the common era as well as in sculptural depictions that date from 3500 BCE. The quintessential manual on meditation, the *Yoga Sūtra*, was composed by approximately 200 CE and includes philosophical positions and meditation techniques from the Sāṃkhya, Jaina, and Buddhist traditions.

Early depictions of meditating figures were found in the excavations of Mohenjodaro and Harappa, Indus Valley cities that date from 3500 BCE. Sculptures and steatite seals show people with half-closed eyes sitting in the lotus posture. In some seals, animals surround a meditating figure, indicating a shamanic, totemic origin of this tradition.

The earliest text of Indian literature, the *R̥g Veda*, which dates from at least 1500 BCE, mentions longhaired ascetics and, amidst hundreds of hymns extolling various gods and goddesses, lays out the philosophical foundations for later traditions of meditation. *R̥g Veda* (1:164.20) describes two birds in the same tree, one eating sweet berries while the other merely witnesses. This theme repeats itself in the *Muṇḍaka Upanishad* (3:1:1) and the *Śvetāśvatara Upanishad* (4:6) and is expressed in the *Bhagavad Gītā* themes of the lower nature subject to constant change and activity (*prakṛti*) and the higher nature or inner true self (*puruṣa* or *ātman*). The worldview presented in this early metaphor delineates two major modalities of engagement with the world. One aspect freely and unreflectively participates in and contributes to the world. The other aspect remains aloof and transcendent, as a spectator or onlooker.

Sāṃkhya philosophy, articulated by the philosopher Ishvarakrishna in the early centuries of the common era, delineates a cosmology based on this dynamic tension between the processes of activity and witnessing. The realm of activity includes psychological states (*bhāva*), operations of the mind (*manas*), sense and motor capacities (*indriya*), as well as the subtle and gross elements (*bhūta*) that manifest as discrete, concrete objects. By understanding and harnessing the karmically influenced outflows that arise when the witnessing consciousness becomes intrigued and defined by the particularity found in the manifest realm of activity, one gains mastery over and release from compulsive behavior, resulting in liberation (*kaivalyam*). This philosophy undergirds the system of Yoga, which presents a variety of meditation tech-

niques to accomplish the goal of liberation. Yoga also appears within non-Vedic traditions such as Jainism, Buddhism, Sufism, and Sikhism.

### THE YOGA SŪTRA

The *Yoga Sūtra* of Patañjali (c. 200 CE) defines Yoga as the restraint of the fluctuations of the mind (*yogaś-citta-vṛtti-nirodha?*). The application of Yoga allows for the gradual diminishment of karmic influences, referred to as seeds (*bīja*) or residues (*saṃskāra*). Yoga specifies five aspects of defilement that must be controlled: ignorance, egoism, attraction, repulsion, and a desire for life to continue. By following the practices of Yoga, including meditation, karma dissipates. The practitioner reshapes his or her identity, abandoning attachment to fixed behaviors. By drawing inward, one reaches deeper self-understanding and approaches a state of lucidity and purification.

Numerous meditation practices can be found in the texts of Yoga, Buddhism, Jainism, and Sikhism. Different objects of meditation are listed, including fixing one's attention on Īśvara through the use of mantra. Patañjali defines Īśvara, sometimes referred to as a deity, as a special soul or *purusa* who has never been tainted by the actions of karma. By fashioning such an ideal through the imagination, one can then strive to emulate this rarefied being. For a Jaina, this state of Īśvara is symbolized through the twenty-four great teachers (Tīrthaṅkāra). For a Buddhist, Lord Buddha serves the same function. In the Hindu bhakti or devotional tradition, fixing one's attention on any one of a variety of deities can result in karmic purification, with Krishna and Rama being the most frequently worshipped Vaisnava deities and Siva and Ganesh and the Goddess Kālī the object of devotion for Saivites. For the Sikhs, the highest soul cannot be named and exists outside time (*akal*). However, the ten Sikh gurus, beginning with Guru Nanak, serve as objects with worship because of their teachings. Patañjali, through his concept of chosen deity (*ia ṭa devatā*), suggests that the meditative procedures engaged in order to purify oneself carry more significance than the actual object of one's meditation.

Several other practices are listed in the *Yoga Sūtra* that do not require the presence of an inspirational, theistic object of devotion. They include becoming one-pointed in one's activities, regulating one's breath, experiencing inner radiance, reflecting on an auspicious dream, or "meditation as desired" (1:39). Patañjali puts forward a progressive technique, where one begins with a gross, outward object (*vitarka*) and then takes it inward, seeing its relationship with and grounding in one's men-

tal constructs. One then moves on to more subtle aspects of one's psychological conditioning (*vicāra*), focusing on the patterns of past karma that tend to govern one's personality. By applying meditation techniques of focusing and calming the mind, and by probing into the root causes of one's motivations, one gradually gains the ability to move into a seedless state of pure being, referred to as *nirbīja samādhi*.

### ETHICS

Ethics plays a crucial role in the meditation systems of India. Buddhists refer to these practices as perfections. Yogis and Jainas share a list of common vows. By holding to nonviolence (*ahiṃsā*) one engenders an atmosphere of well-being that brings calm and solace to others. By holding to truth, one's word corresponds to reality. Through not stealing, one gains appreciation of all that exists without seeking to appropriate or hoard it for oneself. By abandoning sexual obsession, one makes the world safe from one's designs and manipulations. By giving up the acquisition of things, one can learn to understand one's motivations and past predilections. These five vows, common to nearly all India's meditative paths, allow for the deconstruction of destructive habits and the active construction of a safe, ethically-grounded world. For the Buddhists and the Yogis, a purified person naturally exhibits enlightened behavior and is friendly (not jealous) toward successful people, compassionate (not scornful) toward those who suffer, happy (not envious) for those who are meritorious, and retain their equanimity (do not become hateful) in regard to those who lack virtue.

### PRACTICE

Meditation enables the practitioner to avoid the repetition of behavior that can be harmful to oneself and others. Indian philosophy, particularly as found in Buddhism, Sāṃkhya, and Yoga, claims that due to desire or thirst (*kāma/tṛṣṇa*) one engages in actions (karma) prompted by the residues of past actions (*saṃskāra*) that lead to repeated difficulty, darkness, and even despair (*duḥkha*). By the application of meditation and meditative ethical practices, one can cultivate an alternate way of being (*prati-pakṣa-bhāvanā*) rooted in purity. By withdrawing the outward flows of the mind and the senses and reversing the tendency to be defined by external objects and realities, one can become free of psychological entanglements and social expectations, achieving the status of a solitary hero, in charge of one's own reality. The word Jina, an epithet for Vardhamana Mahavira, the

twenty-fourth and most recent Tirthankāra of the Jaina tradition, indicates that he was a great vanquisher, one who conquered his past karma to establish himself as a model for others to emulate. Similarly, the enlightenment of the Buddha is cloaked with martial symbolism, with Siddhartha defeating the evil Mara in a great test of wills.

Meditation results in the accumulation of powers, ranging from enhanced language-learning abilities and physical beauty to memory of one's past lives. Through focusing on the interior energy of the body, one gains intimacy with the various subtle energy centers (*cakras*) that correlate with locations along the spine. These include vortexes of the earth-connected eliminative function, sexuality, and power found in the respective areas of the anus, the sexual organs, and the solar plexus. Above these three lower functions, one finds the seat of compassion in the heart, an array of emotions in the area of the throat, the third eye representing insight between the eyebrows, and in the area above the skull, a magnificent lotus. Through meditation techniques associated with Tantra and popularized from the eighth century forward, one systematically advances from the lower *cakras* toward the higher ones, bring about the ascent of a force known as the *kundalini*. However, whether the philosophy originates from Yoga, Buddhism, or Jainism, all traditions state that the powers (*siddhi*) must not distract one from the ultimate goal of self-purification.

Indian systems of meditation mandate the presence of a qualified teacher guru in order to engage in this variety of techniques. A well-qualified guru, in addition to knowing the mechanics, guides the student through the pitfalls of self-aggrandizement and periodic disappointment. Discovering one's past history can be fraught with frightful memories; the guru assists the disciple in this process of self-discovery. The Jaina tradition of past-life stories and the Buddha's narration of his past births in the Jataka tales, demonstrate that human action derives from ignorant, self-serving motivations, unless one has made a commitment to strive for purification. As shown in the paradigmatic case of the life of the Buddha, a realization of the fleeting nature of reality will often prompt a potential meditator to seek out instruction on how to achieve and maintain peace of mind. In the case of the Buddha, he studied various techniques for six years under two different renowned teachers before he entered into *nirvāṇa* and subsequently decided to teach others how to overcome their own personal difficulties through meditation. Guru Nanak (1469–1539), living in a time of great strife between Hindus and Muslims, underwent a miraculous transformation that prompted him to develop a

new way of meditation that transcended both traditions. Modern day Yoga and meditation practices offer pathways of self-cultivation through the purification of the body, the emotions, and one's way of being situated in the world. These traditions all trace their origins back to an original teacher, whether Swami Vivekananda or Krishnamacarya for many schools of Yoga or to the Buddha himself for Buddhist meditators.

The philosophical texts on meditation in each of the traditions outline different paths and offer different catalogues of the karma that must be overcome. The *Yoga Sūtra* and its commentaries outlines five states of mind, five afflictive karma categories, seven levels of *samadhi*, a threefold path and an eightfold path of practice, and a tenfold ethical system. The core texts of Buddhism set forth an eightfold path and a fivefold assessment of the nature of reality that further subdivides into either seventy-five or one hundred constituent features. The Theravada texts outline nine meditations on objects with form and four formless meditation states. The *Tattvārtha Sūtra*, the foundational meditation text of Jainism, describes 148 forms of karma known as *ṣṭakṛtis* and a fourteen-step analysis of states of increasing purification.

Meditation constitutes an important aspect of Indian philosophy. It requires an active engagement of the world through ethics. It requires the cultivation of a body that can sit for long periods of time. It also requires protracted states of introspection in order to gain mastery over the mind. Meditation comprises a comprehensive system of purification that, regardless of the particular theological context or philosophical point of view, serves to diminish negative karma and bring about states of equanimity.

## MEGARIANS

The Megarians flourished during the fourth and the early third centuries BCE. They derived their name from their connection with Megara on the Isthmus (a city one day's walk west of Athens). They constituted a 'philosophical school' only in a weak sense: no shared lifestyle, no rigid body of doctrine. Since no work of any Megarian has survived, knowledge of them must rely on fragments and reports of other authors.

The earliest Megarian was Euclides of Megara. Diogenes Laertius (2.106) reports that Euclides' followers "were called 'Megarians,' then 'Eristics,' and later 'Dialecticians.'" Modern scholars traditionally understood this report as indicating that a single school had three successive labels. However, in 1977 David Sedley argued that the three labels designated three distinct groups of philosophers that were influenced to some extent by Euclides but, far from constituting a single school, were in competition with one another. Sedley's reconstruction has won widespread, although not universal, scholarly approval. The present entry will cover all those thinkers who have traditionally been regarded as Megarians, including Eristics and Dialecticians, except the Dialecticians Diodorus and Philo, who have separate entries.

Euclides of Megara was probably born after 450 BCE and died before 365 BCE. A pupil of Socrates, he also studied Parmenides' writings. He is mentioned by Plato in the *Phaedo* (59b–59c), where he is portrayed as present at Socrates' death, and in the *Theaetetus* (142a–143c), where he is described conversing with Terpsion, another early Megarian. After Socrates' death, Plato and some of his companions fled Athens to stay for awhile with Euclides at Megara. Euclides authored six dialogues: *Lamprias*, *Aeschines*, *Phoenix*, *Crito*, *Alcibiades*, and a *Discourse on Love*. We know little of Euclides' philosophical views. He claimed that the good is one although it is called by many names (such as 'wisdom,' 'God,' and 'mind'), and that the contrary of the good is mere nonbeing; he thus seems to have borrowed Socratic views in ethics and combined them with Eleatic monism. He attacked proofs by opposing their conclusions, not their premises (he probably did this by reducing to absurdity the conclusions,

wherein an influence of the methods of Zeno of Elea can be detected), and he rejected arguments from parallel cases.

Euclides had numerous pupils: Dionysius of Chalcedon, Diocles of Megara, Thrasymachus of Corinth, Ichthyas, and Clinomachus of Thurii, who founded the Dialectical school. According to Diogenes Laertius (2.112), Clinomachus was "the first who wrote about assertibles, predicates, and the like." Later, in Stoic logic, assertibles and predicates are two of the main types of sayables, incorporeal items that are signified by utterances of linguistic expressions and are themselves neither thoughts nor linguistic expressions (specifically, assertibles and predicates are what is signified, respectively, by utterances of declarative sentences and predicative expressions). It is unclear how much of the Stoic views about assertibles and predicates was already held by Clinomachus, but it cannot be ruled out that the basics were already in place.

According to some sources, one of Euclides' pupils was named 'Bryson.' Modern scholars disagree on whether there was exactly one thinker answering to this name, and whether he is the same as the one who introduced a method for squaring the circle which was criticized by Aristotle.

Later Dialecticians were Polyxenus (to whom the authorship of a 'third man' argument against forms is ascribed) and Eubulides of Miletus. Since he taught Demosthenes and wrote a defamatory book against Aristotle, Eubulides was probably born in the second half of the fourth century BCE. According to Diogenes Laertius (2.108), he fathered seven arguments: the Liar, the Disguised, the Electra, the Veiled, the Heaper, the Horned, and the Baldhead. These arguments, in question-and-answer form, were extensively discussed by later Hellenistic philosophers.

It is not clear whether Eubulides' version of the Liar had already the devastating self-referential character of modern versions. For instance, we cannot rule out that Eubulides' version was presented roughly as follows: The questioner makes an obviously false statement, adds the remark 'I am speaking falsely,' and then asks whether he is speaking truly or falsely—both answers can be regarded as correct with regard to different statements made by the questioner. Note that all ancient versions of the Liar turn on the sentence 'I am speaking falsely' (modern versions instead turn on 'This sentence is false' or variants thereof). The Heaper heaps questions concerning heaps: 'Does one grain constitute a heap?' 'Do two grains constitute a heap?' 'Do ten thousand grains constitute a heap?'

One is likely to answer the first question negatively, and then, on the assumption that the addition of a single grain cannot transform what is not yet a heap into one, is induced to answer negatively each of the following.

The Baldhead was probably an alternative formulation of the same puzzle. On the basis of Lucian (*Vitarum Auctio*, 22–23), we can plausibly reconstruct the Veiled as follows: ‘Do you know your father?—Yes.—If I set a veiled man before you and I ask you whether you know him, what do you answer?—That I do not know him.—But the veiled man is your father. So, you both know and do not know your father.’ The Disguised and Electra were probably variants of the Veiled. On the basis of Diogenes Laertius (7.187), we can plausibly reconstruct the Horned as follows: ‘If you have not lost something, do you still have it?—Yes.—Have you lost horns?—No.—Then you still have horns.’

Pupils of Eubulides were Euphantus of Olinthus, Apollonius, surnamed ‘Cronus’ (his pupil Diodorus inherited this surname from him), and Alexinus of Elis, whose fondness of controversy earned him the nickname ‘Elenxinus’ (‘Refuter’). Some sources describe Alexinus as a Dialectician, others as an Eristic. Active around 300 BCE, he wrote a book *On Education* and works against other thinkers, Aristotle and Zeno of Citium among them. Alexinus attacked Zeno by taking arguments of his and constructing unpalatable ‘parallels,’ namely arguments that were isomorphic to Zeno’s and had plausible premisses but absurd conclusions. For instance, Zeno had offered the following argument: ‘What is rational is better than what is not rational; but nothing is better than the universe; therefore, the universe is rational’ (Sextus Empiricus, *Adversus Mathematicos*, 9.104).

Alexinus constructed the following parallel: ‘What is poetic is better than what is not poetic; but nothing is better than the universe; therefore the universe is poetic’ (Sextus Empiricus, *Adversus Mathematicos*, 9.108). Zeno was thereby left with two options: either claim that his argument is valid whereas Alexinus’s parallel is not, or claim that all the premisses of his argument are true whereas at least one of Alexinus’s parallel is not. The first option was hard to follow because the two arguments are extremely similar (in fact, neither of them is valid in first-order logic as it stands, but becomes such if an uncontroversial premise is added: ‘Something is rational’ in the case of Zeno’s argument, ‘Something is poetic’ in the case of Alexinus’s parallel). Sextus Empiricus (*Adversus Mathematicos*, 9.109–110) reports that Zeno’s followers chose the second option: they insisted that all the premisses of

Zeno’s argument are true but one of Alexinus’s parallel is not.

Little is known of Panthoides, a Dialectician who flourished around 300–280 BCE. The last Megarian about whom we are relatively well informed is Stilpo of Megara, who probably lived between 360 and 280 BCE. According to Diogenes Laertius (2.113), “so far did he excel everyone else in inventiveness and sophistry that nearly the whole of Greece was looking at him and Megarizing.” He had many pupils, Zeno of Citium and Menedemus of Eretria among them, and wrote many dialogues. According to Plutarch (*Adv. Colotem*, 23, 1120a), Stilpo claimed that what is predicated must be identical with what it is predicated of. For example, goodness cannot be predicated of a man because it is not identical with him, nor can running be predicated of a horse because it is not identical with it. Stilpo’s attack on predication recalls a position criticized by Plato in the *Sophist* (251a–c), and therefore lends plausibility to identifying Plato’s target with some Megarian earlier than Stilpo. Stilpo attacked forms. One of his arguments can perhaps be reconstructed on the basis of Diogenes Laertius (2.119) and Alexander of Aphrodisias (*Commentary on Aristotle’s Metaphysics*, 84, 7–14). Suppose that individual perceptible men and the form Man were the only men. It is surely true that man speaks. But who is then the man who speaks? Nobody: for it is none of the particular perceptible men (for why should it be this one rather than this one?), and it is not the form Man (for forms do not speak). If we want to avoid denying that man speaks, we must give up the assumption that individual perceptible men and the form Man are the only men, and therefore introduce a ‘third man.’ This seems to undermine our motivation for assuming there is the form Man.

According to Diogenes Laertius (2. 115), when Demetrius Poliorcetes had taken Megara and wanted Stilpo to list the items he had lost, “he said that he had lost nothing of his own: for nobody had subtracted his learning, and he still had reason and knowledge.” This anecdote suggests that for Stilpo the only human goods are moral and intellectual attainments, which are inalienable (a view close to that of the Cynics).

In the *Metaphysics* (9. 3, 1046b29–32), Aristotle attributes to unnamed Megarians the view that a thing has the capacity to do something when and only when it is actually doing it. For example, whenever the builder is building, he also has the capacity to build, but when he is not building, he lacks the capacity to build. We are unable to link this view to any specific Megarian, and the ideas

about modality we can ascribe to Diodorus Cronus and Philo do not chime with it.

## MEIER, GEORG FRIEDRICH (1718–1777)

Georg Friedrich Meier was a German philosopher and aesthetician. A pupil of Alexander Gottlieb Baumgarten, Meier succeeded Baumgarten as extraordinary professor at the University of Halle in 1740 and became a full professor in 1748, holding that position until his death.

Meier, a prolific writer, developed and commented on Baumgarten's doctrines as an extension and revision of Wolffianism and went far beyond Baumgarten in the reform of Wolffianism. His treatises, used as textbooks in many universities, were perspicuous, sophisticated, and modern renderings of Wolffian doctrine; by their thorough discussion of basic concepts and attention to details

they give one of the best insights into the Wolffian system and its problems. Christian Wolff's and Baumgarten's ideas were rendered more fluid by Meier's work, establishing connections between disparate problems and establishing new distinctions. Meier's style was closer to the style of the "popular philosophers" than to that of orthodox Wolffians, and he made little use of the Wolffian mathematical method in philosophy.

Meier's *Vernunftlehre* introduced into the traditional frame of Wolffian logic lengthy psychological and methodological discussions like those of the Pietist philosophers A. F. Hoffmann and C. F. Crusius. He also presented a detailed typology of concepts. In a marked departure from Wolff, he stressed the limits of the human understanding, devoting an entire work to the subject (*Betrachtungen über die Schranken der menschlichen Erkenntnis*).

Meier's *Metaphysik*, although in general rather close to Baumgarten, shows the same individual features. For instance, in empirical psychology Meier advocated a subjectivism like that of Crusius. He held that the nature of our understanding determines what we can or cannot think. This determination, like the principle of *cogitabilis* in Crusius, is the foundation of the principle of identity.

Meier devoted several pamphlets to the immortality of the soul, which he held could not be theoretically demonstrated. Any a priori proof of God's existence must be completed by an a posteriori one. And in general Meier would not extend the power of reason much beyond basic truths and human experience.

Meier's most typical work was his *Anfangsgründe aller schönen Künste und Wissenschaften* (Principles of All Beautiful Arts and Sciences). He was opposed to the classical thesis that art imitates nature. He stressed the importance of sensitivity (the "lower faculty") and the indispensability of a knowledge of the beautiful within one's whole outlook on the world. Besides Baumgarten, whose views it is difficult to extricate from Meier's because of their close collaboration, Meier was influenced by the Swiss critics Johann Jakob Bodmer and Johann Jakob Breitinger and by English aestheticians. Like Baumgarten, he gave the term *aesthetics* a broad interpretation and, like Baumgarten's, his work contains an extensive discussion of scientific methodology.

## MEINECKE, FRIEDRICH

(1862–1954)

Friedrich Meinecke, the German historian and political philosopher, was small in stature and somewhat frail but remained mentally very vigorous and intellectually prolific until his death at the age of ninety-two. His great charm and influence were due partly to his erudition, partly to his modesty, and partly to two conflicting tendencies in his thinking that he continually sought to reconcile.

One of these tendencies was his patriotism and loyalty to Germany's best traditions of the past. As a boy he had been thrilled by the sight of the victorious German troops marching home through the Brandenburg Gate after the Franco-Prussian War. Later he admired the skill with which Otto von Bismarck established the long-desired unification of his country and saw with pride Germany's industrial and commercial expansion into a great power. After studying under the Prussian nationalist historian J. G. Droysen, Meinecke became an archivist and published in rapid succession several valuable historical works, including accounts of the German uprising against Napoleon Bonaparte and a two-volume biography of Hermann von Boyen, one of the leading figures in the reorganization and liberalization of Prussia in the early nineteenth century. In 1893 he was appointed an

editor of the leading German historical journal, *Historische Zeitschrift*, a post that he filled with distinction for forty years until ousted by the Nazis.

The second tendency in Meinecke's thinking asserted itself in 1901 when he became deeply occupied with the problems of European political philosophy. In that year he was promoted to a teaching position at the University of Strassburg, later moving to Freiburg. Here in these two cities in the beautiful Rhine valley Meinecke's eyes were opened to the charm of the countryside. His talks with the Roman Catholic population and scholars and his contact with French culture widened his outlook and quickened his philosophical interests. These were his happiest years. In 1914 he was appointed to a permanent professorship at Berlin.

Meinecke's dual preoccupation with liberal culture and with Prussia found expression in a perceptive account of German development. *Weltbürgertum und Nationalstaat* (1908) examines the views of many cosmopolitan liberals and political leaders and, at the same time, analyzes the characteristics and pretensions of the Prussian state, which had been exaggerated by G. W. F. Hegel. It was supplemented by some two dozen articles written by Meinecke in the following years and reprinted in *Preussen und Deutschland* (1918).

Can reason of state justify the employment of might against right? May a state properly do things that are ethically forbidden to the ordinary citizen? Does it enjoy a code of morals above and beyond that of the private individual? Meinecke's classic treatment of these old but perennial questions, *Die Idee der Staatsräson in der neueren Geschichte* (1924), examines meticulously the actions of various European rulers and statesmen and the writings of numerous political theorists from Niccolò Machiavelli to Heinrich von Treitschke. Meinecke comes to the conclusion that, since power is the essence of its existence, the state is justified in using such means as are necessary to maintain and even extend its power, but that this power is limited by the state's obligation to protect the rights of its citizens and to promote their cultural and material welfare. It is, however, practically impossible to draw a precise line between state egoism and ideal morality.

Meinecke always preferred to till a small area where he could closely observe concrete facts and deal with them in a rigorously critical scientific manner. For Leopold von Ranke and Jakob Burckhardt he had the highest regard. He rejected the grandiose theoretical constructions of Karl Lamprecht, Oswald Spengler, and Arnold Toynbee. If he could be said to have had any one primary underlying

thought, it would be that of individuality—the unique individual character of every event, person, social group, nation-state, or idea. In addition he believed in evolution—the capacity of every individuality for development either by growth or decay. Hence his preoccupation with Machiavelli, Cardinal Richelieu, Freiherr vom Stein, Friedrich Schleiermacher, Wilhelm von Humboldt, Johann Wolfgang von Goethe, Joseph Maria von Radowitz, Bismarck, and Adolf Hitler. Meinecke's conceptions of individuality and evolution contributed to the new way of historical thinking, now known as "historicism," which developed in the age of Johann Gottfried Herder and Goethe and which Meinecke minutely unfolded in *Die Entstehung des Historismus* (1936). Historicism dealt a sharp blow to unquestioning belief in absolute values, optimistic positivism, religious creeds, and natural law. It opened wide the floodgates of relativism. Meinecke, however, was not unaware of the aberrations resulting from historicism and tried to counteract them by repeatedly insisting that the only sure and safe guide to morality and conduct is the individual's own conscience.

With the advent to power of the Nazis, Meinecke was forced to retire from active teaching, and under their tyranny he suffered spiritual agony and physical hardship. He might have escaped abroad as did so many others; but he remained in the country hoping to hasten Hitler's downfall and by his own advice and influence to help to lead Germany back to its older and better traditions. He was a close personal friend of General Beck and had some inkling of the plots to get rid of Hitler, but did not participate actively in them. His last contribution to an understanding of German history and his own interpretation of it was his little volume *Die deutsche Katastrophe* in 1946. Later, when the University of Berlin fell under communist control he took the lead in founding the new Free University in West Berlin, of which he was appropriately chosen rector.

## Bibliography

### WORKS BY MEINECKE

The principal works of Friedrich Meinecke are *Weltbürgertum und Nationalstaat* (Munich and Berlin, 1908; 7th ed., 1929); *Preussen und Deutschland* (Munich and Berlin, 1918); *Die*

*Idee der Staatsräson in der neueren Geschichte* (Munich and Berlin: Oldenbourg, 1924), translated by D. Scott as *Machiavellism: The Doctrine of Raison d'État and Its Place in Modern History* (London: Routledge and Kegan Paul, 1957); and *Die Entstehung des Historismus*, 2 vols. (Munich and Berlin: Oldenbourg, 1936). *Die deutsche Katastrophe* (Wiesbaden: Brockhaus, 1946), translated by Sidney B. Fay as *The German Catastrophe* (Cambridge, MA: Harvard University Press, 1950, and Boston, 1962), written at the moment of Germany's utter defeat and deepest despair, contains Meinecke's penetrating reflections on the preceding hundred years, the causes of the Nazi disaster, and his faith in the future. Two short autobiographical volumes are *Erlebtes, 1862–1901* (Leipzig: Koehler and Amelang, 1941) and *Strassburg-Freiburg-Berlin, 1901–1914* (Stuttgart: Koehler, 1949). A six-volume edition of part of his works was published for the Friedrich Meinecke Institute of the University of Berlin between 1957 and 1962; this edition contains a volume of his correspondence and a reprint, with valuable editorial introductions and notes, of his more important writings. See also Meinecke's *Cosmopolitanism and the National State*, translated by Robert B. Kimber (Princeton, NJ: Princeton University Press, 1970); *Historism: The Rise of a New Historical Outlook*, translated by J. E. Anderson (London: Routledge and Kegan Paul, 1972); and *The Age of German Liberation, 1795–1954*, edited by Peter Paret, translated by Paret and Helmuth Fischer (Berkeley: University of California Press, 1977).

### WORKS ABOUT MEINECKE

One of the best books on Meinecke and historicism is Walther Hofer, *Geschichtschreibung und Weltanschauung: Betrachtungen zum Werk Friedrich Meineckes* (Munich: Oldenbourg, 1950). A bibliography of writings by and about Meinecke may be found in the *Historische Zeitschrift*, Vol. 174, 503–523.

## MEINONG, ALEXIUS

(1853–1920)

Alexius Meinong studied under Franz Brentano at the University of Vienna from 1875 through 1878 and taught at the University of Graz from 1882 until his death. In 1894 he established at Graz the first laboratory for experimental psychology in Austria. Some of his psychological

writings fall within this area, but most pertain to what Brentano called descriptive psychology. The philosophical works, referred to below, also pertain to descriptive psychology.

Meinong's most important contributions to philosophy concern the theory of objects, the theory of assumptions, the theory of evidence, and the theory of value. He also discussed, at considerable length, the nature of the emotions and their relation to intellectual phenomena, imagination, abstraction, wholes and other "complex objects," relations, causality, possibility, and probability.

## THEORY OF OBJECTS

The two basic theses of Meinong's theory of objects (*Gegenstandstheorie*) are (1) there are objects that do not exist and (2) every object that does not exist is yet constituted in some way or other and thus may be made the subject of true predication. Traditional metaphysics treats of objects that exist as well as of those that merely subsist (*bestehen*) but, having "a prejudice in favor of the real," tends to neglect those objects that have no kind of being at all; hence, according to Meinong, there is need for a more general theory of objects.

Everything is an object, whether or not it is thinkable (if an object happens to be unthinkable then it is something having at least the property of being unthinkable) and whether or not it exists or has any other kind of being. Every object has the characteristics it has whether or not it has any kind of being; in short, the *Sosein* (character) of every object is independent of its *Sein* (being). A round square, for example, has a *Sosein*, since it is both round and square; but it is an impossible object, since it has a contradictory *Sosein* that precludes its *Sein*.

Of possible objects—objects not having a contradictory *Sosein*—some exist and others (for example, golden mountains) do not exist. If existence is thought of as implying a spatiotemporal locus, then there are certain subsistent objects that do not exist; among these are the *being* of various objects and the *nonbeing* of various other objects. Since there are horses, there is also the being of horses, the being of the being of horses, the nonbeing of the nonbeing of horses, and the being of the nonbeing of the nonbeing of horses. And since there is no Pegasus, there is the nonbeing of Pegasus, as well as the being of the nonbeing of Pegasus and the nonbeing of the being of Pegasus.

Meinong's theory must be distinguished from both Platonic realism, as this term is ordinarily interpreted, and the reism, or concretism, of Brentano and Tadeusz

Kotarbiński. (Meinong noted that since his view is broader than realism, it might properly be called objectivism.) Thus, the Platonic realist could be said to argue: "(P) Certain objects that do not exist have certain properties; but (Q) an object has properties if and only if it is real; hence (R) there are real objects that do not exist." The reist, or concretist, on the other hand, reasons from not-*R* and *Q* to not-*P*; that is, he derives the contradictory of Plato's first premise by taking Plato's second premise along with the contradictory of Plato's conclusion. But Meinong, like Plato and unlike the reist, accepted both *P* and *R*; unlike both Plato and the reist, he rejected *Q* by asserting the independence of *Sosein* from *Sein*; and therefore, again unlike both Plato and the reist, he said that the totality of objects extends far beyond the confines of what is merely real (*das Universum in der Gesamtheit des Wirklichen noch lange nicht erschöpft ist*).

This doctrine of *Aussersein*—of the independence of *Sosein* from *Sein*—is sometimes misinterpreted by saying that it involves recourse to a third type of being in addition to existence and subsistence. Meinong's point, however, is that such objects as the round square have no type of being at all; they are "homeless objects," to be found not even in Plato's heaven. Bertrand Russell objected that if we say round squares are objects, we violate the law of contradiction. Meinong replied that the law of contradiction holds only for what is real and can hardly be expected to hold for any object, such as a round square, that has a contradictory *Sosein*.

Russell's theory of descriptions is often thought to constitute a refutation of the doctrine of *Aussersein*; actually, however, his theory merely presupposes that Meinong's doctrine is false. According to Meinong, the two statements "The round square is round" and "The mountain I am thinking of is golden" are true statements about nonexistent objects; they are *Sosein* and not *Sein* statements. The distinction between the two types of statements is most clearly put by saying that a *Sein* statement (for example, "John is angry") is an affirmative statement that can be existentially generalized upon (we may infer "There exists an *x* such that *x* is angry") and a *Sosein* statement is an affirmative statement that cannot be existentially generalized upon; despite the truth of "The mountain I am thinking of is golden," we may not infer "There exists an *x* such that I am thinking about *x* and *x* is golden." Russell's theory of descriptions, however, presupposes that every statement is either a *Sein* statement or the negation of a *Sein* statement and hence that there are no *Sosein* statements. According to Russell, a statement of the form "The thing that is *F* is *G*" may be

paraphrased as “There exists an  $x$  such that  $x$  is  $F$  and  $x$  is  $G$ , and it is false that there exists a  $y$  such that  $y$  is  $F$  and  $y$  is not identical with  $x$ .” If Meinong’s true *Sosein* statements, above, are rewritten in this form, the result will be two *false* statements; hence Meinong could say that Russell’s theory does not provide an adequate paraphrase.

An impossible object, as indicated above, is an object having a *Sosein* that violates the law of contradiction. An *incomplete object*, analogously, is one having a *Sosein* that violates the law of the excluded middle. Of the golden mountains, which most readers will think of on reading the paragraph above, it will be neither true nor false to say that they are higher than Mount Monadnock. And some objects are even more poorly endowed. For example, if I wish that your wish will come true, then the object of my wish is whatever it is that you happen to wish; but if, unknown to me, what you wish is that my wish will come true, then this object would seem to have very little *Sosein* beyond that of being our mutual object. Meinong said that such an object is a *defective object* and suggested that the concept may throw light upon some of the logical paradoxes.

The theory of complexes—that is, the theory of wholes and other such “objects of higher order”—upon which Meinong wrote at length, also falls within the theory of objects.

None of the objects discussed above is created by us, nor does any of them depend in any way upon our thinking. Had no one ever thought of the round square, it would still be true *of* the round square that it does not exist; the round square need not be thought of in order not to exist. We draw these objects, so to speak, from the infinite depths of the *Ausserseienden*, beyond being and not-being.

## THEORY OF ASSUMPTIONS

Meinong’s theory of assumptions, or suppositions, is set forth in *Über Annahmen* (“On Assumptions”; first ed., Leipzig, 1902; 2nd ed., Leipzig, 1910). The theory is best understood by contrasting it with two theses held by Brentano, to which Meinong’s theory may be said to be a reaction. The first of Brentano’s theses is that of reism, or concretism, referred to above: Every object is a concrete thing; there are no objects such as the being of horses or the nonbeing of unicorns; the object of a judgment, therefore, is not a proposition, fact, or state of affairs; it is, rather, a certain concrete thing that the judgment may be said either to accept or to reject. And according to the second of Brentano’s theses, there are basically only two types of intellectual attitudes we can take with respect to

any object: We can simply think about the object, in which case it is the object of a thought or idea, or we can take an intellectual stand with respect to the object, either accepting it or rejecting it, in which case it becomes the object of a judgment. Meinong rejected both these theses of Brentano.

The object of a judgment, according to Meinong, is not a concrete thing; it is an “objective” (*Objektiv*). “That there are horses,” for example, designates an objective—an object of higher order, containing horses as a kind of constituent. (Thus, the nonexisting, nonsubsisting round square is a constituent of that subsisting objective that is the nonbeing of the round square.) Assumptions, like judgments, take objectives as their objects.

What Meinong intended by his term *assumption* (*Annahme*) is most clearly exemplified in deliberation: “Suppose I were to do  $A$ . What would happen then? And now suppose I were not to do  $A$ . What would happen then?” Assumptions belong to a category falling between ideas and judgments. Like mere ideas, they do not themselves involve commitment, belief, or conviction; therefore, as such, they do not involve any possibility of error. Like judgments, they are concerned with objectives (in the above example, with what is designated by “I shall do  $A$ ”), which are either true or false (it is either true or false that I shall do  $A$ ); and, like judgments, assumptions involve either affirmation (“Suppose I do  $A$ ”) or denial (“Suppose I do not do  $A$ ”), but affirmation or denial without commitment.

Meinong argues that only by reference to assumptions can we understand such phenomena as the nature of inference, our apprehension of negative facts, communication in general, desire, art, and the nature of play and of games. *Über Annahmen*, which is probably Meinong’s best book, contains important material on these and many other topics.

## THEORY OF EVIDENCE

The concept of evidence involves three dichotomies: (1) direct and indirect; (2) a priori and a posteriori; and (3) “evidence for certainty” and “evidence for presumption.” Meinong’s conception of the first two dichotomies is similar to that of Brentano. Thus there are axioms of mathematics and logic and the theory of objects, which are directly evident and a priori; and there are facts of “inner perception”—for example, the fact that I am making such-and-such an assumption, or the fact that I take something to be a tree—which are directly evident and a posteriori. (Any psychological process that “presents” an object to us, as memory may be said to present certain

objects of the past, is also a process that “presents itself”; “self-presentation” is thus the source of that evidence which is direct, certain, and a posteriori.) These directly evident judgments may confer evidence upon certain other judgments, which are then said to be indirectly evident.

For Meinong, paradigm cases of what is a priori evident would be expressed by “Round squares are both round and square” and “red is different from blue.” Every a priori judgment has four characteristics: It is grounded in the nature of its object (*gegenständlich begründet*); it is certain; it is necessary; and it does not take into consideration the question whether its object exists. (Brentano had said that every a priori judgment is a judgment to the effect that a certain type of object does not exist.)

An evident presumption (*Vermutung*) may be directly evident but not certain. The concept is needed, according to Meinong, in order for us to understand memory, perception, and induction. In each of these three cases we have a source of knowledge that cannot be impugned as such but may on occasion mislead us. A particular memory judgment, for example, may not be certain, but it may be evident, especially if it is supported by other memory judgments, by perceptual judgments, or by inductive inferences from such judgments; analogously, this holds for any particular perceptual judgment or any particular inductive conclusion. Such items of a posteriori knowledge may be compared with the cards in a pack, “no one of which is capable of standing up by itself, but several of which placed together can serve to hold each other up. Or, for something more solid, consider a stack of weapons in the field.” A consequence of this theory of evident presumptions is that a false judgment may yet be evident, a consequence that Brentano took to be absurd. Evidence does not guarantee truth; but, according to Meinong, evidence resembles truth in that if a judgment is evident, then its being evident—its *Evidentsein*—as well as the *Evidentsein* of this *Evidentsein*, and so on ad infinitum, is also evident.

An essential part of Meinong’s epistemology is his theory of “emotional presentation” There is an analogy between the way in which we come to know, say, that the temperature is high and the way in which we come to know that the temperature is agreeable. Meinong proposed, as a “heuristic principle,” that we try to carry the analogy as far as possible. If it is by means of a subjective feeling that we perceive the temperature to be agreeable, it is also by means of a subjective sensation that we perceive the temperature to be high. In neither case is the subjective experience the object of the presentation; in

neither case is our apprehension a matter of inference or of reasoning from effect to cause. “The sense in which the sky is said to be ‘beautiful,’ for example, is precisely that in which it is said to be ‘blue.’ But the experience by means of which the first property is presented plays an important role in our psychical life in addition to that of enabling us to grasp something else. This fact is reflected in our language; we refer to the one experience directly, but in the other case we must go round about, by way of the object that is presented, and use some such expression as ‘experience of blue.’” Meinong noted that the traditional arguments against a “subjectivistic” or “psychological” interpretation of ordinary sense perception apply equally to any such interpretation of emotional presentation.

## THEORY OF VALUE

In the final version of his theory of value, Meinong made use of the theory of emotional presentation considered above, as well as of Brentano’s doctrine of correct and incorrect emotion—that is, the doctrine according to which emotions, like judgments, may be said to be correct or incorrect, justified or unjustified, and according to which certain things may thus be said to merit or be worthy of certain emotions.

The basic concept of value theory is not that of desire, interest, or utility, but that of value feeling (*Wertgefühle*). Value feelings take objectives as their objects, more particularly, objectives consisting of the being or nonbeing of certain objects. One type of value feeling is *Seinsfreude*, pleasure or joy in the existence or being of a certain object; another type is *Seinsleid*, displeasure or sorrow with respect to the existence or being of a certain object. But the feelings of joy and sorrow may also be directed toward nonexistence and nonbeing; hence there are four fundamental types of value feeling, which may be illustrated by reference to the nature of good and evil. The good is that which merits *Seinsfreude* if it exists and *Nichtseinsleid* (sorrow with respect to its nonexistence) if it does not exist; evil, on the other hand, merits *Seinsleid* if it exists and *Nichtseinsfreude* (joy with respect to its nonexistence) if it does not exist. Meinong noted that human beings are not consistent in their emotional reactions. For example, as far as our health and ordinary comforts are concerned, we experience considerable *Nichtseinsleid* when they are absent, but not the appropriate amount of *Seinsfreude* when they are present.

Our actions have moral qualities other than those of being good, bad, or indifferent. Meinong introduced four moral categories, which he explicated by reference to

good and bad. Actions that are good may be either meritorious or simply required; those that are bad may be either excusable or inexcusable. (Meinong's terms are, respectively, *verdienstlich*, *correct*, *zulässig*, and *verwerflich*.) One may say of any act that performance is meritorious if and only if nonperformance is bad but excusable; nonperformance is meritorious if and only if performance is bad but excusable; performance is required if and only if nonperformance is inexcusable; and nonperformance is required if and only if performance is inexcusable. Given this "law of omission" (*Unterlassungsgesetz*), Meinong's concepts of meritorious, required, excusable, and inexcusable, respectively, approximate what are sometimes called the supererogatory, the obligatory, misdeeds that are venial, and misdeeds that are not venial. According to one of Meinong's followers (Ernst Schwarz), these four moral concepts are related to the concept of justified or correct emotion in the following way: The meritorious is that which it is incorrect to blame and incorrect not to praise; the required is that which it is incorrect to blame, correct to praise, but not incorrect not to praise; the merely excusable is that which it is incorrect to praise, correct to blame, and not incorrect not to blame; and the inexcusable is that which it is incorrect to praise and incorrect not to blame.

## Bibliography

### WORKS BY MEINONG

Meinong summarized his principal philosophical conclusions in *Die deutsche Philosophie der Gegenwart in Selbstdarstellungen*, edited by Raymund Schmidt (Leipzig, 1921), Vol. I, pp. 91–150. His purely psychological writings can be found in the first volume of *Gesammelte Abhandlungen* (2 vols.; Leipzig: Barth, 1913–1914).

### Theory of Objects

Meinong's theory of objects is discussed in "Über Gegenstandstheorie" (1904); this article was reprinted in Vol. II of his *Gesammelte Abhandlungen* and translated as "The Theory of Objects" in *Realism and the Background of Phenomenology*, edited by Roderick M. Chisholm (Glencoe, IL: Free Press, 1960). The theory is discussed also in *Über die Stellung der Gegenstandstheorie im System der Wissenschaften* (Leipzig, 1907) and, indeed, in almost all Meinong's writings after 1904.

### Epistemology

His most important epistemological writings are *Zur erkenntnistheoretischen Würdigung des Gedächtnisses* (1886), reprinted in Vol. II of *Gesammelte Abhandlungen; Über die Erfahrungsgrundlagen unseres Wissens* (Berlin, 1906); *Über Möglichkeit und Wahrscheinlichkeit* (Leipzig: Barth, 1915); and *Über emotionale Präsentation* (Vienna, 1917).

### Value Theory

Meinong's principal writings in value theory are *Psychologischethische Untersuchungen zur Werththeorie* (Graz: Leuschner and Lubensky, 1894) and the posthumously published *Zur Grundlegung der allgemeinen Werththeorie* (Graz: Leuschner and Lubensky, 1923).

### WORKS ON MEINONG

Among the most useful writings on Meinong are Bertrand Russell, "Meinong's Theory of Complexes and Assumptions," three articles in *Mind* 13 (1904): 204–219, 336–354, and 509–524; J. N. Findlay, *Meinong's Theory of Objects and Values* (2nd ed., Oxford: Clarendon Press, 1963); G. Dawes Hicks, "The Philosophical Researches of Meinong," in *Critical Realism* (London: Macmillan, 1938); and Konstantin Radakovic et al., *Meinong-Gedenkschrift* (Graz: "Styria" Steirische Verlagsanstalt, 1952).

Important material on all aspects of Meinong's philosophy can be found in *Philosophenbriefe: Aus der wissenschaftlichen Korrespondenz von Alexius Meinong mit Fachgenossen seiner Zeit*, edited by Rudolf Kindinger (Graz: Akademischen Druck- u. Verlagsanstalt, 1965).

## MELANCHTHON, PHILIPP

(1497–1560)

Philipp Melanchthon, the German reformer, was born at Bretten, Baden, and died at Wittenberg. He was a grandnephew of the great humanist Johannes Reuchlin, who encouraged him in his studies and deeply influenced his outlook. After studying at Heidelberg and Tübingen, Melanchthon, on Reuchlin's recommendation, became professor of Greek at Wittenberg. Because of his persuasiveness in interpreting the humanist spirit, this appointment marked the beginning of a new era in German education. At Wittenberg, Melanchthon collaborated closely with Martin Luther. He helped him both in translating the Bible and in giving systematic shape to the new theology that until that time had existed in a highly subjective form. Melanchthon's task was to reduce this theology to exact form and to set it forth as an integrated and persuasive system. In 1521 Melanchthon published his *Loci Communes Rerum Theologicarum*, a work that in its various editions was one of the most influential manuals of Protestant theology.

During the rest of his career, Melanchthon was much occupied with controversy and debate. In many of the famous conferences of the Reformation era, his influence was thrown on the side of moderation and peace. He was closely identified with some of the most important formularies of the period, such as the Augsburg Confession.

Such activities involved even a man of conciliatory spirit in vigorous debate, and Melanchthon's position in the history of thought is largely determined by the controversies in which he took part. Two of these demand consideration.

The Adiaphoristic controversy was concerned with "indifferent matters"—that is, religious practices or theological beliefs on which flexibility or compromise might be permissible. Melanchthon was unfairly charged with including among the "adiaphora" such major questions as justification by faith. Melanchthon did not minimize the

importance of essentials, but he was inclined to veil them beneath a conscious indefiniteness of expression. This deliberate obscurity extended to many matters that were intensively canvassed in the sixteenth century. He was willing to concede that good works are necessary to salvation, but not in the way in which the connection had traditionally been taught. He was prepared to recognize seven sacraments, but only if most of them were regarded as rites that have no inherent efficacy in securing salvation. Later he retreated from the permissive position he had adopted on the "adiaphora" and maintained a strict interpretation of the doctrines set forth in the *Loci Communes*.

More acute and more important was the controversy about synergism. Here the central issue was the relation between God's grace and man's will in regeneration. In his early period, Melanchthon, strongly influenced by Luther and deeply impressed by the experience of dependence upon God, severely restricted the role of man's will. To defend free will was to rob God's grace of its unique supremacy. But Melanchthon naturally tended to adopt a mediating outlook, and ethical issues were of great importance to him. Desiderius Erasmus, in his controversy with Luther concerning free will, had advanced views that served to modify Melanchthon's position. Melanchthon was now prepared to recognize the part played in conversion by man's will. The position that he reached (called synergism) precipitated a violent debate. Melanchthon's own statements were ambiguous and lacking in precision. His supporters (Johan Pfeffinger and Viktorin Strigel, for instance) and his opponents (Nikolaus von Amsdorf and Matthias Flacius Illyricus) were very explicit indeed. Synergism, however, can best be understood as an ethical protest against attitudes that paralyze the conscience and leave the church powerless in its struggle against moral chaos. Melanchthon's concern with God's moral purity led him to the belief that the problems of evil and of human responsibility have been aggravated by an extreme doctrine of predestination. He therefore abandoned the decree of eternal reprobation. The cause of sin lies in man himself; the hardening of his heart is due to his own perversity. Man has a real measure of responsibility for his spiritual condition. Man's will, therefore, can cooperate with God's grace, and does so. The human will, of course, is never the primary cause of man's regeneration—the Spirit of God and the preaching of the Word always maintain the initiative—but man's will is specifically granted a place, and unless there is consent on man's part there can be no effective regeneration. Melanchthon guarded himself against the charge of Pelagianism, but nevertheless he was accused of yielding to

this heresy. The violence of the controversy was due to the seriousness of the issues involved. A wide range of theological views had to be reexamined, and every aspect of the Christian doctrine of man and of salvation was involved. The controversy was finally silenced by the Formula of Concord, which ruled against the Melanchthonist position.

## MELISSUS OF SAMOS

(fifth century BCE)

Melissus of Samos, the Greek Eleatic philosopher, led the Samian fleet against the Athenians and defeated them (Plutarch, *Pericles* 26, quoting a lost work of Aristotle). The date of the battle was 441–440 BCE, and this is the only reliable date in the biography of Melissus. He was said to have been a pupil of Parmenides, but this may be an inference from his work, which gives ample evidence of dependence on Parmenides.

Portions of Melissus’s book titled *On Nature or What Exists*, written in prose, were quoted and preserved by the Aristotelian commentator Simplicius. The total length of these fragments is a little under one thousand words—enough to provide evidence of the content and quality of Melissus’s argument. No other fragments survive. The pseudo-Aristotelian treatise *On Melissus, Xenophanes and Gorgias* (c. first century CE) adds nothing useful.

Melissus’s argument, as revealed by the fragments, was similar to Parmenides’ in method and results, although it differed in some details. The starting point is the contradictoriness of descriptions of change. Any change ultimately implies the generation of something from nothing or its destruction into nothing, and Melissus, with Parmenides, held both of these to be impossible on the ground that “nothing” is absolutely nonexistent and unthinkable. Hence, what exists must have existed always and must continue to exist (Melissus seems to view eternity as a continual existence through time, whereas Parmenides thought of a timeless present).

From the eternity of what exists, Melissus deduced its spatial infinity. He argued that if what exists did not come into existence, it had no beginning or end, and being without beginning or end, it must be limitless or infinite. He seemed not to have noticed the ambiguity of “beginning” and “end” (or else his defense of the move from time to space has been lost); this is presumably the basis of Aristotle’s criticism of the argument (*De Sophisticis Elenchis* 167b13 and 168b35), although he does not make it quite explicit.

From the spatial infinity of what exists, Melissus deduced its unity. If there are two things in existence, each must limit the extent of the other; there cannot be more than one limitless thing in existence. Thus, Melissus chose a different route to the monism of Parmenides—indeed, according to most interpreters of Parmenides, this route was closed to him since, unlike Melissus, he held that what exists is spatially limited. But this is a dubious interpretation of Parmenides.

Next, Melissus argued that if what exists is one, it cannot have parts and must therefore be incorporeal because any solid body has actual or imaginable parts. Moreover, what exists cannot vary in density since this, according to Melissus, could come about only if one area contained less of being—and hence more of nonbeing—than another, and nonbeing is absolutely nonexistent. For similar reasons there is no motion, since there is no “give” anywhere in the plenum (this is an argument against motion that may not have been used by Parmenides). Every form of change—whether of size, order, or qual-

ity—means the coming into existence of something that previously was nothing, or the annihilation of something that exists, and these are ruled out by the first stage of Melissus's argument.

In the eighth fragment Melissus applies his own criteria of existence to the plural beings of the sensible world. If these things, such as air and fire, exist, then they must be just what our senses tell us they are and nothing else. But our senses tell us that they do change into something else. Our senses must therefore be wrong about this; hence, we can conclude that they were wrong initially in telling us that things are many and not one. The sensible world is therefore illusion.

Melissus was the least important of the Eleatics. Zeno's arguments proved more influential than his, and Parmenides was the original genius who pioneered the way. If Melissus has any claim to special historical importance that is not shared by the other Eleatics, it is perhaps that by applying Eleatic criteria to the plural beings posited by his opponents, he produced a formula (in Fr. 8) that led Leucippus directly to the concept of atoms. In the absence of complete texts it is wiser to refrain from pronouncing on Melissus's originality. Aristotle criticized both Parmenides and Melissus for bad arguments (*Physics* 186a6) and was more severe on Melissus, but perhaps that was because Melissus's clear style made him an easier target.

### Bibliography

Fragments of Melissus's writings in Greek with German translations have been published in Diels-Kranz, *Fragmente der Vorsokratiker*, 10th ed., Vol. I (Berlin, 1960); English translations, in J. Burnet, *Early Greek Philosophy*, 4th ed. (London: A. and C. Black, 1930).

Selected texts with English translation and commentary are in G. S. Kirk and J. E. Raven, *The Presocratic Philosophers* (Cambridge, U.K.: Cambridge University Press, 1957); the commentary should be treated with caution, especially on the subject of infinity and Melissus's relation with the Pythagoreans. The same is true of J. E. Raven, *Pythagoreans and Eleatics* (Cambridge, U.K.: Cambridge University Press, 1948).

See also Harold Cherniss, *Aristotle's Criticism of Presocratic Philosophy* (Baltimore: Johns Hopkins Press, 1935), and G. E. L. Owen, "Eleatic Questions," in *Classical Quarterly* 10 (1960).

## MEMORY

Remembering is one of the most characteristic and most puzzling of human activities. In particular, personal memory—the ability mentally to travel back into the past, as leading psychologist Endel Tulving puts it—often has intense emotional or moral significance: It is perhaps the most striking manifestation of the peculiar way human beings are embedded in time, and of humans' limited but genuine freedom from their present environment and immediate needs. Memory has been significant in the history of philosophy as much in relation to ethics and to epistemology as in theories of psyche, mind, and self.

The philosophy of memory is a fascinating, diverse, and underdeveloped area of study, which offers difficult but rewarding connections not only with psychology and the cognitive sciences, but also with the social sciences and political theory, and with literature and the arts. Outside philosophy, interest in memory increased massively and disproportionately in the late twentieth century in both the neurocognitive sciences and the humanities, driven both by internal developments within disparate disciplines and by wider social and cultural concerns about trauma and recovered memories, about the politics of forgetting and collective responsibility, about memory loss in an aging population, and about the manipulation, control, ownership, and protection of individual memory. The widespread and troubled fascination in Western culture with this last set of concerns in particular, and with challenging associated questions about moral psychology and personal identity, is suggested by the success of films like *Bladerunner* (1982), *Memento* (2000), and *Eternal Sunshine of the Spotless Mind* (2004).

As a result, just as in other areas of the philosophy of mind, it has become increasingly difficult to cordon off a set of questions about memory, or methods for its study, which are uniquely or primarily philosophical. Some philosophers treat memory as a case study in philosophy of science, asking for example whether the psychology of memory might be reducible to the neuroscience of memory. Others begin with the phenomenology of memory, the ordinary experiences and practices of remembering; others still inquire into cross-cultural or historical differences in these practices. It seems likely, further, that psychopharmacological influences on memory, and their potential misuse, will make memory a central topic in the emerging fields of neuroethics and philosophy of psychiatry. This entry covers more traditional philosophical issues about the nature of memory, but includes some

consideration of the need for a broader framework that can encompass the neural, embodied, psychological, and social aspects of remembering.

### FORMS OF REMEMBERING

When a person is remembering, there are many different activities he or she may be engaged in, and the expression of the individual's memory can take many different forms. One reminisces with old allies about shared experiences; one finally calls to mind that obscure fact; one mindlessly cycles off down the lane, despite not having been on a bike for years; one sits alone and ruminates on one joyful or agonizing moment long ago; one gathers with others to commemorate a significant occasion; one writes or fashions something in memory of a person or an event; a photo, an odd memento, or a long-forgotten melody suddenly immerses a person in the emotions of another time.

It is not easy to pinpoint just what is common across this range of activities, and some philosophers have argued that not all of them involve true memory. But the present-day consensus in both philosophy and psychology is that there are at least three distinct forms of remembering that can helpfully be detected in the variety of ordinary experience.

First, in remembering specific events or episodes from an individual's personal past he or she draws on *personal memory* (also known as *experiential* or *event memory*): For example, one remembers walking down by the river with a friend that spring afternoon. Psychologists often call this *episodic memory*, or sometimes *autobiographical memory*.

A different form of memory is naturally expressed with a "that" complement: One remembers that Aristotle was Alexander's tutor. This *factual* or *semantic memory* is akin to simple belief, and the remembered facts can be about events in the remote past, or indeed the future, as well as personally experienced events. One can factually remember details one has been told about one's early life, for example, for which one has no personal memory, no sense at all of what the past experiences were like.

In English, and many other languages, people sometimes contrast things that they "just know" from what they genuinely (personally) remember, thus treating personal memory as the basic or essential kind of memory. But in other contexts people are happy to talk also of remembering facts, and to attribute their general beliefs about the world to "memory" in a broader sense.

Personal/episodic remembering and factual/semantic remembering are both forms of *declarative memory*, in which individuals seek to hook up to reality, to represent the world or the past. Although remembering activities often have quite different functions as well, under normal circumstances such memories aim at truth. This is so even though, as both scientific and common-sense psychology increasingly suggest, people do not always get there. The point is not that memory necessarily or even reliably achieves this aim, but that one's ordinary practices include a general commitment to its reliability in doing so. For example, an individual may or may not in fact have walked by the river with a friend that spring afternoon, and Aristotle may or may not actually have been Alexander's tutor. But if one is sincerely expressing that personal memory, or that factual memory, one is (among other things) making a claim about what happened.

In these declarative forms of memory, the content of one's memory can in principle—at least in central cases—be articulated. But when a person wonders if a friend remembers how to play the flute, or how to drive a car, the person is asking not about the friend's personal or factual memories, but about his or her skills or embodied memories. Philosophers have often talked here of *habit memory*, while psychologists identify these cases as types of *procedural memory*, where this category is also taken to include more basic/primitive forms of conditioning and associative learning.

Procedural memory has been sharply divided from declarative memory for a number of reasons: Perhaps most important is the case of H.M., an epileptic patient who suffered terrible amnesia after brain surgery in the 1950s. H.M., who had lost his hippocampus and other brain structures now known to be central to declarative memory, was no longer able to lay down event memories, so that he would forget everything minutes after its occurrence, and lose any clear sense of time passing. Yet H.M. was still able to learn new games, and to improve his performance at new perceptual-motor skills, despite having no idea each time that he had ever tried them before.

Procedural memory is philosophically important for a number of reasons, although habits and skilled activities have been little studied. For example, neither philosophers nor psychologists have a clear grip on the various ways that personal memory and other high-level cognitive processes interact with remembered embodied skills. Competition and coordination between the different memory systems can both occur. On the one hand, skilled performers in dance or sport know that their motor

habits often run best in a groove, when not consciously or verbally controlled: yet the skills involved are robust and flexible, unlike more primitive forms of procedural memory, and can sometimes be directly shaped by mood, context, verbal instruction, and conscious decision.

These conceptual, grammatical, and experiential distinctions between personal, factual, and habit memory have in contemporary cognitive psychology been developed into theories of distinct memory systems. There is considerable disagreement about the psychological status of these systems, and about whether the distinction between episodic and semantic memory, in particular, should be characterized by reference merely to the kind of information in question, or by an essential phenomenological difference. Since there is little agreement more generally about what a psychological system or module is, or about the nature of any putative natural kinds in psychology, these debates about memory systems are likely to be resolved only in conjunction with progress on broader questions in philosophy of psychology.

## PERSONAL MEMORY

An individual's capacity to conjure up experiences, emotions, and events from long in the past involves the same kind of memory as the mundane ability to keep track of just what he or she has been doing, feeling, and thinking in the last day or week. Personal remembering does not seem to be distinguished from other related activities—imagining, dreaming, factual remembering, for example—by the level of sensory detail or vividness which it involves: some memories, after all, are both faint and fragmentary, while some scenes of fantasy can be richly imagined. Memory capacities, even in their normal and reliable functioning, are both fallible and selective: human beings don't need either total or precise recall to maintain sufficient coherence and continuity of self over time, for personal memory works in part through an ongoing condensing, editing, and summarizing of life experiences, on which people draw in specific autobiographical narratives. One's narratives or other memory expressions can be public or private, and they can be more or less under one's control, either smoothly tailored to specific audiences or emerging in involuntary fragments.

Personal remembering is a context-sensitive activity from the start. As young children build on their earlier abilities to understand typical sequences of events, their capacity to remember particular past experiences is supported and shaped by adults. Joint attention to the shared past emerges in an interactive social environment, as chil-

dren come to see that there can be different perspectives on the same past time. Spontaneous self-conscious thought about the personal past is a gradual development out of these memory-sharing practices, which can vary considerably in nature, frequency, and significance across contexts and cultures. One condition for the full emergence of such self-conscious thought about his or her own past experiences, which may be surprisingly late, is that the child picks up the causal connections between events in time, and within the child's own history. Some grasp of the temporal asymmetry of experience is needed to understand that, in principle at least, remembered events can be integrated on a connected temporal dimension. Children's personal memory, then, is a highly sophisticated achievement closely linked not only to their emerging self-awareness and understanding of other minds, but also to their recognition that they cannot change the past, and that their current and future actions are unique and irrevocable.

Because early personal remembering is socially situated in this way, it is also tightly meshed with emotional and social/moral development. Key social practices, such as promising and forgiving, and some central complex emotions, such as grief, love, and regret, depend essentially on personal memory and on one's grasp of temporal relations. The point here is not just that the fallible but more-or-less reliable operation of memory in two or more people is needed to give those people current informational access to the past times at which their paths have crossed. Memory's affective tone and influence means that, in addition to its role in retaining the past, it also has a forward-looking function, as Richard Wollheim argued in his *Thread of Life* (1984): Remembering can keep what happened in the past alive, giving it significance for one's ongoing relationships and projects. According to this view, memory is not just a means for checking on the continuity of the self over time, but also itself partly produces or creates personal identity: As Wollheim puts it, the past affects people in such a way that they become creatures with a past.

The particular ways in which, through memory, individuals deal with events and experiences that are no longer present varies according to context and aim. Most dramatically, for example, legal contexts impose demands and standards on the memory narratives witnesses must produce that differ greatly from the norms operating in other remembering activities. But questions about the reliability of memory and about its mechanisms arise in many different circumstances just because memory, with its orientation to truth, is in these ways intimately

involved in both personal identity and significant social practices. Two connected lines of thought have raised the most serious concerns about people's access to the past in remembering: philosophical views about representations and memory traces, and psychological accounts of the constructive nature of remembering.

## THEORIES OF MEMORY

People can, sometimes, remember past events and experiences in the absence of immediate external cues or prompts to memory. It is natural, then, to think that somehow individuals carry around with them what they will need in order to remember when circumstances are right. Even one's ordinary conception of memory, C. B. Martin and Max Deutscher argued in their influential causal analysis *Remembering* (1966), requires the existence of an appropriate causal link between one's past experience and one's present remembering. Although the notion of the "memory trace" has appeared in many strange metaphors and theories in the history of philosophy and the history of science, it need be no richer than this idea of a state that causally connects experience and remembering in a certain way. This causal analysis embeds the theory of memory in the broader *representational theory of mind* which has come to characterize mainstream philosophy of cognitive science; however the bare invocation of memory traces is compatible with many quite different views about their nature and operation.

However, even this basic view about memory traces, in the eyes of its critics, engenders serious problems about the nature of a person's access to the past. If the past is thus truly lost, so that a person can only make contact with it by examining certain representations in the present, critics complain, there is a real danger of scepticism, to be countered by affirming that the person is in fact aware of the past directly in memory. The ensuing, long-running debate between representative realists or indirect realists, who accept memory representations, and direct realists or phenomenologists who reject them, is exactly parallel to that found in theories of perception. Although the dichotomous nature of this debate no longer fits the range of positions available, and many quite different views are often condensed by critics into a monolithic target, there is some common ground.

Contemporary trace theorists tend to work in a broadly materialist framework, and do not in general think of traces as *direct* objects of awareness from which the nature of the past is consciously inferred at the personal level of psychological analysis. If complex noncon-

scious processes, operating subpersonally on representations which may themselves be partial and context-sensitive, are involved in the shaping and constructing of the contents of memory, this does not mean that the experience of remembering is indirect. On this point, the positive direct realist contribution is convincing: Remembering, under normal circumstances, is a kind of immersion in which one has a pre-reflective confidence.

But this idea that an individual typically inhabits the memory, rather than judging and assessing it for plausibility and coherence, is in fact entirely compatible with the existence and involvement of subpersonal mechanisms operating on enduring but modifiable traces. Such mechanisms can be typically reliable even if they are fallible in particular instances. To raise a general skeptical worry again at this point against the invocation of memory representations would be unrealistically to demand incorrigible access to the past, to seek a blanket guarantee of accuracy in memory. Such blunt certainty about memory was expressed, for example, by the eighteenth-century Scots philosopher Thomas Reid, the most ardent critic of philosophies of “ideas” or “traces,” who wrote that “those things really did happen which I distinctly remember” (Reid, *Essays*, 1849, p. 444). But this renders the indisputable evidence—both everyday and scientific—of errors in memory quite mysterious, and thereby threatens to erode commonsense realism about the past.

Theorists who posit memory traces are also criticized for adherence to what is seen as an arbitrary metaphor of “storage,” unfortunately entrenched in the philosophy of memory since Plato’s *Theaetetus*. The bare retention of capacities or dispositions to act or respond in certain ways, the critics complain, implies nothing about the means by which such capacities are retained: Storage is a mistakenly concrete way of thinking, as if each memory had to be stashed away separately, like sacks of grain in a storehouse or fixed entries in an archive. Ludwig Wittgenstein, for example, mocked the static but inaccessible inner records he identified in the psychological theories of his time: In notes of 1935–1936, he wondered “whether the things stored up may not constantly change their nature” (Stern 1991, p. 204).

In some invocations of memory representations, each trace has indeed been treated as distinct, with each single remembered item mapped on to one storage element. Such atomist or localist representational schemes make control over the contents of memory easier to imagine or achieve: The remembered items are passive, and must be manipulated or altered by an external executive. In this separation of data from process, ordinary

digital computers exemplify the localist memory scheme: But what is “stored” in human memory displays more intrinsic dynamics than this, tending in some contexts naturally to interfere, blend, and generalize without deliberate or voluntary control. But just as such computers do not exhaust possible computational devices, so localist representational schemes are not essential to the general framework of memory traces. Both historical theories of memories as patterned flows of “animal spirits” through the pores of the brain, and contemporary connectionist models in cognitive science employ distributed (rather than localist) representation: What can be distinctly remembered need not be held distinctly or independently, since each item is spread or “superposed” across many elements in a system or network. This entry examines the implications of these distributed models of memory after setting them in the context of recent developments in cognitive psychology and the cognitive sciences.

## REMEMBERING AND THE COGNITIVE SCIENCES

The recent history of the sciences of memory offers a sharp contrast and corrective to the stereotyped image of cognitive science as a scientific quest to reduce the human mind to the dull mechanism of digital computers. Memory research was one of the first areas to be taken out of the lab in the 1980s and 1990s, as psychologists sought to address the kinds of memory that matter in everyday life (such as autobiographical memory), and to find ecologically valid methods of studying such memories outside artificial isolated situations. The difficulty facing philosophers or scientists with an urge toward synthesis is not that psychological results are irrelevant to wider concerns about memory, but that the daunting diversity of methods and traditions even within cognitive psychology makes it hard to see how different levels of explanation might relate to one another. There are issues of considerable interest for the philosophy of science in understanding the connections between neuroscientific and cognitive-psychological descriptions and methods; and, equally, robust and philosophically intriguing research traditions on autobiographical memory in developmental, personality, and social psychology. This entry briefly examines ideas about the constructive nature of remembering that seem to have direct relevance to concerns about truth in memory.

Remembering is a multifaceted activity that takes place in the present, and so the best explanatory frameworks for understanding it will attend closely to the con-

text of recall, rather than simply investigating the nature of encoded traces. Memories are often compiled or constructed for particular purposes when needed, not held fully formed. There is room for considerable internal plasticity in memory traces, which are (on the connectionist model) always composites shaped by the entire history of their network. The most dramatic work on construction in memory has come not from connectionist modeling, however, but from the research on suggestibility and false memory by Elizabeth Loftus and her colleagues (2003). Misleading information from external sources can be incorporated into personal recollection. Confident, entrenched childhood “memories” of spilling a bowl of punch at a wedding, for example, or of gazing long at an exceptionally colorful mobile in the days after birth, can be elicited artificially in certain circumstances. This work is partly motivated by a wish to confirm the possibility of false confessions, in which individuals may come sincerely and passionately to believe that they have committed horrible crimes in the past; but the mechanisms in play are just the ordinary and normally robust processes of shaping and generalizing memories to make them fit. Although Loftus has adopted the high moral tone of a crusade, ongoing careful investigation of individual differences and integration of these results with social and personality psychology promises a much richer picture of the conditions which make different kinds of distortion more likely.

Again, the point of this research is not to show, implausibly, that reliability in memory is impossible or unlikely. Psychologists assume that understanding the mechanisms of distortion will also throw light on the processes involved in veridical remembering. Reliability and accuracy are not transparent notions here. Pre-reflective confidence in personal memories can, and in certain contexts should, coexist with attention to the other evidence about the past which is often available, and care for the defeasible but subtle and robust capacities to winnow evidence that individuals have developed in the rich and complex social context of early memory-sharing and memory-using practices.

## SOCIAL MEMORY AND SHARED MEMORY

The general constructive picture of remembering can be accepted while acknowledging that external influences—particularly social influences—on memory need not inevitably lead to error. As Sue Campbell argued in her powerful philosophical responses to the “memory wars,” there are vital features of relational interaction with oth-

ers that contribute positively to practices of good remembering, both in development and in adult social life: To treat the true unit of memory as the isolated individual, free from the distorting influence of other people, is to miss the value we often appropriately place on negotiating the past—both the personal past and the shared past—in company.

Indeed a need for attention to shared remembering and social remembering in both psychology and philosophy can be motivated from within the broadly constructivist framework itself. It is because one’s internal memory is partial and context-sensitive, and does not naturally retain information in distinct and unchanging form between experience and recollection, that one relies so pervasively and—in the main—successfully on external social and technological scaffolding. A challenge for psychologists is to find ways to study shared memories that do not focus solely on the conformity induced or sought by powerful external authorities; and a challenge for philosophers is to construct a social ontology of memory by which to understand the diverse ways in which people manage to hook their incomplete inner systems of traces with the vast social and cultural resources in which cognition is situated.

Mark Rowlands (1999) and Rob Wilson (2004), for example, have suggested specific ways in which external symbol systems—in their many distinct historical and cultural forms—allow individuals to leave information and skills out in the world, saving on the resources and capacity required for biological memory. Drawing on the more precise invocations of terms like *social memory* and *collective memory* in the contemporary social sciences, this distributed cognition framework suggests that researchers can study the transmission of particular representations across different individuals and media, and the specific forms of interplay between group dynamics and individual recall. It also promises to throw better light on the influential work on memory by the French sociologist Maurice Halbwachs (1980).

Halbwachs’s notion of the collective memory is often cited by contemporary social scientists and historians as deeply anti-psychological, or as sociologically determinist: but in fact his work focuses on the incomplete or shrouded nature of the individual’s memory, which (outside of dreams) must be sculpted and completed within a social framework, which provides the context and the means for the construction of a specific recollection. Philosophical analysis can potentially be of immense service to empirical disciplines like cognitive anthropology and historical theory in the study of memory by

showing how case studies of remembering activities in particular times and places might be embedded in robust broader theories of memory. So in addition to the long-standing philosophical concerns about truth and the self previously outlined, it is likely that philosophical attention will increasingly engage, through topics like memory, with the urgent challenge of connecting the cognitive sciences and the social sciences.

## MENASSEH (MANASSEH) BEN ISRAEL (1604–1657)

Menasseh (Manasseh) ben Israel, the Jewish scholar, philosopher, and theologian, was probably born in Madeira. His father, a victim of the Spanish Inquisition, escaped with his family to La Rochelle and then to Amsterdam, where Menasseh studied in the growing Jewish community. At eighteen he became a teacher and preacher. Although very successful in his rabbinical career, Menasseh could not support his family with his salary and so became a printer, establishing Holland's first Hebrew press. He printed his own first published work, an index to the *Midrash Rabbah* (1628). Most of his subsequent works are in Spanish, Portuguese, or Latin.

Menasseh's vast erudition in Jewish and Christian theology and philosophy and classical and contemporary literature attracted notice in 1632, when the first part of his *El Conciliador* appeared in Frankfurt (the second, third, and fourth parts appeared in Amsterdam, 1641–1651; the book was translated into English by E. H. Lindo, London, 1842). This work attempted to reconcile the apparent conflicts and contradictions in the Bible and brought Menasseh into the company of Gerhard Johannes and Isaac Vossius, Hugo Grotius, and many other scholars, who came to regard him as the leading expositor of Jewish thought to the Christian world. He corresponded with Christian and Jewish scholars everywhere, and many came to Amsterdam to confer with him.

Menasseh ben Israel was greatly interested in the Jewish and Protestant kabbalistic, mystical, and Messianic views of his time and was involved with some of the strangest seventeenth-century visionaries. This led to his most famous work and the best-known episode of his career. A Portuguese Jew from South America told him of finding some of the lost tribes of Israel in the jungles there. Using this material and other "data," Menasseh ben Israel published his *Hope of Israel* in Latin, Spanish, and English (1650), in which he argued that because the Israelites were spread almost everywhere on Earth, the Messianic age was at hand. If the Jews were readmitted to England, then all might be ready for the Messiah. Several influential Puritans, including Oliver Cromwell, held similar views, and they invited Menasseh ben Israel to London to discuss the readmission of the Jews. Menasseh ben Israel stayed in England from 1655 to 1657, but after much controversy no official solution emerged, although the unofficial readmission of Jews to England did begin. Disappointed, Menasseh ben Israel died shortly after leaving England.

Although his works are not of the first rank, Menasseh ben Israel was extremely influential in developing and disseminating a modernized form of Jewish learning and in making Christian scholars aware of then-current streams of Jewish thought.

## MENCIUS

(fourth century BCE)

Mencius, a Chinese philosopher, is often regarded as the most important Confucian thinker after Confucius. He lived in the Warring States period, during which China was divided into different states with their own rulers, often waging war against each other. He traveled from state to state to convert rulers to the teachings of Confucius. At the same time, he also combated other influential movements of thought, especially those associated with Mozi and Yang Zhu (fifth to fourth century BCE). One's main access to his thinking is through the *Mengzi* (Mencius), probably compiled by his disciples or disciples of his disciples. The text was subsequently edited and shortened by Zhao Qi in the second century CE, and this is the version of the text available today.

Elaborating on Confucius's teachings, Mencius highlighted four ethical attributes: *ren* (benevolence, humanness), *yi* (propriety), *li* (observance of rites), and *zhi* (wisdom). *Ren* has to do with love or concern for others and involves a reluctance to cause harm and the capacity to be moved by the suffering of others. The scope of such concern includes not just human beings but also certain kinds of animals, and there is a gradation in *ren* in that one has special concern for and obligations to those closer to oneself. *Ren* results from cultivating the special love for parents that everyone shares as an infant and the affective concern for others shown in the well-known Mencian example of one's commiseration for the infant on the verge of falling into a well.

The earlier use of *yi* refers to a proper regard for oneself and distancing oneself from disgrace, involving such things as not brooking an insult. Mencius retained this use of *yi*, but disgrace for him is measured not by ordinary social standards but by ethical standards, and *yi* has to do with a firm commitment to such standards. One regards what falls below such standards as potentially tainting oneself and insists on distancing oneself from such occurrences even at the expense of death. One example is that of a beggar starving to death, who would reject food given with abuse despite the resulting loss of life. According to Mencius everyone shares responses of this kind, which provide the starting point for cultivating *yi*.

*Li* originally referred to rites of sacrifice and later to rules of conduct governing ceremonial behavior as well as behavior in other social contexts. Mencius continued to use *li* in this way, and in addition used it to refer to an ethical attribute having to do with the observance of *li*. This

attribute involves a general disposition to follow *li*, as well as a mastery of the details of *li* that enables one to follow *li* with ease. It also involves one's observing *li* with the proper attitude and mental attention, such as reverence in interacting with others or sorrow in mourning.

In early Chinese thought, *xin*, which refers to the physical heart, is regarded as the site of both cognitive and affective activities. It is translated as "heart" or "mind," and sometimes as "heart/mind." *Xin* can form certain directions, which can take the form of long-term goals in life or more specific intentions. The fourth ethical attribute, *zhi*, involves having proper directions of the heart/mind, which in turn requires an ability to assess situations without adhering to fixed rules of conduct. This discretionary judgment may lead one to deviate from established rules of *li*, and may also guide one's behavior in situations in which no general rule is applicable.

For Mencius, these four ethical attributes result from people cultivating four kinds of predispositions of the heart/mind. These include commiseration, the sense of shame, a reverential attitude toward others, and the sense of right and wrong. He referred to these as the four "sprouts" or "beginnings" and regarded the four ethical attributes as growing from these predispositions in the way that a plant grows from a sprout. Besides commiseration and the sense of shame, he also regarded love for parents and obedience to elder brothers as the starting point for cultivating *ren* and *yi*, respectively. His view that the heart/mind has these ethical predispositions provides the basis for his response to the Moist and Yangist challenges.

Mozi advocated the doctrine of indiscriminate concern for everyone. He did not believe that human beings have the appropriate predispositions to begin with and thought that one could restructure one's motivations accordingly after endorsing this doctrine. In the absence of such predispositions, the practice of indiscriminate concern seems humanly impossible, a point seized on by Mozi's opponents. By contrast, Mencius thought that human beings have ethical predispositions that relate to the ethical ideal in the way that a sprout relates to a full-grown plant. Such predispositions contain within them a direction of growth and provide the appropriate emotional resources that one can draw on to achieve the ideal.

The Yangists advocated nourishing *xing* (nature), a term referring to the direction of growth or development of a thing. They understand the *xing* of human beings in biological terms, such as living to an old age, and regarded it as the proper direction of development for humans. Mencius rejected the biological conception of

*xing*, instead, *xing* is constituted by the ethical direction implicit in the predispositions of the heart/mind. The view that *xing* has an ethical direction is expressed in his well-known slogan that *xing* (human nature) is good.

Although the heart/mind has the relevant ethical predispositions, they need to be nourished for them to flourish, and one should also guard against the various factors that can potentially harm their growth. Mencius often highlighted the senses as something that can lead one astray. The senses operate automatically—when they come into contact with their ideal objects, they are just pulled along unreflectively by these objects. By contrast, the heart/mind can reflect on what is proper and can halt any course of action it regards as improper. The heart/mind should constantly exercise these capacities to ensure that one progresses in an ethical direction.

One may also be led astray by erroneous doctrines, such as Mohist and Yangist teachings, which Mencius explicitly opposed. One may also be led astray by problematic desires. For example, in a series of dialogues between Mencius and King Xuan of the state of Qi, the king referred to his great desire to expand territories and his feverish desires for wealth, women, and display of valor. These desires not only led the king to harsh policies but also led him to rationalizations about his inability to be caring toward his people. Mencius's response was to try to steer the king toward seeing that a more caring policy toward the people is not only compatible with the king's desires but actually enables their attainment in a higher form. For example, a king who seeks to be invincible can do so by practicing *ren* government, thereby drawing the allegiance of the people. He will become invincible not in the sense of superior military strength, but in the sense of being without opposition.

While Mencius's teachings competed for influence with other kinds of Confucian teachings for several hundred years after his time, he eventually came to be regarded as the true transmitter of Confucius's teachings. Zhu Xi included the *Mengzi* as one of the Four Books, which became canonical texts of the Confucian tradition. Mencius also came to be regarded as the greatest Confucian thinker after Confucius himself, and his teachings have been influential on the development of Confucian thought in the Song (960–1279), Ming (1368–1644), Qing (1644–1912) Dynasties, and up to modern times.

## MENDELSSOHN, MOSES

(1729–1786)

Moses Mendelssohn, the greatest Jewish philosopher in the eighteenth century, was born in Dessau, the son of a poor Jewish copyist of sacred scrolls. His first studies were devoted to the Bible, the Talmud, and Maimonides' *Guide for the Perplexed*. He followed his teacher Rabbi David Fränkel to Berlin in 1745, where he learned to read German and Latin while living in great poverty. In 1750 he became a tutor in the household of the Jewish silk manufacturer Isaak Bernhard; he was later a bookkeeper and ultimately a partner in Bernhard's firm. In Berlin Mendelssohn became a close friend of G. E. Lessing, C. F. Nicolai, and Thomas Abbt. After 1755 his reputation as a philosopher and critic grew rapidly throughout Germany. By his contemporaries he was regarded as eminently kind and virtuous, and because of his wisdom and ugliness he was called "The Jewish Socrates." Lessing is said to have modeled the character of Nathan in his drama *Nathan der Weise* upon Mendelssohn. In 1763 Mendelssohn's *Abhandlung über die Evidenz in den metaphysischen Wissenschaften* (Essay on Evidence in Metaphysical Science; Berlin, 1764) won a prize from the Berlin Academy, and he was later elected to the academy, although his appointment was never confirmed.

In spite of his Jewish extraction, Mendelssohn's development as a philosopher was notably German in character; he was influenced mainly by Gottfried Wilhelm Leibniz, Christian Wolff, Alexander Baumgarten, G. F. Meier, his Berlin friends, and among foreign philosophers, by John Locke, the earl of Shaftesbury, Edmund

Burke, Jean Baptiste Dubos, and Pierre-Louis Moreau de Maupertuis.

Mendelssohn was a typical “popular philosopher.” He was empirically minded, refrained from final systematizations of his theories, wrote in an easy and attractive style, and was mainly interested in aesthetics, psychology, and religion (although he also discussed methodological and metaphysical questions). His contribution to the emancipation of the Jews was significant. Because of the continuous evolution of his ideas, a summary of his views can only cover the general trends of his thought. He exerted a great influence not only upon his closest friends but upon his whole generation in Germany, and upon Immanuel Kant in particular.

Aesthetics and psychology were, in Mendelssohn’s mind, closely interrelated. He continued the work of Baumgarten and Meier, but amalgamated their doctrines with the tenets of English and French aesthetics translated into the terminology of German psychology. Generally attributed to Mendelssohn is the first clear distinction between Beauty and metaphysical perfection: He held that Beauty was an inferior, subjective kind of perfection. Metaphysical perfection consists in unity in a multiplicity. Aesthetic perfection arises out of the limits of human understanding. Man is unable to conceive, as God can, the real, supreme unity in the enormous variety of things. He must therefore content himself with introducing an artificial unity (uniformity) into some objects in order to be able to perceive them as wholes; and this is beauty.

In this way, Mendelssohn began a trend away from Baumgarten’s and Meier’s aesthetic objectivism toward a subjective aesthetics that soon dominated German aesthetics: A beautiful object is not necessarily perfect in itself, but must be perfect in its capacity to be perceived. The perception of Beauty strengthens the representative activity of the soul and makes it more perfect, thus causing a feeling of pleasure. The perception of Beauty causes intuitive knowledge; in its highest stage it becomes the “aesthetic illusion” in which, for example, fable appears as reality. Mendelssohn’s conception of Beauty permitted him to explain the pleasurable effect of tragedy and of the sublime, whose distinction from Beauty he was the first in Germany to explain clearly. In tragedy, murder is the representation of a morally and metaphysically imperfect event, but its representation may be subjectively perfect. Mendelssohn, clearly under the influence of Burke, held that in the sublime, the pleasure in awareness of immensity of distance, size, or number is mixed with some pain because of our inability to comprehend it completely. In both cases, aesthetic pleasure is the result of the “mixed

feeling” (*vermischte Empfindung*) arising in our soul: Even if some element of the perception is unpleasant, the perception as a subjective whole is pleasurable.

Mendelssohn’s study of the perception of Beauty led him to introduce a doctrine of mental faculties that was later adopted in modified form by Kant and others. Mendelssohn held that aesthetic feelings must be attributed to a faculty different from intellect and desire, a faculty that he called the faculty of approval (*Billigungsvermögen*). The beauty of an object escapes us if we subject it to a process of analysis and definition; therefore, experience of the beautiful cannot be an object of knowledge. A beautiful object gives us aesthetic pleasure even if we do not possess the object; thus, the approval of Beauty must be distinct from desire. Metaphysical perfection, unlike Beauty, is both known by intellect and an object of desire.

Beauty is produced by genius. Genius does not imitate nature, but “idealizes” it; that is, it exhibits natural objects as God would have created them if his aim had been aesthetic and not metaphysical perfection. Genius is independent of rules because it establishes its own rules. A genius’s procedure is instinctive.

Mendelssohn believed that both the existence of God and the immortality of the soul could be demonstrated. Although his *Morgenstunden oder Vorlesungen über das Daseyn Gottes* (Morning Hours, or Lectures on the Existence of God; Berlin, 1785) was written in awareness of Kant’s previously published *Kritik des reinen Vernunft*, in it Mendelssohn accepted both the Ontological Argument and the Argument from Design.

Mendelssohn’s *Phädon oder über die Unsterblichkeit der Seele* (*Phaedo*, or on the Immortality of the Soul; Berlin, 1767) was a dialogue on immortality in imitation of Plato’s *Phaedo*. The soul is a simple substance and therefore indestructible. The soul might nevertheless lose its consciousness, but the divine wisdom and goodness of God would not allow this to happen.

Mendelssohn’s plans to publish a work commemorating Lessing, who had died in 1781, prompted Friedrich Heinrich Jacobi to write to Mendelssohn asking whether he knew that Lessing was a Spinozist. The resulting quarrel, which soon involved Johann Georg Hamann, Johann Gottfried Herder, and Johann Wolfgang von Goethe as well as Mendelssohn and Jacobi, is discussed in the entry “Pantheismusstreit.”

Mendelssohn had been challenged in 1769 by the Swiss physiognomist and religious writer Johann Kaspar Lavater either to demonstrate the falsity of Christian rev-

elation or to become a convert to Christianity. Mendelssohn's answer was that the deism of the Enlightenment, which he had developed into a universal religion of reason, was in fact identical with Judaism. In his *Jerusalem oder über religiöse Macht und Judentum* (Jerusalem, or on Religious Power and Judaism; 2 vols., Berlin, 1783), Mendelssohn supported religious and political toleration, and advocated separation of church and state and civil equality for the Jews. He always fought against both advocates of anti-Semitism and conservative Jews for a cultural and political union of Christians and Jews.

## MENTAL CAUSATION

There is mental causation whenever a mental state, event, process, or activity has a causal effect. The pursuit of our lives seems replete with mental causation. It may thus seem as obvious that it occurs as we pursue our lives. But how mental causation is possible is not obvious. And therein lies a philosophical tale. Any attempt to explain how it occurs must engage the mind-body problem.

René Descartes (1596–1650) maintained that there is body-to-mind causation when we perceive our surroundings, and mind-to-body causation when we act. But one of the most serious charges leveled against his substance dualism, according to which the mind is an immaterial substance that is not extended in space, is that it leaves unexplained *how* mental states and events (etc.) have causal effects on our bodies. Descartes held that the locus of mind-body causal interaction is in the brain (specifically, in the pineal gland). His contemporary, Princess Elisabeth of Bohemia, asked how states of, or changes in, a substance not extended in space (the mind) could causally affect states of, or changes in, a substance extended in space (the brain or pineal gland), and declared such causal interaction too incredible to believe. The absence of a satisfactory answer to her "how-question" contributed to the demise of Cartesian substance-dualism (Watson 1987).

Many contemporary philosophers hold that to have a mind is not to possess an immaterial substance, but rather to possess certain capacities, such as the capacity to think and/or to feel. Brains serve somehow as the material basis of such capacities. (Whether an artificial brain could so serve is the question of whether artificial intelligence is possible.) But because of the many apparent differences between mental and physical properties, some philosophers, while rejecting Cartesian substance dualism, nevertheless embrace Cartesian property dualism. They hold that while there are no immaterial substances, mental properties are distinct from physical properties, and are related to certain of them by irreducible laws of

nature. This view faces the question of how an individual's having a mental property could exert any causal influence on the course of events. Given the absence of a reality underlying both mental and physical reality, an individual's having a mental property would have to exert a direct causal influence on its initial effects in the brain, one unmediated by any mechanism.

The year 1870 marked more than a century of increasingly detailed investigation of human physiology. In that year, Ewald Herring declared at his lecture to the Imperial Academy of Sciences in Vienna that brain physiologists should make "the unbroken causative continuity of all material processes an axiom of [their] system of investigation" (translated and quoted in Butler 1910, pp. 64–65). It remains an axiom of neurophysiology. The fact that there are no "gaps" in physiological brain processes for mental events to fill led Thomas Huxley (1874) to maintain we are "conscious autotmata": conscious events accompany certain physiological brain events as dual effects of other physiological events, but are causally inert. Trained as a medical doctor, William James (1890) appropriated the term *epiphenomena*, a medical term for symptoms of diseases, for mental phenomena that while caused, lack causal efficacy. James Ward (1903) coined the term *epiphenomenalism* for the view that mental phenomena have no causal effects.

The view that mental phenomena are epiphenomena has a dense air of paradox. Epiphenomenalists maintain that we are merely under the illusion that there is mental causation. But, on their view, the illusion could not give rise to our belief in mental causation, for that would require mental causation. Moreover, on pain of inconsistency, they cannot take themselves to have been led to the doctrine by theoretical reasoning, for their being so led would involve mental causation. Indeed, reasoning itself seems to be a causal process. It should thus come as no surprise that virtually no contemporary philosophers who acknowledge the reality of the mental espouse the view that no mental states or events have causal effects. But the question of how they have effects remains.

Some philosophers combine the rejection of Cartesian substance dualism with the rejection of mental and physical event dualism, while nevertheless embracing Cartesian property dualism. C. D. Broad (1925) examined a dual-aspect theory of events, according to which physiological events in "the mind-brain" (1925, p. 439) have two independent aspects, one mental, the other physiological, the two linked by contingent fundamental laws. In discussion of the view, he formulated epiphenomenalism as a disjunctive doctrine: "mental events

either (a) do not function at all as cause factors; or that (b) if they do, they do so in virtue of their physiological characteristics, and not in virtue of their mental characteristics" (p. 473). If, rather than being accompanied by mental events, certain physiological events have mental characteristics, and so are mental events, then it seems, on the evidence, that they function as cause factors in virtue of their physiological characteristics, but not their mental ones. The mental *qua* mental seems causally inert.

Donald Davidson (1970) proposed the doctrine of anomalous monism: every particular mental event is a physical event, but there are no strict psychological or psychophysical laws, and mental characteristics are irreducible to physical characteristics. He did not, however, embrace Cartesian property dualism, which is committed to fundamental psychophysical laws. Moreover, he regarded talk of properties as pleonastic; strictly speaking, there are only predicates, not properties. He held that since mental events (i.e., events mental predicates are true of) are causes or effects, they fall under strict physical laws, and so are physical events because physical predicates that figure in the relevant strict laws are true of them. Still the causal relation, he emphasized, is extensional: if two events are causally related, they are so related however they are described. There is no quacausation.

Many philosophers hold that properties are distinct from predicates, and indeed that predicates apply to things only in virtue of the properties that things have. And they hold that although the causal relation is indeed extensional, it is nevertheless the case that events enter into causal relations in virtue of certain of their properties. The weighs-less-than relation is extensional: If *a* weighs less than *b*, then it does so however *a* and *b* are described. Still *a* weighs less than *b* in virtue of something about each of them, namely their respective weights—their respective masses in the gravitational context in question. Anomalous monism entails the denial of token epiphenomenalism. But its proponents must answer the charge of commitment to type epiphenomenalism, the thesis that no events are causally related in virtue of falling under mental types (McLaughlin 1989, 1994; Kim 1993; Sosa 1993; see also Davidson 1993).

In the early twentieth century, the atomic view of matter was vindicated, and in the 1930s a quantum mechanical explanation of chemical bonding was provided, dispelling the idea that there are fundamental chemical forces; and later monumental advances in organic chemistry and molecular biology led to the demise of any form of vitalism (McLaughlin 1992). It is

now generally held, on empirical grounds, that: for any (caused) microphysical event  $P$  there is a distinct microphysical event  $P^*$  that causally determines the objective probability of  $P$  (if determinism is true, that probability will be 1).

This thesis has been called by various names in the literature, including “the closure of the physical.” Given this thesis, if Cartesian property dualism is correct, then it seems that an individual’s having a mental property could have microphysical effects only if it causally overdetermined those effects. Such overdetermining psychophysical causal transactions would be fundamental in that they would be unmediated by any mechanism. While that may fall within the realm of logical possibility, it is hard to see how the view that it actually occurs could be justified (Kim 1998).

Many contemporary philosophers hold that there is a stronger dependence of mental properties on microphysical properties than Cartesian property dualism allows. There is no received formulation of the dependency. But one leading view is that it is captured by the following *supervenience* thesis: any minimal physical duplicate of the actual world is a duplicate *simpliciter* of it (Jackson 1998). A physical duplicate of the actual world is any world that is exactly like the actual world in every microphysical respect, in respect to its worldwide pattern of distribution of microphysical properties and relations, its worldwide pattern of distribution of microphysical objects, its microphysical laws of nature, and so on. A minimal physical duplicate of the actual world is any physical duplicate of it that contains nothing other than what is metaphysically required to be a physical duplicate of it.

While the supervenience thesis is incompatible with Cartesian property dualism, it does not entail that every property is a microphysical property. The thesis entails that any minimal physical duplicate of the actual world will have exactly the same worldwide pattern of distribution of properties as the actual world. But, as should be made clear below, that does not require that every property be a microphysical property. Indeed, one can embrace the supervenience thesis while holding a kind of property pluralism, according to which not only mental properties, but properties that figure in the laws of the special sciences—economics, psychology, biology, and even most of chemistry—are not microphysical properties. Some proponents of the supervenience thesis are property pluralists and hold, in addition, (token) event and state pluralism, on the grounds that events and states are property exemplifications. They thus hold that men-

tal events, and events within the domains of the special sciences, are not microphysical events. Let us label this kind of “nonreductive physicalism,” which combines the supervenience thesis with property and event pluralism, “NRP.”

NRP theorists acknowledge that every event is such that its objective probability is causally determined by some microphysical event occurring across some cross section of its backward light cone. But they deny that this excludes higher-level events from being causes. Some defend this denial by distinguishing causation from causal determination (Yablo 1992). They hold that to be causally related, events must be appropriately proportional, and that microphysical events are typically disproportional to the higher-level events they causally determine, and are thus disqualified as causes of those events. On this view, when the turning of a key causes a lock to open, some microphysical event will causally determine that the lock opens. But it will not be a cause of the lock’s opening. The reason is that it contains too much superfluous detail to be suitably proportionate to the opening of the lock. Had the key turning occurred without that microphysical event, the lock would still have opened. The key turning thus “screens off” the microphysical event vis-à-vis the lock’s opening. Of course, in the counterfactual situation that is stipulated, some other microphysical event will underlie the key turning and cause the microphysical event underlying the lock’s opening. But it is claimed that is so because higher-level causal transactions are implemented by lower-level ones, and ultimately by microphysical ones.

One charge against this view is that it mistakes causal explanation for causation. Any microphysical event that causally determines the opening of the lock causes it. Nevertheless, an explanation of why the lock opened in terms of a microphysical cause would be an extremely poor one indeed in a typical context since it would contain far too many details that are superfluous to understanding why the lock opened. But whether that charge can be justified remains a matter of dispute. The dispute turns on controversial issues about the nature of causation and the individuation of events.

Many NRP theorists hold that every event is caused by some microphysical event that determines its objective probability. They maintain, nevertheless, that higher-level events are causes. One concern about this view is that if higher-level events were causes, then their effects would include microphysical events. If my decision to walk into the next room causes me to walk into the next room, a result will be that many of the physical particles making

up my body at the time of the decision will end up in the next room. The decision would be a cause (though not of course a sufficient cause) of the movements of the particles. Such “downward causation” is regarded by some philosophers as untenable (Kim 1998). NRP theorists respond that while the movements of the particles are in a sense causally overdetermined, such overdetermination is not the objectionable sort to which the interactionist Cartesian property dualist is committed. For the psychophysical causal interactions are not fundamental: They are implemented by causal transactions between microphysical events. Mechanics can ignore them. Still some critics charge that the fact that the microphysical event was brought about by another microphysical event leaves no work for the decision to do in bringing it about (Kim 1998). Some NRP theorists reply that this sort of worry is based on a productive conception of causation, and that we should eschew such a conception as unrealistic (Loewer 2002). They maintain that this sort of overdetermination can be accommodated by a kind of regularity account of causation (Melynck 2003), or a kind of counterfactual account of causation (Loewer 2002). This strand of the debate also leads to issues concerning causation and event individuation.

Given the supervenience thesis, any minimal physical duplicate of the actual world would have the same worldwide pattern of distribution of mental events and special science events as the actual world. Why is that the case if mental and special science events are not microphysical events? The leading NRP answer is that all mental and special science events are *realized* by microphysical events and such realization guarantees this result. While there is no received view of realization, the leading notion is the functionalist notion, according to which the realization relation is the relation of role-occupancy: a realization is a role-player. This idea, however, has been implemented in two different ways (see Block 1980). Role-functionalism implements it one way; filler-functionalism implements it in another (see McLaughlin forthcoming).

According to role-functionalism, every event token of a mental type *M* is a higher-order event token, an event of participating in some event or other that occupies a certain role *R*, which includes a causal role. Events that occupy *R* realize *M* events, that is, realize events that are exemplifications of *M*. On this view, higher-order events are never identical with lower-order events. Thus, even if mental events are always realized by microphysical events, no mental event is a microphysical event; similarly, for special science events. This event pluralism is compatible

with the supervenience thesis because the basic roles could be filled by microphysical events that fill them in virtue of microphysical laws and conditions.

But NRP theorists would nevertheless face a problem in embracing role-functionalism, for there is a serious question of whether higher-order events have causal effects. While every second-order event is realized by a first order event that has causal effects, a serious question remains whether second-order events themselves have effects. The role-functionalist idea seems most plausible for abilities, but abilities themselves seem not to have causal effects, rather their bases or realizations do. The role-functionalist idea has, however, also been interestingly applied to constituted dispositional states, such as water-solubility, water-absorbency, fragility, ductability, and the like (Jackson, Pargetter, and Prior 1982; Prior 1985). For something to be water-soluble is (arguably) for it to be in some state that, under appropriate conditions, would cause it to begin to dissolve when immersed in a liquid. The state that has the causal role of producing the manifestation of the disposition (dissolving) is the basis (realization) of the disposition. (Being composed of sodium chloride is one such basis; but the dispositional property is multiply realizable.) It is, however, the basis of water-solubility that causes the substance to dissolve when immersed in water, not the disposition—if the disposition is indeed a second-order state (other accounts of such states are possible). On this role-functionalist conception, the substance’s being water-soluble seems to just be the fact that there is some state of it that would (in appropriate circumstances) result in its dissolving were it immersed in water.

The concern, then, is that if (token) mental states and events were functional states and events (i.e., higher-order states and events), they would have no causal effects (Jackson 1996, McLaughlin forthcoming). That would not exclude them from being causally explanatory. The claim that a substance dissolved in water because it is water-soluble provides some information about the causal chain leading to its dissolving (see Prior 1985). But the NRP theorist is after higher-level causation, not just causal explanation. Thus, the NRP theorist must respond to this concern with a compelling account of causation according to which functional states indeed have causal effects. Suffice it to note that the claim that functional states are inefficacious does not presuppose a productive conception of causation (see Lewis 1986).

According to filler-functionalism, an event is of mental type *M* if and only if it occupies or plays a certain role *R*, where *R* includes a causal role. On this view, an event

token *realizes* role *R* by occupying the role—by filling it. For an event to be of type *M* is just for it to fill the role. Thus, if *E* occupies *R*, then *E* is thereby of type *M*. Since the role includes a causal role, filler-functionalists reject token-epiphenomenalism. Note that if, on a particular occasion, event token *E* is the occupant of *R*, then “*E* is the *M* event” will be a contingent statement of identity, like “Benjamin Franklin is the inventor of bifocals.” (The description “the *M* event” will, like the description “the inventor of bifocals,” be nonrigid: it will pick out different things in some possible worlds from those that it picks out in others.)

It may well be that tokens of various types of events can occupy role *R*, and thus be realizations of *M*; if so, then *M* is multiply realizable. Moreover, events of some type *N* can realize *M*, even when *N* itself is multiply realizable. That will be the case when an event is of type *N* if and only if it fills a role *R\**, which includes *R* as a proper sub-role (Shoemaker 1994). If, on a particular occasion, an event realizes *M* in virtue of being an *N* event, and realizes *N* in virtue of being a *C* event, then, on that occasion, the *C* event is the *N* event, the *N* event is the *M* event, and so the *C* event is the *M* event.

Notice, then, that, when conjoined with the thesis that every mental event is realized by some microphysical event, filler-functionalism entails that every mental event is a microphysical event. And indeed the filler-functional explanation of why any minimal physical duplicate of the actual world will have the same worldwide pattern of distribution of mental (and special sciences) events as the actual world is that the only basic fillers of the roles are microphysical events, which fill them solely in virtue of microphysical laws and conditions. Events are of different orders only relative to types. (Moreover, the ordering here, it has been pointed out, is not one of scale [Kim 1998].) The filler-functional account of realization will not serve the NRP theorist’s purposes. On the filler view, every event is a microphysical event, and it is ultimately in virtue of microphysical event types that events enter into causal relations. Mental event types are not microphysical event types, both because of actual multiple microphysical realization, and because of the logical possibility of realization without microphysical realization. Nevertheless, they are relevant to whether events of one sort cause events of another since they implicitly type events in terms of patterns of causal relations. And that may very well make them indispensable to certain causal explanations. But whether such a view is correct turns, of course, not only on the nature of causation and the individuation

of events, but also on the nature of mental (and special science) properties.

Problems remain, moreover, that are specific to the mental. Some philosophers maintain that neither a role nor a filler-functionalist view is tenable for mental states with qualitative or phenomenal characters: states such that it is like something for the subject of the state to be in the state (e.g., the state of feeling pain). And some embrace Cartesian property dualism for phenomenal mental properties (“qualia”; Chalmers 1996, Kim 2005). They thus reject the psychophysical supervenience thesis. They hold that there could be an exact physical duplicate of the actual world that, unlike the actual world, is entirely devoid of phenomenal consciousness (a “zombie world”; Chalmers 1996). But they do not deny the closure of the physical. And they acknowledge that they may thus very well have to hold that an individual’s having a phenomenal property has no causal effects. Suffice it to note that even this restricted epiphenomenalism has an air of paradox. It entails, for instance, that our feeling of pains never cause our pain-behavior, or even our beliefs that we are in pain.

Moreover, even if Cartesian property dualism is rejected for all mental properties, problems remain. Intentional mental states are explanatory, in part, by virtue of their propositional contents. For example, the content that *there is a snake in the room* figures essentially in both the rationalizing explanation, “He decided not to enter because he believed there was a snake in the room,” and the nonrationalizing explanation, “He began to quiver because he feared that there was a snake in the room.” The leading theories of content, however, are externalist theories, according to which the content of a mental state fails to supervene on intrinsic states of the subject (Putnam 1975, Burge 1979). On these views, two intrinsic duplicates (e.g., an inhabitant of Earth and her *doppelgänger* on Twin Earth) could be in intentional states with different contents. Indeed, according to some externalist theories, content depends on historical context (Dretske 1988), and according to others, on social context (Burge 1979). Some philosophers maintain that such highly relational properties are causally irrelevant to behavior, and so must play a noncausal explanatory role. But some philosophers defend the view that intentional states cause behavior, despite being essentially extrinsic (Yablo 1999). Others claim that wide content is causally explanatory because it provides information about the causal history of the agent’s behavioral dispositions (Dretske 1988). And others contend that intentional states have an externalist or wide content in virtue of hav-

ing a “narrow content” in a causal environmental context, and that it is narrow content that is causally relevant to behavior (Jackson 1996). There are other views as well that are as yet less explored. Suffice it to note that these content issues too are matters of ongoing philosophical investigation.

## MENTAL-PHYSICAL DISTINCTION

The distinction between the mental and the physical is central both to commonsense thinking about the world and to many philosophical, scientific, and religious theories. Perhaps it is as important to human thought as the distinction between fact and value, and between the empirical and the a priori. This entry will focus both on the role of the distinction in analytic philosophy and on various proposals about how it is to be understood.

The mental/physical distinction plays a role in two main areas of philosophy. First, in philosophy of mind, many arguments and issues are formulated in terms of it. Philosophers who advance physicalist theories about the mind argue that phenomenal consciousness (for example) is a physical phenomenon similar in kind to electricity or sexual reproduction; dualists deny this, saying that what we have here are two fundamentally different sorts of thing or two different characteristics of things. Second, in the philosophy of science and related parts of metaphysics, there is the issue of how to formulate the picture of the world that is presented to us by modern science. Many contemporary philosophers assume that this picture is in essence a physicalist one, and mean by this that the world-view implicit in modern science bears important affinities with the materialism (also known as physicalism) of the seventeenth and eighteenth centuries, in particular that of La Mettrie and Hobbes. A natural assumption is that to properly evaluate whether the worldview of modern science really *is* a kind of physicalism, and to fully understand the related dispute in philosophy of mind between physicalism and dualism, one would need to clarify the mental/physical distinction. So what exactly *is* it?

There seems to a tacit general understanding of the mental/physical distinction but no rigorous idea of how it is to be drawn *exactly*—the implicit understanding has not been made explicit. That we understand the distinction in some sense is indicated by the fact that we spontaneously sort various features or characteristics of people or animals into two lists, the mental and the physical. So, to focus on a particular person Jones, we have on the mental side the fact that he knows where his car keys are, has itchy feet, wants tickets to the opera, and so on.

On the physical side, we have the fact that he weighs 170 pounds, is currently located in Detroit, Michigan, is moving in such and such a direction with such and such a speed, and so on. The problem comes when we try to say in any detail what the occurrences of “and so on” mean. What precisely places a feature in the mental list, and what distinguishes those on the mental list from those on the physical? What groups *weighing 170 pounds* together with *being currently located in Detroit, Michigan*, and sets it apart from *having itchy feet*? Or take some other property of Jones not mentioned so far: for example, that his brain is releasing certain hormones into his bloodstream—is *it* mental or physical? If, as it seems natural to say, it is physical, what makes it so?

There is no shortage of proposals in the literature about what makes it so, and more generally about how to understand the mental/physical distinction, but all of them face problems, and none commands widespread assent. What immediately follows is a brief catalogue. The first, and historically the most important, proposal is that of Descartes (1641). Descartes said that being physical (or material) is just being extended in space; likewise, he said, the essence of the mind is to think, to engage in the activity of thinking. Descartes went on to argue that, if this is the way to draw the mental/physical distinction, dualism in philosophy of mind is true. This clarification of the distinction is straightforward, but it also has a number of drawbacks. First, we think of matter as something that *occupies* space, rather than being identical to space—but Descartes notoriously makes no room for such a distinction. Second, there are intuitively physical forces—such as the force of gravity—that would not be classified as physical from Descartes’ point of view. Third, the idea that the essence of the mind is to think apparently excludes mental states that are sensory rather than cognitive and those that do not involve some sort of mental activity.

The second proposal—one might view it as an updated version of Descartes—draws the mental/physical distinction by appealing to two ways in which we find out about the world: introspection and perception. On this view, something is mental just in case we can find out about it, at least in principle, by introspection, whereas something is physical just in case we can find out about it, at least in principle, by perception. But this proposal faces difficulties also. One problem is that many things that seem intuitively physical are not directly available to perception even in principle—for example, subatomic particles. One might weaken the criterion and say that something is physical just in case we can find out about it *either* by perception *or* by inference from perception. But

the problem now is that the mental states of other people are such that we can find out about *them* by inference from perception; hence the weakened account entails the physicality of those mental states. Another problem with this second proposal is that it is not clear what the category of introspection is. Introspection seems to be the faculty by which we find out about our own *mental* goings-on—but this drains the idea of content.

The third proposal, prominent in the work of Thomas Nagel (1974, 1986), explains the mental/physical distinction as a special case of the contrast between the subjective and the objective. One obvious problem here is that the distinction between the subjective and objective is itself unclear; it is no advance to take *subjective* to mean “mental.” But Nagel himself interprets the distinction as concerning different conditions of understanding: An objective truth or fact is one that can be understood from more than one point of view, whereas a subjective truth or fact is one that can be understood from at most one point of view. One objection to this is that there are psychological phenomena that are objective in Nagel’s sense; presumably, the psychological properties attributed to humans by theoretical as opposed to folk psychology are as objective as any anything else. (These properties are not available to introspection either—and this causes a problem for the previous proposal, too.) A second objection is that the distinction between mental and physical is now a distinction *within* the realm of things that can be understood. But it is quite unclear that something is physical only if it is understandable.

The two proposals we have just considered inherit from Descartes the idea that we need criteria *both* for the mental and the physical. But contemporary philosophers have also explored the more cautious idea that one might define directly what it is for something to be physical, leaving aside the question of what it is for something to be mental. Hence, the fourth proposal is that something is physical just in case it is the sort of thing that physical theory tells us about or perhaps is entailed by the sort of thing physical theory tells us about. The basic objection to this view is Hempel’s dilemma (Hempel 1969; see also Crane and Mellor 1990). Hempel’s dilemma is that if the physical theory in question is contemporary physics, this proposal entails that physicalism is obviously false—after all, nobody believes that contemporary physics is complete; on the other hand, if the physical theory in question is some idealized or future physics, then the proposal entails that physicalism is empty—after all, who knows what some idealized or future physics will include? Some (for example, Smart 1974) respond by asserting that it is

rational to believe that contemporary physics is complete. Although there is something right about this—surely it is rational to believe contemporary physics—the implicit suggestion that we should *define* the physical in terms of contemporary physics is implausible. Medieval impetus physics (for example) is a false and outmoded theory, but the property that objects have according to it—namely, impetus—is a physical property nonetheless.

According to a fifth proposal—sometimes called the paradigm physical object view—something is physical just in case it is the sort of thing required by or entailed by a complete account of the intrinsic nature of paradigmatic physical objects and their constituents (Block 1980; see also Feigl 1967). The basic idea of this view is that we have some paradigms of physical objects—trees, stones, planets, toasters—and that the physical is whatever you need to explain them. One problem with this view is that it is circular—it explains the physical in terms of physical objects. (The same problem afflicts the previous proposal, which defines the physical in terms of physical theories.) Another problem for this view is that if physical objects turned out very different from how they appear—if, for example, they had a spiritual essence—physicalism and idealism would on this view be indistinguishable.

Perhaps it is unsurprising on reflection that the proposals just reviewed run into difficulties; they are all attempts at saying something positive about what the physical consists in. The sixth proposal is the negative one of saying that *physical* just means “nonmental” (for example, Levine 2001). One problem with this idea is that it assumes some criterion or mark of what it is to be mental; for example, that something is mental just in case it has phenomenal character or intentionality or both. And someone might question or reject both proposals either singly or in combination. But the more serious problem for the *via negativa* is that, construed as a definition of the physical, it gets things quite wrong. A vitalist, for example, thinks that living things instantiate properties—*élan vital*—which are both nonmental and nonphysical. However, while vitalism might be as false and outmoded as medieval impetus physics, it is not self-contradictory.

In view of the fact that every extant proposal about how to clarify the mental/physical distinction faces problems, it is natural to wonder whether there *is* any clear distinction here at all. Perhaps this is a distinction that we draw in ordinary thought but is something that should be done away with in serious scientific or philosophical descriptions of the world. That is the proposal that a number of people have found themselves drawn to, including Chomsky (2000).

One response to this sort of scepticism is that it is driven by overly high standards of clarity. True, it is hard to clarify the mental/physical distinction, but this difficulty does not mean that there is no such distinction—for the same thing might be said for many interesting distinctions and concepts. A different (but consistent) response asks us to look again at why we wanted a clarification of the mental/physical distinction in the first place. If the answer is intellectual curiosity, the Chomskian view is as reasonable as any other. But Chomskian scepticism gains much of its power from the further idea that various intellectual projects in philosophy of mind and science *make no sense unless* the mental/physical distinction can be clarified. But in fact it is not clear that this is so. Earlier we noted that various projects in philosophy of mind and science are formulated in terms of the mental/physical distinction. But it does not follow that the distinction is *essential* to these projects. If the mental/physical distinction can be shown to play only an illustrative or inessential role in these projects, then scepticism about the distinction itself—whether or not it is warranted—will not be as consequential as it would otherwise appear to be.

## MENTAL REPRESENTATION

"Mental representations" are the coin of contemporary cognitive psychology, which proposes to explain the etiology of subjects' behavior in terms of the possession and use of such representations. "How does a subject manage to move through her darkened bedroom without stumbling over the furniture? She has an accurate mental representation of the room's layout, knows her initial position in the room, and is able to use this representation, in roughly the way a mariner uses a chart, to navigate through the room." "How does a sighted subject manage to recover information, available in the retinal image, about 'what's where' in her environment? She computes a series of representations, using information present in the retinal image, that eventuates in a three-dimensional representation of the distal objects present in the subject's visual field." "Why do native speakers of English have difficulty recognizing the grammaticality of so-called garden-path sentences such as 'The horse raced past the barn fell'? In recovering the meaning of a sentence, a speaker first constructs a representation of the syntactic structure of the sentence. In the case of garden-path sentences, the parsing processes that construct this representation mistakenly take the sentence's subject noun phrase to be a complete sentence, thus concluding that the entire sentence is ungrammatical." Cognitive ethologists offer similar explanations of many animal behaviors: Foraging red ants are said to practice a form of dead reckoning to maintain a representation of their current location relative to their nest, which they use to find their way back; migratory birds are said to navigate using representations of various sorts (celestial, magnetometric, topographic, etc.) that are either innate or learned as juveniles.

If, as these explanations apparently assume, mental representations are real entities that play a causal role in the production of a subject's behavior, then presumably it makes sense to ask about the form in which the information contained in these representations is encoded. This question has been the focus of considerable debate, especially with respect to mental imagery. Descriptionalists argue that, subjective impressions to the contrary notwithstanding, all mental representation, including mental imagery, is descriptional in form; mental repre-

sentations are said to represent in a way similar to the ways linguistic descriptions represent. Descriptionists subscribe to a language of thought hypothesis, according to which all human cognition is conducted in a quasi-linguistic medium. Pictorialists, by contrast, argue at least some mental representations, notably those involved in mental imagery, represent in ways similar to the ways pictures represent. The issues in dispute here are not straightforwardly empirical. Neither party believes that we literally have descriptions or pictures in our heads; rather, their claims are about similarities to the respective ways that pictures and descriptions represent. But it is precisely these similarity claims that render this debate obscure. What are the respective ways that pictures and descriptions represent, and what are the salient similarities such that if they hold they would justify characterizing mental representations as being of one form rather than the other? It is not obvious that there is a definitive answer to either of these questions.

To describe the representations to which psychological and ethological explanations appeal as mental is not to imply that their possessors are conscious of them; typically the representations are nonconscious or subconscious. Nor is it to imply that these representations are nonphysical; there is no commitment here to dualism. Psychologists and ethologists presume that the representations to which their explanations appeal are neurologically realized, physical structures. The point of describing the representations as mental is simply to emphasize the particular explanatory role that these representations play in these explanations. The explanations undertake to explain a kind of purposive behavior on the part of a subject, in which the particular behavior exhibited by the subject is typically modulated in a characteristic fashion, not only by the goal or purpose of the behavior, but also by the environment in which the behavior is exhibited. Thus, for example, our subject's movement through her darkened bedroom is modulated by her knowledge of the current layout of the room. The mental representations that figure in these explanations serve two distinct explanatory roles: (1) They explain why a subject behaves in one way rather than another—she behaves as she does because she currently has this particular representation rather than another, and this representation is causally efficacious in the etiology of her behavior—and (2) they explain how the subject's behavior manages to be modulated (in characteristic ways) by her environment. Mental representations are able to play this dual explanatory role by virtue of possessing both physico-formal and semantic (intentional) properties that are linked in such a way as to ensure that a subject's environment can modulate

her behavior. Basically, the cognitive processes that make use of mental representations are causally sensitive to the physico-formal properties of these representations that encode their semantic properties in much the way that sound-reproduction processes are sensitive to the physico-formal properties of records, tapes, and CDs.

Commonsense psychological explanations of behavior standardly appeal to beliefs, desires, intentions, and other so-called propositional attitudes (e.g., "Jones went to the refrigerator because he wanted a beer and believed there to be one there"). Behaviorists and eliminativists have challenged the legitimacy of these explanations, arguing that propositional attitudes either do not exist or do not figure in the etiology of behavior. Impressed with the prominent explanatory role of mental representations in cognitive psychological and ethological explanations, many philosophers of mind, notably Jerry Fodor, have proposed establishing the materialistic respectability of these explanations by appeal to the notion of mental representation. Their strategy is to explicate propositional attitudes in terms of mental representations. They defend a doctrine called the representational theory of mind (RTM), which holds that possessing a propositional attitude (e.g., believing that it is sunny today) is a matter of having a mental representation that (1) expresses the propositional content of that attitude (*viz.*, that it is sunny today) and (2) plays a causal-functional role in the subject's mental life and behavior characteristic of the attitude in question (*viz.*, the characteristic role of beliefs in modulating goal-satisfying behavior). More formally, for any organism *O*, any attitude *A* toward the proposition *P*, there is a mental representation *MR* such that *MR* means that (expresses the proposition that) *P* and a relation *R* (which specifies the characteristic causal-functional role of the *MR*s that are associated with a given *A*); and *O* bears attitude *A* to *P* if and only if *O* stands in relation *R* to *MR*. So formulated, RTM is silent as to the form of the mental representations that express the propositional contents of attitudes; proponents of RTM, however, invariably assume that these representations are syntactically structured entities, composed of atomic constituents (concepts) that refer to or denote things and properties in the world. More colorfully, these representations are sentences in the language of thought. The structure and meaning of these sentential representations purportedly explain the particular semantic and causal properties that propositional attitudes exhibit.

RTM is clearly realist in its construal of propositional attitudes: It purports to explain, not only what they are, but also how they could have both the causal and seman-

tic properties that common sense attributes to them (viz., of being causally efficacious in the production of other thoughts and of behavior, and of being semantically evaluable, as, e.g., true or false). RTM is equally realist in its construal of mental processes, which, it holds, are causal sequences of the tokenings of mental representation. These sequences are said to be proof-theoretic in character, with the sequential states in a thought process functioning like premises in an argument. Thought processes are, like arguments, generally truth preserving.

Proponents of RTM claim to find strong empirical support for the doctrine in the apparent explanatory (and predictive) successes of cognitive science, whose theories are heavily committed to the existence of mental representations. Critics tend to dismiss this claimed support, arguing that what is at issue is not whether there are mental representations but whether there are mental representations with the particular properties demanded by RTM. Critics argue that propositional-attitude contents cannot always be paired with mental representations in the way that RTM requires: A subject may bear a certain attitude to a proposition but lack, among the many mental representations that cognitive scientific theories attribute to her, any mental representation of that particular proposition. Thus, for example, more than one critic has pointed out that, while David Marr's computational theory of early vision (see his *Vision* [1982]) attributes to the visual system the assumption that objects in the visual field are rigid in translation, the theory does not attribute to the visual system an explicit representation of that assumption; rather, the assumption is implicit in the operation of visual processes. Proponents, for their part, have tended to dismiss such counterexamples as "derivative" cases, arguing that RTM nonetheless holds for what they term the "core" cases of propositional attitudes. Such a response presumes that there is a non-question-begging characterization of the class of core cases. It also presumes that the class so characterized includes those propositional attitudes that figure in the commonsense psychological explanations that RTM is intended to vindicate. It remains an open question whether either of these presumptions can be met.

Other critics of RTM have challenged the doctrine's apparent commitment to "classical" cognitive architectures that presume a principled distinction between mental representations, on the one hand, and the computational processes that are defined over these representations, on the other. These critics point out that connectionist computational models of cognition do not preserve such a distinction, so that, if, as these critics pre-

sume, cognitive architecture is connectionist rather than classical, then RTM is untenable. Not surprisingly, proponents of RTM have been in the forefront of efforts to demonstrate that cognitive architecture is not connectionist.

Still other critics of RTM have focused on the semantics of the postulated mental representations, arguing that, if RTM is to provide a materialistic vindication of explanations that appeal to propositional attitudes, it must be possible to provide a "naturalistic" semantics, a theory of content, for these representations. By such a semantics these critics understand a materialistic account, invoking no intentional or semantic notions, of how it is possible for mental representations to have the semantic properties that they do (of being about things in the world, of being truth valued, etc.). There is general agreement among critics and proponents alike that none of the proposed naturalistic semantics is adequate, but, where critics see in these failures the symptoms of RTM's untenability, proponents see the beginnings of a difficult but eventually successful research project. There is disagreement among critics as to the import for cognitive science itself of there possibly being no naturalistic semantics for mental representations. Some argue that it would impugn the claimed explanatory role of mental representations; others argue that it would not. Whatever the upshot of these arguments, the untenability of RTM would not in and of itself impugn the explanatory role of mental representations in cognitive science, since that commitment to mental representations does not entail RTM. One can perfectly well be a representationalist in the way that most cognitive scientists are without also being a proponent of RTM.

## MERCIER, DÉsirÉ JOSEPH (1851–1926)

Désiré Joseph Mercier, a Thomist philosopher and Roman Catholic cardinal, was born in the Walloon section of Brabant, Belgium. At the end of his secondary education, Mercier decided to study for the priesthood; he studied philosophy and theology at the Malines Seminary for five years and subsequently at the University of Louvain. Ordained in 1874, he received the licentiate (equivalent to the current doctorate) in theology in 1877.

The same year he was named professor of philosophy at the Malines Seminary, where he taught logic and psychology for the next five years.

The famous encyclical, *Aeterni Patris*, of Pope Leo XIII, urging the restoration of scholastic, particularly Thomistic, philosophy, was published in 1879. In 1882 a chair of Thomistic philosophy was established at Louvain, and Mercier was named to this post.

For the next several years, Mercier taught courses in the various branches of philosophy, always attempting to relate Thomism to contemporary issues; in the course of this effort, Mercier became convinced that the task of making Thomism a living philosophy would require the combined efforts of many specialists. Hence, he conceived the notion of establishing a special institute of philosophy, with the aim not only of offering courses in Thomistic thought but also of providing the staff and facilities for a genuine research center. After considerable difficulty the Institute of Philosophy was established in 1889 as an integral part of the University of Louvain, with Mercier as its first president. The Philosophic Society of Louvain (still active) was founded by Mercier in 1888; in 1894 this organization founded the philosophical quarterly *Revue néo-scolastique* (still published under the title of *Revue philosophique de Louvain*), with Mercier as its editor.

From 1893 to 1906, Mercier's life was intimately bound up with that of the institute. His teaching activity continued; he published widely; and in the face of many difficulties, he worked incessantly to build and maintain the quality of the institute. His success in this area is measured by the fact that Louvain quickly became an internationally recognized center for philosophical work, attracting students from all over the world.

In 1906 Mercier's career in philosophy was interrupted by his being named archbishop of Malines; he was made cardinal the following year. From this time until his death, Cardinal Mercier's immense energies were directed toward the organizational and pastoral duties of his office. The seven volumes of his *Oeuvres pastorales* (Louvain, 1911–1928) give some indication of the extent of his writings on pastoral, religious, and theological matters. Chief among his interests were social, political, and scientific questions affecting religious life, the liturgy, and church unity. In 1921, at Malines, he initiated the "conversations" with members of the Anglican Church, which continued at intervals until his death.

World War I broke out during Cardinal Mercier's episcopate, and he became a national and international

leader in resisting German imperialism and in articulating the moral rights of peoples and nations during times of war. His death was the occasion of worldwide tributes to Mercier's immense moral stature and influence as an outstanding philosopher, ecclesiastic, and citizen of the world.

### MERCIER'S PHILOSOPHY

An examination of the life of Cardinal Mercier makes it evident that one dimension of his importance for the history of philosophy must be related to his key role in organizing and developing the Institute of Philosophy at Louvain. It becomes equally evident, however, that this dimension cannot be divorced from his originality and depth as a philosopher. Moreover, the significance of Mercier as a philosopher can be fully seen only in the context of the state of philosophy among Roman Catholic thinkers and teachers in Catholic institutions in the latter half of the nineteenth century, on the one hand, and in the light of Mercier's response to and understanding of the papal encyclical *Aeterni Patris*, on the other. Although there were scattered efforts at a renewal of Thomistic thought during this period, philosophy in Catholic circles was by and large eclectic and superficial. Little serious effort had been made to meet either the challenge of Immanuel Kant or the positivism of Auguste Comte and the skepticism of David Hume and the British empiricists. Consequently, Catholic philosophy was generally in serious disrepute.

It is in this setting that the publication of *Aeterni Patris* must be viewed. This encyclical has been misinterpreted by Catholic and non-Catholic thinkers alike as calling for a return to the letter of thirteenth-century thought and as representing ecclesiastical approval, even sanction, of a particular philosophical doctrine. Recent scholarship has amply demonstrated the falsity of both these views and shows Leo XIII's intent to have been a renewal and articulation of a philosophy organically linked to a great philosophical tradition and compatible with Christian faith but rethought in relation to contemporary problems and issues (see J. Collins in *Leo XIII and the Modern World*, edited by Edward T. Gargan, New York, 1961, pp. 181–209).

No one seems to have caught the spirit of this intent or to have grasped the urgency and challenge of the intellectual crisis of the time more accurately than Cardinal Mercier. Perhaps this can best be seen by a brief exposition of Mercier's thought in three crucial areas: the nature of the philosophical endeavor in itself and in its relation to revealed truth and theology, the relation of Thomistic

thought to modern philosophy, and the relation of philosophy to the discoveries of modern science.

For Mercier, philosophy is essentially an effort of reason reflecting on the data of experience. Included in this view is a strong affirmation that philosophy must take its point of departure and find its ultimate grounding in the evidence of the real, objective world, in contradistinction to all forms of idealism and theories of innate ideas. The role of reason is likewise strongly emphasized by Mercier, especially in his opposition to positivism. For him, philosophy must be scientific in the classical Aristotelian sense; the mind is capable of going beyond the contingent order of the factually given and of finding real, general necessity and order underlying the sensibly grasped world. Hence, Mercier makes a strenuous effort to reestablish the viability of a realistic metaphysics in the face of the Kantian critique and the severe limitations placed on reason by Comtian positivism. The doctrine of abstraction and the legitimate use of the analytic and synthetic activity of the mind constitute the operative principles in this effort. Nevertheless, philosophy for Mercier is a highly personal endeavor that must always remain open and be capable of organic growth in the light of new evidence. Thus, Thomistic philosophy is held by him as "neither an ideal which one is forbidden to surpass nor a barrier fixing the limits of the activity of the mind"; rather, it is a source of philosophical inspiration that provides a framework for entering into genuine dialogue with the contemporary situation.

Mercier is in fundamental agreement with St. Thomas Aquinas in expressing confidence in the impossibility of real contradiction between revealed doctrine and philosophically established truth. Revealed truth functions for him as an extrinsic negative norm, but it provides neither the motivation for adherence to a philosophical truth nor a source of evidence or knowledge for the philosopher in his proper task. Thus, Mercier emphasizes the essential autonomy, the rigorously rational character, the intrinsic openness, and the need for internal growth of philosophy.

In his writings Mercier is manifestly impatient with the general tendency of his immediate predecessors among Roman Catholic philosophers to opt for one of two general positions—a superficial eclecticism or a dogmatic and naive realism based on common sense. In sharp contrast to these positions, Mercier felt it absolutely essential to examine the whole of modern philosophy with great sympathy and to integrate its sound insights into an integral and rethought Thomism. This principle did not, however, prevent Mercier from being highly crit-

ical of the various contemporary philosophical positions. His polemical writings are directed against fideism, traditionalism (the view that human reason without the aid of revelation necessarily falls into error), voluntarism, sentimentalism, pragmatism, Cartesianism, positivism, and Kantian critical philosophy. He argued strenuously against the Cartesian principle of universal methodic doubt and against Cartesian dualism, undertaking to show that the Thomistic doctrine of the substantial unity of man could overcome the difficulties to which this dualism gives rise.

Positivism and Kantian philosophy, however, occupied most of Mercier's attention, and it was in relation to these views that Mercier developed his own epistemology (in *Critériologie générale*, 1899), which represents one of his most original contributions to the renewal of Thomistic thought. Against the positivist theories of H. A. Taine, John Stuart Mill, Herbert Spencer and Comte, which he undertook to refute in detail, Mercier insistently affirmed the primacy of the criterion of reason and the absolute value of "ideal judgments." Although the positivists of his day were his principal adversaries, Kant was probably the modern philosopher whom he most admired. His understanding of Kant was limited, however, to the interpretation of his times, and his criticism centers on what he considered to be the psychological subjectivism, hence relativism, of Kant. In the final analysis, then, he feels that both Kantian critical philosophy and positivism lead to skepticism and agnosticism. His response was an attempt to establish a realistic metaphysics on the basis of a sophisticated epistemological critique and a development of a theory of certitude. In his own systematic thought, it is not clear that Mercier fully succeeded in formulating what he intended—that is, a middle term between empiricism and rationalism—for his effort begins with a vigorous defense of the absolute certitude of ideal judgments, and from this position he attempts to establish the degree of certitude proper to judgments of experience. In choosing this starting point, Mercier is forced to infer the reality of the external world on the basis of an ideal principle of causality. Nevertheless, it remains a fact that Mercier's epistemology in its attempt to establish a viable, realistic metaphysics represented a major advance in Thomistic thought.

Apart from his epistemology the most original and commanding dimension of Mercier's thought concerned the relation between philosophy and science. In this area he strongly advocates the necessity for philosophy to be intimately acquainted with the findings of modern science. His own efforts in this area were devoted to a syn-

thesis of the new science of psychology and traditional philosophy; the detail with which he undertook to understand the work of such contemporary psychologists as Wilhelm Wundt and the developments in medical psychology were radically new for his time. Although he clearly held that science and philosophy represent two different modes of thought and although he attributed some real autonomy to science, Mercier probably did not fully appreciate the theoretical component of science (this is hardly surprising given the state of the psychological sciences and the philosophy of science in his day). Hence, his synthesis represents an attempt to understand the facts and laws established by science in the light of metaphysical principles. Once again, however partial Mercier's particular solution to this problem may be, it represents a major advance over the earlier tendency of scholastic philosophy to develop in complete isolation from contemporary thought.

Mercier's own philosophical work represents, then, a vigorous and sustained effort to rethink traditional Thomistic thought in the light of contemporary thought on all fronts; moreover, the spirit of this effort was embraced by colleagues whom Mercier chose to staff the Institute of Philosophy. The true philosophical importance of Mercier must be judged by the caliber of philosophical research and writing that has emanated from the Louvain Institute from his day to the present.

## Bibliography

### WORKS BY MERCIER

For a complete bibliography of Mercier's writings, see *Revue néo-scholastique* 28 (1926): 250–258. Mercier wrote extensively for this and other philosophical journals, and much of his polemical writing appears in articles. His major books were written primarily as textbooks and frequently appeared in several mimeographed forms before publication; the published books were revised and frequently reprinted.

The following are his principal works: "La psychologie expérimentale et la philosophie spiritualiste," in *Bulletin de la Classe des Lettres et des Sciences Morales et Politiques et de la Classe des Beaux-Arts* (Brussels, 1900), which was translated by E. J. Wirth as *The Relation of Experimental Psychology to Philosophy* (New York: Benziger, 1902); *Psychologie*, 2 vols. (Louvain and Paris, 1892; 11th ed., 1923); *Logique* (Louvain and Paris, 1894; 7th ed., 1922);

*Métaphysique générale ou ontologie* (Louvain and Paris, 1894; 7th ed., 1923); *Les origines de la psychologie contemporaine* (Louvain and Paris, 1897; 5th ed., 1922), which was translated by W. H. Mitchell as *Origins of Contemporary Psychology* (New York, 1918); *Critériologie générale* (Louvain and Paris, 1899; 7th ed., 1918).

Mercier collaborated with M. de Wulf and D. Nys in writing *Traité Élémentaire de philosophie*, 2 vols. (Louvain and Paris, 1905; 5th ed., 1920), translated by T. L. Parker and S. A. Parker as *A Manual of Modern Scholastic Philosophy*, 3rd ed., 2 vols. (London: K. Paul, Trench, Trubner, 1928).

#### STUDIES ON MERCIER

The definitive personal and intellectual biography of Mercier is by L. de Raeymaeker, *Le Cardinal Mercier et l'Institut Supérieur de Philosophie de Louvain* (Louvain: Publications Universitaires de Louvain, 1952), which also contains a detailed account of the founding and history of the institute. The best critical study of Mercier's thought is in G. Van Riet, *L'epistémologie thomiste* (Louvain: Editions de l'Institut Supérieur de Philosophie, 1946), pp. 135–178. Also to be noted is L. Noel, "Le psychologue et le logicien," *Revue néoscholastique* 28 (1926): 125–152. Probably the best biography in English is by J. Gade, *The Life of Cardinal Mercier* (New York: Scribners, 1934).

*Alden L. Fisher (1967)*

## MEREOLGY

"Mereology" (from Greek *meros*, "part") is the theory (often formalized) of part, whole, and cognate concepts. The notion of part is almost ubiquitous in domain of application, and for this reason Edmund Husserl assigned its investigation to formal ontology. Aristotle observed that the term *part* was used in various ways, as for a sub-quantity, a physical part (leg of an animal), a part in definition (animal is part of man), a part in extension (man is part of animal). Part concepts had obvious applications in geometry and were among Euclid's undefined terms. Several senses of "part" are expressible using the preposition "in," but not all uses of "in" express parthood.

Until the twentieth century it was generally assumed that the concept of part was sufficiently clear not to require elucidation, but gradually the need for a formal treatment became apparent. Euclid's maxim that the whole is greater than the part appeared to be contradicted by infinite classes, for example. In 1901 Husserl proposed a general theory of part and whole and distinguished several kinds of parts, notably dependent and independent parts. Explicit formal theories of part and whole were developed around 1914 to 1916 by Alfred North Whitehead and Stanisław Leśniewski, who worked independently of each other. They had different motivations: Whitehead wanted an empirical basis for geometry,

whereas Leśniewski wished to offer a paradox-free class theory. Mereology was later formulated within first-order predicate logic by H. S. Leonard and Nelson Goodman, who called it "the calculus of individuals." Mereology has often been employed by nominalists as a partial substitute for set theory, but it is not intrinsically a nominalistic theory: Part relations are definable via endomorphisms in many mathematical domains.

The most natural basic concept of mereology is that of a (proper) part to its (larger) whole. A coincident of an object is the object itself or something that shares all parts with it. An ingredient of an object is a part or coincident of it. Two objects overlap if and only if they share an ingredient, and they are disjoint if and only if they do not. The relation of part to whole has some minimal formal properties: It is (1) existence entailing; (2) asymmetrical; (3) transitive; and (4) supplementative. That means (1) that if one thing is part of another, if either the part or the whole exists, so does the other; (2) that if one thing is part of another, the second is not part of the first; (3) that a part of a part of a whole is itself a part of the whole; and (4) that if an object has a part, it has another part disjoint from the first. Principles (3) and (4) have occasionally been doubted, (4) unconvincingly. Some meanings of "part" are not transitive; for example, a hand is said to be part of the body, but an arbitrary chunk of flesh is not, and for such concepts counterexamples to (3) may sound plausible, but only because they restrict the general (and transitive) concept, to mean, for example, organ, functional part, immediate part, assembly component.

Beyond such minimal properties mereologists often make further assumptions. Very often it is assumed that objects with the same ingredients are identical: Such a mereology is extensional. Extensionality makes good sense for homogeneous domains such as regions of space or masses of matter, but some objects of distinct sorts seem to be able to coincide, at least temporarily, without identity. Another assumption often made is that any two objects make up a third, indeed that any nonempty collection of objects constitutes a single object, their mereological sum. The minimal properties together with extensionality and this general-sum principle constitute the classical mereology of Leśniewski and Leonard/Goodman: It is as rich in parts as an extensional theory can be, differing algebraically from Boolean algebra only in lacking a null element. It does, however, have an ontologically maximal object or universe, the sum of all there is, which by extensionality is unique. Whitehead denied that there was a universe: For him every object is part of something greater, so he rejected the sum principle. Whitehead also

denied there are atoms, that is, objects without parts: For him, every object has a part. This antiatomism, together with supplementarity, ensures that every object has non-denumerably many parts. Whitehead thus denies geometrical points, and his method of extensive abstraction is directed to logically constructing substitutes for points out of classes of extended objects, an idea also carried through by Alfred Tarski. As the examples indicate, the issue whether atomism or antiatomism holds is independent of general mereology. Formally, the best worked-out forms of mereology are those of Leśniewski and his followers; they have shown that any of a wide range of mereological concepts may be taken as sole primitive of the classical theory.

Beyond extensional mereology attention has focused on the combination of mereological notions with those of space, time, and modality. Thus, Whitehead and a number of more recent authors combine mereological with topological concepts to define such notions as two regions' being connected, or their abutting (externally or internally), using mereology as its modern authors intended, as an alternative framework to set theory. When time is considered, matters become more complex. Some objects have temporal parts, including phases, and perhaps momentary temporal sections. States, processes, and events (occurrents) are uncontroversial cases of objects that are temporally extended, but many modern metaphysicians apply the same analysis to ordinary things such as bodies and organisms, giving them a fourth, temporal dimension, though this view is not uncontested. Whether or not continuants (spatially extended objects with a history but not themselves temporally extended) are thus reduced to occurrents, a number of chronomereological concepts may be defined and applied, such as temporary part, initial part, final part, permanent part, temporary overlapping, growth, diminution, and others, though their formulation will vary as applying to occurrents or continuants.

Embedding mereological notions within a modal framework likewise opens up a wider range of concepts such as essential part, accidental part, dependent part, accidental overlapping. Combining these in their turn with temporal notions allows the definition of concepts such as accidental permanent part, essential initial part, and so on. In general, where mereological notions are enriched with others, their interactions become multifarious and lose the algebraic elegance of the classical theory while gaining in applicability and usefulness.

In modal mereology much attention has been paid to R. M. Chisholm's thesis of mereological essentialism,

which states that every part of a continuant is both essential and permanent to that continuant (though, conversely, a part may outlast the whole and need not have it as whole). Chisholm's position is presaged in Gottfried Wilhelm Leibniz and Franz Brentano. Since it appears to be contradicted by everyday experience of such things as rivers, mountains, organisms, and artifacts, it is natural for Chisholm to regard such mereologically fluctuating things as not "real" continuants but as *entia successiva*, supervenient upon successions of continuants for which mereological essentialism holds.

The ubiquity and importance of mereological concepts ensure them a growing place within cognitive science and formal representations of commonsense knowledge, and there is no doubt that mereology is firmly established as a part of formal ontology.

## MERLEAU-PONTY, MAURICE (1908–1961)

Maurice Merleau-Ponty, a French philosopher associated with existential phenomenology, was the youngest philosopher ever to be appointed to the chair once occupied by Henri Bergson at the Collège de France. Merleau-Ponty was born in Rochefort-sur-Mer on March 14, 1908. His father died early in his childhood; he and his brother

and sister were raised by his mother. He attended the Lycée Louis-le-Grand and then the École Normale Supérieure earning his aggregation in 1930. He taught in lycées and then was mobilized in the Fifth Infantry Regiment, and served as a second lieutenant from 1939 until demobilization in 1940. During the occupation he participated in the Résistance. After the liberation in 1945 he taught at the Université de Lyon; during this time he, together with Jean-Paul Sartre, founded the avant-garde journal, *Les temps modernes*. In 1945 that his major work, the *Phenomenology of Perception* was published.

Merleau-Ponty is known primarily for developing an ontology that recognizes the philosophical significance of the human body and for his success in overcoming the dualism that has plagued European philosophy from its inception, but these endeavors also include significant contributions to post-structuralist linguistics, political theory, developmental psychology, and aesthetics. His early interest in the resonance between the emergent school of gestalt psychology and the phenomenology of Edmund Husserl and Martin Heidegger led to a radical reassessment of transcendental philosophy. He died abruptly on May 3, 1961, at the age of fifty-three, leaving his last major manuscript, *Le visible et l'invisible*, unfinished. Claude Lefort has edited the extant text, four chapters and an appendix, and published it together with extensive working notes dated from January 1959 to March 1961.

### THE LIVED BODY

Merleau-Ponty revolutionized European thinking about the body—which since ancient Greece had taken it to be either insignificant or a detriment to knowledge—by demonstrating its constitutive role in the process of human understanding. He showed, for example, that it is through bodily motility that the various adumbrations or perspectival views of an object can be synthesized into a unitary whole. Human understanding of objective space, the three-dimensional Cartesian grid of depth, breadth, and height, is an abstraction from lived space—space articulated by the body's capacity to move purposively, to grasp things, to maintain the equilibrium that allows for stable visual coordinates, and to interrogate its environment. Furthermore, the body's ability to perceive the world is grounded in the body's double role as sensor and sensed, capable of being both subject and object of experience: One could not touch an object were one not oneself, as body—an object capable of being touched; nor could one see were her or his eyes not themselves objects

located within the surroundings to which they are sensitive. The classical dualism, which views the body and other worldly objects as disjunct from the mind as the subject or agency of disembodied thought, is replaced with Merleau-Ponty's model of corporeal intentionality in which the body is revealed as having an intelligence of its own, manifest in reflex as in habitual activities, which allows it to interact with the world at a level prior to the reflexivity of deliberate conceptualization.

### REVERSIBILITY THESIS

The transcendental role of the body, its ability to project its organizational schemas into the world, is inseparable from the body's own status as physical object subject to the worldly forces impinging upon it. These roles are inseparable, but not coincident. There is a divergence of the body as sensing from the body as sensed: The finger that touches the thumb or is touched by it does not form an identity with the thumb; rather the two bodily parts co-exist in an ambiguous relationship of reversibility within the encompassing matrix of bodily being-in-the-world. Finger and thumb can reverse roles, the erstwhile sensor becoming the sensed, just as the hand that feels the table can sense itself being touched by the table. Yet neither of these roles would be possible were it not for the other.

### THE FLESH OF THE WORLD

Merleau-Ponty takes the reversibility of subject and object roles in the case of human flesh as emblematic of a global manner of being which he designates as chiasm or intertwining. The term *flesh* is generalized to encompass worldly being as such. The world is taken as an arena of interaction in which every entity is what it is in relation to every other. This is not a pan-animism, but rather an attempt to rectify the post-Socratic reduction of nature to inert materiality in a movement of thought which is as consonant with the ancient concept of *physis* as it is with the contemporary notion of world as ecosystem. The figure of the chiasm, the intersection marking the point at which things touch each other as they cross, refers to the dynamics of worldly unfolding or global temporality in which the interaction of things brings about change. The brute or savage being of the world, the factuality of its transcendence, is counterbalanced with the relatedness of its denizens apparent in the relatively abiding structures human intelligence organizes under the heading of science. Humans are that aspect of the flesh of the world that is capable of the reflective relationship of conceptualization or understanding, but other aspects of the world betray other forms of corporeal reflexivity in the complex

of interaction that encompasses organic cycles, weather systems, geological formations, and so forth as each of these contributes and responds to all the others.

### VISIBLE AND INVISIBLE

Merleau-Ponty's thesis of the primacy of perception evolves from the middle phase of his thinking when he published the *Phenomenology of Perception* and set forth the view that "the perceived world is the always presupposed foundation of all rationality, all value and all existence" to later phases in which this thesis had to be expanded to accommodate the findings of extensive analyses of language based on his unique interpretation of the philosophical significance of Saussurean semiotics. There is controversy regarding his later thinking on the relative primacy of language and perception, but general agreement that the relationship between the two is that of intertwining: language, conceived as sign system, may be conceived as an invisible nexus of relations that is apparent in the visible world and is itself perceptible in speech and writing. The controversy centers on two questions regarding origins or foundations. Does the invisible structure of language reflect organization perceived in the world or does it constitute that nexus of relations? The second question challenges the legitimacy of asking the first: Is it possible to separate perception from language in such a way that one could even ask about the primacy of one with respect to the other?

Merleau-Ponty regards language as flesh, akin to the flesh of the body in its reflexivity—its relatedness to itself and world—but "less heavy, more transparent." In general, the structure of the visible-invisible relation can be defined as *asymmetrical reversibility*: Just as the object one touches can be seen although its tactile aspect remains invisible as such, so can the hidden or horizontal aspects of a given theme be brought into focal vision but only through the loss of its horizontality.

### POLITICS

Merleau-Ponty's thinking in general is dynamic and emergent; it is unified by an elusive paradigm he would never have captured even if he lived longer than he did. Nowhere is this questing more apparent than in his political thought. He was always a critical reader of Marx—although he refrained from revisionism as long as he could—and was highly suspicious of the Communist revolution, although he initially endorsed its humanist goals. When Merleau-Ponty died at the height of his powers, he was working toward what may be called an ethics of expression and reversibility, and the direction of this

thought can be seen articulating itself as early as his chapter on "Freedom" in the *Phenomenology of Perception*.

The issue that dominated left-wing politics in France—indeed, Europe at large and the USSR—had to do with the tension between party leadership and domination, on the one hand, and the emergence of an increasingly self-conscious proletariat anxious to take up the reins of history, on the other. Was the role of the Central Committee to take charge? Or to take its bidding from the workers of the world? Was the dialectical movement of history objectively determined by materiality? Or subjectively articulated in contests at the level of ideality?

Merleau-Ponty refused to take sides, but sought to undercut the polarity and find a means to embrace the truths to be found on both ends of the spectrum. "The world," he writes, "is already constituted, but also never completely constituted; in the first case we are acted upon, in the second we are open to an infinite number of possibilities. But this analysis is still abstract, for we exist in both ways *at once*. There is, therefore, never determinism and never absolute choice, I am never a thing and never bare consciousness. ... It is impossible to determine precisely the 'share contributed by the situation' and the 'share contributed by freedom'" (p. 453). In short, it is through the expression of his situation on the part of the individual worker and his recognition of others in the same plight that solidarity is formed and action can be undertaken. The worker can benefit from guidance from above, but the task of gaining freedom and overcoming the forces that resist it cannot be displaced on to others, else the worker is reduced to slavery again, this time at the hands of his or her liberators.

This idea of circumscribed freedom was in direct opposition to the thesis of radical freedom then espoused by Merleau-Ponty's colleague and cofounder of *Les temps modernes*, Jean-Paul Sartre. This conflict at the level of ideas came to a head in the early 1950s with the disclosure of the atrocities being committed by Stalin in Russia. How to respond? Sartre maintained solidarity with the Communist Party; Merleau-Ponty distanced himself from both, and resigned from the editorial staff of the journal in 1953. The political writings in *Sense and Non-Sense* (1964 [1948]) were written before this break, and the critical reflections on Marxism (including a chapter on "Sartre and Ultrabolshevism") titled *Adventures of the Dialectic* was published in 1955. In the later *Humanism and Terror* (1969 [1947]), Merleau-Ponty sought to put the dialectical thinking of Hegel and Marx in historical perspective, transcend it, and point in a new direction. His conclusion constitutes another step in the direction

of the ethics of expression and reversibility mentioned above. "To seek harmony with ourselves and others, in a word, truth, not only in ... solitary thought but through the experience of concrete situations and in a living dialogue with others apart from which internal evidence cannot validate its universal right, is the exact contrary of irrationalism, since it accepts our incoherence and conflict with others as constants but assumes we are able to minimize them. It rules out the inevitability of reason and well as that of chaos" (1969 [1947], p. 187).

In his last and unfinished work, *The Visible and the Invisible* (1968 [1964]), Merleau-Ponty returns to the subject of dialectical thought, espouses the thought that ideality and materiality intertwine in a movement of history that can move in the direction of minimizing conflict, but explicitly repudiates the formalism that informs the work of Hegel, Marx, and Sartre in a misguided attempt to impose an abstract structure on the unpredictable and messy historical process in which situated human freedoms collide and intertwine. It is also in this work that he begins to articulate the notion of reversibility, his own response to the Husserlian doctrine of foundation (*Fundierung*).

## PSYCHOLOGY

From the earliest of his writing until the last, Merleau-Ponty maintained the thesis of the irreducibility of the figure-ground or theme-horizon structure articulated by gestalt theory. This thesis holds that perception and cognition are fundamentally relational, hence stand in opposition to such standpoints as that of sense-data theory based on the notions of perceptual atoms, elemental simples, or discrete qualia.

In the *Phenomenology of Perception*, Merleau-Ponty offers an extended case study of Schneider, a World War I soldier debilitated by a shrapnel wound in the occipital region of his brain. The point of the study is to demonstrate the inadequacy of the standpoints of empiricism or physicalism, on the one hand, and intellectualism or transcendentalism, on the other, to provide an accurate description of Schneider's afflictions, which are neither purely physiological nor purely intentional but involve a degeneration of the lived body resulting in aberrant forms of substitution behavior in such domains as sexual responsiveness, existential spatiality, motility, expression, and memory.

Merleau-Ponty is unique among phenomenologists in reinterpreting Freudian notions regarding the unconscious in a positive way and integrating them within his own body of theory. This appropriation involved some

modification, to be sure, specifically that of asserting a continuity between conscious and unconscious aspects of human experience at the level of prereflective horizontality. Merleau-Ponty steers a middle course between Freud's relatively mechanistic account of such phenomena as repression, which attributes it to an autonomous function of censorship and dissemblance, and Jean-Paul Sartre's relatively voluntaristic account, which attributes repression to an act of self-deception on the part of a consciousness recoiling from the implications of its own freedom. Merleau-Ponty interprets behavior traditionally subsumed under the heading of repression in terms of a process of habituation operating at prepersonal or unreflective levels in which the body's response to worldly events becomes sedimented as a style of contending with a domain of existence permeated with negative significance. Thus, the aphonia and anorexia of a girl whose family has forbidden her to see her lover is understood, neither as a reversion to an infantile phase of oral sexuality, as Freud would have it, nor as a recoil from responsibility in the mode of magical transformation, as Sartre would have it, but as a refusal of coexistence, a withdrawal from the communal world of eating and talking, which acquires the autonomy of a habit exacerbated by former habitualities favoring oral modes of responding to the world.

In addition to his interests in gestalt psychology and Freudian psychoanalysis, Merleau-Ponty was also well-acquainted with the work done by his sometime colleague Jean Piaget in developmental psychology and the work of Jacques Lacan, a contemporary known for his reinterpretation of Freudian themes along semiological lines. There are frequent references to Piaget in *The Structure of Behavior* (1963 [1942]) and the *Phenomenology of Perception*, and an extended response to Lacan's seminal thinking on the mirror stage in a late essay titled "The Child's Relations with Others." Perhaps Merleau-Ponty's greatest contribution to psychological theory lies in his articulation of an ontological framework capable of consolidating the findings of thinkers across the full spectrum of ideologies from eidetic analysis to experimental and behavioral research: He unremittingly refused to endorse the radical distinctions between the a priori and the a posteriori, between transcendental and empirical approaches, which have functioned to isolate the various schools through polarized opposition.

## AESTHETICS

Merleau-Ponty revivifies the ancient Greek sense of the term *aesthetics* by focusing on the perceptual foundations

of art rather than concerning himself with judgments of taste. In accordance with his thesis of the primacy of perception, he regards the artist as one who seeks to respond to the world as it manifests itself perceptually rather than to superimpose preconceived conceptual structures upon the world. For example, classical Renaissance painting attempts to render depth on a two-dimensional surface by applying the laws of perspective. Such laws reduce depth to a mere rotation of breadth, seeing it from the side, and overlook the existential or lived aspect of depth as the dimension of exploration and mystery. In classical painting the eye of the artist is fixed and static, whereas in perception the artist's body is spatially mobile and not delimited to an instant of time.

Cézanne, Merleau-Ponty's favorite exemplar, renders depth in his paintings of Mont St. Victoire by using broad, blurred strokes in the foreground, clearer ones in the mid-ground, and an ethereal mistiness in the distance. In his still life paintings, table tops, vases, carafes of wine, and the like are portrayed as a moving eye would see them, not as a photograph would array them from a single point. The painting of galloping horses titled *Derby at Epsom* by Theodore Géricault shows the quadrupeds with their legs extended forward and backward, a distortion of the actual positions of legs in equine movement that succeeds in imparting motion to the animals rather than suspending them awkwardly in the air as a fixed frame, instantaneous representation would. The distortion is actually truer to what people perceive in the extended duration of the lived moment.

Artists have the ability to see what theoretical presuppositions lead people to overlook, and this allows them to bring the invisible to visibility, hence to bring the painting to life. Artists paint what they see rather than what they know of an object. Renoir visually interrogates the water he sees in the Mediterranean sea at Cassis to enable him to paint *The Bathers* in a pool in a sylvan setting. He sees the play of light through the fluid surfaces of the dynamic element that is invisible to the eye of the observer who can only see what he or she thinks is actually there. Artists train themselves to see the speck of light on the glistening surface of eyes that are, themselves, seeing. It is the invisibility of that speck of light to Fra Lippo Lippi, for example, who paints the eye as he thinks it truly is anatomically, that makes the persons in his portraits appear moribund.

The reversibility of seer and seen crosses as in a chiasm with the reversibility of the invisible and the visible. Artists attuned to their own visibility can paint their subjects seeing them and thereby depict the subjectivity of

the subject that remains invisible to those who think that in perceiving others people see only their material bodies. Perception, however, is—or can be—truer to living bodies than Cartesian philosophy that reduces human flesh to *res extensa* and conceives *res cogitans* as invisible.

## MERSENNE, MARIN

(1588–1648)

Marin Mersenne, a French mathematician, philosopher, and scientist, was one of the most influential figures of the scientific and philosophical revolutions of the seventeenth century. Although he is remembered primarily for his relationship with René Descartes, he was a significant figure in his own right and also, through his immense correspondence, publications, and personal acquaintances, a key figure in coordinating and advancing the work of the new philosophers and scientists.

He was born at Oizé, France, and studied at Le Mans and later at the Jesuit college of La Flèche, from 1604 to 1609. (Descartes, eight years his junior, was there from 1604 to 1612, but their friendship began later, around 1623.) He next studied in Paris and then entered the pious and austere order of the Minims. After further theological studies Mersenne taught philosophy at a convent in Nevers until 1619, when he was sent back to Paris by his order. He remained there until his death in 1648, except for some trips to The Netherlands, Italy, and the French provinces. His Parisian monastic cell was the center of the European scientific world, as scholars, scientists, philosophers, and theologians often made their way to Mersenne's quarters.

### MERSENNE'S PUBLICATIONS

From 1623 to 1625 Mersenne published several enormous polemical works attacking all sorts of Renaissance outlooks and figures, ranging from atheists, deists, kabbalists, astrologers, and numerologists to Pyrrhonists. These writings include the *Questiones Celeberrimae in Genesim* (1623), *L'impiété des deists, athées et libertins de ce temps, combatuë, et renversée* (1624), and *La vérité des sciences contre les septiques ou Pyrrhoniens* (1625). The last

work, more than a thousand pages long, was the culmination of this phase of Mersenne's career and the beginning of the scientific phase that was to continue until his death. Thereafter, his writings were on all sorts of scientific and mathematical subjects (including the famous *Harmonie universelle* [1636–1637] on the theory of music, harmonics, and acoustics) and were compendiums of the knowledge in these areas.

Mersenne became involved in the publication of fundamental works of his friends or correspondents, such as Galileo Galilei's *Mechanics* (translated by Mersenne), the objections to Descartes's *Meditations* (gathered by Mersenne), Herbert of Cherbury's *De Veritate* (in a translation by Mersenne), Thomas Hobbes's *De Cive* (the publication of which was arranged by Mersenne), and François de La Mothe Le Vayer's *Discours sceptique sur la musique* (published in Mersenne's *Questions harmoniques*). He also carried on a monumental correspondence that provides a magnificent running record of the intellectual revolution of the time. Mersenne was actively interested in an enormous range of scientific and pseudoscientific questions, from the most complex ones in physics, mathematics, and Hebrew philology to such ones as "How high was Jacob's ladder?" and "Why do wise men earn less money than fools?"

His major philosophical contributions were his massive refutation of skepticism, *La vérité des sciences*, and his later discussions of the nature of scientific knowledge. *La vérité des sciences* is a dialogue between a skeptic, an alchemist, and a Christian philosopher (Mersenne). The skeptic uses his arguments to show that alchemy is not a true science. When he broadens his attack to encompass all claims to knowledge of the real nature of things, Mersenne's Christian philosopher offers his own resolution to the skeptical crisis, starting with a detailed examination of Sextus Empiricus's *Outlines of Pyrrhonism*. He repeatedly contends that although the Pyrrhonian arguments may show that one cannot know the real nature of things, one can gain knowledge of the apparent, phenomenal world in terms of how it seems to one and how the various appearances are related. Although one's sense experiences vary and although one cannot tell what objects are really like, one can find laws that enable one to connect and, thus, to predict experiences. Although one cannot find any absolutely certain first principles, one can discover enough indubitable ones to enable one to construct systematic information about one's experienced world. "This limited knowledge suffices to serve us as the guide for our actions." One is able to know something—namely, the sciences of phenomena—and this has ade-

quate pragmatic value for one in this life. Francis Bacon was trying to find out too much and was raising too many insoluble skeptical problems with his Idols. Instead, the ultimate answer to skepticism was to show how much one could and did, in fact, know. The last 800 pages of the work is a listing of what is known in mathematics and mathematical physics—until the Pyrrhonist gives in. He has been conquered not by being refuted but by being shown what sort of knowledge one can have once one grants that knowledge about reality is unattainable.

#### “CONSTRUCTIVE OR MITIGATED SKEPTICISM”

Mersenne was willing to accept the skeptic’s claims but was unwilling to see them establish that nothing can be known. Instead, he saw an epistemological skepticism as the prelude to a “constructive or mitigated skepticism” which would allow a scientific and systematic development of the truths of the sciences of the empirical world. The rest of Mersenne’s life was devoted to his religious duty, exploring in phenomenalist terms what could be known about the world God had made. Mersenne’s immense contribution to the scientific revolution was the result of his positive views. Although he had originally portrayed skepticism as one of the greatest menaces to humankind, he continued to insist in his scientific tracts that one can gain no certain knowledge about reality but can study only the surfaces of things as they appear to one and employ mathematics as a hypothetical system about things. Like his close friend Pierre Gassendi (in whose arms he died), Mersenne saw scientific endeavors as a via media between complete skepticism and dogmatism. Mersenne tended to emphasize the antiskeptical aspect of this view, whereas Gassendi tended to emphasize the anti-dogmatic one.

In his formulations of the new science Mersenne was probably the first to use a mechanical model to account for the world that one experiences and to develop a thoroughgoing phenomenism (although hardly as well worked out as Gassendi’s) adequate to state the findings and assumptions of modern science. Mersenne’s lifelong devotion to science and scientists can apparently be attributed to their common quest for more information and understanding of the phenomenal world. Hence, Mersenne could see in Descartes a major contributor to the scientific revolution but could see nothing important in his metaphysical revolution. Descartes, Hobbes, Herbert of Cherbury, Gassendi, Blaise Pascal, Galileo, and others were, for Mersenne, together in seeking the truth of the sciences, although some of them still had illusions

that more truth than that could be discovered. For Mersenne, science had no metaphysical foundations and needed none. “Until it pleases God to deliver us from this misery,” one can find no ultimate knowledge, but one can, if one is not destructively skeptical, proceed to gain and use scientific knowledge.

#### MESLIER, JEAN (1664–1729)

Jean Meslier, perhaps the least restrained freethinker of the French Enlightenment, is also one of the most notorious examples of apostasy. As curé of the village of Etrépigny in Champagne from 1689 to his death, Meslier lived in complete obscurity, attending to his pastoral duties. But under the innocuous exterior of the humble

Catholic priest, there seethed a violent hatred and passionate disavowal of the religion that it was his ironic profession to serve. Having resolved sometime in the 1720s to compose his only work, the *Testament*, with the aim of keeping it secret until his death, he felt free to vent fully the anti-Christian, atheistic, revolutionary—indeed, anarchistic—sentiments that he had been obliged to suppress beneath a lifelong mask of prudent duplicity. The available biographical facts are unfortunately too meager to clarify this extraordinary personality. It is known, however, that on one occasion Meslier's abhorrence of injustice and persecution brought him into bitter conflict with the local nobility and, indirectly, almost into rebellion against the archbishop of Rheims, who, siding (as might be expected) with feudal privilege in the dispute, had castigated the morally outraged but powerless curate.

### EDITIONS OF THE TESTAMENT

The three autograph originals of the *Testament* addressed by its author to posterity were succeeded, in eighteenth-century France, by a profusion of manuscript copies that circulated briskly in the philosophical underworld of forbidden literature. The prolixity and other stylistic shortcomings of the work resulted, however, in its being edited in the form of various abridgments that proved more suitable for dissemination. The most important of these summaries was, without question, the *Extrait des sentiments de Jean Meslier*, prepared by Voltaire and published in 1762. This first printed version of the apostate priest's opinions was often reprinted, especially under the rubric of Baron d'Holbach's *Le bon sens du curé Meslier*—a combination of one of his own atheistic tracts and of the *Extrait*—which saw many editions well into the nineteenth century. The integral text of the *Testament* was not published until 1864.

### THOUGHT

Meslier's entire critique follows from the assumption that religion is basically a political means whereby those in power consolidate their control over the vastly greater number of weak and poor members of society. All religious dogmas, beliefs, and rituals, supposedly devised by the ruling class as instruments of government, are considered to be nothing but errors and superstitions serving to dupe and paralyze the victims of tyranny, holding them in ignorant fear and keeping them from any effective action to alleviate their misery by overthrowing their oppressors.

Meslier thought primarily in terms of economic exploitation, asserting that the opulence and power of the

few are, thanks to the protection of civil and religious laws, acquired and maintained at the expense of the near destitution of the people. There is little doubt that, in adopting this general view, he was motivated by deep feelings of sympathy for the sufferings of the poor, with whom he came into daily contact. His condemnation of Christianity therefore had at its root the eminently Christian virtue of pity for the downtrodden and helpless, joined, however, to a fiercely un-Christian zeal to right secular wrongs.

Although Meslier condemned all religions, he attacked Christianity in particular. The bulk of the *Testament* is devoted to fastidious refutations of the many different types of argument by which the "truth" of Christian revelation was presumed demonstrable. Meslier examines and rejects, in turn, the validity of faith, the historicity of miracles, the authenticity of Scripture, the authority of tradition, the accuracy of biblical prophecies, the testimony of martyrdom, the morality of eternal rewards and punishments, and the meaningfulness of such dogmas as the Trinity, the Incarnation, and transubstantiation. The *Testament* is, indeed, a compendium of the historical, exegetical, textual, and logical objections concerning the essentials of the Christian creed discussed in the critical and apologetic literature from the time of Pierre Bayle through the early decades of the eighteenth century. Meslier was conversant with this literature, and although there is relatively little in his criticism that is entirely new with him, the forcefulness, breadth, and intransigence of his "case against Christianity," together with its politicoeconomic basis, give his work a unique character.

Moreover, Meslier did not stop at exposing the fallacies of Christian belief and the social abuses of institutional religion but boldly pursued his train of thought to the affirmation of a materialistic system in which all phenomena can be traced to a physical basis and are subject to the laws of mechanics. He advocated atheism as the only outlook consistent with the interests of the majority of humankind in its struggle against the lust for domination of the unscrupulous few. Among the sources of the *Testament*, special importance should be given to Michel Eyquem de Montaigne's skeptical treatment of time-honored social practices, to the philosophy of Benedict de Spinoza, and to the Epicurean-Cartesian vision of a mechanistic, naturalistic universe in which the supernatural—particularly the doctrines of divine creation and spiritual immortality—no longer found any place.

## INFLUENCE

The impact of Meslier's ideas still has to be studied carefully. During the eighteenth century it was merely his negation of Christianity that proved appealing, and his socioeconomic protest, with its overtones of popular revolution, went largely unheeded. Contrary to the philosophes' estimate of Meslier as compatible with middle-class *bon sens*, some Marxists have been able to see in him an audacious spokesman for the economically repressed class of peasants and urban workers and the advocate of socialistic and egalitarian reform of society. But even if this was the true spirit of Meslier's thought, it did not play its intended role, for his influence was largely assimilated into the mainstream of Enlightenment ideology, with its predominantly bourgeois, liberal, and deistic polemic directed at Christianity. Seen in retrospect, the principal weakness of Meslier's anti-Christian *summa* is his oversimplification of the extreme psychological and cultural complexity of the religious phenomenon and its social applications. Moreover, his ardent wish forever to abolish injustice and wretchedness from the world by the expedient (in his own words) of "hanging and strangling with the bowels of the priests all the nobles and rulers of the earth" was no less utopian than fanatical. Nevertheless, Meslier's indignant and savage denunciation of religion was meaningful at the historical moment that inspired and shaped it, when the Roman Catholic Church of France, owing to its official status and immense riches, actually had a vested interest in the perpetuation of political and economic institutions related to the feudal oppression and exploitation of the people.

## METAETHICS

Judgments to the effect that certain things (or certain classes of things) are good or bad, right or wrong, or just or unjust, are first-order ethical judgments. Metaethics addresses second-order questions about the meaning and status of moral judgments, for example, "What does it mean to say that something is good or bad, or right or wrong?" "Are moral judgments statements that purport to be true or false?" and "In what sense, if any, can moral judgments be true or false (or correct or incorrect)?" Metaethical questions have been discussed throughout the history of philosophy, but systematic work on metaethics began early in the twentieth century with the publication of G. E. Moore's *Principia Ethica* (1993).

The first half of this entry discusses theories about the meaning of moral judgments, specifically, Moore's theory, the Franz Brentano–A. C. Ewing (1899–1973) theory, emotivism, Richard Hare's prescriptivism, Philippa Foot's theory normative relativism, and Allan Gibbard's (1942–) expressivism. The second half addresses the question of whether moral judgments are objectively true or false; it explains and assesses (some of) the main arguments for and against the view that moral judgments are objectively true or false. Questions about the truth of moral judgments are distinct from questions about moral knowledge. If moral judgments are not true or correct, then there is no such thing as moral knowledge. Moral knowledge is possible only on the assumption that there is something *to know* (i.e., moral truths). However, the view that there are objective moral truths does not imply that we have knowledge of them; it is compatible with moral skepticism, the view that there are objective moral truths but we cannot know what they are.

### I. THEORIES OF MEANING

Twentieth-century work on metaethics begins with questions about the meaning of moral judgments.

**1. MOORE'S OPEN QUESTION ARGUMENT.** In *Principia Ethica* Moore claims that the concepts of intrinsic goodness and badness are the most fundamental moral concepts. He says that the concepts of right and wrong can be defined in terms of "good" and "bad." Moore

writes: “To assert that a certain line of conduct is, at a given time, absolutely right or obligatory, is obviously to assert that more good or less evil will exist in the world, if it be adopted than if anything else be done instead” (Moore 1993, p. 77). Moore argues that goodness (the property denoted by the word “good”) is indefinable. By this he means that the property of goodness cannot be analyzed into constituent properties or elements. Goodness is a simple, ultimate property like the property of being yellow as opposed to a complex property such as the property of being a horse. Being a horse is analyzable in terms of other constitutive properties such as having a head, a heart, four legs, four hooves, and so on. Moore defends the claim that goodness is a simple, unanalyzable property with his “open question argument.” This argument can be summarized as follows: Consider any definition of good or goodness according to which goodness is identical with a complex property (*P*). It will always make sense to ask if *P* is good (it is an open question whether *P* is good since it is not self-contradictory to deny that *P* is good). However, it makes no sense to ask whether *P* is *P* (this is not an “open question”—it is self-contradictory to deny that *P* is *P*). Therefore, goodness cannot be identical with *P*.

Moore considers several specific definitions of good, which he subjects to the open question argument. He considers the view that good means pleasure, the view that good means what we desire, and the view that good means what we desire to desire. Clearly the question “Is pleasure good?” is not equivalent to the question “Is pleasure pleasant?” The statement “That which we desire to desire is good” is not equivalent to the statement “That which is good is good.” Moore’s open question test seems to work very nicely for these and many other definitions of good, but he gives no reason to think that *every possible definition of goodness* fails his open question test. Another serious problem with Moore’s argument is that he assumes that goodness cannot be identical with a property *P* unless the statement that *P* is good is analytic or true by definition. It is analytic (true by definition) that pleasure is pleasant, but it is not analytic that pleasure is good. Many contemporary philosophers contend that this assumption has been refuted. According to Hilary Putnam (1975) and Saul Kripke (1972), certain natural properties are identical with each other even though statements to the effect that the properties are identical are not analytic (not true by definition). For example, water is H<sub>2</sub>O (the property of being water is identical with the property of being H<sub>2</sub>O) even though the statement that water is H<sub>2</sub>O is not true by definition.

2. MOORE’S POSITIVE VIEWS. Moore is a *cognitivist* (i.e., he holds that moral judgments are statements that ascribe properties to things). By contrast, *noncognitivism* is the view that moral judgments are not statements that ascribe properties to things. Moore claims that goodness is a simple, unanalyzable property. Goodness is not a natural property like redness that can be perceived or apprehended through the five senses. Nonetheless, Moore claims that we can have direct intuitive knowledge of this property. This view is problematic. It is open to debate whether any such property exists. The quality of goodness that Moore posits is elusive; it is difficult to know what he is referring to. Many people, on careful introspection, report that they do not intuit any such property. Another serious problem for Moore’s view is that it seems to be unable to account for the fact that moral judgments give or purport to give us reasons to act in certain ways as opposed to others. To say that something is intrinsically good implies that we have reasons to choose or prefer it. But it is unclear why this should be so if Moore’s theory is true. It is not clear why we should care whether or not our actions produce or fail to produce instances of the nonnatural properties that Moore postulates and claims are identical to the properties of goodness and badness. (Even if they exist, it is not clear that these nonnatural properties are “reason providing” in the way that something must be in order to be the property of goodness or badness.)

Moore’s open question argument is one of the most influential arguments in the history of philosophy. Noncognitivist ethical theories, such as emotivism and prescriptivism, arose in a context of philosophical debate in which it was widely assumed that: (a) Moore has shown that goodness is indefinable, and (b) Moore’s own positive view is untenable—“good” does not refer to a simple nonnatural property that we directly intuit. Some philosophers concluded that moral terms do not refer to any properties at all and that moral judgments are not statements that ascribe properties to things.

3. BRENTANO AND EWING. Brentano (1969) and Ewing (1947) agree with Moore that moral terms refer to “nonnatural” properties, but they give a very different description of the nature of those properties. They hold that the most fundamental moral properties are nonnatural *relational* properties of “fittingness” or “appropriateness” that hold between objects/ properties and attitudes toward them. Ewing holds that the relation of fittingness is unanalyzable and that our apprehension of it is self-evident. In *The Definition of Good* he says: “Certain characteristics are such that the fitting response to whatever

possesses them is a proattitude, and that is all there is to it" (Ewing 1947, p. 172). According to Brentano, to be good is to be an appropriate (fitting) object of love, and to say that one thing is better than another is to say that it is correct to prefer it to the other. Ewing holds that to say that something is good means that it ought to be the object of a favorable attitude. This theory arguably avoids the second objection to Moore's theory noted above. According to Brentano and Ewing, it is part of the meaning of moral judgments (e.g., judgments to the effect that something is good or bad, or right or wrong) that they claim to give us reasons to have favorable or unfavorable attitudes about certain things and reasons to choose certain things over others.

4. **EMOTIVISM.** Emotivism is the view that moral judgments are *expressions* of attitudes rather than statements that ascribe properties to things. Favorable (unfavorable) moral judgments about something express favorable (unfavorable) attitudes about it. "Lincoln was a good man" means roughly "Yea Lincoln." So understood, emotivism denies the obvious phenomenon of moral disagreement. Suppose that you claim that Stalin was a good man and I claim that he was a bad man. If moral judgments were mere expressions of attitudes, then this could not constitute a disagreement. We might both agree that you like Stalin and I dislike him. Similarly, it is not a disagreement if you express your fondness for a particular flavor of ice cream and I express my distaste for that same flavor.

Alfred Ayer (1952) and Charles Stevenson (1944) defend more sophisticated versions of emotivism. According to Ayer, to make a moral judgment is to express an attitude with the intention of influencing the attitudes or actions of other people: "Lincoln is a good man" means roughly "Yea Lincoln, catch the wave." In cases of moral disagreement, each party is attempting to alter the attitudes of the other. Stevenson holds that moral disagreement involves a disagreement in attitudes (the parties to the disagreement have incompatible attitudes about something), and each party is attempting to change the attitudes of the other party about the thing in question. Stevenson says that "X is good" means roughly "I approve of X; do so as well."

These revised versions of emotivism still do not afford a satisfactory account of moral disagreement. In cases of moral disagreement, people not only disagree in their attitudes and try to cause others to *share their attitudes*, they assert that their own attitudes are correct or justified and that the attitudes of those who disagree with

them are mistaken. If two people disagree about whether or not Stalin was a good man, each claims that the other's attitudes about Stalin are mistaken or inappropriate.

*Ayer on moral reasoning.* Moral disputes often involve disagreements about factual questions. Ayer says that, to the extent that moral disagreements involve disagreements about "factual" questions, they can be rationally debated. For example, we can rationally debate whether the institution of capital punishment deters murder and whether it frequently results in the execution of innocent people. Sometimes, however, moral disagreements are based on differences in basic moral principles. Utilitarians believe that we should always do whatever will have the best consequences. Some people are unconditional pacifists. They believe that killing people is always wrong no matter what, even if killing saves many lives and produces much better consequences than not killing. Utilitarians and unconditional pacifists accept incompatible basic moral principles. According to Ayer, when people disagree about matters of basic principle, their disagreements cannot be rationally debated or rationally resolved. (Gibbard's *Wise Choices and Apt Feelings*, discussed below, is a recent development of emotivism.)

5. **HARE'S PRESCRIPTIVISM.** One of the notable features of this theory is that Hare offers a systematic reply to Ayer's claims about the limits of moral reasoning. Hare claims that moral judgments are prescriptions that are universalizable and overriding. Prescriptions are commands, or imperatives, for example: "Don't lie!" and "Shut the door!" Since commands are not statements that are true or false, prescriptivism is a noncognitivist theory. To say that moral judgments are universalizable means that if one makes a moral judgment about a particular case, then one must make the same judgment about any cases that are similar to it in all morally relevant respects. (If I say that it is morally permissible for me to lie to my customers in a certain situation, then I am committed to the view that it would be permissible for others to lie to me in relevantly similar situations.) To say that moral judgments are overriding means that a person who makes moral judgments takes the prescriptions expressed by them to override any conflicting nonmoral considerations, such as considerations of prudence, etiquette, and the law. According to Hare statements of the form: "It is morally wrong all things considered for you to do X, but, nevertheless, you would be justified in doing X," are self-contradictory. On Hare's view it is also inconsistent to say that it is morally wrong (all things considered) for you to do X but still command or advise you to do X.

In response to Ayer's claims about the limits of moral reasoning, Hare would say that sometimes we can argue against another person's moral judgments by showing that they are *inconsistent*. Hare claims that requirements of consistency severely constrain the kinds of moral judgments we can make. Suppose that a dishonest plumber claims that it is morally permissible (or even obligatory) for him to defraud his customers and bill them for unneeded repairs that cost them thousands of dollars. To be consistent, he must say that it would be morally permissible (obligatory) for others to defraud him and those he cares about in relevantly similar (hypothetical and/or actual) cases. Since moral judgments are prescriptive, he is committed to prescribing that others defraud him and those he loves in relevantly similar circumstances. Consistency also requires that he refrain from objecting if others defraud him and those he loves in such cases.

In *Freedom and Reason*, Hare considers the case of a Nazi who claims that it is his moral duty to kill Jews. To be consistent, the Nazi must hold that others should kill him if he is Jewish. Suppose that we show the Nazi that, unbeknownst to him, he and his wife are Jewish. To be consistent, the Nazi must say (and *mean*) "All right, send me and my family to an extermination camp." Since moral judgments are overriding, the Nazi cannot consistently make any commands or pleas to the contrary. Hare thinks that few people can be consistent Nazis. Hare allows that a Nazi could be consistent if he or she so hates Jews that he or she sincerely holds that, (in Hare's words): "Jews are such an abomination that I and my whole family, if we were Jews, should be sent to the gas chamber" (Hare 1963, p. 172). One can be a consistent Nazi if one is willing to have one's moral principles applied against one's own interests and the interests of those one loves.

Hare gives no reason to think that the Nazi's distinctive moral views are false or mistaken, just that it is difficult to be a consistent Nazi. This concession bodes ill for Hare's theory of moral reasoning since if it cannot establish the correctness of the view that the Nazi's actions are wrong, it is doubtful that it can establish the correctness of *any* ethical judgments. However, Hare is too quick to concede the limits of his arguments in this case. It may be possible to be a consistent Nazi provided that one has a very great hatred of Jews and desires their extermination more than the continuation of one's own life and the lives of one's loved ones. The obvious question to ask here is whether such hatred is rational, and it seems that it is not. Such hatred depends on numerous false beliefs about the characteristics of Jews and their responsibility for the ills of the world. A Nazi could be consistent provided that she

is willing to have her principles applied against herself and her loved ones, but a Nazi could not be *both* consistent and adequately informed about matters relevant to her moral convictions. (See Hare's *Moral Thinking* [1981] for a later development of his views.)

As Hare himself notes, his consistency arguments apply only to people who make moral judgments. They do not apply to amorality who refrain from making moral judgments. Hare's consistency arguments cannot show why we should not be amoral. Even more worrisome for Hare's purposes is that people who employ alternative normative concepts are able to endorse horrendous acts such as the extermination of the Jewish people. Suppose that a Nazi rejects the concepts of morally right and wrong actions in favor of a "Code of Honor" according to which it is "honorable" to kill Jews. Hare's theory does not give us any basis for criticizing such views.

This last possibility raises an important and somewhat neglected set of issues. There are many different alternative normative concepts (e.g., concepts of moral obligation and right and wrong, concepts of virtue, and concepts of honor). People are free to employ any of these concepts and order their lives in accordance with them; people are also free to reject any of these concepts. Philosophers who write about metaethics need to say much more about the *choices* we make in accepting and rejecting various normative concepts. They also need to say much more about the question of how, if it all, we can justify the choices we make in accepting/wielding certain concepts rather than others. (See Friedrich Nietzsche [1967, 1988], Hare [1981], Simon Blackburn [1993], John Mackie [1977], and Bernard Williams [1985] for discussions that shed light on these issues; also see the discussions of Foot, Gibbard, and "Incommensurability" below.)

6. FOOT AND THICK MORAL CONCEPTS. Both emotivism and prescriptivism imply that the concepts of good and bad and right and wrong have no fixed descriptive meaning. One can consistently apply these terms to any things (or any actions). For example, it is perfectly consistent to say that it is morally obligatory to clasp and unclasp one's hands every half hour or to say that bringing it about that the number of hairs on one's head is an even number is a great intrinsic good. These are sincere coherent ethical judgments provided that the person who makes them has the attitudes they express or is willing to consistently universalize the prescriptions that they express. Foot (1978) argues that this is a serious mistake

because there are limits to the things to which “good” and other moral terms can be consistently applied. She thinks that emotivism and prescriptivism make a mistake that is comparable to the sort of mistake one would make if one said that being proud of something consists simply in having a certain sort of attitude about it and that, in principle, *anything* could be the object of one’s pride.

Pride is not just a feeling, a welling up in one’s chest that one can have about anything. The object of one’s pride must be: (a) one’s own somehow, and (b) an achievement or something that one takes to be good. Even if I puff up my chest and feel it welling up as I look at the sky, it is not correct to say that I am (feeling) proud of the sky unless there is some background belief that explains why I think that it is somehow *mine*. Foot claims that something can be called a “good action” only if it satisfies one of the following conditions: (a) It is the fulfillment of a special duty derived from a role or promise or (b) it exemplifies a virtue. It follows that we cannot say that twiddling one’s thumbs four times each day, for instance, is a morally good action in the absence of special reasons for thinking that it fulfills a duty or exemplifies a virtue.

Foot’s own analysis of the meaning of moral judgments is a combination of noncognitivism and (naturalistic) cognitivism. She claims that moral judgments have both evaluative meaning (they express attitudes and guide actions) and descriptive meaning. Moral concepts that have both kinds of meaning are called “thick” concepts. Emotivism and prescriptivism claim that the concepts of right and wrong and good and bad are “thin” concepts. Thin normative concepts have no fixed descriptive meaning, only evaluative meaning.

Foot’s theory aptly describes the meaning of the terms we use to refer to moral virtues and vices. Terms such as “generous,” “cowardly,” and “honest” are thick concepts—they have both evaluative and descriptive meaning. The words “generous” and “honest” commend or express favorable attitudes about the things to which they are applied. There are clear descriptive criteria for using such terms. It is a misuse of language to apply them to things that do not satisfy those criteria. It would be a misuse of the word “generous” to apply it to someone who never gives any tangible goods or time or effort to other people even though that person has a great deal of money and leisure time and many opportunities to help others in need. Foot’s theory helps us to frame some important questions: “In ordinary language, are the terms ‘good’ and ‘bad’ and ‘right’ and ‘wrong’ thick or thin concepts?” “If these concepts are thin concepts, should we

dispense with them in favor of thick concepts?” Foot seems to think that the concepts of good and bad and right and wrong are thick concepts. By contrast, some proponents of “virtue ethics,” including Williams (1985), think that the concepts of good and bad and right and wrong are thin concepts. However, they think that these thin concepts should be dropped or greatly downplayed in favor of the thick concepts that refer to virtues and vices.

Thick concepts mandate particular evaluations of certain kinds of things. Many thick concepts encapsulate objectionable evaluations (e.g., ethnic slurs). The word “n\_\_\_” only applies to people of African origin; it cannot be correctly applied to Chinese or Europeans. The word “n\_\_\_” also expresses contempt for Africans. Those who do not think that Africans, qua Africans, are worthy of contempt do not use the word “n\_\_\_” (or do not use the word nonironically). (Similar comments apply to all other “ethnic slur terms.”) Honor is another example of a thick concept that many people have reasonably chosen to abandon because they reject the evaluations implicit in its use. Given certain concepts of honor, it is dishonorable for me to not to challenge you to a duel to the death if you insult me or show me disrespect. Given other concepts of honor, it is dishonorable for me not to kill my sister if she is raped. These examples make it clear that, for any thick concept that we employ, we should be open to criticisms of the evaluations implicit in that concept and consider the possibility that they are mistaken and cease employing the concept. Thus, it is at least arguable that we need higher-level thin concepts in terms of which to assess the evaluations implicit in the thick concepts we use and encounter.

7. **NORMATIVE RELATIVISM.** This theory is defended by many anthropologists, including Ruth Benedict (1887–1948) and William Sumner (in Moser and Carson 2001). They claim that “X is morally right” means roughly “X is approved of by my society.” This view is open to very serious objections. It implies that statements such as “Slavery is morally wrong, even though my society approves of slavery” are self-contradictory. But such statements are not self-contradictory. A person can criticize or dissent from the moral standards of her own society without contradicting herself. Normative relativism also implies that many ostensible moral disagreements between members of different societies are not genuine disagreements. Suppose that I am a member of a society that approves of the institution of slavery and you are a member of a society that disapproves of slavery. I claim that slavery is just and morally permissible. You object

and claim that slavery is unjust and impermissible. Surely this is a moral disagreement; what I say contradicts what you say. But, according to normative relativism, there is no disagreement in this case. My statement is perfectly consistent with your statement, and both statements are *true*—it is true that my society approves of slavery and true that your society disapproves of slavery.

8. **GIBBARD'S EXPRESSIVISM.** This theory is a recent development of emotivism that incorporates elements of the Brentano–Ewing theory. Gibbard (1990) analyzes moral judgments as claims about the rationality (or aptness) of feelings of guilt and anger. What a person does is *morally wrong* if and only if it is rational for him to feel guilty for having done it and for others to be angry at him for having done it. He defends an expressivist/emotivist analysis of rationality. According to Gibbard, to say that something (an act, belief, or feeling) is rational is to express one's acceptance of norms that permit it. Unlike Moore, Hare, and Foot, Gibbard does not claim to be offering an analysis of the ("ordinary language") meaning of moral terms. Rather, he describes his theory as a *proposal* about how to use normative concepts. Evidently, not every society has a normative system that includes norms for guilt and anger. Thus, on Gibbard's narrow construal of "morality," not every society has a moral code. Gibbard raises important questions about our choices between alternative normative concepts. Among other things, he asks about the value of morality (narrowly construed): Would we be better off with a normative code in which norms for guilt and anger didn't play a central role? Gibbard offers an answer to Nietzschean criticisms about the value of morality. He says that moral norms help coordinate guilt and anger. Guilt assuages anger and thereby helps promote peace between human beings. Normative codes that do not include norms for guilt will not be able to assuage anger and promote reconciliation between human beings as well as *moral* codes.

## II. MORAL TRUTH, MORAL REALITY

We now turn to questions about moral truth and moral reality. In what sense, if any, can moral judgments be true or false or correct or incorrect? Are moral judgments objectively true or false in the way that we take ordinary "factual" statements to be? Is there a moral reality or something else in virtue of which moral judgments are true or false (or correct or incorrect)? We cannot answer these questions simply by appealing to theories of meaning. When we ask whether moral judgments are true or false, we are not simply asking about what we mean or *claim* when we make moral judgments. We are asking

whether there is anything that backs up our moral judgments and makes them true or correct.

**COGNITIVISM, NONCOGNITIVISM, AND THE TRUTH OF MORAL JUDGMENTS.** Cognitivists hold that moral judgments are statements that *purport* to be true. This is compatible with the view that there are no moral facts (no moral reality) that back up our moral judgments and make (some of) them true or correct. Mackie (1977) holds such a view, which he calls an "error theory" of morality. Mackie is a cognitivist who claims that moral judgments are statements that assert or presuppose the existence of objective values. However, he claims that since objective values do not exist, *all moral judgments are false*.

Noncognitivists hold that moral judgments are not statements that purport to be true or false. Strictly speaking, noncognitivists cannot say that moral judgments are true or false. However, they can still say that moral judgments possess something that closely resembles truth or falsity. Emotivists can say that moral judgments are reasonable or unreasonable depending on whether the emotions or attitudes they express are reasonable or unreasonable. (At the very least attitudes and emotions can be unreasonable if they are based on false beliefs.) Prescriptivists can also make sense of something resembling the idea of moral truth. In *Moral Thinking*, Hare claims that there are certain moral judgments that an informed, consistent person must endorse, provided that he or she makes any moral judgments at all. These are judgments that we can reject only by opting out of moral discourse altogether.

**MORAL OBJECTIVISM.** Our ordinary notion of truth is a notion of *objective truth*. If something is true, then it is *true for everyone* (and true for everyone, everywhere, at all times). (Thus, it is misleading to use the word "truth" as many relativists do when they claim that the truth of moral judgments is "relative to" different people so that a moral judgment that is "true for" one person may not be "true for" another.) Let us use the term "objectivism" to refer to the view that moral judgments are objectively true or false (or objectively correct or incorrect in some sense that closely resembles truth or falsity). We should distinguish between the view that there is an objectively correct answer to *every* moral question and the view that there are objectively correct answers to *some*, but not all, moral questions. Call the former view "unqualified objectivism" and the latter view "qualified objectivism." Call the view that there are no objectively correct answers to any moral questions "unqualified nonobjectivism."

Unqualified objectivism implies that for any moral question, for example: “Was it right for Ms. Jones to have an abortion in April 1999?” there is an objectively correct answer and that anyone who gives a conflicting answer is mistaken. Qualified objectivism holds that there are some moral questions about which there are objectively correct answers and other moral questions about which there are no objectively correct answers. Unqualified nonobjectivism implies that, for any moral question, there is no objectively correct answer to that question.

**MORAL REALISM.** Statements such as “the earth is less than 100,000,000 miles from the sun” are true in virtue of facts that hold independently of what we believe or desire. *Moral realism* is the view that there are moral facts in virtue of which moral judgments are objectively true or false and that these facts are logically independent of the beliefs, attitudes, emotions, or preferences of rational beings and independent of the beliefs, attitudes, emotions, or preferences that rational beings would have in hypothetical situations (e.g., the moral beliefs that someone would have if she or he were fully informed about relevant facts). Moral nonrealism is the view that there are no independent moral facts. The truth of moral realism would guarantee the truth of moral objectivism, but one can be a moral objectivist without being a moral realist. Immanuel Kant, Roderick Firth (1917–1987), and Michael Smith (1954–) (see below) are moral objectivists but not moral realists. Hare’s *Moral Thinking* also defends nonrealist moral objectivism.

## IIA. ARGUMENTS AGAINST MORAL OBJECTIVISM

We now turn to arguments against moral objectivism.

1. **DISAGREEMENT.** Moral disagreement is widespread among ostensibly sane and rational people. Consider the following argument:

- (1) There is disagreement among rational people about the answers to all (some) moral questions.
- (2) If there is disagreement among rational people about the answer to a question, then there is no objectively correct or objectively true answer to that question.

Therefore, unqualified (qualified) nonobjectivism is true. (There are no moral questions [there are only some moral questions] for which there is an objectively correct answer.)

The cogency of this argument depends on the account of moral truth or correctness that the objectivist gives. If moral realism is true, then there are moral facts in virtue of which moral judgments are objectively true that are independent of what we believe. So, if moral realism is true, then moral objectivism is true, and the phenomenon of moral disagreement among rational people is not a serious objection to moral objectivism. Similarly, disagreement between reasonable people does not constitute any kind of objection to the view that ordinary historical judgments are objectively true or false. Consider the question: “Did Lee Oswald fire any of the shots that killed President Kennedy?” Rational people disagree about the answer to this question, and, at the present time, it may be impossible to know for certain what the answer is. In spite of the disagreement, there is an objective fact of the matter—either Oswald fired some of the fatal shots or else he did not. However, the phenomenon of ethical disagreement among ostensibly rational and well-informed people constitutes a serious argument against attempts to defend moral objectivism by appeal to theories of rationality because such theories claim that objective moral truths are constituted by the *agreement* of rational people. One standard rejoinder to the objection about disagreement is the claim that “*ideally* rational” or “*fully* rational” people would not have moral disagreements. (See the discussion of the ideal observer theory below.)

**Digression: Disagreement vs. incommensurability.** Moral disagreement should not be confused with moral incommensurability. Two people can disagree about whether an act is right or wrong only if they share the concepts of right and wrong action. Often, the differences between the moral views of different societies constitute cases of incommensurability rather than disagreement. Many philosophers and cultural anthropologists (including Nietzsche and Gertrude Anscombe) claim that the concept of moral obligation is unique to Judaism, Christianity, Islam, and the civilizations that developed from those religions. If this is true, then it is doubtful that Genghis Khan (c. 1167–1227) and his warriors possessed our concept of a moral obligation and morally right and wrong actions. I condemn the Mongol destruction of Iraq in the thirteenth century as a morally wrong action. Many or most of the Mongols who took part in this did so in good conscience, but it would probably be incorrect to say that they thought that what they did was morally right (they could not have this belief unless they employed the concepts of right and wrong actions). Even though we do not disagree about the *moral rightness* of this action, there is surely some kind of disagreement here. My moral judg-

ments and the attitudes they endorse are contrary to many of Genghis Khan's attitudes; Genghis Khan clearly approves of (and thinks it correct to approve of) actions that I disapprove of and condemn as morally wrong.

2. **THE APPEAL TO TOLERANCE.** This argument goes roughly as follows: "We should be respectful and tolerant of other people's moral views; however, moral objectivism implies that many people's views are mistaken and thus not worthy of respect or toleration." This argument is widely accepted and motivates many people to reject moral objectivism, but, on examination, it is a very weak argument that few philosophers take seriously. First, endorsing moral objectivism does not commit one to being intolerant of the moral views of others. If I am an unqualified objectivist, then I think that there are objectively correct answers to every moral question. However, my being an objectivist does not entail that I claim to know what those answers are. Nor does my being an objectivist entail that I think that the views of others who disagree with me are worthy of disrespect or suppression. An objectivist can claim that objectively true moral principles require tolerance and respect for the views of others. Second, nonobjectivism does not imply that we should be tolerant. Nonobjectivists can endorse first-order moral principles that permit or require them to be intolerant of the views of others. All that follows from nonobjectivism is that one's moral judgments, *whatever they happen to be*, are not objectively true or false or objectively correct or incorrect.

3. **MORAL EXPLANATIONS AND MORAL FACTS.** Gilbert Harman argues that it is unnecessary to posit the existence of moral facts in order to explain phenomena. Thus, moral facts are superfluous entities—there is no reason to suppose that they exist.

[O]bservation plays a role in science that it does not play in ethics. The difference is that you need to make assumptions about certain physical facts to explain the occurrence of the observations that support a scientific theory, but you do not seem to need to make assumptions about any moral facts to explain the occurrence of the so-called moral observations I have been talking about. In the moral case, it would seem that you need only make assumptions about the psychology or moral sensibility of the person making the moral observation. In the scientific case, theory is tested against the world.

(HARMAN 1977, p. 6)

Among the phenomena that moral facts might explain are the moral judgments we make and the moral sentiments we feel (e.g., feelings of guilt and indignation). According to Harman, these phenomena are fully explained by our psychology and the fact that we accept certain moral principles; we do not need to assume the existence of moral facts or assume that those principles are true. Harman gives the following example: Someone tortures an animal. You believe that this action is wrong and you feel moral indignation. Harman says that we do not need to postulate moral facts in order to explain *your* belief and *your* indignation. They are explained by the fact that you were taught certain moral principles and have a certain psychological make up. Your *accepting* the moral principles in question is necessary to explain your beliefs and your indignation, but *we* do not need to assume that your moral principles are *true*. By contrast, in science, we can justify the postulation of entities by their ability to explain our observations of the world. The postulation of atoms helps to explain such things as Geiger counters and nuclear bombs. (Nicholas Sturgeon offers an influential reply to this argument. See below.)

## IIB. ARGUMENTS IN FAVOR OF MORAL OBJECTIVISM

Most contemporary philosophers who defend moral objectivism do so on one of the following three grounds:

1. **THE APPEAL TO MORAL REALISM.** As explained earlier, the truth of moral realism would guarantee the truth of moral objectivism. Some versions of moral realism claim that moral properties are "nonnatural" properties. Such theories are widely criticized on the grounds that the entities that they postulate do not exist or that those entities cannot plausibly be identified with moral properties (see above). In light of these criticisms of nonnaturalist versions of moral realism, recent attempts to defend naturalistic versions of realism are particularly noteworthy.

*Sturgeon's naturalistic realism.* Sturgeon claims that moral facts are constituted by natural facts. Sturgeon holds that moral properties are identical with natural properties, but he does not take statements asserting the identity of moral properties and natural properties to be analytic. He claims that his view is invulnerable to Moore's open question argument. Sturgeon also attempts to answer Harman's argument about explanation. He defends his theory on the grounds that moral facts help explain certain phenomena. Sturgeon offers the following

example: Hitler's moral depravity helps explain why he started World War II and ordered the Holocaust. If Hitler had not been morally depraved, he would not have started World War II, and he would not have ordered the Holocaust.

Harman's thesis implies that the supposed moral fact of Hitler's being morally depraved is irrelevant to the explanation of Hitler's doing what he did. To assess this claim, we need to conceive a situation in which Hitler was *not* morally depraved and consider the question whether in that situation he would still have done what he did. My answer is that he would not, and this answer relies on a (not very controversial) moral view: that in any world at all like the actual one, only a morally depraved person could have initiated a world war, ordered "the final solution," and done any number of other things Hitler did. That is why I believe that if Hitler had not been morally depraved, he would not have done those things and hence that the fact of his moral depravity is relevant to an explanation of what he did (Sturgeon "Moral Explanations," in Sayre-McCord 1988, p. 249). Sturgeon's arguments have generated a very lively debate. (Criticisms by Terrance Horgan and Mark Timmons (1951–) are particularly noteworthy.)

**2. THEORIES OF RATIONALITY.** Many nonrealists claim that there are objective moral facts that are constituted by facts about what it is rational for people to believe or desire or "will." Kant, Hare, and Christine Korsgaard defend such views. Kant holds that moral truths (truths about what is right and wrong) are truths about what we can rationally and consistently will. For Kant moral truths are truths of reason.

The ideal observer theory (IOT) uses the idea of an ideally rational moral judge or ideal observer as a standard for the truth of moral judgments. According to Firth's version of the IOT, a favorable moral judgment about *X* ("*X* is good/right") is (objectively) true provided that all ideal observers would feel approval for *X*. An unfavorable moral judgment about *X* ("*X* is bad/wrong") is (objectively) true provided that all ideal observers would feel disapproval for *X* (Hospers and Sellars, pp. 200–221). In *Ethical Theory*, Richard Brandt (1959) defends a different version of the IOT. Brandt says that a moral judgment *X* is objectively true provided that all ideal observers would accept or believe *X*. (David Hume and Adam Smith also defend versions of the IOT.) Firth ascribes the following characteristics to an ideal observer:

(1) Omniscience or knowledge of all nonmoral facts;

(2) omnipercipience, or the ability to imagine vividly any events or states of affairs, including the experiences of others;

(3) disinterestedness, that is, not having any interests or desires that involve essential reference to particular persons or things;

(4) dispassionateness, that is, not having any emotions that are directed upon objects because they are believed to have essentially particular features;

(5) consistency;

(6) normality "in other respects."

Firth thinks that all ideal observers would feel approval and disapproval for the same things. Given this, and given his version of the IOT, unqualified moral objectivism is true. Brandt thinks that ideal observers would agree about the answers to some, but not all, moral questions. He thinks that the IOT commits us to qualified objectivism. If both Firth and Brandt are mistaken and ideally rational moral judges could disagree in their attitudes or judgments about *every moral question*, then the IOT commits us to unqualified nonobjectivism.

Ideal observers are characterized as "informed" or "fully informed." Brandt says that ideal observers must possess all information "relevant to" the issues they judge. Firth notes difficulties in determining which facts are and are not relevant to answering a given moral question. He contends that there is no way to determine which facts are and are not relevant to a given moral question without presupposing answers to controversial moral questions that the IOT is supposed to provide rather than presuppose. Because of this he feels compelled to say that an ideal observer is *omniscient* with respect to all nonmoral facts. There is an unintended irony in Firth's characterization of an ideal observer as a *human being* who is omniscient "but otherwise normal." Humans are very far from being omniscient. It is not clear that it makes sense to talk about how you or I would react if we were omniscient. An omniscient being would have to be God or some kind of deity. If we press this point, then the IOT starts to look a lot like a divine will theory of morality.

Michael Smith's *The Moral Problem* (1994) defends a theory that closely resembles the IOT. With qualifications, Smith holds that to say that an action is morally right means that we have normative reason to do it. What a person has normative reason to do is what he or she *would desire to do* if fully rational (being fully rational includes having no false beliefs and having all relevant true beliefs). Smith stresses that what I have normative

reason to do (in my actual circumstances) depends on what my fully rational self would want (or advise) my actual self to do. (Smith's theory is sometimes called an "ideal advisor theory.") Smith thinks that his theory implies that there are (objective) moral facts. On his account, the judgment "it is right for *S* to do *X*" is objectively true provided that we would *all desire* that *S* do *X* if we were fully rational. Smith thinks that an *ideally rational* process of reflection and debate between people who initially disagree in their desires about what people should do is likely to yield (complete) agreement.

According to Smith, thick moral concepts such as "honesty" and "treachery" reveal considerable agreement about what is right and wrong. The common use of such concepts reveals that nearly everyone agrees that acts of treachery are wrong (other things equal) and that acts of honesty are right (other things equal). Smith also argues that much seemingly intractable moral disagreement has its origins in (unreasonable) appeals to religious authority. (Others take a very different view about the relevance of religion to these issues; see below.) Smith says that the case for moral objectivism ultimately depends on the outcome of (first-order) debates in normative ethics. In order to determine "whether or not there *really are* moral facts," we must "engage in normative ethical debate and ... see where the arguments that we give ultimately lead us" (Smith 1994, p. 202). "The real question is whether we will, by engaging in such debate, come up with answers to moral questions that secure the free agreement of those who participate" (Smith 1994, p. 201).

3. THE APPEAL TO GOD'S WILL. Some hold that God's will constitutes the objective standard for the truth of moral judgments. The view that God created human beings for certain purposes is one way of making sense of the widely held view that ethical theories should be based on theories of human nature or the "telos" of human life. The most well-known theory that attempts to base (objective) morality on God's will is the divine command theory. The traditional divine command theory (TDCT) holds that God's commands constitute the ultimate standard of right and wrong. What makes an act morally obligatory is that God commands it; what makes an act morally permissible is that God permits it; what makes an act morally wrong is that God forbids it.

There are a several standard objections to the TDCT. These objections are widely regarded as fatal or decisive. (1) The TDCT implies that nothing anyone does can be morally obligatory or morally wrong unless God exists and commands and forbids us to do certain things. How-

ever, certain actions would be right or wrong even if God did not exist. (2) The TDCT implies that *any act* would be right if God commanded us to do it. But certain acts (e.g., acts of cruelty or murder) would be wrong even if God commanded us to perform them. (3) The TDCT implies that what is wrong/obligatory is wrong/obligatory *because* God forbids/commands it. The TDCT does not allow us to say that *God forbids murder because murder is wrong*. Rather, the TDCT implies that *murder is wrong because God forbids it*. Thus, the TDCT implies that God has no reason to command one thing rather than another, and God's arbitrary commands cannot be the basis for genuine moral obligations.

These may be fatal objections to the TDCT. However, it does not follow that all theories that attempt to make God's will the basis for an objective morality are subject to fatal objections. Robert Adams (1937–) has formulated a modified version of the TDCT that avoids all of the objections to the TDCT. Adams's modified TDCT can be stated roughly as follows:

If there is a loving God then: (1) an action is obligatory if, and only if, a loving God commands it; (2) an action is morally permissible if, and only if, a loving God permits it; and (3) an action is morally wrong if, and only if, a loving God forbids it. If there does not exist a loving God, then the rightness or wrongness of actions is determined in some other way.

Adams (1987) holds that if there is a loving God, then right and wrong are determined by God's commands; if there does not exist a loving God, then right and wrong are determined in some other way. Thus, Adams's theory avoids the first objection. Adams's modified TDCT also avoids the second objection. It does not imply that we would be morally obligated to obey God's commands if God commanded cruelty. If God commanded cruelty for its own sake, he would thereby show himself to be unloving. Adams's theory does not imply that we would be obligated to follow the commands of a cruel or unloving God. Adams cannot say that God commands what he commands *because* it is morally right (independently of being commanded by God). But Adams is *not* committed to the view that God's commands are arbitrary or that God has no reason to command one thing rather than another. Adams can say that God commands what he commands because of his loving nature and because he is omniscient. (See Linda Zagzebski's *Divine Motivation Theory* [2004] for a very different sort of religiously based moral theory.)

Suppose that there exists an omniscient loving God who created human beings for certain purposes. Suppose *also* that moral realism is false and there are no independent moral facts to which God's will must conform on pain of error. Given all of this, it is plausible to regard God's will and purposes as objective standards of morality; God's standpoint for assessing things is arguably more authoritative than that of a maximally rational human being. If moral realism is false and God does not exist, then the most promising basis for defending moral objectivism is by appeal to a theory of rationality.

## METAPHOR

“Metaphors” have an emotive force and aesthetic dimension that have long been recognized. What has made metaphor so compelling to contemporary philosophers, however, has been its importance to cognition. Aesthetics and philosophy of religion are no longer the sole province of the study of metaphor. Instead, most of the research is located in philosophy of language, philosophy of science, and cognitive science. The ubiquity of metaphor and its contribution to all forms of discourse, the apparent anomaly of metaphor in light of standard accounts of language, and the increased interest by philosophers in providing theories for natural (rather than formal or artificial) languages have made an account of metaphor an important criterion of adequacy for theories of language. The limits of literality have similarly been felt in accounts of science and cognition. Max Black’s (1962) seminal work connecting the use of scientific models to metaphors opened an area of inquiry now pursued by psychologists and cognitive scientists as well as philosophers of science. Some philosophers join questions of the role of metaphor in science to debates concerning scientific realism (Boyd, 1979; Hesse, 1970). The work emanating from theories of language and theories of science and cognition converge in concerns about meaning change, computer modeling of discovery processes, linguistic competencies, creativity, and religious discourse (Soskice, 1985).

While many questions remain, a few issues have been settled. The view of metaphor as an isolated word or phrase that is an occasional, unsystematic, and deviant phenomenon in language valued for its rhetorical force but disdained for its ability to mislead or be used in place of proper argument has been challenged. Metaphors have come to be understood as syntactically complex (Black, 1962; Tirrell, 1991) attributions that may or may not be grammatically deviant (Stern, 1985). In the tradition of I. A. Richards (1936) and Black, metaphors are generally taken to implicate entire conceptual domains or semantic fields (Kittay, 1987) through which a metaphor is interpreted, extended, and even systematically integrated into the language (Lakoff and Johnson, 1980). They either exploit some similarity between the metaphorically used term (the vehicle or source) and the concept spoken of (the topic or target) or create or intimate a similarity. While the similarity appealed to in earlier discussions pertained to intrinsic properties or properties associated with vehicle and topic, similarity has increasingly come to mean a relational or structural similarity—akin to models and analogies—between the contexts or domains

(Black, 1962; Goodman, 1968) implicated in the metaphor.

While earlier debates concerned metaphor’s cognitive value, current debates accept its cognitive function and ask if this function is properly assigned to metaphoric meaning and whether it is a distinctive form of cognition not reducible to other forms such as the capacity to recognize similarity and make comparisons. The outcome of the debate is important to the nature of language, of thought, and of epistemic enterprises such as science. If metaphors have meaning, then a theory of language must explain how such meaning is determined, and any account of mind in which linguistic capacity plays a central role for cognition must similarly explain how cognitive faculties make use of, and make possible, metaphorical thought. Similarly, if the use of metaphorical language in knowledge domains such as science is not reducible to literal language, then we need metaphor in order to understand and explain what is knowable. Furthermore, if we need metaphor to access scientific knowledge, as well as for aesthetic or evocative purposes, then the domains such as art and religion may be more akin to science—or related in more interesting ways—than we have presumed (Fleischacker, 1994). But if metaphors perform their cognitive function without generating a distinctive meaning, then theories of language that are based on literal language suffice; metaphoric contributions to cognition are assimilable to other, already understood or accepted cognitive abilities; the cognitive role of metaphor would be valuable only as heuristic (although, in the case of combinatorially complex problems, the heuristic contribution of metaphor itself may be irreplaceable), and we maintain a clear delineation between the scientific and the poetic.

The position propounding metaphoric meaning and the cognitive irreducibility of metaphor was staked out by Black and has been buttressed by arguments and evidence gathered by philosophers of science, cognitive psychologists, philosophers of language, and linguists. However, the parsimony of the opposing position, and its elegant articulation by Donald Davidson (1978), continues to make it attractive, despite the counterintuitive claim that metaphors have no meaning and the weighty evidence of metaphor’s importance in all cognitive endeavors.

Philosophers claiming that metaphors have meaning generally begin by accepting some version of the interaction theory of metaphor but have utilized the resources of many different semantic theories (e.g., possible-world semantics [Bergman, 1982; Hintikka and Sandu, 1994], semantic-field theory [Kittay, 1987], cognitive semantics

[Gibbs, 1994; Lakoff and Johnson, 1980; Sweetser, 1990], a componential semantics [Levin, 1977], a Wittgensteinian semantic, and David Kaplan's semantics for demonstratives [Stern, 1985]). Some use speech-act theory, claiming that metaphors are a feature of speaker meaning rather than sentence meaning (Searle, 1981) or that metaphors are, in the end, elliptical similes after all (Fogelin, 1988).

Newer comparison theories, versions of the theory that metaphors are elliptic similes or implicit comparisons and so do not have a distinctive meaning, explore the notion of figurative rather than literal similarity (Glucks and Keysar, 1990; Ortony, 1979). Some of these approaches offer a causal theory, opposing it to a semantic theory, claiming that metaphors cause us to make comparison by "intimating similarities" and have a causal effect of creating intimacy among speaker and listener (Cohen, 1978; Cooper, 1986). Questions remain concerning the relation between metaphor and literal language (e.g., Can the distinction be drawn in a clear fashion? Is the interpretative process the same or different? Is language originally metaphorical or literal?) and other non-literal languages (see Hintikka and Sandu, 1994; Jakobson, 1960).

The importance of metaphor in science was stressed by Mary Hesse (1970), who developed the understandings of metaphors as systematic analogies in which the "neutral"—that is, unexplored analogical relations—provide a distinctive source for predictive claims. Dedre Gentner (1982), a cognitive psychologist, along with her associates has identified features, such as systematicity and higher-order relations, that make some metaphors more productive for cognitive purposes than others.

Noting the affinity between metaphor and analogy has permitted a number of researchers in philosophy and psychology to make headway with computational approaches to metaphor—a promising tool for testing theories of metaphor and for understanding the extent to which accounts of metaphor are amenable to formal and precise accounts (Holyoak and Thagard, 1989; Steinhart and Kittay, 1994). Making use of advances in our understanding of metaphor, theorists have explored the role of metaphor in creativity, in language acquisition and concept formation, and in both the consolidation and the breakdown of habituated patterns of thought such as cultural prejudice. These latter developments (which have especially been taken up by feminist philosophers and other social critics) bring the question of the cognitive role of metaphor full circle, reconnecting it to its rhetorical force.

## METAPHOR [ADDENDUM]

This addendum confines itself to general accounts of the nature of verbal metaphor, setting aside work on such more specialized questions as whether metaphors are paraphrasable and such more general and speculative questions as whether the nonverbal arts provide convincing examples of nonverbal metaphor.

### SEMANTIC TWIST THEORIES

Semantic twist theories follow Beardsley in holding that a metaphor is a sentence in which a relation of tension or incongruity obtains among the standing meanings of its constituent words and phrases, a tension which is relieved when some of these meanings (those of what Max Black called the *focus*) change or "twist" so as to come into harmony with the others (those of the *frame*). Semantic twist theories have been devised to fit many different conceptions of meaning and of verbal incongruity (Kittay 1989, Ricoeur 1979, Skulsky 1992). Such theories have trouble accounting for sentences one takes to be metaphors despite the availability of a completely apt and pertinent literal reading, sentences one might call *twice-apt*. An example is the joke epitaph a friend composed for Thomas Hobbes: *This is the true philosopher's stone*.

### PRAGMATIC TWIST THEORIES

Pragmatic twist theories (Grice 1989, Searle 1979, Sperber and Wilson 1985/6) hold that when we indulge in metaphor, we use words and phrases with their standard literal meanings to *say* one thing, yet we are taken to *mean*—*taken as intending to convey*—something else. To put it another way, *our sentence as used by us* means one

thing, *we in using it* mean something else—where both "things" are straightforwardly propositional in character. Only by attributing some special meaning to *us* can listeners portray *our utterance* as an intelligible, cooperative contribution to a shared conversational enterprise. Metaphor becomes a mode of overt insinuation, akin to conversational implicature, loose talk, and indirect speech acts. (Theories of this second kind likewise have difficulty accounting for twice-aptness.)

### COMPARATIVISM

A new and more robust form of comparison theory (Fogelin 1988) holds that a metaphor "A is (a) B" is an elliptically presented comparison of its primary subject (A) to its secondary subject (B, or Bs in general), where this comparison is to be taken in a distinctively *figurative* manner, as a *simile*. Whether one takes it literally or figuratively, a comparison "A is like (a) B" is true just in case A shares sufficiently many of (a) B's most salient properties. Understanding metaphor becomes a matter of identifying a distinctively figurative way of deciding which properties of (a) B count as salient for present conversational purposes and how many of them count as sufficiently many.

### BRUTE FORCE THEORIES

Brute force theories (Davidson 1984, White 1996) hold that in metaphor no words go missing and neither words nor speakers mean anything out of the ordinary. Instead, an utterance that would otherwise be pointless or uncountable produces what Richard Moran (1989) calls a "framing effect": listeners are induced to view or consider or experience a primary subject A in a special light afforded by the sheer mention, in the midst of a discourse devoted to A, of the secondary subject B.

### CONCEPTUAL THEORIES

Conceptual theories (Lakoff 1993, Fauconnier and Turner 2002) hold that verbal metaphor is a manifestation of pervasive modes of thinking wherein people "map" one conceptual domain (e.g., love affairs with their successive stages) onto another (e.g., journeys with their successive stops) or "blend" the systems of terms in which they conceive two different domains.

### SEMANTIC ACCOUNTS

An assortment of recent semantic theories (Stern 2000, Walton 1993, Hills 1997) rehabilitate metaphorical truth and metaphorical sentence content outside the confines

of verbal opposition theories by drawing on more general accounts of pretense, presupposition, and demonstrative thought.

## METAPHYSICS

Physics is the scientific investigation of the fundamental nature of physical being. Metaphysics—at least within that tradition that traces itself back to Aristotle's eponymous treatise—is the philosophical investigation of the even more fundamental nature of being as such. Metaphysics is concerned with the contours of the categories of entity postulated or presupposed by any possible, acceptable, account of the world, whether of the physical world or of any other aspect of the world. The task of metaphysics is to lay out a complete, coherent ontology, embracing all that is necessary to capture the correct account of the world in any of the special inquiries—whether they be empirical, mathematical, modal, or moral.

### THE CHANGING METHODS OF METAPHYSICS

Traditionally, metaphysics was practiced as a top-down, a priori discipline, with Euclidean geometry as its model. The metaphysician begins with self-evident principles of a highly general nature, together with appropriate definitions, and proceeds to draw out the necessary consequences.

This approach is clearly exemplified in the work of two prominent eighteenth-century metaphysicians, Gottfried Wilhelm Leibniz and Benedict (Baruch) de Spinoza. Leibniz spun metaphysical gold out of the dross of the *principles of noncontradiction* and sufficient reason: His entire *Monadology* (1965), replete with an infinite collection of possible worlds, with the actual world (the best of all possible worlds) consisting of a myriad of mutually reflecting, simple, mind-like substances. Spinoza was even more self-consciously imitating Euclid, but his conclusions are almost diametrically opposed to those of Leibniz. Spinoza's ontology comprises exactly one substance (God-or-Nature), of which the mental and the physical realms are two aspects, and everything about the one Substance is absolutely necessary—only the actual is really possible.

In the light of its lofty aim, the conflicting conclusions of its practitioners, and their exaggerated claims to have achieved the aim with completeness and certainty, it

is perhaps unsurprising that the discipline of metaphysics, so practiced, has been regularly contested. Empiricists, led by David Hume, have often attacked a priori metaphysics, contrasting its lackluster or conflicting results with the astonishing successes of empirical sciences, on the one hand, and of mathematics on the other.

At the end of the eighteenth century, Immanuel Kant, in response to Hume's critique, attempted a partial vindication of a priori metaphysics. According to Kant, metaphysics can play a legitimate role as handmaid to science and a less straightforward role in upholding ethics. Through an analysis of the cognitive needs of thinking, sensing beings, it can establish the presuppositions of Newtonianism—Euclidean space, absolute time, deterministic causation, and enduring interacting substances obeying conservation laws. In addition, if a metaphysical hypothesis—the existence of God or the freedom of the will—is required for the smooth and effective operation of morality, then that may be legitimately adopted as though it were true, as a postulate of practical rationality. Kant's compromise evidently failed to rein in the metaphysical spirit, his work unleashing a century's worth of metaphysical system-building in an increasingly problematic idealist tradition.

In the late nineteenth century, the appetite for idealist metaphysics began to fade. A realist assault on this tradition was launched by Alexius Meinong, Bertrand Russell, Gottlob Frege, and George Moore, and their style of argumentation, as much as the content of their conclusions, was influential in shaping the twentieth century's more circumspect approach to metaphysics. Rather more radically a group of scientifically minded thinkers—inspired by Ludwig Wittgenstein's *Tractatus* (1922), rallying under the banner of Logical Positivism and brandishing a verificationist criterion of meaning—declared all metaphysical discourse completely meaningless. They argued that sentences that cannot be either verified by observation or proven by pure logic and are not merely beyond our knowing but are strictly speaking, *meaningless*. Echoing Hume, they denied any legitimate space for metaphysics between a posteriori science and a priori logic. The shortcomings of Logical Positivism were rapidly exposed (mostly by its adherents and fellow empiricists such as Karl Popper), but its offspring—ordinary language philosophy—cast over the metaphysical enterprise a pall that did not lift until the 1960s. Metaphysics, cautiously revived by heirs of both movements (albeit with notable differences in methodology detailed below), is once again a flourishing discipline in the early twenty-first century.

Contemporary metaphysics is characterized by a bottom-up approach rather than the traditional top-down approach. The contemporary metaphysician begins with a problem or puzzle, often generated by some basic data or the consequences of such data. The different sources of this basic data characterize two broad traditions. One tradition—championed by Moore, mediated midcentury by philosophers such as P. F. Strawson, Arthur Prior, and Roderick Chisholm and embraced by contemporary philosophers such as Frank Jackson—takes as prime data the deliverances of everyday discourse and commonsense, so called “Moorean facts”: for example, that I have two hands; that there is a piece of cheese in my left hand and a stick of chalk in my right; that the chalk and the cheese are distinct things; that cheese and chalk have the same color, and so on.

A different tradition, traceable back through the empiricists (such as Russell and Rudolph Carnap), mediated by Willard Quine, and embraced by philosophers such as John Smart, John Mackie, and David Armstrong, is less impressed with commonsense data. It takes the serious data to be constituted by the presuppositions and deliverances of extraordinarily successful scientific theories: that there is no role for the flow of time in a fundamental account of the world; that the fundamental laws are probabilistic rather than deterministic; that simultaneity is relative to motion; and that space-time may be non-Euclidean. The presuppositions and deliverances of the mathematical disciplines essential to science are also treated as serious data: for example, that there numbers, and an infinite class of such; that there are functions from numbers to numbers and that the infinite class of such functions is vastly bigger than the infinite class of numbers; that there can be no complete axiomatization of mathematical truth, and so on.

The two traditions overlap, of course, as exemplified in the work of prominent metaphysicians like David Lewis. Lewis (1981, 1986) draws extensively on both kinds of data, seeking an ontology compatible with and explanatory of both. However, if that's not possible, the data from the sciences usually trump those of commonsense.

To say that contemporary metaphysics is bottom-up is not to saddle it with a crude inductivism—the fallacious inference of general theories from finite data. The task of the contemporary metaphysician is not so much to *prove* an ontology, either from high-level first principles or from lower-level data, as to *propose* an ontology to accommodate and explain the data, to resolve apparent conflicts by explaining away the appearance of such, or

explain why the data are misleading. The methodology is less like that of pure mathematics and more like that of science—conjecture and refutation—with the difference being the kind of data that require accommodation or furnish a counterexample.

Given a finite amount of data, the number of potentially adequate metaphysical theories seems limited only by the imagination of practicing metaphysicians. To decide between theories we need more than data accommodation. Metaphysicians typically subscribe to *Occam's Razor*—the injunction to refrain from multiplying entities beyond necessity. The *Razor*, read as an endorsement of ontological abstemiousness, is sometimes considered a license to slash entities without regard for a complementary principle—the injunction to refrain from eliminating entities that are necessary. Necessary for what? For accommodating and explaining the data. The upshot of these two principles is, then, that a theory must explain the data; and, of two theories that both explain the data, the theory with fewer ontic commitments is to be preferred.

So, we begin with a domain of discourse—such as mind, or mathematics, or morality—and note that, on the surface at least, it supplies data that posit or presuppose an ontology. Our ordinary mind-talk, for example, presupposes mental states (experiences, thoughts, desires, emotions) along with physical states, and a rich network of causal interactions between them. Mathematics posits numbers, classes, functions, spaces, and a rich array of other abstract objects. Morality presupposes goods and evils, rights and obligations, virtues and vices. But there is often a problem with the entities posited or presupposed. For example, if the mind is something over and above the physical, how can it causally interact with the physical without violating physical laws? And if it is difficult to understand how the mind could affect physical states, it is even more difficult to see how numbers, existing outside space and time, could affect the mind. Whence, then, our knowledge of numbers? Finally, a good would have to be something the mere recognition of which would engage the will, and nothing (some will aver) could do that. The question arises, then, whether such things as minds, numbers, and goods should be counted among the indispensable building blocks of the universe. Is it coherent to postulate them? Are they consistent with the rest of what we know? And even if it is coherent, do we really need them to accommodate the data? Can they be explained, or explained away, in a complete, consistent account of the world? Already with the posing of such seemingly

unavoidable questions, the enterprise of metaphysics is up and running.

## A SPECTRUM OF METAPHYSICAL APPROACHES

Whenever entities are posited to explain the data provided by some domain of discourse, three broad responses, differing in ontological commitment, are possible. At one end of the spectrum we have *realism*, at the other, *antirealism*; between, we have *determinationism*. Each can be divided into two subcategories.

The realist with respect to a domain accepts both the discourse and the data at face value; affirms the necessity of the entities postulated to explain the data, and adds that the entities really are basic—they are additional to (or “over and above”) whatever else there may be. Realism comes in two broad varieties. Transcendent realism locates the posited entities outside the spatiotemporal, causal order. By contrast, immanent realism locates the entities within the spatiotemporal, causal order, typically ascribing them an indispensable causal role.

Most realists about numbers and other abstract entities have been of the transcendent variety, but recently, some number-realists have embraced immanence, espousing a role for abstract entities in the causal network. A transcendent realist theory of value is also usually ascribed to Plato—with the Form of the Good, like all the Forms, eternal and unchanging, existing “over and above” the transient realm of particular contingent beings. It is not hard to find naturalist theories of value that ascribe them a causal role, but as we will see below, there is an important sense in which naturalism about value is not fully realist—it does not posit value “over and above” the natural realm. A version of immanent value realism holds, like Platonic realism, that value is real, that it is something “over and above” the purely natural realm, but adds that value plays a causal role with respect to the motivational states of sensitive beings.

At the other end of the spectrum we have antirealism. The antirealist repudiates the entities in question, maintaining that the discourse that delivers the data is fundamentally misleading. But the data can be misleading in one of two very different ways. The data are recorded and delivered in what appear to be genuine, truth-bearing (or assertoric) claims. What masquerades as truth-bearing claims, however, might really be something else, and the nonassertoric antirealist says just that. Rather than being truth-bearing assertions, they might be expressions of desire, or moves in a language game, or instruments in the derivation of genuinely truth-bearing

assertions. In ethics, nonassertoric antirealism is *noncognitivism*; in the philosophy of science, *instrumentalism*; in the philosophy of math, *formalism*; in the philosophy of mind, the *intentional stance theory*; and so on. Nonassertoric antirealism allows apparent reference to the purported entities while denying there are any such.

The assertoric antirealist, by contrast, accepts that the discourse consists of genuine truth-bearing assertions but rejects those assertions as untrue. In the metaphysics of the mind, this constitutes *eliminativism* concerning the entities. In the metaphysics of morality, it is known as the *error theory*. An increasingly popular variant of assertoric antirealism, especially with respect to abstract entities such as numbers, is *fictionalism*. The fictionalist thinks that the relevant claims are untrue but also thinks that there is a point in continuing the discourse just as though they were.

Between realism and antirealism lie a collection of approaches that share a doctrine of *determination*. Like the realist, the determiner acknowledges the discourse and the data that suggest the disputed entities. Like the antirealist, however, the determiner denies that the disputed entities are basic, holding that the truth about the higher level is fully determined by the truth about ontologically more fundamental entities. Determinationism also comes in two varieties, *reductive* and *nonreductive*. The reductionist holds either that the disputed entities are reducible to more basic entities (entity reduction) or that all the facts about the disputed entities are reducible to facts about undisputed entities (fact reduction).

A necessary and sufficient condition for entity reduction is that the (apparently) higher-level entities are identical to lower-level entities, that properties of the reducible entities are identical to properties of the lower-level entities, and consequently that truths about the reducible entities turn out to be truths about the entities to which they reduce. The reduced entities are nothing but the lower-level entities to which they are reduced. Thus, for example, *logicism* claims that numbers are reducible to classes: The number zero, for example, is simply identical to the empty class; the number one is identical to the class of all singleton classes, and so on. The identity theory of the mind claims that mental states are identical to physical states of the brain. The ethical naturalist claims that moral properties (such as the rightness of actions) are identical to natural properties (such as maximizing expected happiness).

A classic example of reduction without entity reduction can be found in Russell's justly famous theory of

descriptions. In his *Principles of Mathematics*, Russell embraced Meinong's theory of nonexistent objects: that there are genuine objects—*possibilia* like the golden mountain and the King of France, and *impossibilia* like the round square—which have a range of features (the golden mountain is made of gold) but which lack the crucial feature of existence. In "On Denoting"—which set the tone for twentieth century analytic philosophy—Russell repudiated this ontology by showing that phrases that apparently denote such *possibilia* are not really denoting phrases at all. They do not denote particulars, and *they do not denote anything else*. Russell shows us a way of dispensing with nonexistent objects, but unlike the eliminativist, he does not repudiate the data or the discourse that suggest them. Rather, he shows how to translate the data into facts about properties. Nonexistents disappear from Russell's ontology theory, but the data that suggested them are fully accommodated. This is a kind of reduction without being a reduction of the problematic entities. It is a reduction of the *facts* about the purported entities while the entities are repudiated or "analyzed away." Let's reserve the term *fact reduction* for those cases in which every fact about some purported entities is equivalent to a fact about some other entities; there is no entity reduction, and the purported entities are repudiated.

Finally, we have nonreductive determinationism, which has gained considerable currency through the notion of supervenience in philosophy of mind. All determination theories affirm that there can be no difference in one kind of entity without a difference in another, more basic kind. For example, a widely held view is that there can be no difference in the moral without some difference in the natural. Another is that there can be no difference in the mental without some difference in the physical. The higher-level entities are thus determined by the lower-level entities. What is characteristic of a supervenience theory as such is that it posits this determination, does not repudiate the higher-level entities, but also denies the reducibility of the higher-level entities to the lower-level entities.

Supervenience is naturally located between reductionism and realism. The supervenience theorist agrees with the realist and the fact reductionist that the higher-level entities cannot be reduced to the lower-level entities but agrees with the entity reductionist that the higher-level entities are not ontologically basic. There is thus a sense (weaker than the reductionist sense) in which supervening entities are "nothing over and above" the basic entities, but there is also a sense in which the supervening entities, while falling short of the independently

real, enjoy some kind of autonomy denied reducible entities.

Those sympathetic to physicalism (viz., there is nothing over and above the physical) but skeptical that mental state kinds are identical to physical state kinds are attracted to the thesis of the nonreductive supervenience of the mental. Those sympathetic to naturalism (viz., there is nothing over and above the purely natural) but skeptical that moral properties are identical to natural properties are attracted to the nonreductive supervenience of the moral on the natural.

Supervenience theories share considerable common ground with *emergence* theories—lately enjoying something of a revival—and it is interesting that supervenience is popular in domains (such as philosophy of mind and philosophy of biology) where emergence theories also seem a promising compromise between realism and reductionism.

Whether or not there is logical space for nonreductive determinationism has not yet been satisfactorily settled. Like other attempts to forge middle paths between two clear alternatives, a supervenience theory embodies a certain instability, suggesting to some that, in the end, the supervenience advocate will either be forced to embrace the reductionism eschewed or lapse into a form of realism.

One particularly important determination theory is worth singling out for special attention since it has played a pivotal role in the history of metaphysics—namely, determination by the mental (or *mind-dependence*). Broadly speaking, this is *idealism*, and it is a perennially attractive option—indeed, so attractive that idealism has often been taken to be *the* rival to realism. Bishop George Berkeley famously claimed that physical objects are nothing but (are identical to) congeries of experiences. The notorious problem of maintaining the intermittently observed tree in the quad in uninterrupted existence led Berkeley to posit an *omniobserver*, someone to keep a perpetual eye on things. A different response to this problem moves beyond actual experiences to various potential experiences. Physical differences that go undetected may be *detectable* by observers under suitable hypothetical conditions. (If you were in the quad, or having in-the-quad experiences, *then* you would have tree experiences.) An idealist could add those conditional states to the determination base. This move, from Berkeleian idealism to phenomenalism, might be a move from entity reduction to fact reduction, or it might be a move from entity reduction to supervenience. If physical objects “disappear” in the final analysis leaving behind the truths that

appear to be about them, then we have fact reduction. If physical objects are not identified with anything else, reference to physical objects as genuine entities remains, and the totality of facts about such objects is determined by the actual and conditional facts about experiences, then we have a version of supervenience.

Faced with the fact that actual minds have various cognitive shortcomings, the idealist may also want to tidy up both actual and potential mental states in various ways. The physical facts are held to be determined not by the actual mental states of existing observers but by the mental states that *ideal observers* would have if they were ideally placed. Hence, variations on the basic idealist theme of mind dependence include *positivism*, *ideal limit* theories of truth, and related accounts such as *internal realism*. Many who regard Berkeleian idealism about the physical world as deeply implausible have embraced some version of idealism in other domains—with respect to mathematical entities, theoretical entities, God, possibilities, colors, values, and universals. This three-fold classification helps explain why there is a certain amount of confusion in debates about realism since *antirealism* and *nonrealism* (the disjunction of antirealism and determinationism) and are not usually defined or carefully distinguished.

#### A PROBLEM IN METAPHYSICS: UNIVERSALS AND PARTICULARS

These patterns of opposition and compromise—realism versus antirealism, with determination seeking a middle way—have played out across the metaphysical spectrum. They find a particularly clear expression, however, in a problem of central concern to metaphysics since its very inception—the problem of universals and particulars, a problem the intrinsic interest of which proves prefatory to its myriad applications. For one’s attitude toward universals and particulars has profound implications for one’s attitude to a host of other problems—those of abstract entities, change, time, causation, identity, possibility, value, and morality.

Consider a stick of chalk (*A*), a wedge of cheese (*B*), and a chunk of chocolate (*C*). *A* is chalk and *B* is not chalk—it follows that *A* and *B* are not identical. This is an application the principle of the *indiscernibility of identicals*, often associated with Leibniz: If entity *X* is identical to entity *Y*, then anything true of *X* is also true of *Y*. This in turn is a consequence of the *principle of non contradiction*: that no proposition can be both true and false. So much seems straightforward, yet this sort of easy observation intersects with a second, equally obvious fact, to

create a puzzle: *A* is yellow and *B* is yellow. How can *A* and *B*, clearly distinct, be *the same*—that is, yellow? How can they be both the same and not the same? That's puzzling.

Whenever we strike an apparent contradiction (*A* and *B* are the same and are not the same), it is natural to make a distinction. *A* and *B* are not *numerically* the same (they are two) but they are *qualitatively* the same (they instantiate the property *yellowness*). Properties are instantiated by particulars one at a time—they are *monadic* universals. But there are also universals that characterize couples and triples. *Resemblance*, for example, is not a property that particulars have or lack. Resemblance involves pairs—it is a *dyadic* relation. And *betweenness*, which characterizes triples, is a *triadic* relation, and so on. The problematic data can be accommodated, and the apparent inconsistency explained away, by an ontology that posits two radically different categories of being—particulars and universals—and a relation of instantiation (itself a universal) holding between particulars and universals.

Responses to this two-tiered ontology have traditionally been categorized as either *nominalist* or *realist*, with a third category—*conceptualist*—sometimes thrown rather awkwardly into the mix. The six-fold schema set out above suggests that the space of possibilities is much richer. With respect to universals, one might be *antirealist* (assertoric or nonassertoric), *determinationist* (reductive or nonreductive), or *realist* (transcendent or immanent). Further, any of those positions might be combined with one of the six distinct approaches to particulars. So in all there are thirty-six possible combinations, not just two or three. For example, one might be a transcendent realist about both universals and particulars, or an immanent realist about one and a reductionist about the other, or a reductionist about both universals and particulars (invoking some third category of entity to which both reduce), and so on. Not all of these combinations have been embraced, but many have. For the purposes of illustrating the approaches and the arguments that characterize them, a few of the more commonly held positions are sketched.

#### REALISM ABOUT PARTICULARS, NONREALISM ABOUT UNIVERSALS

A particular, unlike a universal, lacks the mysterious capacity to be “fully present” in distinct particulars. We feel we understand particulars, perhaps because we are experientially acquainted with them. We do seem to be acquainted with concrete particulars—such as bits of

chalk, cheese, and chocolate. But there are other purported entities that strike us as particular rather than universal that are not like these—for example, numbers, classes, propositions, and possibilities. And there are others that are difficult to categorize—such as space and time.

*Particularism* embraces realism about particulars—there are particulars, and particulars are not reducible to anything more basic—and adds that the *only* basic entities are particulars. It is thus a one-tier ontology with both considerable simplicity and commonsense in its favor. Particularism affirms that anything at all (universals, numbers, classes, possibilities, causation, space, time) is either eliminable or reducible to particulars. *Concrete* particularism is more austere, restricting fundamental being to concrete particulars, the paradigms of which are physical objects. The concrete particularist is a realist about concrete particulars and is typically an immanent realist, assigning particulars both spatiotemporal location and a role in the causal order. There are versions of transcendent realism about particulars although typically transcendent particulars will be abstract rather than concrete (for example, numbers, classes, and possibilities).

In what follows particularism is combined with five different versions of nonrealism about universals. These five accounts have all been called “nominalisms,” but the nomenclature is not particularly perspicuous. Sometimes nominalism connotes *concrete particularism*; at others, the broader doctrine of *particularism*. Sometimes it connotes *antirealism* about universals; at others, *determinationism*. *Predicate nominalism*, which holds that there are just particulars and the words (names) we call them by, is perhaps the clearest candidate for the title. *Mereological nominalism* combines concrete particularism with reduction of universals. *Conceptualism*, sometimes called “concept nominalism,” is a version of idealism—reduction of universals to mental particulars. *Extensionalism*, sometimes called “class nominalism,” is a reduction of universals not to concrete particulars but to classes of concrete particulars. Finally, *resemblance theories* are determinationist and may be of either the reductive or nonreductive kind. The determination base includes concrete particulars and resemblances between them.

**PREDICATE NOMINALISM AS AN ELIMINATIVIST PARTICULARISM.** The most austere version of nominalism—often called *word* or *predicate nominalism*—is naturally construed as concrete particularism combined with eliminativism about universals. It holds that there are concrete particulars and there are the predicates

(words) we apply to them, and that is all. Simply put: Things are yellow because we call them “yellow.” We call things by the same name—*A* and *B* are both called “yellow”—but there is no need to postulate a universal of yellowness instantiated by all things so called. (Distinct people are called “Brian,” but we do not postulate a universal *Brianness*.)

The predicate nominalist repudiates universals rather than reducing them to particulars but accommodates the data by means of the following equivalences:

*A* is yellow  $\Leftrightarrow$  *A* is called “yellow.”

*B* is yellow  $\Leftrightarrow$  *B* is called “yellow.”

*C* is brown  $\Leftrightarrow$  *C* is called “brown.”

On the left-hand side we have some Moorean facts, which apparently presuppose concrete particulars (*A*, *B*, *C*) and universals (yellowness; brownness). However, the right-hand side supplants reference to a property with reference to a predicate. Since it is implausible to identify yellowness with the predicate “yellow,” the position is plausibly construed as denying the universal yellowness: There is a word “yellow,” we call a bunch of things “yellow,” and if we call them “yellow,” they are yellow (end of story).

Some criticisms of word nominalism are worth sketching because they involve argument kinds that crop up repeatedly in this area. The word nominalist’s explanation of the data seems backwards. Distinct things are not made yellow by virtue of being called “yellow;” they are called “yellow” because they are one color, conventionally dubbed “yellow.” If we call a person “Brian,” then for any other similar person—for example, his identical twin—it is a matter of separate convention whether we also call him “Brian.” But if we call a color sample on a chart “yellow,” and another sample is qualitatively indistinguishable from that, the original convention covers the second color sample, and we call it “yellow,” too.

Secondly, since there are only concrete particulars, words must also be concrete particulars. How many words are there on the following line?

yellow, yellow

There are two answers: two and one. There are two concrete words but only one dictionary entry at issue. We must distinguish between *word-tokens* and *word-types*. On the one hand, word-tokens are spatially located, unrepeatable, concrete particulars. A word-type, on the other hand, has distinct word-tokens as instances. Word-types look very like universals. Elimination of one universal—

yellowness—has only been achieved at the cost of accepting another—the word-type “yellow.”

To eliminate this word-type, the nominalist might deploy the complex predicate “called ‘tokens of the word-type ‘yellow.’”” But this launches a regress, for the same problem resurfaces for applications of this new predicate. Universals are eliminated at one level only to have them pop up in the shape of word-types at the next. Only if word-types at all levels are eliminable in favor of word-tokens will universals be exorcised, but that would require an infinite supply of word-tokens, and there are just not enough to go around. The nominalist might invoke *possible* word-tokens here, but that would launch the nominalist beyond the actual world into the problematic outer space of possibility—not a happy place for nominalists to venture.

Finally, chalk is *called* “yellow,” but the cheese is also *called* “yellow.” *Calling* involves many distinct particular-word pairs—it seems to be a dyadic relation linking particulars and word-tokens, and relations are universals. If one tries to eliminate this relation in favor of another word, we are again launched on a tiresome regress.

There is an alternative construal of predicate nominalism according to which yellowness is eliminated in favor of a different property—*being called* “yellow.” But this would be neither elimination of universals (since both properties have an equal claim to being universals) nor a reduction of universals to particulars. It is simply a proposal to economize within the class of universals itself. As Lewis noted in a different context (possibility), it is not just the number of entities that fall within an ontological category that matters to ontic simplicity, but more importantly, it is the number of basic ontological categories countenanced. If there is something unsatisfactory about the *category* of universal, then whether you admit one, or a million, or an infinite array is immaterial—your attempt to eliminate universals fails.

**MEREOLOGICAL NOMINALISM AS ENTITY REDUCTION.** Predicate nominalism is an eliminativist version of concrete particularism, but there are reductionist versions too—*mereological nominalism*, for example. Mereology is the theory of the part-whole relation. Some particulars are parts of other particulars. The top of the pen and the body of the pen are both proper parts of the pen, and the pen is the mereological sum of the body and the top. The pen continues to exist even when the top is removed and its parts are separated. Perhaps the chalk and the cheese are also parts of a particular, a spatially scattered whole made partly of chalk and partly of cheese.

Starting with  $A$ ,  $B$ , and  $C$ , there are at least four such distinct, albeit overlapping, mereological sums— $(A+B)$ ,  $(B+C)$ ,  $(A+C)$  and  $(A+B+C)$ —yielding at least seven distinct concrete particulars in total. Note that sameness of parts entails sameness of whole:  $((A+B)+A)$ , for example, has just two parts,  $A$  and  $B$ , and so is identical to  $(A+B)$ . If there are  $n$  basic (nonoverlapping) concrete particulars, then, assuming the principle of *unrestricted mereological composition* (that every sum of concrete particulars is itself a concrete particular), there are  $2^n - 1$  concrete particulars. The principle is controversial, but one way of characterizing concrete particularism is this: The principle of unrestricted composition places an upper bound on the collection of entities.

Let  $S(F)$  be the mereological sum of all particulars to which predicate  $F$  applies— $S(\text{yellow})$  is the sum of all yellow things. Plausibly, something is yellow if and only if it is a part of  $S(\text{yellow})$ . This suggests the following analysis:

$X$  is  $F \Leftrightarrow X$  is a part of  $S(F)$

Note that the analysis assumes that for any predicate  $F$ , the sum of all things with  $F$  is also a concrete particular. However, it does not assume unrestricted composition—for there may be collections of particulars to which no single predicate applies. This mereological analysis, if adequate, might allow us to identify the property  $F$ -ness with  $S(F)$ , a concrete particular.

Mereological nominalism accommodates quite a lot of data about properties such as *water* and *yellow*. But take two related properties such as *water* and *single H<sub>2</sub>O molecule* that involve the part-whole relation—a quantity of water has parts that are single H<sub>2</sub>O molecules. Mereological particularism entails that for something to be water, it has to be a part of  $S(\text{water})$ , and for something to be a single H<sub>2</sub>O molecule, it has to be part of the  $S(\text{single H}_2\text{O molecule})$ . But these two sums are *identical*—sum all quantities of water, and sum all single molecules of water, and you arrive at the same whole. So mereological nominalism entails that to be water just is to be a single molecule of water—and that, unfortunately for the theory, is just false.

**CONCEPTUALISM AS IDEALISM ABOUT UNIVERSALS.** The attraction of conceptualism is that it reduces universals to something concrete, particular, and also mind-friendly: *concepts*. Concepts are things that the mind can get a handle on whereas universals may be problematic in that respect. The beginning idea is that the cheese is yellow if and only if the cheese falls under the concept of yellow. Quite generally, where  $C(F)$  is the concept of  $F$ , we have:

$X$  is  $F \Leftrightarrow X$  falls under  $C(F)$ .

We can thus explain the data by appealing to a concept—an apparently familiar mental particular—rather than a mind-independent universal.

Our mental vocabulary (such as belief, thought, desire) suffers a pervasive state-content ambiguity. *My belief that the cheese is yellow* might be my state of believing, as in: “My belief that the cheese is yellow, given my aversion to yellow cheese, made me refuse it.” But it might also be the content of my belief, as in: “My belief is just the same as yours: that the cheese is yellow.” Our believings are distinct entities, but what we believe here is the same. Believings are mind-dependent (which believings there are depends on who believes what), but the common content of distinct believings does not depend on what you or I believe.

Concepts also suffer the state-content ambiguity—there are concept-graspings and there are the concepts grasped. Concepts in the state-sense are mind-dependent (which concept-graspings exist depends on who is grasping what), but the contents of such graspings do not appear to be mind-dependent.

The conceptualist may eschew concepts as contents of graspings in favor of a myriad different and individual graspings. But your grasping of yellow has something in common with mine. What is that? If we apply conceptualism to this datum then, as with predicate nominalism, we are launched on a regress and there will not be enough particular concept graspings to accommodate all the data.

**EXTENSIONALISM: REDUCTION OF UNIVERSALS TO CLASSES.** For every predicate  $F$  that may or may not apply to a particular, there is the class of all and only the particulars to which  $F$  applies in fact, the extension of  $F$ — $E(F)$ . In our example, class  $\{A, B\}$  is the extension of *yellow*,  $\{C\}$  the extension of *brown*. Something is yellow if and only if it is in the class of yellow things. So the following is an apparently necessary equivalence:

$X$  is  $F \Leftrightarrow X$  is a member of  $E(F)$ .

This suggests identifying  $F$ -ness with its extension,  $E(F)$ . (After abandoning concrete particularism, Quine adopted extensionalism.)

Extensionalism is sometimes called “class nominalism,” but the postulation of classes marks a real departure from concrete particularism. Classes may be particular, but they are not concrete. Classes are “over and above” the concrete particulars that are their members, and Nelson

Goodman's criterion explains why. Starting with  $A, B, C$  there are at most seven concrete particulars. However, there are many more classes. There are seven nonempty classes of particulars. Each one pairs off with a mereological sum— $\{A, B\}$  with  $A+B$ ,  $\{A\}$  with  $A$ , and so on—but we cannot identify these classes with the corresponding concrete particulars. Classes are individuated by membership: They are identical if and only if they have exactly the same members (the principle of extensionality). So the singleton class  $\{A\}$  is a distinct entity from its sole member  $A$ . A piece of cheese is not a class consisting of a piece of cheese. Quite generally a class is not the mereological sum of its members.

Once we acknowledge classes of classes, the hierarchy of classes “over and above” the concrete particulars,  $A, B, C$  explodes into a vast and infinitely intricate structure, one massively exceeding the modest seven-member ontology of mereological sums countenanced by the concrete particularist. The two-membered class  $\{\{A, B\}, A\}$ , for example, is distinct from the two-membered class  $\{A, B\}$ . The former has a member  $\{A, B\}$  that the latter lacks. Contrast this with  $((A+B)+A)$  and  $(A+B)$ —the same concrete particular.

Extensionalism, a radical departure from nominalism, thus has plenty of resources—but does it have enough to do justice to the data? Being a chordate is the property of being a heart-bearing animal; being a renate, the property of being a kidney-bearing animal. These are distinct properties. As it happens, these two properties have the same extension. Extensionalism thus entails that they are one and the same property. As generous as the ontology of classes is, it is not generous enough. This *coextension problem* is a classic example of an argument against a reduction thesis. The reduction base is shown to be insufficiently rich to capture all relevant entities.

A different criticism suggests that there are too many classes as well. A universal involves sameness. There are, however, “arbitrary” collections of concrete particulars exhibiting no genuine sameness. If the sameness of  $A$  and  $B$  (yellowness) reduces to the fact that both are members of  $\{A, B\}$ , why does not the fact that  $A$  and  $C$  are both members of  $\{A, C\}$  yield a genuine sameness there? The class theorist could bite this bullet and accept that all classes are universals. (Bullet-biting is a rather common response to recalcitrant data.) A different response would be to block the counterexample by declaring that only certain “natural” classes are genuine or have what it takes to be universals. (This response exhibits an ad hocness that is arguably worse than bullet-biting.)

An explanatory asymmetry argument against extensionalism is often deployed. It is claimed that  $A$ 's being yellow *explains*  $A$ 's membership of the class of yellow particulars, not the other way around. This claim contradicts the extensionalist's claim that these facts are really one and the same. The extensionality principle, however, entails that if  $X$  is a member of a class  $C$ , then *that very class* could not have lacked  $X$ —any class  $C^*$  that lacks  $X$  is *necessarily* distinct from  $C$ . That  $A$  is a member of  $\{A, B\}$  is necessary. That  $A$  is yellow is, by contrast, contingent. No contingent fact explains a necessary fact, and so the argument fails. Even though it fails, it suggests a different argument. It follows, by the indiscernibility of identicals, that a contingent fact (such as  $A$ 's being yellow) cannot be a necessary fact (such as  $A$ 's being a member of  $\{A, B\}$ ). But extensionalism entails they are the same fact. Call this the *necessary extension* problem.

The coextension and necessary extension problems are closely related. The reason chordate and renate cannot be identified with the class that is their common extension is that their extensions *might* well have differed from each other. And that presupposes that they have their extensions contingently, not necessarily. Since chordate and renate differ in their possible extensions, one way of modifying extensionalism would be to expand the reduction base to include possibilities. Two accounts have predominated. One embraces possible but nonactual particulars and takes the extension of property  $P$  to be the class of actual and nonactual particulars that have  $P$ . (This presupposes that particulars are world-bound—no particular appears in more than one possible world.) Another is to include possible but nonactual *worlds* with common or overlapping domains of particulars. In each possible world  $W$ , the property  $P$  has an extension in  $W$ . The property  $P$  thus induces a function  $F(P)$  from worlds to extensions—and a reductionist might identify  $P$  with the function  $F(P)$ . These accounts are both reductionist, presupposing different accounts of possibility. They go well beyond the domain of concrete particulars entertained by traditional extensionalists, and they are both known as *intensional* accounts of universals.

Despite the richness of the framework of worlds and functions, however, it may still not be rich enough to capture all the data. Being *triangular* is the property of being a plane figure with three angles. Being *trilateral* is the property of being a plane figure with three sides. Because each logically necessitates the other, these properties induce the very same function from worlds to classes of concrete particulars (or classes of possibilities), and so even these intensionalist accounts render them identical. If

they are not identical, then we need something more discriminating than functions from worlds to classes of particulars with which to identify them.

**RESEMBLANCE THEORIES: REDUCTION AND SUPERVENIENCE.** An important group of theories claim that property facts are determined by facts about resemblance. A crude version of the resemblance theory invokes paradigms, and resemblance to such paradigms—namely, where  $P(F)$  is a specified paradigm of  $F$ :

$X$  is  $F \Leftrightarrow X$  resembles  $P(F)$ .

The shortcomings of the paradigm account are numerous. It entails, for example, that the designated paradigm of yellowness is *necessarily* yellow (since everything necessarily resembles itself). It also entails that anything resembling  $P(F)$  in any respect at all is  $F$ . A far more promising account draws on the notion of *similarity circle*—a class such that all the members of the class resemble every member of the class, and nothing outside the class also resembles every member of the class. Provided that there is sufficient variety in particulars, similarity circles carve out what are, intuitively, the genuine universals without the necessity for privileging any particular. This might be regarded as a reduction of universals to classes of particulars plus resemblances, but it can also be regarded as a supervenience thesis: Properties supervene on a basis consisting of resemblance and the domain of particulars. There can be no difference in properties without some difference in the structure of resemblances—same resemblance structure, same properties.

As Russell famously noted, any account that grounds properties in resemblance faces a problem. Resemblance is a relation between particulars and as such seems to be a universal. It might be considered an ontological saving to reduce myriad universals to one, but as noted in the context of word nominalism, what is important is the number of nonempty ontological *categories*.

This criticism of resemblance theories can be generalized to any attempt to reduce universals to something “else.” Suppose we reduce property  $P$  to some entity  $\text{Reduct}(P)$ : the class of  $P$ s; the mereological sum of  $P$ s; the concept of  $P$ ; the similarity circle that corresponds to  $P$ , and so on. The reductionist says that for  $X$  to be  $P$  is for  $X$  to bear some suitable relation  $R$  to  $\text{Reduct}(P)$ . But the reductionist is then forced either to admit one universal—the relation  $R$ —or to apply the theory to  $R$  itself, launching an unhappy regress.

Resemblance theorists might employ the *tu quoque*, charging that the realist faces a similar regress. Assume

realism: For  $X$  to be yellow is for  $X$  to instantiate ( $I$ ) the universal yellowness ( $Y$ ). But then, for  $X$  to instantiate  $Y$  is for a certain triple— $X, Y, I$ —to stand in a relation,  $I^*$ .  $I^*$  cannot be  $I$ . For one thing  $I$ , is a dyadic relation, and  $I^*$  is a triadic relation. For another, this would involve a relation taking itself as one of its own *relata*. So  $I^*$  is distinct from  $I$ . We can repeat the argument to obtain a third relation  $I^{**}$ , and so on. So the realist is thus as much involved in a regress as any of the reductionist rivals.

The realist might appeal to the category response: The regress is damaging to the particularist because it shows that the category of relation cannot be done away with. That’s an internal inconsistency. But the realist about universals does not object to that category being nonempty, and even an infinite class of distinct instantiation relations constitutes no embarrassment for realism as such. Of course, a realist who wants to keep the number of universals down to a small or finite collection might be embarrassed.

Finally, the resemblance theorist may run out of the kind of variety in actual objects required to set properties apart. (Renate and chordate are still coextensive.) To increase the variety and block a coextension objection, the resemblance theorist might take a now familiar tack—embracing relations of resemblance between *possible* as well as actual particulars. As with the related attempts to deflect counterexamples by invoking possibilities, this constitutes a significant and not entirely unproblematic expansion of the reduction base. Certainly it violates the original nominalistic spirit that inspired it.

## REALISM ABOUT BOTH PARTICULARS AND UNIVERSALS

One explanation for this apparent failure to eliminate or reduce universals is realism—that universals are neither eliminable, nor reducible, nor supervenient. That this is no proof of realism is obvious—we may not have exhausted all possible alternatives. However, realism about universals conjoined with realism about particulars does explain these failures, as well as providing an explanation of the ubiquitous Moorean facts of predication.

**TRANSCENDENT REALISM ABOUT UNIVERSALS.** What is often called *ante rem* realism, or Platonic realism, is a transcendent realism: that irreducible universals exist of necessity, beyond contingency in general, and beyond the contingent causal network in particular. One powerful explanatory principle, typically embraced by transcendent realists (Plato perhaps) states that any

meaningful predicate, whether simple or complex, applies to things in virtue of designating a genuine universal. So not only contingent predicates such as “black” and “raven” designate universals, so, too, do predicates that apply of necessity (such as “self-identical”); predicates that apply to nothing (such as “unicorn”); predicates that apply to nothing of necessity (such as “self-distinct”); and finally, not only simple predicates (such as “black” and “raven”) designate universals, but so do complex predicates (such as “black raven,” “not black,” “black or raven,” “black if and only if a raven,” and so on). Since predicates apply to universals themselves (e.g., *yellowness is a pretty color*), universals are instances of other universals. This *unrestricted transcendent realism* makes the domain of universals a largely a priori affair.

Perhaps the greatest threat to unrestricted transcendent realism is Russell’s paradox. Particulars have properties (such as being honest or cowardly), but properties also have properties (honesty is virtue, chalkiness is a universal, a piece of chalk is not a universal), and those properties have properties in turn (virtue is good, being a universal is something all universals have in common, being a particular is a universal not a particular).

By unrestricted realism the two predicates—*being a universal* and *being a concrete particular*—designate two universals, *U* and *P*. All universals have *U* in common. *U* is a universal, and so *U* itself has *U*. *U* is *self-predicating*. However, *P* is not a concrete particular (it is a universal), and so *P* is *non-self-predicating*. Given unrestricted realism, the meaningful predicate *non-self-predicating* designates a universal, *N*. Each universal either has *N* or lacks *N*. If *N* has *N*, then *N* is non-self-predicating—but then *N* does not self-predicate and so *N* lacks *N* (contradiction). If *N* lacks *N*, then *N* is not non-self-predicating; that is, *N* is self-predicating, and so *N* has *N* (contradiction again).

Russellian paradoxes can be constructed for just about any account of universals, including the most austere version of predicate nominalism. (The predicate “short” is called “short,” but the predicate “long” is not called “long.” Call the former “self-predicating” and the latter “non-self-predicating.” Is the predicate “non-self-predicating” called “non-self-predicating”? Paradox ensues.) Russellian paradoxes are thus too pervasive, the realist might claim, for them to be peculiarly damaging to realism. Still, short of embracing paradoxes, the realist has an obligation to deflect them.

Any adequate realist answer to Russellian paradoxes must involve some restriction on the predicates: namely, not every apparently meaningful predicate necessarily

designates a universal. Russell’s theory of types is a classic restriction. Type theory stratifies entities. Simplifying somewhat: particulars are type-0 entities, properties of particulars are type-1 entities, properties of (type-1) properties are type-2 entities, and so on. A type-0 entity may either have or lack a type-1 property, and a type-1 property may have or lack a type-2 property, but no property either has or lacks a property of the same type. A property is always one type higher than the highest type of entity to which it can be sensibly applied or denied. Thus, the question of whether a universal *P* has or lacks *itself* does not arise. It is neither true nor untrue that *P* lacks *P*. The very attempt to apply *P* to itself is a *category error* (like the attempt to apply the color green to the number 7), and so the predicates “self-predicating” and “non-self-predicating” are literally *meaningless*. (The notion of a category error took on a life of its own long after Russell’s theory of types lost the attention of most philosophers.) The paradox is blocked because there are no universals of self-predication or of non-self-predication.

The chief worry about a type theory is that it rules itself out as unsayable—to state it one must violate its strictures. Take the claim *no universal can be applied to, or denied of, a universal of the same type*. This makes a perfectly general claim about all universals. What type does the universal of being a universal (*U*) belong to? It cannot consistently be assigned a level. It is this problem that undergirds the famous theme of Wittgenstein’s *Tractatus*, that philosophy consists of things that can be shown but cannot be said.

**IMMANENT REALISM ABOUT UNIVERSALS.** An important group of restricted realist theories trace their ancestry to Aristotle. Not every predicate picks out a universal, and it is a contingent matter, to be settled a posteriori, what universals there are. *In rebus* realism is a version of immanent realism. It begins with the simple idea that universals exist only in their instances. If a universal is not instantiated, it does not exist. Consequently, a predicate must apply to a particular for it to designate a genuine universal. This *instantiation condition* prohibits universals such as unicornhood. It also rules out various truth-functional combinations of universals. Even if *black* and *raven* are both universals, the predicate “not black and a raven” does not designate a universal (since all ravens are black).

Armstrong, a prominent advocate of immanent realism, places two further conditions on a predicate for it to designate a universal. Firstly, the predicate must apply in

virtue of a *genuine identity* in the particulars. Even if *yellow* and *raven* are both universals, the disjunctive predicate “yellow or a raven” does not pick out a universal, despite being instantiated, because there is no qualitative identity exemplified by a yellow submarine and a black raven. Secondly, Armstrong draws on a condition inspired by the Eleatic Stranger in Plato’s *Sophist*, who makes the intriguing suggestion (known as the *Eleatic Principle*) that the mark of being is causal power. Armstrong requires that to be real, a universal must feature in causal laws. (Universals must do some work for their living.)

The Eleatic Principle gives natural science a crucial role in delineating the ultimate constituents of being. Interestingly, it also suggests an immanent realism that denies the instantiation condition. Michael Tooley has argued, within the same immanent realist framework, that there could be properties that play a genuine role in the causal order, because they enter into basic causal laws, but that could remain uninstantiated. If causal power is the mark of the real, it would be hard to deny them ontic standing, but if so, they are not *in rebus* universals—they exist independently of their exemplification by particulars. Clearly, there is wide scope for other, quite different versions of both transcendent and immanent realism about universals.

#### REALISM ABOUT UNIVERSALS, REDUCTIONISM ABOUT PARTICULARS

If one embraces realism about universals, then, for the sake of simplicity, it would be worthwhile exploring the reduction of particulars to universals. Every particular  $X$  comes along with a bundle (or a class) of properties,  $B(X)$ —the class of all the properties it has. Further, an object  $X$  has property  $P$  if and only if  $P$  is a member of  $B(X)$ . This suggests that we embrace just one entity (the bundle) rather than two (the particular and its bundle). The bundle theory identifies a particular with the bundle of its properties.

This bundle theory faces problems analogous to the reduction of universals to classes of particulars—both too many classes and not enough classes. Firstly, there are too many classes. The class {golden, mountain} does not pick out any actual concrete particular—the golden mountain does not exist. This fact, however, may not be considered entirely undesirable. Meinong famously argued that metaphysics needs to accommodate data pertaining to the nonactual as well as to the actual. To explain the nonexistence of the golden mountain, the golden mountain must be an object with a specific nature, a nature that it possesses of necessity. If being

golden and mountainous were contingent properties of the golden mountain, then who is to say that Kilimanjaro is not the golden mountain? The bundle theory thus dovetails nicely with this theory of possible objects.

The bundle theorist still owes us an account of the distinction between concrete existent particulars (Kilimanjaro) and merely possible particulars (the golden mountain). Meinong thought that it is their completeness that sets them apart. Kilimanjaro is complete—for every property, Kilimanjaro either has it or lacks it. The golden mountain is incomplete—it is a mountain, and it is made of gold, but for many properties (e.g., *more than 1 mile high*), it neither has the property nor lacks it. But this will not do—we could specify complete bundles of properties that do not correspond to any concrete particular.

Are there enough bundles of properties to accommodate all particulars, or does the bundle theory face a coextension problem? A bundle theory of particulars entails the Identity of indiscernibles (the converse of the indiscernibility of identicals): If  $X$  and  $Y$  are qualitatively identical (share all properties), then  $X$  and  $Y$  are numerically identical. This principle would be trivially true provided conditions such as *being identical to  $X$*  were genuine properties. But the bundle theorist cannot start with properties that presuppose antecedently given particulars. The bundling properties would have to be purely qualitative. But then it does seem possible for distinct particulars to share all their purely qualitative properties. (Quantum theory, for example, entails that it is possible for two bosons to share their fundamental quantum states—including the state corresponding to location.) That is incompatible with the bundle theory.

An essential property of a particular is a property without which that particular would not exist. It is controversial whether there are essential properties, and if so, which properties of any given particular are essential. However, there is widespread agreement that not every property of a particular is essential to it. At least some properties are such that an item could lose them without going out of existence. The bundle theory suffers an analogue of the necessary extension problem. Classes by their nature are necessary, eternal, and unchanging. So the bundle theory would appear to entail *super-essentialism*: that every property of a particular is essential to it; that if a particular lost a property, it would cease to be.

#### REJECTING REALISM ABOUT UNIVERSALS AND PARTICULARS

The space of possibilities is not restricted to reduction in one of two directions. Universals and particulars might

both be reduced to some third, more basic, kind of entity. One prominent example of such an approach is *trope theory*.

A trope (this patch of brownness, that instance of sweetness) is a particularized universal—a particular instantiation of a universal by a particular. Put like that, of course, tropes apparently presuppose both particulars and universals. They appear to be nonbasic entities. But it is a characteristic move in metaphysics to take as ontologically basic something that has hitherto been assumed to be derivative and reverse the ontological order.

Tropes have the advantage of incorporating both particularity and qualitative character in their nature and are thus promising building blocks. The proposal is that particulars and universals are both classes of tropes, albeit different kinds of classes: Particulars are classes of *co-located* tropes—tropes occupying the same space and time—and universals are classes of *exactly resembling* tropes. A particular *X* has property *P* just in case the class of co-located tropes that make up *X* overlaps with the class of resembling tropes that constitute *P*.

Trope theory has the advantages of simplicity and comprehensiveness. Further, it avoids the co-extension problem that besets extensionalism. No redness trope is identical to a roundness trope. So even if *redness* and *roundness* always go together (they are always co-located) the class of all roundness tropes is a distinct class from that of redness tropes.

Trope theory retains the necessary extension problem. Classes have their members by necessity, but a concrete particular does not have its properties by necessity. By identifying predication with the intersection of two classes, trope theory implies that all predications are necessary. Again, such problems may be avoidable by invoking possible worlds, but only at the cost of expanding the reduction base to something that makes the resulting reduction rather costly in terms of ontological resources.

## THE FUTURE OF METAPHYSICS

The proposed schema for locating metaphysical theories is applicable in all of the various domains of the discipline, and the argument patterns for realism, antirealism, and determinationism bear important similarities across those domains. The basic data might involve claims about time, causation, possibility, the fundamental truths of arithmetic, mental states, spatial relations, value, morality, and so on. Theorists will take the data and lay out an ontology to explain them, or explain them away, either taking the surface ontology at face value, explaining it in

terms of something more basic, or occasionally eliminating it altogether.

The modern metaphysician, aware of the underdetermination of theory by data, rarely expects or demands that the arguments conclusively establish any metaphysical proposal. Rather, the metaphysician will examine each metaphysical proposal on its explanatory merits, assessing first its explanatory adequacy with respect to the existing data, searching for new data to test and probe the proposal, and then turning to the more inherently contestable issues of theoretical elegance, economy, and overall coherence with other metaphysical theories. Inevitably, a considerable degree of fallibility and uncertainty remains. Still, that acknowledged, the future of metaphysics is no less secure than the future of science: Human beings can and will continue to probe the fundamental nature of the world right up to the limits of their cognitive abilities. Their doing so will, inescapably, implicate them in the enterprise of metaphysics.

## METAPHYSICS, HISTORY OF

The word *metaphysics* derives from the Greek *meta ta physika* (literally, "after the things of nature"), an expression used by Hellenistic and later commentators to refer to Aristotle's untitled group of texts that we still call the *Metaphysics*. Aristotle himself called the subject of these texts first philosophy, theology, or sometimes wisdom; the phrase *ta meta ta physika biblia* ("the books after the books on nature") is not used by Aristotle himself and was apparently introduced by the editors (traditionally by Andronicus of Rhodes in the first century BCE) who classified and cataloged his works. Later, classical and medieval philosophers took this title to mean that the subjects discussed in the *Metaphysics* came "after the things of nature" because they were further removed from sense perception and, therefore, more difficult to understand; they used Aristotle's frequent contrast of things "prior and better known to us" with things "prior and better known in themselves" to explain why the treatises on first philosophy should come "after the books on physics." In medieval and modern philosophy "metaphysics" has also been taken to mean the study of things transcending nature—that is, existing separately from nature and having more intrinsic reality and value than the things of nature—giving *meta* a philosophical meaning it did not have in classical Greek.

Especially since Immanuel Kant *metaphysics* has often meant a priori speculation on questions that cannot be answered by scientific observation and experiment. Popularly, "metaphysics" has meant anything abstruse and highly theoretical—a common eighteenth-century usage illustrated by David Hume's occasional use of *metaphysical* to mean "excessively subtle." The term has also been popularly associated with the spiritual, the religious, and even the occult. In modern philosophical usage *metaphysics* refers generally to the field of philosophy dealing with questions about the kinds of things there are and their modes of being. Its subject matter includes the concepts of existence, thing, property, event; the distinctions between particulars and universals, individuals and classes; the nature of relations, change, causation; and the nature of mind, matter, space, and time. In the eighteenth and nineteenth centuries *metaphysics* was used broadly to include questions about the reality of the external world, the existence of other minds, the possibility of a priori knowledge, and the nature of sensation, memory, abstraction, and so on. In present usage these questions are included in the study of epistemology.

### THE CLASSICAL PERIOD

The history of metaphysics in Western philosophy (taking "metaphysics" in the contemporary sense) began with speculations by the Ionian cosmologists in the sixth century BCE about the origin of the physical universe, the matter or stuff from which it is made, and the laws or uniformities everywhere present in nature. Our knowledge of these early cosmologists comes mostly from Aristotle and other classical authors; the main figures were the Milesians (Thales, Anaximander, and Anaximenes), Pythagoras, and Heraclitus.

**PARMENIDES.** The beginning of metaphysics, however, is most conveniently dated from Parmenides (fl. c. 475 BCE), since some of the typical characteristics of metaphysics as a distinct philosophical inquiry are present in, or at least suggested by, his surviving writings. These characteristics are, first, the conception of philosophy as an attempt to understand the universe by means of a logical investigation that is a priori, appealing to meanings of terms rather than to the evidence of the senses. This method is in contrast to the method of natural science, which relies on sense perception. Second is a more or less explicit use of very general principles viewed as sufficient to arrive at a true account of reality. Such principles were, for example, noncontradiction and something like a principle of sufficient reason, which is expressed in Parmenides' poem: "Also, what necessity impelled it, if it did

spring from Nothing, to be produced later or earlier? Thus it must Be absolutely, or not at all.” Philosophy was therefore conceived as a deductive science like mathematics. Third is the paradoxical contrast between apparent reality and true reality and the association of the truly real with singleness and unchangingness.

Of these features of Parmenides’ writings, the first is fundamental; it can be taken as a defining characteristic of metaphysics. Like the natural scientist, the metaphysician gives an account of the universe; unlike the scientist, he does not base his account on observations and experiments, at least not on any special observations and experiments made for the purpose. His account is based primarily on analysis of concepts; if he does appeal to the evidence of the senses, he appeals to something generally familiar, not to new evidence he is adding to knowledge. Parmenides himself apparently believed he had done all that could be done by way of a philosophical account of the universe. His account consists in pointing to what he believed were the logical consequences of saying “It is.” He dismissed everything else either as poetic imagery with no claim to truth or as empirical science; he indiscriminately referred to both as opinion. His position was not naive; it is not easy to see how a metaphysician can give an account of reality based on logic alone unless reality in some sense has the features of necessity and vacuous generality belonging to logical truths. And doctrines similar to Parmenides’ logical monism have frequently reappeared in the history of metaphysics—for example, in Neoplatonism, in Benedict de Spinoza, and in nineteenth-century Hegelianism. There is more than a superficial resemblance between Parmenides’ Being, the Neoplatonists’ One, Spinoza’s God or nature, and G. W. F. Hegel’s Absolute as understood by a metaphysician like F. H. Bradley. Perhaps the underlying reasoning is that recognizing that metaphysics gives an account of the world based on analysis of concepts rather than on empirical evidence, these philosophers have felt that logic alone should be sufficient basis for making assertions about the world; since whatever is logically true is thought to be necessarily and always true, they have concluded that the world itself must be unchanging and in some sense necessarily what it is.

**LATER PRE-SOCRATICS.** Parmenides apparently believed he had said all that a metaphysician could say about the world. Accordingly, his followers Melissus and especially Zeno are more critical than constructive—a trait shown by many later metaphysicians who are more often concerned to demonstrate what they take to be logical failures in the ordinary or scientific understanding of

reality than to give a positive account of reality. We learn from Plato’s *Parmenides* that Zeno’s paradoxes of motion were meant to support Parmenides’ system by showing contradictions in the ordinary concept of change. (When does the arrow move? Not now, because at any given instant it is in one place and hence not moving; not at some other time, because if it is moving, it must be moving now.)

Parmenides’ general effect, however, was to interest philosophers in following what seemed to be the logical implications of their assumptions. An example is Anaxagoras, who apparently argued from the assumption that reality is many and changing to the conclusion that the things we ordinarily call real are composed of unendingly smaller parts similar to the whole things, that “all things are together,” that “everything contains a part of every other thing,” and that although there are rearrangements of things, nothing is ever really created or destroyed. Like his contemporaries Empedocles and the atomists Leucippus and Democritus, Anaxagoras did rely on observation and experiments to give an account of nature, but the surviving fragments suggest that his cosmology was arrived at largely by a priori reasoning in the way Parmenides’ was, although the resulting account of reality is the opposite of Parmenides’ account. And in the same way that something like Parmenides’ logical monism is repeated in Neoplatonism, in Spinoza, and in nineteenth-century Hegelianism, something like Anaxagoras’s logical pluralism is repeated in Gottfried Wilhelm Leibniz’s theory of monads and Bertrand Russell’s logical atomism. The common feature of this kind of system is that on logical grounds reality is described as composed of elements viewed as the limit of an unending process of division; the least parts of things are, so to speak, real infinitesimals—things smaller or simpler than any given thing one can mention. The atomism of Leucippus, Democritus, and, later, Lucretius is, by contrast, primarily a physical theory. These thinkers believed that the existence of atoms can be shown empirically; their atoms have finite sizes and such recognizable physical properties as shape and motion and, perhaps, weight, and the theory anticipates Galileo Galilei and Isaac Newton rather than Leibniz and Russell.

**PLATO.** In Plato’s *Phaedo* Socrates is made to say he once studied Anaxagoras but gave up this study and all empirical investigations of nature, deciding instead to “have recourse to conceptions and examine in them the truth of realities.” Anaxagoras, Parmenides, and others had also had recourse to conceptions in contrast to the evidence of the senses; what is new in the *Phaedo* is the theory of

Ideas or Forms, which historians of philosophy sometimes ascribe to Plato (c. 427–347 BCE) and sometimes to Socrates himself. For Plato, at least, ideas exist independently of the things we see and touch; moreover, they are considered the source of existence of things we see and touch, somewhat as a man is the cause of his shadow or of his reflection in a mirror or a pool of water. Popularly, Plato's metaphysics means the theory of Ideas in this sense, and in this way the theory has had a great influence in the history of thought. Plato's own evaluation, however, was considerably more critical than that of many of his followers. The theory of Ideas in this form is presented in the *Phaedo* as a hypothesis that cannot be known to be true; in the *Parmenides* its logical weaknesses are pointed out; in the *Timaeus* it is used as part of a “probable” or “likely” cosmology. Nevertheless, Plato does consistently argue for the existence of mind or soul as a kind of entity distinct from, and in some sense prior to, physical objects. This thesis is developed, notably in the *Phaedo*, where the theory of Ideas is used as a step in proving the immortality of soul, in the *Phaedrus*, and in Book X of the *Laws*. In these contexts Plato argues that since bodies cannot move themselves (apparent self-motion is reduced to one part's moving another) whereas soul can, the ultimate source of observed motions must be soul or mind. In the *Laws* this argument is used to prove the existence of the gods, who are understood as sources of observed motions and changes in the visible universe.

Plato's technical contributions to metaphysics are contained in the difficult later dialogues, especially the *Parmenides* and *Sophist*. Both dialogues purport to be a criticism of Eleatic philosophy, by Parmenides himself in the *Parmenides* and by an “Eleatic stranger” in the *Sophist*. In the *Parmenides* Parmenides is represented as illustrating the method of dialectic by scrutinizing his own hypothesis that “the One exists” and deducing the logical consequences both of asserting and of denying this hypothesis. The point is that what follows depends on how the hypothesis is understood—in particular, on how one understands unity and existence. If, for example, unity is thought to be in no way compatible with plurality, a thing that has unity can hardly have anything else. Thus, it cannot have spatial extension, for it would then have a right and a left, an up and a down. The more straightforward *Sophist* classifies philosophers into materialists and idealists according to their criteria of reality. A general criterion of reality as power is suggested, and a number of concepts of equal generality with that of being are introduced and discussed—sameness, difference, rest, and motion. The apparent paradox in negation is explained by distinguishing absolute nonbeing (*A* does

not exist) from relative nonbeing (*A* is non-*B*) or otherness and by distinguishing the existential is (*A* exists) from the is of predication (*A* is characterized by *B*). In the *Timaeus* the generic concepts are used in the mythical account of the construction of the physical universe by a godlike artisan using an ideal pattern as a blueprint.

ARISTOTLE. Aristotle (384–322 BCE) is indirectly the source of the term *metaphysics*; he is also the source of a systematic list of metaphysical issues, a technical language in which these issues are stated, and a metaphysical system that has had followers down to the present and has proved immensely fruitful. In part, the importance of this system has been in serving as an object of criticism, although this function has been served by Plato as much as by Aristotle and Aristotle himself illustrates Plato's importance as an object of criticism in the history of metaphysics.

The problems of “first philosophy,” or metaphysics, listed by Aristotle in books Beta and Kappa of the *Metaphysics* are partly about metaphysics itself: Does its subject matter include all the basic concepts and assumptions of all the special sciences? Does it include the principles of logic? Is there metaphysical knowledge in contrast to opinion? These questions ask, in effect, whether metaphysics is a superscience proving the assumptions made by the special sciences and also the assumptions it itself uses—whether, in short, it is a logically self-contained body of knowledge contrasting with the logically incomplete special sciences. This concept of metaphysics was held, for example, by René Descartes, but on the whole Aristotle rejected this view. Metaphysics is less the capstone of a hierarchy of sciences than a discussion of problems left over by the special sciences. Physics, for example, assumes there is motion, but it is not part of the metaphysician's job as Aristotle saw it to prove this assumption; at most, he should explain it or defend it from criticism. Aristotle thought of metaphysics as explaining things we already know to be true rather than as giving reasons for the assumptions we make in the sciences and everyday life, thereby providing the underpinnings of science and common sense.

Some of the problems of metaphysics listed by Aristotle are questions about the kinds of things there are. In addition to physical objects perceived by the senses, do such abstractions as Plato's Ideas or the mathematician's numbers, points, lines, and so on also exist? Are all existing things particulars, or do universals like man or whiteness exist, too? Do particulars of the same kind have anything in common, and if so, what and how? Are phys-

ical objects something more than the material parts that compose them, and if so, what?

For Aristotle, however, the most fundamental questions of metaphysics concerned the concepts of being and unity. Are being and unity properties of things (since everything both is and is one thing), or are they entities or substances of some kind (as Parmenides seemed to have thought)? If being and unity are things in their own right, what kind of things are they? These questions are suggested by Plato's *Parmenides* and *Sophist*. Aristotle's answers are his most important contribution to metaphysics. In the *Sophist* Plato suggested a general definition of being as power but gave little by way of an explicit analysis of this sense of being, which does not correspond to the use of the word in ordinary language. Such an explicit analysis is the center of Aristotle's metaphysics; his contribution can be summarized as the view that although there are many ways in which things are and are one (and there are therefore many senses of being and unity) and although these ways are irreducibly distinct, they nevertheless depend on one basic kind of being. Being is neither an attribute nor a thing and cannot therefore be defined in the ways *triangular* or *horse* can be defined. But we can pick out a basic sense of being, illustrated in such statements as, "This is a horse" or "This is a man," and show how the other senses of being depend on it. "Being a horse," "being a man," and, in general, "being an *X*" in the basic sense of being means to have attributes and therefore to be a subject of thought and discourse without in turn being an attribute of something else; "being a horse" is not, for Aristotle, an attribute of some more basic subject of thought and discourse. Primarily, what there is, is this horse, this man, and so on when we are speaking of an individual; secondarily, what there is, is horse, man, and so on understood as species or kinds of things. Qualities, dates, locations, motions, relations, and the like are attributed to the things that exist in the basic sense; they themselves do not have independent existence and "are" only in a derivative and borrowed sense of being.

Aristotle's analysis of being is the heart of his metaphysics; it is not the whole of it or the part most stressed by his later followers. What is often referred to as Aristotle's metaphysics is his account of the universe. Roughly, it states that there are a large but finite number of things that for the most part (with exceptions such as the sun, the only thing of its kind, and biological "mistakes" resulting from mutation and crossbreeding) belong to definite kinds—for example, plant and animal species. In most cases the individual members of these kinds or

classes are born and die, but the classes themselves do not change. Some things—for example, the stars—exist forever and apart from uniform motions do not change at all. There is an ultimate prime mover that is the source of all observed motion and change but is itself completely immaterial and therefore completely motionless and changeless. This set of ideas is in the *Metaphysics*, and the pluralism and some theory of natural kinds do follow from Aristotle's analysis of being. But the theory of prime movers and the Unmoved Mover is also in the *Physics* as a scientific—that is, demonstrable—account of the physical universe; it is not therefore a true part of his metaphysics, which is dialectical (arguing from common opinion and logic) rather than scientific.

The central chapters of the *Metaphysics* elucidate and defend the claim that such commonsense things as this horse, this man, and so on are the fundamental subjects of discourse. Aristotle upheld this claim against (1) the view that the ultimate material parts of things are the ultimate subjects of discourse (so that "This is a horse" would be understood as "These material elements have horselike attributes"); (2) the view that Platonic Ideas are the ultimate subject of discourse (where "This is a horse" is understood as "The horse is exemplified by these sensible qualities"); and (3) the view that the basic sense of being is illustrated in, for instance, "There is a horse in the barn"—the view according to which "there is" means "it is true that" or "it is a fact that." For Aristotle to be is to be an individual, and the being of a thing is primarily its nature or identifying features rather than the fact that it is. Aristotle hardly even recognized the sense of being involved in such sentences as "There are good men, and there are wicked men," which can be read as "Among all the things that are, some are—that is, have the identifying features of—good men; others are wicked men." Such sentences suggest that what exists primarily are featureless particulars, which can be referred to collectively as "the things that exist," not commonsense things.

In general, the question "What is being?" became for Aristotle "What is an individual?," a horse, a man, a house, and so on being understood as paradigms of an individual. And, positively, the central argument of the *Metaphysics* is that an individual is primarily the distinguishing features by which we identify and classify it. Aristotle himself believed that these classifications are learned through experience; he was a realist in the sense that he thought the groups and classes of things are there to be learned by observation and are not simply mental constructions. Therefore, there is a sense in which we learn empirically what being is. But metaphysics is not

itself an empirical study of being; Aristotle did not, for instance, think of metaphysics as a science of high-level generality describing the properties that all beings (individuals) have.

Aristotle's *Metaphysics* in its present form—and there is no reason to think it ever had a very different form—is barely readable in large stretches. Other parts read like outmoded astronomy; still other parts read like rather tedious lexicography. The devastating criticism of Plato is largely borrowed from Plato himself. However, the *Metaphysics* gives a surprisingly coherent set of answers to the questions it raises, and the questions themselves are those that metaphysicians still ask.

**NEOPLATONISM.** The Neoplatonists in the late classical period were metaphysicians of great power and originality. They were also of great importance in the development of metaphysics since they formed a link between ancient and medieval philosophy. The main figure of this movement, Plotinus (c. 204–270), associated metaphysics with mysticism and personal asceticism. The mystical and religious side of his philosophy was stressed by his disciple and editor Porphyry (c. 232–304), and such later Neoplatonists as Iamblichus and Proclus gave a further religious and even occult and superstitious emphasis to the movement. But the intellectual power of the movement is shown in as late a philosopher as Ancius Manlius Severinus Boethius (c. 480–524), and through Boethius Neoplatonism had a very strong influence on medieval philosophy and, therefore, indirectly on modern philosophy.

**Plotinus.** Plotinus's philosophy is a paradigm case of a metaphysical system according to one common conception of metaphysics. It asserts the unreality or half reality of the things of everyday experience; the illusory character of change, motion, and even space and time; the superior reality of soul or mind over matter. It conceives of goodness and intelligence as substantial things and stresses personal mysticism and an ascetic way of life. The line of thought by which Plotinus arrived at this position is not easy to follow, but, briefly, it seems to have been somewhat as follows. Whatever is, is one thing (even a collection of things is said to “be” only when counted as one thing—a collection); the answer to the question “What is being?” understood as a request for a description of being, is therefore unity or singleness. But unity or singleness cannot be described any further, although a direct, intuitive experience of it is in some sense possible. Since being is equivalent to unity and since things can have unity to a greater or lesser degree, we can speak of

degrees of being. Although unity is itself ineffable, it does duplicate itself in a kind of descending series of things—in goodness and intelligence—in a lesser way in disembodied spirits, in a still lesser way in human souls, least of all in physical objects and their properties and relations. The emanation of successively less real things from unity is to be understood in a logical rather than a physical sense. Speaking accurately, unity or singleness (the One) is not a cause at all, although it can be described metaphorically, for example, as an inexhaustible fountain of being bringing existence to all the things that are by its continuous overflow. Plotinus's writings are full of these metaphors, but he recognized them as metaphors, and the underlying position is rigorously argued, granting the not implausible identification of being with unity or singleness.

Plotinus's line of thought begins with the assumption that being and unity are properties that things have—properties of utmost generality, to be sure, but still properties in the same way that black or being four-legged are properties of a horse. Combined with this seems to be the Platonic assumption that properties are not simply modifications of particulars or ways that particulars exist; properties are entities in their own right that particular things instance or exemplify. The first of these two assumptions is clearly made in the *Isagoge*, Porphyry's short introductory treatise on Aristotle's *Categories*. In Porphyry's account—and in this account he is presumably expressing a typically Neoplatonic point of view—the theory of categories or types of predication is a theory of kinds of predicates: genus, species, difference, property (that is, essential property), and accident. These kinds of predicates (the predicables) are distinguished from individuals. But even expressions designating individuals are predicates of a sort according to Porphyry; such expressions as “Socrates,” “this man here,” and “this thing here” are attributes, differing from the predicables because they are “only said of a single thing” whereas the predicables “are said of several things.” The distinction is between attributes belonging to several things and attributes belonging to only one thing. But of individuals themselves, in contrast to attributes, nothing is said; they can apparently be characterized only indirectly, as the ultimate subjects of predication.

This account of predication makes the distinction between thing and property peripheral to metaphysics. The important distinction is between relatively less general and relatively more general attributes, culminating in the most general attributes, being and unity. Porphyry spoke of substance as “the most general genus” and in a

sense the only real genus, since unlike animal, for example, which is a genus relative to man but only a special case relative to “living thing,” substance is not itself a special case of some higher genus. Neoplatonic metaphysics is largely an analysis, similar to Plato’s *Parmenides*, of these ultimate genera; the main force of Plotinus’s writings is the argument that the ultimate genera cannot be described in any ordinary way but are in some sense manifest in lower orders of being. Neoplatonism thus easily lends itself to religious interpretation; in the late classical world it actually was a theological system associated with a religious way of life competing with Christianity.

## THE MIDDLE AGES

Porphyry’s *Isagoge*, translated into Latin by Boethius in the sixth century, gave philosophers some basic tools and stimulated speculation on two questions in particular: (1) What is a thing considered just by itself, as a bare existent, apart from all its attributes? (2) Do attributes exist (or subsist) separately from human thought and discourse and from the things that are said to have attributes? The first question, implicit in Porphyry’s account of predication, is roughly the problem of distinguishing essence from existence, what a thing is from the fact that it is. The second question (really, group of questions) was explicitly raised but not answered by Porphyry; it is the problem of universals much discussed throughout medieval philosophy.

For Aristotle the contrast between what a thing is and the fact that it is, is at best peripheral to metaphysics. Aristotle recognized that the question “Does *X* exist?” is distinct from “What is *X*?” but he attached no metaphysical importance to the distinction. Particular questions of the form “Does *X* exist?” are decided by sense perception or by proof; there is no general metaphysical question about the nature of existence (“thatness”) in contrast to essence (“whatness”). The metaphysician is concerned with what things are rather than with their existence or nonexistence. Aristotle’s position was that what things are—that is, their being—is primarily what is contained in their definitions; the definition of a thing describes its essence, which is equivalent to its species (the traits that identify it as the kind of thing it is) which is in turn identified with its genus, differentia, and essential properties. But when, as in Porphyry, genus (mammal), difference (solid-hoofed), species (horse), property (neighs), and accident (gray) are indiscriminately called attributes of the thing itself, it is natural to ask what it is that has these attributes or what it is that gives this collection of attributes an actual rather than a merely possible existence.

The problem of universals dominated metaphysics in the early Middle Ages; it was discussed by metaphysicians from Boethius in the sixth century to Roscelin and Peter Abelard in the twelfth century. The main philosophical tradition during this period was the Augustinian tradition, represented by Boethius himself, John Scotus Eriugena (c. 810–c. 877), St. Anselm (1033–1109), William of Champeaux (d. c. 1120), St. Bonaventure (c. 1217–1274), and many others. This tradition favored realism; species and genera like horse and animal were thought to exist not only apart from human thought and discourse (epistemological realism) but also apart from particular horses and animals. Species and genera were regarded as paradigms, archetypes, or exemplars of particular things; as such, they exist in the mind of God and are used by him as models in creating nature. As in St. Augustine and Plato, the fundamental contention is that particulars cannot be recognized and identified as one of a general type unless we first have independent knowledge of the type; the inference is that these general types must exist apart from, and in some sense prior to, the particulars exemplifying them.

St. Anselm’s proof of God’s existence (anticipated by St. Augustine), has had an important history in its own right; it is also an illuminating example of Christian Platonism in the early Middle Ages. The argument cannot be appreciated apart from its context of religious meditation, but it can be picked out and studied (as it has been by philosophers to this day) as a kind of supreme test case of Platonic (or Neoplatonic) metaphysical assumptions. Briefly, the argument is that (1) we have a concept of a supreme being (a being “than which nothing greater can be conceived”) so that (2) the Supreme Being “exists in the understanding.” Since (3) it is greater to exist in reality than merely in the understanding, it is contradictory to say the Supreme Being exists only in the understanding; hence, we can infer that (4) the Supreme Being does exist in reality. Kant’s objection seems decisive. The existence (as contrasted with the concept of existing) of the Supreme Being cannot be a part of our concept of the Supreme Being. If it were, our concept would be the Supreme Being, not its concept. But the argument seems inevitable if one assumes, as the Neoplatonists did, that existence is an attribute that things have and, in consequence of having it, are, as things are red in consequence of having the attribute redness. Combined with the assumption that attributes have an independent existence, this line of thought leads to the conclusion that existence or being is itself an existing thing; the existence of things in nature is thought of as being due to their receiving a part of the inexhaustible thing, being, some-

what as an illuminated object receives its light from a source of illumination. Furthermore, it seems to follow that existence must itself necessarily exist as an analytic consequence of what it is (just as “Redness is red” seems to state an analytic necessity). Given these assumptions, the Ontological Argument for God’s existence, as Kant later called it, is at least a strong temptation; the argument has had a history identical with the history of logical monism in metaphysics, from Parmenides to Hegel and beyond, as well as a close association with Christian theology.

### REVIVAL OF CLASSICAL PHILOSOPHY

Although the realism-nominalism controversy occupied philosophers in the eleventh and twelfth centuries, new ways of thinking in metaphysics were being prepared by translations of Greek and Arabic texts into Latin, especially translations of Aristotle and his Arabian commentators. In the early Middle Ages there was very little firsthand knowledge of the Greek philosophers. Plato’s *Timaeus*, *Phaedo*, and *Meno* were known, but the important later dialogues, including *Parmenides* and *Sophist*, were not. The Greek texts had been preserved, however, and, especially after the capture of Constantinople by crusaders in 1204, were slowly recovered in the West. In the thirteenth century William of Moerbeke made a literal Latin translation of Proclus’s *Commentary on the Parmenides*; the commentary contained the text of the *Parmenides* through the first hypothesis, thereby giving philosophers some firsthand knowledge of that important dialogue.

Aristotle was even less known and understood in the early Middle Ages. Only his logic, the text of *De Interpretatione*, and the other logical treatises in Neoplatonized versions through Boethius were known. As late as the thirteenth century, two Neoplatonic texts—the “Theology of Aristotle” (actually a compilation from Plotinus’s *Enneads*, IV–VI) and the *Liber de Causis* (a work based on Proclus’s *Elements of Theology*)—were wrongly attributed to Aristotle. However, Aristotle’s writings had been translated into Syriac by Nestorian Christians in the fifth century and from Syriac into Arabic in the ninth century; Latin translations of Arabic texts were made in the twelfth century and directly from Greek texts by Robert Grosseteste and William of Moerbeke in the thirteenth century. By the end of the thirteenth century most of Aristotle was translated into Latin and was generally available to philosophers. In effect, Aristotle was a new philosopher who appeared on the scene and dominated it as if he were a contemporary; the *Metaphysics* was the

stimulus for such metaphysicians as Albert the Great, St. Thomas Aquinas, John Duns Scotus, William of Ockham, and others in the thirteenth and fourteenth centuries.

**THOMAS AQUINAS.** Thomas Aquinas’s metaphysics is an attempt to explain the distinctions between essence and existence, necessary and contingent existence, and particulars and universals, using the language and much of the metaphysical outlook of Aristotle. For Thomas commonsense things like horses and houses do exist in a literal and straightforward sense apart from human observers and also apart from God and paradigms of things in the mind of God. The existence of these commonsense things is not an attribute that they receive from outside; it is not like the light the earth receives from the sun. The existence of finite things in nature is an intrinsic act of existing that these things exercise. But Thomas also held that the ordinary things we experience exist contingently in the sense that their existing is not an analytic consequence of what they are; it is not something they do by nature. There must therefore be a cause (in a metaphysical, not a physical, sense of “cause”) of their existence; this must be a necessary being, identified with God, who exists by his own nature. Contingent beings, like horses and houses, are obviously contingent because being composed of matter, their existence is finite—they begin to exist and cease to exist. Matter also accounts for the individuality of things; things that are identical insofar as what they are, or, in other words, things that have the same nature, are still different things because the matter of which they are composed is different. God, on the contrary, is immaterial and, hence, one and unchanging. Thomas, like the Neoplatonists, associated finitude, contingency, plurality, and change with matter. He differed from the Neoplatonists chiefly in his view that finite things—in particular, human persons—exist in their own right (by virtue of a delegated power, as it were) and do not merely participate in the existence of a higher order of being. In this view Thomas agreed with Christian theology and was close to Aristotle.

**DUNS SCOTUS.** John Duns Scotus (c. 1266–1308) seems to have agreed with Thomas that being is not an attribute or a thing in some sense shared by all the things said to be. On the other hand, he criticized Thomas’s contrast of essence with existence, arguing that whatever we are aware of must be an essence in some sense, including even individuality or “thisness,” which he treats as an attribute of individuals (“this horse here”), distinguishing them from indeterminate beings (“a horse” or “the horse” in general).

**WILLIAM OF OCKHAM.** William of Ockham (c. 1285–1349) held that general or indeterminate expressions like “a horse” or “the horse” do not correspond to general beings either in the mind or in reality but refer indifferently to individual horses. He was therefore conventionally called a nominalist in contrast to Duns Scotus, a realist. But William of Ockham’s main point seems to be that logical distinctions between universal, particular, and singular are not distinctions between kinds of things—not an enumeration of what there is—but are, rather, ways of referring to the one and only one kind of thing that does exist—namely, the commonsense things we encounter in everyday experience. For this reason William was probably closer to Aristotle’s own view than either Thomas or Duns Scotus; unlike them his explicit aim was to state Aristotle’s original position as accurately as he could. But William’s successors—notably, John of Mirecourt and Nicholas of Autrecourt—pushed William’s views in a direction that anticipated Hume and even twentieth-century logical positivism. We can talk meaningfully only about what we are acquainted with through the senses, and we are acquainted only with particulars, so that all discourse about things refers ultimately only to particulars. The existence of a particular is never an analytic necessity or an analytic consequence of the existence of some other; hence, all meaningful statements about things are only probable.

## DESCARTES TO KANT

**DESCARTES.** The revival of metaphysics in the seventeenth century begins with René Descartes (1596–1650), who has been traditionally considered the originator of modern philosophy. The ideas most commonly associated with Descartes are not original with him. In St. Augustine’s writings can be found the *cogito ergo sum* argument and the view that our own existence is the ultimate certainty since we can be certain of it while the existence of all other things is in doubt. The argument that nothing less than God could have produced the idea of God in the human mind can also be found in St. Augustine. The Ontological Argument had a famous history in the Middle Ages, and the view that physical objects have only geometrical attributes of shape and motion was held by early Greek atomists. The concept of mind as a substantial thing more or less externally attached to the body is hardly original with Descartes. But to say this is to say only that Descartes used a good deal of material from old ruins in his work of “building from the foundation” in metaphysics in order “to establish a firm and abiding superstructure in the sciences.”

Descartes was most original in his conception of philosophical method and philosophical truth. No metaphysical assertion is to be believed unless (1) it is understood with the kind of clarity and distinctness that mathematical propositions have and (2) its truth is either so intrinsically obvious that, like the postulates of geometry, it cannot be doubted or it is proved with the same rigor with which theorems are proved in geometry. Descartes’s philosophy can be viewed in large part as an effort to reduce the second criterion to the first—that is, to show that at least in the case of metaphysical propositions, if we understand them clearly and distinctly, we are thereby certain of their truth. These claims made for his or any other metaphysical assertion were revolutionary and most influential. As Descartes and his followers understood them, they amounted to a demand that metaphysics be scientific, understanding by the word *scientific* being subject to a kind of rigorous intellectual discipline best illustrated in mathematics and the exact physical sciences.

**SPINOZA.** Benedict de Spinoza (1632–1677), following one interpretation of Descartes’s demand for clarity and distinctness in metaphysics, thought of metaphysics as a deductive account of the universe to be developed from a few definitions—notably, the definition of substance as a being that requires nothing outside itself to be or to be conceived—and self-evident assumptions. His inferences are that there must logically be one and only one substance, uncreated and everlasting; there are an infinite number of attributes of the one substance, only two of which, thought and extension, are known to us; attributes are faces of the one substance—self-contained ways of describing it—rather than properties inhering in it the way we commonly think of colors as inhering in physical objects; the universe, described in terms of the attribute extension, is a mechanical system in which all happenings are links in a chain of physical causation; an equally complete causal determinism holds when the universe is conceived in terms of the attribute thought.

**LEIBNIZ.** Gottfried Wilhelm Leibniz (1646–1716) was also a follower of Descartes in the sense that he agreed with the demand for a rigorously scientific metaphysics and for clear and distinct ideas in contrast to scholastic verbiage. But while Leibniz agreed that metaphysical assertions are true if clearly and distinctly understood, he interpreted this to mean that metaphysical truths (and truths of reason generally, in contrast to contingent truths of fact) are logically necessary; their denial involves a self-contradiction. Leibniz understood clarity and dis-

tinctness in a logical rather than a psychological sense; for him “the true mark of a clear and distinct notion of an object is the means we have of knowing therein many truths by *a priori* proofs.” And we know a truth by an *a priori* proof when “by the help of definitions or by the resolution of concepts” we “reduce” it to an explicit tautology of the form “*A is A*” or “*A is not non-A*.”

Leibniz’s metaphysical system is, in effect, an effort to get a clear and distinct idea of the universe in his own rather special sense of clarity and distinctness. And his technical writings in metaphysics consist largely of a series of somewhat different *a priori* proofs of a number of metaphysical assertions, including the following: There are an infinite number of substances, each of which is logically complete in that it contains in some sense all the properties it ever has exhibited or will exhibit; no two substances exhibit exactly the same properties (“identity of indiscernibles”); a complete description of any one substance would be a description of the entire universe “from a point of view”; space and time are relations among things, not things in their own right; the appearance of causal relations between things is illusory, reflecting God’s deliberate prearrangement rather than any real influence exerted by one thing on another. In proving these assertions, Leibniz relied on a principle of sufficient reason stating, in effect, that there is always a rational explanation for a fact. But the principle of sufficient reason is not really a description of the universe for Leibniz. What it really expresses is the idea that in principle any truth can be given an *a priori* proof; the underlying thought is that when any statement is understood with perfect clarity and distinctness, it will be seen to be an explicit tautology.

LOCKE. Spinoza and Leibniz are usually grouped with Descartes as rationalists, as contrasted with British empiricists, represented in the seventeenth century by John Locke (1632–1704). But in an important way Locke, too, was a follower of Descartes; he was also mainly interested in replacing scholastic jargon with clear and distinct ideas and opening the way for the sciences. Locke’s main contribution to metaphysics lies in his critical discussion of substance and essence. Descartes had laid it down as an indubitable common notion that “nothing is possessed of no attributes, properties, or qualities,” so that “when we perceive any attribute, we therefore conclude that some existing thing or substance to which it may be attributed, is necessarily present.” Locke did not deny that this is a valid inference; he does not question the distinction between thing and property. But he asked what we know (or, as he phrased it, “What is our idea”) of a thing

beyond its attributes, powers, and so forth. His answer was that we have no clear and distinct idea at all; we know only what the common notion itself says—namely, that if there are attributes, there must be something underneath that has them. We have no clear idea what is underneath or what “underneath” means in this context. We know only the attributes, powers, and so on (indiscriminately called qualities by Locke) of things, not the things in themselves.

Here, however, Locke was criticizing only the notion of substance as substratum underlying properties. And this is a concept of substance minimized by Aristotle and never stressed by metaphysicians. Thomas Hobbes, for example, argued that the accidents of body, such as shape or hardness, are the very “manner of our conception of body.” To ask for a description of body apart from its accidents would be, for Hobbes, a senseless request. Locke’s more important and original criticism concerns the notion of essence—the notion of what a thing is in contrast to what it is made of, how big it is, its location, its age, and the like. Locke argued at length that the distinction is a useless one; the question “What is *X*?” can be answered only by enumerating *X*’s observed properties, and (most important) we cannot see any logical necessity for the coexistence of just these and not some other combination of properties. We do not therefore have any knowledge of real essences except in cases where we ourselves construct the thing in question, as in mathematics. Locke reasoned, roughly, that we know the attributes and powers of things only through the simple sense impressions we have of them. Since, for the most part at least, there are no noticeable necessary connections between simple sense impressions, we cannot explain why things appear as they do but can only describe how they do appear. Locke never denied there is a reason for things’ having just the attributes and powers they have and not some others, but he denied our ability ever to have clear and distinct ideas of these reasons. The effect of Locke’s view is to deny the possibility of metaphysical knowledge when metaphysics is conceived of in the way Francis Bacon, for example, conceived of it, as a very general but still empirical and even experimental study of the formal causes of things, as distinguished from natural science, which studies material and efficient causes.

BERKELEY AND HUME. Locke never questioned the distinction between ideas of things and the qualities in things that cause ideas, and he thought we have at least a “relative and obscure” idea of a thing in contrast to its qualities. But George Berkeley (1685–1753) questioned both distinctions, partly on grounds of fact but more

especially on grounds of a general theory of meaning. For Berkeley the grammatical distinction between subject and predicate has no counterpart in a distinction between things and properties; we can talk meaningfully only about what we are acquainted with, and we are acquainted only with individual colors, sounds, tastes, and the like. Since these individual colors, sounds, and tastes have characteristics that are admittedly mental, such as pleasantness and painfulness, and are relative to the human observer in various ways, Berkeley concluded we can talk meaningfully only about mental entities or, as he called them, following the usage of Descartes and Locke, ideas in the mind. In this way Berkeley arrived at phenomenalism (things exist exactly as they appear to the senses) and idealism (things exist only as objects of conscious perception; their being consists in being perceived). Berkeley was not thoroughgoing in these positions; he thought it meaningful to talk about other minds and about God even though we cannot directly perceive such phenomena.

These qualifications, however, were swept aside in the thoroughgoing phenomenalism of David Hume (1711–1776). Hume criticized the notion of a mind as distinguished from the ideas said to be in the mind for the same reasons that Berkeley criticized the notion of matter. According to Hume, the notion of existence itself signifies nothing beyond a greater or less degree of force and vivacity attaching to sense impressions and mental images. Our beliefs in the continuous existence of physical objects and the presence of causal connections between them are explained as effects of habitual associations of ideas for which there is, strictly speaking, no evidence. Although Hume is usually and correctly called an empiricist in contrast to speculative metaphysicians like Leibniz or Spinoza, there is a sense in which he was as much a rationalist as his contemporary Christian Wolff. Hume assumed that the ultimate subject of thought and discourse must be something we are directly conscious of, that we are directly conscious only of individual sensations (or their more or less faint copies), and that whenever we can discriminate one sensation or feeling from another, these exist separately and hence count as different things. These assumptions amount to a theory of empiricism, but they are not themselves empirical assertions. Nor, on the other hand, are they necessary truths in Leibniz's sense—propositions whose denial involves a self-contradiction. In effect, they demonstrate how Hume understood Descartes's demand for clarity and distinctness in metaphysics and are analogous to Leibniz's principle of sufficient reason, which expressed his understanding of the same demand. For Leibniz clarity

and distinctness meant, in the end, reduction to an explicit tautology; for Hume clarity and distinctness meant, in the end, reduction to directly verifiable assertions about sensations and feelings.

KANT. By the time of Hume's death, in 1776, the difficulties and ambiguities in Descartes's program for metaphysics were apparent. Cartesianism inspired both the speculative constructions of Spinoza, Nicolas Malebranche, Leibniz, and others and the critical and—at least, on the surface—increasingly skeptical philosophies of Locke, Berkeley, and Hume. This, at least, was the view taken by Immanuel Kant (1724–1804). It led Kant to ask whether metaphysics could be scientific—whether metaphysical knowledge is even possible and if not, how the questions that gave rise to metaphysics in the past could be answered. In discussing these problems, Kant made a very penetrating analysis of metaphysics as a discipline and a set of assertions and as a “human propensity”; Kant's contribution, apart from his own system, was to raise questions about what metaphysical assertions, as distinguished from scientific assertions, are, about the sense in which they claim truth, and about the grounds on which they are to be believed or disbelieved.

From Kant's point of view the history of metaphysics (insofar as metaphysics had claimed to be a science) had been a story of dogmatism versus skepticism. Dogmatists like Leibniz have held that metaphysics can, on the basis of purely logical or conceptual considerations, answer with absolute certainty questions about the origin of the universe, the existence of God, and the immortality of the soul. “Dogmatists,” as Kant used the word, can be materialists, panpsychists, or dualists, monists or pluralists. What they share is a confidence that a metaphysician can give an account of the nature of reality using a priori reasoning. Skeptics, on the other hand, are empiricists; for them there are no universal and necessary truths of fact and reasoning alone, in contrast to observing and experimenting, is of no use whatsoever in answering questions about the existence or natures of things. For Kant this alternating dogmatism and skepticism was the effect of alternating overconfidence and lack of confidence in the abilities of the human mind. Accordingly, his critical philosophy is an effort to show what human knowledge is like and what its limits must necessarily be.

Dogmatic metaphysics in Kant's sense is not mere ad hoc speculation; it is an understandable and correctable misuse of basic concepts. The dogmatic metaphysician rightly sees that we actually use concepts like substance (in contrast to accidents) or causation (in contrast to

mere succession). He also correctly saw that we are a priori certain of such things as the irreversibility of time or the impossibility of two physical objects' occupying the same space. But he uncritically concluded that we have a power other than sense perception of knowing what things are like, whereas the true conclusion is that we ourselves determine in advance what any object of knowledge must be like. The questions we ask about things and the answers we look for are determined by our own a priori forms of perceiving (space and time) and of judging (every attribute must belong to some substance, every event must have some cause and so on). Mistaking these a priori forms of perceiving and judging for descriptions of things-in-themselves, the dogmatic metaphysician is led to speak of ultimate subjects and first causes. In Kant's view these speculations are misguided and even meaningless. But metaphysical ideas, such as an ultimate subject or a first cause, do have a regulative use in encouraging us never to be satisfied with what we actually know at any given time. And Kant did not infer that the beliefs that metaphysicians have tried to prove—beliefs in personal immortality or in the existence of God—are illusory. These beliefs are not like belief in perpetual motion machines; they can be justified and can even be supported by arguments—but by moral arguments, not speculative arguments. Dogmatic metaphysics can thus be explained and even in a sense vindicated. It cannot be taken seriously as a source of knowledge, however.

### METAPHYSICS SINCE KANT

Kant's own metaphysical position was idealistic. Aristotle's categories reappear somewhat altered in Kant's philosophy as forms of judgment. The most immediate and obvious effect of Kant's thought can be seen in the idealistic systems of his younger German contemporaries and successors, Johann Gottlieb Fichte (1762–1814), Friedrich Schelling (1775–1854), Arthur Schopenhauer (1788–1860), and, above all, Georg Wilhelm Friedrich Hegel (1770–1831).

**HEGEL.** Among the idealists, however, it was Hegel whose metaphysical outlook has probably had more general intellectual influence than that of any other single recent philosopher. Kant's critical idealism assumes a clear-cut contrast between what is given in experience (sense impressions) and the forms we use to arrange and interpret what is given. In general, Kant assumed a clear distinction between what is directly perceived and what is inferred or constructed by the mind. Hegel's absolute idealism consists largely in denying this contrast; for him the underlying notion of a plurality of separately existing

particulars, uniquely located in space and time (conceived as containers in which things are unambiguously placed), was a false, even a logically incoherent notion. He appears to have arrived at this conclusion from the assumptions that things-in-themselves cannot be distinguished meaningfully from things as we know them and that things as we know them gradually take shape in our consciousness and become defined only in contrast to other things. On this basis he concluded that all things shade off into their opposites and that the connections between things we establish in thought are as much a part of the things as their so-called inherent properties. Hegel was thus led to the monistic position that there is only one kind of substance and only one truly substantial entity. His idealism is an evolutionary pantheism in which the only self-subsistent reality is spirit; it contrasts not only with materialism in the traditional sense but with any metaphysical position associating reality with some kind of hard definiteness.

Outside of philosophy proper Hegel's influence was apparent mainly in inspiring a view of things as phases of a living and growing history; institutions, languages, ideas, even philosophies themselves, were seen as quasi-living and even quasi-personal phenomena whose histories were to be sympathetically grasped and appreciated rather than appraised by themselves on the basis of a priori standards. This widely held view has been encouraged by Hegel's absolute idealism, in which reality is associated with self-expression and all-inclusiveness, not with given things or facts. Within philosophy Hegel's influence can be seen in the many evolutionary idealisms of the nineteenth and early twentieth centuries. It can also be seen in the more rigorous and critical thought of Hegelians like F. H. Bradley (1846–1924) and J. M. E. McTaggart (1866–1925). Bradley in particular stressed the negative side of Hegelianism, finding logical antinomies in the ordinary concepts of things, properties, relations, causation, and space and time. McTaggart, on the other hand, attempted to rephrase Hegelianism as a clear and straightforward speculative system. This tradition is continued by such contemporary metaphysicians as Brand Blanshard.

**METAPHYSICS AND PRAGMATISM.** Largely through the influence of German idealism and especially of Hegel, metaphysics in the nineteenth century generally meant a priori cosmology and, in particular, an idealist cosmology contrasted and even opposed to the alleged mechanistic and materialist assumptions of science. Auguste Comte's positive—that is, nonmetaphysical—philosophy did not attack metaphysics as such; it attacked speculative philos-

ophy as a way of providing substitutes for religious beliefs. Popularly, metaphysics was associated with religion, idealism, and spiritualism and opposed to science, which was associated with empiricism and materialism. But this concept of metaphysics, although still popular, was only a temporary alignment in the history of metaphysics and was strongly challenged even in the nineteenth century.

A notable example is the American philosopher C. S. Peirce (1839–1914). Peirce was a Hegelian to the extent that he believed there are no self-identical particulars that can be unambiguously located or identified. Reality is indeterminate both in the sense that it is characterized by novelty and unpredictability and in the sense that things are not just what they are but shade off continuously into other things; reality is an evolutionary process that is in some sense rational. But for Peirce this outlook is required by reflection on experience and the sciences, metaphysics itself being an observational science whose job is “to study the most general features of reality and real objects” and whose backward condition is due chiefly to the fact that “its leading professors have been theologians.” Science and experience force us to give up the concept of definite, unambiguous facts and fixed a priori assumptions; science is a community of inquirers sharing methods and a kind of moral and intellectual discipline rather than a body of knowledge or a set of assumptions (as Kant, for example, had thought). Metaphysics for Peirce was an attempt to describe how reality must seem to men imbued with science; reality is what will eventually be agreed on by the community of inquirers; general laws and relations among things are real since these, rather than particular facts, are the objects of scientific research. Peirce’s concept of metaphysics influenced John Dewey (1859–1952), and largely through Dewey it has had considerable importance in recent American philosophy. Like Peirce, Dewey hoped metaphysics could be a descriptive account of generic traits exhibited in all experience.

**LOGICAL POSITIVISM.** The mainstream of metaphysics in the nineteenth and early twentieth centuries was idealistic; metaphysicians responded to Kant by constructing systems meant to extend or deepen Kant’s critical idealism. But another response was to question dogmatic metaphysics more profoundly than Kant himself. This more radical questioning was begun by such nineteenth-century philosophers of science as Ernst Mach (1839–1916), who criticized the notion that general concepts of science (for example, force) described unob-

served entities or that scientific laws are more than convenient formulas for summarizing observations.

This line of criticism has been most forcefully and systematically carried out by twentieth-century logical positivism. For the logical positivists metaphysics has a special meaning; an assertion is metaphysical if it purports to make a statement of fact but fails to do so—and therefore fails to have a meaning—since no observations count as evidence for or against it. This special use of metaphysics should be understood in the context of the belief of logical positivists that traditional questions of metaphysics do have a point, but a point that traditional formulations of the questions obscure. They are not questions about things at all but about language—in particular, about the types of words and sentences and the logical vocabulary needed to express the findings of the sciences.

The hope of some logical positivists was that if traditional metaphysical questions were translated into questions about the language of science, the answers would be immediately and clearly seen. If, for example, “Does non-being exist?” is phrased as “Are sentences of the form ‘*X* is not an *F* ever true?,” the answer is obviously “Yes.” But it became increasingly clear that in the construction of languages expressing the findings of the sciences problems analogous to traditional metaphysical problems occur. For example, some positivists suggested that sentences such as “Two plus two equals four” owe their truth to linguistic usage rather than to a necessary connection between things, perceived by reason, as past metaphysicians often assumed. Critics pointed out, however, that since it is an empirical fact that we use language as we do, the substitution of “true by virtue of linguistic convention” for “necessary truth” threatens to make “Two plus two equals four” a merely empirical statement. Thus, a distinction is needed between what we merely do not say and what our language will not allow us to say. This does not, of course, mean that nothing was gained over traditional metaphysics, but it does mean that the achievement of logical positivism has been to elucidate or reconstruct traditional metaphysical issues rather than give a method for easily solving them. Accordingly, logical positivists now tend to accept metaphysics in its conventional sense, as the name of a legitimate part of philosophy, along with the special use of metaphysical to refer to pseudoinformative assertions that in reality are meaningless.

**ORDINARY-LANGUAGE PHILOSOPHY.** The logical positivists were strongly influenced by Bertrand Russell’s

view that much of traditional metaphysics resulted from a superficial and hasty analysis of ordinary language as well as by the view of Russell and Peirce that past failures of metaphysicians were due to a narrowly restricted logic that prevented them from analyzing ordinary language correctly. The notion that traditional metaphysics resulted from a superficial understanding of ordinary language has been developed independently of logical positivism (although sometimes popularly confused with it) by Ludwig Wittgenstein, Gilbert Ryle, and a large number of contemporary British and American philosophers. Like the logical positivists the ordinary-language philosophers agree that traditional metaphysical questions are in some sense intelligible but need to be radically reformulated; unlike the positivists they are not concerned with rephrasing them as questions about the language of science. They want to show, rather, how metaphysical questions can be solved (or dissolved) by exhibiting the less obvious but essential presuppositions that give linguistic expressions the meanings they actually have in ordinary discourse. Positively, ordinary-language philosophers use linguistic analysis (for example, naming, referring, describing, and so on) to deal with traditional metaphysical issues, and like logical positivists they accept metaphysics in this positive sense as a legitimate area of philosophy.

**PHENOMENOLOGY AND EXISTENTIALISM.** Both logical positivism and ordinary-language philosophy could be viewed as extensions of Kant's criticism of dogmatic metaphysics; they both sharply contrast with Hegelianism and, in general, with the more or less speculative metaphysical systems inspired by Kant's idealism. A third major development in nineteenth-century and twentieth-century metaphysics, represented by phenomenologists and existentialists, agreed with Hegelians that metaphysics is not an observational science in any ordinary sense and also agreed with analytically minded philosophers that a priori reasoning cannot establish anything about the nature of reality. Accordingly, these philosophers sought new and unconventional ways of experiencing or encountering reality. This response is shown by more conventional metaphysicians like Henri Bergson (1859–1941), who stressed the inability of spatializing and static conceptual thinking to represent correctly the reality of immediate experience, especially its temporal flow, or by Alfred North Whitehead (1861–1947), who stressed imaginative feeling and emotion as a way of gaining access to the inner natures of things. Phenomenologists hold that common sense and science presuppose a more primitive experience that can be grasped by a delib-

erately naive description of how things actually appear to us; existentialists argue that the subject of metaphysics is a reality that cannot be described in an emotionally neutral way but is in some sense possessed or encountered in personal commitment to a cause or in facing the certainty of one's own death. Phenomenology and existentialism have been combined by systematic philosophers like Martin Heidegger and Jean-Paul Sartre, whose systems attempt to express an intuitive understanding of time, contingency, and particularity as these are experienced in human life.

**PHILOSOPHICAL ANALYSIS.** In the English-speaking world at least, the most original and important contributions to metaphysics at the present time come from analytic philosophers largely influenced by logical positivism or ordinary-language philosophy. These philosophers see the present situation in metaphysics somewhat as Aristotle did when he reviewed the history of metaphysics up to his own time. In a sense, Aristotle thought, everything had been said, but in a sense nothing had been said because the early philosophers were vague and inarticulate. Contemporary metaphysicians, however, are in a better position to review and analyze the history of their subject than was Aristotle, partly because the history itself is so much richer and partly because contemporary insights make the work of past metaphysicians more intelligible.

## Bibliography

### GENERAL WORKS

Copleston, F. C. *A History of Philosophy*, 7 vols. London: Burns, Oates and Washbourne, 1946–. A careful, detailed work requiring close study; probably the most comprehensive and scholarly general history available. Includes excellent bibliographies and sections on metaphysics in chapters on individual philosophers.

De George, Richard T., ed. *Classical and Contemporary Metaphysics: A Source Book*. New York: Holt, Rinehart and Winston, 1962. A book of readings emphasizing contemporary authors but also including selections from classical texts.

Gilson, Étienne. *Being and Some Philosophers*, 2nd ed. Toronto: Pontifical Institute of Mediaeval Studies, 1952. A challenging essay on the history of metaphysics argued with great subtlety by an outstanding Roman Catholic philosopher.

Kaufmann, Walter, ed. *Philosophic Classics*, 2 vols. Englewood Cliffs, NJ: Prentice-Hall, 1994. A comprehensive sourcebook for the history of philosophy, with some excellent introductory essays.

Lovejoy, Arthur O. *The Great Chain of Being*. Cambridge, MA: Harvard University Press, 1936. Traces some main themes of metaphysics from the Greeks to the nineteenth century; a wide-ranging essay in the history of ideas rather than the conventional history of philosophy.

Smith, T. V., ed. *Philosophers Speak for Themselves*, 4 vols. Chicago: University of Chicago Press, 1956. A collection of readings from Thales to Kant.

Whitehead, A. N. *Adventures of Ideas*. New York: Macmillan, 1933. Suggestive and sometimes profound nontechnical essays on movements in science and philosophy by a great twentieth-century metaphysician.

### PRE-SOCRATICS

Burnet, John. *Early Greek Philosophy*, 4th ed. New York, 1930. Lucid and authoritative; contains translations of some important fragments.

Freeman, Kathleen. *Ancilla to the Pre-Socratic Philosophers*. Cambridge, MA: Harvard University Press, 1948. English translations of the surviving pre-Socratic writings collected in Hermann Diel's monumental *Fragmente der Vorsokratiker*.

### PLATO

Cornford, F. M. *Plato and Parmenides*. New York: Liberal Arts Press, 1957. Translations with running commentaries of Parmenides' *Way of Truth* and Plato's *Parmenides*; for advanced students.

Cornford, F. M. *Plato's Theory of Knowledge*. New York: Liberal Arts Press, 1957. Translations with running commentaries of Plato's *Theaetetus* and *Sophist*.

Lynch, William F. *An Approach to the Metaphysics of Plato through the Parmenides*. Washington, DC: Georgetown University Press, 1959. An attempt to see the *Parmenides* as a straightforward assertion of "basic positions in Platonic metaphysics."

Ryle, Gilbert. "Plato's *Parmenides*." *Mind* 48 (1939): 129–151, 302–325. Article by a leading contemporary British ordinary-language philosopher; suggests a modern reading.

Vlastos, Gregory. "The Third Man Argument in the *Parmenides*." *Philosophical Review* 63 (3) (1954): 319–349. Technical but clear and acute analysis of the third-man argument against the theory of ideas in the first half of the *Parmenides*.

### ARISTOTLE

Aristotle. *Metaphysics*. Translated by Richard Hope. New York: Columbia University Press, 1952. With an analytical index of technical terms; a useful edition for advanced students. Index contains Greek terms with Latin equivalents.

Brumbaugh, Robert S. "Aristotle's Outline of the Problems of First Philosophy." *Review of Metaphysics* 7 (3) (1953). A brief but very helpful analysis of the organization of the *Metaphysics*.

Owens, Joseph. *The Doctrine of Being in the Aristotelian Metaphysics*. Toronto: Pontifical Institute of Mediaeval Studies, 1951. Highly technical but original and forcefully argued interpretation of the *Metaphysics*.

### NEOPLATONISM

Bréhier, Émile. *The Philosophy of Plotinus*. Translated by Joseph Thomas. Chicago: University of Chicago Press, 1958. Readable sympathetic account of Plotinus and his school by a modern French historian of philosophy.

Porphyry. *Isagoge*. Translated by J. Tricot. Paris: J. Vrin, 1947. A translation into French of the complete text, with introduction and notes.

### EARLY MIDDLE AGES

Anselm. *Proslogium and Monologium*. Translated by S. N. Deane. La Salle, IL: Open Court, 1962.

Malcolm, Norman. "Anselm's Ontological Arguments." *Philosophical Review* 69 (1) (1960): 41–62. A closely reasoned analysis of Anselm's argument and medieval and modern criticisms.

### LATE MIDDLE AGES

Copleston, F. C. *Aquinas*. Harmondsworth, U.K.: Penguin, 1955. Clearly written, relatively simple introduction to Thomas; contains a useful bibliography.

Moody, Ernest A. *The Logic of William of Ockham*. New York: Sheed and Ward, 1935. A scholarly study of William of Ockham and medieval logic and metaphysics; difficult but searching and persuasive.

Thomas Aquinas. *Concerning Being and Essence*. Translated by George C. Leckie. New York: Appleton, 1937. Difficult but important treatise on a basic distinction in Thomistic metaphysics.

### SEVENTEENTH CENTURY

Aaron, R. I. *John Locke*. London, 1955.

Balz, A. G. A. *Descartes and the Modern Mind*. New Haven, CT: Yale University Press, 1952.

Beck, Leslie J. *The Method of Descartes*. Oxford: Clarendon Press, 1952.

Descartes, René. *Selections*. Edited by R. M. Eaton. New York, 1927.

Hampshire, Stuart. *Spinoza*. Harmondsworth, U.K.: Penguin, 1987. An excellent exposition and criticism with a general concluding chapter on the nature of metaphysics.

Jackson, Reginald. "Locke's Distinction between Primary and Secondary Qualities." *Mind* 37 (1929): 56–76. Explains and criticizes Locke's contrast between ideas in the mind and qualities in things and between primary and secondary qualities.

Leibniz, Gottfried Wilhelm. *The Monadology and Other Philosophical Writings*. Edited by Robert Latta. London, 1948.

Leibniz, Gottfried Wilhelm. *New Essays concerning Human Understanding*. Translated, with notes, by Alfred G. Langley, 3rd ed. La Salle, IL, 1949. A standard edition containing some very interesting but little-known essays by Leibniz in an appendix.

Locke, John. *An Essay concerning Human Understanding*. New York: Dover, 1958.

Whitehead, A. N. *Science and the Modern World*. New York: Macmillan, 1925. Early chapters contain a brilliant critique of seventeenth-century and eighteenth-century science and philosophy.

#### EIGHTEENTH CENTURY

Kant, Immanuel. *Prolegomena to Any Future Metaphysics*. Edited by Lewis White Beck. New York: Liberal Arts Press, 1951. A good introductory text by a leading authority on Kant; contains a useful bibliography.

Smith, N. K. *Immanuel Kant's Critique of Pure Reason*, 2nd ed. New York, 1933. A classic translation of Kant's major work.

Warnock, G. J. *Berkeley*. Harmondsworth, U.K.: Penguin, 1953. An exceptionally good introductory work; highly critical of some of Berkeley's leading arguments.

#### METAPHYSICS SINCE KANT

Ayer, A. J., ed. *Logical Positivism*. Glencoe, IL: Free Press, 1959. A collection of the most important and influential papers in the logical positivist movement; includes an unusually complete bibliography covering the entire range of twentieth-century analytic philosophy.

Findlay, J. N. *Hegel*. New York: Humanities Press, 1964. A very clearheaded sympathetic exposition of Hegel's system.

Passmore, John. *A Hundred Years of Philosophy*. London: Duckworth, 1957. A useful and very well written survey of philosophy since 1860; emphasizes metaphysics and theory of knowledge in English-speaking countries.

Royce, Josiah. *The Spirit of Modern Philosophy*. Boston and New York, 1926. Lectures on post-Kantian philosophy, especially nineteenth-century German idealism.

White, Morton. *Toward Reunion in Philosophy*. Cambridge, MA: Harvard University Press, 1956. A forceful and lively essay on main issues in recent British and American philosophy; Part I is devoted to recent metaphysics.

Wolheim, Richard. *F. H. Bradley*. Harmondsworth, U.K.: Penguin, 1959. An introduction to Bradley; quite critical but closely and skillfully argued.

**Roger Hancock (1967)**

## METAPHYSICS, HISTORY OF [ADDENDUM]

### THE CRITIQUE OF METAPHYSICS

In the years just before and after World War II a decidedly negative attitude toward metaphysics pervaded the analytic tradition. Before the war the logical positivists appealed to their empiricist criterion of significance to conclude that taken at face value as claims about the non-linguistic world, metaphysical statements are literally meaningless. After the war ordinary language philosophers were not much kinder in their assessment of metaphysical claims. Here, Ludwig Wittgenstein led the charge with his claim that metaphysical statements are nothing more than nonsense born of linguistic confusion; but even ordinary language philosophers who found the Wittgensteinian critique overblown thought defenders of traditional metaphysics naïve if not totally misguided. Then, in the space of just a single year, two books appeared that did much to soften these pervasive antimetaphysical prejudices: P. F. Strawson's *Individuals: An Essay in Descriptive Metaphysics* (1959) and Willard Van Orman Quine's *Word and Object* (1960). Although each of these books was written by a philosopher whose roots were squarely within one of the two traditions that had been so critical of metaphysics, both were avowedly metaphysical works, and both exerted enormous influence on succeeding generations of philosophers.

### STRAWSON

For Strawson, metaphysics is an inquiry into the most general features of our thought about the world, what Strawson calls our conceptual framework. Revisionary metaphysicians find that framework philosophically problematic and seek to replace it with a superior framework; whereas descriptive metaphysicians have the more humble goal of describing the conceptual framework we actually employ. Strawson himself had been a leading figure in the ordinary language tradition that identified philosophy with conceptual analysis; but he denies that descriptive metaphysics is simply a form of conceptual analysis. It is both more general and more comprehensive than conceptual analysis, and it seeks to identify the presuppositions of the various uses of language that constitute the subject matter for conceptual analysis.

The topics that Strawson discusses in *Individuals* are those that provide the focus for traditional metaphysics: the individuation and persistence of particulars, the relationship between material bodies and the frameworks of

space and time, the mind-body problem, and the problem of universals. Nonetheless, Strawson's approach to these topics is colored by his ordinary language roots. He asks about the identification and reidentification of particulars, the attribution of psychological and physical predicates, and the underpinnings of the subject-predicate distinction. But not only is the methodology of *Individuals* rooted in the ordinary language tradition. Its substantive conclusions serve to vindicate the commonsense picture of the world that gets expressed in ordinary language; nor is this surprising since the book is supposed to be an exercise in descriptive metaphysics. Accordingly, the material bodies of everyday experience are taken to be the ontologically basic particulars; psychological and physical properties are construed as irreducibly different; the notion of a person is treated as a primitive concept not susceptible of any form of reductive analysis; and the distinction between particulars and the universals they instantiate is treated as ontologically fundamental.

## QUINE

The metaphysical framework at work in Quine's *Word and Object* could hardly be more different. By Strawson's standards Quine is a revisionary metaphysician. In Quine's book the commonsense metaphysics Strawson defends gives way to an austere ontological scheme geared to accommodate the core insights of what Quine takes to be the most successful scientific theory: physics. Accordingly, we have the view that time is just another dimension along with the three spatial dimensions; familiar particulars are construed as space-time worms; we have a strictly materialist account of thought and experience; talk of meanings, properties, and propositions along with the appeal to the modal notions of necessity and possibility are rejected; and the only abstract entities we countenance are the classes or sets of the mathematician.

Furthermore, while Strawson pays close attention to the ways words function in ordinary language, Quine is an heir to the logical positivist tradition and employs the technical tools of formal logic in formulating and justifying his metaphysical theory. As Quine sees it, simply by endorsing the claims of physics one is committed to the metaphysical framework he defends. Here, he relies on an account of ontological commitment he developed in works before *Word and Object*. According to that account, to determine the ontological commitments associated with endorsing a certain body of discourse, one translates the sentences making up that body into the language of first-order logic. If we call the sentences resulting from

that translation  $S1 \dots Sn$ , then we can say that in accepting the original body of discourse, one commits oneself to the existence of all those entities that must exist if  $S1 \dots Sn$  are to come out true.

So if, by this criterion, one discovers that a given statement commits one to the existence of entities of a certain sort, then, provided one accepts that statement, one is required to include entities of the relevant sort in one's ontological framework; or, better, one is so required unless one can show that the commitment is only apparent; and one succeeds in showing that if one can come up with a plausible paraphrase of the original statement that, by Quine's test, is innocent of any commitment to entities of the kind in question. The underlying theme of *Word and Object* is that there is no plausible paraphrase of the sentences making up physical theory that shows them to be free of the metaphysical commitments expressed in the ontology of *Word and Object*.

## RECENT BRITISH METAPHYSICS

The work of Strawson and Quine led to a revival of traditional metaphysics. The change was gradual, and it tended to take different forms on the two sides of the Atlantic. In Britain the influence of Strawson's approach was especially strong. Strawson's view that metaphysics is concerned with the structure of our thought about the world led to a style of metaphysics where the emphasis is on our conceptual practices and the presuppositions of those practices. Given the centrality of the idea of conceptual structures in terms of which we talk and think about the world, it is not surprising that British metaphysicians over the past four decades or so have been deeply concerned with questions about the relationship between our thought and the world that thought is about. Pivotal here has been the opposition between what Michael Dummett (1978) calls realists and antirealists. Whereas Dummett's realists want to claim that there is a mind-independent world, correspondence to which makes our statements and beliefs true, his antirealists question the idea of a reality whose constitution is independent of our conceptual activities and the conceptual structures we bring to bear in inquiry, and they hold that what we call truth is some epistemic property like that of being supported by adequate evidence.

## RECENT METAPHYSICS OUTSIDE BRITAIN

During the 1960s and 1970s metaphysical discussion outside Britain was heavily influenced by Quine. While they tended to endorse Quine's account of ontological com-

mitment, many philosophers from this period were uncomfortable with the austere metaphysical framework he had defended in *Word and Object*. A major area of concern was Quine's unwillingness to accept properties and propositions. He had argued that whereas sets have clear-cut identity conditions (a set  $\alpha$  is identical with a set  $\beta$  just in case  $\alpha$  and  $\beta$  have the same members), no such identity conditions are possible for properties and propositions. Critics such as Roderick M. Chisholm (1976) replied that we have no option but to accept abstract entities like these. The existence of properties, they said, is presupposed by our talk of similarity, by subject-predicate discourse, and by talk involving abstract singular terms like *wisdom*, *triangularity*, and *mankind*; and they argued that propositions are required to serve as the objects of our beliefs.

But in endorsing properties and propositions philosophers from this period found themselves confronted with important metaphysical questions. Familiar objects, we say, have properties, but what exactly is the relationship between an object and its properties? What is called the bundle theory provided one answer to this question. On this theory there is nothing more to an individual than the properties associated with it; familiar objects are just bundles of properties. But if that is so, it should be impossible for numerically different individuals to share all their properties. Critics of the bundle theory such as Gustav Bergmann (1967) and David Armstrong (1989) argued that since this is not impossible each familiar object incorporates a constituent over and above its properties, a constituent unique to that object. This individuating constituent was variously called a bare particular or a thin particular and was construed as the literal bearer of the properties copresent with it.

The notion of a proposition gave rise to other problems. Propositions, we think, are not just true or false; they can be necessarily true or necessarily false, contingently true or contingently false, and possibly true or possibly false. Now, Quine had notoriously rejected talk of modality. Modality, he said, is mired in obscurity. To make sense of modal notions, critics such as Saul Kripke (1972), David Lewis (1986), and Alvin Plantinga (1974) appealed to the Leibnizian notion of a possible world. The idea was, first, that our world (the actual world) is just one of many possible worlds and, second, that what is unique about modal discourse is that it takes the full range of possible worlds and not just the actual world as its subject matter. These theorists did not all agree about the nature and status of possible worlds, but they did agree in endorsing the Leibnizian idea that to say that a

proposition is necessarily true is to say that it is true in all possible worlds and to say that it is possibly true is to say that it is true in some possible world. This approach to modality proved tremendously fruitful. Not only did the framework of possible worlds shed light on talk of propositional necessity and propositional possibility, but it proved helpful as well in clarifying a whole variety of otherwise puzzling phenomena like the distinction between essence and accident, the concept of meaning, counterfactual conditionals, the concept of causation, and the notion of a law of nature.

The influence of these possible worlds metaphysicians was felt throughout philosophy, and by the 1980s metaphysics had come back into its own. For metaphysicians trained in that decade and after, the positivist and ordinary language attacks on metaphysics were quaint episodes from a distant past. These younger metaphysicians were not in the least apologetic about their discipline. Indeed, they were anxious to develop and defend comprehensive metaphysical theories. The result has been a tremendously active period in which all of the topics on the traditional metaphysical agenda have come under debate. Questions about universals, the structure and individuation of ordinary objects, and possible worlds and modality continue to be discussed; but in recent years metaphysicians have dealt with a much broader range of questions including those about the nature of time and space-time, the nature of identity and existence, the existence and structure of events, persistence through time, material constitution, the nature of fictional entities, freedom of the will, causality, and the nature of the mental.

## METAPHYSICS, NATURE OF

Almost everything in metaphysics is controversial, and it is therefore not surprising that there is little agreement among those who call themselves metaphysicians about what precisely it is that they are attempting. In beginning a discussion of the nature and validation of metaphysical arguments and theories, the best course we can follow is to list some of the standing preoccupations and ambitions of metaphysicians. For this purpose we need to make the assumption that there is a distinct class of metaphysical philosophers, a class into which such thinkers as Plato, Thomas Aquinas, René Descartes, Benedict de Spinoza, and G. W. F. Hegel would fall and from which purely critical or analytic philosophers like the later G. E. Moore would be excluded. It has to be admitted, however, that the line between metaphysical and nonmetaphysical philosophy is exceedingly hard to draw, for many metaphysicians from Plato on have been expert in the supposedly nonmetaphysical pursuit of analyzing or clarifying ideas, while few self-styled analysts have contrived to stick to pure analysis without the open or covert advocacy of a metaphysical point of view.

Setting these difficulties aside, we may note three main features of metaphysics as traditionally practiced. First, metaphysicians have constantly aspired to say what there is in the world or to determine the real nature of things; they have been preoccupied, that is, with the concepts of existence and reality. Their interest in these concepts springs from a double source: from the reflection that the surface show of things often misrepresents them, with the result that we are set the task of determining their real as opposed to their apparent constitution, and from the need to specify what ultimately different kinds

of things there are in the world, a need that presses itself on our attention when we wonder whether, for example, minds or numbers are independent existents. The first of these tasks might seem to belong to the scientist rather than the philosopher, for science, too, makes constant use of the distinction between the apparent and the real; we shall indicate in the next paragraph why metaphysicians have not been ready to accept this proposal for lightening their labors.

Second, metaphysics has been commonly presented as the most fundamental and also the most comprehensive of inquiries. It claims to be fundamental because questions about what there is or about the ultimate nature of things underlie all particular inquiries. If you are to assess the results of mathematical investigations, for instance, you need to determine the ontological status of mathematical objects, and according to the theory, this is a task for the metaphysician. The claim of metaphysics to be comprehensive is more difficult to justify. One possible line of support for it, followed by Aristotle, is found in the reflection that questions about existence and reality, along with those about potential and actual being and about causation that are also raised by metaphysicians, cut across the boundaries of particular sciences and arise in connection with every sort of subject matter. Thus, metaphysics is comprehensive just because of its extreme generality. But there is another way in which the claim to comprehensiveness has been advanced. It has been customary to say that whereas sciences like physics and mathematics are departmental studies each of which deals only with a part or particular aspect of reality, metaphysics, by contrast, is concerned with the world as a whole. This explains why philosophers have been unwilling to accept the suggestion that scientists might be left to determine the true nature of things. A scientific theory purports to explain, for example, the real constitution of matter or the fundamental mechanisms of the human body but not to draw the distinction between appearance and reality in an entirely general way, not to tell us, to give an instance, whether matter is the ultimate reality, as materialists suppose, or whether it is itself a manifestation of spirit, as Hegel tried to argue.

This contrast between metaphysics and the particular sciences is sometimes developed in yet another way, again, as will be apparent, to the great advantage of metaphysics. It is said that inquiries in the individual sciences are carried out under assumptions it is the business of metaphysics to make explicit and either to justify or to correct. Metaphysics, by contrast, proceeds without assumptions and is thus fully self-critical where the par-

ticular sciences are in part credulous. This line of argument goes back to Plato, who tells us that mathematicians postulate the existence of “odd and even numbers” and “three kinds of angles,” and implies that these “hypotheses,” taken as “starting points” or “bases” in mathematics, could find their justification and thus lose their hypothetical character in the comprehensive “synoptic” study Plato called dialectic. The dialectician is a man who leaves nothing unquestioned, and just because of this the results of all other inquiries must be seen as no more than provisional; they await ratification or correction from the dialectician. The apparently arbitrary and obviously vague character of this suggestion has not prevented its having a continued appeal to philosophers. Even today, we sometimes hear it said that we need not be unduly disturbed by, for example, the findings of physiologists and psychologists, since the proponents of these sciences work under assumptions it is the business of philosophers to uncover and correct in the light of their knowledge of the whole man (for an argument on these lines see J. S. Haldane, *The Philosophy of a Biologist*, Oxford, 1935).

If metaphysics is to make good its claim to be uniquely self-critical, its propositions must be shown to be exempt from intellectual challenge as those of no other study are. Descartes, in fact, tried to offer such a demonstration. He argued first that such commonsense assertions as “There is a table under the window” were in every case open to theoretical doubt: However much I seemed to perceive a table, it might be that I was under perceptual illusion or was dreaming. Next, he maintained that even propositions whose truth appeared to be evident, such as those of mathematics, could not be accepted as necessarily in order. An evil demon could be deceiving me into thinking them clear and distinct when they did not really deserve this description. But matters were different when we came to the fundamental metaphysical truth “I think, therefore I am.” This truth was such that in the very act of doubting it, one reaffirms it. To doubt is to think, and in thinking that I might not exist, I make clear that I do. Hence, there is at least one truth about whose correctness I could not be in error, and this is a truth of metaphysics. But Descartes was not content to stop at this point. He went on to argue that if I, a being with obvious limitations, certainly exist, then just as certainly there exists a perfect being whose nature is such that he would never deceive me into thinking that true which is not in fact so, once I have satisfied myself that it is by the test of clear and distinct perception. The effect of this move was to provide a guarantee for the findings of the sciences, which were otherwise open to “hyperbolic” doubt. We

could henceforth be assured on metaphysical grounds that whatever was clearly and distinctly perceived was true. As for the propositions of metaphysics itself, their truth was guaranteed by their connection with the *cogito*, which, as we have seen, could not be intelligibly questioned.

The interest of these arguments for our present purpose lies not in their details but in the basic claims they involve. The propositions of metaphysics, according to Descartes, are intellectually impregnable, and in this respect they contrast not only with the beliefs of common sense but also with the pronouncements of the sciences, at least when these are considered apart from their metaphysical guarantee. But from where can they derive their unique certainty? The only possible answer is from their being the products of reason when that faculty is put to work in the fullest and freest way. The result will be that metaphysics is not only the most fundamental of studies; it is also one that relies for its results on the efforts of reason alone.

#### METAPHYSICS AND THE SUPERSENSIBLE

Thus far, we have observed three main features in the projected science of metaphysics. It claims to tell us what really exists or what the real nature of things is, it claims to be fundamental and comprehensive in a way in which no individual science is, and it claims to reach conclusions that are intellectually impregnable and thus possess a unique kind of certainty. Now, many critics of metaphysics have suggested that these claims could be justified only if metaphysics were a factual science providing us, on the strength of rational insight, with knowledge of things or aspects of reality that lie beyond the range of the senses. Nor is this view without support from practicing metaphysicians. Plato drew a contrast between “things seen” and “things unseen” and argued that only things unseen were proper objects of knowledge. From his time on there was a standing tendency to identify the province of the metaphysician with what was vaguely called the supersensible, or the realm of the intellect. Aristotle, for example, distinguished between sensible and insensible substance and assigned the investigation of insensible substance to “first philosophy,” or metaphysics. Medieval and early modern philosophers thought of God, the “being of beings,” as an entity without bodily extension or shape and for that reason considered him outside the province of the empirical sciences. More generally, it was widely believed that behind the phenomena that present themselves in everyday experience, there lie realities

whose existence and properties can be established only by use of the intellect and that can hence be described as noumena, or intelligible objects. In this view, the proper concern of metaphysics was to give us news about noumena.

From the eighteenth century on much ingenuity has been displayed in showing the untenability of this position. The idea that there might be a science that was at once factual and purely intellectual drew its firmest support from the example of mathematics. David Hume suggested, however, that the concern of the mathematician was not with matters of fact and existence but solely with “relations of ideas”: His aim was only to make explicit what was already implicit in the premises from which he started. The propositions of mathematics were indeed necessary truths, but by the same token they gave no information about the world. If an inquiry was to pronounce on matters of fact, its method must be empirical, not conceptual, and this meant that its results could not possibly claim to be intellectually impregnable, for anything established on the strength of experience might need to be amended or even withdrawn in the light of further experience. There were no final empirical truths.

A natural reply to this is to argue that even if every factual inquiry must begin from experience, it need not necessarily terminate there. Why should not the metaphysician argue from the characteristics of things sensible to the existence and the nature of things supersensible, as, for instance, Thomas Aquinas and John Locke thought they could? Immanuel Kant was much concerned about the proper answer to this question. He allowed—and here he showed more sympathy with metaphysicians than empiricists then or now—that such concepts as cause and substance, which figure prominently in supposed inferences from the phenomenal to the noumenal, have a necessary character; in Kant’s terminology they are a priori, as opposed to empirical, concepts. But he denied as stoutly as Hume that they can therefore be used to carry us beyond the range of possible experience. The question “What brought that about?” is a necessary question, one we cannot rationally refuse to ask, but the answer to such questions must always be sought within experience. If we try, as, for example, Descartes did, to maintain that there must be a First Cause, a necessary being entirely different from the contingent things with which we are familiar, we cease to attach any clear meaning to the concept of cause, for, as Hume saw, it is an essential part of the idea of cause that a cause precede its effect. We can talk about causes as long as we remain within the sphere of the temporal; once we step outside it, the concept loses its determinate char-

acter. And what is true of cause here is also true of substance and other metaphysical notions. We can give sense to the concept of substance if we understand it as the permanent that persists through change, but if we eliminate the reference to time, we are left with no more than the logical notion of that which is always a subject and never a predicate, an idea that in its pure form is too indeterminate to be put to metaphysical or, indeed, any other use.

Another attack on metaphysics as the supposed science of intelligible reality was made by the logical positivists. It is a mark of those propositions that belong to accredited sciences like mechanics or genetics, they argued, that we know in principle how to test them; we can see what difference it makes that they are true rather than false. But if a metaphysician comes along and tells us that what really exists is not trees or tables but, say, monads, what tests can we apply to determine the truth of his statement, and what difference does it make if it is true? By definition monads are entities that could never be encountered within experience, nor is their presence supposed to have particular empirical consequences like that of electrons and similar unobservables postulated by natural scientists. Thus, a metaphysical thesis will be compatible with any state of affairs whatsoever, just as the propositions of logic and mathematics are. But if this is so, how can it possibly be maintained that metaphysics gives us information about the world, even the unseen world? The news it purports to bring can only be news from nowhere.

These highly general refutations of a particular conception of metaphysics have seldom been found convincing by metaphysicians. One reason for this is that they fail to come to grips with individual metaphysical arguments, for example, with the *cogito*. Another is that they appear to prejudge the case against this sort of metaphysics. Why, for example, should it be supposed that a metaphysical thesis must make an empirical difference? Another cause of their failure to carry conviction, however, may be found in the fact that many metaphysicians have worked with a different concept of their subject, one that does not involve it in the claim that it provides information or rivals the empirical sciences. This conception will be considered below.

## METAPHYSICS WITHOUT ONTOLOGY

We have already seen that metaphysicians have wanted to say both that their propositions possess a peculiar certainty and that they are significant as a purely analytic proposition is not. In Kantian terminology they pretend to the status of synthetic a priori truths. Now, many crit-

ics of metaphysics have made the assumption that a proposition could be synthetic a priori only if it at once stated a truth of fact and was established by conceptual means alone, a combination they regard as impossible. Facts must be established empirically; pure thinking can lead to the knowledge only of analytic truths. But if we look at Kant's alleged synthetic a priori judgments, particularly those he called principles of the understanding, we see that they make no claim to state facts, even very general facts. A principle like the principle of causality is not a very wide empirical truth, mysteriously known in a nonempirical way; it is, on the contrary, the expression of a rule of procedure that serves to tell us not what properties things have but how to interpret them. Kant supposed that principles of this sort had a special sort of necessity, though they did not logically compel; they owed this, he thought, to the fact that they are prescribed by the human mind as principles specifying what is to count as objective in our experience. Thus, we take it to be a feature of what is objectively there that no quality is present except in a determinate degree, that nothing ever goes entirely out of existence (all change is transformation), that nothing happens except for a reason, and so on.

Kant himself intended this doctrine to have limited application. He thought of the principles of the understanding as prescribing the form of the phenomenal world that we know by means of the senses and investigate in the natural sciences. In his view there were other aspects of experience, in particular the activities of the moral agent, in regard to which they had no legislative force. But it is possible to think of an extension of Kant's doctrine and imagine a set of principles that would prescribe the form not just of one department of experience, but of experience as a whole. A set of principles of this kind would tell us how to organize the data of our experience in such a way that we could give a unitary account of them; it would thus help us make sense of the scheme of things entire. Possessed of concepts of this sort, we could hope to resolve the apparent inconsistencies of science and common sense, together with the more serious conflicts between science and religion and science and morality. We should then be masters of an overall point of view enabling us to see things synoptically or have a set of ideas that would allow us to differentiate the real nature of the universe from its merely superficial aspects. We should, in short, be in possession of a metaphysics.

There can be no doubt that many of the classical metaphysical systems can be thought of as conforming to this schema. In the system of Aristotle, for instance, the key concepts are teleological, and their articulation is to

be found in the doctrine of the four causes. It is axiomatic in Aristotle's thought that everything serves a purpose; Aristotle's ambition is to find the point of each phenomenon and thus specify its place in the articulation of the whole. He attempted to carry through his program not only at the biological level, the most obvious source of the concepts involved, but also above and below it—in moral, political, and social life, on the one hand, and in physical science, on the other. His success in these spheres is unequal, but that does not affect the general character of the enterprise.

The popular philosophy of materialism, again, can be seen as an attempt to make sense of the world as a whole on the basis of a distinctive set of first principles. The primary thought of the materialist might be expressed in the axiom that there is nothing that cannot be satisfactorily explained in natural terms; belief not merely in the competence, but also in the omnicompetence, of natural science is a prominent item in his credo. The materialist sees the world as a vast mechanism; whatever happens is the result of natural causes, and all other phenomena must be assessed and understood on this basis. Thus, the phenomena that characterize religious and moral life can be taken in psychological and social terms as things whose causes are ultimately natural, though scarcely in the terms favored by those who engage in them. Religion, as Sigmund Freud said, is an illusion but not an unintelligible illusion; science can account for it, as it can account for everything else.

Finally, Hegelianism made a conscious attempt to produce a metaphysics that constitutes an overall reading of experience. The central concept here is the concept of spirit; it is alleged that everything can be understood in terms of this concept once we take account of the fact that spirit cannot fulfill its potentialities except by working on and against something not itself—in Hegel's peculiar language, "its own other." Thus, we can make sense of the existence of a world of nature in this system; it is there to subserve the purposes of spirit. We can make sense of the social world, too, for many of the characteristics of mind are intelligible only when people are aware of one another and know that others are aware of them. Self-respect and self-contempt would be cases in point.

Each of the systems mentioned could be said to rest on a basic idea or intuition, an idea articulated in a series of concepts taken as definitions of reality and applied, with greater or less success, to the whole range of experience. To appreciate the force of such a system, we need to grasp the basic idea as well as understand the articulated concepts; we have to see the world as the metaphysician

in question saw it. The deviser of a metaphysical theory thus becomes a man with a vision of the scheme of things entire. It is important to add, however, that he is not merely a man with a vision, in which case he would be indistinguishable from a philosophical poet. He needs to work his vision out in a theory; he needs to argue his case both by adducing those facts that immediately support it and by explaining those that on the face of things do not.

It seems clear that most of the standard claims for metaphysics can be understood with this account of the matter. Since the first principles of a metaphysical system have prescriptive force, exactly as Kant's principles of the understanding had in regard to the world of nature, they can be properly thought to compel every rational thinker. Their certainty is not the certainty of logic, and yet it exceeds that of any individual statement of fact, for facts are described only within a framework that these principles provide. Again, even if a system of this kind does not tell us precisely what there is, it nevertheless pronounces on the real character of the world as opposed to the surface show. According to the materialist, for instance, there seem to be features of experience that transcend the natural realm, but in the end it turns out that this is not so. Everything, including men's thoughts and actions, can be accounted for satisfactorily in natural terms. That a scheme of this kind is comprehensive, wider than that of any particular science, goes without saying; that it is fundamental because it is concerned with the coordination of ways of thinking in widely differing spheres is also obvious. True, there is no straightforward counterpart in this type of theory for the criticism by metaphysics of the assumptions of the particular sciences: Metaphysics not being a source of knowledge in itself, it cannot be claimed that other studies are dependent on it as, say, chemistry is dependent on physics. But this circumstance will not prevent this type of metaphysician from putting his own construction on the results of the sciences, as the example of Hegelianism shows. He may have no warrant to question such results, but all the same he may insist on interpreting them in his own way when he offers his reading of experience as a whole. Hegel was doubtless too brusque in his treatment of Isaac Newton and John Dalton, but it does not follow that the whole project for a philosophical treatment of natural phenomena is a mistake.

#### ARGUMENT AND TRUTH IN METAPHYSICS

If metaphysics answers the description given above, a description that would fit many if not quite all of the best-known metaphysical systems, two questions imme-

diately arise. First, we may be asked what sort of a study metaphysics is in this account. Is it a priori or empirical, and to what sorts of argument does it appeal? Second, there is the question what criteria to use in choosing among metaphysical systems. Seeing that many systems are possible, are there any objective ways of deciding that one system embodies the true or the proper way to look at the world?

ARGUMENT. The answer to the first query is that metaphysics, according to this account, is neither a priori nor empirical, though it makes constant use of both deductive and probable reasoning. A metaphysician is concerned to advocate, articulate, and apply a set of basic interpretative principles, categorical principles we might call them, and principles of this kind cannot be grounded in either conceptual considerations or an appeal to empirical fact. They cannot be supported conceptually since no contradiction is involved in disputing them; they cannot be deduced from facts since they claim to apply with unrestricted validity, no matter what data turn up in experience. They may indeed be suggested by experience and commonly are, but that is not to say that they can be shown to be acceptable or unacceptable by simple empirical methods. Apart from anything else there are no absolutely neutral data to which we can appeal when supporting or attacking a metaphysical theory. For though it is the case that every metaphysician has the duty of explaining all the facts as he sees them, he also has the privilege of being able to decide what really is to count as fact. To see the importance of this we have only to reflect on the different views of religious phenomena taken by materialists and their opponents.

However, though it is true that a metaphysical theory on this account can be established neither deductively nor inductively, deductive and inductive argument both bulk large in metaphysical discussion. Like any other thinker the metaphysician is much concerned with consequences and consistency. He often wants to make the point that since  $p$  is true and  $p$  implies  $q$ ; which in turn implies  $r$ , we are logically committed to  $r$  or to contending that since  $q$  is false and  $p$  implies  $q$ ,  $p$  must also be false. The very fact that a metaphysician has a theory to put forward means that he must be preoccupied with the logical connections between the concepts that constitute his system. To say this, however, is not to deny his preoccupation with fact or with probable arguments. Unlike an empirical scientist he establishes no new facts, but all the same he has a double interest in fact. First, he is concerned, more than any specialized inquirer, to see similarities in widely different areas of fact, a process that is

relevant to both the formulation and the application of his theory and that involves him in much reasoning by analogy. Second, he needs to pay constant attention to the state of factual knowledge in working out and pressing home his central insight. He promises, after all, to make sense of all the data of experience, and he must consequently take continuous account of these data. The legend that metaphysicians are indifferent to fact has no foundation; on the contrary, they have a primary interest in facts of all sorts even though they do not originate any factual propositions. The extent to which advances in cybernetics have been discussed in recent years by philosophers interested in the truth of materialism affords an apt and striking illustration of this point.

**TRUTH.** We saw that one charge made against metaphysics as a doctrine of what there is was that no decisive considerations can be adduced either for or against such a theory; the monads of Gottfried Wilhelm Leibniz and the Forms of Plato make no empirical difference. In this respect are things any better in our revised form of metaphysics? It must be confessed that the initial appearance is not favorable. We have emphasized that the first principles of such a system are neither analytic nor empirical; the temptation to conclude that they must accordingly be no more than arbitrary prescriptions, representing a point of view taken up for no good reasons, is strong. And though we have also urged that metaphysicians of this sort have a special interest in fact, the force of that contention is considerably weakened by the admission that they claim the right to decide for themselves what really is fact. If we arm them with this veto—and it is hard to see how they could be refused it—the question of metaphysical truth seems wholly intractable.

It could be, however, that we are setting an impossible standard for metaphysics in requiring it to possess a decision procedure as clear-cut as those of mathematics and the natural sciences. One reason that we can get a straight answer about the acceptability of a theory in physics is that physics works on principles that it does not question (such as that every natural happening will have a sufficient natural explanation). In metaphysics, by contrast, we are concerned with the comparison and assessment of precisely this type of principle. As the widest and most general of all forms of thinking, metaphysics can appeal to no fixed criteria beyond itself except to the requirements of internal consistency that any theory must satisfy. Nor is it true that every reputable branch of knowledge possesses obvious and easily applicable decision procedures. If, for example, we compare metaphysics with history instead of physics, we may begin to see that

there are areas of study where dispute and disagreement play a prominent part and that still can claim to proffer understanding and enlightenment. Once we pass beyond the mere ascertaining of fact, there are many histories written from many points of view and resting on many judgments about what is historically important; it is not really possible to hope for a final decision about which, if any, is correct or even about the relative merits of any two equally sophisticated interpretations. However, we do not conclude from this that history is a pointless pursuit rational men would do well to avoid. We realize that a study like history can enlarge the mind and educate the understanding even when it does not add to the sum of public knowledge.

A comparison with metaphysics that is in some respects even closer is provided if we consider the interpretation of a literary text. The data the literary critic confronts—I am thinking of someone who offers a reading of a controversial literary work like *Hamlet* or *Faust*—are “harder” than in the case of metaphysics, but this does not prevent the appearance of a wide variety of conflicting theories. And it happens that there are no accepted criteria for deciding among the various theories; all that each critic can do, in the last resort, is explain his way of looking at the text, marshal the points in its favor, and invite the reader to test the matter for himself. But we need not conclude from this that it will be a matter of luck or, perhaps, of psychology which theory will win the reader’s approval. At the end of the day, he can be entirely convinced of the authenticity of one particular reading, and he can be persuaded that it offers more enlightenment, covers the central points more impressively, and does better justice to the evidence than its rivals. He may not be able to produce knockdown grounds in favor of his choice, but that is not to say that he has made it for no reason at all.

Metaphysical argument is like literary argument in that it reaches no apparent end; it is like it again in terminating, insofar as it ever does terminate, in an insight that is more personal than public. The old dream of a demonstrated metaphysics whose propositions were even more certain than those of mathematics could scarcely be further from realization. But it would be wrong on that account to think that the concepts of truth and falsity have no application in metaphysics. At the lowest estimate we can describe one system of metaphysics as more illuminating than another. We must, however, decide for ourselves what is really illuminating and what is not. As in the case of the humanities in general, we cannot just learn the truth from another.

## CONTEMPORARY ANTIMETAPHYSICS

Theories that profess to deal with “the world as a whole,” however they are meant to be taken, are today more often objects of suspicion than of interest, thanks to the influence of G. E. Moore and the later work of Ludwig Wittgenstein. Moore himself never attacked metaphysics explicitly, and indeed his early work, both in logic and in moral philosophy, showed pronounced metaphysical leanings of a generally Platonic kind. But the “Defence of Common Sense” with which he came to be most prominently associated was evolved as a counterblast to views put forward by contemporary metaphysical philosophers, views that, as Moore saw them, could be maintained only by someone prepared to disregard what he evidently knew to be true. When F. H. Bradley, for instance, argued that time is not real, Moore thought this an absurd paradox since the reality of time is taken for granted in any statement containing a temporal expression. If time is not real, it cannot be true that yesterday was Friday or that I had my breakfast before leaving for work. Moore’s procedure here, which is to call the metaphysician’s bluff by reminding him of what in an off-duty moment he will himself acknowledge that he knows, was generalized by some of his followers into an all-round exposé of metaphysics, which they represented as necessarily consisting of paradoxes and evident falsehoods. For this purpose the thesis that everything is material did not differ from its rival that everything is spirit; both were, when taken seriously, obviously false. There might be a point in maintaining such a thesis (it could be a revealing paradox, according to John Wisdom, or serve a deep-seated psychological purpose, according to Morris Lazerowitz), but in no sense could it express what was really the case.

Moore and his followers assume here that there can be only one correct description of a situation and that in matters like dating or temporal precedence it is known to all of us. It is not obvious that this view is correct, for it could be, as Bradley thought, that a description that was valid and serviceable at the commonsense level would need to be superseded when wider considerations were taken into account. One way of putting Bradley’s view is to say that metaphysics claims to offer a conceptual scheme in terms of which we can give a description of the world that is ultimate and comprehensive, but that it also recognizes the existence of many subordinate and more limited schemes, each of which has its point in the characterization of appearances. The Bradleian doctrine of degrees of truth and reality is obviously relevant here, and it cannot be said that Moore gives it very serious consideration. But even if this point had to be granted, the

respectability of metaphysics might still be in doubt, for the whole notion of an ultimate description of the world is itself suspect thanks to the work of Wittgenstein.

According to Wittgenstein, a principal source of philosophical error has been the idea that the primary function of language is to describe. The truth is, rather, that we engage in many different “language games,” each of which serves its own purpose and each of which is authentic at its own level. There can be no question of ruling any such game out of court; the fact that it is played is sufficient evidence that it is appropriate. Nor are different sets of language users rivals; it could not be said, for instance, that physics gives a truer picture of the world than common sense or that the naïvetés of everyday moral language are corrected by the psychologist. If we keep these diverse languages apart, we see that each has its own point and utility. The idea of a finally correct language that would embrace and replace them all is clearly the height of absurdity, and, hence, metaphysics in its revised form is no more acceptable than was metaphysics in the shape of news from nowhere.

But this analysis, too, is built on questionable assumptions. First, is it really clear that language games or areas of linguistic activity are as distinct as Wittgenstein says they are? The point is by no means clear as far as the language games of science and common sense are concerned, for most scientists and many plain men think that the scientific account of the physical world gives a truer picture of it than that embodied in the ordinary man’s everyday beliefs. Nor can we agree without further argument with the thesis that sufficient authentication is found for a language game when we note that it is played. There are, after all, games and games. In a form of game much played in the ancient world, elaborate formulas to appease the god of the sea were devised by those about to embark. As a result, a certain way of talking commanded a wide use and approval. But could that fact alone be invoked to show that it was legitimate? Surely, we should want to object that however much such language was used, its use could not be legitimate if in fact there was no god of the sea or if he exercised no influence on whether seafarers reached their destinations safely. To do this, however, is to make the propriety of a language game subject to the tenability of the factual assumptions on which it rests. Although this is not to maintain that the only use of language is to describe (which would be absurd), it is to claim a certain priority for the language game in which we say how things are.

Metaphysics as we have expounded it is concerned with resolving conceptual conflicts by finding a way of

speaking that will enable us to express the true nature of the world. If we possess such a way of speaking, we have a yardstick by which to measure the ultimate tenability, as opposed to the immediate use, of particular language games—the languages of religion, science, law, and so on. It is not self-evident that each of these is in order as it is, and though the fact that they are constantly used and understood is enough to show that they serve some purpose, it does not in itself show that they are suited for the purposes those who use them have in mind. These games are indeed played, but they could, for all that, be played on false pretenses. To decide whether they are, we must have recourse to metaphysics.

### METAPHYSICS AS ANALYSIS

Even if the foregoing account of the nature of metaphysics were accepted as generally unobjectionable, there are many philosophers who would deny that it covers everything metaphysicians have attempted or are attempting to do. In particular, it fails to accommodate an activity pursued by many contemporary analytic and linguistic philosophers that has a clear affinity with the work of some of the classical metaphysicians. The classical metaphysicians were led to ask what there is partly because of puzzles about the status of numbers and qualities. Plato had produced arguments to show that these must be independently real, and Aristotle elaborated the doctrine of categories as an answer to them. Now, there are plainly parallels to this controversy in contemporary philosophy, both in the discussions among logicians about names and descriptions (which revive the ancient dispute about the relative priority of universals and particulars) and in the arguments about the relation of the mind and body that have recently been so prominent in British and American philosophy. What is notable about these issues, as opposed to those mentioned above, is that matters of fact appear to have no relevance to their solution. If we can solve them at all, we can solve them only by thinking.

This contrast is both genuine and important; there certainly are philosophical activities that are traditionally connected with metaphysics and that cannot be subsumed either under the schema given above or under that which it was meant to replace. These activities are in essence logical or analytic, and insofar as it is confined to them, metaphysics is indistinguishable from analysis. But there is no reason to confine metaphysics to such inquiries. That metaphysicians have been speculative theorists as well as ontologists in the restricted modern sense is almost too obvious to need mention; to decide, as some

commentators do, that the speculation can be set aside as regrettable and the ontology played up is at best arbitrary. Nor is it true that we can make an entirely clear-cut distinction between the two. If we look at recent work on the mind-body problem, for instance, we see that much of it is indeed logical in a wide sense of that word but that considerations of substance also come in, for example, when we discuss the nature of consciousness or of thought bearing in mind the properties and possibilities of thinking machines. An all-important motive that impels men to persist with these questions is the need to take account once more of the claims of materialism against a background in which new scientific and technical discoveries seem to lend increased support to those claims. However fascinating logical problems may be, interest in them cannot be long sustained without some external stimulus. It is such a stimulus that metaphysics of the broad kind argued for above may be expected to provide.

## METAPHYSICS, NATURE OF [ADDENDUM]

What is metaphysics? An answer to this question requires a specification both of the *scope* of metaphysics—that is, of the nature of the questions that metaphysicians raise and attempt to answer—and of the *methods* that they employ in this enterprise.

### THE SCOPE OF METAPHYSICS

As regards scope, a natural answer is that metaphysics is concerned with the investigation of the ultimate nature of reality, where this involves the attempt, first, to arrive at the most fundamental truths about what exists, and, second, to provide an account of the concepts that are involved in such fundamental truths. This characterization immediately gives rise to the question of the relation between metaphysics and science. The goal of physics, surely, is to arrive at the ultimate truth concerning the nature of the physical world. Similarly, the goal of psychology is to determine the ultimate nature of minds and mental states. How, then, do the sciences leave any room for the discipline of metaphysics?

This is a crucial question. But if one considers the issues that metaphysicians address, a clear answer will emerge. First of all, then, a central part of metaphysics involves offering accounts of concepts that are essential to scientific theories in general but of which no account is offered within any of the sciences themselves. These will include such concepts as those of particulars, properties, relations, persisting entities, events, states of affairs, causation, and laws of nature, and, with regard to these concepts, metaphysicians will ask, for example, whether causal relations logically supervene on noncausal states of affairs and whether laws of nature logically supervene upon the total history of the universe.

Second, philosophers attempt to establish necessary truths involving some of those concepts. Some of these possible necessary truths—such as the claim that any particular must have some intrinsic properties—may very well have no bearing upon scientific theories. Others, however, certainly do so. Thus, for example, the thesis that any particular must have some categorical properties implies that some current scientific theories are incomplete since they attribute propensities to objects without supplying any categorical basis. Or, more dramatically, other metaphysical theses—such as the much-discussed proposition that it is impossible for a cause to be either earlier than or simultaneous with its effect—are on a collision course with some scientific theories that have been

advanced. So, for example, this claim entails that tachyons cannot exist and that positrons cannot be electrons traveling backward in time. It also means that the General Theory of Relativity, in allowing for causal and temporal loops, is allowing for something that is logically impossible. Or, again, if a cause cannot be simultaneous with its effect, then the mathematical formulation of Newton's Second Law of Motion— $F = ma$ —is not satisfactory since it fails to assign different times to the force and the acceleration that it causes.

Third, science is typically silent on questions that have no bearing on the experimental content and predictions of scientific theories. A vivid illustration here is provided by the philosophy of time. For, contrary to what Putnam and others have claimed, current scientific theories such as the Special Theory of Relativity do not settle the issue between tensed and tenseless accounts of the nature of time. Metaphysicians are, then, addressing a perfectly legitimate question when they ask whether a tensed view of time is right, or a tenseless view, and this is clearly not a question that physics attempts to answer.

Fourth, physics and the other sciences involve presuppositions for which they offer no justification. In particular, it is assumed that there is an external world and that it is a material world. Metaphysics, by contrast, makes no such assumption, and so treats it as a question to be investigated and, hopefully, answered whether there is a material world or whether, instead, the basic concrete particulars are mental entities so that some form of idealism is true.

Fifth, physics, in attempting to arrive at theories that will provide explanations of physical events, takes for granted the idea that the world of physical events is causally closed so that the only causes of physical events are other physical events. Our ordinary experience, on the other hand, appears to provide considerable support for the view that experiences involve qualitative properties, or qualia, that, in the first place, are not reducible to the fundamental entities, properties, and relations postulated in physics, and that, in the second place, appear to enter into the causation of some physical events. It is very natural to think, for example, that when a person sees something and says that it is red, that there was a property of qualitative redness that the person was aware of and that that property played a causal role in producing that person's utterance. Metaphysicians, accordingly, working in the philosophy of mind, view it as a controversial matter whether the causation of physical events involves only the entities, properties, relations, and states of affairs that are the stuff of physics. In addition, the idea that the world of

physical events is causally closed rules out libertarian free will, and again, a metaphysician will insist, correctly, that until this issue is examined and settled, the assumption that physical events have only physical causes is not a justified assumption.

Sixth, the sciences rely upon induction in the form of the method of hypothesis or inference to the best explanation. The question of the justification of such methods—or of induction in general—is, of course, a question within epistemology. However, the answer to this epistemological issue may very well turn upon questions in metaphysics. So, for example, some philosophers have argued that, on the one hand, if laws are merely certain sorts of cosmic regularities, then one can never be justified in believing that any exceptionless, nonprobabilistic law obtains, and, on the other hand, that such beliefs can be justified given a metaphysically stronger conception of laws—such as the view that they are second-order relations between universals. A justification of the methods of science may depend, accordingly, upon the answers to important metaphysical questions.

Seventh, one of the crucial questions concerning the nature of reality is whether the natural world was brought into existence by God, or, at least, by some sort of immaterial being, possibly of a much more limited sort. Scientifically-based arguments have, of course, been offered both for and against the existence of an immaterial creator, but the evaluation of such arguments continues to be something that falls outside of the scope of science as presently practiced.

Finally, the sciences are concerned exclusively with the existence of contingent entities and states of affairs whereas metaphysics is not. For while questions about whether there are properties that are not reducible to those of physics, about whether the world of physical events is causally closed, about whether humans have libertarian free will, and, most would say, about whether God exists, are questions about contingent matters, metaphysics is also concerned about the existence of various things such that, if they do exist, it appears that their existence is necessary rather than contingent. Do numbers and other mathematical entities exist? Does the null set exist? Do other set-theoretical entities not involving any contingent entities exist? Is there a Platonic realm consisting of transcendent or uninstantiated universals? Do objective values exist—perhaps, as Plato thought—also in the same realm as transcendent universals? Is there a world containing intentional entities—such as concepts, propositions, or nonconcrete possible worlds? In conclusion, then, it seems clear that there are an enormous

number of very important issues that are concerned with the ultimate nature of reality and that do not fall within the scope of science.

### THE METHODS OF METAPHYSICS

Metaphysical claims vary in their modal status: Some, if true, are contingent truths while others, if true, are necessary truths. One would expect, then, that quite different methods must be employed in these different cases. In fact, however, the variety is considerably greater than this suggests. Let us consider, then, some of the more important methods that philosophers use in the attempt to arrive at knowledge of metaphysical truths.

**DIRECT ACQUAINTANCE WITH MENTAL ENTITIES.** Consider disputes in present-day philosophy of mind concerning the existence and nature of qualitative properties of experiences, or qualia. Philosophers who affirm the existence of qualia appeal, for example, to logical possibilities of zombies and inverted spectra. Arguably, however, such appeals involve the idea that there are properties that one is directly aware of—properties that would be absent in the case of zombies and differently correlated with physicalistic properties in the case of inverted spectra. At bottom, accordingly, there seems to be an appeal to the idea of direct acquaintance with instances of properties and relations.

The idea of direct acquaintance is least controversial when invoked in support of properties and relations that can be completely given in experience. Many philosophers, however, maintain that one can also be directly acquainted with mental states that involve intentionality—such as thoughts, beliefs, preferences, emotions, and so on—while some philosopher claim that one can also be directly acquainted with a self that enjoys those various mental states.

**DIRECT PERCEPTION OF NONMENTAL ENTITIES.** If it exists, direct acquaintance provides one with noninferential knowledge—or, at least, noninferentially justified beliefs—concerning mental states of oneself. Many philosophers argue, however, that the scope of noninferential knowledge is not restricted to one's own current mental states. Thus it is claimed, for example, that one can have noninferentially justified beliefs about events that happened yesterday—which will therefore allow one to set aside Bertrand Russell's suggestion that perhaps the world came into being five minutes ago. Or, one can have noninferential knowledge about the existence of external, material objects, and so know that one is not a brain in

vat and that idealism is not true. Or, one can be directly acquainted with objective moral values, such as the non-natural properties of George Edward Moore, or with mathematical entities, such as the natural numbers, or with supernatural minds, such as God.

None of these claims is, of course, uncontroversial. Indeed, some of them are highly contentious. The point is simply that in trying to get clear about what legitimate methods are available to the metaphysician, the idea of noninferential knowledge of contingent states of affairs—an idea often associated with such notions as direct awareness, direct acquaintance, and direct perception—deserves serious examination.

**INDUCTIVE METHODS.** However broad the scope of noninferential knowledge may be, it is surely true that many important metaphysical propositions concerning contingent matters of fact are such that they cannot be known in that way: They must, on the contrary, be justified on the basis of other justified beliefs. Consider, for example, the thesis that humans have immaterial, immortal souls, or the thesis that the mind is identical with the brain, or the thesis that the theoretical entities postulated by physics are real.

How do metaphysicians proceed in such cases? It is hard to see any alternative to the inductive methods employed within science where one employs such notions as hypothetico-deductive method, crucial experiments, and inference to the best explanation.

Thus, one possibility is to try to arrive at plausible entailments of the relevant proposition that can be experimentally tested. So, for example, the proposition that humans have immaterial minds would certainly seem to entail conclusions concerning what will happen in cases of brain damage. If this is so, one can then determine whether those predictions hold true. Here, as elsewhere, of course, if the predictions turn out to be false, one can modify the theory so that one has a theory that no longer has those entailments. But then considerations of simplicity and ad hocness, which are appealed to within science, will become relevant.

In some cases, one may not be able to construct an experimental test since one is dealing with theories that are experientially equivalent. Consider, for example, the problem of deciding between Berkeley's theory of reality and the view that there is a mind-independent, physical world. In such cases philosophers have sometimes been tempted to embrace the view that there are competing, interpretative, conceptual schemes between which there is no rational way of deciding. But here it is important to

notice that one can equally well have competing scientific theories that are observationally equivalent—a fact that does not mean that there cannot be rational grounds for preferring one theory to the other. Two theories may, for example, differ radically with regard to simplicity, and one may be able to show, within a sound, inductive logic, that the simplicity of a theory is directly related to the a priori probability that the theory is true.

Many metaphysical propositions, however, are not concerned with contingent matters of fact. What methods are available, then, when one is dealing with propositions that, if true, are necessary?

**ANALYTIC DERIVATION.** One fundamental method for establishing metaphysical truths that are necessary is by showing that they are analytically true statements, where this is a matter of showing that they follow from logical truths in the narrow sense via substitution in accordance with relevant definitions.

But how are the definitions to be assessed? Here there are at least two fundamental criteria: one positive and one negative. As regards the negative criterion, a definition must not be exposed to counterexamples, so a very important task in evaluating a definition is to see whether it is possible to construct counterexamples to the definition. If it appears to satisfy this negative criterion, then the next question is whether the definition enables one to derive what seem to be the fundamental necessary truths involving the concept in question.

**THE SEARCH FOR TRUTHMAKERS.** Another important technique that metaphysicians use in attempts to establish necessary truths is that of asking what sorts of facts or states of affairs could suffice to make relevant statements true. Thus, David Lewis (1986), for example, argued for the existence of a plurality of possible worlds by attempting to show that, on the one hand, such concrete worlds can serve as truthmakers for statements about what is logically possible, logically necessary, and logically impossible, and, on the other hand, that nothing else, including ersatz possible worlds, can do so. If this is right, and if, as is surely the case, at least some modal statements are true, then it follows that there is a plurality of concrete worlds.

Another illustration is provided by laws of nature. Thus, it is possible first of all to describe worlds that contain fewer and fewer instances of some basic law of nature that obtains in our world, and then, second, to argue that even if there were no instances, the law in question *could* still obtain. If this is so, then the truthmakers for nomo-

logical statements cannot be cosmic regularities, and other possibilities will have to be canvassed—such as states of affairs involving either dispositions that are never manifested or second-order relations between universals.

**THE APPEAL TO INTUITIONS.** A third important method that philosophers employ in attempting to arrive at necessary truths is that of appealing to intuitions. Where a metaphysical truth, if necessary, appears to be an analytic truth, the appeal to intuition would not seem to be a satisfactory terminus since it provides no account of why the proposition that seems to be necessarily true is true whereas an analytic derivation would do precisely that.

Many philosophers hold, however, that there are a priori necessary truths that are not analytic. So, for example, there are propositions concerning apparently simple, incompatible properties, such as the proposition that nothing can be both red and green at the same place at the same time. In addition, if ethical statements have cognitive content, then it is natural to think that there are basic moral statements that would be true in any possible world and thus which are necessary—such as the proposition that pain is intrinsically bad and the proposition that the killing of innocent persons is *prima facie* seriously wrong. But if this is right, then, if it can plausibly be argued that such propositions are not analytically true, there may be no alternative to the view that the truth of such propositions is known by means of some sort of direct, intellectual intuition, however uninformative such an account may seem.

## MEYERSON, ÉMILE

(1859–1933)

Émile Meyerson, a French epistemologist and philosopher of science, was born in Lublin, Poland (at that time Russia). He was educated in Germany, where, after completing his classical studies, he studied chemistry under Robert Wilhelm Bunsen. In 1882 he settled in Paris; following a disappointing experience with industrial chemistry, he served as foreign editor of the Havas news agency and later as director of the Jewish Colonization Association for Europe and Asia Minor. After World War I he became a naturalized French citizen.

Meyerson never held an official teaching position. But a group of philosophers and other scholars, attracted by his celebrated erudition, formed an eager and attentive audience. He was especially well versed in the history of the sciences (chiefly, but not exclusively, the physico-chemical sciences) from their origins to their most recent developments. His command of language, his clarity of

thought, and his extraordinary capacity for work served him well. Both his writings and his person gave an impression of great robustness—"solid as a Roman wall," as André Lalande once remarked.

Meyerson's philosophy was offered not as a philosophy of nature but as a "philosophy of the intellect." He set himself the tasks of disentangling the principles that govern the advance of thought and of extracting from reason the kernel that constitutes the *intellectus ipse*. This search for the a priori, he held, this new critique of pure reason, should not itself be conducted in an a priori manner. It had to proceed empirically—not directly, through a psychological analysis of the activity of thought, but indirectly, through reflection on the products of thought. These products may be true or false, so long as they bear witness to a serious effort of the intellect. From this point of view, the history of the sciences provides unique documentation. Thus it is that, of Meyerson's three major works, the first (*Identité et réalité*, Paris, 1908) is almost exclusively epistemological; but in the second, *De l'explication dans les sciences* (Explanation in the sciences; 2 vols., Paris, 1921), and especially in the third, *Du cheminement de la pensée* (The ways of thought; 3 vols., Paris, 1931), the scope is widened to encompass the whole of knowledge. In the last two works it is shown that the mind works always and everywhere in the same fashion, and this catholicity of reason proves that it does indeed include a portion that is a priori.

Each of Meyerson's works begins with an attempt to dispel the positivist bias that weighed so heavily on his years of apprenticeship. Science requires the concept of thing; science searches for explanation. It is not content simply to bind together by laws the phenomena given us in sense experience in order only to predict and control them. Science tends to dissolve the qualitative datum—but only to reach behind it for a more lasting and more objective, substantial *real*. Science not only seeks to know the how, but also to understand the why. Its aim is speculative. Its theories are not merely edifices built of laws; they claim to reveal to us the innermost causes of things. Realism and causalism are two fundamental tendencies that, taken together, govern the entire activity of the scientist. For the scientist, "phenomenism" and "legalism," when he submits to them, are only provisional stages. His ambition is to get to the bottom of things, his ultimate purpose is an ontological one.

In what does explanation consist? It is at this point that the Meyersonian theory proper begins. In every domain, whether it be philosophy, science, or everyday life, to explain is to identify. Causality is nothing but a

form of logical identity. We understand a change only when it becomes evident to us that, at bottom, nothing has happened, that the entire effect was already present in the cause—or at least that the change has been reduced to the minimum, to a simple displacement. The old adage *causa aequat effectum*, mechanistic theories, and chemical equations all manifest this identifying tendency. As the Eleatic paradoxes attest, we are troubled even by change of place and by the mere passage of time. Reason is satisfied only to the degree that it succeeds in eliminating time. The principle of inertia, the reversibility of mechanical phenomena, the conservation of matter and energy, the permanence and immutability of the ultimate elements, show in what direction we insistently turn as we strive for intelligibility.

Yet in a world thus rigidly set, there still remains a qualitative diversity that is the source of new attempts at identification: the elimination of “secondary qualities,” the explanation of apparent differences in terms of combinations of quite similar elements from which all but geometrical properties have been removed. Thus the world is fully intelligible to us only if we succeed in assimilating it, in the final analysis, to homogeneous space. Being, like becoming, tends to turn into its opposite when our reason seeks to explain it.

But reality resists this persistent will to identify. Carnot’s principle defeats any hope of eliminating time. It proves that the irreversibility of the course of time is not a subjective illusion, that the future is not interchangeable with the past, in brief, that something really does happen. Furthermore, in denying sense qualities any place in the physical world, mechanism has not thereby made them disappear. The heterogeneity of the data of sense exists unexplained and indeed inexplicable from a mechanistic point of view. In addition, atomic discontinuity puts an obstacle in the way of geometrization. Reality rejects the identity to which reason would reduce it. The real is only partly intelligible; it contains elements that are irreducible, and hence irrational. It is in fact the presence of these irrational elements, contradicting the rationalist idealism of the philosophers, that can serve to define the real in opposition to the structures erected by our thought. Thus while reason may well move from success to success in the quest for identity that essentially motivates its activities, it can never win a definitive victory. In the end, it is condemned to defeat.

Indeed, how could matters be otherwise? There is something odd and almost absurd about this endeavor of reason, for its complete success would betoken its ultimate failure. To explain reality fully would amount pre-

cisely to denying it as real, to dissolving it into a motionless and undifferentiated space, that is, into nothingness. A perfect explanation of the world would end up in acosmism. And the conflict would be met with again even if the object studied were only an ideal one, as in the case of mathematical speculation. Reasoning, even that which is apparently formal, is never tautological. Thought, at work, advances; it does not just repeat interminably that *A is A*. Meyerson came to emphasize more and more reason’s need for something diverse to assimilate, and he tended to define reason not so much by its end, identity, as by its activity, identifying. Reason is thus essentially divided against itself. This is the epistemological paradox.

Meyerson later extended these views to other domains, from scientific reason to philosophical reason, from the modern physicist to primitive man and the medieval thinker; but they were first suggested to him by reflection upon classical science. Have the revolutions in physics served to confirm or contradict them? In *La déduction relativiste* (Paris, 1925), Meyerson easily showed that relativity theory was inspired throughout by the same ideal of objectivization and geometrization. Like Parmenides’s sphere or René Descartes’s world, Albert Einstein’s universe is resorbed into space. However, quantum physics, because it sets bounds to continuity and objectivity, contains something “unassimilable.” Meyerson believed, nonetheless, that quantum theory, in the interpretation given it by the Copenhagen school, was a passing “aberration,” and that as soon as the physicists recognized the possibility of doing so, they would hasten to return to traditional views—a conjecture that was in part subsequently verified.

If the detail is rich, the broad outlines of Meyerson’s philosophy are simple and clear. It enjoyed great prestige about 1930. Since then, it has been somewhat overshadowed by the philosophy of the scientific theorists of the Copenhagen school, although Louis de Broglie retains the high estimate of it stated in his preface to Meyerson’s *Essais*. Meyerson’s philosophy has also been neglected because of the general shift of interest among contemporary philosophers from epistemological to existential problems.

## MIDDLETON, CONYERS

(1683–1750)

Conyers Middleton was an English historian and clergyman; he entered Trinity College, Cambridge, in 1700. He took orders in the Church of England and became a fellow of his college, but he had to resign his fellowship at the time of his first marriage in 1710. He held various livings but never obtained any considerable preferment in the church. The course of Middleton's life unfortunately provides several grounds for questioning his integrity and ingenuousness.

Middleton's first major publication was *A Letter from Rome, showing an exact conformity between Popery and Paganism* (London, 1729). His theme was certainly not entirely original. It can, for instance, be traced to Part IV of Thomas Hobbes's *Leviathan* (1651), and there is even some suspicion of plagiarism at the expense of a little-known French treatise, *Conformité des cérémonies modernes avec les anciennes* (Leiden, 1667). What was

remarkable was the force and skill with which Middleton traced the relics of the worship of Vesta in the cult of the Virgin and deployed passages from the Christian Fathers that excoriated as heathen such practices as the erecting of votive tablets or the use of holy water.

Daniel Waterland, in his *Scripture Vindicated* (London, 1731–1732), had attacked the deist Matthew Tindal's *Christianity as Old as the Creation* (London, 1730). In 1731 Middleton published an anonymous *Letter to Waterland*, in which he urged that it was unwise to insist on the literal truth of every sentence in the Bible, and in particular ridiculed bits of the book of Genesis. His authorship was discovered, and during the ensuing uproar the public orator of Cambridge was heard to cry for a book burning. Middleton next wrote a very profitable *Life of Cicero*; in this instance the charge of plagiarism seems to have been borne out.

After writing an *Introductory Discourse* (1747), Middleton published *A Free Enquiry into the Miraculous Powers, which are supposed to have subsisted in the Christian Church from the Earliest Ages, through several successive Centuries* (London, 1748). Coincidentally, David Hume's first *Enquiry*, containing the section "Of Miracles," which later became notorious, was published in the same year. Many years later, in *My Own Life* (London, 1777), Hume confessed his chagrin: "On my return from Italy, I had the mortification to find all England in a ferment, on account of Dr. Middleton's *Free Enquiry*, while my performance was entirely overlooked and neglected."

There was every reason to compare the two books, for the tendency of both was to undermine belief in the miraculous. But whereas Hume was raising methodological difficulties about the possibility of providing adequate historical proof of such occurrences, especially in a religious context, Middleton was concerned primarily with the historical evidence actually available. His argument was addressed in the first instance to those, including the great majority of educated Protestants, who believed both that the occurrence of miracles was a guarantee of religious truth and that the age of miracles was now past. This position was obviously precarious, for where precisely was the crucial dividing line to be drawn? Middleton directed his onslaught at this weak point. It was, as Leslie Stephen said, "incomparably the most effective of the whole deist controversy." Although Middleton himself never ventured to question the miracle stories of the New Testament, he attacked the credibility of similar accounts in the early Christian church. In a series of damaging quotations, he displayed the credulity of the Fathers, including some of the most respected, such as St.

Augustine, and even cited passages in which others seem to have been deliberately approving pious frauds. The impact of Middleton's attack would have been smaller on a position that was less inherently precarious. Arguments of this kind would not have been effective, for instance, with Protestant "enthusiasts" such as the Wesleys or with the Roman Catholics, who insisted that the age of miracles was not past. As a historian, Middleton displayed the faults characteristic of his period, particularly the naive view that stories must be either wholly and straightforwardly true or else just lies. His importance lies in the contributions he made toward undermining the arbitrary barriers between secular and sacred history.

## MIKHAILOVSKII, NIKOLAI KONSTANTINOVICH

(1842–1904)

Nikolai Konstantinovich Mikhailovskii (Mikhailovsky), the Russian philosopher, social thinker, and literary critic, was a theorist of Russian Populism and an exponent of a form of positivism first advanced by his contemporary, Pëtr Lavrov. Mikhailovskii was born near Meshchovsk, Russia, the son of a landowner of moderate means. After his parents' death, he was enrolled in the St. Petersburg Mining Institute in 1856. Expelled in 1861 for leading student protests against the government, he became a writer on social and literary topics for progressive St. Petersburg reviews. From 1869 to 1884 he edited *Otechestvennyye zapiski* (Annals of the fatherland), at that time the chief organ of Russian radicalism. Mikhailovskii was

periodically banished from the capital by the tsarist authorities, but he sufficiently tempered the expression of his views to avoid imprisonment and permanent exile. He remained an influential radical spokesman until his death in St. Petersburg.

Mikhailovskii's humanistic, democratic outlook took shape early in his career, under the influence of John Stuart Mill, Pierre-Joseph Proudhon, and the Russian thinkers Aleksandr Herzen and Vissarion Belinskii. The most direct and extensive philosophical influence on Mikhailovskii was that of Lavrov, whose combination of an antimetaphysical positivism with an emphasis on the "subjective," moral demands of the human consciousness provided Mikhailovskii with his basic philosophical orientation. In his numerous philosophical essays, chief of which is *Chto takoe progress?* (What is progress?; 1869–1870), Mikhailovskii strongly developed the ethical foundation and the individualism of this orientation and defended it against the views of Herbert Spencer, Auguste Comte, Charles Darwin, and later against those of Karl Marx and Friedrich Engels.

In opposition to Spencer, Mikhailovskii argued that human progress cannot be understood "objectively," or nonteleologically, and that in general the phenomena of man's historical and social life can only be approached through a "subjective method" that takes into account the feelings and aims of the individual and makes moral evaluations. Mikhailovskii protested the stunting of the individual by the division of labor in modern industrial society, maintaining that the goal of progress should be a more homogeneous social order in which each individual would be able to develop his diverse abilities comprehensively and harmoniously. Against the social Darwinists he maintained that in human society a struggle for survival is neither inevitable nor desirable, and he asserted that as the division of labor was eliminated, economic competition would yield to cooperation. During the last quarter of the nineteenth century, Mikhailovskii was a leading exponent of Russian Populism—a form of agrarian socialism that emphasized the *obshchina*, or peasant village commune.

Like Comte, Mikhailovskii viewed historical progress as occurring in three stages. Adhering to the "subjective method," however, he distinguished these stages by reference to their teleology. In the objectively anthropocentric stage man sees himself as the end or purpose of nature. In the eccentric stage he still finds ends in nature but no longer regards himself as their unique focus. In the subjectively anthropocentric stage man finally realizes that ends or purposes do not inhere in nature but are pro-

duced by him; the individual dispenses with supernaturalism and metaphysics of every sort and relies on his own active energies for the promotion of his moral ideals.

Mikhailovskii's doctrines, and in particular his emphasis on the autonomous moral individual, brought him into sharp conflict with nascent Russian Marxism. In the 1890s his critiques of Marxism were extensively attacked by both Georgii Plekhanov and V. I. Lenin.

## MIKI KIYOSHI

(1897–1945)

Miki Kiyoshi, a Japanese philosopher of history and leading intellectual in the stormy years before World War II, was born in Isseimura, Hyogo prefecture. He was a student of Nishida Kitarō and of Hatano Seiichi at Kyoto University. He developed an early interest in the philosophy of history and studied in Germany (1922–1924) under Heinrich Rickert and Martin Heidegger, absorbing

also some socialist ideas. In 1927 he accepted a chair of philosophy at Hōsei University, Tokyo, but he had been rejected as a teacher by his alma mater for dubious reasons—he had a love affair with a widow, in his day a more than sufficient reason to be excluded from a state university. Feeling resentment, and moved by the social climate of the time, he became Japan's first spokesman for philosophical Marxism. His essays on historical materialism (1927–1930) created a stir in academic circles and in the general public. His Marxism, however, was strongly colored by Heidegger's *Anthropologie* and by Blaise Pascal's conception of man, two views he had studied as a youth. His later works are not at all Marxist. In 1930 he was briefly imprisoned for contributing money to leftist causes; as a result he had to give up his teaching career and make a living as a social critic. During the crucial years before World War II, as ultranationalism became pervasive, Miki at first held to liberal principles without compromise. In 1936, he joined the Shōwa Research Society, which was led by Prince Konoe Fumimaru and which strove to moderate though not to oppose the mounting militarist trend. As the Shōwa became more and more nationalistic, Miki, though liberal at heart, had to compromise. For opposing Japan's entry into World War II and for aiding prosecuted leftists, he was returned to prison toward the war's end, and there he died.

Miki's best works are *Rekishite tetsugaku* (Philosophy of history; Tokyo, 1932) and *Kōsōryoku no ronri* (The logic of the power of imagination; Tokyo, 1939). In the first work Miki's starting-point is the subjective existential and sensible experience of life. From this he proceeds to formulate the structure of “history-in-the-making.” Fundamental experience of life, he says, creates selfhood, the historical subject that is the only maker of history, since in selfhood there are not subjective and objective factors, but only lived experience. *Kōsōryoku no ronri* reflects Miki's use of Immanuel Kant's *Einbildungskraft* (“imaginative power”) as it was revived by Heidegger and also reveals the evolution of Miki's thought away from the logos as social rationality that dominated *Rekishite tetsugaku* and toward a major role for pathos, the subjective inspiration that in Japan led to ultranationalist feelings. Miki was perhaps hinting that rationality was losing ground to ultranationalist passion. At any rate, for Orientals, the logic of the imagination, with its creation of myths and of what Miki calls “forms” of technocultural systems, is said to have some advantages, such as artistic inventiveness and creativity, over conceptual knowledge and usual logic. Miki uses terms borrowed from his master Nishida, the originator of the Oriental “logic of field.”

## MILHAUD, GASTON

(1858–1918)

Gaston Milhaud, a French philosopher, came to philosophy by way of mathematics, which he taught for nearly ten years in the lycées before becoming a professor of philosophy at the University of Montpellier. In 1909 he went to the University of Paris, where the chair of history of philosophy in its relationship to the sciences was created especially for him.

His courses on Antoine Augustin Cournot and Charles Renouvier were published (*Études sur Cournot*, Paris, 1927; *La philosophie de Charles Renouvier*, Paris, 1927). Under the influence of Paul Tannery, his works on the history of science were at first devoted to Greek science: *Leçons sur les origines de la science grecque* (Paris, 1893) and *Les philosophes géomètres de la Grèce* (Paris, 1900). Later they were extended to include modern science. Examples are *Études sur la pensée scientifique chez les Grecs et chez les modernes* (Paris, 1906); *Nouvelles Études sur l'histoire de la pensée scientifique* (Paris, 1911); and *Descartes savant* (published posthumously, Paris, 1923).

Milhaud was both a historian and an epistemologist. With Henri Poincaré, Pierre Duhem, and Édouard Le Roy he belongs to that group of French scholars who around 1900, following the path opened for them by Émile Boutroux, denounced scientific dogmatism, using as a basis the precise analysis of past and contemporary examples in history of science. They emphasized the role of

spiritual initiative, and thus the element of contingency, in the construction of scientific theories. Milhaud himself generally avoided the dangerous words *convention* and *commodité* used by Le Roy and Poincaré. He spoke, rather, of free creations, of the activity of the mind, and of the spontaneity of reason (*Le rationnel*, Paris, 1898). In his thesis, *Essai sur les conditions et les limites de la certitude logique* (Paris, 1894), he maintained that certitude, which is founded on the principle of noncontradiction, is limited to the domain of pure mathematics. He believed that it was thus possible to establish a radical break between the realm of mathematical knowledge and the realm of knowledge of the real world.

However, almost immediately thereafter (2nd ed., 1897), he regretted having shown himself to be too much the logician: "I see today that even in the extreme example of absolute rigor dreamed of by the mathematician, the living and dynamic identity of thinking always takes precedence over the static immobility of the principle of identity." The fundamental concepts and principles of all sciences result from rational decisions that simultaneously transcend both experience and logic, in the sense that they are not determined by either external or internal necessities. Positivism is, therefore, outmoded. A "fourth stage" consists of the liberation of thought from the obstacles imposed on it by the dogmatism of Auguste Comte (*Le positivisme et le progrès de l'esprit*, Paris, 1902). Nonetheless, scientific contributions are not arbitrary, and they have a universal value, in that they have matured on a basis of fact and have gradually imposed themselves upon the mind as a network of relations in which logical exigencies are composed and harmonized with the demands of a practical and aesthetic order.

## MILL, JAMES

(1773–1836)

James Mill, a British historian, economist, psychologist, utilitarian philosopher, and father of John Stuart Mill, was born in Scotland but spent most of his adult life in London. His father was a shoemaker, but his mother was ambitious for James to get a good education and to rise to a higher rank in society. He attended the University of Edinburgh, supported by the patronage of Sir John Stuart (1759–1815), for whom John Stuart Mill was named. Mill distinguished himself as a Greek scholar, receiving his MA in 1794. He then studied divinity and was licensed to preach in 1797. He gave some sermons, but by this time he was an agnostic, basing his disbelief in a benevolent deity, according to his son, on the degree of evil in the universe. He did some tutoring in Scotland, but in 1802 he moved to London where he sought to make a living as a writer and editor. He contributed to a wide assortment of newspapers and journals, and, from 1803 to 1806, he edited the *St. James Chronicle* and the *Literary Journal*. The latter was an ambitious periodical that professed to give a summary view of all the leading departments of human knowledge. In 1805 he married Harriet Burrow, and their first child, born in 1806, was John Stuart Mill.

In 1808 Mill made the acquaintance of Jeremy Bentham (1748–1832), the founder of the utilitarian tradition in modern philosophy. Mill adopted Bentham's utilitarian philosophy and used it as the foundation for his writings on government, education, freedom of the press, and other topics. In 1806 Mill began an ambitious project: to write *The History of British India*, emphasizing the social conditions and movements rather than battles and rulers. This was not completed until 1818, but it immediately became the definitive work on the subject and led to Mill being offered a position at India House, from which the East India Company managed British interests in India. He rose to the position of head of the office and served there until his death.

Mill was not only a “disciple” of Bentham. He was a friend and for a time financially dependent on Bentham's support. At times he and his family lived in houses owned by Bentham, and he and his family spent several summers at Bentham's summer houses. On these summer visits Bentham depended on Mill to be his conversational companion. Mill also edited some of Bentham's writings.

One of Mill's life works, and that for which he is now most famous, is the education that he gave his son John Stuart Mill. From infancy John Stuart was tutored by his father, seven days per week, studying in the room where

James was writing the *History of British India* and other articles to support the family. At the end of each day they would take a walk at which time John Stuart would report to his father what he had learned, and he was severely reprimanded if he had not gotten it right. At age three John Stuart was learning Greek from vocabulary cards; so he had already learned English. At age eight he began Latin. By the time that he was twelve he had read, in Greek and Latin, enormous tomes of classical literature, as reported in John Stuart Mill's *Autobiography* (1873).

James Mill was active in promoting the Benthamite philosophy in current politics. He was one of the founders of what came to be known as “philosophical radicalism,” a force to the left of the two major parties, the Tories and Whigs. The group included such well-known persons as Francis Place (1771–1854), a successful tailor and organizer of London demonstrations by working people; David Ricardo (1772–1823), the economist, who was probably Mill's best friend; and John Austin (1790–1859), the utilitarian jurist. The radicals advocated extension of suffrage to all tax payers, if not universal suffrage; the secret ballot in elections; the removal of tariffs on imported grain and, in general, free trade; and other legislation for the benefit of the mercantile and working classes.

## WRITINGS

Mill wrote on a wide variety of topics for a number of periodicals. These show the breadth of his interests and expertise. Subjects included money and exchange, Spanish America, China, General Francisco de Miranda (1750–1816), the East India Company, liberty of the press, Bentham's law reforms, education, prison discipline, slavery, and religious toleration. In 1805 he published a translation of C. F. Villers's *History of the Reformation*. In 1807 he wrote *Commerce Defended*, an answer to a book that claimed that Britain could be independent of commerce. He wrote a number of articles for the supplement to the fifth edition of the *Encyclopaedia Britannica*, which appeared from 1816 to 1823. Some of these articles were later published independently, the most important being those on “Jurisprudence,” “Prisons,” “Education,” and “Government.” Mill's *History of British India*, in three volumes, was finished and published in 1818. In 1821 Mill published *Elements of Political Economy*, which he intended as a “schoolbook” based on his teaching Ricardian economic theory to John Stuart Mill. From 1824 to 1826 he contributed to the *Westminster Review*, a periodical started as an organ of the Radicals to answer the *Quarterly Review* of the Tories and the *Edinburgh Review* of the Whigs. In 1829 appeared his

*Analysis of the Phenomena of the Human Mind*, in two volumes, putting forward his “associationist” psychological theories. His last major work was the *Fragment on Mackintosh*, published in 1835 after a delay caused by Sir James Mackintosh’s (1765–1832) death. In it he presents his ethical views in opposition to those of Mackintosh.

## PHILOSOPHY

Mill’s philosophy is empiricist, assuming that all knowledge ultimately comes from sense experience, including muscular contractions and sensation from bodily organs. He believed that the inductive method, which had been fruitful in the physical sciences, would be equally effective in philosophy. In *Analysis of the Phenomena of the Human Mind* Mill, using the method of introspection, attempts to give a complete analysis of mental phenomena, resolving them into the primitive feelings from which they are derived by association. “Feeling,” according to him, includes every phenomenon of the mind. One’s experience is either a knowledge of feelings separately or a knowledge of the order in which they follow each other. Some philosophers had claimed that there are feelings not derived from sensations, but Mill thinks that this is a mistake. He follows David Hume in distinguishing between impressions and ideas. “Ideas” are copies of previous “impressions.” Impressions, for Mill, are caused by the external world acting in some way on the mind. The philosopher can only classify the various modes in which they present themselves. One’s consciousness reveals simply a series of “sensations” and “ideas.” The mind is a stream of these phenomena. The connections of ideas are due to association in either “synchronous” or “successive” order.

When Mill turns to an analysis of sensations and ideas exciting to action, he again attempts to resolve them into simple laws. A desire is an idea of a pleasant sensation; an aversion, an idea of a painful sensation; each having tacit reference to a future time. One associates these pains and pleasures with their causes, coming to desire the causes, and one associates these with one’s own actions as possible causes. In this theory of action Mill is a psychological hedonist, but he is not a psychological egoist, in one meaning of that term. Although the pleasure or pain is the agent’s own pleasure or pain, it may be associated with the pleasure or pain of another person, such that one desires that person’s pleasure or pain. This can even be generalized to a love for humanity, such that one has pleasure at the thought of anyone’s pleasure. Thus, it can be possible to be motivated to seek the greatest happiness of everyone, the utilitarian criterion of right action. Mill held, however, that actions are right when

they are foreseen to produce the greatest happiness, whether or not this is the motive of the action. But the motive to produce the greatest happiness is important in admiring or despising the character of the agent.

At the same time that Mill recognizes the possibility of altruistic action, of an agent finding pleasure in the sacrifice of his or her own good to the greater good of others, he does not rely on this motive in his political philosophy. He argues from the predominance of selfish interests in his arguments for representative democracy. In his article “Government” he starts from the utilitarian premise that the end of government, as of all conduct, is the greatest happiness. He claims that this can be achieved by assuring for all persons the greatest possible quantity of the produce of their labor. Thus, he defends property, if it reflects this objective. Government is people uniting to delegate to a few the power necessary for protecting this legitimate property. The difficult problems of government relate to the means of preventing these few from themselves having an interest contrary to that of the many. The key is representation. The community as a whole cannot desire its own misery, and, although it cannot act as a whole, it can act through representatives. If these representatives can be prevented by adequate checks from misusing their powers, good government is possible. He believes that responsible representation is possible if election is for brief periods, perhaps annual; by secret ballot; and if the right to vote is extensive enough to prevent the class of electors from having an interest contrary to the whole community. One problem that he addresses is that the people do not understand their own interests. His answer is that ignorance is curable, whereas government by a minority class is sure to be bad.

In *Fragment on Mackintosh* Mill engages in a polemic against a moral sense ethical theory, even one based on associationist psychology and a greatest happiness principle. Mackintosh agrees that the criterion of right and wrong is the greatest happiness, but he claims that the moral sense is a feeling produced by the contemplation of right and wrong that becomes an independent unit, no longer resolved into its origin. It becomes a particular faculty, necessary to discern right and wrong. On the contrary, Mill says that no particular faculty is necessary to discern utility. To say that conduct is right is the same thing as to say that it produces greatest happiness. If the moral sense orders conduct opposed to the general happiness, it is so far bad. If it never orders such conduct, then it is superfluous. Mackintosh uses the example of Fletcher of Saltoun to illustrate his point. Fletcher would have sac-

rificed his life to save his country, but would not do anything base to save his country. Mill attacks this. If you refuse to save your country because you think the means base, your morality is immoral. All general rules, he says, imply exception, but only when they conflict with the supreme rule. If a rule for increasing utility diminishes utility in a given case, then it must be broken in that case.

## INFLUENCE

Mill was a significant contributor to the liberalism of nineteenth-century Britain. His articles calling for expansion of suffrage, freedom of the press, freedom of religion, free trade, abolition of slavery, state-supported education, and legal and prison reform no doubt had an influence on his contemporaries and the next generation. He was significant in popularizing Bentham's and Ricardo's views. His psychological theories were a foundation on which Alexander Bain and other psychologists sought to use associationism as one element in a more complete psychology. His most significant influence, however, was by way of his son, John Stuart Mill, who reflects, although he significantly revises, the philosophy of his father.

## MILL, JOHN STUART

(1806–1873)

John Stuart Mill, the English philosopher, economist, and administrator, was the most influential philosopher in the

English-speaking world during the nineteenth century and is generally held to be one of the most profound and effective spokesmen for the liberal view of man and society. In the belief that men's opinions are the dominant influence on social and historical change, Mill tried to construct and to propagate a philosophical position that would be of positive assistance to the progress of scientific knowledge, individual freedom, and human happiness. Despite numerous flaws in his theories, he succeeded in providing an alternative to existing views on morals and politics and their foundations that was both specific and cohesive enough to give a markedly liberal tendency to social and political opinion, and also sufficiently tolerant and inclusive to gain it access to an extraordinarily large and diverse public. Mill cannot be ranked among the greatest of pure philosophers, either for his originality or for his synthesizing power. His work in logic, however, broke new ground and gave a badly needed impetus to the study of the subject, while his reformulations of classical British empiricism and Benthamite utilitarianism gave these positions a relevance and continuing vitality that they would not otherwise have had.

Although Mill's views on economics will not be discussed in the present article, an excellent summary of them is contained in the article on Mill by F. Y. Edgeworth in Palgrave's *Dictionary of Political Economy*.

## LIFE

John Stuart Mill was born in London, the son of James and Harriet Burrow Mill. Outwardly his life was not eventful. He was educated by his father and never attended school, although for a short time he read law with John Austin. In 1823 he became a clerk in the East India Company, where his father was a high official, and worked there until 1858. Eventually he became chief of his department, a post involving considerable administrative responsibility. In 1831 he was introduced to Harriet Taylor, the wife of a successful merchant and mother of several children. Friendship between Mill and Mrs. Taylor rapidly developed into deep though Platonic love, and for the next twenty years they saw each other constantly, despite the increasing social isolation this involved. Mill was convinced that Mrs. Taylor was a great genius: He discussed all of his work with her and attributed to her an enormous influence on his thought. Her husband died in 1849, and three years later she married Mill. In 1858, while the Mills were on a tour of France, Harriet died in Avignon. Mill bought a house nearby so that he could always be near her grave.

In 1857 Mill had written a brilliant defense of the East India Company for the parliamentary debate on renewal of the company's charter. When renewal was not granted, Mill retired, refusing an offer of a position in the government as an official for Indian affairs. In 1865 he was invited to stand for election to Parliament as an independent member for Westminster. He accepted, and although he refused to campaign, contribute to expenses, or defend his views, he won, and served until the next election, in 1868, when he was defeated. Thereafter he spent his time alternately in London and in Avignon, admired and sought after by many, accessible to few. He died after a very brief illness, attended by his wife's daughter Helen, who had looked after him since her mother's death.

**EDUCATION AND PHILOSOPHICAL RADICALISM.** Until 1826 Mill's thought was completely controlled by his father. James Mill gave him one of the most formidable educations on record, starting him on Greek at the age of three and Latin at eight. By the age of fourteen he had read most of the major Greek and Latin classics, had made a wide survey of history, and had done intensive work in logic and mathematics. He had also been prepared for acceptance of the central tenets of philosophical radicalism, a set of economic, political, and philosophical views shared by the group of reformers who regarded Jeremy Bentham and James Mill as their intellectual leaders. When at the age of fifteen John Stuart Mill read Bentham's *Traité de législation*, it had the effect on him of a religious revelation. It crystallized his thoughts and fixed his aim in life—to be a reformer of the world. Guided by his father, he threw himself into the work of the radicals; he edited Bentham's manuscripts, conducted a discussion group, wrote letters to the press and articles critical of laws, judicial decisions, and parliamentary debates and actions.

**DEPRESSION AND CHANGE OF VIEWS.** Late in 1826, Mill suffered a sudden attack of intense depression, which lasted for many months. The attack led him to reconsider the doctrines in which he had been raised and to seek other than Benthamite sources of thought. He believed that his capacity for emotion had been unduly weakened by strenuous training in analytic thought, with the result that he could no longer care for anything at all. In the poetry of William Wordsworth he found something of a cure—an education of the feelings that helped to balance the education of intellect given to him by his father. In 1828 he met Gustave d'Eichthal, a French follower of Comte de Saint-Simon, who sent him an early essay by

Auguste Comte and a great deal of Saint-Simonian literature. He also met John Sterling, a disciple of Samuel Taylor Coleridge. Mill came to admire both the Saint-Simonians and the Coleridgeans, and he attempted to incorporate into his own thinking what he took to be sound in their doctrines. In 1829 he published nothing at all, but by the following year he had reached a philosophical position that seemed to him far more adequate than the older Benthamism. He never again changed his philosophical views so radically.

**COMTE AND SAINT-SIMON.** The historical standpoint of the Saint-Simonians, as well as the appreciation of the value of old institutions emphasized by Coleridge, impressed Mill as important additions to Benthamism, which, he thought, simply neglected such factors. He accepted the outlines of the Saint-Simonian–Comtian philosophy of history, and particularly its theory that in social change there is an alternation between “critical” periods, in which society destroys outmoded forms of life and tends toward disintegration, and “organic” periods, in which new forms of common life are evolved and social cohesion is reestablished. He agreed also with the French view that in his own times society had come to the end of a critical period. From Coleridge he learned to think of the cultured class as the leader of opinion in a nation. He also came to believe that the problem he had in common with other intellectuals was that of assisting the world, and especially England, to emerge from the critical period and progress toward a new organic period. Unless this was done, he thought, the tendency toward disintegration might possibly grow too strong to be controlled.

Three important consequences followed from this. First, merely negative remarks upon institutions, laws, and political arrangements were no longer sufficient. Although much remained that needed to be changed, it was necessary now to replace what had been destroyed with something better. Second, the views of those who defended the old and outmoded could no longer be dismissed, in Benthamite fashion, as mere lies used in defense of vested interests. What is now outmoded must, at one stage of historical development, have served a valuable purpose; otherwise it could not have survived. Those who defend it are those who see the good still in it; hence we must seek for the truth in their views, and not merely reject the falsity. The particular vice plaguing social thought is not the tendency to make mistakes of fact or faulty inferences from facts, but the great ease with which data can be overlooked: in a word, one-sidedness. Hence, if we are to obtain sound social views, our greatest need is

for a complete survey of data, and this is possible to achieve only if we can appreciate the truth that our opponents have learned. For each man is naturally one-sided and can overcome this only by education and effort. Third, the tactics of a reformer must be adapted to the period in which he lives. In particular, during a critical period there is no point in promulgating an entire system: no one will listen, and the ideas will not serve to improve social cohesion. One must proceed cautiously, piecemeal, educating one's public as one goes. One must—especially in England, Mill held, where any appearance of system is abhorrent—confine oneself to particular issues, only slowly insinuating more general principles; or else work only from points on which there is general agreement, so as to avoid any shocking appearance of novelty.

This set of views dictated the program that Mill followed for the next twenty or more years. He did not abandon his early epistemology or ethical beliefs, but in developing them he always tried to emphasize their inclusiveness and their constructive power, rather than their critical and destructive powers. He refrained (with one major exception) from publishing a systematic account of his ideas, but wrote instead occasional essays dealing with fairly specific issues, in which he always tried to bring out the value of the books he was criticizing. (These tactics are largely responsible for the common view of Mill as a wavering, halfhearted, muddled thinker, appreciative of what others had to say but holding no clear opinions of his own.) He defended what he held to be sound views on philosophy, but he did not explicitly link these views together, except in his *System of Logic*, which was an entirely different case. Methods of investigation, Mill held, could be relatively neutral as regards political and moral opinion. Since these methods could be discovered from analysis of subjects like physical science, in which there was widespread agreement on results, there was a good chance of obtaining general agreement on the methods. The methods could thus serve as a cohesive, rather than a disruptive, social force.

### THE SYSTEM OF LOGIC

Mill's *Logic* is in fact by no means neutral with regard to substantive issues. It is the first major installment of his comprehensive restatement of an empiricist and utilitarian position. It presents (sometimes, to be sure, only as "illustration") a fairly complete outline of what would now be called an "empiricist" epistemology, although Mill himself used "empiricist" in a deprecatory sense to mean "miscellaneous information," as contrasted with "scien-

tific knowledge." It begins the attack on "intuitionism" that Mill carried on throughout his life, and it makes plain his belief that social planning and political action should rely primarily on scientific knowledge, not on authority, custom, revelation, or prescription. The *Logic* had a rapid and wide success. Adopted as a text first at Oxford and eventually at Cambridge, it was also read by many outside the universities, including workmen. Its success can be explained in part by its enormous superiority to any book then existing in the field, but credit must also be given to its clear and unmistakable relevance to social problems (and to religious questions: it was attacked as atheistic by some of its earliest reviewers).

With the publication of the *Logic*, Mill took a major step toward showing that the philosophy of experience, which had hitherto been identified primarily as a skeptical position, could offer at least as much in the way of constructive thinking as any other kind of view. His treatment of deductive inference was far more sympathetic to formal logic than that of previous empiricists; and by arguing that, with care, certainty could be attained even in inductive reasoning, he made it plain that empiricism was not committed to a Humean standpoint. Mill held that the philosophy of experience was more likely than any other to encourage the development of society along liberal lines. He therefore held that it was a matter of considerable importance to show that empiricism was a viable alternative to the less progressive views—notably, Scottish commonsense philosophy and German idealism—which were then dominant. The *Logic* succeeded in doing this.

The *Logic* is primarily a discussion of inferential knowledge and of the rules of inference. (The discussion of noninferential, or as Mill also called it, immediate or intuitive, knowledge belongs, in Mill's view, to metaphysics.) It contains six books. In the first two, Mill presented an empiricist theory of deductive inference, and, since mathematics is the chief deductive science, a discussion of the nature of the truth of mathematics, especially of its axioms. In Book III, Mill discussed induction, its grounds, its methods, and its results. Book IV, titled "Of Operations Subsidiary to Induction," contains chapters on observation and description, abstraction, naming, and classification. Book V is a discussion of fallacies. Book VI contains Mill's attempt to extend the methods of the physical sciences, as derived in Book III, to what were then called "moral sciences," that is, psychology and sociology. He argued for the possibility of a science of human nature and action, and assessed the value of the various methods for attaining it. He concluded with a chapter on

the logic of morality, discussing primarily the relation between rules for actions and the factual statements that serve as their foundations.

No adequate summary of the contents of the *Logic* can be given here, but some of Mill's leading views may be indicated.

**DEDUCTIVE REASONING.** Mill's argument in Book I of the *Logic* is intended to show the mistake of those who say that deductive inference (as found, for example, in the syllogism) is entirely useless because it involves a *petitio principii*, but at the same time to make it clear that deduction in general is never the source of new knowledge. Mill agreed that the conclusion of a syllogism may not contain more than is contained in the premises and that "no reasoning from generals to particulars can, as such, prove anything, since from a general principle we cannot infer any particulars, but those which the principle itself assumes as known."

It is useless to defend deduction by saying that it shows us what was "implicit" in our premises, unless we can go on to explain how something can be implicitly contained in what we already know. Mill's solution to this problem and his explanation of the value of rules of deduction rest on his view that "all inference is from particulars to particulars." When we reason "All men are mortal; Jones (not yet dead) is a man; so Jones is mortal," our real evidence for the assertion that Jones will die is our knowledge that Smith, Peters, Wilkins, and many other individuals who resemble Jones in many respects did die. We infer from their deaths to his. The general premise that all men are mortal is not itself our evidence. It is rather a note, or register, of the particular evidence on which the conclusion really depends, together with the prediction that what we have found in cases that we have already observed will also hold in similar cases not yet observed. The real inference, Mill thought, comes in constructing the general proposition on the basis of observation of particular cases. Deduction is to be understood as a way of interpreting the note that has been made of our previous inference. It is valuable because misinterpretation is very easy; but it no more gives us new information than do propositions that are true by definition. Such propositions, which Mill called "verbal," only pull out of a word what was previously put into it; and in the same way, a syllogism simply retrieves from a general proposition a particular one that was previously assumed to be in it. Since there is no real progress of thought in deduction, deductive inference is merely *apparent* inference. Induction is the only procedure that gives us nonverbal general

propositions that go beyond what has actually been observed. Hence, only in induction do we make *real* inferences.

Mathematical knowledge is no exception to this. Taking geometry first, as the deductive science par excellence, Mill argued that its conclusions are necessary only in the sense that they necessarily follow from the premises from which they are deduced. But the premises themselves—ultimately, the axioms—are grounded on observation and are generalizations from what we have always experienced. (The definitions are in a somewhat different position, although an experiential element is involved in the belief that the entities they define, such as a geometric point or line, really exist.) That two straight lines do not enclose a surface is evident to us every time we look at two straight lines that intersect. The laws of psychology, operating on such experiential data, are sufficient to explain the production in us of the belief that such lines cannot possibly enclose a surface: hence we need not appeal to intuition or to some other nonexperiential source to explain the belief. Even the inconceivability of the denial of the axioms of geometry does not show, Mill argued, that they are not based on experience. For inconceivability is psychological, and the fact that we cannot think of something does not show that that thing cannot exist. Mill went on to offer an account of the way in which arithmetic and algebra are founded on experience. Here the essential point is that groups of four items, for example, may be rearranged into, or formed from, two groups of two items each, or a group of three items together with a group of one item. Seeing that this is always so, we come, through the operation of psychological laws, to believe that  $2 + 2$ , or  $3 + 1$ , *must* be the same as 4. Algebra is simply a more abstract extension of this sort of belief.

With these explanations Mill hoped to show how mathematics can yield propositions that are not merely verbal and that are certainly true of the world of experience, but that do not depend on any nonexperiential sources of knowledge. His account has never been accepted by philosophers as it stands, but there have been some attempts, among thinkers influenced by pragmatism, to work out a philosophy of mathematics along lines analogous to Mill's.

**INDUCTIVE REASONING AND SCIENTIFIC EXPLANATION.** In Mill's view, induction is clearly of central importance, since it is the only possible source of substantive general propositions. While the details of his theory are complicated, its main lines may be concisely

indicated. All methodical and critical induction rests on the fundamental principle of the uniformity of nature; namely, that what has happened once will happen again, if circumstances are sufficiently similar. Mill thought that this is a factual proposition that is itself derived by a primitive and natural process of induction: we first note a few limited regularities and predict that they will hold in the future. After our predictions come true, we spontaneously generalize, saying that since some events have been found to occur in repeating patterns, all events will be found to occur in repeating patterns. Belief in the uniformity of nature is thus derived from, and resolvable into, belief in the existence of less sweeping patterns of occurrences, or into particular causal laws. Mill defined “cause of a phenomenon” as “the antecedent, or concurrence of antecedents, on which it is invariably and unconditionally consequent.” Like the “axiom” of the uniformity of nature, the principle that every occurrence has a cause is confirmed by all our experience. It is, in fact, simply a more precise way of stating the principle of the uniformity of nature. The hope of science is to formulate propositions about specific sequences of phenomena that can be relied on to the same degree as the law of causation. And the problem of methodical induction—which is the core of the problem of scientific reasoning—arises when it is discovered that the simplest method of induction (that of assembling positive instances of a sequence of phenomena and generalizing directly from them) often leads to general propositions that turn out to be false. We then seek ways of obtaining better results. The fundamental technique is to obtain evidence which will allow us to argue as follows: Either *A* is the cause of *a*, or else there are some events which have no cause; and since we are certain that every event has a cause, we may be certain that *A* causes *a*.

According to Mill, there are four inductive methods: the method of agreement, the method of difference, the method of residues, and the method of concomitant variations. He also discussed a combination of the first two, calling it the joint method of agreement and difference. We use the first two methods in this way. If we find that *A* under circumstances *BC* is followed by *abc*, while under circumstances *DE* it is followed by *ade*, then *A* cannot be the cause either of *bc* or of *de*, since they sometimes do not occur when *A* occurs (and hence by the definition of “cause,” cannot be caused by it). But *a* occurs under both sets of conditions; hence it could be the effect of *A*: This illustrates the method of agreement. To ascertain if something other than *A* might be the cause of *a* we use the method of difference. Will *BC* without *A* be followed by *a*? If not, we have so far confirmed our view that *A* causes

*a*, for, in the cases we have examined, *A* is always followed by *a* and *a* never occurs without being preceded by *A*. Hence, by the definition of “cause,” *A* is, so far as our evidence goes, the cause, or part of the cause, of *a*—or else there are events without any regular cause.

Science does not rely upon induction and experiment alone. It is only infrequently, Mill thought, that we will find genuine causal laws, that is, absolutely invariable sequences. More frequently we will find regularities that hold as far as a limited experience shows but which, we have reason to believe, might well not hold under quite different circumstances. These “empirical laws” are not to be considered basic laws of nature. Much of the practical application of science depends on them, but we cannot claim to have truly scientific knowledge until we can deduce empirical laws from basic laws of nature, showing why the combination of circumstances and laws renders inevitable the limitations within which the empirical laws hold. This makes clear the aim of science: to discover laws of nature and empirical laws, and to connect them, in a deductive system, in such a way as to show how the unrestricted laws would give rise to the regularities reported by the empirical laws. The various sciences are differentiated by the ways in which these two types of laws must be discovered and connected. In some sciences it is possible to discover laws of nature directly, deduce what the empirical laws must be, and then proceed to verify the deductions by checking against experimental data. In others, empirical laws are discovered first, and laws of nature are presented as hypotheses to explain them. These alleged laws of nature are then tested by deducing further empirical laws from them and testing these deductions. In any science, however, explanation comes to an end when laws of nature are reached: These are simply ultimate facts that are to be accepted.

THE MORAL SCIENCES. In the last book of the *Logic*, Mill argued that the phenomena of individual or social human life are no exception to the law of causation, and that consequently it must be possible to determine what are the natural laws of human behavior. He investigated the various modes of inquiry used in the different physical sciences to determine which are most suited to this sort of investigation, and he sketched an outline of what a completed science of man will be. Here as elsewhere, Mill thought that “however complex the phenomena, all their sequences and coexistences result from the laws of the separate elements.” Since the separate elements in this instance are men, it is the basic laws of psychology from which, when the science is completed, all the laws and regularities concerning social phenomena must be

deduced. Because of the enormous number of interacting elements, however, the complexity of social action is so great that no direct deduction of its regularities from basic psychological laws will be possible. In order to make this deduction it will be necessary first to construct a science of human character that will cover both the development of human character and the tendencies to action of different types of persons. From the laws of this science, which Mill called “ethology,” we may hope eventually to get sociological laws. Even then, however, we will at best obtain statements of tendencies toward action, for the enormous number of factors involved in determining social action will not allow any more accurate predictions. Still, Mill held, “knowledge insufficient for prediction may be most valuable for guidance” in practical affairs. His chief interest lay in the possibility of obtaining scientific guidance for the direction of political decisions.

How far, then, had social science actually progressed? Mill thought that the basic laws of psychology were by then well established: they were the laws put forward by psychologists of the associationist school, among whom James Mill was preeminent. But the science of ethology, which John Stuart Mill had hoped to found himself, eluded him, and he gave up work on it shortly after he published the *System of Logic*. Although the absence of the intermediate laws that this science was designed to contribute made impossible the completion of sociology, Mill thought that at least one basic law of social change had been discovered and substantially proven: Comte’s law of three stages. One element, Mill argued, is more important than any other single factor in causing change in society: “This is the state of the speculative faculties of mankind, including the nature of the beliefs which ... they have arrived at concerning themselves and the world by which they are surrounded. ... the order of human progression in all respects will mainly depend on the order of progression in the intellectual convictions of mankind.” Comte had shown that opinion always passes through the same three phases. Men first try to understand their universe in theological terms, then in metaphysical terms, and finally in scientific or, as he called them, positive terms. He had also shown that correlated with these three stages of opinion are types of social organization, which change as opinions change. This generalization, for Mill, was enormously important to our understanding of history and to our practical decisions, and up to that time it was the sole example of a well-founded sociological law. But Mill had high hopes that, with work, much progress could be made in constructing a social science; and he looked forward to a time when

“no important branch of human affairs will be any longer abandoned to empiricism and unscientific surmise.”

## EPISTEMOLOGY AND METAPHYSICS

With respect to metaphysics in the contemporary sense of systematic knowledge transcending experience, Mill claimed to have none; and his epistemology consists largely of an account of experiential knowledge in which he intended to show why nothing beyond such knowledge is either possible or necessary. Mill presented an empiricist theory of our knowledge of the external world and of persons which is equally free of the skepticism of David Hume and the theology of George Berkeley. He consequently covered quite thoroughly a good deal of the ground that was gone over again in the discussions among empiricists and logical positivists in the second and third decades of the twentieth century.

**AIM AND METHOD.** Mill held that we must know some things intuitively, without inference, if we know anything at all, and he rejected skepticism as failing to make a relevant distinction between knowledge and doubt (“In denying all knowledge it denies none”). For if all knowledge were inferential, there would be no firm starting point for inference, and we should be led into a vicious infinite regress of premises. But because whatever can be known only by intuition is beyond the realm of rational discussion and experimental test, such intuitive knowledge is not easily distinguished from dogmatic opinion. Hence, it was Mill’s aim to reduce to an absolute minimum the number of points at which intuitions are required. In the *Logic* he argued that no intuitions are necessary for mathematics, logic, or the procedures of natural science. In the *Examination of Sir William Hamilton’s Philosophy* (1865), he pursued these questions further and explicitly took up the questions he had claimed to avoid in the earlier work—especially those concerning the foundations and nature of our knowledge of bodies and of minds.

Mill argued that we cannot tell by intuition or by introspection what we know intuitively. In order to distinguish what is directly given to consciousness from what is there as a result of inference, we must try to investigate the *origins* of the present contents of our minds. And again, this cannot be done directly, because the minds of infants are not accessible to us. Hence, Mill concluded, “the original elements can only come to light as a residual phenomena, by a previous study of the modes of generation of the mental facts which are confessedly not original.” This is the psychological method that was orig-

inated by John Locke. In using it, Mill attempted always to show how experience, acting in accordance with known laws of psychology, can explain all of our knowledge. If successful, such accounts make unnecessary (and therefore unwarranted, according to sound scientific methodology) any appeal to extraordinary faculties or to nonexperiential sources of knowledge.

**MATTER AND MIND.** Mill attempted to explain our belief in the existence of matter and in the existence of our own and other minds by using a psychological method. The “Psychological Theory of the Belief in an External World,” as he called it, postulates first, a mind capable of expectation (that is, of forming the conception of possible sensations that would be felt if certain conditions were realized), and second, the psychological laws of association. The claim is that these two factors, operating on experienced sensations and reminiscences of them, would generate not only a belief in an external world but, in addition, a belief that this belief was immediate or intuitive. Mill argued first that by an external object we mean only something that exists whether it is thought of or not, that stays the same even if the sensations we get from it change, and that is common to many observers in a way that sensations are not. One’s concept of the external world, Mill said, is made up only to a slight degree, at any moment, of actual sensations, but to a large degree of possible sensations—not of what I am sensing, but of what I would sense *if* I moved, or turned my head, and so forth. These possible sensations, moreover, are thought of as being in groups: numbers of them would be present if I did this, numbers of others if I did that. Contrasted with any particular actual sensation, these groups of possible sensations seem stable and permanent. Moreover, there is not very much regularity in the sequences of our actual sensations, but there is considerable regularity associated in our minds with the groups of possible sensations: We will regularly get this sensation following that one if we do this following that. Hence ideas of cause and power, which (as had been argued in the *Logic*) depend on regularity and succession, are associated with the groups of possible sensations, and not with the actual sensations. At this stage we begin to refer any actual sensation to some group of possible sensations, and even to think of the possibilities as the cause or root of the actual sensation. The groups of possibilities, having permanence and causal power, are so different from fleeting actual sensations that they come to be thought of as being altogether different from them. When it finally becomes clear that the permanent possibilities are publicly observable, we have a concept answering in all respects to our definition

of externality. Hence, Mill said, matter “may be defined, a Permanent Possibility of Sensation”; this is all, he held, that the plain man believes matter to be, and indeed, Mill shared this belief. Mill’s aim, however, was not so much to defend the belief, as to account for it. And his account, which appeals only to psychological laws known to operate in many other kinds of cases, is simpler than accounts that would make the belief in matter an original part of our mind or an intuitive belief: Consequently, he held, it is a better account.

Mill went on to ask how far a similar theory is adequate to account for mind. The theory will work, he thought, to a large extent, since we know nothing of our mind but its conscious manifestations, and since we know other minds only through inference from the similarities of other bodies and their actions to ours. But memory and expectation pose a fatal difficulty. They involve a belief in something beyond their own existence, and also the idea that I myself have had, or will have, the experience remembered or expected. Hence, if the mind is really a series of feelings, it is an extraordinary series, for it is one that is “aware of itself as a past and future.” And if it is not this paradoxical series, it is something more than a series—but what that can be we have no idea. Mill concluded that at this point we are “face to face with that final inexplicability at which ... we inevitably arrive when we reach ultimate facts,” and all we can do is accept the facts as inexplicable. Hence, mind is not simply a permanent possibility of sensation.

Sensations and feelings—the data of experience—are, then, intuitively known; the fact of memory (a consequence of which Mill thought to be expectation) is also known directly; and the kind of link between past and present involved in memory (which Mill took to be the central inexplicable reality about the self) is known directly. Aside from these, there is only one additional inexplicable fact, and that is belief—the fact that there is a difference between contemplating, or imagining, or supposing, and actually believing. Mill rejected his father’s analysis of belief, but could develop no adequate account of his own.

## ETHICS

According to Mill, agreement on moral beliefs is the most important single factor making for cohesion in society, and where it is lacking society cannot be unified. In his own times he saw and recognized the significance of the first serious widespread breakdown of belief in the Christian moral scheme. He thought it a task of first importance to provide an alternative view of morality that

would be both acceptable to those who still clung, in part, to their older views, and capable of redirecting these older moral attitudes into newer paths. He was a utilitarian in ethics: that is, he held that an action is right if, and only if, it brings about a greater balance of good over bad consequences than any other act open to the agent, and he also believed that only pleasure is intrinsically good and only pain intrinsically bad. Bentham and James Mill had held a similar position, but John Stuart Mill modified their view in a number of ways, attempting always to show that utilitarianism need not be a narrow or selfish view and that it did not force one to rely, for social progress, purely on impersonal institutional arrangements and thereby compel one to leave human personality out of account. By arguing that the utilitarian could appreciate the wisdom embodied in traditional morality as well as offer rational criticism of it, and that he could also accept and account for the high value of self-sacrifice and could make the development and perfection of individual character the key obligation of morality, Mill sought to rebut the most frequent criticisms of the Benthamite morality and thereby make it more generally acceptable. Although his ethical writings (especially *Utilitarianism*) have been much criticized, they contain the most influential philosophical articulation of a liberal humanistic morality that was produced in the nineteenth century.

In his ethical writings, Mill pursued the attack on intuitionism that was so constant a feature of his other work. This issue is especially important with regard to moral problems. Intuitionism, he said in the *Autobiography*, is “the great intellectual support of false doctrines and bad institutions” because it enables “every inveterate belief and every intense feeling ... to dispense with the obligation of justifying itself by reason.... There never was such an instrument devised for consecrating all deep-seated prejudices.” The intuitionists supposed, Mill believed, that only their view could account for (1) the uniqueness of moral judgments, (2) the rapidity with which the plain man passes moral judgments, and (3) the authority to be given to commonsense moral judgments. To the first point, Mill answered with the theory that moral feelings may have unique properties, just as water has, and yet may still be derived, by a chemical compounding process, from simpler elements that do not have those properties. Hence, so far there is no need to say that these feelings are caused by unique intuitions. To the second point he replied that rapidity of judgment may be due to habit and training as well as to a faculty of intuition. And with regard to the third point, which is the crucial one, he argued that the utilitarian can give at least as

good an account as the intuitionist of the authority of common sense in moral matters. Rules such as those that enjoin the telling of truth, the paying of debts, the keeping of promises, and so forth (Mill called these “secondary rules”) were taken by him to indicate, not widespread intuitions, but the results of hundreds of years of experience of the consequences of actions. These rules, based on so much factual knowledge, are of considerable value in helping men to make correct decisions when time or data for a full calculation of the results in a particular case are lacking. The wisdom of the ages, thus embodied in the rules and precepts of commonsense morality, is an indispensable supplement to the limited knowledge and almost inevitable one-sidedness of any single person. It is for these reasons, utilitarians claim, that these rules and precepts have a certain cognitive authority. There is no need to appeal to a faculty of intuition to explain the authority, and therefore such an explanation is, from a scientific point of view, unwarranted.

Mill thus gave a prominent place to moral directives other than the utilitarian principle. But he was basically an act-utilitarian, believing that each particular obligation depends on the balance of pleasure and pain that would be produced by the act in question. The utilitarian principle is so abstract, Mill thought, that it is unlikely to be actually used, except in cases where two secondary rules come into conflict with each other. But it serves the invaluable function of providing a rational basis for the criticism of secondary rules (this is brought out especially well in the essay on justice, Ch. 5 of *Utilitarianism*), and there was no doubt in Mill’s mind that there can never be a right act that contravenes the principle. This is true even with regard to the rule (to which Mill gave so much emphasis) dictating the development and perfection of individual character. It often seems that Mill placed more stress on individuality, or self-realization, than on general welfare, and critics frequently claim that he contradicted himself by saying that both of these constitute the sole highest good. But there is no contradiction in his views, for he held that self-development is the best way for an individual to work for the common good.

Mill’s concern with the problem of free will sprang from his view of the importance of self-development. (He presented this view both in the *Logic* and in the *Examination of Hamilton*.) The doctrine of necessity, which he had been taught to believe, seemed to him to make a man a creature of his environment, and this doctrine depressed and disturbed him for many years. When he realized that the desire to improve oneself could be a powerful motive and that actions dictated by this desire, although not con-

travening the law of causation, are properly said to be due to oneself rather than to one's environment, he felt "as if an incubus had been raised off him." He thought that this view enabled him to make determinism compatible with his emphasis on the individual's responsibility for his own character.

Two aspects of Mill's *Utilitarianism* have been attacked more frequently than any others. The first is his attempt to broaden utilitarianism by making a distinction between *kinds* of pleasure, so that an act producing a smaller amount of a more valuable kind of pleasure might be obligatory, rather than an act producing a larger amount of a less valuable kind of pleasure. This line of reasoning has been said to involve him in flagrant contradictions, or else to be sheer nonsense.

The second aspect is his attempt to give some sort of reasoned support to the utilitarian principle itself, which led G. E. Moore to accuse him of committing the "naturalistic fallacy." Moore thought Mill was trying to give a conclusive proof of a first moral principle, but he was mistaken. Throughout his life, Mill consistently held that no such proof of the principle was possible, either deductively or inductively. There is, however, no agreement as to the manner in which Mill attempted, in the fourth chapter of *Utilitarianism*, to support his first principle so that he would not be open to the same reproach of dogmatism that he had made against the intuitionists. Mill's remarks here are extremely unclear. His problem arises because, while he insisted that there must be a factual basis for moral judgments, he held that moral judgments are different in kind from factual propositions and therefore cannot be strictly derived from them. Although he failed to solve this problem, he at least propounded it in precisely the form in which it has perplexed (not to say obsessed) recent moral philosophers.

## SOCIAL AND POLITICAL PHILOSOPHY

Mill was more aware than were the older Benthamites of the importance of nonrational and noninstitutional factors to an understanding of society, and was consequently less disposed to rely on legal and governmental reforms for the improvement of it. He believed in democratic government, but he was convinced that it could not work well unless the citizens who lived under it were reasonably well educated, tolerant of opposing views, and willing to sacrifice some of their immediate interests for the good of society. He was profoundly worried about the tendency of democracies to suppress individuality and override minorities: Indeed, this, and not the problem of forcing those who control government to work for the

interests of the people, seemed to him the crucial problem of his times. Hence, in his writings on social and political philosophy, his central concern was to show the importance of personal freedom and the development of strong individual character and to devise ways of encouraging their growth.

**ECONOMIC THEORY.** With regard to economic theory Mill at first supported a general policy of *laissez-faire*, but increasing awareness of the uselessness to the individual of political freedom without economic security and opportunity led him to reexamine his objections to socialism. By the end of his life he had come to think that as far as economic theory was concerned, socialism was acceptable. His reservations about it sprang from his fear that it would give overwhelming strength to the tendencies of the age toward suppression of individuality.

**ON LIBERTY.** Mill thought that his essay *On Liberty* was the most likely of all his works to be of enduring value. In it he maintained the view, which he had expressed as early as 1834, that "the sole end for which mankind are warranted, individually or collectively, in interfering with the liberty of action of any of their number, is self-protection." Mill argued for this view especially in regard to freedom of thought and discussion. "We can never be sure," he wrote, "that the opinion we are endeavoring to stifle is a false opinion; and if we were sure, stifling it would be an evil still": These are the lines of his defense, which rests ultimately on his assessment of the importance of sociological knowledge to the direction of social action and on his view of the peculiar difficulties in obtaining it. In the third chapter, Mill argued at length for the importance of "individuality," which, he held, comes from, or indeed is identical with, continued effort at self-development. Even eccentricity is better, he held, than massive uniformity of personality and the stagnation of society that would result from it. Mill's strong emphasis on this point stems from his conviction, here strongly influenced by Alexis de Tocqueville, that the chief danger of democracy is that of suppressing individual differences and of allowing no genuine development of minority opinion. Democratic tyranny would be far worse, he held, than aristocratic or despotic tyranny, since it would be far more effective in utilizing the most efficient of means of social control, the pressure of public opinion. Against this the only reliable safeguard would be the development of personalities strong enough to resist such pressures.

**REPRESENTATIVE GOVERNMENT.** In more specifically political matters the same concerns are evident. Mill

defended representative democracy, but not solely on the grounds used by the older Benthamites. Representative government, he held, is ideally the best form of government because it does more to encourage the growth and development of individuality than any other form of government. By leading people to participate in the processes of governing, representative government makes them more active, intelligent, and well rounded than even the best-intentioned of despotisms could. It thereby gives them vitally important moral training, by cultivating their public sympathies, strengthening their habit of looking at social questions from an impersonal point of view, and aiding their identification of personal interests with the interests of society. Care must be taken, however, to get a true democracy, one in which minorities as well as majorities are represented. For this reason Mill enthusiastically endorsed Thomas Hare's scheme of proportional representation. He also favored plural voting, which would allow educated and responsible persons to have more influence than the uneducated, by giving the former several votes. Mill's view of the function of the representative also shows his concern to get as much intelligence as possible into government. A properly educated constituency, he held, would be able and willing to select the best men available; and since those elected would be better informed and wiser on particular issues than the electorate, it would be absurd to bind the representatives to anything but a very general agreement with the beliefs and aims of the electors.

**INDIVIDUALS AND SOCIETY.** Mill is frequently criticized for overlooking the organic elements in society and for thinking of society as a mere aggregate of units in which each unit is what it is regardless of its membership in the whole. Mill certainly held this view as far as the most fundamental laws of psychology are concerned. But his view of individual character involves new considerations. Individuals, he held, are radically affected by their membership in society and inevitably formed by the customs, habits, morality, and beliefs of those who raise them. There is, however, no impersonal assurance, metaphysical or otherwise, that the individual will feel himself an organic member of any group. He will do so, Mill thought, only if he is educated to do so. Mill cannot be accused of underestimating the importance of ensuring that men are so educated, and it is not clear that an organic theory has anything better to offer on a practical level.

### RELIGIOUS VIEWS

Mill maintained for the most part a determined silence on religious questions. Although he had written "On

Nature" and "The Utility of Religion" by 1858, and although he lived during a period of increasingly free discussion of all possible religious subjects, he thought that the British public would not listen patiently to what he had to say on these questions and that he could not publish his views without alienating readers and losing public influence. And this, as he made quite clear in his correspondence with Auguste Comte, he was determined not to do. Despite his precautions, however, he was generally taken to be atheistic, and he was sometimes criticized for not openly stating the views that, so it seemed, he insinuated but did not defend. The consternation of his followers and the delight of his opponents was therefore considerable when it became apparent from the posthumously published *Three Essays on Religion* (1874) that Mill did not entirely condemn religious aspirations and hopes and even thought that there might be some faint possibility of the existence of rational support for a religious view of the world. Admirers felt betrayed, and religious critics proclaimed that Mill's secular education and materialistic position here issued in collapse and evident moral and intellectual bankruptcy.

**GOODNESS OF GOD.** Mill's most famous pronouncement on religion occurs not, however, in the *Three Essays*, but in the *Examination of Hamilton*. Discussing the use made by one of Hamilton's philosophical followers, Henry Mansel, of Hamilton's view that we cannot know the Absolute, Mill particularly criticized Mansel's theory that even the moral terms we apply to God do not mean what they mean when we apply them to men. Mill objected to this theory in the name of logic: If terms are not to be used in their usual sense, they ought not to be used at all. But, more strongly, he went on to say that a being, no matter how powerful, whose acts are not sanctioned by the highest human morality conceivable, is not deserving of worship. If Mill were convinced of the existence of such a being he would not worship him. "I will call no being good," Mill proclaimed, "who is not what I mean when I apply that epithet to my fellow creatures, and if such a being can sentence me to hell for not so calling him, to hell I will go."

**NATURE.** Of the *Three Essays*, the first two, at least, show no reversal or collapse of Mill's views. In "On Nature" Mill argued that the maxim "Follow Nature" is of no use as a guide to action. For "Nature" either means "everything that happens, good as well as bad," in which case it offers no guidance whatsoever; or it means "what happens without any human interference," and in that case the maxim is self-contradictory. Nature in the second

sense, Mill went on to argue, offers at least as much evil to our observation as good; it is rather a challenge to amendment than an ideal for imitation. From this, two conclusions follow. First, it is our job to improve nature, especially human nature; for it is only insofar as men have intervened to change things that the world has become civilized, safe, and happy, even to the limited extent that it has. Human virtues are not natural: They are preeminently the results of cultivation. Even justice is an artificial virtue, Mill said, and the idea of natural justice does not precede, but follows, it. Second, in view of the suffering and ugliness presented by much of the natural world, the only religious view that is at all tenable is one which holds that the deity is not omnipotent, that “the Principle of Good *cannot* at once and altogether subdue the powers of evil,” and that, consequently, men should think of themselves as the far from useless helpers of a limited but benevolent God.

**UTILITY OF RELIGION.** In “The Utility of Religion,” Mill argued that much of the social usefulness attributed to religion is actually due to the influence of a widely accepted and instilled moral code, and to the force of public opinion guided by that code. The belief in the supernatural origin of morality may once have helped it to gain acceptance, but is no longer needed, or indeed, even effectual, in maintaining this acceptance. The effect of religion on individuals springs largely from our need to have ideal conceptions that move us to action. “The essence of religion is the strong and earnest direction of the emotions and desires towards an ideal object, recognized as of the highest excellence, and as rightfully paramount over all selfish objects of desire.” But a religion of humanity, Mill argued, can have this effect to an even greater extent than a supernatural religion. The religion of humanity would cultivate our unselfish feelings and would free us from any need for intellectual juggling or willful blindness with regard to its tenets, since it would rather point out than deny the evil in the world and urge us to work to remove it.

**GOD.** Thus, the first two essays of the *Three Essays* together suggest that the alternative to a supernatural religion is not simple acceptance of Nature, but the construction of an alternative way of living based on education and convention; and these themes are to be found throughout Mill’s thought. The third essay, “Theism,” drafted from 1868 to 1870, which assesses arguments in support of a supernatural religious view, seems to make more concessions to traditional religiosity than the other essays; but even these are slight. In this essay, Mill dis-

cussed the possibilities of rational support for supernatural beliefs. Dismissing all a priori reasoning, he found only the Argument from Design at all convincing, and this argument gives us at best “no more than a probability” that some intelligent creator of the world exists. For the same evidences that thus support the existence of a creator also go to show that he was not omnipotent and do not prove that he was omniscient. Mill suggested that we think of a limited deity faced with the independent existence of matter and force. To this picture of a Platonic demiurge, Mill thought we are entitled to add that benevolence may have been one (although surely not the only) moral attribute of the creator. But Mill emphasized strongly the importance of the work of man in improving the world. “If man had not the power,” he said, “by the exercise of his own energies for the improvement both of himself and of his outward circumstances, to do for himself and other creatures vastly more than God had in the first instance done, the Being who called him into existence would deserve something very different from thanks at his hands.”

**IMMORTALITY AND MIRACLES.** Mill argued that there is no evidence for the immortality of the soul and none against it. After a lengthy discussion of Hume’s arguments on this point he found that roughly the same is true of miracles. But in each case he pointed out that there is room for *hope*: One may, if it is comforting and encouraging, hope that the soul is immortal and that the revelations attested by miracles are true. And it is this point more than any other in the essay that upset Mill’s admirers. For while he concluded that the proper rational attitude to supernatural religion is skepticism rather than belief or positive disbelief and that “the whole domain of the supernatural is thus removed from the region of Belief into that of simple Hope,” he also held that it may be valuable and justifiable to encourage religious hopes. This, he said, can be done without impairing the power of reason; and indulgence in such hopes may help some men to feel that life is more important and may strengthen their feelings for others. Furthermore, to construct a picture of a person of high moral excellence, such as Christ, and form the habit of seeking the approval of this person for one’s acts, may aid that “real, though purely human, religion, which sometimes calls itself the Religion of Humanity, and sometimes that of Duty.” Critics may wish to call these views objectionable, but in Mill at least they are not inconsistent. They hark back to his early discovery of the importance of cultivating the feelings and develop the further implications of his idea of the moral importance of educating the emotions. His

assessment of the degree to which scientific support can be given to a supernaturalist theory by evidences of design, low though it is, may seem far too high; but his interest in the theory of a limited deity with whom we must cooperate to bring about improvement in the world is hardly great enough or personal enough to lend credence to the accusations that he had undergone an emotional collapse.

## Bibliography

### WORKS BY MILL

Mill's works have not yet been collected. Even the projected University of Toronto Press edition of his Works will probably not contain all of them. Mill's own *Bibliography*, edited by M. MacMinn, J. R. Hains, and J. M. McCrimmon (Evanston, IL, 1945), is not quite complete.

Mill's books (all of which were published in London, unless otherwise noted) are as follows: *System of Logic*, 2 vols. (1843; 8th ed., 1872); *Essays on Some Unsettled Questions of Political Economy* (1844; written 1830–1831); *Principles of Political Economy*, 2 vols. (1848; 7th ed., 1871; variorum ed., W. J. Ashley, ed., 1909); *On Liberty* (1859); *Dissertations and Discussions*, periodical essays, 2 vols. (1859), 4 vols. (1875); *Considerations on Representative Government* (1861); *Utilitarianism*, reprinted from *Frasers Magazine*, 1861 (1863); *An Examination of Sir William Hamilton's Philosophy* (1865; 6th ed., 1889); *Auguste Comte and Positivism* (1865); *Subjection of Women* (1869; written in 1861); *Autobiography* (1873; more complete edition, J. J. Coss, ed., New York, 1924).

Among Mill's shorter writings of philosophical interest (most reprinted in *Dissertations and Discussions*) are the following: "Whately's Elements of Logic," *Westminster Review* (1828); "The Spirit of the Age," in the *Examiner* (1831), included in *The Spirit of the Age*, edited by F. Hayek (Chicago, 1942); "Prof. Sedgwick's Discourse" (1835); "Civilization" (1836); "Bentham" (1838); "Coleridge" (1840); "M. de Tocqueville on Democracy in America" (1840); "Bailey on Berkeley's Theory of Vision" (1842); "Michelet's History of France" (1844); "Dr. Whewell on Moral Philosophy" (1851); "Bain's Psychology" (1859); "Austin on Jurisprudence" (1863); "Plato" (1866); "Inaugural Address to the University of St. Andrews" (1867); "Berkeley's Life and Writings," *Fortnightly Review* (1871); "Grote's Aristotle" (1873); "Chapters on Socialism," *Fortnightly Review* (1879), reprinted as *Socialism*, edited by W. D. P. Bliss (Linden, MA, 1891).

Of Mill's literary essays, the best known are "What Is Poetry?" and "The Two Kinds of Poetry," in *Monthly Repository*

(1833), reprinted in part in *Dissertations and Discourses* as "Thoughts on Poetry and Its Varieties."

### WORKS ON MILL

#### Life

For Mill's life, see his *Autobiography*; F. E. Mineka, ed., *Earlier Letters*, 2 vols. (Toronto, 1963); H. S. R. Elliott, ed., *Letters*, 2 vols. (1910); J. Stillinger, ed., *Early Draft of John Stuart Mill's Autobiography* (Urbana: University of Illinois Press, 1961). See F. Hayek, ed., *John Stuart Mill and Harriet Taylor* (1951), for their correspondence. See also the standard M. St. John Packe, *The Life of John Stuart Mill* (1954); A. Bain, *John Stuart Mill* (1882); and W. L. Courtney, *Life of John Stuart Mill* (1886); H. O. Pappé, *John Stuart Mill and the Harriet Taylor Myth* (Melbourne, 1960); A. W. Levi, "The Writing of Mill's Autobiography," in *Ethics* 61 (1951).

Among many estimates of Mill's life and character are those by R. H. Hutton, reprinted in *Criticism on Contemporary Thought and Thinkers*, Vol. 1 (1894); J. Martineau, in *Essays* 3 (1891); J. Morley, in *Critical Miscellanies* 2 (1877); B. Russell, in *Proceedings of the British Academy* (1955); W. Ward, in *Men and Matters* (1914).

#### General Works

For general commentary on the thought of Mill see Sir Leslie Stephen, *English Utilitarians*, Vol. 3 (1900); R. P. Anschutz, *Philosophy of John Stuart Mill* (Oxford, 1953); Karl Britton, *John Stuart Mill* (1953).

#### Logic

See O. A. Kubitz, *Development of John Stuart Mill's System of Logic*, Illinois Studies in the Social Sciences, VIII (Urbana, IL, 1932); R. Jackson, *Deductive Logic of John Stuart Mill* (Oxford, 1941); W. Whewell, *Of Induction, with especial reference to Mr. J. Stuart Mill's System of Logic* (1849), and see E. A. Strong, "W. Whewell and John Stuart Mill," *Journal of the History of Ideas* (1955). Classic criticisms include: T. H. Green, "The Logic of John Stuart Mill," *Works*, Vol. II (1886); F. H. Bradley, *Principles of Logic* (Oxford, 1883), Bk. II, Part II, Chs. 1–3; W. S. Jevons, "John Stuart Mill's Philosophy Tested," reprinted in *Pure Logic* (1890).

#### Metaphysics

Among older studies of interest are: W. L. Courtney, *The Metaphysics of John Stuart Mill* (1879); C. M. Douglas, *John Stuart Mill: A Study of His Philosophy* (Edinburgh and London: Blackwood, 1895); J. McCosh, *An Examination of Mr. John Stuart Mill's Philosophy* (London and New York, 1866); and John Grote, *Exploratio Philosophica* (Cambridge, U.K.: Deighton Bell, 1865; 2 vols., 1900). Few recent discussions center explicitly on Mill.

#### Ethics and Utilitarianism

E. Halévy, *La formation du radicalisme philosophique*, 3 vols. (Paris: F. Alcan, 1901–1904), translated into English by Mary Morris as *Growth of Philosophic Radicalism* (London: Faber and Gwyer, 1928), is the basic study of the development of Benthamite doctrine; see also E. Albee, *History of English Utilitarianism* (1900) and J. Plamenatz, *The English Utilitarians* (Oxford: Blackwell, 1949). Especially valuable older critical works are John Grote, *Examination of the Utilitarian Philosophy* (Cambridge, U.K., 1870) and F. H. Bradley, *Ethical Studies* (Oxford, 1876), Ch. 3. Recent discussions start from the criticisms of G. E. Moore,

*Principia Ethica* (London: Cambridge University Press, 1903), Chs. 1 and 3. Compare J. Seth, "Alleged Fallacies in Mill's Utilitarianism," in *Philosophical Review* 17 (1908); E. W. Hall, "The 'Proof' of Utility in Bentham and Mill," in *Ethics* 9 (1949); J. O. Urmson, "Interpretation of the Moral Philosophy of John Stuart Mill," in *Philosophical Quarterly* 3 (1953). I. Berlin's lecture, "John Stuart Mill and the Ends of Life" (London, 1962), is more general.

### Political Philosophy

See G. H. Sabine, *History of Political Theory*, 3rd ed. (New York: Holt, Rinehart and Winston, 1961); M. Cowling, *Mill and Liberalism* (Cambridge, 1963). J. F. Stephen, *Liberty, Equality, Fraternity* (1873) is an interesting early attack; others are summarized in J. C. Rees, *Mill and His Early Critics* (Leicester, U.K., 1956). B. Bosanquet, *Philosophical Theory of the State* (1899) and D. G. Ritchie, *Principles of State Interference* (1891) present representative criticism. J. H. Burns, "John Stuart Mill and Democracy," in *Political Studies* 5 (1957), traces the development of Mill's views. For criticisms of Mill's views on sociological method, see K. Popper, *Open Society and Its Enemies*, 2 vols. (London: Routledge, 1945), Ch. 14, and P. Winch, *Idea of a Social Science* (London: Routledge and Kegan Paul, 1958), especially Ch. 3.

*J. B. Schneewind (1967)*

## MILL, JOHN STUART [ADDENDUM]

The most important development in John Stuart Mill scholarship of the past half century is the publication of the *Collected Works of John Stuart Mill* in thirty-three volumes (1963–1991), with John M. Robson as general editor. This is a monumental publication by the University of Toronto Press, which will provide data for Mill scholars in years to come. The seven volumes of letters and many volumes of essays, speeches, and journals, show that most of his writing was not on narrowly philosophical topics: Much of it was on concrete political issues of his day. There are four volumes of newspaper writings. The *Collected Works* also makes available all of the revisions in successive editions of his major works, such as *System of Logic* (Vols. VII–VIII) and *Principles of Political Economy* (Vols. II–III), and it makes available out-of-print works such as his *An Examination of Sir William Hamilton's Philosophy* (Vol. IX). The exhaustive index in the final volume enables scholars to find Mill's views on various topics scattered throughout his writings.

Another development is the publication of a periodical devoted to utilitarian studies. *The Mill Newsletter* began publication in 1965 by the University of Toronto Press under the editorship of John M. Robson. It carried

long and short articles, news of new and forthcoming books and articles, and a continuing bibliography of works on Mill. In 1989 it merged with *The Bentham Newsletter* to become *Utilitas: A Journal of Utilitarian Studies*, now being published by Cambridge University Press. It has provided a vehicle for Mill scholarship including but not limited to his philosophy.

The most substantial studies of the totality of Mill's philosophy are *John Stuart Mill*, by John Skorupski (1989) and the collection of essays that he edited in *The Cambridge Companion to Mill* (1998). In the former, Skorupski gives a critical but sympathetic account of Mill's philosophy of language, his philosophy of science, his philosophy of mathematics, and his epistemology and metaphysics as well as a discussion of his moral and political philosophy. In *The Cambridge Companion to Mill*, the same areas are addressed by various contributors. Mill's radical empiricist theory of mathematical truth has been dismissed by most philosophers of mathematics since his time. But the essay by Philip Kitcher (Skorupski 1998, pp. 57–111) gives it a sympathetic interpretation.

The most widely read philosophical works of Mill continue to be his essays *Utilitarianism* (Mill 1963–1991, vol. X, p. 203–206) and *On Liberty* (Mill 1963–1991, vol. XVIII, p. 215–310). Debates concerning utilitarianism in the last half century, such as the distinction between act-utilitarianism and rule-utilitarianism and the plausibility of each, have included controversies over the interpretation and plausibility of Mill's position on these issues. Also, those attacking or defending liberalism have inevitably included references to Mill's essay as one of the most representative statements of the liberal position. With the development of feminist philosophy, his essay *The Subjection of Women* (Mill 1963–1991, vol. XXI, p. 259–348) has also received renewed attention as an early feminist statement, sometimes dismissed as the *liberal feminist* position, but sometimes defended against its critics.

Two controversial topics in Mill's utilitarianism continue to receive a focus of attention: his distinction between pleasures on grounds of superiority or inferiority of quality as well as quantity and his alleged *proof* of the principle of utility. In the early part of the twentieth century, the first of these was generally regarded as either inconsistent with his hedonism or as nonsense, and the second was regarded as a classic case of fallacious reasoning. In the last half century, these have been defended, although not always in the same ways. Some "friends" of Mill have tried to reduce the distinction of qualities to a quantitative distinction; others have insisted that Mill is

correct in recognizing the phenomenal diversity of pleasurable experiences. But even among the latter there is disagreement about whether Mill is correct in correlating the distinction with the distinctively human, as opposed to nonhuman animal, faculties and whether qualitatively distinct pleasures are consistently preferred by those who are qualified by experiences of both. Important works on these topics are found in books by Wendy Donner (1991) and Henry West (2004). Donner emphasizes that those qualified by experience to judge the qualities of pleasure are not simply those who have experienced different pleasures but those whose experience has been developed by education and enlightenment. Mill's *proof* has been the subject of numerous interpretations and controversy. It is no longer dismissed as a collection of fallacies, but whether it is a sound argument with plausible assumptions is still a matter of great debate. West defends it as a sound argument.

The consistency between Mill's apparently hedonistic utilitarianism and his essay *On Liberty* has been another topic of extensive discussion. Here again, more recent discussion has been more friendly to Mill but with differences in interpretation. Some commentators have claimed consistency for him by a reinterpretation of his utilitarianism to make it nonhedonistic, with a conception of happiness that essentially involves the free exercise of rational capacities. Others have seen in Mill's psychological assumptions, with a complex phenomenal account of pleasure, including *higher* and *lower* and the necessity for self-development as a necessary condition for the higher pleasures, a basis for consistency that remains hedonistic. Mill's *On Liberty* attempts to distinguish between conduct that concerns others and that concerns only oneself. Strictly construed, very little conduct concerns only oneself. Studies of *On Liberty* by C. L. Ten (1980), John Gray (1983, rev. ed. 1996), and J. C. Rees (1985) have reinterpreted the distinction in terms of conduct concerning the *interests* of self or others. Mill is seen to be holding the view that there is a right to liberty, which is a right to autonomy. There is controversy, however, over the substance of this right and also over the *harm principle* which limits it.

Whether Mill was a rule-utilitarian was one of the questions that generated the distinction between act-utilitarianism and rule-utilitarianism. The essay by J. O. Urmson (1953) interpreting Mill as a rule-utilitarian has been challenged and supported by citations from Mill texts both pro and con. A middle position, argued by Fred R. Berger (1984) and others, is that Mill endorsed a strategy for achieving the greatest happiness that was in prac-

tice rule-utilitarian but that Mill seemed to think that if all hidden utilities were taken into consideration, there would be no conflict between the two positions. Acts that violate useful rules weaken the rules and undermine the rule-abiding character of the agent. Acts that form part of a collection of acts that have bad consequences can theoretically be assigned a fraction of those bad consequences. Whether these moves are adequate to remove the conflict is suspect.

Perhaps most significant as a way of resolving the conflict in favor of a rule-utilitarian interpretation has been the attention drawn to the importance of sanctions in Mill's theory of morality. Most commentators make a distinction between act-utilitarianism as a criterion of right action and act-utilitarianism as a decision procedure for action. It is generally recognized that Mill rejected act-utilitarianism as a decision procedure in all cases, but some commentators, such as Roger Crisp (1997), still hold that he was an act-utilitarian with regard to the criterion of right action. Essays by David Lyons and by L. W. Sumter (in Cooper, et. al. 1979, 1–19 and 99–114), and in the study by West (2004) claim that Mill cannot be regarded as either an act-utilitarian or a rule-utilitarian but that his moral theory is more complex than either. Lyons's essays on various aspects of Mill's ethics are reprinted in *Rights, Welfare, and Mill's Moral Theory* (Lyons 1994).

In Chap. V of *Utilitarianism*, Mill has a theory of rights correlative to some but not all morally significant actions, and he restricts the morally obligatory to those actions for which punishment has utility; in *August Comte and Positivism*, (Mill 1963–1991, vol. X, p. 337–339), he clearly states a theory of morally meritorious action that goes beyond what is morally required. These would indicate that Mill's moral theory has a structure that is more complicated than any simple act- or rule-formulation.

Mill's contribution to the development of psychological theory is the subject of an important study by Fred Wilson (1990), who interprets Mill as a pioneer in turning psychology into an empirical science. A major study of Mill's economic theory is by Samuel Hollander (1985). Geoffrey Scarre has published a study of Mill's metaphysical views (1989).

Michael St. John Packe's *The Life of John Stuart Mill* (1954) continues to be the standard biography of the details of the Mill's life. But Nicholas Capaldi (2004) has recently written a thorough intellectual biography, arguing that Mill combined a Coleridgean/Germanic romanticism with his Benthamite Enlightenment heritage.

Mill continues to have his critics. H. J. McCloskey finds fault with nearly everything in Mill's philosophy (1971), and his liberalism has been attacked by Gertrude Himmelfarb (1974). McCloskey, however, does recognize that Mill's philosophy of language anticipated Ludwig Wittgenstein's notion of *family resemblances* in his rejection of Plato's essentialism.

Henry R. West (1996, 2005)

### MILLER, DICKINSON S. (1868–1963)

Dickinson S. Miller was an American ethical philosopher and epistemologist who published both under his own name and under the pseudonym R. E. Hobart. He was born in Philadelphia and studied at the University of Pennsylvania, Clark University, the universities of Berlin and Halle, Hobart College, and Harvard University. He held a doctorate in philosophy from Halle and a D.Sc. from Hobart.

At Harvard, Miller was a student of William James, who became his longtime friend and with whom he often discussed and argued points of philosophy. James was

instrumental in getting Miller an appointment as associate professor of philosophy at Bryn Mawr College in 1893, the year after Miller's graduation from Harvard.

Miller left Bryn Mawr in 1898 to become first an instructor and then a professor of philosophy at Harvard. He subsequently joined the Columbia faculty, where he remained until the 1920s. He had also received a D.D. at Berkeley (California) Divinity School and in 1911 started to teach apologetics at the General Theological Seminary in New York City.

In his later days he lived for several years (1927–1932) close to his friend the critical realist Charles Augustus Strong, in Fiesole, near Florence, Italy. Strong appreciated Miller's company, especially because of Miller's neorealistic tendencies as opposed to Strong's different epistemological outlook. Their discussions were lively and interminable. George Santayana occasionally joined them, coming to Florence from Rome. Miller was a visitor during 1926 at the Vienna circle of logical positivists; although mostly a silent listener at the circle's sessions, he was an intensely interesting and challenging discussant in individual conversations. During his last twenty-five years he lived in Boston.

Miller's was an extremely penetrating and constructively critical mind. In a number of remarkable articles he addressed himself mainly to such topics as direct realism, the philosophy of mind, and also the controversy between William James and E. A. Singer on behaviorism. Especially interesting is "Is Consciousness 'A Type of Behavior'?" (1911), mainly about the "automatic sweetheart" puzzle. In 1951, Miller wrote "'Descartes' Myth' and Professor Ryle's Fallacy," a sharp critique of Gilbert Ryle's logical behaviorism. He also wrote on David Hume's views on causality and induction, on various topics in moral philosophy, and most notably, on the free-will–determinism issue. Miller's article provocatively titled "Free Will as Involving Determination and Inconceivable without It" (1934), published, for obscure reasons, under the name R. E. Hobart, has become a locus classicus of the free-will controversies. With remarkable lucidity and perspicacity Miller brought up to date the essentials of the point of view of Hume and J. S. Mill. He argued that once we realize the clear distinctions between causality and compulsion and between indeterminism and free will, the traditionally vexing problem disappears, and a fully adequate account of human freedom, responsibility, reward, and punishment can be given. Miller's views on religion and theology were extremely liberal and modern, close to the outlook of Unitarianism (in fact, he

occasionally served as a Unitarian minister in the Boston area).

Miller's contributions to the epistemological controversies of his time may now seem a bit old-fashioned, but they are worthy of renewed attention because the same issues are still being debated, albeit in a different style and terminology.

### MILLIKAN, RUTH GARRETT (1933–)

Born December 19, 1933, and raised in Swarthmore, Pennsylvania, where her father taught physics, Millikan received her Ph.D. from Yale University in 1969. She began her career as a self-described "faculty housewife," raising four children before publishing her first book. Internationally recognized, Millikan has made significant contributions to philosophy of biology, animal cognition, philosophy of language, mind, and ontology. A unifying theme is the importance of the fact that humans are products of evolution. (Millikan's mother held a Ph.D. in paleontology—perhaps influencing Millikan's orientation to Darwinism.) A student of Wilfred Sellars, Millikan rejects epistemic *givens* and takes *meaning* talk to have the function of helping speakers bring their use into conformity with others; unlike other Sellarsians, Millikan

sees the sort of function that underwrites intentional content everywhere, not just in linguistic creatures. Her first book (Millikan 1984) is a detailed articulation of teleosemantics, a Darwinian account of both mental representations and language.

Millikan's work reaches far beyond her account of intentionality, as a small sample of her conclusions shows—among them: that dogs have perfectly good concepts, that some thoughts have two *directions of fit* at once, that understanding language is a form of direct perception. Difficult to summarize, Millikan's program can nonetheless be seen to be framed by three questions: In the philosophy of mind, What is it for one's *thoughts* to be of something?; in epistemology, What is it for one to *know what* one is thinking of?; and in metaphysics, What makes for the *objective samenesses* in the world that one's thoughts are of? Her interlocking answers form a picture of human cognition that challenges tradition on several scores, even as she seeks to defend tradition in the form of scientific realism and the correspondence theory of truth.

## THOUGHT

What one's thoughts are of is, according to Millikan, determined by their historically selected function. All intentional items (bee dances, linguistic forms, perceptions, desires, fears, and so forth) have such *proper functions*, and what any particular intentional item is about, its content, is determined by such functions. (That individual words or token mental states have proper functions and that their content owes to proper functions are claims that have encountered vigorous opposition.) Specifically, a *proper function* of a feature *F* of an organism *O* is a task whose performance by earlier instances of *F* in other organisms of *O*'s kind in *O*'s lineage accounts for the proliferation of *F* in *O*'s kind here and now. Importantly, there are nonbiological cases of proper function—for example, customs, hammers, and nails—so the relevant notions of *task* and *lineage* must be understood broadly. The *content* of a representation type *R* is given by the connection between instances of *R* and worldly circumstances, recurrent exploitation of which by consumers of *R* has contributed to their proliferation over time.

What makes *mental representations*, such as thoughts, beliefs, and desires, distinct from other information-bearing items, such as bee dances? Mental representations are representations that “when they perform their proper function, their referents are identified” (Millikan 1984, p. 13). By *identified*, Millikan means that the referent is represented as being the same thing again. For

example, Clarence's visual perception that a spider is crawling up his leg is an intentional state with a job to do, and such states exist in us because historically selected for performance of that job. The function of his thoughts is to coordinate information he already has about the spider with new information he is acquiring as well as with his subsequent action, trying to brush the self-same spider off his leg. For Clarence's thoughts to be of the spider, then, they must meet the additional requirement of functioning to create this sort coordination of information. The capacity to think of the same *as being the same*, or “coidentifying” (Millikan 2000), is an important accomplishment, distinctive of advanced cognition.

Millikan here joins company with P. F. Strawson and Gareth Evans in claiming that some form of reidentificatory capacity is necessary for thought about the objective world. Unlike Strawson or Evans, Millikan takes her insight about coidentification to have dramatic consequences for self-knowledge.

## SELF-KNOWLEDGE

What sort of access do we have to our own thoughts? Millikan is a content externalist—just as the meanings of one's words are not settled by one's intentions, the content of one's thoughts are also determined by facts outside one's ken. To know what one is thinking of, then, is not an a priori matter. Some find this consequence troubling and seek to reconcile content externalism with first-person authority. But Millikan (1993) embraces this result, and argues that a still more radical conclusion follows from her functional account of cognition, namely, that *nothing* is epistemically “given” to thinkers. In particular, “meaning rationalism”—the doctrine that sameness and difference of meaning, univocity, and meaningfulness are all a priori accessible—is false. (It is a good question just who qualifies as a *meaning rationalist*—some argue, pace Millikan, that even Gottlob Frege not.) Millikan's rejection of meaning rationalism has several startling consequences: We can have no a priori access to logical possibility; there is nothing rationally wrong with believing contradictions; the validity of inferences is not an a priori property; and the very idea of a Fregean *mode of presentation* must be discarded. In short, like meaning, rationality ain't in the head.

Millikan's radical anti-individualism about meaning and rationality might be opposed by more moderate externalisms. And her attack on the very idea of modes of presentation meets with resistance from those who see a genuine explanatory role for modes, even within naturalistic accounts of the mind.

## ONTOLOGY

Coidentification is the heart of thought because the goals of organisms are served by coidentifying. But the goals of organisms would only be thus served if there were genuine coidentifiables in the objective world. Millikan's ontology is decidedly realist. Her functional take on concepts has her carving nature at different joints than others might, however. For Millikan, empirical concepts are of *substances*, that is, *coidentifiables*. The category *substance* includes real kinds (e.g., *mouse*), individuals (e.g., *Mama*), event types (e.g., *breakfast again*), and numerous other stuffs and types (e.g., *ice*, *Starbucks Coffee House*). At an important level of abstraction, there is no genuine ontological distinction to be made among these things.

## SUMMARY

In briefest summary: Millikan's program for understanding the nature of representation—which is to say, for understanding ourselves—is impressive for its combination of detail and scope.

## MILL'S METHODS OF INDUCTION

John Stuart Mill, in his *System of Logic* (Book III, Chapters 8–10), set forth and discussed five methods of experimental inquiry, calling them the method of agreement, the method of difference, the joint method of agreement and difference, the method of residues, and the method of concomitant variation. Mill maintained that these are the methods by which we both discover and demonstrate causal relationships, and that they are of fundamental importance in scientific investigation. Mill called these methods "eliminative methods of induction." In so doing, he was drawing an analogy with the elimination of terms in an algebraic equation—an analogy that is rather forced, except with respect to the various methods that are classed under the heading of method of difference. As will be demonstrated, it is perhaps best to use the term "eliminative methods" with reference to the elimination of rival candidates for the role of cause, which characterizes all these methods.

## ILLUSTRATIONS OF THE METHODS

The general character of Mill's methods of experimental inquiry may be illustrated by examples of the two simplest ones, the methods of agreement and of difference. Mill's canon for the method of agreement is this: "If two or more instances of the phenomenon under investigation have only one circumstance in common, the circumstance in which alone all the instances agree is the cause (or effect) of the given phenomenon."

For example, if a number of people who are suffering from a certain disease have all gone for a considerable time without fresh fruits or vegetables, but have in other respects had quite different diets, have lived in different conditions, belong to different races, and so on, so that the lack of fresh fruits and vegetables is the only feature common to all of them, then we can conclude that the lack of fresh fruits and vegetables is the cause of this particular disease.

Mill's canon for the method of difference is this: "If an instance in which the phenomenon under investigation occurs, and an instance in which it does not occur, have every circumstance in common save one, that one occurring in the former; the circumstance in which alone the two instances differ, is the effect, or the cause, or an indispensable part of the cause, of the phenomenon."

For example, if two exactly similar pieces of iron are heated in a charcoal-burning furnace and hammered into shape in exactly similar ways, except that the first is dipped into water after the final heating while the second is not, and the first is found to be harder than the second, then the dipping of iron into water while it is hot is the cause of such extra hardness—or at least an essential part of the cause, for the hammering, the charcoal fire, and so on may also be needed. For all this experiment shows, the dipping alone might not produce such extra hardness.

The method of agreement, then, picks out as the cause the one common feature in a number of otherwise different cases where the effect occurs; the method of difference picks out as the cause the one respect in which a case where the effect occurs differs from an otherwise exactly similar case where the effect does not occur. Both are intended to be methods of ampliative induction, that is, methods by which we can reason from a limited number of observed instances to a general causal relationship: The intended conclusion is that a certain disease is always produced by a lack of fresh fruits and vegetables, or that dipping iron into water while it is hot always hardens it, if it has been heated and hammered in a particular way. And the other three methods are intended to work in a similar manner.

These methods have been criticized on two main counts: First, it is alleged that they do not establish the conclusions intended, so that they are not methods of proof or conclusive demonstration; and second, that they are not useful as methods of discovery. Such criticisms have been used to support the general observation that these methods play no part, or only a very minor part, in the investigation of nature, and that scientific method requires a radically different description.

In order to estimate the force of such criticisms, and to determine the real value of the eliminative methods, Mill's formulation need not be discussed in detail. Instead, one need only determine what would be valid demonstrative methods corresponding to Mill's classes, and then consider whether such methods, or any approximations of them, have a place in either scientific or commonsense inquiry.

## METHODS OF AGREEMENT AND OF DIFFERENCE

To avoid unnecessary complications, let us assume that the conclusion reached by any application of the method of agreement or of difference is to have the form "Such-and-such is a cause of such-and-such kind of event or phenomenon." For a formal study of these methods and the joint method we could regard a cause as a necessary and sufficient condition of the effect—or, in some cases, as a necessary condition only, or as a sufficient condition only—where to say that *X* is a necessary condition for *Y* is just to say that wherever *Y* is present, *X* is present, or briefly that all *Y* are *X*; and to say that *X* is a sufficient condition for *Y* is just to say that wherever *X* is present *Y* is present, or briefly that all *X* are *Y*.

In general we shall be looking for a condition that is both necessary and sufficient for the phenomenon, but there are variants of the methods in which we look for a condition that is merely necessary or merely sufficient. In practice, however, we are concerned with conditions that are not absolutely necessary or sufficient, but that are rather necessary and/or sufficient in relation to some *field*, that is, some set of background conditions, which may be specified more or less exactly. We are concerned, for example, not with the cause of a certain disease in general, but with what causes it in human beings living on the earth, breathing air, and so forth. Again, we are concerned not with the cause of hardness in general, but with that of a greater-than-normal hardness in iron in ordinary circumstances and at ordinary temperatures. The field in relation to which we look for a cause of a phenomenon must be such that the phenomenon sometimes occurs in that field and sometimes does not. We may assume that this field is constituted by the presence of certain qualities or at least of some general descriptive features, not by a specific location.

The *observation* that supports the conclusion is an observation of one or more instances in each of which various features are present or absent. An instance may be one in which the phenomenon in question occurs, which we may call a *positive instance*, or one in which the phenomenon does not occur, which we may call a *negative instance*.

To reason validly, however, from any such observation to a general causal conclusion, we require an additional general premise, an *assumption*. We must assume that there is some condition which, in relation to the field, is necessary and sufficient (or which is necessary, or which is sufficient) for the phenomenon, and also that this condition is to be found within a range of conditions

that is restricted in some way. For these methods fall within the general class of eliminative forms of reasoning, that is, arguments in which one possibility is confirmed or established by the elimination of some or all of its rivals. The assumption will state that there is a cause to be found and will limit the range of candidates for the role of cause; the task of the observation will be to rule out enough of the candidates initially admitted to allow some positive conclusion.

**POSSIBLE CAUSES.** It follows from the above that the assumption must indicate some limited (though not necessarily finite) set of what we may call *possible causes*. These are the factors (Mill calls them *circumstances* or *antecedents*) that, it is initially assumed, may be causally relevant to the phenomenon. Any possible cause, any factor that may be causally relevant in relation to the field in question, must, like the phenomenon itself, be something that sometimes occurs and sometimes does not occur within that field.

But are we to assume that a possible cause acts singly, if it acts at all? If the possible causes are  $A, B, C$ , etc., the phenomenon is  $P$ , and the field is  $F$ , are we to assume that the cause of  $P$  in  $F$  will be either  $A$  by itself or  $B$  by itself, and so on? Or are we to allow that it might be a conjunction, say  $AC$ , so that  $P$  occurs in  $F$  when and only when  $A$  and  $C$  are both present? Are we to allow that the necessary and sufficient condition might be a disjunction, say ( $B$  or  $D$ ), so that  $P$  occurs in  $F$  whenever  $B$  occurs, and whenever  $D$  occurs, but only when one or other (or both) of these occurs? Again, are we to allow that what we have taken as possible causes may include counteracting causes, so that the actual cause of  $P$  in  $F$  may be, say, the absence of  $C$  (that is, the negation not- $C$ , or  $\bar{C}$ ) or perhaps  $\bar{B}\bar{C}$  so that  $P$  occurs in  $F$  when and only when  $B$  is present and  $C$  is absent at the same time?

There are in fact valid methods with assumptions of different sorts, from the most rigorous kind, which requires that the actual cause should be just one of the possible causes by itself, through those which progressively admit negations, conjunctions, and disjunctions of possible causes and combinations of these, to the least rigorous kind of assumption, which says merely that the actual cause is built up out of these possible causes in some way.

**CLASSIFICATION OF THESE METHODS.** There will be, then, not one method of agreement, one method of difference, and one joint method, but a series of variants of each. A complete survey could be made of all possible

methods of these types, numbered as follows: A number from 1 to 8 before a decimal point will indicate the kind of assumption. Thus, it is assumed that there is an actual cause that is

- (1) one of the possible causes;
- (2) one of the possible causes or the negation of a possible cause;
- (3) a possible cause or a conjunction of possible causes;
- (4) a possible cause or a disjunction of possible causes;
- (5) a possible cause or the negation of a possible cause, or a conjunction each of whose members is a possible cause or the negation of a possible cause;
- (6) a possible cause, or the negation of a possible cause, or a disjunction each of whose members is a possible cause or the negation of a possible cause;
- (7) a possible cause, or a conjunction of possible causes, or a disjunction each of whose members is a possible cause or a conjunction of possible causes;
- (8) a possible cause, or the negation of a possible cause, or a conjunction each of whose members is a possible cause or the negation of one; or a disjunction each of whose members is a possible cause or the negation of one, or a conjunction each of whose members is a possible cause or a negation of one.

The first figure after the decimal point will indicate the sort of observation, as follows:

- (1) a variant of the method of agreement;
- (2) a variant of the method of difference;
- (3) a variant of the joint method;
- (4) a new but related method.

The second figure after the decimal point will mark further differences where necessary, but this figure will have no constant significance.

The complete survey cannot be given here, but a few selected variants will be considered, numbered in the manner set forth above.

**POSITIVE METHOD OF AGREEMENT.** Let us begin with an assumption of the first kind, that there is a necessary and sufficient condition  $X$  for  $P$  in  $F$ , that is, that for some  $X$  all  $FP$  are  $X$  and all  $FX$  are  $P$ , and  $X$  is identical

with one of the possible causes  $A, B, C, D, E$ . (It may be noted that a condition thus specified may sometimes not be what we would ordinarily regard as the cause of the phenomenon: We might rather say that it *contains* the real cause. However, in our present account we shall call such a condition the cause; it is explained below how the cause of a phenomenon may be progressively located with greater precision.)

We obtain a variant of the method of agreement (1.12) by combining with this assumption the following observation: A set of one or more positive instances such that one possible cause, say  $A$ , is present in each instance, but for every other possible cause there is an instance from which that cause is absent. This yields the conclusion that  $A$  is necessary and sufficient for  $P$  in  $F$ .

For example, the observation might be this:

	$A$	$B$	$C$	$D$	$E$
$I_1$	$p$	$a$	$p$	$\cdot$	$a$
$I_2$	$p$	$p$	$a$	$a$	$\cdot$

where  $p$  indicates that the possible cause is present,  $a$  that it is absent, and a dot that it may be either present or absent without affecting the result.  $I_1$  and  $I_2$  are positive instances:  $I_1$  shows that neither  $B$  nor  $E$  is necessary for  $P$  in  $F$ ,  $I_2$  that neither  $C$  nor  $D$  is necessary, and hence, given the assumption, it follows that  $A$  is necessary and sufficient.

Since this reasoning eliminates candidates solely on the ground that they are not necessary, there is another variant (1.11) that assumes only that there is some necessary condition for  $P$  in  $F$  identical with one of the possible causes, and (with the same observation) concludes that  $A$  is a necessary condition for  $P$  in  $F$ .

**Negative method of agreement.** Besides the positive method of agreement, in which candidates are eliminated as not being necessary because they are absent from positive instances, there are corresponding variants of a negative method of agreement in which candidates are eliminated as not being sufficient because they are present in negative instances. This requires the following observation: A set of one or more negative instances such that one possible cause, say  $A$ , is absent from each instance, but for every other possible cause there is an instance in which it is present. For example:

	$A$	$B$	$C$	$D$	$E$
$N_1$	$a$	$p$	$\cdot$	$\cdot$	$\cdot$
$N_2$	$a$	$\cdot$	$p$	$p$	$\cdot$
$N_3$	$a$	$\cdot$	$\cdot$	$\cdot$	$p$

If the assumption was that one of the possible causes is sufficient for  $P$  in  $F$ , this observation would show (1.13) that  $A$  is sufficient, while if the assumption was that one of the possible causes is both necessary and sufficient, this observation would show (1.14) that  $A$  is necessary and sufficient.

**METHOD OF DIFFERENCE.** For the simplest variant of the method of difference (1.2) we need this observation: a positive instance  $I_1$  and a negative instance  $N_1$  such that of the possible causes present in  $I_1$ , one, say  $A$ , is absent from  $N_1$ , but the rest are present in  $N_1$ . For example:

	$A$	$B$	$C$	$D$	$E$
$I_1$	$p$	$p$	$p$	$a$	$\cdot$
$N_1$	$a$	$p$	$p$	$\cdot$	$p$

Here  $D$  is eliminated because it is absent from  $I_1$ , and hence not necessary, and  $B, C$ , and  $E$  are eliminated because they are present in  $N_1$  and hence not sufficient. Hence, given the assumption that one of the possible causes is both necessary and sufficient for  $P$  in  $F$ , it follows that  $A$  is so. (Note that since it would not matter if, say,  $E$  were absent from  $I_1$ , the presence of the actual cause in  $I_1$  need not be the only difference between the instances.) We may remark here that the method of difference, unlike some variants of the method of agreement, requires the assumption that there is some condition that is both necessary and sufficient for  $P$ . It is true, as we shall see later with variants 4.2 and 8.2, that the "cause" detected by this method is often not itself a necessary condition, or even a sufficient one; but the assumption needed is that *something* is both necessary and sufficient.

**JOINT METHOD.** The joint method may be interpreted as an indirect method of difference, that is, the job done by  $I_1$  above may be shared among several positive instances, and the job done by  $N_1$  among several negative instances. That is, we need (for 1.3) the following observation: a set  $S_i$  of one or more positive instances and a set  $S_n$  of one or more negative instances such that one of the possible causes, say  $A$ , is present throughout  $S_i$  and absent throughout  $S_n$ , but each of the other possible causes is either absent from at least one positive instance or present in at least one negative instance. Given that one of the possible causes is both necessary and sufficient, this yields the conclusion that  $A$  is so.

**SIMPLE VARIANTS OF THESE METHODS.** With an assumption of the second kind (that the requisite condi-

tion is either a possible cause or a negation of a possible cause) we need stronger observations. Thus, for variants of the positive method of agreement (2.11 and 2.12) we need this: two or more positive instances such that one possible cause (or negation), say  $A$ , is present in each instance, but for every other possible cause there is an instance in which it is present and an instance from which it is absent. This is needed to rule out, as candidates for the role of necessary (or both necessary and sufficient) condition, the negations of possible causes as well as the possible causes other than  $A$  themselves.

For the corresponding variant of the method of difference (2.2) we need this: a positive instance  $I_1$  and a negative instance  $N_1$  such that one possible cause (or negation), say  $A$ , is present in  $I_1$  and absent from  $N_1$ , but each of the other possible causes is either present in both  $I_1$  and  $N_1$  or absent from both. For example:

	$A$	$B$	$C$	$D$	$E$
$I_1$	$p$	$p$	$a$	$a$	$p$
$N_1$	$a$	$p$	$a$	$a$	$p$

Since  $B$  is present in  $N_1$ ,  $B$  is not sufficient for  $P$  in  $F$ ; but since  $B$  is present in  $I_1$ , not- $B$  is not necessary for  $P$  in  $F$ ; thus neither  $B$  nor not- $B$  can be both necessary and sufficient. Similarly,  $C$ ,  $D$ ,  $E$ , and their negations, and also not- $A$ , are ruled out, and thus the necessary and sufficient condition must be  $A$  itself. This is the classic difference observation described by Mill, in which the only (possibly relevant) difference between the instances is the presence in  $I_1$  of the factor identified as the actual cause; but we need this observation (as opposed to the weaker one of 1.2) only when we allow that the negation of a possible cause may be the actual cause.

The joint method needs, along with this weaker assumption, a similarly strengthened observation: That is, each of the possible causes other than  $A$  must be either present in both a positive and a negative instance or absent from both a positive and a negative instance, and then this variant (2.3) still yields the conclusion that  $A$  is both necessary and sufficient.

(What Mill and his followers describe as the joint method may be not this indirect method of difference, but rather a double method of agreement, in which a set of positive instances identifies a necessary condition and a set of negative instances identifies a sufficient condition. Such a combination is redundant with an assumption of either of the first two kinds, but not when the assumption is further relaxed.)

**MORE COMPLEX VARIANTS.** We consider next an assumption of the third kind, that the requisite condition is either a possible cause or a conjunction of possible causes. (This latter possibility seems to be at least part of what Mill meant by “an intermixture of effects.”) This possibility does not affect the positive method of agreement, since if a conjunction is necessary, each of its conjuncts is necessary, and candidates can therefore be eliminated as before. But since the conjuncts in a necessary and sufficient condition may not severally be sufficient, the negative method of agreement as set forth above will not work. The observation of (1.13 or) 1.14 would now leave it open that, say,  $BC$  was the required (sufficient or) necessary and sufficient condition, for if  $C$  were absent from  $N_1$  and  $B$  from  $N_2$ , then  $BC$  as a whole might still be sufficient: It would not be eliminated by either of these instances. This method now (in 3.14) needs a stronger observation, namely, a *single* negative instance  $N_1$  in which one possible cause, say  $A$ , is absent, but *every* other possible cause is present. This will show that no possible cause or conjunction of possible causes that does not contain  $A$  is sufficient for  $P$  in  $F$ . But even this does not show that the requisite condition is  $A$  itself, but merely that it is either  $A$  itself or a conjunction in which  $A$  is a conjunct. We may express this by saying that the cause is  $(A_{\dots})$ , where the dots indicate that other conjuncts may form part of the condition, and the dots are underlined, while  $A$  is not, to indicate that  $A$  *must* appear in the formula for the actual cause, but that other conjuncts may or may not appear.

The corresponding variant (3.2) of the method of difference needs only the observation of 1.2; but it, too, establishes only the less complete conclusion that  $(A_{\dots})$  is a necessary and sufficient condition of  $P$  in  $F$ . For while (in the example given for 1.2 above)  $B$ ,  $C$ ,  $D$ , and  $E$  singly are still eliminated as they were in 1.2, and any conjunctions such as  $BC$  which, being present in  $I_1$ , *might* be necessary, are eliminated because they are also present in  $N_1$  and hence not sufficient, a conjunction such as  $AB$ , which contains  $A$ , is both present in  $I_1$ , and absent from  $N_1$ , and might therefore be both necessary and sufficient. Thus this assumption and this observation show only that  $A$  is, as Mill put it, “the cause, or an indispensable part of the cause.” The full cause is represented by the formula  $(A_{\dots})$ , provided that only possible causes that are present in  $I_1$  can replace the dots.

In the corresponding variant of the joint method (3.3), we need a *single* negative instance instead of the set  $S_n$ , for the same reason as in 3.14, and the cause is specified only as  $(A_{\dots})$ .

With an assumption of the fourth kind (that the requisite condition is either a possible cause or a disjunction of possible causes), the negative method of agreement (4.13 and 4.14) works as in 1.13 and 1.14, but the positive method of agreement is now seriously affected. For with the observation given for 1.12 above, the necessary and sufficient condition might be, say, ( $B$  or  $C$ ), for this disjunction is present in both  $I_1$  and  $I_2$ , though neither of its disjuncts is present in both. Thus the observation of 1.12 would leave the result quite undecided. We need (for 4.12) a much stronger observation, that is, a single positive instance in which  $A$  is present but all the other possible causes are absent together; but even this now shows only that the cause is ( $A$  or...). This assumption (that the cause may be a disjunction of possible causes) allows what Mill called a "plurality of causes," for each of the disjuncts is by itself a "cause" in the sense that it is a sufficient condition; and what we have just noted is the way in which this possibility undermines the use of the method of agreement.

The method of difference, on the other hand (4.2), still needs only the observation of 1.2; this eliminates all possible causes other than  $A$ , and all disjunctions that do not contain  $A$ , either as being not sufficient because they are present in  $N_1$  or as not necessary because they are absent from  $I_1$ . The only disjunctions not eliminated are those that occur in  $I_1$  but not in  $N_1$ , and these must contain  $A$ . Thus this observation, with this assumption, shows that a necessary and sufficient condition is ( $A$  or...), that is, either  $A$  itself or a disjunction containing  $A$ , where the other disjuncts are possible causes absent from  $N_1$ . This, of course, means that  $A$  itself, the factor thus picked out, may be only a sufficient condition for  $P$ .

The joint method with this assumption (4.3) needs a *single* positive instance, but can still use a set of negative instances and it specifies the cause as ( $A$  or...).

As the assumptions are relaxed further, the method of agreement requires stronger and stronger observations. For example, in 6.12, which is a variant of the positive method with an assumption allowing that the necessary and sufficient condition may be a disjunction of possible causes or negations, the observation needed is a set  $S$ , of positive instances such that one possible cause, say  $A$ , is present in each, but that for every possible combination of the other possible causes and their negations there is an instance in which this combination is present (that is, if there are  $n$  other possible causes, we need  $2^n$  different instances). This observation will eliminate every disjunction that does not contain  $A$ , and will show that the requisite necessary and sufficient condition is ( $A$

or...), and hence that  $A$  itself is a sufficient condition for  $P$  in  $F$ . A corresponding variant of the negative method of agreement (5.14) shows that ( $A$ ...) is a necessary and sufficient condition, and hence that  $A$  itself is necessary—a curious reversal of roles, because in the simplest variants, the positive method of agreement was used to detect a necessary condition and the negative one a sufficient condition.

In the method of difference, however, the observation of 1.2 (or, where negations are admitted, that of 2.2) continues to yield results, though the conclusions become less complete, that is, the cause is less and less completely specified. For example, in 8.2, where we assume that there is a necessary and sufficient condition for  $P$  in  $F$  which may be one of the possible causes, or a negation of one, or a conjunction of possible causes or negations, or a disjunction of possible causes or negations or of conjunctions of possible causes or negations—which in effect allows the actual condition to be built up out of the possible causes in any way—the observation of 2.2 establishes the conclusion that the requisite condition is ( $A$ ... or...). that is to say, it is either  $A$  itself, or a conjunction containing  $A$ , or a disjunction in which one of the disjuncts is  $A$  itself or a conjunction containing  $A$ . Since any such disjunct in a necessary and sufficient condition is a sufficient condition, this observation, in which the presence of  $A$  in  $I_1$  is the only possibly relevant difference between  $I_1$  and  $N_1$ , shows even with the least rigorous kind of assumption that  $A$  is at least a necessary part of a sufficient condition for  $P$  in  $F$ —the sufficient condition being ( $A$ ...).

The joint method, as an indirect method of difference, ceases to work once we allow both conjunctions and disjunctions; but a double method of agreement comes into its own with this eighth kind of assumption. In 8.12, as in 6.12, if there are  $n$  possible causes other than  $A$ , the set of  $2^n$  positive instances with  $A$  present in each but with the other possible causes present and absent in all possible combinations will show that ( $A$  or...) is necessary and sufficient, and hence that  $A$  is sufficient. Similarly in 8.14, as in 5.14, the corresponding set of  $2^{2^n}$  negative instances will show that ( $A$ ...) is necessary and sufficient and hence that  $A$  is necessary. Putting the two observations together, we could conclude that  $A$  is both necessary and sufficient.

A new method, similar in principle, can be stated as follows (8.4): If there are  $n$  possible causes in all, and we observe  $2^n$  instances (positive or negative) which cover all possible combinations of possible causes and their negations, then the disjunction of all the conjunctions found in the positive instances is both necessary and sufficient

for  $P$  in  $F$ . For example, if there are only three possible causes,  $A, B, C$ ,

$A$	$B$	$C$	$P$
$p$	$p$	$p$	$a$
$p$	$p$	$a$	$p$
$p$	$a$	$p$	$p$
$p$	$a$	$a$	$a$
$a$	$p$	$p$	$a$
$a$	$p$	$a$	$p$
$a$	$a$	$p$	$a$
$a$	$a$	$a$	$a$

and we have the observations listed in the accompanying table, then ( $\overline{ABC}$  or  $\overline{A\overline{B}C}$  or  $\overline{A\overline{B}\overline{C}}$ ) is a necessary and sufficient condition for  $P$  in  $F$ . For if these are the only possibly relevant conditions, each combination of possible causes and negations for which  $P$  is present is sufficient for  $P$ , and these are the only sufficient conditions for  $P$ , since in all the relevantly different circumstances  $P$  is absent; but the disjunction of all the sufficient conditions must be both necessary and sufficient, on the assumption that there is some condition that is both necessary and sufficient.

**MANY VALID METHODS.** We thus find that while we must recognize very different variants of these methods according to the different kinds of assumptions that are used, and while the reasoning that validates the simplest variants fails when it is allowed that various negations and combinations of factors may constitute the actual cause, nevertheless there are valid demonstrative methods which use even the least rigorous form of assumption, that is, which assume only that there is some necessary and sufficient condition for  $P$  in  $F$ , made up in some way from a certain restricted set of possible causes. But with an assumption of this kind we must be content either to extract (by 8.2) a very incomplete conclusion from the classical difference observation or (by 8.12, 8.14, the combination of these two, or 8.4) to get more complete conclusions only from a large number of instances in which the possible causes are present or absent in systematically varied ways.

**AN EXTENSION OF THE METHODS.** An important extension of all these methods is the following: Since in every case the argument proceeds by eliminating certain candidates, it makes no difference if what is *not* eliminated is not a single possible cause but a cluster of possible causes which in our instances are always present

together or absent together, the conclusion being just as we now have it, but with a symbol for the cluster replacing  $A$ . For example, if in 2.2 we have, say, both  $A$  and  $B$  present in  $I_1$  and both absent from  $N_1$ , but each possible cause either present in both or absent from both, it follows that the cluster  $(A,B)$  is the cause in the sense that the actual cause lies somewhere within this cluster. A similar observation in 8.2 would show that either  $A$ , or  $B$ , or  $AB$ , or  $(A \text{ or } B)$  is an indispensable part of a sufficient condition for  $P$  in  $F$ .

## METHOD OF RESIDUES

The method of residues can be interpreted as a variant of the method of difference in which the negative instance is not observed but constructed on the basis of already known causal laws.

Suppose, for example, that a positive instance  $I_1$  has been observed as follows:

	$A$	$B$	$C$	$D$	$E$
$I_1$	$p$	$p$	$a$	$p$	$a$

Now if we had, to combine with this, a negative instance  $N_1$  in which  $B$  and  $D$  were present and  $A, C$ , and  $E$  absent, we could infer, according to the kind of assumption made, by 2.2 that  $A$  was the cause, or by 8.2 that  $(A\dots \text{or}\dots)$  was the cause, and so on. But if previous inductive inquiries have already established laws from which it follows that given  $\overline{ABCDE}$  in the field  $F$ ,  $P$  would not result, there is no need to observe  $N_1$ ; we already know all that  $N_1$  could tell us, and so one of the above-mentioned conclusions follows from  $I_1$  alone along with the appropriate assumption.

Again, if the effect or phenomenon in which we are interested can be quantitatively measured, we could reason as follows. Suppose that we observe a positive instance, say with the factors as in  $I_1$  above, in which there is a quantity  $x_1$  of the effect in question, while our previously established laws enable us to calculate that with the factors as in  $N_1$  there would be a quantity  $x_2$  of this effect; then we can regard the difference  $(x_1 - x_2)$  as the phenomenon  $P$  which is present in  $I_1$  but absent from  $N_1$ . With an assumption of kind (1) or (2) or (4) or (6)—that is, any assumption that does not allow conjunctive terms in the cause—we could conclude that the cause of  $P$  in this instance  $I_1$  was  $A$  alone, and hence that  $A$  is a sufficient condition for  $P$  in  $F$ . With an assumption of kind (1) or (2) we could indeed infer that  $A$  is both necessary and sufficient, but with one of kind (4) or (6) we could con-

clude only that a necessary and sufficient condition is (*A or...*).

To make an assumption of any of these four kinds is to assume that the effects of whatever factors are actually relevant are merely additive, and this lets us conclude that the extra factor in  $I_1$ , namely *A*, by itself produces in relation to *F* the extra effect ( $x_1-x_2$ ). But with an assumption of kind (3) or (5) or (7) or (8), which allows conjunctive terms, and hence what Mill calls an "intermixture of effects," we could only infer that the cause of ( $x_1-x_2$ ) in this instance was (*A...*). With the other factors that were present in both  $I_1$  and  $N_1$ , *A* was sufficient to produce this differential effect, but it does not follow that *A* is sufficient for this in relation to *F* as a whole. (Though Mill does not mention this, such a use of constructed instances along with some observed ones is in principle applicable to all the methods, not only to the method of difference in the way here outlined.)

#### METHOD OF CONCOMITANT VARIATION

The method of concomitant variation, like those already surveyed, is intended to be a form of ampliative induction; we want to argue from a covariation observed in some cases to a general rule of covariation covering unobserved cases also. To interpret this method we need a wider concept of cause than that which we have so far been using. A cause of *P* in the field *F* must now be taken, not as a necessary and sufficient condition, but as something on whose magnitude the magnitude of *P*, in *F*, functionally depends. For our present purpose this means only that there is some true lawlike proposition which, within *F*, relates the magnitude of the one item to that of the other. The *full cause*, in this sense, will be something on which, in *F*, the magnitude of *P* wholly depends, that is, the magnitude of *P* is uniquely determined by the magnitudes of the factors that constitute the full cause.

A full investigation of such a functional dependence would comprise two tasks: first, the identification of all the factors on which, in *F*, the magnitude of *P* depends, and second, the discovery of the way in which this magnitude depends on these factors. The completion of the first task would yield a mere list of terms, that of the second a mathematical formula. Only the first of these tasks can be performed by an eliminative method analogous to those already surveyed.

We should expect to find concomitant variation analogues of both the method of agreement and the method of difference, that is, ways of arguing to a causal relationship between *P* and, say, *A*, both from the observation of

cases where *P* remains constant while *A* remains constant but all the other possibly relevant factors vary, and also from the observation of cases where *P* varies while *A* varies but all the other possibly relevant factors remain constant. And indeed there are methods of both kinds, but those of the second kind, the analogues of the method of difference, are more important.

As before, we need an assumption as well as an observation, but we have a choice between two different kinds of assumption. An assumption of the more rigorous kind would be that in *F* the magnitude of *P* wholly depends in some way on the magnitude of *X*, where *X* is identical with just one of the possible causes *A, B, C, D, E*. Given this, if we observe that over some period, or over some range of instances, *P* varies in magnitude while one of the possible causes, say *A*, also varies but all the other possible causes remain constant, we can argue that none of the possible causes other than *A* can be that on which the magnitude of *P* wholly depends, and thus conclude that *X* must be identical with *A*, that in *F* the magnitude of *P* depends wholly on that of *A*. (But *how* it depends, that is, what the functional law is, must be discovered by an investigation of some other sort.)

An assumption of the less rigorous kind would be that in *F* the magnitude of *P* wholly depends in some way on the magnitudes of one or more factors *X, X', X''*, etc., where each of the actually relevant factors is identical with one of the possible causes *A, B, C, D, E*. Given this, if we again observe that *P* varies while, say, *A* varies but *B, C, D, E* remain constant, this does not now show that *B, C, D, E* cannot be identical with *X*, etc.; that is, it does not show that variations in *B* are causally irrelevant to *P*. All it shows is that the magnitude of *P* is not *wholly* dependent upon any set of factors that does not include *A*, for every such set has remained constant while *P* has varied. This leaves it open that the full cause of *P* in *F* might be *A* itself, or might be some set of factors, such as (*A,B,D*) which includes *A* and some of the others as well. All we know is that the list must include *A*. This observation and this assumption, then, show that a full cause of *P* in *F* is (*A, ...*); that is, that *A* is an actually relevant factor and there may or may not be others. Repeated applications of this method could fill in other factors, but would not *close* the list. (And, as before, it is a further task, to be carried out by a different sort of investigation, to find *how* the magnitude of *P* depends on those of the factors thus shown to be actually relevant.)

To close the list, that is, to show that certain factors are actually irrelevant, we need to use an analogue of the method of agreement. If we assume, as before, that the

full cause of  $P$  in  $F$  is some set of factors ( $X, X', X'',$  etc.), but also that  $P$  is *responsive* to all these factors in the sense that for any variation, in, say,  $X$  while  $X', X'',$  etc. remain constant  $P$  will vary, and that  $X, X', X'',$  etc. are identical with some of the possible causes  $A, B, C, D, E,$  then if we observe that  $P$  remains constant while, say,  $A, C, D,$  and  $E$  remain constant but  $B$  varies, we can conclude that  $B$  is causally irrelevant, that none of the  $X$ 's is identical with  $B.$

## USES AND APPLICATIONS OF THE ELIMINATIVE METHODS

We have so far been considering only whether there are demonstratively valid methods of this sort; but by stating more precisely what such methods involve, we may incidentally have removed some of the more obvious objections to the view that such methods can be applied in practice. Thus, by introducing the idea of a *field*, we have given these methods the more modest task of finding the cause of a phenomenon in relation to a field, not the ambitious one of finding conditions that are absolutely necessary and sufficient. By explicitly introducing the possible causes as well as the field, we have freed the user of the method of agreement from having to make the implausible claim that the user's instances have only one circumstance in common. Instead, the user has merely to claim that they have in common only one of the possible causes, while admitting that all the features that belong to the field, or that are constant throughout the field, will belong to all the instances, and that there may be other common features too, though not among those that he has initially judged to be possibly relevant.

Similarly, the user of the method of difference has only to claim that no *possibly relevant* feature other than the one he has picked as the cause is present in  $I_1$  but not in  $N_1.$  Also, we have taken explicit account of the ways in which the possibilities of counteracting causes, a plurality of causes, an intermixture of effects, and so on, affect the working of the methods, and we have shown that even when these possibilities are admitted we can still validly draw conclusions, provided that we note explicitly the incompleteness of the conclusions that we are now able to draw (for example, by the method of difference) or the much greater complexity of the observations we need (for example, in variants of the method of agreement or method 8.4).

**ELIMINATIVE METHODS AND INDUCTION.** By making explicit the assumptions needed and by presenting the eliminative methods as deductively valid forms of argument, we have abandoned any pretense that methods

such as these in themselves solve or remove the "problem of induction." Provided that the requisite observations can be made, the ultimate justification of any application of one of these methods of ampliative induction will depend on the justification of the assumption used; and, since this proposition is general in form, it will presumably have to be supported by some other kind of inductive, or at least nondeductive, reasoning. But we must here leave aside this question of ultimate justification.

**ELIMINATIVE METHODS AND DETERMINISM.** Some light, however, can be thrown on the suggestion frequently made that causal determinism is a presupposition of science. If these eliminative methods play some important part in scientific investigation, then it is noteworthy that they all require deterministic assumptions: They all work toward the identification of a cause of a given phenomenon by first assuming that there is some cause to be found for it. However, it has emerged that what we require is not a single universally applicable principle of causality, namely, that every event has a cause, but something at once weaker in some ways and stronger in other ways than such a principle. The principle assumed is that the particular phenomenon  $P$  in the chosen field  $F$  has a cause, but that a cause of  $P$  in  $F$  is to be found within a range of factors that is restricted in some way. We have also found that different concepts of a cause are required for concomitant variation and for the other methods. The complaint that the phrase "uniformity of nature" cannot be given a precise or useful meaning, incidentally, has been rebutted by finding in exactly what sense our methods have to assume that nature is uniform.

**EMPLOYMENT OF THE METHODS.** Such assumptions are in fact regularly made, both in investigations within our already developed body of knowledge and in our primitive or commonsense ways of finding out about the world. In both these sorts of inquiry we act on the supposition that any changes that occur are caused; they do not "just happen." In a developed science, the causal knowledge that we already have can limit narrowly the range of possibly relevant causal factors. It can tell us, for this particular phenomenon, what kinds of cause to be on the lookout for, and how to exclude or hold constant some possibly relevant factors while we study the effects of others.

In more elementary discoveries, we restrict the range of possibly relevant factors mainly by the expectation that the cause of any effect will be somewhere in the near spatiotemporal neighborhood of the effect. The possible

causes, then, will be features that occur variably within the field in question in the neighborhood of cases where the effect either occurs, or might have occurred, but does not.

**USE OF METHOD OF DIFFERENCES.** As an example of the above, singular causal sequences are detected primarily by the use of variants of the method of difference. Antoine-Henri Becquerel discovered that the radium he carried in a bottle in his pocket was the cause of a burn by noticing that the presence of the radium was the only possible relevant difference between the time when the inflammation developed and the earlier time when it did not, or between the part of his body where the inflammation appeared and the other parts.

Similar considerations tell us that a certain liquid turned this litmus paper red: The paper became red just after it was dipped in the liquid, and nothing else likely to be relevant happened just then. The situations before and after a change constitute our negative and positive instances respectively, and we may well be fairly confident that this is the only possibly relevant factor that has changed. We do not and need not draw up a list of possible causes, but by merely being on the lookout for other changes we can ensure that what would constitute a large number of possible causes (identified as such by their being in the spatiotemporal neighborhood) are the same in  $I_1$  as in  $N_1$ .

Repeating the sequence—for example, dipping another similar piece of litmus paper into the liquid—confirms the view that the liquid caused the change of color. But it is not that in this case we are using the method of agreement; the repetition merely makes it less likely that any other change occurred to cause the change of color simultaneously with each of the two dippings, and this confirms our belief that the instances are what the use of the method of difference would require.

Since, in general, it will not be plausible to make an assumption more rigorous than one of kind (8), the conclusion thus established will only be that this individual sequence is an exemplification of a *gappy* causal law, of the form that (*A... or...*) is necessary and sufficient for *P* in *F*. But this is exactly what our ordinary singular causal statements mean: To say that this caused that says only that this was needed, perhaps in conjunction with other factors that were present, to produce the effect, and it leaves it open that other antecedents altogether (not present in this case) might produce the same effect.

General causal statements, such as “The eating of sweets causes dental decay,” are to be interpreted similarly

as asserting gappy causal laws. Anyone who says this would admit that the eating of sweets has this effect only in the presence of certain other conditions or in the absence of certain counteracting causes, and he would admit that things other than the eating of sweets might produce tooth decay. And such a gappy causal law can be established by the use of method 8.2, or the method of concomitant variation, or by statistical methods that can be understood as elaborations of these. Such general causal statements are, however, to be understood as asserting gappy causal laws, not mere statistical correlations: Anyone who uses such a statement is claiming that in principle the gaps could be filled in.

**USE IN DISCOVERING EFFECTS.** The use of the above methods is not confined to cases where we begin with a question of the form “What is the cause of so-and-so?” We may just as well begin by asking “What is the effect of so-and-so?”—for example, “What is the effect of applying a high voltage to electrodes in a vacuum tube?” But we are justified in claiming that what is observed to happen is an effect of this only if the requirements for the appropriate variant of the method of difference are fulfilled.

**USE OF METHOD OF AGREEMENT.** The simpler variants of the method of agreement can be used to establish a causal conclusion only in a case in which our previous knowledge narrowly restricts the possible causes and justifies the belief that they will operate singly. For example, if the character of a disease is such as to indicate that it is of bacterial origin, then the microorganism responsible may be identified through the discovery that only one species of microorganism not already known to be innocent is present in a number of cases of the disease. Otherwise, the observation of what seems to be the only common factor in a number of cases of a phenomenon can be used only very tentatively, to suggest a hypothesis that will need to be tested in some other way.

Where, however, we have a very large number of extremely diverse instances of some effect, and only one factor seems to be present in all of them, we may reason by what is in effect an approximation to method 8.12. The diverse instances cover at least a large selection of all the possible combinations of possibly relevant factors and their negations. Therefore it is probable that no condition not covered by the formula (*A or...*) is necessary, and hence, if there is a necessary and sufficient condition, (*A or...*) is such, and hence *A* itself is a sufficient condition of the phenomenon.

Similarly, by an approximation to 8.14, we may reason that the one possibly relevant factor that is found to be absent in a large number of very diverse negative instances is probably a necessary condition of the phenomenon (that is, that its negation is a counteracting cause).

**USE OF METHOD OF CONCOMITANT VARIATION.** The method of concomitant variation, with statistical procedures that can be considered as elaborations of it, is used in a great many experimental investigations in which one possibly relevant factor is varied (everything else that might be relevant being held constant) to see whether there *is* a causal connection between that one factor and the effect in question. (Of course, what we regard as a single experiment may involve the variation of several factors, but still in such a way that the results will show the effects of varying each factor by itself: Such an experiment is merely a combination of several applications of concomitant variation.)

**FURTHER USES.** The “controlled experiment,” in which a control case or control group is compared with an experimental case or experimental group, is again an application of the method of difference (or perhaps the method of residues, if we use the control case, along with already known laws, to tell us what would have happened in the experimental case if the supposed cause had not been introduced.)

An important use of these methods is in the progressive location of a cause. If we take “the drinking of wine” as a single possible cause, then an application of 8.2 may show that the drinking of wine causes intoxication: That is, this factor is *a* necessary element in *a* sufficient condition for this result. But we may then analyze this possible cause further and discover that several factors are included in this one item that we have named “the drinking of wine,” and further experiments may show that only one of these factors was really necessary: The necessary element will then be more precisely specified. But the fact that this is always possible leaves it true that in relation to the earlier degree of analysis of factors, the drinking of wine was a necessary element in a sufficient condition, and the discovery of this (admittedly crude) causal law is correct as far as it goes and is an essential step on the way to the more accurate law that is based on a finer analysis of factors.

### CRITICISM OF THE METHODS

The sort of example presented above helps to rebut one stock criticism of these methods, which is that they take

for granted what is really the most important part of the procedure, namely, the discovery and analysis of factors. Any given application of one of these methods does presuppose some identification of possible causes, but it will not be completely vitiated by the fact that a finer analysis of factors is possible. Besides, the use of the methods themselves (particularly to discover singular causal sequences and hence the dispositional properties of particular things) is part of the procedure by which factors are further distinguished and classified. Also, the assumptions used, especially with regard to the range of possible causes allowed, are corrigible, and in conjunction with the methods they are self-correcting. A mistaken assumption is likely to lead, along with the observations, to contradictory conclusions, and when this happens we are forced to modify the assumption, in particular, to look further afield than we did at first for possibly relevant factors.

A fundamental and widely accepted objection to the claim that these methods form an important part of scientific method is that science is not concerned, or not much concerned, with causal relations in the sense in which these methods can discover them. It may be conceded that the formulation and confirmation of hypotheses and theories of the kind that constitute the greater part of a science such as physics is a scientific procedure quite different from the actual use of these methods. Even the discovery of a law of functional dependence is, as was noted, a task beyond what is achieved by our method of concomitant variation. It may also be conceded that many sciences are concerned largely with the simple discovery of new items and the tracing of processes rather than with causal relationships. Further, it was noted that these methods logically *cannot* be the whole of scientific procedure, since they require assumptions which they themselves cannot support.

In reply to this objection, however, it can be stressed, first, that a great deal of commonsense everyday knowledge, and also a great deal of knowledge in the more empirical sciences, is of causal relations of this sort, partly of singular causal sequences and partly of laws, especially of the incomplete or gappy form at which these methods characteristically arrive.

Second, it is largely such empirical causal relations that are explained by, and that support, the deeper theories and hypotheses of a developed science. But if they are to be used thus, they must be established independently.

Third, although descriptions of the eliminative methods of induction have often been associated with a kind of ground-floor empiricism that takes knowledge to

be wholly concerned with empirical relations between directly observable things, qualities, and processes, the methods themselves are not tied to this doctrine but can establish causal relations between entities that are indirectly observed. For example, as long as there is any way, direct or indirect, of determining when a magnetic field is present and when there is an electric current in a wire, the methods can establish the fact that such a current will produce a magnetic field.

Finally, even where such causal relations are not the main object of inquiry, in investigation we constantly make use of causal relations, especially of singular causal sequences. In measuring, say, a voltage, we are assuming that it was the connecting of the meter across those terminals that caused this deflection of its needle, and the precautions that ensure that this is really so are to be explained in terms of our methods.

In fact, these methods are constantly used, explicitly or implicitly, both to suggest causal hypotheses and to confirm them. One should not, of course, expect any methods of empirical inquiry to establish conclusions beyond all possibility of doubt or all need of refinement, but in using these methods we can frequently say at least this: We have reason to suppose that for an event of this kind in this field there is some cause, and if the cause is not such-and-such, we cannot see what else the cause might be.

## Bibliography

### WORKS ON INDUCTION

The classical study of eliminative induction remains that of J. S. Mill, *A System of Logic* (London, 1843), Book III, Chs. 8–10. Mill acknowledges that his study owes much to John Herschell, *A Preliminary Discourse on the Study of Natural Philosophy* (London: Longman, Rees, Orme, Brown, and Green, 1831), Part II, Ch. 6, and both are fundamentally indebted to Francis Bacon, *Novum Organum* (London: Joannem Billium, 1620), Book II. Since Mill, the literature has become extensive, but mostly in textbooks rather than in original works on logic or philosophy. There have been many worthwhile treatments of eliminative induction that are far above the textbook level—notably those of John Venn, *Empirical Logic* (London, 1889), Ch. 17; Christoff von Sigwart, *Logic*, 2nd ed. (Freiburg, 1893), translated by Helen Dendy as *Logic* (London: Sonnenschein, 1895), Vol. II, Part II, Ch. 5; and H. W. B. Joseph, *An Introduction to Logic* (Oxford: Clarendon Press, 1906), Ch. 20. But there are only a small number of writers who, either by criticizing Mill or developing his account, have added something new and

substantial to either the logic or the philosophy of eliminative induction.

### CRITICISMS OF MILL'S METHODS

Mill's most important critics are William Whewell, *The Philosophy of Discovery* (London, 1860), Ch. 22; W. S. Jevons, *The Principles of Science* (London: Macmillan, 1874), Chs. 11, 19, and 23; F. H. Bradley, *The Principles of Logic* (London: K. Paul, Trench, 1883), Book II, Part II, Ch. 3; and M. R. Cohen and Ernest Nagel, *An Introduction to Logic and Scientific Method* (New York: Harcourt Brace, 1934), Ch. 13.

### ELABORATIONS ON MILL'S METHODS

The main writers who have tried to develop Mill's ideas on the logical side are W. E. Johnson, *Logic* (Cambridge, U.K., 1924), Part II, Ch. 10; C. D. Broad, "The Principles of Demonstrative Induction" in *Mind* 39 (1930): 302–317 and 426–439; and G. H. von Wright, *A Treatise on Induction and Probability* (London: Routledge and Paul, 1951). Broad, following Johnson, undertakes a demonstrative reconstruction of Mill's methods and tries to extend eliminative methods to reasonings that terminate in quantitative laws. Von Wright's is the most thorough treatment so far published and studies the conditions under which "complete elimination" can be achieved even with what are here called the "less rigorous" kinds of assumptions. His account, however, seems somewhat unclear.

### FURTHER STUDIES

The only major addition to the pure philosophy of induction is that of J. M. Keynes, *A Treatise on Probability* (London: Macmillan, 1921), Part III. Three more recent books that contain some discussion of it are J. O. Wisdom, *Foundations of Inference in Natural Science* (London: Methuen, 1952), Ch. 11; S. F. Barker, *Induction and Hypothesis* (Ithaca, NY: Cornell University Press, 1957), Ch. 3; and J. P. Day, *Inductive Probability* (London: Routledge and Paul, 1961), Sec. 5.

*J. L. Mackie (1967)*

## MILTON, JOHN

(1608–1674)

John Milton, the English poet, author, and political writer, was born in London, the son of a prosperous scrivener. He was educated at St. Paul's School in London and Christ's College, Cambridge. After receiving an M.A. in 1632, he spent six years in study at his father's estate in Horton. In 1638 and 1639 he traveled to Italy, where he met Galileo Galilei, and on his return to London he found employment as a tutor. He wrote five pamphlets (1641–1642) attacking episcopacy, and his unhappy marriage in 1642 lent intensity to his subsequent tracts on divorce. In 1644 he published the tract *Of Education*, as well as *Areopagitica*, his famous attack on censorship of the press. His pamphlet justifying regicide, *Tenure of*

*Kings and Magistrates* (1649), probably brought him the post of secretary for foreign tongues to the Council of State. He wrote several defenses of the revolutionary government, but after 1652 total blindness forced him to withdraw gradually from public life. He turned to the completion of his theological treatise, *De Doctrina Christiana*, and his *History of Britain* and to the fulfillment of his poetic ambitions. Despite a brief return to public controversy in 1659 and 1660, Milton was treated leniently by the Restoration government. His epic, *Paradise Lost*, was published in 1667; *Samson Agonistes* and *Paradise Regained* appeared together, in one volume, in 1671. He died in 1674, survived by his third wife.

### APPROACH AND METHOD

Milton was essentially a religious and ethical thinker, and his views are a striking blend of Christian humanism and Puritanism. The fullest statement of his position is *De Doctrina Christiana*, which was complete in all but certain details by 1660.

Milton believed that the Bible is divine revelation, plain and perspicuous in all things necessary to salvation. In matters of religion Scripture is the only outward rule or authority, and conscience, illuminated by the spirit of God, the only guide within. This scrupulous biblicism, however, is linked (as in Socinianism) with a strong emphasis on reason. Conscience, even when illuminated by the spirit, operates in rational terms rather than through mystical insight, so that "right reason" becomes the guide to Scripture. At the heart of this view, authorizing yet limiting the role of reason, is the doctrine that Scripture is an accommodation of God's will to the limited understanding of man. God has made in the Bible as full a revelation of himself as man is capable of receiving, and the safest approach is thus to form in the mind "such a conception of God, as shall correspond with his own delineation and representation of himself." This view eliminates speculations of a transcendental kind, reserving an area of mystery into which reason may not trespass; at the same time it encourages reason to assimilate biblical revelation to the categories of ethics. Thus, the theological treatise, like *Paradise Lost*, is a theodicy; its aim is to discover a view of God that is both worthy of him and consistent with revelation.

### THEOLOGY

Milton's aim led him to some unorthodox conclusions, the most striking of which is his rejection of the doctrine of the Trinity. Embracing a loosely Arian position, he insisted on the unity of God and the consequent subordi-

nation of the Son and the Holy Spirit to the Father. The Son is the first of the creatures, and although he is the perfect image of the Father and even made of the same substance, he is not of one essence with the Father. The Spirit, a rather supernumerary figure, was created at a later date than the Son. Milton maintained that the doctrine of the Trinity is a purely manmade mystery, with no scriptural foundation; it defies logic and degrades our conception of deity.

There was a second deviation from orthodoxy in the direction of monism. Milton rejected the Augustinian doctrine of the creation of the world *ex nihilo* and presented a theory of creation *de Deo*. Drawing support from both Scripture and reason, he argued that the universe was made out of the substance of God. This view, he claimed, is not only more logical than the alternative position, but in its assertion of the goodness of matter it underlines more emphatically the benevolence of the creator. The same antiascetic impulse is present in Milton's theory of body and soul; he argued that the higher comprehends the lower, that spirit contains matter, and that the body should thus be seen not as the prison house of the soul but as integral to it: "The whole man is soul, and the soul man." From this conclusion two corollaries proceed: first, the human soul is not created immediately by God but is propagated from father to son in a natural order; second, the whole man dies, body and soul, and does not live again until the end of time. Milton's view of spirit and matter probably encouraged both his rejection of traditional Eucharistic theory and his radical endorsement of divorce and polygamy.

**FREE WILL.** The doctrines we have examined, which are departures from the main traditions of Christianity, were designed to avoid dualism and to make theology conform to the canons of logical thought. A second group of doctrines emerged as a defense of free will against Calvinism. Milton rejected the orthodox Calvinist view of predestination and reduced the decree of predestination to a general offer of salvation to all men who are willing to believe. Other Arminian views reinforced his conviction that man is free to pursue or refuse salvation. Milton wished to show that regeneration is a matter neither of faith nor of works but of works of faith. Faith, it is true, is a gift of God, but every man is given sufficient grace to put a saving faith within his reach. Finally, the object of a saving faith is God the Father rather than Christ, so that such a faith is possible beyond the bounds of the Christian religion.

## ETHICS

The relation of the individual to the community absorbed Milton's attention during two decades of public controversy (1640–1660). His tracts, written in response to the disturbing events of the period, received force and direction from his lasting concern with liberty. Reason is “but choosing”; it is the power of ethical action, and man must therefore be free to choose between good and evil. Only by knowing evil and rejecting it can one become virtuous, for, as Milton remarked in *Areopagitica*, “That which purifies us is trial, and trial is by what is contrary.” Prescriptive morality, enforced by church or state, prevents both the real understanding of truths already known and the discovery of new truths.

Milton defended the autonomy of reason by appealing from manmade authorities—positive law, canon law, custom, or tradition—to the law of nature. The work of John Selden probably encouraged him to develop a distinction between the primary law of nature, given to Adam at the creation, and the secondary law, the imperfect remnants of the primary law in fallen man. Secondary law allows for the “hardness of heart” that was introduced by the Fall and thus prescribes for such aspects of man's fallen state as war, servitude, divorce, and private property. In *De Doctrina Christiana*, however, Milton stressed the importance of the primary or unwritten law of nature that was “given originally to Adam, and of which a certain remnant, or imperfect illumination, still dwells in the hearts of all mankind; which, in the regenerate, under the influence of the Holy Spirit, is daily tending towards a renewal of its primitive brightness.” This law teaches whatever is intrinsically good and agreeable to right reason, and in making it the final authority, Milton gave his ethic a religious orientation.

Thus, Milton's ethical position was that of the Christian humanist. Grace, he believed, comes to perfect nature, not to destroy it; by means of grace reason is illuminated and natural virtue sanctified. In this emphasis he resembled the Cambridge Platonists, writers like Benjamin Whichcote, John Smith, and Nathanael Culverwel, who sought to unify man's natural and religious experience by insisting that reason is “the candle of the Lord.” Milton also resembled these philosophers in his habit of drawing upon Platonic writings, particularly on Plato's myths, in order to enrich his treatment of reason and the passions. Although his stress on the Bible prevented classical philosophy from making a direct contribution to his theology, Platonism nonetheless played a major and continuous part in shaping his ethical idealism.

The influence of Puritanism, as well as of humanism, led Milton to stress the importance of liberty. Believers are a “royal priesthood,” and those who force the conscience of the individual are guilty of forcing the spirit of God. Central to Milton's conception of Christian liberty is the distinction between the Mosaic law, a law of bondage that extorts servile obedience through fear, and the Gospel, which offers a free, elective, and spiritual service based on man's filial relation to God. Spiritual regeneration, moreover, brings about a renewal of man's natural powers; the understanding is restored in large measure to its primitive clearness, the will to its primitive liberty. This strong emphasis on inner law led Milton to the antinomian view that Christ, by his life and death, abrogated the whole Mosaic law, the moral parts as well as the judicial and ceremonial parts. The sum of the law—love God and love your neighbor—remains and must be fulfilled by following the spirit, or the “internal scripture” (*De Doctrina Christiana*, I, xxvii). At this point, in spite of a continuing emphasis on reason, Milton had moved toward a position similar to the Quaker doctrine of inner light.

## CHURCH AND STATE

Despite his early support of Presbyterianism, Milton soon came to believe that “*New Presbyter* is but *Old Priest* writ large.” He defended the growth of religious sects on the ground that God requires unity of spirit rather than unity of doctrine, and he denied both the claim of the church to exercise secular power and that of the state to wield ecclesiastical power. His final view was that a particular church is a purely voluntary association of believers. Ministers should be elected by their congregations and supported by free offerings, and no ceremonial observances, such as the Sabbath, should be made obligatory. Despite his separation of the powers of church and state, however, Milton could not follow his more radical contemporaries in divorcing civil good from the good of religion. Although he denied the magistrate “compulsive” powers in matters of religion, he left him the “defensive” function of protecting Protestant Christianity from the threat of open “popery and idolatry.”

Milton's view of the state varied in accordance with the changing conditions in which he was called upon to defend the revolutionary party. A basic line of his argument founds the state upon a social contract. Men are born free, but the effects of the Fall cause them to agree to a common league to bind one another from mutual injury. The people are thus the sovereign power in the state and have the right to revoke the power that they

have delegated. When it became apparent that the Puritan party represented a small part of the nation, Milton resorted to a further argument that was not entirely consistent with the social contract theory. The revolutionary party, he maintained, was guided by providence and consisted of those most worthy to rule and to interpret the good of the people. The minority must force the majority to be free.

## POETRY

The themes and preoccupations of Milton's prose gain in power when expressed in the "more simple, sensuous, and passionate" language of poetry. All the major poems center on the theme of temptation and move toward a clarification of true heroism. Temptation works through passion, in its simplest form through sensuality and anger but more subtly through specious reasoning and the lure of evil means to good ends. The definition of true heroism involves the exposure of such false forms as the romantic sensuality of Comus in the early "Masque" (1634) or Satan's courage of despair in the late epics. *Paradise Lost*, which was written to justify God's ways to man by dramatizing man's freedom and responsibility, ends with Adam setting out to imitate the spiritual heroism of the Son of God—revealed to him in a vision—and thus to achieve a "paradise within" that will be "happier far" than the outward paradise he has lost. Samson, in *Samson Agonistes*, also achieves a victory over himself through suffering and discovers that freedom is enjoyed only in the service of God. *Paradise Regained*, which has as its subject the temptation of Jesus in the wilderness, presents Milton's final and most complete study of heroism. Avoiding the temptations to distrust and presumption, the Son rejects Satan's offers of worldly power and authority and realizes the spiritual sense in which he is Messiah.

## ARTS AND SCIENCES

In his literary theory Milton emphasized the importance of genres and of decorum and urged the power of literature to create moral order in the individual and the society. (See his preface to Book II of *The Reason of Church Government*, the preface to *Samson Agonistes*, and the invocations to Books I, III, and IX of *Paradise Lost*.) His view of education (*Of Education*) was humanistic in its stress on languages and classical texts, its dislike of scholasticism, and its ethical aim. He showed no deep interest in the new science, and he used the traditional science in his poetry because it was for him a better source of metaphor. As a historian he had a critical sense of the value of evidence, but his view of history moved

from millenarian optimism to the pessimism that informs the survey of history in the last two books of *Paradise Lost*.

## Bibliography

### WORKS BY MILTON

The definitive edition of the text is *The Works of John Milton*, edited by Frank Allen Patterson et al., 18 vols. (New York: Columbia University Press, 1931–1938), with an index, 2 vols. (New York, 1940). A supplement to the Patterson edition, *A Variorum Commentary on the Poems of John Milton*, with Merritt Y. Hughes as the general editor, was also published by Columbia University Press (New York, 1970).

There are editions of the poetry and selected prose by Frank Allen Patterson, *The Student's Milton* (New York: F. S. Crofts, 1930; rev. ed., 1933); Merritt Y. Hughes, *Complete Poems and Major Prose* (New York: Odyssey Press, 1957); and others. Editions of the poetry include those by James Holly Hanford, *Poems* (New York, 1937; 2nd ed., 1953); Harris Francis Fletcher, *Complete Poetical Works* (Boston, 1941); and Helen Darbishire, *Poetical Works*, 2 vols. (Oxford, 1952–1955).

Scholarly introductions provide continuous commentary on the prose in the closely annotated *Complete Prose Works*, edited by Donald M. Wolfe et al. (New Haven, CT: Yale University Press, 1953–1982), 8 volumes.

### WORKS ON MILTON

#### General Criticism

Douglas Bush provides a penetrating review of Milton's life and works in *English Literature in the Earlier Seventeenth Century* (Oxford: Clarendon Press, 1945; rev. ed., 1962); a survey of the scholarship is found in James Holly Hanford, *A Milton Handbook*, 4th ed. (New York: F. S. Crofts, 1946). The standard biography is still David Masson's *The Life of John Milton*, 6 vols. (London: Macmillan, 1859–1880; rev. ed., with index, 1881–1896).

#### Milton's Thought

Pioneer work is found in Denis Saurat's stimulating if erratic *Milton: Man and Thinker* (London: Dent, 1925; rev. ed., 1944) and in the more literary *Milton* (London, 1930) by E. M. W. Tillyard. G. N. Conklin considers theological method in *Biblical Criticism and Heresy in Milton* (New York: King's Crown Press, 1949), and the growth and significance of Milton's theology are examined authoritatively by Maurice W. Kelley in *This Great Argument* (Princeton, NJ: Princeton University Press, 1941). On Milton's political and ethical views, see A. S. P. Woodhouse, "Milton, Puritanism and Liberty," in *University of Toronto Quarterly* 4 (1934–1935): 483–513; William Haller, *The Rise of Puritanism* (New York: Columbia University Press, 1938) and *Liberty and Reformation in the Puritan Revolution* (New York: Columbia

University Press, 1955); Arthur Barker, *Milton and the Puritan Dilemma, 1641–1660* (Toronto: University of Toronto Press, 1942; reprinted, 1955); Michael Fixler, *Milton and the Kingdoms of God* (London: Faber and Faber, 1964); Ernest Sirluck, “Milton’s Political Thought: The First Cycle,” in *Modern Philology* 61 (1964): 209–224.

Other aspects of Milton’s thought are covered in Kester Svendsen, *Milton and Science* (Cambridge, MA: Harvard University Press, 1956); Howard Schultz, *Milton and Forbidden Knowledge* (New York: Modern Language Association of America, 1955); Walter C. Curry, *Milton’s Ontology, Cosmogony and Physics* (Lexington: University of Kentucky Press, 1957); and Irene Samuel, *Plato and Milton* (Ithaca, NY: Cornell University Press, 1947). Further criticism is listed in a selective bibliography by Douglas Bush, *op. cit.*; in the bibliographies by David H. Stevens, *A Reference Guide to Milton, from 1800 to the Present Day* (Chicago: University of Chicago Press, 1930); Harris Francis Fletcher, *Contributions to a Milton Bibliography, 1800–1930* (Urbana: University of Illinois, 1931); and Calvin Huckabay, *John Milton: A Bibliographical Supplement, 1929–1957* (Pittsburgh: Duquesne University Press, 1960); and the annual bibliographies of *Studies in Philology* and *PMLA*.

## MIMESIS

Mimesis has been a cardinal concept for those traditions of aesthetics, from antiquity to the present, that focus on the status and value of artistic representation. The semantics of the Greek term *mimēsis* cover much more than simple imitation; its senses include resemblance, dramatic impersonation, and other species of correspondence or likeness. The idea of mimesis came to designate the relationship between certain art forms (poetry, dance, music, painting/sculpture) and the aspects of reality they are capable of depicting or evoking. Although some strands of mimeticist thinking appeal to standards of verisimilitude and mirroring, it is mistaken to reduce all models of mimesis to a single canon of realism.

Plato’s highly influential approach to mimesis is less straightforward than usually claimed. From *Cratylus* to *Laws*, he applies the language of mimesis to numerous relationships of ontological and/or semantic dependence (even, in *Timaeus*, e.g., 39e, the whole material universe’s dependence on a divine prototype). Mimetic entities match, but never reproduce, their exemplars; the relationship can be construed as “qualitative,” not “mathematical” (*Cratylus* 432). In representational art, moreover, those exemplars may be (partially) imaginative/fictive: witness, for example, the idealized painting that furnishes a metaphor for philosophy at *Republic* 472d. When, in *Republic* 10, Socrates notoriously critiques the

mirror-like limitations of mimetic poetry and painting, locating artistic images at two removes from “the truth,” his argument does not convict all mimesis of worthlessness but provocatively challenges lovers of art to identify a moral justification that transcends pleasure at merely simulated appearances (and the emotions they can excite). As *Sophist* 235d–6c, distinguishing *eikastic* (objective) from *phantastic* (viewer-dependent) mimesis, shows, Plato does not ascribe a uniform rationale to all artistic representation. At a psychological and cultural level, arguments such as *Republic* 392c–401a suggest that the impact of mimesis necessarily reflects the qualities of the supposed reality it projects.

Aristotle explicitly accepts that the contents of mimetic art, both musicopoetic and visual, can legitimately vary between the actual, the putative, and the ideal (*Poetics* 25). Regarding mimesis as an instinctual factor in the human need to model and understand the world, he embeds it in an anthropology of cognition that stretches from children’s play to philosophy (*Poetics* 4). He also appreciates the powerful emotional effects of mimetic works on their audiences, a point equally illustrated by the *Poetics* and by the treatment of music as mimetic (i.e., affectively expressive) in *Politics* 8.5; for him, the passions, when well induced, are a medium of ethical judgment. Furthermore, Aristotle has a dual-aspect conception of mimesis that allows him to distinguish—more than Plato had done—between internal (work-centered) and external (truth-related) criteria of mimetic value. The resulting aesthetics is, importantly, neither formalist nor moralist.

Hellenistic and later Greek philosophers continued to grapple with epistemological and ethical issues raised by mimesis. Especially notable is Neoplatonism’s ambivalent engagement with the concept; Plotinus, for instance, who discerned mimetic relationships hierarchically structuring all reality, disparaged much actual art yet allowed some artistic mimesis, *qua* creative intuition, to grasp the authentic forms of nature (*Enneads* 5.8.1). The legacy of this and other ancient versions of mimesis was revived in the Renaissance; it has remained a vital element in debates about the complex position of representational art between the poles of truth and fiction, realism, and imagination.

## MINAGAWA KIEN

(1734–1807)

Minagawa Kien, a Japanese Confucianist, painter, and writer, was born in Kyoto. At the age of twenty-eight, having established himself as a Confucianist, he became the official scholar for Lord Matsudaira Nobumine. His literary skill made him an outstanding figure in Kyoto circles; he had a following of three thousand. For a Confucianist his life was unusually dissipated. His era was a time of moral decline, but this was eventually checked by several edicts. The 1790 edict against “heterodox doctrines” affected Minagawa and he reformed his habits, though his ideas did not change.

Minagawa’s philosophical reputation has recently grown among Japanese philosophers because of his positivist approach to Confucian studies. He is considered an eclectic because he upheld neither the official Zhu Xi school of Neo-Confucianism nor the rival Wang Yang-ming school. Minagawa was analytic and positivist, which made him a kind of forerunner of Western philosophy in Japan. This assessment stems largely from two of Minagawa’s works, *Ekigaku kaibutsu* (The learning of the book of changes on the discovery of things) and *Meichū rokkan* (Six chapters on categories).

*Ekigaku kaibutsu* starts from the Chinese classic *I Ching*, the “Book of Changes” or “Book of Divination,” which despite its esoteric nature stimulated Minagawa and other Confucianists to make a study of celestial phenomena. *Ekigaku kaibutsu* clearly manifests his lifetime search for the nature of things. However, for him “things” are mainly human affairs seen from the ethicopolitical point of view, and their “discovery” or investigation is in relation to the ruling of the realm.

*Meichū rokkan* analyzes the origins of basic concepts or categories. Starting with words, Minagawa shows that they are abstract expressions of reality itself. He believes that we grasp reality objectively through its manifestation in words. This rather naive realist epistemology is an attempt to penetrate the nature of things without employing *ri*, Zhu Xi’s abstract “principle,” or the “innate knowledge” of Wang Yangming. Among Minagawa’s categories, significant ones are learning or science (*gaku*) and

wisdom (*tetsu*). Although he did not wholly grasp modern science or philosophy, he came very close.

Another topic of interest to Minagawa is the samurai class, which he criticizes in many of his writings. He hoped the samurai would survive as the intellectual and moral leaders of the ordinary people.

## MIND

See *Idealism; Mind-Body Problem; Other Minds; Personal Identity; Psychology; Reason; Thinking*

## MIND AND MENTAL STATES IN BUDDHIST PHILOSOPHY

A fundamental idea of all nonmaterialist Indian schools of philosophy, whether orthodox ones that follow the Vedas or heterodox ones such as Buddhist and Jaina that do not, is the cultivation of mind and mental states. Techniques of *yoga* in Hindu tradition aim at attaining a conscious state in which ordinary mental activities, such as perception and imagination, are suspended. Classical *yoga*, as expounded by Patanjali’s *Yogasutra* (Woods, 1927), is widely influential in the Hindu tradition.

### ORTHODOX AND HETERODOX SCHOOLS

In Buddhism, *citta*, *mano*, and *vinnana* are three of the main terms to do with mind and mental states. These terms are highly nuanced but are roughly translatable as heart, mind, and consciousness, respectively. These are best understood as processes, not substances, and none are permanent. The *Majjhima Nikaya* (Middle length sayings), *Digha Nikaya* (Long discourses), *Samyutta Nikaya* (Kindred sayings), and *Anguttara Nikaya* (Gradual say-

ings) are the basic four collections of *suttas* (discourses) expounding the early Buddhist position, and *Vissudhimagga* (The path of purity) is a salient text.

Indian schools of philosophy include three heterodox (*nastika*) schools, which do not accept the Vedas as divine revelation. These three schools (Carvaka, Jainism, and Buddhism), each in their different ways, put more emphasis upon experience than revelation. The three schools represent a continuum on metaphysical matters from most materialistic (Carvaka) to least materialistic (Buddhism). Jainism at midpoint asserts a material, adhesive soul that gets darkened with negative karmic particles due to wrong actions such that many *jivas* (souls) cannot retain their natural luminosity.

According to ancient Indian materialism (Carvaka school), perception is the basic *pramana* (valid means of knowing), and accordingly, matter is the only reality because it alone is perceived. Here the soul is understood as a living body with the quality of consciousness. But how could materialists show that consciousness does not exist independently of body? Orthodox schools as well as the other two heterodox schools, Jainism and Buddhism, found materialistic reductionism of the mental to the physical unconvincing.

**JAINISM.** Jainism is especially well known for two doctrines: the view that all judgments of non-omniscient beings need to be qualified—that is, the “somehow view” (*syadvada*); and non-injury to sentient beings—that this, the nonviolence view (*ahimsa*). According to Jainism, consciousness is the essence of the *jiva*, and human consciousness is limited so that ordinary judgments of nonomniscient beings must be qualified by *syat* (somehow) to express conditional knowing. Only one of the *Tirthankaras*, that is, those who cross over to liberation, have omniscience in regard to salvific knowledge. In Jainism the *jiva* is self-luminous and illuminates other things, filling out the body like a radiant, eternal light within it. Jains believe that the *jiva* can attain complete freedom (*kaivalya*). When the *jiva* is in a state of ignorance or bondage, it is because its vision is obscured due to karmic particles adhering to it. So, although Jainism has a spiritual, ethical outlook that aspires to personal self-transformation, its metaphysics of the soul holds that the soul is material, of the shape of the body, and is afflicted by karmic particles. When these are thrown out of the *jiva* due to penance or good works, the *jiva* can see clearly. Harming living beings is one thing that causes karmic particles to cloud the soul’s vision. In ethics, Jains think that the passions impeding liberation are anger, pride,

infatuation, and greed. These sorts of passions bind the *jiva* to matter. Since there is consciousness in all parts of the body, the soul is coextensive with the body. Potentially, all souls are equal since all have the capacity for liberation (*kaivalya*).

**BUDDHISM.** Another of the heterodox schools, Buddhism, holds that right concentration of mind through four stages is the way to *nirvana* (enlightenment). The first stage is on reasoning and investigation regarding the truths; here there is the joy of pure thinking. The second stage of concentration is unruffled meditation, freedom from reasoning, and the arising of the joy of tranquillity. The third stage of concentration is detachment from even the joy of tranquillity; here there is indifference even to such joy and a feeling of bodily ease. The fourth stage of concentration is detachment from this bodily ease: At the fourth *jhana* (level of consciousness in meditation), there is perfect equanimity and the attainment of nirvana. At this level the psychic powers (*abhinna*) are said to develop. Overall, *sila*, *samadhi*, and *panna* (morality, concentration, and wisdom, respectively) form the essentials of the eight-fold noble path in Buddhism (right view, right intention, right speech, right action, right livelihood, right mindfulness, right effort, right contemplation, right concentration). In Buddhism there is no permanent substance (*svabhava*) either in humankind or in deities, for experience shows that all things are impermanent, nonsubstantial, and unsatisfactory. The doctrine of *anatman* (no self, or nonsubstantiality) implies that there is no substance of a permanent, blissful, center of consciousness anywhere in the universe.

The doctrinal context of *jhana* is four noble truths: suffering, its arising, passing away, and the path to its passing away. The cessation of suffering occurs through meditation. The *ghanas* were instrumental in Buddha’s enlightenment in that *ghanas* prepare one for higher insights (*abhinna*), are associated with liberating wisdom (*panna*), and are the spiritual endowment of the fully liberated person (*tathagata*). *Jhanas* have their own internal dynamic, contributing to purification and liberation of mind. In developing *jhanic* insight, one focuses on experience, eliminates ignorance, and achieves wisdom. There are really two systems: tranquillity and insight. The development of serenity or tranquillity meditation (*samatha bhavana*) is one system; the other is the development of insight meditation (*vipassana bhavana*) is the other. The former is also called development of concentration (*samadhi bhavana*); the latter is also called the development of wisdom meditation (*panna bhavana*). The practice of serenity meditation aims at developing a calm,

concentrated, unified state of consciousness to experience peace and wisdom. Insight meditation requires development of *samadhi*, and serenity is useful for this too, so the two systems work together. *Jhana* belongs inherently to the serenity side. Translation of *jhana* is difficult, with absorption coming closest. *Jhanas* involve total absorption in the object.

## CONCEPTUAL STRUCTURES IN BUDDHISM

**ORALITY AND MENTALITY.** Oral tradition and group recitation of sutras marked the very beginnings of Buddhism of the Pali Nikayas (collections of *suttas* in different texts, e.g., *Majjhima Nikaya*). Despite the strong tradition of text, commentary, and subcommentary, Buddhism initially developed from oral tradition, as did Hinduism. In contrast with the European and North American preoccupation with journal articles and books as vehicles for intellectual debate, the power of the spoken word remains very much a part of Buddhism. This power of the spoken word can be seen, for example, in the Indo-Tibetan tradition of debate and the Sino-Japanese *kung-an* and *koan* traditions of perspectival shifts while becoming one with the *koan*.

It is clear that Buddhism did not begin with manuscripts. It is not a religion as in the monotheistic (Judeo-Christian-Islamic) tradition but developed out of a forest tradition of meditation in which monks stayed in orchards, deer parks, mango groves, and forests, periodically reciting the words of the Buddha aloud in group recitation. Eventually, councils and canons of texts emerged. It was not so at first, and it is reasonable to believe that the authority of individual experience is at the heart of early Buddhism rather than hierarchy and the authority of promulgated texts.

**MIRACLES OF INSTRUCTION, CONVERSION, AND MINDFULNESS.** An unrepeatable event, violation of law of nature, and any extraordinary event are senses of *miracle* ordinarily recognized in Anglo-American philosophy of religion as a starting point for discussion. In Buddhism, the miracle of instruction is the starting point. Traditionally, one has to come and sit down by the side of the teacher. Texts show that *dhamma* (truth, doctrine) teaching sometimes includes a miracle, where conversion occurs and miracle becomes part of the experience of a Buddhist practitioner.

Oral recitation makes of oneself a holy scripture as the embodiment of truth: Truth is not so much a property of abstract disembodied proposition as it is embod-

ied in the lives of those who practice Buddhism. Belief in the Buddha, the doctrine, and the Sangha (order of monks and nuns) is the recited *three refuges* formula for being Buddhist. Both confidence and knowledge are operative in Buddhism, both *belief in* and *belief that*. Buddhism did not emphasize authority of the guru or pundit but the authority of one's own experience, so there is no *blind faith*.

The baseless faith of the Brahmins is contrasted with the rational faith of the Buddhists. Brahmins are depicted as a string of blind people, each relying on the other but none of them seeing things as they really are. Buddhism is, by contrast, self-reliance, with several stages of confidence or faith. There is initial faith in coming to hear whether there is anything in the Buddhist doctrine, then there is path faith that is compatible with doubt and struggle, and then there is the achievement of a realized nonbacksliding faith; realized faith is the wisdom of knowing and seeing for oneself as things really are.

**MIND AND MORALITY.** By mind all things are made, all things are made by mind: Thus begins the *Dhammapada* (The path of purity), a popular Buddhist text. Morality is intimately connected with mentality on the Buddhist view, and intention is far more important than consequences in assessing *sila*, or morality. It would go too far to say that consequences are totally irrelevant to Buddhists: Following the first precept of harmlessness shows a concern with outcomes as well.

Buddhism defies categorization in Aristotelean, Utilitarian, and Kantian categories, not because of this conceptual confusion but because of its distinctive voice. Buddhism is most importantly about wisdom, not knowledge alone, and it is also about compassion, which is one of the ways to enlightenment. Although Mahayana Buddhism emphasized altruism and Theravada Buddhism had comparatively little to say about kindness and compassion, it is clear that there are Pali Canon texts that commend kindness, and value it as a means of attaining nirvana (Gombrich 1998). *Metta*, *karuna*, and *mudita* (loving kindness, compassion, and sympathy) are valued, ethically related mental states in even the earliest stratum of Buddhism, just as *priti* (joy) is a characteristic of Buddhist monks.

**MEDITATION AND CONFIRMATION OF PRE-EXISTING BELIEFS.** There is an epistemological basis for belief in propositions concerning *kamma* and *punabbhava* (rebirth; literally, "again becoming"). This emphasis on one's own experience extends even to epistemology,

where the *pramana* (valid means of knowing) of experience and, to a limited extent, inference based on experience, are emphasized instead of testimony, comparison, and divine revelation. The epistemological basis of belief in karma and rebirth is said in the texts and by modernist interpreters such as K. N. Jayatilleke (1963), K. N. Upadhyaya (1998), and D. J. Kalupahana (1992), to rest on meditational experience at the fourth *jhana*.

Some in Buddhism hold that knowing and seeing rebirth provides *empirical justification* for belief in karma and rebirth. These same thinkers believe that Buddhism has no metaphysics. However, first, it is dubious that memory, bodily continuity, or self-awareness will work as meaning conditions for the reidentification of the same person across lives. Second, metaphysics is not the same as speculation, and Buddhism can be antispeculative and still have metaphysical commitments to beliefs such as rebirth.

It is tempting to think of Buddhism as empiricism since it is described in the Pali texts as a *come and see* (*ehipassika*) doctrine, but while its claims may, in a weak sense, be experientially verifiable if true, they are not falsifiable if false. Hence they are not verifiable in a sufficiently robust sense to distinguish Buddhism from other path faiths and to count as *empirical verification*. What is at work, instead, is *experiential confirmation*. In addition, the mind and senses are not separated in Buddhism but are together the *six gateways* to knowledge so that there is no sharp cleavage between empiricism and rationalism, as there is in European and North American thought. All that can be had in Buddhism is experiential confirmation, as in the cases of other worldviews, such as that of Christianity. Psychological certainty is not identical to logical certainty. Experiential justification may be entirely convincing on a personal basis yet fall short of the objectivity involved in establishing the truth of observation, sentences that are testable and repeatable at will.

**CONTINUITY, PERSONAL IDENTITY, AND NAMARUPA.** The strength of a cord does not always depend on something running end to end, as in Buddhism where there is continuity of process but no speculative belief about a permanent substance underlying it all. In Buddhism, *vinna* (consciousness) develops (rather than descends) in the womb in the rebirth process across lives. There is no one term that provides a link between lives in early Buddhism. Perhaps *sankhara* (dispositions) comes closest.

A view that superficially looks like the Buddhist one is Hume's *phenomenalist* view of the self. Here, the self is

a bundle of perceptions. Hume famously says that all perceptions are distinct existences and that the mind never recognizes any necessary connections between these perceptions. However, one does not find exactly this view in Buddhism. Hume had a problem with combining the two assumptions about distinct existence of perceptions and no necessary connections, but early Buddhism's problem is not Hume's problem: To ask what keeps the perceptions of a person together in early Buddhism is to make what from an early Buddhist view is the unwarranted assumption of the distinct existence of perceptions.

*Namarupa* may be understood as that which appears (appearance or phenomenon) in its interrelationship with *nama*, or that which one uses to get a handle on an appearance (the concept). So *namarupa* is the reality formed by the unity of concept and phenomenon; it is conceptualized reality or the process of ordinary experiencing. Inadequate are "mind and body" or "name and form" as translations (Ross Rheat, in Potter: 1996 VII 45). It is evident that *namarupa* provides no evidence for substantialist mind-body dualism in early Buddhism. As Surendranath Dasgupta rightly observes (1922), matter and mind dualism and opposition are absent from Buddhism, Upanishads, and Samkhya schools of philosophy. Overall, Buddhism—which differs from Hume on the point of distinct existences—on the issue of *self*, is closer to Process philosophy than to either Humean empiricism or Cartesian rationalist dualism.

**"LIFE AFTER DEATH": ETERNAL LIFE AND ENDLESS LIFE.** In macro view the *punabbhava* rebirth realms, that is, humans, gods, animals, hungry ghosts, purgatory beings, and titans, may be viewed ontologically or psychologically. Viewed ontologically, in the Buddhist metaphysical view of the process of rebirth, the ordinary case is that one is reborn. There is also the extraordinary case of the *Tathagata* (the *thus gone* liberated one, e.g., Buddha Sakyamuni) who passes away in *parinibbana* (final enlightenment) having achieved *nibbana* (enlightenment) in this very life. Yet, no early Buddhist text gives a theory about what, if anything, happens after death in the case of the *Tathagata*. Afterlife views are regarded as speculative and discussing them not conducive to enlightenment. The antispeculative emphasis informs the Ten Speculative Questions (speculative questions that the Buddha would not commit to answering because they involve knowledge claims that go beyond experience) set aside by Buddha. The deathless (*amata*) may be viewed simply as the elimination of obsession, hate, and confusion in everyday life of the Buddhist practitioner.

Heaven (*devaloka*), the world of the gods, is simply another rebirth station. What is translated, *devaloka* is neither a permanent resting place nor a monotheist's beatific vision. From it some *devas* (the shining ones) may be reborn elsewhere, including as humans, before attaining final liberation.

The Buddhist goal is stopping the wheel of birth and death rather than attaining endless life. The emphasis is on attaining eternal life in the here and now by purifying ones heart and living well. In this conceptual scheme in which impermanence, nonsubstantiality, and suffering play key roles, the idea of striving after an immortality viewed as endless life would be not simply be unattainable but logically incoherent.

Accordingly, terms for mind and mental states in Buddhism are not terms for a permanent stuff or substance that is independent of conditions. Saying so does not deny continuity across lives. There is continuity without self-same substance. There is a stream of consciousness depending for its continuance on union of male and female, proper timing, and presence of *gandhabba* (cupid). Without these three conditions, there is no rebirth.

NIRVĀṆA. That Buddhist rebirth is not Hindu transmigration is evident from the anatta doctrine of Buddhism juxtaposed with the atman doctrine of Hinduism. At the level of meditation, there is considerable overlap of technique; however, such that an attempt to forge a complete disjunct between these two traditions will distort both history and practice. Buddha was born a Hindu and is considered by Hindus as an avatara of Vishnu. For polemical and practical purposes of building a Sangha, Buddhist texts routinely depict Buddhists triumphing over Jains and Brahmins in debate. So there is a distinctive Buddhist mentality such that Buddhism will never be rightly described as assimilable to Hinduism without remainder.

Early Buddhist texts are not perfectly consistent in the use of terms for the state of consciousness called enlightenment or being awake. However, a frequent finding is that *nibbana* (enlightenment) while alive is distinguished from *parinibbana* (final enlightenment) after death of a *Tathagata*. This distinction is subject to a range of textual emphases and resultant interpretations. The simplest, most clear way to draw the distinction is to say that enlightenment in life is the destruction of *raga*, *dosa*, and *moha* (obsession, hate, and confusion) in everyday life; that final enlightenment is death of one who has already been enlightened in life.

That dying is, but death is not, an experience in life is itself a conceptual truth. Hence, it is not logically possible to experience death and describe it, and there are no mental states to be ascribed to *the Tathagata after death*. Asked whether the Tathagata exists, does not exist, both, or neither, Buddha refused to assent to any of these. Buddha's silence shows that the matter of final enlightenment (*parinibbana*) is beyond experience.

## MIND-BODY PROBLEM

In Genesis 3:19, God tells Adam, “dust thou art, and unto dust thou shalt return,” reminding Adam that he was fashioned from the dust of the earth. Modern science tells us that the earth was formed from the dust of the sun and that we are composed of materials formed from star dust. We are, however, also possessed of mind: We can think, feel, and exercise our will—as did Eve when she ate the forbidden fruit of the tree of knowledge of good and evil. The ancient mind-body problem is how the mind or soul or spirit is united with the body. It has now been known for several centuries that our minds are related to our bodies via their relation to a certain bodily organ, the brain. The ancient problem led to the mind-brain problem: How are our minds related to our brains? Are they one thing or two? And if two, how are the two united? But the fundamental problem is: What is the place of mental phenomena in nature?

The doctrine that the soul is distinct from the body, existing prior to it and after bodily death, is found in the writings of Plato. (In the *Phaedo*, one argument of Socrates for immortality is that the soul is not made of parts, and so cannot come apart.) The Platonic idea of a soul independent of the body was embraced by Augustine of Hippo, a major figure in the development of the Christian doctrine of an immaterial, immortal soul. But as to how soul and body are united, Augustine could only marvel: “The manner in which spirits are united to bodies is altogether wonderful and transcends the understanding of men” (*On the City of God*, XXI, 10 Haldane 1994, p. 335).

René Descartes tried to lay the foundation for a science of nature according to which all bodies are located in a physical realm—a substance, *res extensa*, which pervades all of space—and all interactions among them are governed by mechanistic laws. But mind (*res cogitans*), he argued, lacks spatial extension (and even location at a spatial point) and so is not subject to the mechanistic laws of the physical realm, thus leaving the will free. Minds, moreover, are substances and so capable of existence independently of physical substance; thus, immortality of the mind is possible. Descartes argued that it is certain that he is his mind since doubt itself requires a doubter and thus a thinking subject, an *I*. And he argued that he is not his body since he can clearly and distinctly conceive of his existing without a body and that it is thus possible for him to exist disembodied.

He nevertheless also acknowledged in *Meditations on First Philosophy* (1641): “there is nothing nature teaches me more expressly, or more sensibly than that I have a body, which is ill disposed when I feel pain, which needs to eat and drink when I have feelings of hunger and thirst, etc. ... I am joined to it very closely and indeed so compounded and intermingled with my body, that I form, as it were, a single whole with it” (Cottingham et. al. 1985, p. 59). On his view, what unites body and mind is causation, from body to mind (as in perception), and from mind to body (as in action), with the pineal gland in the brain being the primary locus of such interaction. In correspondence with Descartes, Princess Elisabeth of Bohemia pressed the issue of how states of, or changes in, a substance not in space could causally affect states of, or changes in, something in space, and declared such causal interaction too incredible to believe. Descartes was never able to provide a satisfactory answer to her how-question, and in a candid moment remarked: “It does not seem to me that the human mind is capable of conceiving quite distinctly and at the same time both the distinction between mind and body, and their union” (Kenny 1970, p. 142).

Nicholas Malebranche denied mind-body causal interaction, maintaining that God is the only causal agent (Nadler 1999). Were a certain a type of brain state *B* and mental state *M* to co-occur, then that would be because God, who is continually engaged in acts of creation of the world, only causes an instance of one of them when he causes an instance of the other; *B* and *M* would thus co-occur are a result of being dual-effects of God’s acts of creation. This brand of *parallelism* is called *occasionalism*. Of course, if God is without spatial extension or location, then Elisabeth’s how-question will recur for God’s causal

interaction with the physical world. But it was thought that how-questions come to an end where the ways of God are concerned. Gottlieb Leibniz held a version of parallelism, *preestablished harmony*, according to which there is no causal interaction among substances, any regularities among them being the result of God's having actualized a world in which those regularities hold. And he held a kind of *idealism*, according to which all substances are monads, which have only states of perception and appetite (Sleigh 1999). Benedict (Baruch) Spinoza rejected Descartes's claim that the mind is a substance, arguing that only God or Nature (*Deus, sive Natura*) is capable of independent existence, and took all mentality and physicality to be different modes of God or Nature. On his view, a kind of pantheism, we are each finite modes of God or Nature, and our mind and body are identical modes though conceived of under two different kinds of attributes: bodily and mental (Garrett 1999). He thus held a kind of *dual-aspect theory*. Thomas Hobbes, an atheist, held a version of *materialism*, reminiscent of the ancient atomism of Democritus and Lucretius—Lucretius wrote of atoms moving in an infinite void—according to which all that exists is matter in motion (Gert 1999). He tried to show how mental processes are just mechanical brain processes, maintaining that thinking is just computation, thereby anticipating the computational view of mental processes prevalent in contemporary cognitive science.

There is something deeply commonsensical about Descartes's interactionism. It seems that bodily sensations such as aches, pains, itches, and tickles cause us to moan, wince, scratch, or laugh and do so by causing brain states that result in bodily movements. In deliberate action, we act on our desires, motives, and intentions in trying to carry out our purposes; and acting on them seems to involve their causing brain states, which cause our muscles to contract, and so our bodies to move, thereby affecting our environment. Perception of the environment seems to involve physical to mental causal transactions: What we perceive causes us to undergo a sense experience. Thus, when we see the scenes before our eyes, for instance, those scenes cause our visual experiences via their effects on our brains. Descartes's substance dualism, however, seems untenable.

But suppose that minds have not just temporal location but spatial location as well. (It is worthwhile pausing to note that according to the theory of general relativity, nothing can be in time without being in space.) Indeed, suppose that they are located where appropriately biologically functioning brains are but that they are nevertheless

neither identical with brains nor composed of material particles, being entirely devoid of matter and lacking physical properties such as mass or charge. The spatiotemporal coincidence of minds and brains would be no violation of the principle that two physical objects cannot occupy exactly the same place at exactly the same time since, by hypothesis, minds are not physical objects. They are entirely disembodied even though they are spatiotemporally coincident with appropriately functioning brains. They are a kind of fundamental energy field coincident with such brains. On this conception might minds causally contribute to the animation of their coincident brains and the brains in turn causally influence them?

This sort of view was a subject of debate in the late nineteenth and early twentieth century, as were debates in biology concerning whether there are wholly immaterial entelechies that are spatiotemporally coincident with organisms and which generate a vital force that causally contributes to guiding the development of organisms and sustaining their integrity (McLaughlin 2003). This view of mentality offers no conception of the nature of minds beyond the negative one that they lack any physical properties save spatiotemporal location and the positive one that they are the seat of mental capacities and abilities, the bearers of mental properties, and what undergo mental change. No hint is offered as to how they could be the seat of mental capacities or abilities—of how such abilities and capacities could be exercised within them. No hint is offered as to what their operations might be, as they are entirely devoid of material constituents. Such matters must be taken as primitive; such how-questions are unanswerable.

Many philosophers have argued that to have a mind is not to bear a relation to an object (physical or otherwise) that is the mind but, rather, to have certain capacities and abilities, such as the capacity to think and to feel and the ability to will. We ourselves have these capacities and abilities. We ourselves are the bearers of mental properties, undergo mental events, and engage in mental activity. Moreover, we are embodied. It does not follow that we are identical with our bodies or some part of them such as our brains. A clay statue may fail to be identical with the lump of clay with which it is spatially coincident. They may fail to be identical because they have different temporal properties (perhaps the lump existed before being shaped into a statue) and because they have different modal properties (the lump can survive being squashed while the statue cannot). Rather, the lump may materially constitute the statue (Pea 1997). On a four-dimensionalist conception of objects, however, the lump

and statue are space-time worms that have spatiotemporal segments that are identical (Sider 2001). Perhaps we are materially constituted by our bodies (or brains) but fail to be identical with them since they, unlike us, lack mental properties. They may also have different temporal properties from us. If we could exist in a disembodied form after the death and disintegration of our bodies and their organs, then, of course, we are not identical with our bodies or brains.

But it is also true that we are not identical with our bodies or brains if they can continue to exist after we have ceased to exist. We may cease to exist at brain death; but at brain death, the brain still exists. Albert Einstein's brain was removed from his skull shortly after his death with the hope that it would yield insight into his prodigious intelligence. But if he ceased to exist upon the death of his brain, then he was not his brain; and it was not he who was removed from the skull of his corpse. Einstein with his famous equation  $E=mc^2$ , taught us that mass and energy are interconvertible. (Some contemporary New Age Spiritualists would tell us that Einstein's unique energy was released from the matter of his brain upon the expiration of his body, and so that he continues on decoupled from any body. Why any energy released would be Einstein is left entirely obscure, however; and the question of how his mentality was linked to his brain while it was carrying out its normal biological functions remains unanswered. Suffice it to note here that the study of matter-energy in space-time is the subject of physics. We will return to physics shortly.)

Our biologically functioning brains serve somehow as the basis of our capacities to think and to feel and of our volition. Another topic of debate in the late nineteenth and early twentieth centuries was whether, despite the nonexistence of any immaterial object that is the mind, the brain serves as only the causal basis of mental capacities and abilities. On this conception, when we exercise our mental capacities and abilities, mental events (and states) occur within our brains. But they are not identical with occurrences of any kinds of nonmental brain events such as physiological ones; and, indeed, mental events are linked to brain occurrences of other kinds only spatiotemporally and causally: They may accompany them and be causes or effects of them. Since, on this conception, mental events occur within the brain, it might be claimed that they thereby count as physical since the brain is a physical object. But that seems merely a verbal issue. The dualist will claim the important point is that types of mental events are not identical with any other types of brains events and that the only (relevant)

relations that token mental events bear to tokens of other kinds of brain events are spatiotemporal and causal. The chief concern raised about this view was whether mental events exert any causal influence on other brain events.

Ewald Herring, in his 1870 lecture at the Imperial Academy of Sciences in Vienna, declared that physiologists should make "the unbroken causative continuity of all material processes an axiom of [their] system of investigation" (Butler 1910, pp. 64–65). He took this position on the grounds that, on the evidence, there seem to be no *gaps* in the physiological processes in the brain to be filled by mental events. The relationship between mental and physiological events, he maintained, should be left as a question for philosophy; brain physiologists can safely bracket it. The fact that there seem to be no gaps in physiological causal chains for mental events to occupy led Thomas Huxley (1874) to maintain that we (and other animals) are *conscious automata*: conscious events accompany certain physiological brain events as dual effects of other physiological events but are themselves causally inert. Trained as a medical doctor, William James (1890) appropriated the term *epiphenomena*, a medical term for symptoms of diseases, for mental phenomena that while caused, lack causal efficacy. James Ward (1903) coined the term *epiphenomenalism* for the view that mental phenomena have no causal effects. The claim that conscious phenomena are epiphenomena is, however, deeply perplexing. If they are, then our belief that we are in pain is never caused by our feeling of pain. And our experience of control over some of our bodily movements cannot give rise to our belief that we are in control of them, for that, too, would require mental causation.

During this period concern was also raised about whether mental causation would violate the law of conservation of energy. (Leibniz had argued earlier that Descartes was committed to minds affecting the motion of material particles in the pineal gland in violation of the conservation laws of momentum and kinetic energy; his mechanics, however, required contact forces, and was eclipsed by Isaac Newton's mechanics, which rejected that requirement [Woolhouse 1985, Papireau 2001].) One response made to the concern about conservation of energy is that causation may very well not require energy transfer; it does not, for instance, on a regularity theory of causation, according to which causation is subsumption under a law of nature, or on a conditional theory of causation, according to which one event causes another if, had the first not occurred, the second would not have occurred either (Broad 1925, ch. III).

Another point made in response was that the conservation of energy principle is silent about the causes of motion, stating only that energy must be conserved within the total system (Broad 1925, ch. III). (Given general relativity, it is mass-energy that is conserved within the total system.) Unlike on Descartes's conception of the mental, on the conception under consideration, mental events occur within the total system of space-time. Indeed, it seems logically possible that certain mental properties are fundamental force-generating properties, just as in classical mechanics the masses of bodies generate the gravitational force, and the electrical charges of bodies generate the electrostatic force.

Perhaps our will involves such a force. There could be a force that is exerted only when matters becomes so configured as to constitute a brain in which certain sorts of mental properties are realized, and that affects the behavior of material particles in ways that causally contribute to bodily behavior that we regard as being under the (partial) control of our volition. Perhaps, further, this *configurational force* is fundamental, affecting the behavior of bodies in ways unanticipated by laws governing matter at lower-levels of complexity. If so, then in the framework of classical mechanics, there would be a mental force law on a par with the inverse square laws—the law of gravity and Coulomb's law.

In the framework of nonrelativistic quantum mechanics, mental energy would contribute to determining the value of the Hamiltonian of Erwin Schrödinger's equation. Since mechanics is a branch of physics, it might be claimed that if mechanics has to take mental properties into account, then the properties would thereby count as physical. But the dualist would regard that as a merely verbal point and note that the important point is that mental properties would be fundamental, irreducible force-generating properties. It should be noted, however, that while such configurational forces could be accommodated within Newtonian mechanics and are compatible with Schrödinger's equation, the role of mental properties would by no means be straightforward on the view in question. By hypothesis, the configurational forces would be exerted only when certain enormously complex microstructural properties were realized by minute physical structures of portions of the brain. On the dualist hypothesis in question, mental properties are distinct from any microstructural properties—at most, accompanying them as a matter of fundamental law. But, then, mechanics would, arguably, have to advert only to the microstructural properties in question, taking them

to be the configurational force-generating properties (McLaughlin 1992).

Another view discussed during the period in question is that every mental event is a physiological event but that mental properties are not physiological properties (Lewes 1985, Alexander 1920, Broad 1925). If mental events are physiological events, then they have causal effects. And the mistake made by theorists who found no gaps to be filled by mental events would be that they failed to realize that certain physiological events are mental events in that they fall under mental event types. This view faces the following issue: What is it about a physiological event in virtue of which it falls under a mental event type (or exemplifies a mental property)? Suppose that physiological event  $P$  falls under mental event type  $M$  and that physiological event  $P^*$  does not. It seems, then, that there must be some difference between  $P$  and  $P^*$  in virtue of which  $P$  is and  $P^*$  is not an event of type  $M$ . The issue is what that difference is. George Henry Lewes (1875) seems to have anticipated a functionalist answer of a kind sometimes given today (See Lewis 1966): He spoke of the role of the physiological event in the organism. But the most widely discussed answer during the period in question was that there are fundamental, irreducible laws of nature linking physiological properties with mental properties (Alexander 1920, Broad 1925).

Thus, the reason  $P$  is and  $P^*$  is not an instance of  $M$  is that  $P$  is an instance of a physiological event type that is linked via a fundamental noncausal law of nature to  $M$  while  $P^*$  falls under no such physiological type. Charles Dunbar Broad (1925–) called this view *emergent materialism*, and he called such laws of nature *transordinal laws*. (Transordinal laws were later denigrated as *nomological danglers* [Feigl 1950].) The guiding idea was that through the course of evolution, complex structures are formed that have genuinely new kinds of properties that are fundamental and thus irreducible. The emergent properties of wholes are linked to properties of their parts and relations among their parts only by fundamental laws. Emergent materialism is thus a kind of dual-aspect theory according to which the mental and physiological aspects of events are linked only by fundamental laws. On this view mental events are causes. But Broad raised the issue of whether they enter into causal relations only in virtue of their physiological properties and so not in virtue of their mental properties (Broad 1925, p. 473). If so, then emergent materialism is committed to a kind of property or type epiphenomenalism (McLaughlin 1989).

In the twentieth century science made truly momentous advances. The atomic theory of matter was vindi-

cated, a quantum mechanical explanation of chemical bonding was provided—dispelling the idea that there are fundamental chemical forces—and organic chemistry and molecular biology made giant strides leading to the demise of any form of vitalism. There seem to be no fundamental mental forces of nature, no mental energy on par with electromagnetic energy, no mental force fields. At least mechanics has as yet no need of such hypotheses. It is now thought that all the fundamental forces are ones that are exerted below the level of the atom: the gravitational force, the electromagnetic force, the weak force, and the strong force. There is some hope for unification, but no role is envisioned for the mental. Of course, current microphysics may well be false; there is at present no quantum theory of gravity. It is, moreover, at least logically possible that our current physics is profoundly mistaken and that the physics in fact true of our world is a kind of Cartesian physics in which mentality plays a fundamental role. But that seems just a fantasy. It is fairly widely assumed that whatever revisions lie ahead for physics, they will not substantially change the dialectic as concerns the mind-body problem.

The mind-body problem is fundamentally the problem of the place of mental phenomena in nature. Contemporary philosophical discussions of the mind-body problem typically proceed under the (often) tacit assumptions that: We are wholly constituted by atoms and more fundamental physical particles, all of which are ingredients of beings entirely devoid of mentality; any fundamental forces at work in us are also at work in many such beings; and that for any (caused) microphysical event  $P$ , there is a distinct microphysical event  $P^*$  that causally determines the objective probability of  $P$  (if determinism is true, that probability will be 1). The last—which, unlike the others, is often explicitly stated—is sometimes called *the closure of the microphysical* though it goes under other names as well.

Of course, one way of responding to the question of the place of an alleged mental phenomenon in nature is by denying that there actually is any such phenomenon. One can be an *eliminativist* about it. Most contemporary philosophers are eliminativists concerning not only non-spatial, immaterial minds, but also spatiotemporally located immaterial minds: They deny that there are any such things. And they do so for much the same reasons mentioned earlier. Moreover, most contemporary philosophers deny that there are sense data, essentially private mental objects of which only the subject can be aware. Nevertheless, most hold that there are mental properties, capacities, abilities, states, events, and

processes. And discussion mainly focuses on their place in nature.

There are many unresolved questions. One central issue concerns the manner in which biologically functioning brains serve as a basis for our capacities to think and to feel and our ability to will: Are they merely a causal basis, or are they rather a constitutive basis? Other issues include whether freedom of the will is compatible with the manner in which they are, such a basis, and with the closure of the microphysical; whether there could be other kinds of material bases for mental capacities and abilities (e.g., silicon-based brains); and what the conditions for personal identity are given the fact of our material embodiment. And there are, as well, theological questions such as whether immortality may somehow be possible despite the fact of our material embodiment. (Might it be possible through the resurrection of the body?)

Among our mental capacities is the capacity to reflect on our own mental lives. Indeed, it is because we have such a capacity that we are able to formulate the mind-body problem. We are not only conscious (as are most kinds of animals), but self-conscious as well. The place in nature of our capacities for self-consciousness must be found. Engagement with the mind-body problem, moreover, requires theoretical reasoning. We form beliefs on the basis of others that provide reasons for them. And we engage in practical reasoning when we deliberate about courses of action (e.g., whether to finish reading the present article). Our capacities for theoretical and practical reasoning must also be located in nature.

The exercise of mental capacities and abilities involves mental states and events (including mental acts). The fundamental problem of the place of mental states and events in nature is that, on the one hand, they have or are instantiations of properties that seem *sui generis*, and on the other hand, they occur in space-time (arguably, within our skulls) and seem to enter into causal relations with other states and events, including microphysical ones (as, for example, when we deliberately move our bodies across the room with the result that physical particles in our bodies come to be on the other side of the room). The apparently *sui generis* properties primarily include those of intentionality and phenomenal consciousness.

Properties of intentionality divide into two broad kinds: modes of representation and representational contents. Beliefs, desires, hopes, and intentions, for example—so called *propositional attitudes*—are representational. They have an intentional (representational) mode—

belief, desire, hope, intention—and they have an intentional (representational) content, a content that is (semantically) satisfied or not, depending on the way the world is. States of phenomenal consciousness have phenomenal characters (*qualia*): It is like something for the subject of such a state to be in the state (Nagel 1974). States of phenomenal consciousness include bodily sensations, sense experiences, acts of mental imagery, felt emotions, and occurrent thoughts. Thus, for instance, it is like something for a subject to feel pain, or to visually experience red, or to visualize a sunset. Emotions such as fearing that *P* and being joyous that *P* have contents, and their characteristic manifestations in phenomenal consciousness—feelings of fear and feelings of joy—have phenomenal characters. An occurrent thought such as thinking to oneself that it will rain tomorrow will have a representational content and a phenomenal character as well (even if not a distinctive, characteristic one). (Suffice it to note that the relationship between intentionality and phenomenal consciousness and whether one is primary are highly controversial issues.)

Many contemporary philosophers of mind are engaged in the project of trying to naturalize either intentional properties or phenomenal characters—that is to say, to locate them in nature conceived as fundamentally microphysical. It has been argued that such naturalization projects are doomed to failure where intentional properties are concerned because such properties are identifiable only by their place in a network of normative, rational relations and are thus irreducible, having *no echo* in the physical sciences (Davidson 1970). But even some philosophers who are optimistic about the prospects of naturalizing intentional properties maintain that the attempt to naturalize phenomenal consciousness may face insuperable difficulties. Huxley mused: “How it is that anything so remarkable as a state of consciousness comes about as a result of irritating nervous tissue, is just as unaccountable as the appearance of the Djinn, when Aladdin rubbed his lamp” (Huxley 1986, p.193). Indeed, it has been claimed that “consciousness is what makes the mind-body problem really intractable” (Nagel 1974, p. 435); that it is “the hard nut of the mind-body problem” (McGinn 1989, p. 394); that it is “the hard part of the mind-body problem” (Strawson 1994, p. 93); and that phenomenal character poses “the hard problem” of consciousness (Chalmers 1996, p. xiii).

Some philosophers have maintained that the link between phenomenal characters and physicality is so mysterious that it is reasonable to hypothesize that the particles—the star dust—from which we are composed must

have as yet undiscovered *protoment*al properties, which, though their mode of combination somehow constitute phenomenal characters (James 1890; Nagel 1979). Physics, however, has as yet found no need of this *panpsychism* hypothesis. Moreover, if the protoment properties are not themselves phenomenal characters and are objective in nature, then the concern arises that their link with phenomenal characters would also be mysterious. In any case, so mysterious has the connection between phenomenal character and physicality seemed that some philosophers have maintained that we are cognitively closed to the sorts of concepts required for understanding the place of phenomenal characters in nature and thus that the matter transcends human understanding (McGinn 1989).

There are a variety of different naturalizing projects, and some are incompatible with others. However, there have been attempts to state a commitment shared by them all. One leading formulation of such a shared commitment is the following global supervenience thesis: Any minimal physical duplicate of our world is a duplicate *simpliciter* of it (Jackson 1998). A physical duplicate of our world (the actual world) is any possible world that is exactly like our world in every microphysical respect, in respect to its world-wide pattern of distribution of microphysical properties and relations, its world-wide pattern of distribution of microphysical objects, its microphysical laws of nature, and so on. A minimal physical duplicate of our world is any physical duplicate of it that contains nothing other than what is metaphysically required to be a physical duplicate of it. Proponents of different naturalizations programs will offer different explanations of why mental phenomena do not yield a counterexample to the supervenience thesis.

Philosophers, however, who maintain that mental properties of certain sorts are emergent properties, fundamental constituents of nature, linked to other properties only by contingent fundamental laws of nature, will deny the supervenience thesis. Since the laws in question (Broad’s *transordinal laws*) are contingent and fundamental, it is possible for them to fail to hold even though all of the actual microphysical laws of our world hold. Such philosophers are committed to there being a possible world that is a minimal physical duplicate of our world yet not a duplicate *simpliciter* of it because the world is devoid of the mental properties in question (or instantiations of them). For example, someone who holds that phenomenal characters are fundamental in nature will claim there is a possible world that is a minimal physical duplicate of our world yet, unlike our world, is devoid of phenomenal consciousness—a *zombie world* (Chalmers 1996)—and

thus not a duplicate *simpliciter* of our world. And, similarly, someone who held that intentional properties are fundamental will be committed to their being a possible world that is a minimal physical duplicate of our world but which fails to be a duplicate *simpliciter* of our world since it is devoid of intentionality.

Any world that is a minimal physical duplicate of our world will be one in which exactly the same microphysical causal transactions occur as do in our world. If either normative intentional properties or phenomenal characters yield counterexamples to the supervenience thesis, then such properties make no difference to what microphysical causal transactions occur in our world. And they could make a difference to whether certain causal transactions occur in our world only if those transactions fail to be implemented by microphysical ones. Such, it seems, are the facts of our world.

Whether intentionality and phenomenal consciousness can be naturalized—whether they can be located in nature conceived of as fundamentally microphysical—are the fundamental issues of the contemporary mind-body problem. These are issues of intensive, ongoing debate.

## MIRACLES

The term "miracle," like the word *nice*, is often used to refer primarily to the responses of the user. In this usage, a miracle is merely some event that astounds the speaker, with perhaps some presumption that others will or should react to it in the same way; just as in the parallel case *nice* means simply "agreeable to me," with perhaps again some suggestion that all right-minded people will feel the same. But the senses of "miracle" that are of philosophical and methodological interest are stronger and less subjectively oriented. Although they include the idea that wonder is called for as at least part of the appropriate response, the crux as well as the ground for the wonder is that a miracle should consist in an overriding of the order of nature. A miracle is something that would never have happened had nature, as it were, been left to its own devices.

This idea of overriding is essential; however, it is certainly subject to various variations and additions. Some writers, for instance, insist that the word *miracle* should be used in such a way that it becomes necessarily true that a miracle can be worked only by God or by his specially deputed agents. Others even build into their very defini-

tion of *miracle* some reference to the purposes for which Authority is supposed to be prepared to consider making such an exception. Certainly, most theist theologians are also at great pains to maintain that a miraculous event could not properly be considered a violation, since it would not really represent any infringement, of the fundamental hierarchical order. "It is not against the principle of craftsmanship (*contra rationem artificii*) if a craftsman effects a change in his product, even after he has given it its first form" (Thomas Aquinas, *Summa contra Gentiles*, III, 100). But these very labors to show that and how such "violations" need involve no ultimate irregularity still admit and presuppose the essentially overriding character of the miraculous. There would be no point in trying to show in this way that a miracle must ultimately be no violation of regularity unless it were taken for granted that it apparently is such a violation.

This point is fundamental, and it needs to be stressed more heavily today than in the past. For in addition to the traditional theist reluctance to ascribe to the Deity anything savoring of unseemly irregularity, it is nowadays usual to encounter a certain shyness about any apparent repudiation of scientifically accepted modes of explanation. Thomas Aquinas, earlier in the chapter referred to above, gave a perfectly clear and unequivocal definition of *miracle* that makes no bones at all about the crux of the matter, namely, that "those things are properly called miracles which are done by divine agency beyond the order commonly observed in nature (*praeter ordinem communiter observatum in rebus*)." Again, in the twentieth century, Dr. Eric Mascall, remaining in the same forthright tradition, insisted in his article in *Chambers' Encyclopaedia* that the word *miracle* "signifies in Christian theology a striking interposition of divine power by which the operations of the ordinary course of nature are overruled, suspended, or modified."

## MIRACLES AND NATURAL ORDER

To seize the fundamental point that a miracle is an event that violates the "ordinary course of nature" is to appreciate that the notion of a miracle is logically parasitical on the idea of an order to which such an event must constitute some sort of exception. This being so, a strong notion of the truly miraculous—a notion involving something more than the notions of the merely marvelous, the significant, or the surprising—can only be generated if there is first an equally strong conception of a natural order. The inevitable tension between the ideas of rule and of exception thus gives concepts of the miraculous an inherent instability. It is perhaps relevant to notice how this

tension has been felt in the history of ideas. Where there is as yet no strong conception of a natural order, there is little room for the idea of a genuinely miraculous event as distinct from the phenomenon of a prodigy, of a wonder, or of a divine sign. But once such a conception of a natural order has taken really firm root, there is a great reluctance to allow that miracles have in fact occurred or even to admit as legitimate a concept of the miraculous.

An interesting early case of this is provided by Benedict de Spinoza in his *Tractatus Theologico-Politicus*, in which he tried to reconcile his vision of a natural order (*Deus sive natura*) with an acceptance of the Bible as in some sense a privileged document. He did this partly by admitting the limitations of observatory powers of the men of biblical days, but mainly by urging that conventional interpreters of the Bible read far more miracles into it than it contains, because they constantly read poetic Hebrew idioms literally. Today, more and more theologians seem to be noticing the exact words used by the New Testament writers in describing the sorts of alleged events that, in more scientific ages, have been characterized (and perhaps dismissed) as miraculous. These words are *τέρατὰ* (“wonders,” or “prodigies”), *δυναμεις* (“powers”), *σημεία* (“signs”); and, particularly in St. Paul, *χαρισματα ιαμάτων* (“graces of healing”) and *ἐνεργήματα δυνάμεων* (“effects of powers”). None of these words seems to carry any entailments about the overriding of a natural order. On the other hand, once a really strong conception of natural order has arisen, its adherents tend to dismiss out of hand all stories of putative occurrences in the belief that if they allowed that these occurrences had taken place at all, they would have to admit them to have been miraculous. One may refer here to R. M. Grant’s recent *Miracle and Natural Law in Graeco-Roman and Early Christian Thought* (Amsterdam, 1952) and to William E. H. Lecky’s classic study *History of the Rise and Influence of Rationalism in Europe* (London, 1890). The former summarizes its own thesis as follows: “Credulity in antiquity varied inversely with the health of science and directly with the vigor of religion” (p. 41). This, however, was later qualified by the important observation that “at least in some respects Christians were far less credulous than their contemporaries, at least in the period before Augustine” (p. 120). Lecky traced a development in which stories of the ostensibly miraculous, from being accepted as a chief guarantee of the authenticity of the Christian revelation, become instead “a scandal, a stumbling block, and a difficulty” (Vol. I, p. 143). In the nineteenth century the radical biblical critic David Strauss announced in the introduction to his *Das Leben Jesu* (2 vols., Tübingen, 1835; translated by Mary Ann Evans as

*Life of Jesus Critically Examined*, London, 1848), “We may summarily reject all miracles, prophecies, narratives of angels and demons, and the like, as simply impossible and irreconcilable with the known and universal laws which govern the course of events.” And in the twentieth century there was even a bishop of the Church of England capable of saying of the author of Mark, “He was credulous inasmuch as the miracles, as they are narrated, cannot, in the light of our modern knowledge of the uniformity of nature, be accepted as historical facts” (F. W. Barnes, *The Rise of Christianity*, London and New York, 1947, p. 108).

**DILEMMA OF HOLDING STRONG RULES WHILE ADMITTING EXCEPTIONS.** The spokesman for the occurrence of the miraculous faces a dilemma that arises from the very essence of the concept he espouses. It is tempting, but wrong, for the believer in the miraculous to think that he can afford to gloat over any little local difficulties and embarrassments that may from time to time beset the forward march of science. But insofar as a miracle involves an alleged overriding of a law of nature, he too is committed to showing the subsistence of a natural order. Exceptions are logically dependent upon rules. Only insofar as it can be shown that there is an order does it begin to be possible to show that the order is occasionally overridden. The difficulty (perhaps an insoluble one) is to maintain simultaneously both the strong rules and the genuine exceptions to them. The oscillations in the history of thought are to be understood by reference to this tension (amounting perhaps to a contradiction) that is inherent in the concept of the miraculous, and it is on this same tension that the various logical and methodological problems also center.

#### LOGICAL AND METHODOLOGICAL PROBLEMS

It is with logical and methodological problems that we are primarily concerned. The classical, and by far the best, approach is by way of the notorious section X, “Of Miracles,” in David Hume’s *Enquiry concerning Human Understanding* (1748). This and Section XI of this *Enquiry*, both of which were parts of a single coordinated case, constitute Hume’s answer to what was, in his day, the stock program of Christian apologetic. This program had two stages: the first was an attempt to establish the existence and certain minimal characteristics of God by appealing only to natural reason and experience, the second was an attempt to supplement this rather sketchy religion of nature with a more abundant revelation. This program,

in its characteristically eighteenth-century form, received its archetypal fulfillment in Archdeacon William Paley's *Natural Theology* (London, 1802) and also in his *Evidences of Christianity* (London, 1794). In the eighteenth-century form, the weight of the first part of the case was borne primarily by the Argument to Design. If from a watch we may infer a watchmaker, then the orderliness of the universe entitles us to infer, by parity of reasoning, a Maker of the universe. The second part of the case rested on the claim that there is ample historical evidence to show that the biblical miracles, including the crucial physical resurrection of Jesus bar Joseph, did in fact occur, and that this in turn proved the authenticity of the Christian revelation.

Paley's style of systematic rational apologetic has no doubt gone out of fashion, at least among Protestants. But Hume's challenges to the whole idea of a substantial natural theology and to the project of establishing the authenticity of any alleged revelation by proving that its claims have been supported by miracles are not, and are not likely to become, dead issues. For in 1870 the third session of the First Vatican Council defined as constitutive dogmas of the Roman Catholic religion both of the positions that Hume had challenged. The relevant passage of the canon dealing with the second reads, "If anyone shall say ... that miracles can never be known for certain, or that the divine origin of the Christian religion cannot properly be proved by them: let him be cast out" (*si quis dixerit ... aut miracula certo cognosci numquam posse nec iis divinam religionis christianae originem rite probari: anathema sit*; H. Denzinger, ed., *Enchiridion Symbolorum*, 29th ed., Sec. 1813, Freiburg im Breisgau, 1953).

**PROBLEM OF SUPERNATURAL REVELATION.** Hume's main contention was thus, in his own words, that "a miracle can never be proved so as to be the foundation of a system of religion." For him, all other questions about the miraculous were, officially at least, merely incidental to this basic tenet. He defined a "miracle" as "a transgression of a law of nature by a particular volition of the Deity, or by the interposition of some invisible agent." This definition has been attacked on various counts, but the criticism is misconceived, for two reasons. First, this was in fact the way in which the opponents whom Hume had in mind defined the term "miracle." Thus, Dr. Samuel Clarke, in his famous Boyle lectures (*The Works of Samuel Clarke*, Vol. II, London, 1738, p. 701), had defined "miracle" as "a work effected in a manner ... different from the common and regular method of providence, by the interposition either of God himself, or of some intelligent

agent superior to men." Second, if, as Clarke and the orthodox tradition would have it, the occurrence of a miracle is to serve "for the proof or evidence of some particular doctrine, or in attestation of the authority of some particular person," then surely a miracle must be conceived in this way. It is only and precisely insofar as it is something really transcendent—something, so to speak, that nature by herself could not contrive—that such an occurrence could force us to conclude that some supernatural power is being revealed.

In this context it would be worse than useless to appeal to revelation for criteria by which genuinely miraculous events may be identified, and thus distinguished from the unusual, the untoward, or the merely ordinary. For if the occurrence of a miracle is to serve as the endorsement of a revelation, then we have to find some means entirely independent of that revelation by which the endorsement itself may be recognized. Exactly the same point applies, of course, if, with what is now a rather fashionable school of apologetic, it is urged that miracles are not essentially overridings, but signs. If a sign is to signify to the unbeliever, then there must be some means independent of the doctrinal system itself by which the signs may be identified and read. As has been suggested already, there is much to be said for trying to interpret the records of *τέρατα* and *σημεία* in the New Testament in terms of some notion of sign, rather than as miracle stories proper. But it is necessary to insist on two facts that seem to be often overlooked—namely, that part of the price that must be paid for this method of interpretation is the sacrifice of the use of these stories as independent evidence of the genuinely revelatory character of the doctrines; and that such a sacrifice presumably entails the rejection of at least one defined dogma of the Roman Catholic Church, and hence of the truth of Roman Catholicism as a theological system.

A similar but different point applies if a relativistic definition of "miracle" is adopted, as was done, for instance, by John Locke. In his *Discourse of Miracles* (written 1702, published posthumously), he defined the word *miracle* as "a sensible operation, which, being above the comprehension of the spectator, and in his opinion contrary to the established course of nature, is taken by him to be divine." It was also done, in a slightly different way, by St. Augustine, who insisted that "nature is the will of God" (*Dei voluntas rerum natura est*), and hence that "a portent is not contrary to nature, but contrary to our knowledge of nature" (*Portentum ergo fit non contra naturam, sed contra quam est nota natura*; *De Civitate Dei*, XXI, 8). To operate with a relativistic notion of this sort is

necessarily to be deprived of the possibility of arguing that a miracle is a miracle regardless of whatever anyone may happen to know or to believe about it, and hence to rob the attempt to base an apologetic on the occurrence of miracles of whatever initial plausibility it might otherwise possess. For the occurrence of events that are merely inexplicable *to us*, and *at present*, provides no good ground at all for believing that doctrines associated with these occurrences embody an authentic revelation of the transcendent. There is, of course, no particular reason why Locke himself should have been disturbed about this. The case of Augustine, however, is more interesting, for he is a recognized saint and one of the four great doctors of the church. And yet insofar as he held to a relativistic notion of a miracle, he was safeguarding the vital doctrine of the total dependence of the whole creation—but at the price of subverting a sort of apologetic which it has since become essential for Roman Catholics to believe in as a possibility.

**PROBLEM OF IDENTIFYING AN EVENT AS MIRACULOUS.** Up to this point it has been insisted that if the occurrence of a miracle is to serve—as Clarke and the orthodox tradition would have it—“for the proof or evidence of some particular doctrine, or in attestation of the authority of some particular person,” then in a traditional sense, miracles must be conceived of as involving the overriding of some natural order that is at least partly autonomous. The importance of this crucial point is often overlooked. Another immediately consequential point, however, is overlooked perhaps even more often, namely, that if an occurrence that is miraculous in the traditional sense is to serve as evidence for anything, it must be possible to identify it as being miraculous. Furthermore, as was urged above, if its occurrence is to serve as an endorsement of some doctrinal system, the method of identification must be logically independent of that system. The difficulty of meeting this last requirement is often concealed by the acceptance of what seems, for many people, to be an almost unquestionable assumption. Protagonists of the supernatural, and opponents too, take it for granted that we all possess some natural (as opposed to revealed) way of knowing that and where the unassisted potentialities of nature (as opposed to a postulated supernature) are more restricted than the potentialities that, in fact, we find to be realized or realizable in the universe around us.

This is a very old and apparently very easy and tempting assumption. It can be found, for instance, in Cicero’s *De Natura Deorum*, and hence presumably much earlier, in Cicero’s Greek sources. Nevertheless, the

assumption is entirely unwarranted. We simply do not have, and could not have, any natural (as opposed to revealed) criterion that enables us to say, when faced with something that is found to have actually happened, that here we have an achievement that nature, left to her own unaided devices, could never encompass. The natural scientist, confronted with some occurrence inconsistent with a proposition previously believed to express a law of nature, can find in this disturbing inconsistency no ground whatever for proclaiming that the particular law of nature has been supernaturally overridden. On the contrary, the new discovery is simply a reason for his conceding that he had previously been wrong in thinking that the proposition, thus confuted, did indeed express a true law; it is also a reason for his resolving to search again for the law that really does obtain. We certainly cannot say, on any natural (as opposed to revealed) grounds, that anything that actually happens is beyond the powers of unaided nature, any more than we can say that anything that any man has ever succeeded in doing transcends all merely human powers. For our evidence about the powers of nature in general, and of men in particular, is precisely and only everything that things and people do. For a scientist to insist that some recalcitrant fact constitutes an overriding of a still inviolably true law of nature is—to borrow Rudolf Carnap’s mischievous analogy—as if a geographer were to maintain that the discrepancies between his maps and their objects show that there is something wrong with the territories concerned.

The insistence of the scientist, insofar as he is simply a scientist, on always seeking strictly universal laws is itself rooted in the fundamental object of the whole scientific quest: if scientists are to find comprehensive explanations, they must discover universal laws. A scientist’s refusal to accept the idea that in any single case nature has been overridden by supernatural intervention is grounded partly on precisely the above-mentioned lack of any natural (as opposed to revealed) criterion for distinguishing natural from supernatural events, and partly on his commitment—which is chiefly what makes him a scientist—to continue always in the search for completely universal laws, and for more and more comprehensive theories. In view of this, it need be neither arbitrary nor irrational to insist on a definition of a “law of nature” such that the idea of a miracle as an exception to a law of nature is ruled out as self-contradictory.

The seductive but erroneous idea that we do possess some natural means for the identification of the supernatural is one that, in some respects, parallels the notion that it is logically possible to derive prescriptive norms

from knowledge of what is, in some purely descriptive sense, natural. In each case there are adherents for whom the division between natural and supernatural, or between natural and unnatural, is nothing but an incoherent muddle. Likewise, in each case there are others who, in support of their choice, are prepared to deploy some more or less elaborate structure of theoretical justification.

**PROBLEM OF EVIDENCE.** All of this argumentation, although both relevant and (in spirit at least) thoroughly Humean, has little in common with the line of argument Hume chose to develop in the section “Of Miracles.” Although this line of argument is equally methodological, it treats the question of miracles as it arises in the field of history rather than as it might impinge upon natural science. Hume was primarily concerned not with the question of fact but with that of evidence. The problem was how the occurrence of a miracle could be proved, rather than whether any such events ever had occurred. Consequently, even if Hume was successful, the way would still remain clear for people to believe in miracles simply on faith. In his own mordant way, Hume himself was happy to allow for this, but he always insisted that “a wise man proportions his belief to the evidence.”

This concentration on the evidential issue means that Hume’s thesis, however offensively expressed, is nevertheless at bottom defensive. Hume hoped that he had discovered “a decisive argument ... which must at least silence the most arrogant bigotry and superstition, and free us from their impertinent solicitations ... an argument which ... will ... with the wise and learned, be an everlasting check to all kinds of superstitious delusion....” These words were very carefully chosen. The whole argument was directed to the wise—to those, that is, who insist on proportioning their belief to the evidence. It did not show that the substantive claims of the bigoted and superstitious are in fact false. It was intended to serve as a decisive check on any attempt to solicit the assent of rational men by producing proof of the occurrence of the miraculous. In particular, the object was to interdict the second movement of the standard apologetic attack as outlined above.

If for present purposes a certain amount of misguided psychologizing is ignored, the following would appear to be the gist of Hume’s “everlasting check.” There is, he remarked, “no species of reasoning more common, more useful, and even necessary to human life than that derived from the testimony of men and the reports of eye-witnesses and spectators.” Yet all testimony must ulti-

mately be subject to assessment by the supreme court of experience. Certainly there are, as Hume observed, “a number of circumstances to be taken into consideration in all judgments of this kind.” Yet “the ultimate standard by which we determine all disputes ... is always derived from experience and observation.” (Of all people, Hume, as the author of that most famous paragraph in the *Treatise of Human Nature*, should have said not “is,” but “ought” always to be so derived.)

The weight of the testimony required must depend on the apparent credibility of the events reported. If the events are in some way marvelous and rare, then the testimony for them has to be treated with more circumspection than the witness to everyday occurrences. But supposing that the testimony is for events that, had they occurred, would have been genuinely miraculous: we are then confronted with a paradoxical dilemma, proof balanced against proof. However overwhelming the testimony might have appeared were it not being considered as evidence for a miracle, in this peculiar case the testimony must always be offset against a counterproof. In Hume’s own words, “A miracle is a violation of the laws of nature; and as a firm and unalterable experience has established these laws, the proof against a miracle, from the very nature of the fact, is as entire as any argument from experience can possibly be imagined.”

In the first part of section X, Hume argued generally from the concept of the miraculous—from, as he put it, “the very nature of the fact.” In the second he deployed several more particular assertions about the corruptions to which testimony is liable, urging that such corruptions are exceptionally virulent where any religious issue is involved. He also added a further consideration relevant to any attempt “to prove a miracle and make it a just foundation for any ... system of religion.”

This consideration was expressed badly and was entangled in one or two inessential errors and confusions. But a letter makes clear Hume’s intent. The point is that if the occurrence of some sort of miracle is to serve as a guarantee of the truth of a system of religion, then there must not have been any similar miracle under the auspices of a rival system, the truth of which would be incompatible with the truth of the first. Consequently, insofar as we are considering a miracle not as a putative bald fact but as a possible endorsement of the authenticity of a revelation, we have to throw into the balance against the testimony for the miracles of any one candidate revelation all the available testimony for all the miracle stories presented by all the rival systems that are inconsistent with the first. In its appeal to a necessary

conflict of evidence, this argument resembles the paradoxical dilemma expounded above.

## MIRACLES AND THE PHILOSOPHY OF HISTORY

Enough already has been said to suggest that there is more to Hume's check than a trite insistence that since the occurrence of a miracle must be very improbable, it would have to be exceptionally well evidenced in order to be believed. C. S. Peirce was in possession of the vital clue (which he seems never to have exploited fully) when he remarked, "The whole of modern 'higher criticism' of ancient history in general, and of Biblical history in particular, is based upon the same logic that is used by Hume" (*Values in a Universe of Chance*, edited by P. P. Wiener, New York, 1958, pp. 292–293). When we follow this clue, it becomes obvious that Hume himself saw "the accounts of miracles and prodigies to be found in all history, sacred and profane" as presenting a methodological problem. This section on miracles constitutes the outer ring of Hume's defenses against the orthodox religious apologetic. But at the same time it is also part of his contribution to an understanding of the presuppositions and the limitations of critical history.

This fact seems not to have been appreciated as it should have been. There is, for instance, no reference to Hume's section "Of Miracles" in R. G. Collingwood's *The Idea of History* (Oxford, 1946); and neither Collingwood nor F. H. Bradley seems to have had any idea of the extent to which Bradley's own essay, "The Presuppositions of Critical History" (*Collected Papers*, Vol. I., Oxford, 1935), echoed arguments first developed by Hume. It is worthwhile to consider possible causes of this neglect. In part it is to be attributed to the insistence (at one time universal) on treating section X, "Of Miracles," as though it were a separate and disingenuous essay, irrelevantly inserted into the first *Enquiry* simply to cause scandal and thereby push up sales. This perverse and gratuitously offensive notion has misled interpreters to overlook some extremely relevant remarks in Part I of section VIII which concern the inescapably uniformitarian presuppositions of both the natural and the social sciences. Even those who have succeeded in appreciating section X as a very considerable piece of argumentation have been inclined to pigeonhole it as being a contribution to the philosophy of religion only. Certainly Hume's argument does, in the first instance, belong to the philosophy of religion; and this, of course, is how Hume presented it. Yet, as we have already seen, it also has a place in the philosophy of science. The fact that Hume appreciated this is perhaps sug-

gested by his proposal that if, against all reasonable expectation, there were to be sufficient historical evidence to establish that the "miracle" of a universal eight-day eclipse had occurred in January 1600, "then our present philosophers [scientists], instead of doubting the fact, ought to receive it as certain; and ought to search for the causes whence it might be derived." It is surely significant that in this one context, and inconsistently with his own official definition of *miracle*, he spoke not of "a violation of the laws of nature," but rather, and more weakly, of "violations of the usual course of nature."

The same nodal argument which thus has a place in both the philosophy of religion and the philosophy of science belongs equally in the philosophy of history. For what Hume was contending (with certain lapses and hesitations) is that the criteria by which we must assess historical testimony, and the general presumptions which alone make it possible for us to interpret the detritus of the past as historical evidence, must inevitably rule out any possibility of establishing, upon purely historical grounds, that some genuinely miraculous event has indeed occurred. Hume concentrated on testimonial evidence because his conception of the historian, later illustrated in his own famous *History of England*, was of a judge assessing with judicious impartiality the testimony set before him. But the same Humean principles can be applied more widely to all forms of historical evidence.

The fundamental propositions are first, that the present detritus of the past cannot be interpreted as historical evidence at all, unless we presume that the same basic regularities obtained then as today; and second, that in trying his best to determine what actually happened, the historian must employ as criteria all his present knowledge, or presumed knowledge, of what is probable or improbable, possible or impossible. In his first work, the *Treatise of Human Nature* (II, iii, i), Hume had argued that it is only on such presumptions that we can justify the conclusion that ink marks on old pieces of paper constitute testimonial evidence. Early in the first *Enquiry*, in the first part of section VIII, he urged the inescapable importance of having such criteria. In a footnote to section X, he quoted with approval the reasoning of the famous physician De Sylva in the case of a Mlle. Thibaut: "It was impossible she could have been so ill as was proved by witnesses, because it was impossible she could, in so short a time, have recovered so perfectly as he found her."

**FLAWS IN HUME'S ACCOUNT.** Two very serious faults in Hume's presentation of his argument may obscure the

force and soundness of De Sylva's reasoning, as well as the fact that this sort of application of canons to evidence is absolutely essential to the very possibility of critical history.

The first fault is a rather wooden dogmatism of disbelief. For against all his own high, skeptical principles, Hume tended to take it for granted that what in his own day he and all his fellow men of sense firmly believed about the order of nature constituted not just humanly fallible opinion, but the incorrigible last word. He was thus betrayed into categorically dismissing as downright impossible certain reported phenomena that the later progress in the study of abnormal psychology and of psychosomatic medicine has since shown to have been perfectly possible. But the moral to be drawn from these lapses into dogmatism is not that Hume was mistaken in insisting that the critical historian must apply canons of possibility and probability to his evidence, but that he failed to appreciate that all such canons are themselves subject to criticism and correction.

The second major fault in Hume's treatment is both more serious and more excusable. He was unable to provide an adequate account of the logical character of a law of nature. Hence, he could not offer any sufficiently persuasive rationale for employing, as canons of exclusion in historical inquiry, propositions that express, or that are believed to express, such natural laws. The way may thus seem to be open for a historian who holds different presuppositions, yet still remains truly a historian, to endorse as veridical stories of events that, had they occurred, would have been truly miraculous. (For a sustained study of such attempts to have it both ways, see T. A. Roberts, *History and Christian Apologetic*, London, 1960.)

This problem of the logical nature of natural laws has, of course, many more aspects than those that immediately concern us here. But it is important first to emphasize that it is at least as much a problem for Hume's immediate opponents as for Hume. For it is his opponents who need a strong sense of "miracle," in which the miraculous can be distinguished from the merely marvelous. It is tempting, but entirely wrong, for the spokesman for the miraculous to think that he can afford to triumph over Hume's difficulties without being himself committed in any way to producing his own account of the character of laws of nature—an account that shall be more satisfactory as an analysis and yet, at the same time, consistent with the things the spokesman himself wants to say about the miraculous. His dilemma, to repeat, is that he needs to be able to accommodate simul-

taneously both the strong laws and the spectacular transgressions.

**NOMOLOGICAL PROPOSITIONS.** Casting back to the reasoning of De Sylva, it can now be seen that (and how) it constitutes a paradigm of critical history. For it is only and precisely by presuming that the laws that hold today held in the past and by employing as canons all our knowledge—or presumed knowledge—of what is probable or improbable, possible or impossible, that we can rationally interpret the detritus of the past as evidence and from it construct our account of what actually happened. But in this context, what is impossible is what is physically, as opposed to logically, impossible. And "physical impossibility" is, and surely has to be, defined in terms of inconsistency with a true law of nature. Or rather, since this sense of "impossible" is prior to the development of science proper, it might be said that what is physically impossible is whatever is inconsistent with a true nomological proposition.

Both causal propositions and those expressing laws of nature fall under the genus nomological. Although Hume himself concentrated on the causal species, what he said can easily be extended. In his view, when we say that *A* is the cause of *B*, the main thing we are saying is that *B*'s are constantly conjoined with *A*'s—never as a matter of fact *A* and not *B*, or, in modern terminology, *A* materially implies *B*. Of course, he went on, people think they are asserting not a mere constant conjunction, but some real connection, and in a way this is right. The fact is, according to Hume, that there *is* a connection, but that it is a psychological one: we have formed a habit of associating the idea of an *A* with the idea of a *B*.

Yet this account of causal propositions cannot be adequate. All causal propositions entail subjunctive conditionals. (A subjunctive conditional, appropriately enough, is a proposition of the form, "If it were ... it would.") Thus, "*A*'s are the only things which cause *B*'s" entails "If *A* were not to occur (or to have occurred) *B* would not occur (or have occurred)." But no variation on the material implication theme, with or without benefit of associationist psychological speculation, can be made to entail any such subjunctive conditional. Furthermore, the same essential inadequacy afflicts any extension of a Humean analysis to cover nomologicals in general. For a nomological is, by the above definition, a contingent proposition that entails some contingent subjunctive conditional.

The essential difference between the contingent "All *X* are  $\phi$ " and the equally contingent "Any *X* must be  $\phi$ " is

that the former can be expressed as a material implication, “Not both  $X$  and not  $\phi$ ,” whereas the latter cannot be so expressed, because it is a nomological, entailing such subjunctive conditionals as “If there were to have been an  $X$  (which in fact there was not) it would have been a  $\phi$ .” The nomological goes far beyond the statement of a mere conjunction of  $X$  and  $\phi$  as a matter of fact. It asserts also a (contingent) connection between  $X$  and  $\phi$ . For although the nomological is no more logically necessary than the corresponding material implication, it says not merely that, as it happens, a constant conjunction has been, is being, and will be maintained, but also that it would be and would have been maintained regardless of what anyone did or might have done. To assert the nomological is to assert that the conjunction is one that can be relied upon. It is for this reason that experimental evidence is so essential to our knowledge of nomologicals: the obvious and ultimately the only satisfactory test of the reliability of a law is to subject it to strains. It is for the same reason that a knowledge of nomologicals provides, at least in principle, a guarantee of repeatability. To say that the conjunction of  $B$ 's with  $A$ 's is reliable is to say that any time anyone likes to produce an  $A$  he will thereby bring about a  $B$ .

**THE HISTORIAN'S APPROACH.** In the light of the above discussion, we can again consider the question of historical evidence for the miraculous. The critical historian, confronted with some story of a miracle, will usually dismiss it out of hand, asking first only whether it can be used as evidence, not for the occurrence reported, but for something else. To justify his procedure he will have to appeal to precisely the principle Hume advanced: the “absolute impossibility or miraculous nature” of the events attested must, “in the eyes of all reasonable people ... alone be regarded as a sufficient refutation.” Our sole ground for characterizing the reported occurrence as miraculous is at the same time a sufficient reason for calling it physically impossible. Contrariwise, if ever we became able to say that some account of the ostensibly miraculous was indeed veridical, we can say it only because we now know that the occurrences reported were not miraculous at all.

**OBJECTIONS TO THE HISTORIAN'S APPROACH.** To this representation of the procedure of the critical historian there are two main objections. First, it will be argued that such an approach to what purports to be historical evidence for the miraculous is irrationally dogmatic, for in this instance the historian seems to be represented as dismissing all evidence that conflicts with his own funda-

mental prejudices and as defending a closed system in which his professional predilections are guaranteed against falsification by a “Heads-I-win: Tails-you-lose” argument. This is a very understandable objection. It is made more plausible by the regrettable fact that there have been, and still are, many historical writers whose actual procedures correspond rather too closely to this suggested representation. Also it is, of course, true that the dilemmas generated by the tension implicit in the concept of the miraculous must necessarily seem to their victims to have a “Heads-you-win: Tails-I-lose” aspect. Nevertheless, the critical historian is not committed to the sort of bigoted dogmatism the present objection attributes to him.

*Nomological laws and reports of miracles.* As Hume was insisting from first to last, the possibility of miracles is a matter of evidence and not of dogmatism. For, to proceed beyond Hume, the nomological proposition that provides the historian's canon of exclusion will be open and general and of the form “Any  $X$  must be  $\phi$ .” The proposition reporting the (alleged) occurrence of the miracle will be singular, particular, and in the past tense; it will have the form “This  $X$  on that particular occasion was not  $\phi$ .” Propositions of the first sort can in principle be tested at any time and in any place. Propositions of the second sort cannot any longer be tested directly. It is this that gives propositions of the first sort the vastly greater logical strength that justifies their use as criteria of rejection against the latter. It will indeed be only and precisely insofar as we have evidence sufficient to warrant our assertion of the general nomological that excludes the particular historical proposition that we shall have sufficient reason to claim that the event it reports would have been genuinely miraculous.

*The logic of evidence.* Suppose that in some particular case the evidence for a miracle appears extremely strong. Then perhaps the historian may ask himself whether the nomological proposition that precludes this event is after all true. It could, in principle at any rate, be further tested. If, as is possible, it were shown to be false after all, then perhaps the event so strongly evidenced did indeed occur. But by the same token, that event could now no longer be described as truly miraculous. This, surely, is what has happened in the case of so many of the reports of astonishing psychosomatic cures, which Hume himself, in his capacity as a historiographer, too rashly dismissed. (Consider, for example, his contemptuous rejection of the stories of faith healings by the Emperor Vespasian and of the many cures associated with the tomb of the Jansenist Abbé Paris, all in section X of his

first *Enquiry*.) Alternatively, the nomological proposition might survive even our further tests. Hume should be the last one to deny that it must remain always conceivable—logically, that is, as opposed to physically possible—that the event in question did in fact occur. Yet in this case, no matter how impressive the testimony might appear, the most favorable verdict that history could ever return must be the agnostic, and appropriately Scottish, “not proven.”

**Need for canons of evidence.** The second objection to the above representation of the procedure of the critical historian suggests that there is something arbitrary or at least optional about the appeal to canons provided by some of our knowledge, or presumed knowledge, of what is probable or improbable, possible or impossible. Once again there is some ground for this objection. Certainly we can choose whether or not we will try to act as critical historians. But once that fundamental choice is made, there is nothing arbitrary and nothing optional about insisting on the employment of these canons. For the essential aim of the historian is to get as near as he can to a full knowledge of what actually happened, and why. To do this he must find and interpret evidence, for belief unsupported by evidence may be true, but it cannot constitute knowledge. Yet to interpret the detritus of the past as evidence, and to assess its value and bearing as such, we must have canons. And for a rational man, these canons can only be derived from the sum of his available knowledge, or presumed knowledge. It is not the insistence on the systematic employment of these always corrigible canons that is arbitrary; what is arbitrary is to pick and choose in the interests of your ideological predilections among the available mass of miracle stories, or to urge that it is (psychologically) impossible that these particular witnesses were lying or misinformed and hence that we must accept the fact that on this occasion the (biologically) impossible occurred. If one once departs in such arbitrary ways from these canons of critical history, then anything and everything goes. (For examples of precisely this sort of arbitrariness, see M. C. Perry, *The Easter Enigma*, London and New York, 1959.)

**Possible justifications for belief in miracles.** Nothing that has been said in this article decisively closes the door on faith. We have been concerned only with questions about the possibilities of having good reasons for belief in the miraculous. Again, nothing has been said to preclude the production of nonhistorical and nonscientific considerations that might, either by themselves or with the aid of historical or scientific evidence, justify our belief that certain miracles did indeed occur. Perhaps one might

develop some defensible system of rational theology that would provide criteria both for identifying particular occurrences as miraculous and for separating the true miracle stories from the false. Hume tried to rule this out also, of course, in section XI of his *Enquiry*, and elsewhere. But it has been no part of our present task to examine arguments against natural theology. Finally, it is perfectly possible to develop a new concept and to apply to it the term “miracle.” There is never anything to keep anyone from simply changing the subject.

## MIRACLES [ADDENDUM]

Consistent with standard eighteenth-century accounts by Christian apologists, English deists, and skeptics like David Hume, a miracle is still usually thought of as an event with religious significance that is in some sense contrary to the laws of nature. There is no consensus about the best definition. Thus, in their investigations concerning the credibility of miracles, philosophers often have recourse to paradigmatic cases of purported miracles such as the resurrection of Jesus from the dead.

Most philosophers endorse a conception of miracles consistent with the possibility of a violation of the laws of nature. J. L. Mackie (1982) calls a miracle "a supernatural intrusion into the normally closed system that works in accordance with the laws of nature." Richard Swinburne (1970) holds that a miracle is "a non-repeatable counterinstance to a law of nature." A counterinstance to a given law of nature will either be a miracle or will require the formulation of some new alternative law. The second option will be unattractive to the degree that the new law fails to predict the phenomena supporting the original law and/or gives what most likely are false predictions, thus playing havoc with regularities of science. In that event, it would be better to postulate the occurrence of a miracle than to modify our formulae for the laws of nature.

A miracle may, in principle, be identifiable. But is belief in miracles ever epistemically justified? Hume argued that it is not, but his interpreters have disagreed about the specific nature and the overall success of his argument. The controversy centers on Hume's "general maxim" about testimony on behalf of a miracle, which states the following:

That no testimony is sufficient to establish a miracle, unless the testimony be of such a kind, that its falsehood would be more miraculous, than the fact, which it endeavours to establish; and even in that case there is a mutual destruction of arguments, and the superior only gives us an assurance suitable to that degree of force, which remains, after deducting the inferior. (Hume 1975, 115–116)

J. L. Mackie (1982) perceived a need for three specific improvements on Hume's argument: (1) decisions about the value of specific testimonial evidence must always be more provisional than Hume acknowledged; (2) a more accurate conception of inductive generalization is needed than what Hume assumed in his conception of a well-established law of nature; and (3) Hume misunderstood the potential exponential increase in probability conferred by multiple witnesses to an event. But, on balance, with these provisos in place, Hume's argument, Mackie concluded, succeeds in showing that the "intrinsic improbability" of a miracle is too great to be overturned by any degree of testimonial support.

More recently, several of Hume's interpreters have favored the translation of Hume's maxim into the language of the Bayesian probability calculus. This reformulation is desirable if there is to be a more precise exposition of the maxim and of its use in Hume's argu-

ment against miracles. Since Hume's informal statement of his maxim in English harbors ambiguities about conditional probabilities, this is easier said than done.

Let  $M$  be some miracle statement; let  $t(M)$  be testimony to the occurrence of  $M$ ; let  $E$  be the evidence of "constant and uniform experience" confirming the laws of nature; and let  $K$  be background evidence. On a probabilistic reading, the first part of Hume's maxim mentions two probabilities—the probability of the event ( $M$ ) that some testimony  $t(M)$  seeks to establish, and the probability of the falsehood of the testimony,  $t(M) \& \sim M$ —and indicates that the first probability must be greater than the second if the testimony is to make the miracle statement credible. For Bayesian purposes, this relation needs to be translated into a comparative probability statement reflecting conditional probabilities. Everything depends on how each probability statement is rendered.

Jordan Howard Sobel concludes that Hume's maxim, when rendered in the language of probability theory, furnishes the critic with a powerful means of arguing against miracles. One probabilistic reading he has favored is the following:

$$\Pr (M/E \& K) > \Pr [\sim M \& t(M)]/E \& K]$$

as if the antecedent probability of the miracle given the laws of nature— $\Pr (M/E \& K)$ —should count as the crucial thing. If this probability is less than 0.5, as it surely is, then the miracle statement lacks credibility.

Sobel (1987) has also proposed the following alternative reading of Hume's maxim:

$$\Pr [M \& t(M)/E \& K] > \Pr [\sim M \& t(M)]/E \& K]$$

This version differs from the first in proposing an estimation of the prior probability of the *conjunction* of  $M$  &  $t(M)$  and in stipulating that this probability must be greater than the falsehood of the testimony.

John Earman (2000) identifies one general problem with Hume's maxim and objects to Sobel's rendition of it. First, Hume needs a maxim that specifies a *sufficient* condition for the actual occurrence of a miracle to be more likely than the falsehood of testimony for a miracle. But he specifies only a *necessary* condition.

Second, Earman argues that neither of the two probabilities alluded to in the maxim is captured in the right way by Sobel's translation. Both probabilities should be conditioned on  $t(M)$ , the testimony to the miracle. This is because Hume is assuming a situation where the one seeking to determine the credibility of a miracle state-

ment is aware of existing testimony to the occurrence of a miracle. The investigator is not concerned with the prior probability of testimony, or, for that matter, with the prior improbability of the miracle. The probability of the falsehood of the testimony should therefore be rendered

$$\Pr [\sim M/t(M) \& E \& K]$$

This makes sense of the plausible idea that the probability of falsehood is best determined by "the percentage of cases where no miracle occurs on occasions when the witness testifies to a miracle" (Earman 2000, 41). And the probability of the event some testimony seeks to establish should instead be represented as follows:

$$\Pr [M/t(M) \& E \& K]$$

The resulting probabilistic reading of Hume's maxim is as follows:

$$\Pr [M/t(M) \& E \& K] > \Pr [\sim M/t(M) \& E \& K]$$

This formula is tautologous and unexceptionable. It doesn't have the consequence that either Hume or Sobel intend; it does not deliver an *a priori* argument against the credibility of miracle statements. It turns out, Earman argues, that this rendition of the first part of Hume's maxim also spells trouble for the coherence of the second part, because it would then appear to be counseling an illicit double counting of countervailing factors in the evidence.

The upshot of Earman's analysis is that there is no way to deploy Hume's maxim in an argument against miracles without a careful exploration of the details of historical evidence concerning a miracle statement and testimonial evidence offered in support of it. This Hume failed to do. Earman himself stops short of carrying out this investigation and is, in effect, agnostic about the occurrence of miracles.

While there seems to be no *a priori* philosophical argument against the credibility of miracle statements, there are philosophical resources for estimating the value of historical evidence, such as that developed by New Testament historians for the resurrection (see, for example, N. T. Wright [2003]). Richard Swinburne (2003) goes further, estimating the value of background evidence for theism together with specific historical evidence for the resurrection of Jesus. The background evidence, he argues, provides good reason to expect a miracle or two, reducing the weight that must be carried by specific historical evidence in order to establish the actual occurrence of a miracle. In turn, the historical evidence tends

to confirm the theistic hypothesis because it indicates the fulfillment of the expectation generated by the background evidence and is itself additional evidence for the existence of God.

The philosophical study of the concept of miracle has led to a fruitful exploration of more general issues, such as the metaphysics of causation, the epistemology of testimonial evidence, and, in the philosophy of science, the proper conception of a law of nature.

*See Pico Della Mirandola, Count Giovanni*

## MIURA BAIEN (1723–1789)

Miura Baien, a Japanese Confucianist who in the era of Tokugawa rule most closely approached Western philosophy, was born in Ōita prefecture on the island of Kyūshū.

After the usual training in Chinese classics, Miura went to Nagasaki and learned astronomy, physics, medicine, and economics and developed a great admiration for Western experimental methods. This explains in part his rationalism in opposition to the general reliance on the authority of the classics. He devoted his life to scholarship, refusing several offers to serve feudal lords. To help the poor he organized a relief society based on communal principles. Miura's encyclopedic knowledge also included economics. In *Kagen* (The origin of price) he discussed currency like his contemporary Adam Smith. Miura wrote "if bad money finds wide circulation, good money will go into hiding," a statement similar, in words at least, to Gresham's law.

Miura's main philosophical works are three: *Gengo* (Abstruse words), an exposition of logic; *Zeigo* (Superfluous words), an exposition of the philosophy of nature; and *Kango* (Presumptuous words), an exposition of ethics. *Gengo* is highly esteemed as original because in it he expounds his ideas of *jori*, or the logic of "things" (an abstract concept covering everything). This logic is based not on ancient authority but on rational or experimental grounds. Miura built his logic according to the laws of nature and things. In these he saw a unity and order of antithetic natural elements. He called his dialectic *hankan gōitchi*, or "synthesis of the contraries." This dialectic is both a logical device and the inner reality of things. Things, which are always in the process of becoming, pass from unity to multiplicity and back again, through antithesis and synthesis. His merits as the forerunner of modern trends in science and philosophy notwithstanding, Miura had rather staid political and theological ideas. His criticism of Christianity, in *Samidare-shō*, focuses on the idea that a foreign religion that puts God before devotion to one's lord and one's father cannot be tolerated.

## MODAL INTERPRETATION OF QUANTUM MECHANICS

The term *modal interpretation* is ambiguous. It is a proper name that refers to a number of particular interpretations of quantum mechanics. And it is a term that singles out a class of conceptually similar interpretations, which includes proposals that are not generally referred to as modal ones.

This ambiguity was already present when Bas C. van Fraassen coined the term in the 1970s by transposing the semantic analysis of modal logics to quantum logic. The resulting modal interpretation of quantum logic defined a class of interpretations of quantum mechanics, of which van Fraassen developed one instance in detail, called the Copenhagen modal interpretation. In the 1980s Simon Kochen and Dennis Dieks developed independently an interpretation of quantum mechanics that became known as *the* modal interpretation, turning the term into a proper name. In the 1990s further research produced new proposals, broadening attention to the class of modal interpretations.

The development of modal interpretations can be positioned as attempts to understand quantum mechanics as a theory according to which some but not all observables of physical systems have definite values. Quantum mechanics predicts the outcomes of measurements of observables pertaining to systems and is typically silent about whether these observables have values themselves. Attempts to add to quantum mechanics descriptions of systems in which all quantum-mechanical observables have values became deadlocked in the 1960s: Kochen and Ernst Specker's no-go theorem proved that such descriptions are inconsistent if these values have to comply to the same mathematical relations as the observables themselves; John S. Bell's inequalities showed that the descriptions easily lead to nonlocal phenomena at odds with relatively theory (Redhead 1987). Modal interpretations add descriptions to quantum mechanics according to which only a few *preferred observables* have values, and avoid in this way specifically the Kochen-Specker theorem.

A second common element is that modal interpretations do not ascribe one state to a system, as quantum mechanics does, but two: a dynamical state and a value state. By doing so another peculiarity of quantum mechanics is overcome, namely that states of systems evolve alternately by *two* mutually incompatible laws: the Schrödinger equation that yields smooth state evolution in between measurements, and the projection postulate that yields discontinuous evolution at measurements. In modal interpretations dynamical states of systems evolve with the Schrödinger equation only, and value states evolve typically discontinuously. A particular modal interpretation is now characterized by the value states it assigns to systems; value states fix the preferred definite-valued observables and their values.

Finally there is the claim that modal interpretations stay close to quantum mechanics. The dynamical states that modal interpretations assign can be taken as the states that quantum mechanics assigns, the only difference being that the former do not evolve by the projection postulate. Modal interpretations may thus be said to incorporate quantum mechanics instead of replacing it, as some hidden-variables theories do.

## QUANTUM-MECHANICAL HILBERT-SPACE MATHEMATICS

In quantum mechanics the state and observables of a physical system are represented by mathematical entities defined on a Hilbert space associated with the system. A Hilbert space  $H$  contains vectors  $|\psi\rangle$ , and if it is an  $n$ -dimensional space, there exist sets  $\{|e_1\rangle, |e_2\rangle, \dots |e_n\rangle\}$  of  $n$  vectors that are pair-wise orthogonal. Such a set is called a basis of the space, which means that any vector  $|\psi\rangle$  in  $H$  can be decomposed as a weighted sum of the elements of the basis:  $|\psi\rangle = \sum_i c_i |e_i\rangle$ . The Hilbert space associated with two disjoint physical systems consists of the tensor product  $H_1 \otimes H_2$  of the Hilbert spaces associated with the separate systems. If  $\{|e_1\rangle, \dots |e_n\rangle\}$  is a basis of  $H_1$  and  $\{|f_1\rangle, \dots |f_m\rangle\}$  a basis of  $H_2$ , then any vector  $|\Psi\rangle$  part of  $H_1 \otimes H_2$  can be decomposed as a sum  $|\Psi\rangle = \sum_{i,j} C_{ij} |e_i\rangle \otimes |f_j\rangle$  (a double summation).

Linear operators  $A$  on a Hilbert space are linear mappings within that space. The operator that projects any vector on the vector  $|\psi\rangle$  is called a projector and is written as  $|\psi\rangle\langle\psi|$ . In quantum mechanics the state of a system is represented by such a projector, or by a density projector  $W$  which is a complex sum  $\sum_i \lambda_i |\psi_i\rangle\langle\psi_i|$  of projectors. An observable pertaining to a system (e.g., its momentum or spin) is represented by a self-adjoint operator  $A$ . Self-adjoint operators and density operators can be decom-

posed in terms of their eigenvalues  $a_i$  and projectors on their pair-wise orthogonal eigenvectors  $|a_i\rangle$ , that is,  $A = \sum_i a_i |a_i\rangle\langle a_i|$ . (Complications due to degeneracies, phase factors, and infinities are ignored.)

### PARTICULAR MODAL INTERPRETATIONS

In all interpretations named modal, the dynamical state of a system is represented by a density operator  $W$  on the system's Hilbert space. This dynamical state evolves with the Schrödinger equation and has the usual quantum-mechanical meaning in terms of measurement outcomes: If observable  $A$  is measured, its eigenvalue  $a_i$  is found with probability  $p(a_i) = \langle a_i | W | a_i \rangle$ .

The value state of a system is represented by a vector  $|\nu\rangle$  and determines the values of observables by the rule:  $A$  has value  $a_i$  iff  $|\nu\rangle$  is equal to the eigenvector  $|a_i\rangle$  of  $A$ . This rule leaves many observables without values; a specific value state is an eigenvector of only a few operators, which then represent the preferred observables. Particular modal interpretations fix the value states of systems differently.

In van Fraassen's (1973, 1991) Copenhagen modal interpretation  $|\nu\rangle$  is a vector in the support of the dynamical state (which implies that  $W$  can be written as a convex sum of  $|\nu\rangle\langle\nu|$  and other projectors). Van Fraassen is more specific about value states after measurements. If an observable  $A$  of a system is measured, the dynamical state of the composite of system and measurement device may become  $|\Psi\rangle\langle\Psi|$ , with  $|\Psi\rangle = \sum_i c_i |a_i\rangle \otimes |R_i\rangle$ . The vectors  $|a_i\rangle$  are eigenvectors of the measured observable, and the  $|R_i\rangle$ 's are eigenvectors of a device observable that represents the outcomes (the pointer readings). The value states after this measurement are, according to van Fraassen, with probability  $|c_i|^2$  simultaneously given by  $|a_i\rangle$  for the system and by  $|R_i\rangle$  for the measurement device, respectively.

The decomposition  $|\Psi\rangle = \sum_i c_i |a_i\rangle \otimes |R_i\rangle$  is mathematically special because it contains one summation (as said, a decomposition of a vector  $|\Psi\rangle$  in a product space  $H_1 \otimes H_2$  relative to bases of the separate Hilbert spaces has usually a double summation). This special single-sum decomposition is called the bi-orthogonal decomposition of  $|\Psi\rangle$ , and a theorem (Schrödinger 1935) states that every vector  $|\Psi\rangle$  in  $H_1 \otimes H_2$  determines exactly one basis  $\{|e_1\rangle, \dots, |e_n\rangle\}$  for  $H_1$  and one basis  $\{|f_1\rangle, \dots, |f_m\rangle\}$  for  $H_2$  for which its decomposition becomes such a bi-orthogonal decomposition.

Kochen (1985) and Dieks (1989) use this decomposition to define value states in their modal interpretation:

If two disjoint systems have a composite dynamical state  $|\Psi\rangle\langle\Psi|$  and the bi-orthogonal decomposition of the vector  $|\Psi\rangle$  is  $|\Psi\rangle = \sum_i c_i |e_i\rangle \otimes |f_i\rangle$ , then the value states are with probability  $|c_i|^2$  simultaneously  $|e_i\rangle$  for the first system and  $|f_i\rangle$  for the second. Kochen adds a perspectival twist to this proposal, absent in Dieks's earlier writing: For Kochen the first system witnesses the second to have value state  $|f_i\rangle$  iff it has itself value state  $|e_i\rangle$  (which is the case with probability  $|c_i|^2$ ) and the second system then witnesses, conversely, the first to have value state  $|e_i\rangle$ .

The Kochen-Dieks proposal applies to two systems with a composite dynamical state represented by a projector  $|\Psi\rangle\langle\Psi|$  only. The spectral modal interpretation by Pieter Vermaas and Dieks (1995) generalizes this proposal to  $n$  disjoint systems with an arbitrary composite dynamical state  $W$ . This composite state fixes the dynamical states of all subsystems. Let  $W(x)$  be the dynamical state of the  $x$ -th system part of the composite and let it have an eigenvalue-eigenvector decomposition  $W(x) = \sum_i w_i(x) |w_i(x)\rangle\langle w_i(x)|$ . The value state of this  $x$ -th system is then  $|w_i(x)\rangle$  with probability  $w_i(x)$ . Vermaas and Dieks gave, moreover, joint probabilities that the disjoint systems have simultaneously their value states  $|w_i(1)\rangle$ ,  $|w_j(2)\rangle$ , etcetera.

In the spectral modal interpretation a composite system, say, system 1+2 composed of the disjoint systems 1 and 2, has an eigenvector  $|w_k(1+2)\rangle$  of its dynamical state  $W(1+2)$  as its value state. The atomic modal interpretation by Guido Bacciagaluppi and Michael Dickson (1999) fixes the value states of such composite systems differently. Bacciagaluppi and Dickson assume that there exists a set of disjoint atomic systems, for which the value states are determined similarly as in the spectral modal interpretation, and propose that the value states of composites of those atoms are tensor products of the value states of the atoms: the value state of the composite of atoms 1 and 2 is  $|w_i(1)\rangle \otimes |w_j(2)\rangle$  iff the value states of the atoms are  $|w_i(1)\rangle$  and  $|w_j(2)\rangle$ , respectively.

### THE CLASS OF MODAL INTERPRETATIONS

The class of modal interpretations comprises those proposals according to which only a few observables have values, and that can be formulated in terms of dynamical and value states. The interpretations by Richard Healey (1989) and by Jeffrey Bub (1997) have this structure quite explicitly and are therefore often called modal ones (Healey's proposal has a number of similarities with the Kochen-Dieks proposal; in Bub's the value state of a system is an eigenvector of an observable fixed independ-

ently of the system's dynamical state). One may argue that David Bohm's mechanics (1952) is also a modal interpretation.

## RESULTS

The development and application of modal interpretations have led to mixed results. The maximum set of observables that can have values by modal interpretations without falling prey to the Kochen-Specker theorem has been determined (Vermaas 1999). Bub and Rob Clifton showed that this set is the only one that satisfies a series of natural assumptions on descriptions of single systems (Bub, Clifton, and Goldstein 2000). The evolution of value states, which determines the description of systems over time, can be given (Bacciagaluppi and Dickson 1999). This evolution was, however, shown not to be Lorentz-covariant for the spectral and atomic modal interpretations and, to a lesser extent, for Bub's interpretation, revealing that the assumption that only a few quantum-mechanical observables have values, still may lead to problems with relatively theory (Dickson and Clifton 1998, Myrvold 2002).

Moreover, even though this assumption yields consistent descriptions of single systems, joint descriptions of systems were still proved to be problematic. First, it is commonly assumed in quantum mechanics that the observable of a system 1 represented by the operator  $A$  defined on  $H_1$ , and the observable of a composite system 1+2 represented by the operator  $A_1 \otimes I_2$  on  $H_1 \otimes H_2$  ( $I_2$  is the identity operator on  $H_2$ ) are one and the same observable. The Copenhagen, Kochen-Dieks, and spectral modal interpretations have the debatable consequence that these observables should be distinguished (Clifton 1996). Second, the spectral modal interpretation cannot give joint probabilities that systems 1, 2, ..., and their composites, 1+2, ... , have simultaneously their value states  $|w_i(1)\rangle$ ,  $|w_j(2)\rangle$ ,  $|w_k(1+2)\rangle$ , etcetera (Vermaas 1999, ch. 6).

These negative results motivated in part the formulation of the atomic modal interpretation but can also be avoided by adopting Kochen's perspectivalism, which implies that one accepts constraints on describing different systems simultaneously. Finally, the Kochen-Dieks, spectral, and atomic modal interpretations have problems with properly describing measurements, doubting their empirical adequacy. David Albert and Barry Loewer (1990) argued that after a measurement, the dynamical state of the system-device composite need not be  $|\Psi\rangle\langle\Psi|$  with  $|\Psi\rangle = \sum_i c_i |a_i\rangle \otimes |R_i\rangle$ , and that the mentioned interpretations then need not yield descriptions in which the device displays an outcome (Bacciagaluppi and Hemmo 1996).

## ASSESSMENT

These results allow critical conclusions about particular modal interpretations and raise doubts about the viability of the class of modal interpretations. Three remarks can be made about this assessment.

First, an evaluation of the results may depend on what one expects from interpretations. If interpretations are to provide descriptions that allow realist positions about quantum mechanics, the inability of, say, the spectral modal interpretation to give joint probabilities that systems have simultaneously value states, proves this interpretation problematic. But if interpretations, in line with van Fraassen's view, are to yield understanding of what quantum mechanics means, this inability of the spectral modal interpretation is an interesting conclusion about how quantum-mechanical descriptions of systems differ from those of other physical theories. The result that some modal interpretations may be empirical inadequate, is, however, fatal independently of one's expectations for interpretations.

Second, the set of particular modal interpretations that is analyzed so far does not exhaust the class of modal interpretations. Research therefore continues (e.g., Bene and Dieks 2002).

Third, these results are relevant to the project of interpreting quantum mechanics in general. Existing and new interpretations, modal or not, according to which only some observables have definite values, are constrained by the negative results and can now be assessed as such; and existing and new interpretations may benefit from the positive results about modal interpretations.

## MODALITY, PHILOSOPHY AND METAPHYSICS OF

Some things are true; some are false. Some are true, but might have been false. Some are true but could not have been false. Some are false, but might have been true. Some are false but could not have been true. Thus, there are at least these different modes of truth and falsity: necessity and possibility. A truth bearer—a proposition, a statement, or an interpreted sentence—is necessarily true if and only if (iff) it is not possible that it be false; it is possibly true iff it is not necessary that it be false. A contingency is what is possibly true as well as possibly false. The study of the ways in which truth and falsity interact with necessity and possibility is the subject of modal logics.

If there are modal distinctions to be made about truth bearers—because, say, while the sum of seven and five could not fail to be twelve, there might have been twelve planets orbiting the sun even though there are not—arguably there are modal distinctions to be made regarding the attributes objects possess. While Socrates could have failed to be snub-nosed, he could not have failed to be human or perhaps a person. Modality as it pertains to the bearers of truth is *de dicto* modality; modality that concerns the way in which an object possesses an attribute is *de re*. Conventionally,  $\Box$  and  $\Diamond$  express necessity and possibility, respectively.

### KINDS OF NECESSITY

Necessities may be distinguished according to their scope or, perhaps, their subject matter. Some concern the limits of meaning and inference and are systematized by formal logical systems. Classical logicians maintain that meaning and inference are best understood in terms of a two-valued logic according to which truth bearers may take only the values of true or false and that exactly one of a truth bearer and its negation is true. These ideas are encoded by, though not strictly equivalent to, the laws of excluded middle,  $P \vee \neg P$ , and noncontradiction,  $\neg(P \ \& \ \neg P)$ . Where objects and their attributes are concerned, there are analogous laws: Each thing either has or lacks a given attribute and neither both has and lacks the same attribute, formally represented as  $\forall x(Fx \vee \neg Fx)$  and  $\forall x\neg(Fx \ \& \ \neg Fx)$ . Some nonclassical logics have correspondingly different foundational laws. Such laws of logic are treated as necessary truths, though usually they are stated without any *de dicto* modal qualifier. Logical truths, the truths that follow validly from the axioms of logic, are the logical necessities. Whatever is consistent

with the laws of logic are the logical possibilities and if the falsity of something follows from the laws of logic, then it is a logical impossibility.

Disputes about which of the many logical systems is the single correct system that formalizes valid inference are, then, disputes about what the logical necessities are. Disputes about whether there is a single such correct system are disputes about whether there is a plurality of sets of logical necessities, one corresponding to each system of logic. Broader notions of logical necessity are sometimes given by adding linguistic or conceptual truths. Analytic or conceptual necessities are those that follow from the laws of logic plus the linguistic or conceptual truths. That all bachelors are unmarried is a favorite example of such an analytic truth.

Laws of nature and their associated counterfactual conditionals are often thought to be necessary in one sense and contingent in another. There are many true universal generalizations and many unbroken sequences of types of events. Not all of these, however, form part of some scientific theory; some generalizations and patterns are accidental. Those that are not accidental and constitute the fundamentals of a scientific theory are the laws of nature and whatever follows from those laws are the natural necessities. Whatever is consistent with the laws of nature are the natural possibilities. It is sometimes useful to make distinctions among the natural necessities and separate the physical, chemical, biological, psychological, and perhaps other necessities.

The natural necessities are not logical truths, however. Orthodoxy has it that logical truth is known *a priori*, without any specific experiences, while scientific truth is knowable only *a posteriori*, on the basis of experience. That empirical investigation is required for scientific knowledge is taken to show that the natural necessities are contingent; they might have been otherwise. Certainly, they are not analytic and cannot be known simply by reflecting on their contents. If one takes the most central laws of physics to be the axioms of physics, then what follows from those laws are the physical necessities. That the basic physical laws are required to infer the physical necessities demonstrates more conclusively that the physical necessities are not logical truths and, so, are not logical necessities. If laws of nature are necessary in some legitimate sense, then the meaning of  $\square$  when applied to laws of nature must differ from its meaning when it is applied to laws of logic.

Somewhat more controversial is the idea that there is an intermediate modality between the logical and the natural: the metaphysical. Like natural necessities, meta-

physical necessities are not logical truths and yet, unlike the natural necessities, the central metaphysical principles are to be known *a priori* even if knowledge of some particular metaphysical necessities requires some empirical knowledge. While there is no contradiction in denying such metaphysical principles, their proponents maintain that they are, nevertheless, necessary and that they express limits on genuine possibilities for existence. Accordingly, logical possibilities that fail to be metaphysical possibilities would be merely formal possibilities.

Thus, if there are two distinct attributes that are essentially related, then while there is no contradiction in asserting that an object could possess the one without the other, it would be, strictly speaking, impossible for any object to possess the one without the other. There might be attributes such that if an object even possibly possesses it, then that object possesses that attribute essentially. Arguably, if something is a concrete object such as a brick, then it must be concrete and could not be an abstract object such as the power set of the real numbers. Those who embrace this intermediate modality think that metaphysical principles state nontrivially what is at least part of the essence of an object—that without which it could not be—and, so, they are known as essentialists or sometimes Aristotelian essentialists since Aristotle advocated a form essentialism.

While the philosophy of modality is dominated by controversies about whether there are the three modalities mentioned and, if so what their relations are, there are others of interest. If one takes up the general pattern used earlier and recognizes that a common way to characterize the content of a modality is to formulate a set of axioms and define a sense of  $\square$  so that it applies to all and only whatever follows from those axioms, then there are indefinitely many kinds of modality. For each formally characterized system of logic there is a candidate for logical necessity, not all of which are equivalent. Such a plurality cascades down through any modality that relies on logical consequence for its own characterization.

Among the most commonly discussed of the other modalities are the epistemic, doxastic, and moral necessities. Epistemic necessity can be thought of as whatever follows from what is known and the scope of the known can be specific to an individual or to a community. Doxastic necessity is what follows from what is believed. Moral necessities are the relevant moral obligations and duties. Whether any of the modalities mentioned is nothing but a special form of any of the others is a substantial question, but the only clear connection, given the way they have been characterized, is that all the nonlogical

modalities tacitly embed the logical. The axiom-theorem structure demands this, making each of them an extension of the logical and not a special case of it.

### SOURCES OF NECESSITY

For any recognized kind of necessity there is the substantive question of what accounts for the fact that some truths, and not some others, are necessary in the relevant sense. As with other forms of discourse, there are deep philosophical questions about whether one has any knowledge involving modality. These questions have at least two forms. The first form is a standard challenge from the skeptic who does not deny, in this context, that there are necessary truths but who denies either that one has any knowledge of which truths are necessary or that nonskeptics are entitled to their knowledge claims according to their own standards of knowledge. The second form comes from the modal antirealist, one who either denies that there are any modal truths or who claims that modal truth is so closely bound to cognizers that statements involving modality lack significant objectivity, making them more like statements of taste or preference than statements of fact. Modal noncognitivists maintain that modal discourse is used not to make assertions but to, perhaps, express an attitude or a commitment toward some nonmodal truths. David Hume (1739) adopted a kind of noncognitivism about the relation of cause and effect. Simon Blackburn (1986) and Crispin Wright (1980, 1989) advanced contemporary defenses of versions of modal antirealism.

Realist interpretations of modal discourse treat some statements involving modality as true in some person-independent manner. If modal truth is to be a species of truth more generally then, thinks the realist about modal discourse, modal truth must concern sufficiently determinate and objective facts. This is the question of what grounds modal truth or, perhaps, what the truth conditions are for modal claims. Common suggestions have been that something is possible iff it is conceivable, iff it implies no contradiction, iff it is true in at least one mathematical model, or iff it is true in at least one possible world.

The success conditions for a theory of modality depend on the purpose of that theory. Any successful theory should be extensionally adequate; it should declare as necessary all and only what is necessary. Philosophical theories are often put forward as being more than merely extensionally adequate, sometimes because they are intended as linguistic or conceptual analyses. A conceptual analysis would state not only the appropriate bicon-

ditionals that fix the extension of *necessary*, it would do so in such a way that analyzed the meaning of that term. Successful conceptual analyses must not only be extensionally adequate, they must also be noncircular by avoiding the use of what is to be analyzed in the analysis or definition. Analyses of modal notions would need to avoid analyzing *necessary* in terms of any modal notions like *necessary*, *possible*, or their cognates. When empirical confirmation of the extensional adequacy of a theory is impossible to obtain, conceptual analyses are attractive. The conceptual analysis guarantees extensional adequacy because the analysis given means nothing more and nothing less than that for which it is a theory. Theories not intended as conceptual analyses must involve some other warrant for the thesis that the theory is extensionally adequate.

If proposed as an analysis, a conceivability theory faces difficulties regarding both extensional adequacy and circularity. If it is formulated in terms of conceivers who are not perfect conceivers, then extensional adequacy is not guaranteed; there may be possibilities of which no one is capable of conceiving or else conceivers may be capable of conceiving what is impossible without noticing that it is impossible. Formulating the theory in terms of what is merely conceivable, whether by an ideal or fallible conceiver, renders the analysis circular because the semantic analysis of *possible* is given in terms of what it is possible to conceive. Formulating it in terms of what is actually conceived by an omniscient being avoids this circularity but brings metaphysical commitments that few want to make on the basis of their philosophy of modality alone.

The logical positivists wished to maintain that logical and mathematical truths were necessary, but they resisted all substantive metaphysics as distinct from the ontologies of the sciences. Alfred J. Ayer (1936) developed a version of conventionalism about modality. By dividing propositions into the classes of those that concern ideas or concepts only and those that concern facts, Ayer maintained that only propositions regarding ideas were both necessary and knowable *a priori*. They make no claims about the empirical world and, so, are not subject to empirical falsification and are either necessarily true or necessarily false. These propositions are analytically true or analytically false according to Ayer because they are true or false due solely to the definitions or analyses of their constituent symbols, both logical and nonlogical. It is necessarily true that all bachelors are unmarried not because of the way the world is but because of what is meant by *all*, *bachelors*, *unmarried*, and tacitly, *if, then*.

Willard Van Orman Quine provided what has become the received critique of attempts to ground necessary truth and falsehood in the facts of language. In “Two Dogmas of Empiricism” (1951) Quine argued that there is no hard and fast distinction between propositions that are about the world and those that are not and, so, that no proposition is immune from refutation on partly empirical grounds. Thus, he argued that there is no interesting analytic-synthetic distinction on which the positivist program depends. In “Truth by Convention” (1948) he argued that stipulations regarding the meanings of expressions cannot be a general source of necessity, since at most they can transform obvious logical truths into more convenient but less obvious truths.

So, it is a logical truth that all unmarried males are unmarried and if bachelors just are, by definition, unmarried males, then the logical truth plus the definition of *bachelor* is sufficient for the truth of “all bachelors are unmarried.” However, this transforming work of definitions requires something to begin with that is already necessarily true: the relevant logical truth. Linguistic conventions are unable to account for the necessity of the logical truths. Rudolf Carnap (1954) tried to solve this problem by avoiding the semantic foundation of meaning, thus avoiding Quine’s critique, and by relying on syntactic facts of grammar and rules of logical proof. He understood logical truth as what is derivable from the null class of sentences.

While not relying on meanings, the standard problems regarding extensional adequacy and circularity arise. Standard understandings of logical systems have it that there are infinitely many sentences that may be derived from the null set, not all of which have been derived. Framing the theory in terms of what has actually been derived renders the account extensionally inadequate, while framing it in terms of facts of derivability renders it circular. A successful form of the linguistic theory of modality might retreat from the positivist’s rejection of all metaphysics and appeal to facts about concepts or propositions in a Platonic Heaven of abstract objects. Alternatively, there could be a stipulation by a kind of ostension according to which *necessary* is stipulated to apply to some already established classes of truths, say logical, mathematical, and analytic truths. This would give one a kind of conventional basis for necessity, but not for the truth of what is by this convention called *necessary*. This account assumes that there are logical, mathematical, and analytic truths before the stipulation. While each account avoids the problems posed for Ayer’s (1936) and Carnap’s, they do not deliver what the positivists

wanted: a general theory that demonstrates why logical, mathematical, and analytic truths are completely immune from empirical refutation while at the same time avoiding all metaphysics that they found philosophically distasteful. Alan Sidelle (1989) attempted to present a more defensible version of conventionalism.

## POSSIBLE WORLDS AND MODAL LOGIC

Before and during the time that the positivists were developing their philosophical approach to modality and Quine (1948, 1951) was subjecting it to critical scrutiny, elementary first-order predicate logic was being extended with the use of modal operators, most famously by Clarence Irving Lewis (1918) and Lewis and Cooper Harold Langford (1932). Unlike the developments of nonmodal logics up to that time, about which there was widespread agreement that alternative axiom systems were equivalent, there were many inequivalent axiomatic systems of modal logic. Worse, standard first-order logics had been provided with mathematical semantic foundations from which the systems of proof could be shown to be adequate for proving all theorems of first-order logic and for never permitting the derivation of any nontheorems. Modal logics lacked a similar semantic framework. The many inequivalent systems made it impossible, on formal grounds alone, to determine which logic was the proper formalization of modal concepts that, in turn, caused some to wonder whether modal concepts were sufficiently respectable to be given systematic treatment.

Part of the difficulty arose because the modal expressions in formal languages,  $\Box$  and  $\Diamond$ , were treated like the negation symbol,  $\neg$ . Thus, if  $P$  were a sentence of the formal language,  $\neg P$ ,  $\Box P$ , and  $\Diamond P$  would also be sentences of the language. Like negation, the modal operators could be used in quantified sentences of the language, so that if  $\forall xFx$  and  $\exists xFx$  were sentences of the language,  $\Box\forall xFx$ ,  $\forall x\Box Fx$ ,  $\Box\exists xFx$ , and  $\exists x\Box Fx$  would be as well. The *de dicto* use of modality in  $\Box\forall xFx$  and  $\Box\exists xFx$  seemed innocent enough to those who were not convinced by Quine’s (1951) critique of analyticity. More troublesome were the *de re* forms,  $\forall x\Box Fx$  and  $\exists x\Box Fx$ . In stating that everything is necessarily or essentially  $F$  and that something is necessarily or essentially  $F$ , these sentences seem to make metaphysical claims, about which the positivists had succeeded in raising suspicion.

In 1963 Saul Kripke made prominent some developments in the semantics of modal logic. The central idea was to mimic an important aspect of the formal semantics for first-order logic. The mathematics of model the-

ory that had enabled logicians to define what it is for an argument to be formally valid involved appealing to a domain of objects, mathematical models, that were customarily thought to be abstract objects. In these models, one could define the extensions of predicates, intuitively the sets of objects that possessed the relevant attributes or that stood in the relevant relations to each other. Logical notions like validity could be defined in terms of these mathematical models.

Kripke and others saw that if this model-theoretic framework were extended, a similar formal semantics could be given for modal logics. Whereas standard models had concerned only everything that does exist, the extension of this approach was simply to take as the domain everything that exists not only in the actual world but also everything that exists in every possible world. The second key idea was to treat the modal operators like quantifiers. If  $\Box$  was treated as  $\forall$  and  $\Diamond$  as  $\exists$ , then  $\Box P$  could be thought of as expressing the claim that  $P$  is true in every possible world and  $\Diamond P$  could be thought of as expressing the claim that  $P$  is true in at least one such world, whether this world or not. A historical overview of developments of this general approach before Kripke's elegant presentation can be found in B. J. Copeland (1996).

## POSSIBLE WORLDS AND METAPHYSICS

Those proposing this possible worlds semantics for modal logic thought of the structure quite abstractly. The suggestion to think of the main domain as the set of all possible worlds was merely a heuristic to illuminate the intuitive idea behind the abstract structure of the semantics. It was David Lewis (1973) who recommended taking this heuristic to have metaphysical significance. He argued that modal claims can be paraphrased with claims about possible worlds. Many agreed with this much, but resisted Lewis's genuine modal realism," according to which each world in this plurality was as robust and concrete as one thinks of this world. In some of these worlds there are donkeys that talk and in some there are blue swans. So, while those concerned with the semantics of modal logic were concerned with providing a formal mathematical structure according to which important logical notions like logical consequence could be precisely characterized, Lewis was concerned with the issue of the grounds for the truth values of modal claims. So, for Lewis,  $\Box P$  is true iff  $P$  is true in all the worlds; otherwise, not.

The formal apparatus involved an accessibility relation over this set of worlds and that relation could have variable extension. This permitted Lewis (1973) to assess counterfactual conditionals in terms of what happens not merely in some world or other, but what happens in close or sufficiently similar worlds. Thus, in some circumstances I could have done otherwise because in an appropriately similar world one similar to me does otherwise.

Lewis's (1973) genuine modal realism served as the focus of much discussion about the philosophy and metaphysics of modality, although the position has had relatively few adherents. The possible worlds theorist was able to take the mathematical results about modal logic and to find in them the grounds for modal truth. Initial discussions of the possible worlds framework, however, focused on reasons for thinking that while the framework should be adopted, Lewis's metaphysics of possible worlds should be resisted.

One serious problem for the genuine modal realist is epistemological. Suppose that there really is a plurality of concrete worlds and that it is facts about these worlds that make true or false one's modal assertions. How can this account of the truth conditions for modal claims be squared with the often-unstated starting point in the philosophy of modality: that one possesses some knowledge of modal truth that is not merely trivial? One thinks that one knows that there could be talking donkeys, blue swans, and many more things that do not actually exist. One also thinks one knows the truth of some counterfactual conditionals, such as that were the sun to cease to exist, then the earth would cool rapidly and that were a thin pane of ordinary glass to be struck by a flying rock, it would break. If the modal facts, however, really are facts about other worlds, how could one have gained any of this knowledge?

A second apparent problem is that the possible worlds framework looks ill suited to the task of philosophical analysis of modal idioms. If one says that  $\Diamond P$  is true iff  $P$  is true in every possible world, then the analysis certainly appears to be extensionally adequate, but at the cost of circularity. If one says, rather, that  $\Diamond P$  is true iff  $P$  is true in every world that there is, then obvious circularity is avoided at the cost of no longer exhibiting the extensionally adequacy of the analysis.

The epistemological problem was addressed by those who proposed accounts of the nature of possible worlds in terms of objects that, it was maintained, one already had reason to accept. Instead of thinking of truth in possible worlds as truth in or about concrete maximal spatiotemporal wholes, it was argued that truth in possible

worlds is really truth in maximal states of affairs (Plantinga 1974), truth in world stories—maximal consistent sets of propositions (Adams 1974), or truth about properties of a special kind—ways the world might have been (Stalnaker 1976). Each theory was actualist in that it recognized only objects that actually exist or, to use the vocabulary of possible worlds, each recognized only objects that exist in the actual world. To that extent each of these alternatives had the advantage of locating the ground for modal truths in this world and not another. That there was a useful solution to the general form of the epistemological problem posed for Lewis's (1973) genuine modal realism depends on whether the central feature of the problem was that the modally relevant facts inhabited or constituted worlds distinct from one's own.

Arguably, the central feature of the problem was that it was hard to wed the metaphysics of concrete worlds with plausible accounts of the nature of knowledge. Lewis's account of worlds permitted no physical or causal contact with features of other worlds. To avoid this general problem, some mutually favorable accounts of the natures of states of affairs, propositions, or properties on the one hand and knowledge on the other hand are required. To the extent that these entities are abstract and to the extent that abstract entities are not spatiotemporally or causally located, these actualist theories do not solve this epistemological problem. To the extent that spatiotemporal connectedness is not necessary for access to, say, propositions, then the genuine modal realist could, perhaps, take advantage of an alternative account of knowledge to avoid this particular problem.

Lewis (1986) recognized that his theory of modality could not serve as the basis for a proper analysis of modal notions, if he could not analyze the concept of a possible world. If he could not, possible truth would be analyzed in terms of possible worlds that, while involving some philosophical advance perhaps, does not constitute a full analysis of modal concepts in nonmodal terms. Lewis (1986) argued that each world is a maximal spatiotemporally connected whole; objects inhabit the same world when they spatiotemporally connect to each other. On the reasonably safe assumption that these spatiotemporal notions are not themselves modal, obvious circularity is avoided.

Extensional adequacy must still be secured. Lewis (1986) tries to secure it by somewhat contentious means. He appeals to a Humean principle of recombination to support the thesis that there are sufficiently many possible worlds. Recombination is the denial of necessary connections between distinct existences. So long as the

objects occupy distinct spatiotemporal locations, anything could exist with anything else or, strictly speaking, a duplicate of anything could exist with a duplicate of anything else. This basis for plenitude is more contentious than was the avoidance of obvious circularity because it depends on the more controversial Humean principle. Essentialists reject that principle as do those who maintain that laws of nature are metaphysically necessary.

There may yet be some hidden circularity or other theoretical impropriety as argued by Scott A. Shalkowski (1994, 2004). Of course, if there is a plurality of concrete worlds in which sufficiently much of what one takes to be possible is true, then knowing this would be sufficient warrant for declaring that possible truth just is truth in some world or other. It is knowing that there is this match between one's apparent modal knowledge and the internal workings of the worlds in the plurality that is difficult to secure in a nonquestion-begging way. Were philosophical analysis sufficient to justify not only that there are possible worlds, but that they are concrete and sufficiently plentiful for the required correlation, then all would be well for the genuine modal realist. John Divers and Joseph Melia (2002), however, argued that analysis is inadequate to establish that there are sufficiently many worlds. The danger, then, is that the grounds for genuine modal realism as a full theory of modality are question-begging or else inadequate. Furthermore, they argue that the framework may not even be extensionally adequate because there may be no complete set of all possible worlds.

Some objections to genuine modal realism concerned whether the conditions it provides really are adequate to grounding the modal claims one thinks one is entitled to make. For example, one knows that in some instances one could have behaved otherwise than one did. Strictly speaking, though, I am a world-bound individual. I inhabit only this spatiotemporal whole and not another. However, it is what goes on in other worlds that is supposed to account for the fact that I could have behaved otherwise. I could have behaved otherwise because some world contains a counterpart of me that does, in a suitably similar situation, behave otherwise. This is Lewis's counterpart theory (1968, 1986).

Kripke (1972/1980) argued that counterpart theory is inadequate precisely because the modal claim under consideration concerns what I could do. How does what someone else somewhere else does make it the case that I could have followed that alternative course of action? That someone else in this space-time does something else

does not make it the case that I could have done the same, so someone else in another space-time seems no more relevant.

Though Kripke's (1972/1980) objection has intuitive appeal, arguably it is question-begging. Lewis (1986) develops counterpart theory so that the identity of individuals across worlds, transworld identity, just is a matter of having a counterpart in those other worlds. Just as there are philosophical issues about in what identity over time consists, there are philosophical issues about in what identity in modal contexts consists. According to some theories of identity over time, an object that lives for a hundred years is constituted by distinct temporal parts. There is, therefore, precedent for something like counterpart theory. What counts as a counterpart of an object in a distinct world is a matter of relevant similarity, where relevance is determined by, for example, the counterfactual conditional to be assessed. Similar remarks apply to Alvin Plantinga's (1974) objection from numerical identity.

D. M. Armstrong (1989) argued for a somewhat less ontologically ambitious modal realism: combinatorialism. According to combinatorialism possible worlds are recombinations of individuals, properties, and relations of the actual world. Like Lewis (1968), Armstrong relies on a Humean principle of recombination. A recombination of actual objects and actual properties and relations constitutes a nonactual possible world. One difference is that Lewis formulates his principle in terms of duplicates of objects, whereas Armstrong does so in terms of the objects themselves. Where Lewis has no need to countenance qualitatively indiscernible worlds as distinct, Armstrong does. That an object, *a*, is *F* and that another, *b*, is exactly like *a* except that it is *G* instead of *F*, provides for a recombination exactly like the actual world save that in this recombination it is *b* that is *F* and *a* that is *G*. This seems to involve a commitment to haecceitism, the view that there are nonqualitative differences between worlds. Though this seems to be a natural consequence of his basic combinatorial insight, Armstrong rejects haecceitism.

There are two important issues that confront the combinatorialist. First, some principled, nonmodal restriction on the principle of recombination must be given, since if there is no such restriction, impossible worlds will result and the theory will be extensionally inadequate. With no restriction, there is a recombination in which some object is both wholly red and wholly green, thus rendering it false that  $\Diamond P$  is true iff *P* is true in at least one of the combinatorialist's worlds. Armstrong (1989)

attempts restrictions that arise naturally from his own theory of universals in an attempt to solve this problem.

More significant is the problem of alien properties. It is plausible that there could be objects that possess properties that no actual object possesses and that cannot be constructed from any properties that actual objects possess. Unless one is prepared to claim that one's world is maximally qualitatively rich, this consequence is unwelcome. Those who, like Armstrong (1989), wish to acknowledge the existence only of properties that are exhibited, must concede that this is a feature of the theory, in spite of strong reasons to the contrary. For other than special pleading, what reason is there for thinking that this world does not stand to another world in the relation of relative-impoverishment with respect to properties as some simpler worlds stand in relation to this one? Those who adopt a more Platonistic theory of properties and recognize uninstantiated abstract properties avoid this problem of alien properties, but at the cost of needing to solve the epistemological problems regarding one's knowledge of properties rather than one's knowledge of the genuine modal realist's worlds.

## FICTIONALISM AND MODALISM

One development that at least initially promises to retain the advantages of genuine realism without this epistemological trouble is modal fictionalism. Strictly speaking, while it is possible that there be talking donkeys, there are none. However, it is also literally true that according to the fiction of possible worlds, there are worlds in which there are talking donkeys. Gideon Rosen (1990) suggested that  $\Diamond P$  is true iff according to the fiction of possible worlds, *P* or some appropriate paraphrase is true in some possible world. Possible worlds are taken to be useful fictions in the same way that scientists have found ideal gases and frictionless planes to be theoretically useful. Whether fictionalism gains any theoretical advantage over modal realism depends on the content of the operator "according to the fiction of possible worlds." It is natural to think that this should be interpreted as something like: "if the fiction of possible worlds were true, then," which is apparently modal.

Whether this is a problem for fictionalism is a matter of its point. If it is to possess all the advantages that Lewis (1986) claimed, specifically an account of all modal truth, then if the fictional operator is modal, fictionalism fails. The fictionalist also confronts a problem with incompleteness. No modal realist has given a complete specification of the contents of each world, so strictly speaking the modal fictionalist is confronted with truth value gaps

for the modal claims about which the modal realist has been silent. The realist can be content with this silence since the realist need not be committed to anyone being modally omniscient. That there are gaps in the fictionalist account is a departure from orthodoxy that must be warranted by significant argument.

Kit Fine (1977), Christopher Peacocke (1978), and Graeme Forbes (1989) suggested a modalist approach that rejects the call for a reductive theory of modality in nonmodal terms. If anything, the explanation goes in the opposite direction: something is true in a possible world iff it is possibly true. For the modalist, reality is irreducibly modal and this is exhibited by the attempts to translate the whole of the possible worlds theory into a modal language, expanding the basic modal language to include an actuality operator as well as indices for the operators to permit the tracking of modal contexts. For example, if one permits oneself  $w_1$ , to be a variable ranging over worlds,  $w^*$  to stand for the actual world, and  $E$  to be a two-place predicate by which one can express that an object exists in a world, then the possible worlds translation of “There could have been more things than there actually are” is:

$$\exists w_1[\forall w\forall x(Exw^* \rightarrow Exw_1) \ \& \ \exists y(\neg Eyw^*)].$$

Where  $\Diamond_1$  permits one to express a given possibility,  $A$  expresses actuality, and  $A_1$  expresses what is actual in a specific possibility, the modalist translation for this is:

$$\Diamond_1\{[\Box\forall x(AEx \rightarrow A_1Ex)] \ \& \ \exists y\neg AEy\}.$$

Melia (1992) argued that the modalist translation is not a reduction of possible worlds discourse at all, but merely a notational variant of the possible worlds statement. Even if it is granted that one has a firm grasp on the modalist’s basic modal and actuality operators, once the subscripts are added and one operator is placed within the scope of others, one has no intuitive grasp of their meanings in those contexts. The only way to understand them, indeed the way the modalist explains them, is by reference to the possible worlds semantics. Contrary to the modalist claims, this makes it appear as though possible worlds discourse, not the modalist’s, is semantically basic and more perspicuous.

Some assumed that modalism is to be recommended only if it can reduce possible worlds discourse in modal terms. However, why, exactly, should the modalist provide translations of all possible worlds claims? What must be determined is what, if any, possible worlds claims are merely artifacts of the possible worlds framework. It is no reason to give up modalism if it cannot accommodate

mere artifacts of the possible worlds framework that is, ultimately, rejected as a literal account of modal metaphysics. For instance, according to Lewis’s (1968) developments, each world is as it is. It is not essential that a world be that way, but it is essential that that specific world be that particular way. Being that way is precisely what distinguishes that world from all others. Modalists are not bound to make this essentialist claim part of their theory. So long as the modalist can say all that one has either theory-neutral or modalist grounds for asserting, the failure to translate all the modal realist’s claims should not count against modalism.

Though modalism is not wedded to essentialism, Fine (1977) argued not only that reality is irreducibly modal but also that *de re* modality is more basic than *de dicto*, defending the most general aspects of essentialism defended by Kripke (1972/1980) and Hilary Putnam (1975). These works brought essentialism back into philosophical discussion among analytic philosophers. Each was concerned with the semantics for proper names and natural kinds terms. Once necessity, analyticity, and *a priority* were clearly separated from each other, some essentialist theses—such as that the origins/genealogy are essential to some objects and that substances have their chemical constitution essentially—became more plausible. Fine extended this so that *de dicto* modality, concerned as it is with the necessary truth and falsehood of some propositions, is explained by *de re* modal facts about the natures of truth bearers or concepts or logical functions. This provides essentialism with an explanatory role so that if objects, whether concrete or abstract, have properties without which they would not be those very objects, then modal truth is on a par with nonmodal truth. Truth, whether modal or nonmodal, depends on being. The modalist simply maintains that being is irreducibly modal.

## MODALITY AND METAPHYSICS

In the end, the philosophy and metaphysics of modality rests on metaphilosophical foundations. Many of the objections to the various positions have been piecemeal, showing that a theory has some consequence that is supposed to be intolerable. Lewis (1986) made quite clear that the case for genuine modal realism was a philosophical inference to the best explanation, not a single silver bullet-like argument. He claimed that when all things were considered his theory possessed the best balance of theoretical virtues and vices. Other theories might rely on less controversial ontologies or they may avoid some other counterintuitive consequences of modal realism.

Nevertheless, when all things are taken into account, Lewis thinks that his theory is the best package. Those willing to engage Lewis on his own terms must provide comparable details about the relative merits and difficulties of an alternative to properly undercut the warrant that Lewis thinks that he has given for modal realism.

An alternative is to question the appropriateness of inference to the best explanation in metaphysical contexts. That argument form is typically associated with contexts in which prior experience showed that one kind of event or fact—the activity of mice—explained another—the disappearance of cheese. When one confronts another instance of missing cheese and one has been unable to observe rodents, the inference to the activity of mice might well be appropriate. In metaphysics there is no analogue to prior experience. If the legitimacy of an argument form is not knowable *a priori*, some *a posteriori* basis is needed for thinking that the argument is appropriate to a given context of application. One knows that statistical inferences are appropriate under some conditions and not others because of what one knows from empirical investigation of the world. In the absence of some general reason to think that a metaphysical theory is more likely to be true when it is the conclusion of an inference to the best explanation, the application of an inference form may be warranted in some empirical contexts but unwarranted in metaphysical contexts. Thus, warrant for a specific theory of modality depends on deeper considerations about forms of argument appropriate to metaphysics.

## MODALITY AND LANGUAGE

See Appendix, Vol. 10

## MODALITY AND QUANTIFICATION

Quantified modal logics combine quantifiers ( $\forall$  for *all*, and  $\exists$ , for *some*) with an intensional operator  $\Box$  (for such expressions as 'necessarily' and 'Ralph believes that'). Quantifying into intensional contexts (or quantifying in, for short) occurs when a quantifier binds an open variable that lies within the scope of  $\Box$ , as in sentences with the form  $\exists \Box Fx$ . Systems of quantified modal logic (QML) routinely include formulas of this kind, but Willard Van Orman Quine (1963) famously argues that quantifying in is incoherent.

Here is a quick summary of his main line of reasoning. Consider (1)–(3), an apparent counterexample to the law of substitution for identity:

- (1) 9 equals the number of planets
- (2) Necessarily 9 is greater than 7
- (3) Necessarily the number of planets is greater than 7

Although (3) is the result of the substituting 'the number of planets' for '9' in (2), and both (1) and (2) are true, (3) is presumably false. Quine calls term positions where substitution fails opaque contexts and argues that terms occupying them do not play their normal referring roles. Both '9' and 'the number of planets' refer to nine, so something other than the terms' referents must explain why the truth values of (2) and (3) differ. Presumably, the difference is in the manner of referring to or describing nine. Now note that the standard truth condition for  $\exists$  says that (4) is true if and only if (iff) the open sentence (5) is true of some object:

- (4)  $\exists x(\text{necessarily, } x \text{ is greater than } 7)$
- (5) Necessarily,  $x$  is greater than 7

However, (5) results from putting 'x' for either '9' in (2) or 'the number of planets' in (3), and (2) and (3) were sensitive to the manner in which nine is described. Since 'x' does not describe anything at all, information needed to make sense of (5) being true of an object is now missing. As Quine puts it, what object is (5) true of? Presumably, it is nine, that is, the number of planets. However, the

number of planets appears not to satisfy (5), since (3) was false.

Arthur F. Smullyan (1948) was one of the first to respond to Quine's argument. He notes that when 'the number of planets' is translated away according to Bertrand Russell's theory of definite descriptions, (1)–(3) does not constitute a violation of the law of substitution (LS). On the analysis that matches the intuition that (3) is false, it is not possible to derive the translation of (3) from (2) and the translation of (1) in predicate logic, even given LS. If one adopts the position that any purported failure of substitution for an expression is a good reason to treat it as a definite description, then there are no terms in opaque contexts in the first place, and Quine's reasoning does not get off the ground. However, this solution, Quine notes, is limited to those cases where Russell's technique can be plausibly applied.

Alonzo Church (1943) and Rudolf Carnap (1947) propose a different tactic. Presuming that variables of quantification range over concepts rather than objects, Quine's complaint that satisfaction of (5) by an object is unintelligible does not apply. However, Quine finds quantification over concepts ontologically disreputable; and furthermore, citing an alternative treatment of quantification would not rebut an argument concluding the incoherence of quantifying in for quantification over objects, a result damaging enough to QML.

There are a number of different strategies for responding to Quine's objection in the case of quantifying over objects. One popular tactic, exemplified in David Kaplan's "Quantifying In" (1969), involves selecting a privileged class of terms (for Kaplan, the so-called vivid names). Although the truth values of (3) and (2) are sensitive to the ways nine is described, one argues that there is no corresponding indeterminacy in (5) because one of these ways is privileged. Presuming '9' is privileged, (2), and not (3), is used to resolve the status of (5). Since (2) is true, (5) is true of nine, and the fact that that (3) is false is irrelevant.

In note 3 of "Quantifying In" (1969) Kaplan suggests another way to circumvent Quine's objections to (5) without using privileged terms. The idea is (roughly) to revise the truth condition for  $\exists$  so that  $\exists x(\text{necessarily}, x \text{ is greater than } 7)$  is T iff some object satisfies the open sentence (6):

(6)  $x$  bears the property of being necessarily greater than seven

Since ' $x$ ' in (6) lies outside the scope of 'necessarily', substitution holds in this position, and Quine's worries

no longer apply. (Something like this tactic is used by Quine himself in "Quantifiers and Propositional Attitudes" [1955] to analyze quantification into belief contexts.)

Kaplan's (1969) strategy is reflected in a solution implicit in the earliest published QML. The system (developed by Ruth Barcan Marcus [1946]) includes the axiom  $\forall x\forall y(x = y \rightarrow \Box x = y)$ , which is now known to correspond to the condition that variables are rigid designators, that is, they pick out the same object in every possible world. Under these circumstances (5) is equivalent to (6), and so (6) can be used to make sense of (5).

Kit Fine's "The Problem of De Re Modality" (1989) makes yet another contribution to the problem. Here a formal definition of satisfaction by objects for open sentences like (5) is provided in cases where 'necessarily' indicates logical or analytic necessity.

In "A Backward Look at Quine's Animadversions on Modalities" (1990) Marcus records how the force and variety of such criticisms of Quine's argument led him to a strategic retreat. He conceded that quantifying in is at least coherent, but raised a different objection. Quine perceived early on that attacks on his argument appear to pay a serious price. Appeals to privileged ways of describing things, to rigid designators, or to the cogency of (6) boil down to having to make sense of the idea that some objects bear necessary properties that other objects do not. Quine complains that this amounts to an unacceptable form of essentialism. What sense can it make to assert of an object itself (apart from any way of describing it) that it has necessary properties?

An influential response to this worry appears in the early pages of "Naming and Necessity" (1972), where Saul Kripke undermines Quine's presumption that it only makes sense to attribute necessary properties to an object under a description. Here, the focus shifts from brands of logical or analytical necessity, which were the main concern when Quine first wrote, to metaphysical or physical necessity. Kripke defends the view that objects in themselves do have essential properties. For example, molecules of water are necessarily composed of hydrogen and oxygen, because water just is  $H_2O$ .

Kripke and others rescued some brands of essentialism from the negative reputation it had when Quine first wrote. However, one need not respond to Quine by arguing for the coherence of a robust essentialism. In "Opacity" (1986) Kaplan argues that the essentialism produced by quantifying in is so weak as to be entirely innocuous. Terence Parsons, in "Essentialism and Quantified Modal

Logic" (1969), reports the technical result that sentences of QML that express a controversial essentialism will not be theorems, nor will they be derivable from any collection of premises expressing (nonmodal) facts.

Parsons (1969) and others point out that while quantifying in allows one to assert essentialist claims, this hardly qualifies as a reason for abandoning it. QML should provide an impartial framework for analyzing and evaluating argumentation on all philosophical positions, however misguided. That quantifying in provides resources to express (even the most obnoxious) essentialism is a point in its favor. In any case, Quine's complaint that QML is essentially essentialist amounts to a retraction of the view that quantifying in is (literally) incoherent, for if that were true, quantifying in would not entail essentialism, it would express nothing at all.

It is important to note that Quine's main argument against quantifying in would appear to apply equally well to expressions for propositional attitudes such as "Ralph believes that," for these also create opaque contexts. However, in the case of belief, the situation is different, since charges of essentialism are out of place. In "Intensions Revisited" (1981) Quine explores failings for belief that are analogs to essentialism for necessity.

Despite attacks on Quine's main argument, many still accept the conclusion that quantifying in is incoherent. Graeme Forbes (1996) notes that adherents of this view face a new puzzle, posed by strong intuitions in favor of the intelligibility of English sentences like those represented by  $\exists x(\text{Ralph believes that } x \text{ is a spy})$ . So those adherents need an alternative analysis of the logical form of propositional attitude sentences that avoids quantifying in, one Forbes sets out to provide. A tension Quine faces here is that explanations placating intuitions that quantifying in is coherent for belief will provide tools that resolve his worries about necessity.

QML has come a long way in the sixty years since Quine first launched his attack on it. Possible worlds semantics has flourished, bringing a wealth of technical results. For example, soundness and completeness have been proven for a variety of systems that allow quantifying in but reject LS in modal contexts. Theorems are also available on exactly how and where essentialist features arise in QML (e.g., see Fine 1978, 1981). Though work in modal semantics employs ideas that are anathema to Quine (notably the notion of a possible object), it provides tools for better understanding worries about quantifying in. An interest in answering Quine's objections to QML has motivated many of these developments. So,

oddly, Quine's legacy has enriched what he hoped to disinherit.

## MODAL LOGIC

Traditionally, the modes implicit in modal logic are the modes of truth and ultimately the modes of being: necessary, possible, impossible, and contingent. While the study of the formal properties of those notions is still an important part of modal logic, other interpretations have been added over the years, such as temporal, epistemic, and deontic. Furthermore, more recently, other formal languages have been suggested, which, although not modal logic in a strict sense, are closely related to it, such as dynamic logic.

### BRIEF HISTORY

Modern modal logic began in 1912 when Clarence Irving Lewis published a paper in *Mind*, in which he recommended that the logic of *Principia Mathematica* be supplemented with what he called intensional connectives. Among the latter was a binary connective of strict implication for which he introduced a new symbol, a “fish-hook” to distinguish it from the “horseshoe” of the material conditional. Thus,  $\phi \rightarrow \psi$  and  $\phi \supset \psi$  would both be read “if  $\phi$  then  $\psi$ ,” but Lewis specifically intended for the former to model the elusive notion of entailment. Other connectives were possibility, for which he used the symbol  $\diamond$  (a diamond), and necessity, for which F. B. Fitch would later suggest  $\Box$  (a box): thus,  $\diamond\phi$  and  $\Box\phi$  were read “it is possible that  $\phi$ ” and “it is necessary that  $\phi$ ,” respectively. The interest in strict implication declined somewhat after it was discovered that there are paradoxes of strict implication in parallel with those of material implication in classical logic. Lewis’s legacy was not lost, however. On the one hand, philosophers like Alan Ross Anderson and Nuel Belnap went on to develop logics of entailment and relevance, a tradition that has proved hardy. On the other hand, since necessity and possibility seem more interesting than strict implication— $\phi \rightarrow \psi$  is in any case analyzable as either  $\Box(\phi \supset \psi)$  or  $\neg \diamond(\phi \wedge \neg \psi)$ —later logicians preferred to do their modal logic in terms of those concepts.

Lewis’s original ambition was to find the logic of strict implication. Much to his surprise he later found himself confronted by a veritable embarrassment of riches: an ever increasing number of modal logics—not only his own famous quintuple of systems S1, S2, S3, S4, and S5 (his own tentative favorite was S3, the so-called Survey system) but also many, in fact, infinitely many others. Since he never translated his semantic intuitions into a formal structure, the differentiation between different proposals became a problem. Some help in this

regard arrived in the form of the concept of a matrix, essentially a set of truth-values (usually but not necessarily finitely many) plus a truth-value table for each connective. This idea, which was due to Jan Łukasiewicz, was then generalized into the notion of an algebra (essentially a set with operators) and taken into modal logic by Alfred Tarski and his collaborators. The advent of algebraic logic revitalized modal logic. Two works from this period are particularly noteworthy. One was the first formal result in modal logic worth the name, J.C.C. McKinsey’s algebraic characterization of S2 and a proof that it is decidable. The other was a paper in 1951 by Bjarni Jónsson and Tarski foreshadowing the next major development: the era of possible-worlds semantics.

Since the term *possible-worlds semantics* is today used pretty much synonymously with the term *Kripke semantics*, it is germane to ask: Who invented Kripke semantics? In fact, this question has been the object of much discussion, some heated. When the new semantics emerged at the end of the 1950s, Rudolf Carnap had laid the ground work; his states really played the role that possible worlds would later play, even if he only worked with descriptions of them. What Carnap did not have, and which turned out to make all the difference, was the accessibility relation (this concept is explained later on). The accessibility relation did appear in the Jónsson-Tarski paper mentioned earlier, and it now seems likely that Arthur Prior and C. A. Meredith had also discovered it in the early 1950s. But it was Saul A. Kripke, along with Stig Kanger and Jaakko Hintikka, who first published accounts in which the accessibility relation was a central concept and its versatility recognized. That Kripke’s work overshadowed the work by Kanger and Hintikka and proved so much more influential than theirs is perhaps not surprising, given the clarity and mathematical maturity Kripke’s papers and the systematic development of his theory.

After Kripke’s early work followed a period of increasingly formal concern. Not surprisingly, the philosophers have focused on the philosophy of modal logic, including modal metaphysics, while the mathematicians have pursued the mathematics of modal logic, including model theory, algebra, and even category theory. Another significant development has been the expanding use of modal logic in theoretical computer science: with energy and inventiveness—but of course guided by their own interests—computer scientists have, within a short time, transformed modal logic.

## SYNTAX

This entry only considers classical modal logic, that is, logic that extends classical logic. Historically, even though for a long time it is modal predicate logic that has been of particular interest to philosophers, propositional modal logic has received much more attention from formal logicians, probably because agreement on what constitutes a generally accepted conceptual framework for research was reached much earlier in the latter area.

**PROPOSITIONAL LOGIC.** To the set of the usual truth-functional connectives, add two new connectives: a box operator  $\Box$  and a diamond operator  $\Diamond$ . After Tarski, a theory, in a technical sense, is a set of formulas (called theses of the logic) that contains all classical two-valued tautologies and is closed under *modus ponens* (if  $\phi$  and  $\phi \supset \psi$  are theses of the logic, then so is  $\psi$ ). Similarly, a logic, in the technical sense used here, is a theory that is closed under uniform substitution (if  $\phi(\chi/P)$  results from a formula  $\phi$  by replacing all occurrences of a certain propositional letter  $P$  with a formula  $\chi$ , then  $\phi(\chi/P)$  is a thesis of the logic if  $\phi$  is). A normal modal logic is a logic that contains as theses all instances of the schema  $\Diamond\phi \equiv \neg\Box\neg\phi$  as well as of the so-called Kripke schema  $\Box(\phi \supset \psi) \supset (\Box\phi \supset \Box\psi)$  and, in addition, is closed under the rule of necessitation (if  $\phi$  is a thesis, then so is  $\Box\phi$ ). A great number of normal modal logics have been studied, many of them definable in terms of further schemata, for example,

$$(D) \Box\phi \supset \Diamond\phi,$$

$$(T) \Box\phi \supset \phi,$$

$$(4) \Box\phi \supset \Box\Box\phi,$$

$$(5) \neg\Box\phi \supset \Box\neg\Box\phi,$$

$$(G) \Diamond\Box\phi \supset \Box\Diamond\phi,$$

$$(H) (\Diamond\phi \wedge \Diamond\psi) \supset (\Diamond(\phi \wedge \psi) \vee \Diamond(\phi \wedge \Diamond\psi) \vee \Diamond(\psi \wedge \Diamond\phi)),$$

$$(W) \Box(\Box\phi \supset \phi) \supset \Box\phi.$$

To bring some order into the bewildering multiplicity of modal logics, E. J. Lemmon suggested  $KX_1, \dots, X_n$  as a code name for the smallest normal modal logic that contains all substitution instances of schemata  $X_1, \dots, X_n$ . In this notation, one may identify  $K$  as the smallest normal logic,  $KT$  as the Gödel/Feys/von Wright logic, and  $KT4$  and  $KT45$  as the logics  $S4$  and  $S5$ , respectively. The logics  $KD$ ,  $KD4$ , and  $KD45$ , of special interest to deontic and doxastic logic, are sometimes called weak  $T$ , weak  $S4$ , and weak  $S5$ , respectively. The logics  $KT4G$  and  $KT4H$  are better known as  $S4.2$  and  $S4.3$ , respectively, and the logic

$K4W$  as the Gödel/Löb logic  $GL$ . The set of all normal logics, ordered by set inclusion, forms a lattice of immense complexity, as do sets of more inclusive classes of nonnormal modal logics. The efforts to explore these structures continue but are increasingly a concern for mathematicians rather than for philosophers.

**PREDICATE LOGIC.** Modal predicate logic does not exhibit the relative orderliness or maturity of its propositional relative. Philosophical questions such as the proper treatment of individuals persist. Quantification, in particular into opaque contexts—that is, contexts within the scope of modal operators—has been a main problem, as evidenced by Quine's unrelenting criticism over a lifetime. A formal beginning was made by Ruth Barcan Marcus, after whom two central formulas have been named—the Barcan formula (BF) and the converse Barcan formula (CBF):

$$(BF) \forall x\Box\phi \supset \Box\forall x\phi,$$

$$(CBF) \Box\forall x\phi \supset \forall x\Box\phi$$

Other examples of formulas that were much discussed in early literature are

$$\forall x\forall y(x = y \supset \Box(x = y)),$$

$$\forall x\forall y(x \neq y \supset \Box(x \neq y)),$$

$$a = b \supset \Box(a = b),$$

$$a \neq b \supset \Box(a \neq b),$$

where  $a$  and  $b$  are individual constants. Various authors have held different views on which of these, if any, are valid. It would seem that to take a stand in such matters is to rely on implicit semantic ideas, however sketchy. It was accordingly an important step when at last, thanks to Kripke and others, formal semantics were articulated.

## SEMANTICS

The development of modal logic, both material and formal, preceded in steps. Propositional logics were studied extensively before predicate logicians had been able to work out a generally accepted common ground. Till this day, the area of modal propositional logic is more definitive than the relatively more unsettled area of modal predicate logic.

**PROPOSITIONAL LOGIC.** The possible-worlds semantics, introduced by Kripke in the early 1960s, may be cast in the following form (which differs from Kripke's original formulation in terminology and, to some extent, in

substance). A frame is a pair  $(U, R)$ , where  $U$ , the universe of discourse or simply the universe of the frame, is a non-empty set of elements that are often called possible worlds but that may more neutrally be called points, and  $R$  is a binary relation in  $U$ , called the accessibility relation or sometimes the alternativeness relation or even the alternative relation. If two points  $u, v$  of  $U$  are related by  $R$  (i.e., if  $(u, v) \in R$ ), then one says that  $v$  is accessible from  $u$  or that  $v$  is an alternative to  $u$ . A valuation in  $U$  is a function  $V$  assigning to each propositional letter  $P$  a subset  $V(P)$  of  $U$ . A model is a structure  $(U, R, V)$  where  $(U, R)$  is a frame and  $V$  is a valuation in  $U$ . Truth in modal logic is doubly relative: to a model and to a point in the model. Thus, if  $\mathfrak{M} = (U, R, V)$  is a model,  $u$  a point in  $U$  and  $\phi$  a formula, one may inductively define the notion of  $\phi$  being true at  $u$  in  $\mathfrak{M}$ , schematically  $u \models^{\mathfrak{M}} \phi$ , as follows:

$u \models^{\mathfrak{M}} P$  iff  $u \in V(P)$ , if  $P$  is a propositional letter;

$u \models^{\mathfrak{M}} \neg\phi$  iff not  $u \models^{\mathfrak{M}} \phi$ ,  
 $u \models^{\mathfrak{M}} \phi \wedge \psi$  iff  $u \models^{\mathfrak{M}} \phi$  and  $u \models^{\mathfrak{M}} \psi$ ,  
 $u \models^{\mathfrak{M}} \phi \vee \psi$  iff  $u \models^{\mathfrak{M}} \phi$  or  $u \models^{\mathfrak{M}} \psi$ ,

and similar conditions for other truth-functional connectives:

$u \models^{\mathfrak{M}} \Box\phi$  iff, for all points  $v$ , if  $(u, v) \in R$  then  $v \models^{\mathfrak{M}} \phi$ ,  
 $u \models^{\mathfrak{M}} \Diamond\phi$  iff there is some point  $v$  such that  $(u, v) \in R$  and  $v \models^{\mathfrak{M}} \phi$ .

(Readers may note the roles played in this definition by  $R$  and  $V$ : The latter is needed to get the definition started, the former to evaluate formulas beginning with a modal operator; the truth-functional connectives are taken care of by the usual truth tables.) A formula is valid in a frame if it is true at every point in every model definable on that frame; and it is valid in a class of frames if it is valid in each one of the frames of the class.

There is a sense in which this semantics fits modal logic. The set of formulas that are valid in a given class of frames will always be a normal modal logic and can be called the logic determined by that class of frames. A logic is sound with respect to a class of frames if every thesis of the logic is valid in that class, and it is complete with respect to the class if every formula that is valid in the class is a thesis of the logic; hence a logic is determined by a class of frames if and only if it is both sound and complete with respect to that class. It is an interesting fact, and no doubt one reason for the popularity of Kripke semantics, that many of the logics defined in the philosophical literature are determined by simply defined classes of

frames. For example, T, S4, and S5 are determined by the class of frames whose accessibility relations are reflexive, reflexive and transitive, and reflexive, symmetric, and transitive, respectively. Similarly, KD, KD4, and KD45 are determined by the class of all frames whose accessibility relations are serial, serial and transitive, and serial, transitive and euclidean, respectively. (A binary relation  $R$  is serial if, for every element  $u$  in its field there is some element  $v$ , not necessarily distinct from  $u$ , such that  $(u, v) \in R$ , euclidean if, for all elements  $u, v, w$  in its field, if  $(u, v) \in R$  and  $(u, w) \in R$  then  $(v, w) \in R$ .) At the extremes are the smallest normal modal logic K and the inconsistent logic, which are determined by, respectively, the class of all frames and the empty class of frames.

The way in which Kripke's semantics seems to fit modal logic led some authors, for example, Lemmon, to conjecture that all normal modal logics are complete, that is, determined by some class of frames. However, that the fit is less than perfect was proved in 1971 by Kit Fine and S. K. Thomason, who exhibited, independently of one another, instances of incomplete normal modal logics.

PREDICATE LOGIC. Among several possible versions of semantics for modal predicate logic, the following is essentially a modified version of Kripke's semantics for first-order modal logic from 1963. For simplicity, assume a formal language for predicate logic containing predicate letters and individual constants (but, for example, no descriptions or functional operators); thus, the terms of this language are individual variables or individual constants. To generalize the central concepts *frame* and *model* used in propositional modal logic, several new notions must be introduced. To begin with, besides a universe  $U$  of points (possible worlds) and an accessibility relation  $R$ , as before, one needs a nonempty set  $D$  of objects and a function  $E$  defined on  $U$  that takes values in the set of subsets of  $D$ . One can refer to  $D$  as the domain and to  $E$  as the existence function, to the elements of  $D$  as possible individuals and to the elements of  $E_u$  as individuals existing at  $u$  or individuals actual at  $u$  (where  $u$  is a point in  $U$ ). Altogether, a structure  $(U, R, D, E)$ , where  $U, R, D, E$  are as specified, is a frame. Next, one can say that  $I$  is an interpretation (in  $D$  with respect to  $U$ ) if it is a family of functions  $I_u$ , where  $u$  ranges over  $U$ , such that  $I_u$  assigns a set of  $n$ -tuples of elements of  $D$  to each  $n$ -ary predicate letter and an element of  $D$  to each individual constant. If  $\mathfrak{F} = (U, R, D, E)$  is a frame, then  $\mathfrak{M} = (\mathfrak{F}, I) = (U, R, D, E, I)$  is a model (on  $\mathfrak{F}$ ) if  $I$  is an interpretation in  $D$  with respect to  $U$ .

The following observation shows the sense in which the present concept of model is a generalization over that of propositional semantics: Nullary predicate letters behave in the present setting as propositional letters do in the propositional case. To see this, let  $P$  be a nullary predicate letter. By the definition, the interpretation of  $P$  is a set of 0-tuples, hence  $I_u(P)$  is either  $\emptyset$  (the empty set) or  $\{0\}$  (the singleton set whose only member is the one and only 0-tuple). If one arbitrarily identifies  $\{0\}$  with truth and  $\emptyset$  with falsity, one thereby also in effect identifies the set  $\{u \in U : I_u(P) = \{0\}\}$  with the proposition expressed by  $P$  in  $\mathfrak{M}$ . Thus, the interpretation plays a role in the predicate case similar to that of the valuation in the propositional case, albeit a much bigger role.

Besides all this, one needs yet another concept to define truth-conditions: something to take care of the quantifiers. An assignment (in a set  $D$ ) is a function from the set of individual variables of one's formal language to  $D$ . Notice that if  $A$  is an assignment in  $D$  and  $x$  is a variable, then  $A(x)$  is an element of  $D$  but perhaps not of  $E_u$ , if  $u$  is an arbitrary point in  $U$ . If  $\mathfrak{M} = (U, R, D, E, I)$  is a model and  $A$  is an assignment in  $D$ , then the denotation of  $t$  in  $\mathfrak{M}$  under  $A$  is a function  $\|t\|_A^{\mathfrak{M}}$  defined on  $U$  as follows:

$$\|t\|_A^{\mathfrak{M}}(u) = \begin{cases} I_u(t), & \text{if } t \text{ is an individual constant,} \\ A(t), & \text{if } t \text{ is an individual variable.} \end{cases}$$

The truth of a formula  $\phi$  in a model  $\mathfrak{M}$  under an assignment  $A$  at a point  $u$ , in symbols  $u \models_A^{\mathfrak{M}} \phi$ , may now be defined:

$$u \models_A^{\mathfrak{M}} P(t_0, \dots, t_{n-1}) \text{ iff } (\|t_0\|_u^{\mathfrak{M}}, \dots, \|t_{n-1}\|_u^{\mathfrak{M}}) \in I_u(P),$$

if  $P$  is an  $n$ -ary predicate letter,

$$u \models_A^{\mathfrak{M}} \forall x \phi \text{ iff } u \models_B^{\mathfrak{M}} \phi, \text{ for all assignments } B \text{ such that } B(x) \in E_u \text{ and, for all variables } y, \text{ if } x \neq y \text{ then } A(y) = B(y).$$

The remaining clauses of the definition (for the truth-functional connectives and the modal operators) are as before. In particular,

$$u \models_A^{\mathfrak{M}} \Box \phi \text{ iff, for all } v, \text{ if } (u, v) \in R \text{ then } v \models_A^{\mathfrak{M}} \phi.$$

As in the propositional case, one associates truth with models and validity with frames. Thus, one can say that a formula is true in a model if it is true under all assignments at all points in the model. By the same token, one

can say that a formula is valid in a frame if it is true in all models on the frame.

Some object languages contain constant predicates besides predicate letters. Common examples of such predicates are the unary  $E$  (the existence predicate) and the binary  $=$  (the identity predicate) with corresponding truth-conditions:

$$u \models_A^{\mathfrak{M}} Et \text{ iff } \|t\|_A^{\mathfrak{M}}(u) \in E_u, \text{ if } t \text{ is a term,}$$

$$u \models_A^{\mathfrak{M}} t = t' \text{ iff } \|t\|_A^{\mathfrak{M}}(u) = \|t'\|_A^{\mathfrak{M}}(u), \text{ if } t = t' \text{ are terms,}$$

The meaning of  $E$  and  $=$  depends neither on the interpretation  $I$  nor the assignment  $A$ ; for this reason  $E$  and  $=$  may be called logical constants. Notice that if the identity predicate is available, the existence predicate is definable: Provided that  $t$  is distinct from  $x$ , if  $t$  is a variable,  $E(t) \equiv \exists x(x = t)$  is a valid schema.

The following remarks apply to this particular modeling. All instances of the Barcan formula (BF) are valid in all and only frames satisfying the condition of decreasing domains, that is,

$$\text{for all } u \text{ and } v, \text{ if } (u, v) \in R \text{ then } E_u \supseteq E_v.$$

Similarly, all instances of the converse Barcan formula (CBF) are valid in all and only frames that satisfy the condition of increasing domains, that is

$$\text{for all } u \text{ and } v, \text{ if } (u, v) \in R \text{ then } E_u \subseteq E_v.$$

Of the other predicate logical formulas discussed earlier,  $\forall x \forall y (x = y \supset \Box(x = y))$  and  $\forall x \forall y (x \neq y \supset \Box(x \neq y))$  are valid, while neither  $a = b \supset \Box(a = b)$  nor  $a \neq b \supset \Box(a \neq b)$  is valid. This reflects an important difference between how individual variables and individual constants are treated in this modeling: In spite of their name, the denotation of individual constants may vary from point to point in the universe, whereas the denotation of variables, their name notwithstanding, remains fixed throughout the universe. Here is obviously a niche to be filled! Suppose one introduces a new syntactic category of names and requires that the interpretation of a name  $n$  be constant over the universe of points; formally,  $I_u(n) = I_v(n)$ , for all  $u, v \in U$ . Then, if  $m$  and  $n$  are any names,  $m = n \supset \Box(m = n)$  and  $m \neq n \supset \Box(m \neq n)$  are both valid. The proposed modification amounts to treating the elements of the new category of names as what is now known, after Kripke, as rigid designators.

Among other modelings for modal predicate logic, David Lewis's counterpart theory should be mentioned.

According to the Kripke paradigm, an individual may exist in more than one possible world (with respect to the formal modeling defined above, it is possible that  $E_u$  and  $E_v$  should overlap, in a model, even if  $u \neq v$ ). For Lewis, however, each individual inhabits its own possible world; but it may have counterparts in other possible worlds. This approach has also been influential, both in philosophical and in mathematical quarters.

## INTERPRETATIONS

The original interpretation of modal logic—the official interpretation, if one prefers—was of course the one that led to its construction: the interpretation in terms of necessity and possibility. But over time there have been many others.

**THE ALETHIC INTERPRETATION.** In formal philosophy, as in formal conceptual analysis generally, there is a constant interplay between intuition and formalism. Efforts to explicate pretheoretical notions lead to a formalism, for example, an axiom system in a formal language or a set theoretical modeling. Once a formalism is in place, it takes on a life of its own: Not only may it undergo a formal development but it can also be interpreted, sometimes in ways that are not foreseen. Reflections on such interpretations lead to refined, sometimes revised, intuitions. The latter in turn may inspire more sophisticated formalisms. And so it goes. The formalism described earlier in this entry is a product of such interplay, having arisen principally as a result of efforts to understand what Georg Henrik von Wright called the alethic modalities necessity and possibility. Not surprisingly, questions persist about to what extent this formalism is a successful explication of one's informal understanding of necessity and possibility.

Formal semantics for modal logic is, by itself, philosophically neutral. The elements of the universe of a modal logical frame, which from a formal point of view are just points in a logical space, must be given a substantial meaning by philosophers who wish to use them outside the realm of pure abstraction. In tense logic the points will be points of time, in epistemic logic perhaps epistemic situations, and so on. Under the alethic interpretation they are often referred to as possible worlds, an ordinary language word with no clear content. Indeed, the question as to what a possible world is has exercised philosophers since the beginning of the Kripke era. Answers—besides those rejecting the entire modal logical enterprise—have been numerous. Lewis argued for an extreme modal realism according to which possible

worlds are concrete alternative universes existing in parallel with the actual world. Other philosophers, like Kripke, Alvin Plantinga, Robert Stalnaker, and David M. Armstrong also argued for one kind of modal realism or other but have taken them to be abstract entities. Still other philosophers regarded possible-worlds talk as a kind of convenient fiction or refer to linguistic conventions. The debate continues.

An exact and expressive formalism has the advantage that old informal questions falling within its range of interpretation can be addressed anew. One such question is the venerable distinction between *de dicto* and *de re*. To take Willard Van Orman Quine's well-worn example, consider the claim that the number of planets is necessarily greater than seven. Is it true? There seem to be two different ways of understanding this claim. To bring them out, one can translate them into an ad hoc, quasi-formal language:

(1)  $\exists x((x = \text{the number of planets}) \wedge \Box(x > 7))$ ,

(2)  $\Box\exists x((x = \text{the number of planets}) \wedge (x > 7))$ .

Statement (1) is said to be *de re*, statement (2) *de dicto*. It may be argued that they say different things (presumably, most would agree that the former is true but that the latter is false). The former seems to “say of an object” (the *res*, the number of planets) that, by necessity, it has a certain property (“being greater than seven”). By contrast, the latter statement says that a certain statement is necessarily true (the *dictum*, namely, that the number of planets, whatever that number may be, is greater than seven). This example illustrates the important interaction between quantifying and modalizing: It is one thing to put a modal operator in front of a closed sentence, as in (2), it is another, arguably more problematic, to quantify into the scope of a modal operator, as in (1). The old topic of essences is obviously not far away.

Another distinction, which has been argued by Kripke, is that between logical modalities and metaphysical modalities (there may also be others, such as physical modalities). Logical necessity implies metaphysical necessity, but the converse is not true. For example, “Phosphorus is identical with Hesperus” (assuming the names *Phosphorus* and *Hesperus* are regarded as rigid designators) and “The chemical composition of water is  $H_2O$ ” (again assuming that *water* and  $H_2O$  are rigid designators) have been offered as examples of statements that are metaphysically, but not logically, necessary.

The (epistemological) distinction between *a priori* and *a posteriori* also comes in here. In Kripke's theory, the two examples given in the preceding paragraph exemplify

statements that, although metaphysically necessary, are nevertheless *a posteriori*. By contrast, given certain assumptions, “The Paris meter is one meter long” may be an example of a statement that is true *a priori* but is not metaphysically necessary.

**TWO EARLY MATHEMATICAL INTERPRETATIONS.** In the 1930s two technical interpretations of modal logic were made by the two greatest logicians of the twentieth century. One was the so-called provability interpretation, due to Kurt Gödel, according to which  $\Box\phi$  is interpreted as “ $\phi$  is provable” or “ $\phi$  is provable in  $S$ ,” where  $S$  is a certain formal system. This interpretation was never forgotten, but it attracted major attention only relatively recently. The other interpretation, due to Tarski, is in terms of topology: Let  $C$  and  $I$  denote the closure  $CX$  and the interior  $IX$ , respectively, of any subset  $X$  of a topological space  $U$ . Tarski noted that the closure operator and the interior operator behave in a way analogous to the way the possibility operator and the necessity operator behave in S4. For example, if  $\phi$  and  $\psi$  correspond to  $X$  and  $Y$ , respectively, then the formulas  $\Diamond(\phi \vee \psi) \equiv (\Diamond\phi \vee \Diamond\psi)$ ,  $\Diamond\phi \equiv \Diamond\Diamond\phi$ ,  $\phi \equiv \top$ , and  $\phi \equiv \perp$  correspond to the equations  $C(X \cup Y) \equiv CX \cup CY$ ,  $CX = CCX$ ,  $X = U$  and  $X = \emptyset$ . More generally, Tarski proved that an equation in topological terms is true in all topological spaces if and only if the corresponding formula is a thesis of S4. Like Gödel’s interpretation, Tarski’s interpretation, which is related to the development of the theory of closure algebras, was seminal.

**THE TEMPORAL INTERPRETATION.** A long-standing interest in the work of early Greek logicians combined with a passion for modal logic led Arthur Norman Prior, in the 1950s, to the idea of a modal logic of time. He dubbed his creation tense logic since one of his original motivations was to throw light on the grammatical notion of tense. In the beginning Prior was led to study frames  $(U, R)$  in which  $R$  is a linear relation on  $U$  (i.e., reflexive, transitive, and connected). Under that interpretation, the interpretation of the modal operators  $\Box$  and  $\Diamond$  in effect becomes “always in the future” and “some time in the future.” One focus for his early interest was the frame  $(\mathbb{N}, \leq)$ , where  $\mathbb{N}$  is the set of natural numbers, which he associated with Diodorus Cronus. Trying to axiomatize the set of formulas valid in this frame—the Diodorean logic, as he called it—Prior successively made three conjectures. The first was that it is S4. This conjecture was disproved by Hintikka, who pointed out that all instances of the schema

$$(H) (\Diamond\phi \wedge \Diamond\psi) \supset (\Diamond(\phi \wedge \psi) \vee \Diamond(\phi \wedge \Diamond\psi) \vee \Diamond(\psi \wedge \Diamond\phi))$$

are theses of the Diodorean logic but not all of S4. Prior’s response was the new conjecture that it is S4.3, that is, the logic whose Lemmon code is KT4H. However, Michael Anthony Eardley Dummett showed that all instances of the schema

$$(Dum) \Box(\Box(\phi \supset \Box\phi) \supset \Box\phi) \supset (\Diamond\Box\phi \supset \Box\phi)$$

are theses of the Diodorean logic but not all of S4.3. Prior’s third conjecture was that the Diodorean logic is S4.3Dum. This final conjecture turned out to be correct, proved by R. A. Bull and, independently, by Kripke.

In general, Prior allowed the temporal ordering to be irreflexive. He also introduced operators for past time as well as for future time. Thus, the basic operators of tense-logic are the diamond operators  $F$  and  $P$ , with readings “it will be the case (some time in the future) that” and “it was the case (some time in the past) that,” and the box operators  $G$  and  $H$  with the reading “always in the future” and “always in the past.” Their truth-conditions in a frame  $(U, <)$ , where  $<$  is at least a strict partial ordering (i.e., irreflexive and transitive), are:

$$u \models^{\mathfrak{M}} F\phi \text{ iff } v \models^{\mathfrak{M}} \phi, \text{ for some point } v \text{ such that } u \leq v,$$

$$u \models^{\mathfrak{M}} P\phi \text{ iff } v \models^{\mathfrak{M}} \phi, \text{ for some point } v \text{ such that } v \leq u.$$

$$u \models^{\mathfrak{M}} G\phi \text{ iff } v \models^{\mathfrak{M}} \phi, \text{ for all points } v \text{ such that } u \leq v,$$

$$u \models^{\mathfrak{M}} H\phi \text{ iff } v \models^{\mathfrak{M}} \phi, \text{ for all points } v \text{ such that } v \leq u.$$

Tense logic is in effect a kind of bimodal logic: It is natural to think of a tense-logical frame as a frame with two accessibility relations, one for the future and one for the past. What is special to tense logic is that those two relations are inverses of one another (and, consequently, all instances of the schemata  $PG\phi \supset \phi$  and  $FH\phi \supset \phi$  are valid).

The temporal operators mentioned are not the only ones possible. A particularly important pair of operators studied by Hans Kamp are *SINCE* and *UNTIL*:

$$u \models^{\mathfrak{M}} \phi \text{ SINCE } \theta \text{ iff there is some } w \in U \text{ such that } w < u \text{ and } w \models^{\mathfrak{M}} \theta \text{ and, for all } x \in U, \text{ if } w < x < u \text{ then } x \models^{\mathfrak{M}} \phi,$$

$$u \models^{\mathfrak{M}} \phi \text{ UNTIL } \theta \text{ iff there is some } w \in U \text{ such that } u < w \text{ and } w \models^{\mathfrak{M}} \theta \text{ and, for all } x \in U, \text{ if } u < x < w \text{ then } x \models^{\mathfrak{M}} \phi.$$

(In the literature,  $\phi$  SINCE  $\theta$  and  $\phi$  UNTIL  $\theta$  are often written  $S(\theta, \phi)$  and  $U(\theta, \phi)$ , respectively.) Kamp proved that in certain contexts, for example, over  $(\mathbb{R}, <)$  (where  $\mathbb{R}$  is the set of reals and  $<$  is the natural strict linear order) his

operators suffice for temporal completeness; that is, in those contexts, all operators corresponding to first-order conditions on the temporal relation can be defined in terms of SINCE and UNTIL and truth-functional connectives. But in general there is no temporal completeness in this sense.

Still another important tense-logical operator is NOW, which refers to a designated, fixed point of reference. A language involving that operator requires a somewhat modified truth-definition: Where before the definition is with respect to a model and a point, it will now be with respect to a model and two points, which one might call the current point and the point of reference—the former is variable, the latter is fixed throughout the definition. The clauses pertaining to the old operators, which only involve the current point, are obvious. The novel clause is

$$(u, t) \models^{\text{M}} \text{NOW } \phi \text{ iff } (t, t) \models^{\text{M}} \phi.$$

**THE EPISTEMIC INTERPRETATION.** The possibility of epistemic logic (the logic of knowledge) and doxastic logic (the logic of belief) was realized by von Wright, who coined the terms, but it was Hintikka who set the field going. Hintikka associated, with each agent  $a$ , two operators  $\mathbf{K}_a$  and  $\mathbf{B}_a$ , reading “ $a$  knows that  $\phi$ ” for  $\mathbf{K}_a\phi$  and “ $a$  believes that  $\phi$ ” for  $\mathbf{B}_a\phi$ . By the same token, the formal counterparts of “for all that  $a$  knows,  $\phi$ ” and “ $\phi$  is consistent with everything  $a$  believes” are  $\neg\mathbf{K}_a\neg\phi$  and  $\neg\mathbf{B}_a\neg\phi$ . Already Hintikka’s new notation was useful. To know that someone Qs is not the same as knowing someone who Qs, but Hintikka’s notation makes this patent— $\mathbf{K}_a\exists x\mathbf{Q}x$  has to mean something different from  $\exists x\mathbf{K}_a\mathbf{Q}x$  (compare the distinction between *de dicto* and *de re* mentioned earlier). Discussion about logical relationships was also facilitated. For example, is it reasonable to regard the type (4) schema  $\mathbf{K}_a\phi \supset \mathbf{K}_a\mathbf{K}_a\phi$  (positive introspection, the KK-thesis) and the type (5) schema  $\neg\mathbf{K}_a\phi \supset \mathbf{K}_a\neg\mathbf{K}_a\phi$  (negative introspection) as valid for rational knowledge? (Hintikka’s own inclination was to accept the former but reject the latter.) Another example of the applicability of Hintikka’s logic was to the puzzle known after George Edward Moore as Moore’s paradox. Suppose I am ignorant of the fact, say, that it is currently raining in Cambridge, England, but that I am sufficiently informed of my own beliefs to be aware of my ignorance. Then someone who knows me may say, truly, “It is raining, but you don’t believe it.” But, as observed by Moore, it would be distinctly odd of me to agree, saying, “Yes, it is raining, but I don’t believe it.” Hintikka accounts for the oddness by suggesting that a belief operator  $\mathbf{B}_a$  must satisfy certain

minimum conditions to count as an operator expressing rational belief. For example, it would be enough if the logic of  $\mathbf{B}_a$  was at least as strong as the normal modal logic KD4, for in that logic a sentence  $\phi \wedge \neg\mathbf{B}_a\phi$  may be consistent, but a sentence  $\mathbf{B}_a(\phi \wedge \neg\mathbf{B}_a\phi)$  is always inconsistent (or, in Hintikka’s terminology, doxastically indefensible).

Knowledge and belief about knowledge and belief has been an issue of late, of interest not only to philosophers but also to computer scientists and game theorists. It may be that everyone in a group of agents knows that  $\phi$ , but this does not mean that  $\phi$  is common knowledge in the group (a concept first studied by David Lewis); for that to be the case it is also required that everyone knows that everyone knows that  $\phi$ , knows that everyone knows that everyone knows that  $\phi$ , and so on. Interestingly, this concept can be axiomatized. If  $G$  is a nonempty, finite set of agents—for simplicity, assume that  $G = \{1, \dots, n\}$ —write  $\mathbf{E}_G\phi$  for “every member of  $G$  knows that  $\phi$ ” and  $\mathbf{C}_G\phi$  for “it is common knowledge among the members of  $G$  that  $\phi$ .” Assuming that  $\mathbf{K}_i$  is an S4-operator, for each  $i \in G$ , the logic of the two new operators may be characterized by requiring  $\mathbf{C}_G$  also to be an S4-operator and adding the following conditions:

$$\mathbf{E}_G\phi \equiv (\mathbf{K}_1\phi \wedge \dots \wedge \mathbf{K}_n\phi),$$

$$\mathbf{C}_G\phi \supset \mathbf{E}_G\phi,$$

$$(\phi \wedge \mathbf{C}_G(\phi \supset \mathbf{E}_G\phi)) \supset \mathbf{C}_G\phi.$$

**THE DEONTIC INTERPRETATION.** When von Wright published his seminal paper “Deontic Logic” in 1951, he in effect delivered a discipline just waiting to be born. The next decades saw a great number of papers and books written on this topic, but it is probably fair to say that the results are less definitive than those of several other subfields of modal logic. The basic idea is to study operators  $\mathbf{O}$ ,  $\mathbf{P}$ , and  $\mathbf{F}$  with the informal readings “it is obligatory that  $\phi$ ” for  $\mathbf{O}\phi$ , “it is permitted that  $\phi$ ” for  $\mathbf{P}\phi$ , and “it is forbidden that  $\phi$ ” for  $\mathbf{F}\phi$ . In so-called standard deontic logic (STD),  $\mathbf{O}$  is treated as the box operator and  $\mathbf{P}$  as the diamond operator of a normal logic;  $\mathbf{F}$  may then be defined by a condition such as  $\mathbf{F}\phi \equiv \mathbf{O}\neg\phi$  or  $\mathbf{F}\phi \equiv \neg\mathbf{P}\phi$  (to be compared with the validities  $\mathbf{P}\phi \equiv \neg\mathbf{O}\neg\phi$  and  $\mathbf{O}\phi \equiv \neg\mathbf{P}\neg\phi$ ). STD—not a precise concept—provides the schema (D)  $\mathbf{O}\phi \supset \mathbf{P}\phi$ . One schema that for obvious reasons would be inappropriate in a deontic logic is (T), but weaker schemata such as  $\mathbf{O}\mathbf{O}\phi \supset \mathbf{O}\phi$  and  $\mathbf{O}(\mathbf{O}\phi \supset \phi)$  are sometimes included in STD.

Efforts to apply STD to even fairly simple everyday situations will often fail, as shown by the existence of so-called paradoxes, a topic much discussed in the literature.

Best known among the latter are perhaps the paradoxes of William David Ross, Roderick Chisholm, and James W. Forrester. (Ross's paradox was originally formulated within the logic of imperatives, but it is equally relevant for deontic logic.) A person is under an obligation to see to it that ( $\phi$ ) a letter is posted. Should he or she do it by seeing to it that ( $\psi$ ) the letter is burned? Since  $\phi \supset (\phi \vee \psi)$  is a tautology,  $\mathbf{O}\phi \supset \mathbf{O}(\phi \vee \psi)$  is a thesis of STD. Evidently, according to STD the person should see to it that the letter is posted or burned; Ross found this conclusion bizarre. In Chisholm's paradox there are two things A and B that you may or may not do: Whether ( $\phi$ ) you do A is logically independent of whether ( $\psi$ ) you do B. On the one hand, it ought to be the case that you do B if you do A ( $\mathbf{O}(\phi \supset \psi)$ ). On the other hand, if you do not do A, then neither ought you to do B ( $\neg\phi \supset \neg\mathbf{O}\psi$ ). Furthermore, even though A is something you ought to do ( $\mathbf{O}\phi$ ), you will not do it ( $\neg\phi$ ). In STD this description of a situation, regrettable perhaps but otherwise unremarkable, leads to contradiction. Forrester's paradox is subtler: suppose there is something one must not do, but that if one nevertheless does it, then one should do it in such and such a way. Again, STD comes to grief.

Among the many problems still not resolved in modern deontic logic—Hector–Neri Castañeda's work and his distinction between propositions and practitioners notwithstanding—is the age-old question about the relationship between *Seinsollen* (ought to be) and *Tunsollen* (ought to do). It is interesting that von Wright, the father of the discipline, originally had intended for his deontic operators to take as arguments, not propositions, but actions; he seems to have changed his mind for technical reasons. With the advent of dynamic logic, it is nowadays possible to reconsider this option.

**OTHER INTERPRETATIONS.** The techniques of modal logic have been applied to a number of other areas of philosophical interest: imperatives, action, preference, place, even questions. Many of the more interesting applications make use of several modalities. For example, Kanger's theory of rights, which builds on Wesley Newcomb Hohfeld's famous analysis, combines concepts from deontic logic and the logic of action.

## EXTENSIONS OF MODAL LOGIC

**CONDITIONAL LOGIC.** The analysis of conditionals has occupied philosophers for generations. Not all the resulting analyses belong to the field of modal logic, but there is a natural sense in which the conditional logics of Robert Stalnaker and David Lewis may be seen as gener-

alizations of classical modal logic. This is obvious if one employs a notation suggested by Brian Chellas: writing  $[\phi]\psi$  and  $\langle\phi\rangle\psi$  where Lewis had  $\phi \Box \rightarrow \psi$  ("if it were the case that  $\phi$ , then it would be the case that  $\psi$ ") and  $\phi \Diamond \rightarrow \psi$  ("if it were the case that  $\phi$ , then it might be that  $\psi$ "), respectively. By this device, one moves from the language of traditional modal logic, where there is one box operator  $\Box$ , to a language in which there are as many box operators  $[\phi]$  as there are well-formed formulas  $\phi$ . Corresponding to the minimal normal modal logic K is the minimal normal conditional logic in which every box operator satisfies the Kripke schema and the rule of necessitation, and which is also closed under the rule of congruence (if  $\theta^*$  is the result of replacing all occurrences of  $\phi$  in  $\theta$  by an occurrence of  $\psi$ , then  $\theta \equiv \theta^*$  is a thesis if  $\phi \equiv \psi$  is). Lewis's logic VC of counterfactuals is the smallest normal conditional logic that contains all instances of the schemata:

$$\begin{aligned} & [\phi]\phi, \\ & \langle\phi\rangle\psi \supset \langle\psi\rangle\top, \\ & \phi \supset (\psi \supset [\phi]\psi), \\ & \phi \supset ([\phi]\psi \supset \psi), \\ & [\phi \wedge \psi]\theta \supset [\phi](\psi \supset \theta), \\ & \langle\phi\rangle\psi \supset ([\phi](\psi \supset \theta) \supset [\phi \wedge \psi]\theta). \end{aligned}$$

Stalnaker's logic is obtained by requiring that also all instances of the schema

$$\langle\phi\rangle\theta \equiv [\phi]\theta$$

be theses.

**DYNAMIC LOGIC.** Looking for a useful way to formalize reasoning about programs, Vaughan Pratt, a computer scientist, arrived at what is nowadays known as dynamic logic, a formalism similar to modal logic; in fact, dynamic logic may be viewed as a generalization of modal logic in the same way as Chellas-formulated conditional logic may be seen as a generalization of modal logic. With each program  $\alpha$  Pratt associated a box operator  $[\alpha]$  and a diamond operator  $\langle\alpha\rangle$ , reading  $[\alpha]\phi$  as "after every terminating computation according to  $\alpha$ ,  $\phi$ " and  $\langle\alpha\rangle\phi$  as "after some terminating computation according to  $\alpha$ ,  $\phi$ ." The resulting logic, originally called the modal logic of programs, evidently contains two basic categories of expressions, terms (for programs), and formulas (for propositions). A further complication over modal logic is the existence of term operators for the so-called regular operations. Thus, if  $\alpha$  and  $\beta$  are programs, then  $\alpha + \beta$  is

the program consisting of  $\alpha$  or  $\beta$  (the latter concept is of course of interest only in the context of nondeterministic automata) while  $\alpha ; \beta$  is the program consisting of  $\alpha$  immediately followed by  $\beta$ , and  $\alpha^*$  is the program consisting of  $\alpha$  some finite number of times, possibly 0 (again, of interest only in a nondeterministic context). Finally, Pratt allowed a test program:  $?\phi$  is a program that, if run, fails if  $\phi$  is false but otherwise returns to status quo. An axiomatization of PDL (propositional dynamic logic) is obtained by requiring each box operator  $[\alpha]$  to be a normal modal operator and adding the following axiom schemata:

$$\begin{aligned} [\alpha + \beta]\phi &\equiv ([\alpha]\phi \wedge [\beta]\phi), \\ [\alpha ; \beta]\phi &\equiv [\alpha][\beta]\phi, \\ [\alpha^*]\phi &\supset \phi, \\ [\alpha^*]\phi &\supset [\alpha]\phi, \\ [\alpha^*]\phi &\supset [\alpha^*][\alpha^*]\phi, \\ (\phi \wedge [\alpha^*](\phi \supset [\alpha]\phi)) &\supset [\alpha^*]\phi, \\ [?\phi]\chi &\equiv (\phi \supset \chi). \end{aligned}$$

**OTHER INTERPRETATIONS.** Some of the generalizations of modal logic that have been made over the last few decades have an origin far from modal logic. Dynamic logic is one example that has already been mentioned. Another example is description logic, which is a family of formalisms used by computer scientists to represent knowledge that is already expressed in a certain regimented form; only after extensive work did those practitioners realize that what they were doing could be seen as a version of multimodal logic, that is, modal logic with several normal operators.

An example closer to ordinary modal logic is hybrid logic, a way of doing modal logic actually anticipated by Prior. Here, the object language of traditional modal logic is augmented by the introduction of concepts belonging to semantics, a device that can greatly increase the expressive strength of the formal language. One such augmentation is to allow a new category of syntactic objects, called nominals, a special set of propositional constants whose semantic interpretation is as singleton sets; in other words, nominals represent propositions that are true at exactly one point in the universe of a model. If  $i$  is a nominal and  $\phi$  an ordinary formula, then  $(i \supset \phi) \vee (i \supset \neg\phi)$  and  $\diamond(i \wedge \phi) \supset \Box(i \supset \phi)$  exemplify formulas valid in every frame. By contrast  $i \supset \Box\neg i$  is an example of a formula valid in exactly the class of frames  $(U, R)$  in which

$R$  is irreflexive. This is a striking fact, for irreflexivity is notoriously not expressible in ordinary modal logic—the logic determined by the class of all frames with irreflexive accessibility relations is the same as the logic determined by the class of all frames, that is,  $K$ .

Like description logic, hybrid logic is actually a family of logics with different object languages. This proliferation of languages bears witness to the many different uses to which modal logic is nowadays being put. In this regard it is interesting to note a certain trade-off between more restrictive and more permissive options: in general, the more expressive a language is, the more endangered are desirable properties like completeness and decidability. Some philosophers may find the multifariousness of present-day computer science-driven modal logic bewildering. At any rate, we have come a long way from the beginning of modal logic when C. I. Lewis sought, and for a while thought he had found, the one and only logic of strict implication.

## MODEL THEORY

In 1954 Alfred Tarski proposed the name *theory of models* for the study of "mutual relations between sentences of formalized theories and mathematical [structures] in which these sentences hold." This definition hides a program that was to apply metamathematical results (particularly the Compactness Theorem of first-order logic) in

what Abraham Robinson in 1950 had called "the development of actual mathematics." Anatolii I. Mal'tsev had launched this program in the Soviet Union in 1940, but communications were bad in this period and the program started afresh in the late 1940s with Tarski in the United States and Robinson in Britain. Mathematical model theory in the sense of this program has been remarkably successful, particularly in its applications to group theory and geometry, and it has far outgrown Tarski's initial definition of the theory of models.

Tarski's definition rested on the fact that one can use formal languages to define classes of structures. For mathematical applications it has turned out to be just as important that one can use formal languages to define sets and relations within a single structure. But at its base, model theory is more general even than this. Arguably it stands in the same relation to the traditional theory of definitions as modern proof theory stands to the traditional theory of syllogisms.

Most sentences are true in some contexts and false in others. If  $S$  is a sentence, then by an *interpretation* of  $S$  we mean a parcel of information about some possible context, which is enough to make  $S$  either true or false in that context. Suppose  $I$  is an interpretation of  $S$ . If  $I$  makes  $S$  true, we call  $I$  a *model* of  $S$  and we say that  $S$  is *true in I*. "Truth-in-a-model" is honest to goodness truth, no less than (say) being true at 3 o'clock.

The sentence  $S$  defines a class of interpretations, namely the class of its models. A simple example is the mathematical equation

$$x^2 + y^2 = 1$$

where  $x$  and  $y$  are variables ranging over real numbers. An interpretation of this equation consists of a pair of real numbers  $b, a$  where  $x$  is to name  $a$  and  $y$  to name  $b$ . Under this interpretation the sentence is true if and only if the point  $b, a$  lies on the circle  $C$  of radius 1 around the origin in the cartesian plane. So the circle  $C$  is the class of models of the equation. This example assumes that we have specified what form an interpretation of the equation should take. In concrete applications of model theory one begins with such a specification.

The sentence  $S$  can come from a natural language or a formal one. The range of information that might appear in interpretations is vast. They can specify the time of utterance, the time spoken of, the place, the speaker's identity, salient objects in the context (to give reference to "the previous owner", "the latter symbol", "Peter", etc.). They can also supply meanings for words that have none. But mathematical model theory concerns itself almost

entirely with interpretations of a kind called *structures*. A structure supplies a set of objects, called the *domain* or *universe* of the structure. Besides giving a domain, a structure interprets expressions by attaching them to elements of the domain, or to set-theoretic objects built up from elements of the domain. For example a mathematical model theorist, to interpret the sentence

The mome raths outrabe.

would probably supply two sets  $X$  and  $Y$ , together with the information that  $X$  is the set of things that count as mome raths and  $Y$  is the set of things that count as having outrabben. This interpretation is a model of the sentence if and only if  $X$  is a subset of  $Y$ .

When the sentence  $S$  comes from a formal language of logic, one can describe precisely how the truth value of  $S$  depends on the sets or objects used to interpret symbols of  $S$ . Tarski's model-theoretic definition of truth and satisfaction is a paradigm for this kind of description. The model-theoretic truth definition was an adaptation of the truth definition that Tarski gave in 1933 for formal languages. In that earlier definition Tarski assumed that all symbols needing an interpretation already had one (in general a set-theoretic one), and so the definition was strictly not model-theoretic. But truth definitions that run along similar lines to Tarski's, for example the definitions of truth underlying Richard Montague's semantics for fragments of English, are called "model-theoretic"; probably the use of set theory and recursion on the complexity of formulas are the features that this name brings to mind.

As a discipline, model theory takes no stand at all on whether there are possible worlds or on what objects there are in the universe. If you believe in possible worlds you can study interpretations that involve possible worlds; if you don't, you probably won't. There are branches of model theory where one puts strong limits on the kinds of interpretation that are allowed: For example in *recursive model theory* the structures are built up from computable functions of natural numbers. But since structures are set-theoretic objects, most mathematical model theorists make free use of the axioms of Zermelo-Fraenkel set theory, including the Axiom of Choice.

One should distinguish between model theory and "mathematical modeling". Modeling a phenomenon usually involves constructing a formal theory rather than a set-theoretic structure. But there are overlaps. For example abstract state machines, introduced by the model theorist Yuri Gurevich, are set-theoretic structures used to

model parallel computation. In another direction, papers in Morgan and Morrison discuss the relations between theories and structures in scientific research, with particular reference to physics and economics.

## FIRST-ORDER MODEL THEORY

First-order model theory is the most developed part of model theory, and other parts of model theory tend to be generalizations or analogues of the first-order case. We begin with some preliminary definitions that rest on first-order logic.

**DEFINING STRUCTURES, TRUTH, AND SATISFACTION.** First we define signatures. A *signature* is a collection of symbols as follows:

(1) *Relation symbols*, usually

$$P, Q, R, R_0, R_1, R_2, \dots$$

(2) *Individual constant symbols*, or more briefly *constants*, usually

$$a, b, c, c_0, c_1, c_2, \dots$$

(3) *Function symbols*, usually symbols such as

$$F, G, H, F_0, F_1, F_2, \dots$$

Each relation symbol and each function symbol in a signature has an *arity*, which is a positive integer. If a symbol has arity  $n$ , we say that the symbol is *n-ary*. We normally require that no symbol occurs in more than one of these three kinds, and that no relation or function symbol occurs with more than one arity. We say that a signature  $\sigma$  is a *reduct* of a signature  $\tau$  (and that  $\tau$  is an *expansion* of  $\sigma$ ) if every constant in  $\sigma$  is also a constant in  $\tau$ , every relation symbol of  $\sigma$  is also a relation symbol in  $\tau$  with the same arity, and likewise for the function symbols in  $\sigma$ .

Let  $\sigma$  be a signature. A  $\sigma$ -*structure* is an ordered pair  $A = \langle \text{dom}(A), f_A \rangle$  as follows:

$\text{dom}(A)$  is a nonempty set, known as the *domain* of  $A$ .

$f_A$  is a function whose domain is the set of symbols in the signature  $\sigma$ .

For each constant  $c$  of  $\sigma$ ,  $f_A(c)$  is an element of  $\text{dom}(A)$ ; we write this element as  $c_A$ .

For each relation symbol  $R$  of  $\sigma$ ,  $f_A(R)$  is an  $n$ -ary relation on  $\text{dom}(A)$ , where  $n$  is the arity of  $R$ ; we write this relation as  $R_A$ .

For each function symbol  $F$  of  $\sigma$ ,  $f_A(F)$  is an  $n$ -ary function  $F_A : \text{dom}(A)^n \rightarrow \text{dom}(A)$ , where  $n$  is the arity of  $F$ .

By a *structure* we mean a  $\sigma$ -structure for some signature  $\sigma$ .

If  $A$  is a  $\tau$ -structure and  $\sigma$  is a reduct of  $\tau$  then we can make  $A$  into a  $\sigma$ -structure by removing the symbols not in  $\sigma$ ; the resulting  $\sigma$ -structure is written  $A|\sigma$  and called a *reduct* of  $A$ . Likewise  $A$  is an *expansion* of  $A|\sigma$ .

By the *elements* of a structure  $A$  we mean the elements of  $\text{dom}(A)$ . (For example a structure  $A$  and its reduct  $A|\sigma$  have the same elements.) By the *cardinality* of  $A$  we mean the cardinality of  $\text{dom}(A)$ .

For each signature  $\sigma$  there is a corresponding first-order language  $L(\sigma)$  as in the entry “First-Order Logic”. Since each first-order language  $L$  is of the form  $L(\sigma)$  for a unique signature  $\sigma$ , we can also refer to  $\sigma$ -structures as *L-structures*. We borrow the following facts and definitions from the entry “First-Order Logic”, under the assumption that  $L$  is a first-order language and  $A$  is an  $L$ -structure.

If  $\phi$  is a sentence of  $L$  then  $\phi$  is either true or false in  $A$ . If  $\phi$  is true in  $A$ , we write  $A \models \phi$  and we call  $A$  a *model* of  $\phi$ . If  $\phi$  is false in  $A$  we write  $A \not\models \phi$ .

By a *theory* in  $L$  we mean a set  $T$  of sentences of  $L$ . By a *model* of  $T$  we mean a model of all the sentences in  $T$ . We say that  $T$  is *consistent* if  $T$  has a model; otherwise it is *inconsistent*.

Let  $T$  be a theory in  $L$  and  $\phi$  a sentence of  $L$ . We say that  $\phi$  is a *consequence* of  $T$ , and that  $T$  *entails*  $\phi$ , in symbols

$$(1) \quad T \models \phi,$$

if every  $L$ -structure that is a model of  $T$  is also a model of  $\phi$ . The theory  $T$  is said to be *complete* if for every sentence  $\phi$  of  $L$ , either  $\phi$  or  $\neg\phi$  is a consequence of  $T$ . The expression (1) is called a *sequent*; it is *valid* if  $T$  does entail  $\phi$ .

We write  $\phi(x_1, \dots, x_n)$  for a formula of  $L$  whose free variables are all among  $x_1, \dots, x_n$ . If  $a_1, \dots, a_n$  are elements of  $A$ , we write

$$A \models \phi[a_1, \dots, a_n],$$

pronounced “ $a_1$  to  $a_n$  satisfy  $\phi$  in  $A$ ”, if  $\phi$  is true in  $A$  when each free variable  $x_i$  is interpreted as a name of  $a_i$ . This notion can be defined set-theoretically without relying on the semantic notion “name of”.

These fundamental facts and definitions allow us to use first-order sentences in order to define classes of

structures, and to use first-order formulas in order to define classes of elements in structures.

**DEFINING CLASSES OF STRUCTURES.** We write  $\text{Mod}(T)$  for the class of all  $L$ -structures that are models of the theory  $T$ . If  $A$  is an  $L$ -structure, we write  $\text{Th}(A)$  for the set of all sentences  $\phi$  of  $L$  which are true in  $A$ ;  $\text{Th}(A)$  is known as the *complete first-order theory* of  $A$ . If  $\mathbf{K}$  is a class of  $L$ -structures, we write  $\text{Th}(\mathbf{K})$  for the set of those sentences of  $L$  which are true in every structure in  $\mathbf{K}$ . We say that two  $L$ -structures  $A$  and  $B$  are *elementarily equivalent*, in symbols  $A \equiv B$ , if  $\text{Th}(A) = \text{Th}(B)$ . Elementary equivalence is an equivalence relation on the class of  $L$ -structures. We say that two theories  $S$  and  $T$  in  $L$  are *equivalent* if  $\text{Mod}(S) = \text{Mod}(T)$ ; this is an equivalence relation on the class of theories in  $L$ .

**Theorem 1** *The notions Mod and Th are related as follows:*

1. If  $T \subseteq U$  then  $\text{Mod}(T) \supseteq \text{Mod}(U)$ .
2. If  $\mathbf{J} \subseteq \mathbf{K}$  then  $\text{Th}(\mathbf{J}) \supseteq \text{Th}(\mathbf{K})$ .
3.  $\mathbf{K} \subseteq \text{Mod}(\text{Th}(\mathbf{K}))$  and  $\text{Th}(\mathbf{K}) = \text{Th}(\text{Mod}(\text{Th}(\mathbf{K})))$ .
4.  $T \subseteq \text{Th}(\text{Mod}(T))$  and  $\text{Mod}(T) = \text{Mod}(\text{Th}(\text{Mod}(T)))$ .

These facts are all immediate from the definitions.

The theory  $\text{Th}(\text{Mod}(T))$  is called the *deductive closure* of the theory  $T$ ; it consists of all the consequences of  $T$ . A theory is said to be *deductively closed* if it is its own deductive closure. By 3 of Theorem 1, a theory is deductively closed if and only if it is of the form  $\text{Th}(\mathbf{K})$  for some class  $\mathbf{K}$  of structures. (In some older literature, deductive closure was included in the definition of “theory”.)

A class of structures of the form  $\text{Mod}(\{\phi\})$ , where  $\phi$  is a single sentence, is said to be *first-order definable*, or an EC class. A class of structures of the form  $\text{Mod}(T)$ , where  $T$  is a theory, is said to be *first-order axiomatisable*, or *generalised first-order definable*, or an  $\text{EC}_\Delta$  class. A class  $\mathbf{K}$  of  $L$ -structures is said to be *closed under elementary equivalence* if every  $L$ -structure elementarily equivalent to a structure in  $\mathbf{K}$  is also in  $\mathbf{K}$ .

We pause for some examples.

**Example 1:** Equivalence relations. We use the signature with one binary relation symbol  $E$ ; call this signature  $\sigma$ . We write  $Exy$  for  $E(x,y)$ . An equivalence relation is a  $\sigma$ -structure that is a model of the following finite theory, which we shall call  $T_{eq}$ :

- $\forall x Exx$  (reflexive)
- $\forall x\forall y (Exy \rightarrow Eyx)$  (symmetric)
- $\forall x\forall y\forall z (Exy \wedge Eyz \rightarrow Exz)$  (transitive)

**Example 2:** Fields. The following example has been central in the development of model theory. We adopt a signature with constants 0 and 1, binary function symbols + and · and a 1-ary function symbol −. This signature is appropriate for talking about rings, so it is known as the *signature of rings*. We normally write  $+(x,y)$ ,  $\cdot(x,y)$  and  $-(x)$  as  $x + y$ ,  $xy$  and  $-x$  respectively, and we use standard mathematical notation such as  $x \neq y$  for  $\neg(x = y)$ . The *theory of fields*,  $T_p$  consists of the following sentences:

1.  $\forall x\forall y\forall z (x + (y + z) = (x + y) + z)$
2.  $\forall x\forall y (x + y = y + x)$
3.  $\forall x (x + 0 = x)$
4.  $\forall x (x + -x = 0)$
5.  $\forall x\forall y\forall z (x(yz) = (xy)z)$
6.  $\forall x\forall y (xy = yx)$
7.  $\forall x (x \cdot 1 = x)$
8.  $\forall x\forall y\forall z (x(y + z) = xy + xz)$
9.  $0 \neq 1$
10.  $\forall x\exists y (x \neq 0 \rightarrow xy = 1)$

We write 2 for  $1 + 1$ , 3 for  $1 + 1 + 1$  and so on. A field is said to be of *characteristic 0* if it is also a model of the infinitely many axioms

$$11. n \neq 0$$

where  $n$  is any positive integer. We write  $x^2$  for the term  $xx$ ,  $x^3$  for  $xxx$  and so on. Let  $t_n(x,y_1, \dots, y_n)$  be the term

$$x^n + y_1x^{n-1} + y_2x^{n-2} + \dots + y_{n-2}x^2 + y_{n-1}x + y_n.$$

A field is said to be *algebraically closed* if it is a model of the infinitely many axioms

$$12. \forall y_1 \forall y_2 \dots \forall y_n \exists x (t_n(x, y_1, \dots, y_n) = 0)$$

where  $n$  is any positive integer. The classes of fields, fields of characteristic 0 and algebraically closed fields were all well known before these axioms were written down as first-order sentences, and the first-order sentences say exactly the same as the earlier informal definitions of those classes.

In the light of our earlier definitions, several natural questions arise. For example:

Question One. Is there an algorithm to determine whether any given sentence  $\phi$  is a consequence of  $T_{eq}$ ?

Question Two. For which equivalence relations  $A$  is  $\text{Mod}(\text{Th}(A))$  first-order definable?

Question Three. If  $A$  and  $B$  are two algebraically closed fields of characteristic 0, how can we tell whether they are elementarily equivalent?

Question Four. What is an example of a class  $\mathbf{K}$  that is closed under elementary equivalence but not first-order axiomatisable?

We will return to these questions below.

The *infinite spectrum* of a class  $\mathbf{K}$  is the class of infinite cardinals  $\kappa$  such that  $\mathbf{K}$  contains a structure of cardinality  $\kappa$ . Questions about the possible infinite spectra of classes of the form  $\text{Mod}(T)$  were first raised by Leopold Löwenheim in 1915, and below we shall see some “Löwenheim-Skolem” theorems that describe these spectra.

**DEFINING CLASSES OF ELEMENTS.** The notions described above have analogues within a single structure. Suppose  $A$  is an  $L$ -structure. By an  $n$ -tuple in  $A$  we mean an ordered  $n$ -tuple  $(a_1, \dots, a_n)$  of elements of  $A$ . We write  $\Phi(x_1, \dots, x_n)$  for a set  $\Phi$  of formulas of  $L$  of the form  $\phi(x_1, \dots, x_n)$  (the same integer  $n$  for each formula). We say that an  $n$ -tuple  $(a_1, \dots, a_n)$  in  $A$  *realises*  $\Phi$  if

$$\text{for all } \phi \text{ in } \Phi, A \models \phi[a_1, \dots, a_n].$$

We write  $\Phi(A^n)$  for the set of all  $n$ -tuples in  $A$  that realise  $\Phi$ . If  $\Phi$  contains just one formula  $\phi$ , we write  $\Phi(A^n)$  as  $\phi(A^n)$  and we say that this set of  $n$ -tuples is (*first-order*) *definable without parameters*. The sets  $\Phi(A^n)$  are said to be *infinitarily definable without parameters*, or  $\wedge$ -*definable without parameters*.

For the analogous notions of definability *with parameters* we allow the formulas  $\phi$  to contain constants (in an expanded signature) to name some elements of  $A$ . For example if we are talking about the rational numbers in a signature whose symbols are  $<$  for the ordering and 0, 1 for the corresponding numbers, then the interval (0,1) of rational numbers strictly between 0 and 1 will be definable without parameters, the interval (3,4) will be definable with parameters, and the interval  $(\sqrt{2}, \pi)$  will not be definable at all. When model theorists talk about definable sets, they sometimes mean with parameters and sometimes without; if in doubt you have to ask.

Let  $T$  be a theory in the first-order language  $L$ , and  $\phi(x_1, \dots, x_n)$  and  $\psi(x_1, \dots, x_n)$  formulas of  $L$ . We say that  $\phi$  is *equivalent to  $\psi$  modulo  $T$*  if  $\phi(A^n) = \psi(A^n)$  for every model  $A$  of  $T$ ; this is equivalent to saying that the sentence

$$(2) \quad \forall x_1 \dots \forall x_n (\phi \leftrightarrow \psi)$$

is a consequence of  $T$ . Likewise we say that  $\phi$  is *equivalent to  $\psi$  in the  $L$ -structure  $A$*  if  $\phi(A^n) = \psi(A^n)$ ; this is equivalent to saying that (2) is true in  $A$ .

If  $\Phi(x_1, \dots, x_n)$  is a set of formulas of  $L$ , we can ask whether there is an  $L$ -structure  $A$  in which  $\Phi(A^n)$  is not empty. If the answer is Yes, we say that  $\Phi$  is an  *$n$ -type*, or more briefly a *type*, and we say that the structure  $A$  *realises* the type. There may be other structures  $B$  for which  $\Phi(B^n)$  is empty; these structures are said to *omit* the type. We say that the type  $\Phi$  is *complete* if for every formula  $\phi(x_1, \dots, x_n)$  of  $L$ , exactly one of  $\Phi \cup \{\phi\}$  and  $\Phi \cup \{\neg\phi\}$  is a type.

For example let  $\mathbb{N}$  be the ‘natural number’ structure whose domain is the set of natural numbers  $0, 1, 2, \dots$ , with symbols to express 0, 1, addition, multiplication and ‘less than’  $<$ . Consider the infinite set  $\Phi(x)$  of formulas

$$0 < x, 1 < x, 2 < x, \dots$$

The set  $\Phi(x)$  is in fact a type, but it is clear that  $\mathbb{N}$  omits this type; there are no infinite natural numbers. A natural question is:

Question Five. Are there structures elementarily equivalent to  $\mathbb{N}$  which realise this type?

The answers to Questions One to Five are not obvious. Many of the techniques of model theory were devised in order to answer just such questions. Historically the first three major techniques in this area were elimination of quantifiers, back-and-forth, and the Compactness Theorem. The next three sections discuss these.

### ELIMINATION OF QUANTIFIERS

Thoralf Skolem, Charles Langford, and Alfred Tarski developed the method of elimination of quantifiers during the 1920s as a way of analyzing structures or classes of structures.

As the name indicates, the idea of elimination of quantifiers is to express as much as possible without using quantifiers. Let  $\Phi$  be a set of formulas of a language  $L$ . Write  $\Phi'$  for the smallest class of formulas of  $L$  such that (i)  $\Phi \subseteq \Phi'$ , (ii) if  $\phi$  is in  $\Phi'$  then  $\neg\phi$  is in  $\Phi'$ , and (iii) if  $\phi$  and  $\psi$  are in  $\Phi'$  then  $(\phi \wedge \psi)$  and  $(\phi \vee \psi)$  are in  $\Phi'$ . The formulas in  $\Phi'$  are called the *boolean combinations* of formulas in  $\Phi$ . There can be quantifiers in the formulas in  $\Phi$ , but

when we form boolean combinations of them we add no more quantifiers.

Let  $L$  be a first-order language and  $\mathbf{K}$  a class of  $L$ -structures. A successful elimination of quantifiers for  $\mathbf{K}$  consists of the following items:

- (i) a set  $T$  of sentences of  $L$  that are true in all structures in  $\mathbf{K}$ ;
- (ii) a set  $\Phi$  of formulas of  $L$ , called the *elimination set*;
- (iii) a proof that if  $\psi(x_1, \dots, x_n)$  is any formula of  $L$  then  $\psi$  is equivalent modulo  $T$  to a boolean combination  $\psi^*(x_1, \dots, x_n)$  of formulas in the elimination set.

We carry out an elimination of quantifiers as follows. The class  $\mathbf{K}$  of structures already determines the signature. We begin by choosing  $T$  to be—provisionally—a set of sentences that are clearly true in all structures in  $\mathbf{K}$ ; our exact choice could depend on aesthetic or pedagogic considerations. We launch (ii) by including all atomic formulas in the elimination set. From this point on, we aim to prove (iii) by induction on the number of occurrences of quantifiers in  $\psi$ , with a subinduction on the complexity. If  $\psi^*(x_1, \dots, x_n)$  and  $\chi^*(x_1, \dots, x_n)$  have been found, we can take  $(\psi \wedge \chi)^*$  to be  $\psi^* \wedge \chi^*$ , and likewise for other truth-functional combinations. We can take  $(\forall x_n \psi)^*$  to be  $\neg \exists x_n \neg(\psi^*)$ . This leaves the case  $\exists x_n \psi$ , and this is where we “eliminate the quantifier”.

We first put  $\psi^*$  into disjunctive normal form, and then we use the logical equivalence

$$\exists x (\phi_1 \vee \phi_2) \equiv (\exists x \phi_1 \vee \exists x \phi_2)$$

to reduce to the case of a formula  $\exists x_n \theta$  where  $\theta$  is a conjunction of formulas in the elimination set and negations of formulas in the elimination set. The next step depends on  $\mathbf{K}$  and perhaps on our mathematical skill. If we can find a boolean combination  $\phi$  of formulas in the elimination set, and a proof that  $\phi$  is equivalent to  $\exists x_n \theta$  modulo  $T$ , then this case is taken care of. Otherwise we have two options. First if we can find a suitable formula  $\phi$  that is certainly equivalent to  $\exists x_n \theta$  in all structures in  $\mathbf{K}$  but we can’t prove this equivalence from  $T$  then we can add the equivalence statement to  $T$ . Second, as a last resort, we can add  $\exists x_n \theta$  to the elimination set. We hope to reach a point where we can prove (iii) for all formulas. When this point is reached the quantifier elimination proper is complete. If heaven favors us (and this is not guaranteed) by this stage we will also know which boolean combinations of sentences in the elimination set are true in all structures in  $\mathbf{K}$ . Adding these to  $T$  gives a theory  $T'$  equivalent

to  $\text{Th}(\mathbf{K})$ . With more good luck we may find that the reductions in (iii) allow us to construct an algorithm to determine whether any given sentence of  $L$  is a consequence of  $T'$ , so that we have a decision procedure for  $\text{Th}(\mathbf{K})$ .

**Example 1 continued:** Equivalence relations. For  $T$  we take the theory  $T_{\text{eq}}$  defining the class of equivalence relations. As a first attempt at the elimination set  $\Phi$  we take all atomic formulas of  $L$ . There are two kinds of atomic formula, namely  $(x = y)$  and  $Exy$ . Trial and error shows that for every positive integer  $n$  the formula  $\chi_n(x)$  expressing “There are at least  $n$  elements that are in the same equivalence class as  $x$ ” is not reducible to a boolean combination of atomic formulas; so we put  $\chi_n$  in the set  $\Phi$  too. Similarly we add to  $\Phi$  all the sentences  $\sigma_{m,n}$  expressing ‘There are at least  $m$  equivalence classes containing at least  $n$  members each’, where  $m$  and  $n$  are any positive integers, and the sentences  $\theta_{m,n}$  expressing “There are at least  $m$  equivalence classes of size exactly  $n$ ”. It turns out that this is enough for an elimination set. There is an algorithm reducing each sentence to a boolean combination of sentences in  $\Phi$ , and there is an algorithm determining which boolean combinations of sentences in  $\Phi$  are consequences of  $T$ . Thus  $T$  is a decidable theory and we have an answer to Question One.

**Example 3:** The field  $\mathbb{R}$  of real numbers. We take the signature to be the expansion of the signature of rings got by adding a binary relation symbol  $<$  for the ordering of the reals. (Without this added symbol we would need to put  $\exists y (x = y^2)$  into the elimination set; with  $<$  this formula is equivalent to  $(x = 0 \vee 0 < x)$ .) Tarski showed that a set of axioms for  $\text{Th}(\mathbb{R})$  is given by the theory  $T_f$  of Example 2 together with an axiom saying that for every element  $r$ , either  $r$  or  $-r$  is a square, an axiom saying that  $r < s$  if and only if  $r \neq s$  and  $s - r$  has a square root, axioms saying that  $-1$  is not a sum of squares, and the axioms 12 for odd positive integers  $n$ . It then came to light that these axioms define the class of real-closed fields. Tarski also gave a decision procedure for the set of consequences of this theory. The elimination set is interesting: it consists exactly of the atomic formulas. As a corollary, the subsets of  $\mathbb{R}$  that are first-order definable with parameters consist of the finite unions of sets of the following kinds: singletons  $\{a\}$ , intervals  $(a, b)$  (the set of elements  $r$  with  $a < r$  and  $r < b$ ), intervals  $(-\infty, b)$  (the set of all elements  $< b$ ) and intervals  $(a, \infty)$  (the set of all elements  $> a$ ).

A structure  $A$  whose elements are linearly ordered by an ordering relation  $<_A$ , and for which the sets first-order definable with parameters are exactly the finite unions of singletons and intervals as in Example 3, is said to be *o-*

*minimal*. The knowledge that a structure is *o-minimal* gives powerful information about the structure. Beginning with Alex Wilkie’s demonstration in 1991 that the expansion of the field of real numbers with an exponentiation function  $x^y$  is *o-minimal*, many other *o-minimal* expansions of  $\mathbb{R}$  have been found, and there is promise of deep applications in real function theory.

From around 1950 more powerful and algebraic methods were found that gave largely the same information as the method of elimination of quantifiers. But it remains one of the best methods for discovering decision procedures when the theory is decidable.

### BACK-AND-FORTH

Suppose  $A$  and  $B$  are  $\sigma$ -structures, where  $\sigma$  is a signature. By a *partial isomorphism* from  $A$  to  $B$  we mean a function  $e$  from a subset  $X$  of  $\text{dom}(A)$  to  $\text{dom}(B)$  such that if  $\phi(x_1, \dots, x_n)$  is an atomic formula of  $L$  and  $a_1, \dots, a_n$  are any elements in  $X$  then

$$A \models \phi[a_1, \dots, a_n] \text{ if and only if } B \models \phi[e(a_1), \dots, e(a_n)].$$

If  $e$  is a partial isomorphism from  $A$  to  $B$  and the domain  $X$  of  $e$  is the whole of  $\text{dom}(A)$ , we say that  $e$  is an *embedding* of  $A$  into  $B$ . If  $e$  is an embedding of  $A$  into  $B$  and every element of  $B$  is of the form  $e(a)$  for some element  $a$  of  $A$  then we say that  $e$  is an *isomorphism* from  $A$  to  $B$ . We say that  $A$  is *isomorphic* to  $B$ , in symbols  $A \cong B$ , if there is an isomorphism from  $A$  to  $B$ . The relation  $\cong$  is an equivalence relation on the class of  $L$ -structures, and its equivalence classes are called *isomorphism types*.

If  $A$  and  $B$  are isomorphic  $\sigma$ -structures, then  $A$  and  $B$  must be elementarily equivalent,  $A \equiv B$ . The definition of “partial isomorphism”, and hence also the definition of  $\cong$ , are easily rewritten in ways that refer to the signature  $\sigma$  but not to any formula of the language  $L(\sigma)$ . In the 1950s one aim of research was to find an “algebraic” description of elementary equivalence that doesn’t mention formulas either. Roland Fraïssé gave essentially the following answer, which is known as the *back-and-forth* method.

A *back-and-forth system* from  $A$  to  $B$  is a set  $I$  of partial isomorphisms from  $A$  to  $B$  such that

- (a)  $I$  is not empty.
- (b) If  $i$  is in  $I$  and  $a$  is an element of  $A$  then there are an element  $b$  of  $B$  and a partial isomorphism  $j$  in  $I$  such that

$$i \cup \{ \langle a, b \rangle \} \subseteq j;$$

(c) If  $i$  is in  $I$  and  $b$  is an element of  $B$ , then there are an element  $a$  of  $A$  and a partial isomorphism  $j$  in  $I$  such that

$$i \cup \{ \langle a, b \rangle \} \subseteq j.$$

By a *finite relational signature* we mean a signature with only finitely many symbols, none of which are function symbols. (Constants are allowed.)

**Theorem 2** *If there is a back-and-forth system  $I$  from  $A$  to  $B$  then  $A \equiv B$ . If  $A \equiv B$  then for every finite relational signature  $\sigma$ , there is a back-and-forth system from  $A|\sigma$  to  $B|\sigma$ .*

**Example 4:** Dense linear orderings without endpoints. We adopt a signature  $\sigma$  with one binary relation symbol  $<$ , and we write  $x < y$  for  $<(x, y)$ . A *dense linear ordering without endpoints* is a  $\sigma$ -structure that is a model of the following set of sentences:

1.  $\forall x \neg(x < x)$  (irreflexive)
2.  $\forall x \forall y \forall z (x < y \wedge y < z \rightarrow x < z)$  (transitive)
3.  $\forall x \forall y (x < y \vee y < x \vee x = y)$  (linear)
4.  $\forall x \forall y \exists z (x < y \rightarrow x < z \wedge z < y)$  (dense)
5.  $\forall x \exists y \exists z (y < x \wedge x < z)$  (no endpoints)

We shall write this set of sentences as  $T_{dlo}$ .

Suppose  $A$  and  $B$  are dense linear orderings without endpoints. An *order-preserving partial map* from  $A$  to  $B$  is a function  $e$  from a finite set  $X$  of elements of  $A$  to the domain of  $B$  such that if the elements of  $X$  are  $a_1, \dots, a_n$  with

$$(3) \quad a_1 <_A a_2 <_A \dots <_A a_n$$

then

$$(4) \quad e(a_1) <_B e(a_2) <_B \dots <_B e(a_n).$$

Write  $I(A, B)$  for the set of all order-preserving partial maps from  $A$  to  $B$ .

One can check from the definitions that every function in  $I(A, B)$  is a partial isomorphism from  $A$  to  $B$ . Also  $I(A, B)$  is a back-and-forth system from  $A$  to  $B$ . Suppose for example  $e$  is in  $I$  with domain  $\{a_1, \dots, a_n\}$  as in (3), and  $a$  is an element of  $A$  that is not in the domain of  $e$ . One possibility is that  $a <_A a_1$ . By sentence 5 of  $T_{dlo}$  there is an element  $b$  of  $B$  with  $b <_B e(a_1)$ ; then  $e \cup \{ \langle a, b \rangle \}$  is a function in  $I$  that extends  $e$  and has  $a$  in its domain. The other possibilities for  $a$  are similar, using sentences 4 and 5. The same argument, going from  $B$  to  $A$ , shows that if  $e$  is in  $I$  and  $b$  is an element of  $B$  then there is a function in  $I$  that extends  $e$  and takes some element of  $A$  to  $b$ .

By Theorem 2 it follows that  $A \equiv B$ ; so any two dense linear orderings without endpoints are elementarily equivalent, and the theory  $T_{dlo}$  is complete.

We can say more. Suppose  $A$  and  $B$  both have countably many elements; list the elements of  $A$  as  $a_0, a_1, \dots$  and the elements of  $B$  as  $b_0, b_1, \dots$ . Let  $e_0$  be any function in  $I(A, B)$ . There is  $e_1$  in  $I(A, B)$  that extends  $e_0$  and has  $a_0$  in its domain and  $b_0$  in its image. Then there is  $e_2$  that extends  $e_1$  and has  $a_1$  in its domain and  $b_1$  in its image; and so on through  $e_3, e_4$ , and so on. Finally define a function  $e$  by putting  $e(a_i) = e_{i+1}(a_i)$  for each element  $a_i$  of  $A$ . By construction all elements of  $A$  are in the domain of  $e$  and all elements of  $B$  are in the image of  $e$ , and it follows that  $e$  is an isomorphism from  $A$  to  $B$ . We have proved a famous theorem of Cantor:

**Theorem 3** *If  $A$  and  $B$  are countable dense linear orderings without endpoints, then  $A$  and  $B$  are isomorphic.*

There are many adaptations of Fraïssé's idea. One different presentation (though with the same content) uses the idea of a game between two players who take turns to choose elements from the structures  $A$  and  $B$ . The criteria for the second player to win can be set up so that this player has a winning strategy if and only if there is a back-and-forth system from  $A$  to  $B$ .

In another adaptation, we require that the domains of the functions in the back-and-forth system all have cardinality  $\leq n$  for some positive integer  $n$ , dropping the requirements (b) and (c) when  $i$  has domain of size  $n$ . The existence of a back-and-forth system of this kind corresponds (as in Theorem 2) to the condition that  $A$  and  $B$  agree in all sentences with quantifier rank  $\leq n$ , in symbols  $A \equiv_n B$ . We omit the full definition of  $\equiv_n$  here, but we note that any sentence with at most  $n$  occurrences of quantifiers in it has quantifier rank  $\leq n$ , and that in a finite relational signature there are only finitely many pairwise nonequivalent sentences of rank  $\leq n$ . It follows that a class  $\mathbf{K}$  with finite relational signature is first-order definable if and only if it is closed under  $\equiv_n$  for some  $n$ . This leads quickly to an answer to Question Two.

**Theorem 4** *The equivalence relations  $A$  with  $\text{Mod}(\text{Th}(A))$  first-order definable are precisely the finite ones.*

Back-and-forth methods are a model-theoretic generalisation of techniques developed in several areas of mathematics, notably in the study of linear orderings and abelian groups. They also adapt to some languages that are not first-order, and unlike much of first-order model theory, they work as well for finite structures as for infi-

nite ones. This has made them useful tools of theoretical computer science, for example in database theory.

One shouldn't come away from this section with the impression that proving elementary equivalence is a matter of finding a clever model-theoretic technique. Model-theoretic ideas can help to bring to the surface the place where work has to be done, but most proofs of elementary equivalence involve substantial mathematics. For example a problem that Tarski posed in the 1950s, namely whether all free groups with more than one generator are elementarily equivalent, resisted decades of efforts. About half a century after Tarski put the problem, a positive solution was announced by Zlil Sela; besides quantifier elimination, it used a range of techniques from different parts of group theory.

### THE COMPACTNESS THEOREM

Almost everything in first-order model theory depends on the Compactness Theorem.

**Theorem 5 (Compactness Theorem)** *Let  $L$  be a first-order language and  $T$  a theory in  $L$  such that every finite subset of  $T$  has a model. Then  $T$  has a model.*

We sketch a proof using Hintikka sets as in the entry "First Order Logic." The proof needs a little set theory in the form of infinite cardinals and ordinals. (For the special case in which  $L$  has finite or countable signature, one needs only finite numbers.) Suppose the number of formulas of  $L$  is  $\kappa$ . We expand the language  $L$  to a language  $L^+$  by adding  $\kappa$  new constants, the *witnesses*. Each of the clauses (H1)–(H6) in the definition of a Hintikka set describes a set of requirements on a Hintikka set; for example (H4) describes, for each formula  $\phi(x)$  of  $L^+$  and each equation  $(s = t)$  where  $s$  and  $t$  are closed terms of  $L^+$ , the requirement that if  $\phi(s)$  and  $(s = t)$  are in the Hintikka set then  $\phi(t)$  is in the Hintikka set. We list all these requirements as  $(r_i : i < \kappa)$ , in a list of order-type  $\kappa$ , arranging that each requirement appears as  $r_i$  for  $\kappa$ -many ordinals  $i$ .

Now we define a sequence of theories  $(T_i : i \leq \kappa)$ , by induction on  $i$ , in such a way that three properties hold:

- (i) If  $i < j \leq \kappa$  then  $T_i$  is a subset of  $T_j$ .
- (ii) Each theory  $T_i$  has the property that every finite subset of  $T_i$  has a model.
- (iii) For each  $i < \kappa$  the number of sentences that are in  $T_{i+1}$  but not in  $T_i$  is finite.

The intention is that  $T_\kappa$  will be a Hintikka set.

We start by putting  $T_0 = T$ ; this ensures that (ii) holds for  $T_0$ . If  $i$  is a limit ordinal then we take  $T_i$  to be  $\bigcup_{j < i} T_j$ ; since (assuming (i)) every finite subset of  $T_i$  is already a subset of some  $T_j$  with  $j < i$ , this ensures that (ii) holds for  $T_i$  provided it already holds for each  $T_j$  with  $j < i$ .

Now for each ordinal  $i < \kappa$  we define  $T_{i+1}$ , assuming that  $T_i$  has been defined, in such a way that requirement  $r_i$  will be met if it applies. (When  $r_i$  doesn't apply, we put  $T_{i+1} = T_i$ .) The details depend on  $r_i$ . We consider some typical cases.

Suppose  $r_i$  is the requirement (from (H1)) that if  $(\phi \wedge \psi)$  is in the Hintikka set then so are  $\phi$  and  $\psi$ . If this requirement applies, that is, if  $(\phi \wedge \psi)$  is in  $T_i$ , then we take  $T_{i+1}$  to be  $T_i \cup \{\phi, \psi\}$ . It has to be checked that every finite subset of  $T_{i+1}$  has a model. Suppose  $U$  is a finite subset of  $T_{i+1}$ . Put  $V = (U \cap T_i) \cup \{(\phi \wedge \psi)\}$ . Then  $V$  is a finite subset of  $T_i$ , so by induction hypothesis it has a model, say  $A$ . Since  $A$  is a model of  $(\phi \wedge \psi)$ , it is also a model of  $\phi$  and  $\psi$ , and hence it must be a model of  $U$ .

Suppose  $r_i$  is the requirement (also from (H1)) that if  $\neg(\phi \wedge \psi)$  is in the Hintikka set then so is at least one of  $\neg\phi$  and  $\neg\psi$ . If  $\neg(\phi \wedge \psi)$  is in  $T_i$  then  $r_i$  applies. Put  $S_1 = T_i \cup \{\neg\phi\}$  and  $S_2 = T_i \cup \{\neg\psi\}$ . If every finite subset of  $S_1$  has a model then we put  $T_{i+1} = S_1$ . If not then there is some finite subset  $U$  of  $T_i$  such that  $U \cup \{\neg\phi\}$  has no model. We claim that in this case every finite subset  $V$  of  $S_2$  has a model. For consider  $U \cup (V \cap T_i) \cup \{\neg(\phi \wedge \psi)\}$ , which is a finite subset of  $T_i$  and hence has a model, say  $B$ , by induction hypothesis. Then  $B$  is a model of  $U$  and hence a model of  $\phi$ ; but  $B$  is also a model of  $\neg(\phi \wedge \psi)$ , so it must be a model of  $\neg\psi$  and hence of  $S_2$ , as claimed. Hence in this case we can put  $T_{i+1} = S_2$ .

Suppose  $r_i$  is the requirement (from (H5)) that if  $\exists x \phi(x)$  is in a Hintikka set then so is  $\phi(c)$  for some constant  $c$ . Suppose that this applies, that is, that  $\exists x \phi(x)$  is in  $T_i$ . By (iii) the number of witnesses used in sentences in  $T_i$  is less than  $\kappa$ , and so there must be at least one witness  $c$  not used yet. Choose such a  $c$  and put  $T_{i+1} = T_i \cup \{\phi(c)\}$ . Let  $U$  be a finite subset of  $T_{i+1}$ . Then  $(U \cap T_i) \cup \{\exists x \phi\}$  is a finite subset of  $T_i$ , and so by induction hypothesis it has a model, say  $C$ . Since  $C$  is a model of  $\exists x \phi$ , there is an element  $a$  of  $C$  such that  $C \models \phi[a]$ . Let  $D$  be the same structure as  $C$ , except that  $c_D = a$ . Then since  $c$  appears nowhere in sentences of  $T_i$ ,  $D$  is also a model of  $U \cap T_i$ . But by choice of  $c_D$  it is a model of  $\phi(c)$  too, so it is a model of  $U$ .

Now suppose we have completed the definition of  $T_\kappa$  as described. Suppose  $(\phi \wedge \psi)$  is in  $T_\kappa$ . Then  $(\phi \wedge \psi)$  is already in  $T_i$  for some  $i < \kappa$ . Since the requirement referring to  $(\phi \wedge \psi)$  is  $r_j$  for  $\kappa$  distinct ordinals  $j$ , it is  $r_j$  for some

$j > i$ . So the requirement will have been met when  $T_{j+1}$  was defined, and hence  $T_\kappa$  meets the requirement. A similar argument for each of the requirements (H1)–(H6) shows that  $T_\kappa$  meets all these conditions for a Hintikka set. Condition (H7) holds because every finite subset of  $T_\kappa$  has a model. So  $T_\kappa$  is a Hintikka set, and by Metatheorem 16 in the entry “First-Order Logic,” it has a model, say  $A$ . Since  $T$  is a subset of  $T_\kappa$ ,  $A$  is a model of  $T$ , proving the theorem.

Now we can answer Question Five. Let  $L^+$  be the first-order language of the structure  $\mathbb{N}$ , but with one extra constant  $c$ . Let  $T$  be  $\mathbb{N}$  together with the infinitely many sentences

$$\underline{0} < c, \underline{1} < c, \underline{2} < c, \dots$$

If  $U$  is any finite subset of  $T$ , then  $U$  includes at most finitely many of the sentences  $\underline{n} < c$ , and so we can choose a natural number  $m$  greater than any of the numbers  $n$  for which  $U$  mentions  $\underline{n}$ . Let  $\mathbb{N}^+$  be the expansion of  $\mathbb{N}$  got by putting

$$c_{\mathbb{N}^+}^+ = m.$$

Then  $\mathbb{N}^+$  is a model of  $U$ . It follows that every finite subset of  $T$  has a model, and hence by the Compactness Theorem there is a model  $A$  of the whole of  $T$ . Let  $B$  be the reduct of  $A$  to the language of  $\mathbb{N}$ . Then  $B \equiv \mathbb{N}$  since  $T$  contains  $\text{Th}(\mathbb{N})$ . But also  $B$  contains the element  $c_A$  which realizes the type consisting of all the formulas  $\underline{n} < x$ .

This argument illustrates the model-theoretic idea behind nonstandard analysis.

We can also answer Question Four. In any signature  $\sigma$ , let  $\mathbf{K}$  be the class of finite structures. If  $A$  is a structure in  $\mathbf{K}$  and  $B$  is a  $\sigma$ -structure elementarily equivalent to  $A$ , then  $A$  and hence also  $B$  are models of a sentence expressing “There are exactly  $n$  elements”, for some finite  $n$ . So  $B$  is also in  $\mathbf{K}$ . This shows that  $\mathbf{K}$  is closed under elementary equivalence. But let  $\tau$  be the expansion of  $\sigma$  got by adding infinitely many new constant symbols  $c_0, c_1, \dots$  and let  $T'$  be the theory consisting of all the sentences  $(c_i \neq c_j)$  where  $i < j$ . Since every finite subset of  $\text{Th}(\mathbf{K}) \cup T'$  has a model (expanding a structure in  $\mathbf{K}$ ), the Compactness Theorem tells us that  $\text{Th}(\mathbf{K}) \cup T'$  has a model, and hence that  $\text{Th}(\mathbf{K})$  has an infinite model. Thus  $\mathbf{K}$  is not first-order axiomatisable.

The general setting of our proof of the Compactness Theorem has many adaptations in model theory. A structure is built in a well-ordered sequence of steps, and we list in advance what feature of the structure has to be ensured at each step. Typical examples are the construction of models of a theory that omit certain types, the

construction of “existentially closed” models of a theory, and the construction of “two-cardinal” models in which some definable parts are large but other definable parts are kept small.

### SUBSTRUCTURES AND ELEMENTARY EMBEDDINGS

If  $X$  is a subset of  $Y$  then the *inclusion map* from  $X$  to  $Y$  is the function  $i : X \rightarrow Y$  such that  $i(x) = x$  for each element  $x$  of  $X$ . Let  $\sigma$  be a signature and  $A$  a  $\sigma$ -structure. We say that a  $\sigma$ -structure  $B$  is a *substructure* of  $A$ , and that  $A$  is an *extension* of  $B$ , in symbols  $A \subseteq B$ , if

- $\text{dom}(B)$  is a subset of  $\text{dom}(A)$ ,
- the inclusion map from  $\text{dom}(A)$  to  $\text{dom}(B)$  is an embedding of  $A$  into  $B$ .

An embedding  $e : A \rightarrow B$  between  $L$ -structures (for some first-order language  $L$ ) is said to *preserve* a formula  $\phi(x_1, \dots, x_n)$  of  $L$  if

$$A \models \phi[a_1, \dots, a_n] \Rightarrow B \models \phi[e(a_1), \dots, e(a_n)]$$

for all elements  $a_1, \dots, a_n$  of  $A$ . We say that  $e$  is an *elementary embedding* if  $e$  preserves all formulas of  $L$ . If  $A$  is a substructure of  $B$  and the inclusion map is an elementary embedding, then we say that  $B$  is an *elementary extension* of  $A$  and that  $A$  is an *elementary substructure* of  $B$ , in symbols  $A \preceq B$ . Always  $A \preceq A$ . Also if  $A \preceq B$  and  $B \preceq C$  then  $A \preceq C$ . If  $A \preceq B$  then  $A \equiv B$ .

Two important facts about elementary extension are:

**Theorem 6 (a)** *Let  $A$  be a substructure of the  $L$ -structure  $B$  such that*

*for every formula  $\phi(x_1, \dots, x_n)$  of  $L$  and all elements  $a_1, \dots, a_{n-1}$  of  $A$  such that  $B \models \exists x_n \phi[a_1, \dots, a_{n-1}]$  there is  $b$  in  $A$  such that  $B \models \phi[a_1, \dots, a_{n-1}, b]$ .*

*Then  $A \preceq B$ .*

**(b) (Union of elementary chains)** *Suppose  $\alpha$  is an ordinal and for every ordinal  $i < \alpha$  an  $L$ -structure  $A_i$  is given, so that  $A_i \preceq A_j$  whenever  $i < j < \alpha$ . Then writing  $A_\alpha$  for the union of all the structures  $A_i$ , we have  $A_i \preceq A_\alpha$  for all  $i < \alpha$ .*

Part (a) of Theorem 6 can be used to prove the following important result.

**Theorem 7 (Downward Löwenheim-Skolem Theorem)** *Let  $L$  be a first-order language,  $A$  an  $L$ -structure,  $X$  a set of elements of  $A$ , and  $\kappa$  an infinite cardinal number which is (i) at least as great as the number of sentences of  $L$ , (ii) at least as great as the cardinality of  $X$  and (iii) no*

greater than the cardinality of  $A$ . Then  $A$  has an elementary substructure of cardinality  $\kappa$  whose domain contains all the elements of  $X$ .

This is the result that creates the Skolem paradox. If the axioms of set theory have a model at all, then by this theorem they have a model of countable cardinality, although a sentence expressing “There are uncountably many real numbers” is true in the model!

Part (b) of Theorem 6 is useful for proving a similar result in the other direction. The argument after Theorem 5 adapts to show that every infinite structure has a proper elementary extension. By making repeated elementary extensions and using (b) to take unions at limit ordinals, we reach arbitrarily large elementary extensions.

**Theorem 8 (Upward Löwenheim-Skolem Theorem)** *Let  $L$  be a first-order language,  $A$  an infinite  $L$ -structure and  $\kappa$  a cardinal number which is at least as great as (i) the cardinality of  $A$  and (ii) the number of sentences of  $L$ . Then  $A$  has an elementary extension of cardinality  $\kappa$ .*

There is also a more algebraic construction that yields a proof of Theorem 8. It involves taking a cartesian product  $A^I$  of copies of the structure  $A$  and defining a homomorphic image in terms of an ultrafilter  $D$  on the set  $I$  indexing the copies. The resulting elementary extension  $A^I/D$  of  $A$  is called an *ultrapower* of  $A$ . Ultrapowers also yield a characterisation of  $\equiv$ :

**Theorem 9** *The following are equivalent, for any two  $L$ -structures  $A$  and  $B$ :*

- (a)  $A \equiv B$ .
- (b) *There are a set  $I$  and an ultrafilter  $D$  on  $I$  such that  $A^I/D$  is isomorphic to  $B^I/D$ .*

Many useful properties of ultrapowers spring from the fact that we can make them “highly saturated,” that is to say, realizing many types. One can also use the Compactness Theorem and union of elementary chains to build highly saturated structures.

The upward and downward Löwenheim-Skolem Theorems led to a natural question about first-order theories: How far can a first-order theory restrict its models? Assuming that the theory  $T$  is in a countable language and has an infinite model, we know that it has a model in each infinite cardinality. So the tightest restriction possible is that in every infinite cardinality  $\kappa$ ,  $T$  is  $\kappa$ -categorical, that is, it has a model of cardinality  $\kappa$  but all its models of cardinality  $\kappa$  are isomorphic to each other.

Michael Morley published the following theorem in 1965. Its main importance lies in its proof, which revolu-

tionised the techniques of model theory and began the developments reported in the final part of this article.

**Theorem 10 (Morley’s Theorem)** *Let  $L$  be a countable first-order language with infinite models, and  $T$  a theory in  $L$ . If  $T$  is  $\kappa$ -categorical for at least one uncountable cardinal  $\kappa$  then  $T$  is  $\lambda$ -categorical for all uncountable cardinals  $\lambda$ .*

A theory that is  $\kappa$ -categorical for all uncountable  $\kappa$  is said to be *uncountably categorical*. One major effect of Morley’s Theorem was to switch attention from theories to the detailed construction of their models, and a mark of this is that the models of an uncountably categorical theory are now also said to be *uncountably categorical*. A theory that is  $\kappa$ -categorical in all infinite cardinalities  $\kappa$  is said to be *totally categorical*, and so are its models.

By linear algebra, the theory of infinite dimensional vector spaces over a given finite field is totally categorical. A well-known theorem of Ernst Steinitz says that any two algebraically closed fields of the same characteristic and transcendence degree are isomorphic, and it follows that the theory of algebraically closed fields of a given characteristic is uncountably but not totally categorical. An answer to Question Three follows as well. Suppose  $A$  and  $B$  are any two algebraically closed fields of the same characteristic. Choose a cardinal  $\kappa$  greater than the cardinalities of both  $A$  and  $B$ . By Theorem 8,  $A$  and  $B$  have elementary extensions  $A'$  and  $B'$  of cardinality  $\kappa$ . Then  $A' \equiv B'$  by uncountable categoricity, and hence  $A \equiv A' \equiv B' \equiv B$ .

## INTERPOLATION AND DEFINABILITY

Let  $L$  be a first-order language containing a relation symbol  $R$ . Suppose  $\phi$  is a sentence of  $L$ . We say that  $R$  is *upwards monotone* in  $\phi$  if the following holds:

If  $A$  and  $B$  are two  $L$ -structures which are identical except that  $R_A \subset R_B$ , and  $A \models \phi$ , then  $B \models \phi$ .

Likewise we say that  $R$  is *downwards monotone* in  $\phi$  if the following holds:

If  $A$  and  $B$  are two  $L$ -structures which are identical except that  $R_A \subset R_B$ , and  $B \models \phi$ , then  $A \models \phi$ .

In the late middle ages a relation symbol (a ‘term’ in the medieval terminology) was described as *undistributed* in a sentence if it was upwards monotone in the sentence, and *distributed* if it was downwards monotone in the sentence. For example one can symbolise ‘All swans are white’ as  $\forall x (S(x) \rightarrow W(x))$ ; in this sentence  $S$  is distributed and  $W$  is undistributed. (“All swans are white” entails both of the sentences “All Bewick swans are white”

and “All swans are non-red”. The medievals said that “swans” is distributed and “white” is undistributed in “All swans are white.”)

There is a syntactic test for upwards and downwards monotonicity. We say that a formula  $\phi$  is in *negation normal form* if  $\rightarrow$  and  $\leftrightarrow$  never occur in  $\phi$ , and  $\neg$  never occurs in  $\phi$  except immediately in front of atomic formulas. Every formula is logically equivalent to one in negation normal form and with the same free variables. For example

$$(5) \quad \forall x (S(x) \rightarrow W(x))$$

is logically equivalent to

$$(6) \quad \forall x (\neg S(x) \vee W(x)).$$

When  $\phi$  is in negation normal form, we say that an occurrence of a relation symbol  $R$  in  $\phi$  is *negative* if it has  $\neg$  immediately to the left of it, and *positive* otherwise. For example the occurrence of  $S$  in (6) is negative and the occurrence of  $W$  in (6) is positive. The next theorem is a straightforward consequence of the definition of satisfaction.

**Theorem 11** *Let  $L$  be a first-order language,  $R$  a relation symbol of  $L$  and  $\phi$  a sentence of  $L$  in negation normal form. If  $R$  has no negative occurrences in  $\phi$  then  $R$  is upwards monotone in  $\phi$ . If  $R$  has no positive occurrences in  $\phi$  then  $R$  is downwards monotone in  $\phi$ .*

Since upwards and downwards monotonicity clearly aren't affected when we pass between logically equivalent sentences, Theorem 11 confirms that  $S$  is downwards monotone and  $W$  is upwards monotone in (5).

Unlike Theorem 11, the next theorem is deep. It is known as *Lyndon's Interpolation Theorem*, after Roger Lyndon who published it in 1959.

**Theorem 12** *Let  $L$  be a first-order language and  $\phi, \psi$  sentences of  $L$  in negation normal form, such that  $\phi$  entails  $\psi$ . Then there is a sentence  $\theta$  of  $L$  in negation normal form such that*

- $\phi$  entails  $\theta$  and  $\theta$  entails  $\psi$ ,
- any relation symbol (apart from  $=$ ) with a positive occurrence in  $\theta$  has positive occurrences in both  $\phi$  and  $\psi$ , and
- any relation symbol (apart from  $=$ ) with a negative occurrence in  $\theta$  has negative occurrences in both  $\phi$  and  $\psi$ .

The sentence  $\theta$  in the theorem is called a *Lyndon interpolant*.

The following immediate consequence of Lyndon's Interpolation Theorem is called *Craig's Interpolation Theorem*.

It was proved by William Craig before Lyndon's theorem was known.

**Theorem 13** *Let  $L$  be a first-order language and  $\phi, \psi$  sentences of  $L$  such that  $\phi$  entails  $\psi$ . Then there is a sentence  $\theta$  of  $L$  such that*

- $\phi$  entails  $\theta$  and  $\theta$  entails  $\psi$ ,
- any relation symbol (apart from  $=$ ) that occurs in  $\theta$  occurs in both  $\phi$  and  $\psi$ .

The sentence  $\theta$  here is called the *Craig interpolant*.

We give two applications of these interpolation theorems.

**LAWS OF DISTRIBUTION.** A *sylogistic sentence* is a sentence of one of the forms  $\forall x (R(x) \rightarrow S(x))$ ,  $\forall x (R(x) \rightarrow \neg S(x))$ ,  $\exists x (R(x) \wedge S(x))$  and  $\exists x (R(x) \wedge \neg S(x))$ , where  $R$  and  $S$  are different relation symbols. For each sylogistic sentence and each relation symbol in it, Theorem 11 tells us that the relation symbol is distributed or that it is undistributed. A *sylogism* is a sequent of the form  $\phi, \psi \models \chi$  where each of  $\phi, \psi$  and  $\chi$  is a sylogistic sentence, three relation symbols are used, and each of them occurs in two sentences. For example one sylogism is

$$(7) \quad \forall x (P(x) \rightarrow Q(x)), \forall x (R(x) \rightarrow Q(x)) \models \exists x (P(x) \wedge R(x)).$$

This sylogism happens to be invalid, but there are many examples of valid sylogisms.

Late medieval logicians looked for criteria to tell when a sylogism is valid. Two of their criteria were the following, known as the *laws of distribution*:

If a relation symbol occurs in both premises, then it must be distributed in at least one of them. If a relation symbol occurs in a premise and the conclusion, and is undistributed in the premise, it must be undistributed in the conclusion.

Why do these criteria work? The answer is Lyndon's Interpolation Theorem. We illustrate with the invalid sylogism (7) above, which fails the first distribution law by having  $Q$  undistributed in both premises. The same recipe works for all cases.

Suppose for contradiction that (7) is valid. Then after a small rearrangement we have

$$\forall x (P(x) \rightarrow Q(x)) \models \forall x (R(x) \rightarrow Q(x)) \rightarrow \exists x (P(x) \wedge R(x)).$$

Convert the sentences to negation normal form, and let  $\theta$  be a Lyndon interpolant for the resulting sequent. Since  $Q$

occurs only positively on the left and only negatively on the right, it never occurs in  $\theta$ . So we can introduce a new relation symbol  $Q'$ , and we have a valid sequent

$$\forall x(P(x) \rightarrow Q'(x)) \vDash \theta.$$

Hence by combining the sequents again we infer that the sequent

$$\forall x(P(x) \rightarrow Q'(x)) \vDash \forall x(R(x) \rightarrow Q(x)) \rightarrow \exists x(P(x) \wedge R(x))$$

is valid, and hence so is

$$\forall x(P(x) \rightarrow Q'(x)), \forall x(R(x) \rightarrow Q(x)) \vDash \exists x(P(x) \wedge R(x)).$$

But it can't be because the two premises have no relation symbols in common and hence can't establish any non-trivial relationship between  $P$  and  $R$ .

The Port-Royal Logic of Arnauld and Nicole (1662) explains that (7) is invalid because  $Q$  “may be taken for two different parts of the same whole” (Rule I in their III.iii). This is vague and not properly justified, but one can see our argument above as a repair of the Port-Royal argument.

**EXPLICIT AND IMPLICIT DEFINABILITY.** Suppose  $L$  is a first-order language, one of whose symbols is a relation symbol  $R$  of arity  $n$ , and  $T$  is a theory in  $L$ . One can ask whether  $R$  is redundant in  $T$ , in the sense that in any model  $A$  of  $T$  the relation  $R_A$  is determined by the rest of  $A$ . Here are two different ways of making this notion of redundancy precise. (We write  $\sigma$  for the signature of the language  $L$  but with  $R$  removed.)

(a)  $T$  has a consequence of the form

$$(8) \quad \forall x_1 \dots \forall x_n R(x_1, \dots, x_n) \leftrightarrow \phi(x_1, \dots, x_n)$$

where  $\phi$  is a formula of  $L(\sigma)$ .

(b) Whenever  $A$  and  $B$  are two  $L$ -structures that are models of  $T$ , and  $A|_{\sigma} = B|_{\sigma}$ , we have  $A = B$ .

When (a) holds we say that  $R$  is *explicitly definable* in  $T$ , and the sentence (8) is called an *explicit definition* of  $R$  in  $T$ . When (b) holds we say that  $R$  is *implicitly definable* in  $T$ .

It turns out that explicit definability and implicit definability are equivalent. (This is for first-order logic; part (b) in the theorem below fails for many other logics.)

**Theorem 14** *Let  $L$  be a first-order language,  $R$  a relation symbol of  $L$  and  $T$  be a theory in  $L$ .*

(a) *If  $R$  is explicitly definable in  $T$  then  $R$  is implicitly definable in  $T$ .*

(b) *If  $R$  is implicitly definable in  $T$  then  $R$  is explicitly definable in  $T$ .*

Part (a) of the theorem, or more strictly its contrapositive, is known as *Padoa's method*, after Alessandro Padoa who was a researcher in Giuseppe Peano's school around 1900. The proof is straightforward.

Part (b) is called *Beth's Theorem*. It was proved by Evert Beth in 1953, but the following derivation from Craig's Interpolation Theorem is due to Craig. Assume that  $R$  is implicitly definable in  $T$ . Let  $T'$  be  $T$  but written with a new relation symbol  $R'$  in place of  $R$ , and let  $L^+$  be  $L$  with  $R'$  added. Then the statement that  $R$  is implicitly definable in  $T$  implies the following:

Suppose an  $L^+$ -structure  $A$  is a model of  $T \cup T'$ . Then  $R_A \subseteq R'_A$ .

We can rewrite this as a sequent:

$$(9) T \cup T' \vDash \forall x_1 \dots \forall x_n (R(x_1, \dots, x_n) \rightarrow R'(x_1, \dots, x_n)).$$

Add  $n$  new constants  $c_1, \dots, c_n$  to the language  $L^+$ . By (9), using Metatheorem 10 of the entry “First-Order Logic”,

$$(10) \quad T \cup T' \vDash R(c_1, \dots, c_n) \rightarrow R'(c_1, \dots, c_n).$$

Now by the Compactness Theorem there are finite subsets  $U, U'$  of  $T, T'$  respectively, such that

$$(11) \quad U \cup U' \vDash R(c_1, \dots, c_n) \rightarrow R'(c_1, \dots, c_n).$$

Adding sentences to  $U$  and  $U'$  if necessary, we can suppose that  $U'$  is the same as  $U$  except that  $R$  is replaced by  $R'$ . Write  $\psi$  for the conjunction of the sentences in  $U$ , and  $\psi'$  for  $\psi$  with  $R$  replaced by  $R'$ . Then after some rearrangement (11) gives

$$(12) \quad \psi \wedge R(c_1, \dots, c_n) \vDash \psi' \rightarrow R'(c_1, \dots, c_n).$$

Now apply Craig's Interpolation Theorem to find an interpolant  $\theta$  such that the following sequents are valid:

$$(13) \quad \psi \wedge R(c_1, \dots, c_n) \vDash \theta,$$

$$(14) \quad \theta \vDash \psi' \rightarrow R'(c_1, \dots, c_n).$$

Since  $R$  occurs only on the left of (12) and  $R'$  occurs only on the right, neither symbol occurs in  $\theta$ . So by (14) we have the following valid sequent:

$$(15) \quad \theta \vDash \psi \rightarrow R(c_1, \dots, c_n).$$

By (13) and (15),

$$\psi \vDash R(c_1, \dots, c_n) \leftrightarrow \theta.$$

Now let  $\phi$  be  $\theta$  but with each constant  $c_i$  replaced by the variable  $x_i$ . (If necessary we first change the bound vari-

ables of  $\theta$  so that no quantifier in  $\theta$  binds any of these variables  $x_i$ .) Then by Metatheorem 10 again, we have

$$(16) \quad T \models \forall x_1 \dots \forall x_n (R(x_1, \dots, x_n) \leftrightarrow \phi(x_1, \dots, x_n))$$

as claimed.

There are many model-theoretic results that are close relatives of the examples above, either in their statements or in their proofs. For example a *preservation theorem* is a theorem stating that some syntactic condition is necessary and sufficient for a formula to be preserved under some algebraic operation. Here follows a typical preservation theorem. We say that a formula  $\phi$  is a  $\forall$  formula if  $\phi$  has the form  $\forall y_1 \dots \forall y_n \psi$  where  $\psi$  is quantifier-free.

**Theorem 15 (Łoś-Tarski Theorem)** *Let  $L$  be a first-order language,  $\phi(x_1, \dots, x_n)$  a formula of  $L$  and  $T$  a theory in  $L$ . Then the following are equivalent:*

(a) *For every embedding  $e : A \rightarrow B$  between models of  $T$  and all elements  $a_1, \dots, a_n$  of  $A$ ,*

$$B \models \phi[e(a_1), \dots, e(a_n)] \Rightarrow A \models \phi[a_1, \dots, a_n].$$

(b)  *$\phi$  is equivalent modulo  $T$  to a  $\forall$  formula  $\psi(x_1, \dots, x_n)$ .*

### EXTENSIONS OF FIRST-ORDER LOGIC

The structures that we defined above are sometimes called *first-order structures* because of their connection with first-order languages. There are other kinds of structure that have analogous connections with other kinds of formal language. Here are two important examples.

(a) Suppose  $L$  is a first-order language. Let  $I$  be a nonempty set carrying a binary relation  $R$ , and for each element of  $I$  let  $A_j$  be an  $L$ -structure. Then, given an element  $i$  of  $I$  and a sentence  $\phi$  of  $L$ , we can ask whether  $A_j \models \phi$  for all  $j$  such that  $Rij$ . We can introduce a sentence  $\Box\phi$  which counts as true in  $A_i$  if and only if the answer is Yes. Indexed families of structures of this type appear in modal logic, temporal logic and some logics of action.

(b) We can consider structures with two domains, where the second domain is a set of subsets of the first domain. Structures of this kind appear in second-order logic, where we have first-order and second-order variables ranging respectively over the first domain and the second domain. They are also found in topological logics, where the second domain contains (for example) a base of open sets for a topology over the first domain.

*Sortal* structures and languages are a less drastic extension. A sortal signature lists a set of “sorts” and may

put restrictions on the function symbols in terms of the sorts. Each sortal structure with this signature has a family of domains, one for each sort. The corresponding sortal language has separate variables for each sort. Sortal structures have some natural mathematical applications. For example a vector space involves a set of vectors and a set of scalars; we can multiply a vector by a scalar, but in general we can’t multiply two vectors. So it is natural to work with one sort for vectors and another sort for scalars, and to restrict multiplication so that two vectors can’t be multiplied.

If the only changes we make in passing from first-order to sortal are those just described, then the resulting languages behave very much as ordinary first-order languages, and the model theory of sortal structures and languages is hardly distinguishable from ordinary first-order model theory. If we put further restrictions the situation may change; for example if we require that the elements of one sort are exactly the sets of elements of some other sort, then we move into second-order logic.

But even for ordinary first-order structures we need not restrict ourselves to first-order languages. For example we can add to first-order logic

- quantifiers  $Q_\kappa x$  that express ‘There are at least  $\kappa$  elements  $x$  such that ...’;
- infinitary conjunctions of formulas  $\bigwedge_{i < \kappa} \phi_i$  meaning ‘ $\phi_0$  and  $\phi_1$  and ...’, and likewise infinitary disjunctions;
- transitive closure operators that express, given a formula  $\phi(x, y)$ , the property ‘There is a finite sequence  $a_1, \dots, a_n$  such that  $\phi(x, a_1)$  and  $\phi(a_1, a_2)$  and  $\phi(a_2, a_3)$  and ... and  $\phi(a_{n-1}, a_n)$  and  $\phi(a_n, y)$ ’.

For example the models of the infinitary disjunction

$$\bigvee_{i < \omega} \text{There are at most } i \text{ elements}$$

are exactly the finite structures. In section 5 we saw that there is no first-order sentence defining this class.

Some of these extensions of first-order logic, using first-order structures, have an elegant and well-developed model theory. But the general truth seems to be that none of them work as smoothly as first-order logic. In 1969 Per Lindström proved some theorems that capture this fact. He showed that if a logic  $\mathcal{L}$  contains first-order logic and obeys some of the metatheorems that hold for first-order logic, then  $\mathcal{L}$  must be equivalent to first-order logic, in the sense that for every sentence  $\phi$  of  $\mathcal{L}$  there is a first-order sentence with exactly the same models as  $\phi$ . For example

**Theorem 16** Let  $\mathcal{L}$  be a logic that contains first-order logic. Suppose that  $\mathcal{L}$  has the properties:

- (a) Every sentence of  $\mathcal{L}$  with infinite models has a model that is at most countable.
- (b) If  $T$  is a set of sentences of  $\mathcal{L}$  and every finite subset of  $T$  has a model then  $T$  has a model.

Then  $\mathcal{L}$  is equivalent to first-order logic.

A fuller account would explain more precisely what is meant by a “logic that contains first-order logic”.

## STABILITY AND GEOMETRIC MODEL THEORY

Mathematical model theory has become a highly sophisticated branch of mathematics. The items below can be no more than pointers.

Morley’s Theorem (Theorem 10) created a new paradigm for model theory. He made it possible to show that a purely model-theoretic condition—uncountable categoricity—on a theory  $T$  imposes some strong structural features on all the models of  $T$ . Each such model must contain a *strongly minimal set*, which is a set carrying a dependence relation that behaves like linear or algebraic dependence. In particular the strongly minimal set has a dimension in the same sense as a vector space, and the strongly minimal set is determined up to isomorphism by its dimension and  $T$ . (Steinitz’ Theorem in section 6 is a special case of this fact, since every algebraically closed field is a strongly minimal set.) The rest of the model is very tightly constructed around the strongly minimal set. We can define a function assigning a “rank” to each set definable with parameters in the model; this *Morley rank* is a generalisation of Krull dimension and it allows a very detailed analysis of the model.

Much of the work following on from Morley’s Theorem organised itself around one or other of two heuristic principles, known as *Shelah’s dichotomy* and *Zilber’s trichotomy*. Both of these principles rest on the fact that uncountably categorical theories are “good” in the sense that their classes of models are well-behaved. Both of them have been proved as theorems in certain cases.

For Saharon Shelah, “good” theories form one end of a scale from good to bad. There are several ways that a theory can be bad. One is that it has too many non-isomorphic models to allow any kind of cataloguing by invariants. Another is that it has models that are not isomorphic but are hard to tell apart. Shelah’s policy is that at each point of the scale from good to bad, one should aim to maximise the difference between the theories on

the “good” side and those on the “bad” side. On the “good” side one should aim to find as much good behaviour as possible, in terms of dependence relations, definability properties, rank functions, and so forth. On the “bad” side one should aim to construct intractable families of models, for example large families of models none of which is elementarily embeddable in any other. Though he applies this principle at all points of the scale, he also identified a *main gap* between the good side and the bad side, and when one speaks of “Shelah’s dichotomy” one often has this particular gap in mind.

Shelah created a powerful body of techniques for handling models of theories towards the “good” end of the scale. Together with Morley’s work it forms the bulk of *stability theory*. Shelah has also done a large amount of work towards eliminating the restriction to first-order theories. He has suggested several abstract frameworks, for example *excellent classes*, in which there is no counterpart of the Compactness Theorem but some techniques of stability theory still work.

Boris Zilber is more interested in exploiting the “goodness” of the good end of the scale. He is convinced that uncountably categorical structures should all be mathematically interesting, and in fact that they should all be equivalent, up to model-theoretic interpretation, to structures of interest in “classical” mathematics. So he set out to catalogue them, and in the early 1980s he pointed out a natural three-way division of uncountably categorical structures. The division rests on the dependence relation of the strongly minimal set. In the first place there are structures where this relation is “trivial”. If it is not trivial, one looks at the lattice of closed sets under the dependence relation. The second class is where this lattice is modular, the third is where it is non-modular. So we have a division of uncountably categorical structures into trivial, modular, and non-modular. The trivial structures are now essentially all known. Modularity turns out to be a strong property, guaranteeing that the structure contains an infinite definable abelian group which exerts a controlling influence; broadly speaking, modular structures exhibit linear algebra.

Zilber conjectured that all non-modular uncountably categorical structures are (up to model-theoretic interpretation) algebraically closed fields. Several pieces of evidence pointed in this direction, notably (i) Angus Macintyre’s observation in 1971 that an uncountably categorical field must be algebraically closed, and (ii) observations by Zilber himself and Greg Cherlin that uncountably categorical groups behave remarkably like algebraic groups over an algebraically closed field. *Zilber’s trichotomy* is the

division into trivial, modular and non-modular, together with the conjecture that the non-modular structures are algebraically closed fields (up to interpretation). Zilber's trichotomy has been proved to hold for *Zariski geometries*; these are uncountably categorical structures that obey an axiomatisation of the Zariski topology. Ehud Hrushovski saw how to use this fact to solve some major open problems of diophantine geometry, for example proving the Mordell-Lang conjecture for function fields in all characteristics. (His proof in characteristic 0 has since been simplified by replacing the Zariski geometries by differential jet spaces). In 1998 Ya'acov Peterzil and Sergei Starchenko showed that a version of Zilber's trichotomy is true for o-minimal fields.

In 1989 Hrushovski found counterexamples to Zilber's conjecture: uncountably categorical non-modular structures containing no infinite field. At first Hrushovski's examples were mysterious. But Zilber was sure that they must have classical interest, and after some years he discovered structures of Hrushovski's type arising in complex analysis. He also pointed out a close link between Hrushovski's construction and Schanuel's Conjecture in number theory. At the same time Zilber gave examples from complex analysis to illustrate Shelah's excellent classes, thus bringing together two separate lines of research in model theory.

Through the 1990s a body of results converged to show that tools of stability theory are useful in contexts far outside those of 'good' first-order theories. In fact the complete theory  $\text{Th}(A)$  of a structure  $A$  can be largely irrelevant to the application of these tools to  $A$ . The need to translate classical descriptions into first-order sentences had always been a practical obstacle to integrating model theory with classical mathematics, and this need seemed to be receding in part. In this context Ludwig Faddeev, after reading the relevant papers presented to the International Congress of Mathematicians in Beijing in 2002, said at the closing ceremony

Take for instance the sections of logic, number theory and algebra. The general underlining mathematical structures as well as language, used by speakers, were essentially identical.

## MODERNISM

Modernism was a movement in Catholic religious thought, and particularly in biblical criticism, that developed in the late nineteenth century and spent itself, as a distinctive movement, before World War I. It aimed at bringing Catholic traditions into closer accord with modern views in philosophy and in historical and other scholarship and with recent social and political views. Modernism ran parallel to liberal Protestantism; both tended to reject authority and rigid forms and, in their more extreme versions at least, to aspire to a kind of Christianized rationalism.

The kind of Christology and biblical exegesis undertaken in Germany by D. F. Strauss and in France by Ernest Renan, aided and encouraged by such philosophical currents as positivism and evolutionism, culminated in the late-nineteenth-century attempt to reconcile science with religion and historical criticism with belief. Renan's rejection of the supernatural, combined with his vague evolutionary religiosity, anticipated much that was to be written during the fifteen years following his death in 1892.

Modernism was represented in England by George Tyrrell, Friedrich von Hügel (a friend of Alfred Loisy), and Maude Petre; in Italy by Antonio Fogazzaro, Romolo Murri, and Salvatore Minocchi; and in Germany by Franz Xavier Kraus and Hermann Schnell. However, most of the controversy centered in France, on account of the writings and influence of Loisy, Édouard Le Roy, and Lucien Laberthonnière, who brought to their approach to religion the spirit of contemporary science and philosophy. Loisy, like Renan, rejected the supernatural and explained religion in terms of an immanent rather than a transcendent principle. Le Roy circumvented the difficulties inherent in Catholic dogmas by treating them as pragmatically true. Laberthonnière edited the *Annales de philosophie chrétienne*, a journal that was committed, according to its program, to a rationalistic interpretation of religion, recognizing "the duty to submit to reflection what we believe no less than what we do and think." The review's general policy favored the view that religion is progressively revealed, primitive revelation being only potentially complete. The maneuverings necessitated by the desire to reconcile faith and reason led to some inconsistency and self-contradiction.

From its inception, modernism was in constant trouble with the ecclesiastical authorities, but orthodoxy did not become militant until the accession of Pope Pius X in 1903. In 1907 the papal decree *Lamentabili Sane Exitu*, a

collection of sixty-five condemned propositions aimed chiefly at Loisy, and the more general and philosophically grounded encyclical *Pascendi Dominici Gregis*, condemned the modernists' views. The requirement in 1910 that all clerics take the antimodernist oath, known as *Sacrorum Antistitum*, marked the end of the movement as such, although its spirit persisted and prospered in less rebellious forms.

## MODERNISM AND POSTMODERNISM

Modern philosophy is construed as beginning sometime in the Renaissance. A philosophy that seeks new foundations for knowledge was offered as an alternative to that provided by the ancient philosophers. Modern philosophy was presented as starting afresh from new beginnings—turning to nature directly (Francis Bacon), turning to the mind directly (René Descartes), turning to experience directly (Thomas Hobbes). The "quarrel between the ancients and the moderns" resulted from this basic disagreement as to the sources of philosophical knowledge.

Modern philosophy turned away from the past and toward the future, toward the advancement of knowledge, toward human understanding, and toward progress through method or through experience. With the break between the Continental rationalists (Descartes, Nicolas Malebranche, Gottfried Wilhelm Leibniz, and Benedict de Spinoza) and the British empiricists (Hobbes, John Locke, and David Hume) at the end of the eighteenth-century Enlightenment, a new formulation in modern philosophy was called for. Immanuel Kant brought together in his "critical" philosophy the commitments to the analytic exercise of the mind, on the one hand, and the empirical reception through the senses on the other. With Kant, modern philosophy combined the "transcendental unity of apperception" with the "manifold of expe-

rience.” Modern philosophy was no longer based on a theory of representation—representation to the mind through reason or representation to the mind through experience—but on the linking of transcendental subjectivity and empirical objectivity. This “doublet,” as Michel Foucault came to name it, accounted for a whole new way of philosophizing.

Modernism is distinguished from modern philosophy in that it is linked to certain movements in art and literature that began sometime around the end of the nineteenth century. While drawing upon some similar characteristics of “modern philosophy,” modernism in art, literature, and philosophy involved novelty, break with tradition, progress, continuous development, knowledge derived either from the position of the subject or from claims to objectivity, and concomitantly the crisis in knowledge produced by this very dichotomy. Hence in modernism, at the same time that certain theories based knowledge on a centered, transcendental, interpreting subjectivity, and others based knowledge on certain, atomistic, analytic, empirical objectivity, the crisis in knowledge created a sense of uncertainty, paradox, incompleteness, inadequacy, emptiness, and void. Modernism in art and literature involved a shift away from the dichotomies of romanticism and realism to the stream of consciousness, lived and internal time-consciousness, transcendental subjectivity, narrated remembrance and awareness, portrayed speed, mechanisms, objects, and abstractions. Latent content was allowed to penetrate through the surfaces of manifest content. Understanding would have to delve more deeply than surfaces and mere appearances. A phenomenology would be needed in order to inventory the contents of consciousness (Edmund Husserl) or a psychoanalysis to delve the depths of what the mind was really thinking (Sigmund Freud), or a logical positivism would take the alternative tack by excluding all knowledge that cannot be verified logically and empirically (Bertrand Russell, early Ludwig Wittgenstein, A. J. Ayer). Modernism in philosophy involved at each stage the Kantian combination of the empirical and the transcendental, the objective and the subjective, the material and the intellectual—but each time measuring the doublet with weight on one side or the other.

The disintegration of modernism in philosophy was internal. The radical claims of logical positivism excluded all that was of value: metaphysics, aesthetics, axiology, and so forth. The rigorous science of transcendental phenomenology excluded the very existence of what it was investigating. The dualism of creative evolutionism left

an irreparable dichotomy between lived experience and objective knowledge. The pragmatism of radical empiricism failed to provide a way to interpret the meanings of experience. The center of modernism in philosophy could not hold because its very foundations were in question. But attempts to retrieve it from itself by the turn to language—ordinary language, analytic philosophies of language, hermeneutics of language, semiologies of language—could not resolve the dilemmas of human existence. Modernism in philosophy faced the absurd, the ambiguous, and the dialectical. And it worked these theories to their limits.

In the mid-1960s philosophy came to look at its epistemological formations and to ask whether the humanisms and anthropologisms of modern philosophy had not circumscribed themselves. Maurice Merleau-Ponty’s interrogations were reformulated in Foucault’s archaeology of knowledge. The human sciences placed the optimisms and pessimisms of modern philosophy in question by circumventing the theory of “man.” Knowledge formations were articulated in terms of multiple spaces of knowledge production and no longer according to a central source or position, or ego, or self, or subject, nor according to a multiplicity of sense-data, objective criteria, material evidence, or behaviors. Knowledge formations crossed disciplines and operated in multiple spaces where questions of structure, frame, margin, boundary, edge, limit, and so on would mark any discursive practice. In other words, knowledge was no longer produced from a center, foundation, ground, basis, identity, authority, or transcendental competency. Knowledge was dispersed, multiple, fragmented, and theoretically varied. Knowledge was no longer based on continuity, unity, totality, comprehensiveness, and consistency. Knowledge began to be understood in terms of discontinuity, difference, dissemination, and differends.

By the early 1970s postmodernism—a term that Daniel Bell used in connection with postindustrial society in the 1950s, that architects appealed to in the 1960s, and that art and literary historians invoked in the 1970s—had still not been invoked in connection with philosophy. Jacques Derrida’s grammatology and theory of “difference” in 1967 (building upon Martin Heidegger’s account of “the end of philosophy and the task of thinking”) turned into a full-fledged deconstruction in the 1970s. Gilles Deleuze and Felix Guattari’s notion of rhizomal thinking (as opposed to hierarchical, authorizing arborescent thinking) marked a move against psychoanalytic theories based on Oedipal authority and paternal insistence. Their idea of nomadism placed emphasis on

knowledge, experience, and relations that were not organized around a central concept. J. Kristeva's account of the revolution in poetic language marked the distinction between the semiotic and the symbolic. Where symbolic—scientific, theoretical, phallic, paternal—thinking had pervaded philosophy and science, Kristeva invoked the semiotic as the poetic, fluid, receptacle-like, maternal thinking that has been hidden in modern thought. Yet postmodern was hardly the term that was invoked to describe this kind of philosophizing. Correspondingly, the more restricted study of phenomenology and existentialism in philosophy gave way to the more multiple and diverse theories implicit in Continental philosophy: deconstruction, archaeology of knowledge, semanalysis, schizoanalysis, feminist theory, and so forth. Yet, while poststructuralism (in connection with Foucault, Derrida, Deleuze, Kristeva, et al.) was hailed as the successor to structuralism (Claude Lévi-Strauss, Roland Barthes, Jacques Lacan, Louis Althusser), and existential phenomenology (Heidegger, Jean-Paul Sartre, Merleau-Ponty, Simone de Beauvoir), postmodernism was still not a relevant category in philosophy until well into the 1980s. As time passed, postmodernism and postmodern thought came to take precedence over poststructuralism as the prevalent theoretical formulation.

Postmodern thought means the appeal to differences—differences in theories, differences in formulations, differences in identities. Postmodern thought rejects hierarchies and genealogies, continuities and progress, resolutions and overcomings (*Überwindungen*). Postmodern thought, in fact, cannot operate outside of the modern, for it is itself what can be called an “indecidable.” The postmodern signals the end of modernity, but it operates at the same time necessarily within the modern. To claim that the postmodern is outside the modern is to identify it as other than the modern, but that which is outside or other reinscribes the identity of the modern and therefore the postmodern inscription within it. Hence the postmodern both marks places of difference within the modern and calls for an alternative to the modern. The postmodern in any case does not call for the destruction of the modern, not does it seek to deny the modern, since it is necessarily part of the modern.

The postmodern involves the question of the end or limit or margin of what is in question. History, man, knowledge, painting, writing, the modern—each is posed in terms of its end. The end is not a matter of termination or conclusion any more than a matter of goal and aspiration. The postmodern involves, as G. Vattimo notes, a *Verwindung* of modernity—a getting over, a convales-

cence, a recovering from modernity. This means that modernity is itself placed in question and no longer taken as an unquestioned given. The cracks and fissures in modernity, the places where modernity cannot be fully aware of itself, the moments of unrepresentability in the modern—these are the concerns of postmodern thought. As J.-F. Lyotard has noted in his famous *The Postmodern Condition* (1984), the postmodern involves the presentation of the unrepresentable in presentation itself—that is, in modernity, the concern was to present something new, something unheard of, something unique, something shocking, something unrepresentable. The postmodern involves the presentation of the unrepresentable in presentation itself—the formulation of the moments of unrepresentability as they mark what is presented. Lyotard calls attention to the role of the “differend” as the place of conflict between two alternative positions. The differend does not belong to either side. It belongs only to the place between, to the gap between the two presentations on either side. This is the postmodern moment—such moments or events with which the modern is distinctively scarred and animated.

## MOIRA/TYCHĒ/ANANKĒ

All three Greek words denote causal powers that are beyond the reach of human control, and hence were often personified as goddesses.

The word “moira” means a share, part, or portion, and by derivation, the fate allotted to a person. In mythological contexts, it was personified either as a single goddess or, as in Hesiod’s *Theogony* and in the myth of Plato’s *Republic X*, as a group of three goddesses (Clotho, Lachesis, Atropos). Moira or the Moirai determine the fate of individuals by “spinning” the thread of one’s life. The word “moira” sometimes euphemistically refers to death, as the fate of all humans. In other contexts it refers to one’s rank or distinction or to the positive abilities allotted by the gods, such as poetic inspiration. In Stoic determinism, it is used in relation to universal fate (*heimarmenē*).

The noun “tychē” (fortune) is related to the verb “tynchano” (happen, befall). Tychē was taken to be the cause of chance events—events that one could not or did not calculate and that do not fit into a regular pattern. While moira determines one’s course of life as a whole, tychē tends to be responsible for singular events of varying importance. The connotations of the word were originally more positive, but by Hellenistic times it regularly had the pejorative meaning of blind, impersonal, arbitrary chance. In philosophical contexts it is most often contrasted with rational choice and goal-driven action. Plato, in the *Laws X*, grouped tychē together with the mechanistic force of nature and opposed it to the rational, purposeful activity of a cosmic god. Aristotle, in the *Physics II.5–7*, classified tychē under spontaneity (*automaton*) and defined it as an accidental and indeterminable cause in the sphere of purposeful actions involving rational choice. In other words, tychē for Aristotle is the cause of events that might have been the outcome of rational human choice but in fact are not.

The word “anankē” originally referred to an external constraining force, and from this meaning it obtained the more abstract meaning of logical and physical necessity

during the pre-Socratic period. It is often represented as the ultimate power with which even the gods must comply. In Parmenides’ *Aletheia*, the personified Anankē guarantees that Being is unchangeable and immobile, and “holds [Being] in the bonds of a limit” (Diels and Kranz 1954, B8.30), while in the *Doxa* she keeps the starry heaven enchained (B11.6). In Empedocles’ writings, Anankē’s oracle sets the punishment of those who commit the ultimate sin of bloodshed (B115.1). In the myth of Plato’s *Republic X*, Anankē is the mother of the three Moirai. Her function is primarily cosmological in that she holds a spindle whose movement stands for the celestial motions. In Plato’s *Timaeus*, anankē is the regular but nonteleological causal force inherent in the physical realm. Insofar as the physical properties of the elements can be put into the service of the purposeful activity of reason, anankē becomes the auxiliary cause (*sunaition*) in teleological causation. Aristotle’s distinction between simple and hypothetical necessity in the *Physics II.9* shows clear traces of the conception of anankē in the *Timaeus*.

## MOLESCHOTT, JACOB

(1822–1893)

Jacob Moleschott, a physiologist and philosopher often regarded as the founder of nineteenth-century materialism, was born in Holland. After studying at Heidelberg, Moleschott practiced medicine in Utrecht. He later became lecturer in physiology at Heidelberg. The controversial doctrines expressed in his book, *Der Kreislauf des Lebens* (The circuit of life; Mainz, 1852), and the materialistic tendencies of his teaching forced him to move to

Zürich. He later became professor of physiology at Rome, where his lectures were popular and his important research on diet earned him respect and many honors.

Materialism at that period was a philosophical trend with political, social, and scientific implications. The state-controlled German universities had produced an official philosophy (a watered-down Hegelianism) that was used as a defense against social reform and as a shield for religion or the spiritual life. Certain important scientists held conservative views about the role of science. The biologist Rudolf Virchow, for example, believed that all speculation about consciousness should be left to the church or even to the state. The German materialists, attempting to free scientific inquiry from such control, saw these conventional philosophical tendencies as obstructing intellectual and social progress.

### PHILOSOPHIC MONISM

Moleschott's *Der Kreislauf des Lebens* went through many editions and helped to spur the materialist movement. The book was directed against Justus von Liebig's theologizing views as he had expressed them in his *Chemischen Briefen*. Liebig had especially objected to Moleschott's famous statement epitomizing materialist monism: "No thought without phosphorus." The German materialists of this period criticized dualists as being engaged in a system of philosophic double-entry bookkeeping.

Moleschott maintained, as did Ludwig Büchner, that force and matter were inseparable. Force cannot be viewed in an Aristotelian way, nor teleologically, nor as a vital force. It is not an entity separate from a material substratum, but is rather "one of its eternal indwelling properties." Matter cannot occur or be conceived without force, and vice versa; "A force unconnected with matter, hovering loose over matter, is an utterly empty conception."

Thus, any materialism attributing existence to matter independently of force was rejected. Moleschott maintained that to call his theory materialistic in this sense would be as wrong as to call it spiritualistic: "I myself was well aware that the whole conception might be converted, for since all matter is a bearer of force, endowed with force or penetrated with spirit, it would be just as correct to call it a spiritualistic conception." On the other hand, once the restriction of the term *material* to "dead matter" is given up, Moleschott appears materialistic indeed. He regarded the brain as the source of consciousness and emphasized physical conditions as the major determinants of human life. He was fascinated by circular processes, such as the miner digging lime phosphate from

the earth, and the peasant later fertilizing his field with the same chemical. Life circulates through all parts of the world, and with life goes thought.

As was also typical of the materialists of the time, Moleschott emphasized the doctrine of the conservation of matter. This notion, he held, was discovered by the eighteenth-century encyclopedists. Recent science had confirmed it, and future science had to be built upon it. Chemistry is the basic science, and the solution to social questions depends on our discovering the proper way to distribute the matter with which thought and will are bound up. A rigid determinism was emphasized: "Natural law is the most stringent expression of necessity."

### THEORY OF KNOWLEDGE

Moleschott inveighed against the Kantian thing-in-itself and emphasized the importance of what things could be known as rather than what they are alleged to be. All knowledge, he maintained, presupposes someone who knows and, thus, a relation between the object and the observer. The observer could be an insect or other creature; there is no restriction to man. All existence is by means of qualities; there is no quality that exists other than through a relation. In the case of a man's perceiving a tree, "it is just as necessary for the tree as for the man that it stands to him in a relation that manifests itself by the impression upon his eye."

Moleschott maintained a certain relativism, but also a certain objectivism: "Steel is hard as opposed to soft butter, ice is only cold to the warm hand, trees only green to a healthy eye." He argued that a vorticella with an eye having only a cornea must receive different representations of objects than a spider, which has a more complex eye with lenses. Yet, "Because an object is [exists] only through its relation to other objects, for instance, through its relation to the observer, because the knowledge of the object resolves itself into the knowledge of their relations, all my knowledge is an objective knowledge." Although there are difficulties in understanding Moleschott's doctrine here, it appears to have a strong family resemblance to recent objective relativism.

### ETHICS

The German materialists were frequently criticized for promulgating doctrines subversive of received morality, especially theologically sanctioned morality. In general, they did protest against duty-centered, puritanical views of morality and adopted a kind of utilitarian hedonism. However, they did not advocate a continuing round of sensual pleasures. Moleschott argued that even a mis-

guided hedonism was socially less dangerous than some other views of morality: “The erroneous theory of seeking after pleasure will scarcely find half as many disciples, as the rule of priests of all shades had claimed unfortunate victims.”

As was true of other contemporary materialistic theories, many of Moleschott’s doctrines that once aroused immense wrath seem relatively mild today. His insistence that scientific inquiry is relevant to the solutions of many problems is now commonplace, but it caused shudders in the nineteenth century. The materialists’ struggle against giving theological answers to scientific questions seems to have been largely successful.

## MOLINA, LUIS DE (1535–1600)

Luis de Molina, S.J., was a central figure in the sixteenth-century renaissance of scholasticism on the Iberian peninsula. He was born in Cuenca, Spain, in 1535. At eighteen he entered the Jesuit order. He studied and later taught at Coimbra and Évora in Portugal. In 1583, he left his academic post to devote himself to writing. He spent the next fifteen years in Cuenca, Lisbon, and Évora. He died on October 12, 1600, shortly after being called to

take a chair in moral theology at the newly established Jesuit University in Madrid.

Molina’s best known work, *Liberi arbitrii cum gratiae donis, divina praescientia, providentia, praedestinatione et reprobatione concordia* (The compatibility of free will with the gift of grace, divine foreknowledge, providence, predestination, and reprobation) was first published at Lisbon in 1588; a second, expanded edition was published at Antwerp in 1595. He also authored a three volume commentary on Part One of St. Thomas’s *Summa Theologiae*, titled *Commentaria in primam divi Thomae partem*, published at Cuenca in 1592. Although these works, especially the *Commentaria*, range broadly over theological and philosophical topics, critical attention focused on Molina’s theory of *middle knowledge* (*scientia media*), which was formulated to reconcile God’s comprehensive foreknowledge and providence with a strongly indeterministic conception of human free will.

According to the tradition shared by Molina and his rivals, at the moment of creation, God has perfect and infallible foreknowledge of everything that will happen in the created world. The tradition also maintains that God’s knowledge is not like that of a passive observer. Rather, he specifically intends or knowingly permits everything that takes place, and he arranges created causes and exercises causal influence sufficient to bring about his creative plan to the last detail. God’s foreknowledge, consequently, is to be explained in terms of his providence. He knows what will happen in the created world by his knowledge of his own decrees, together with his knowledge of what follows from those decrees, either directly or through the mediation of created causes. The fundamental difference between the positions of Molina and his adversaries lies in where they locate the main resources for God’s providential foreknowledge. The Molinists emphasize the role of God’s practical knowledge, his adversaries emphasize the role of his voluntary decrees.

The tradition distinguishes God’s *prevolitional* knowledge, which he has independently of his will from his *postvolitional* knowledge, which depends on his free decrees. A majority of traditional philosophers and theologians maintain that God’s knowledge of metaphysically necessary truths exhausts his prevolitional knowledge. On this view, God’s knowledge of necessary truths (which Molina calls *natural knowledge*) is identified with his prevolitional knowledge, and his knowledge of contingent truths is identified with his postvolitional knowledge (which Molina calls *free knowledge*). Call this the standard view. It is also commonly held that proposi-

tions concerning what is metaphysically possible are themselves metaphysically necessary.

Consequently, God's knowledge of these propositions is part of his natural knowledge. According to the standard view, God is able to bring about any metaphysically possible state of affairs. God's creative activity can thus be described as (1) deciding which metaphysically possible states of affairs will be actual, and (2) making a causal contribution sufficient to actualize those states of affairs. It must be emphasized that, on the standard view, God's causal activity completely determines what is going to take place in the created world.

According to Molina, however, the *free* choices of a rational creature are not causally or logically necessitated either by God's causal activity or by the operation of created causes, including the beliefs, desires, character, and dispositions of the agent. For any free choice a rational creature makes in a fully specified set of circumstances, it is metaphysically possible that that creature makes a different choice in those very same circumstances. So, on Molina's view, God's natural knowledge of metaphysical possibilities, together with his knowledge of his own causal activity, cannot provide him with foreknowledge of the free choices that his creatures will make. Therefore he holds that an essential component of the theory of divine foreknowledge and providence is God's knowledge of a special class of propositions called *conditional future contingents*. These propositions concern what choices rational creatures *would* freely make in any of possible circumstances in which they may find themselves. Molina contends that God must have knowledge of these propositions *prior* to his creative decrees to exercise providence over the world, otherwise he would be unable to guarantee that his creation conforms to his providential design in all its detail.

Molina calls God's knowledge of conditional future contingents *middle knowledge*, because it stands between his natural knowledge of what is merely possible and his free knowledge of what is actually, though contingently, the case. Like his natural knowledge, but unlike his free knowledge, God's middle knowledge is prevolitional. Like his free knowledge, but unlike his natural knowledge, the objects of God's middle knowledge are contingent truths. According to Molina, then, God's providence and foreknowledge is a function of (1) his prevolitional natural knowledge of the possible arrangement of created causes, (2) his prevolitional middle knowledge of the contingent choices free creatures would make in each of these possible arrangements, and (3) his postvolitional free knowledge of the way in which he has decided to arrange

created causes. This is how Molina reconciles God's providence and foreknowledge with his strongly indeterministic conception of freedom. In addition, Molina and his followers maintain that the theory of middle knowledge has fruitful applications in explaining a broad range of philosophical and theological issues such as the efficacy of grace, predestination and reprobation, petitionary prayer and prophecy.

Perhaps the weakest point in the Molinist theory is his explanation of *how* God can know what free creatures would do in various possible circumstances, given his strongly indeterministic conception of freedom. Critics maintain that there can be no basis for God's perfect and infallible knowledge of the choices that free creatures would make, given that these choices are not logically or causally determined by the activity of God or the operation of secondary causes. Unlike other defenders of middle knowledge (such as Suarez), Molina refuses to appeal to the determinate truth of conditional future contingents to explain God's knowledge of them. In fact, Molina follows Aristotle in maintaining that contingent propositions concerning the choice a free creature would make in specified circumstances do not have determinate truth prior to the creature making that choice in those circumstances.

Molina's explanation of God's knowledge of conditional future contingents involves what later came to be called *supercomprehension*. Given the indeterminacy of future contingent propositions, Molina believes that God's certain and infallible knowledge of them is due to the cognitive perfection of the knower. For Molina and his contemporaries, all of God's knowledge is ultimately grounded in his self-knowledge, either knowledge of his own essence or knowledge of his decrees. God's middle knowledge is grounded in his knowledge of his own essence, in which all possible creatures are eminently contained.

By perfectly comprehending his own essence, according to Molina, God is able to infallibly cognize the choices each possible creature would make in any possible circumstance in which they may find themselves, even though these choices are metaphysically indeterminate. Supercomprehension, on Molina's view, is a mode of cognition possible only for an infinite intellect with respect to finite creatures. Molina's readers, including those who defend middle knowledge (e.g., Suarez), are nearly unanimous in their rejection of the theory of supercomprehension. However, for Molina, the theory has the advantage over its competitors in explaining why God cannot have prevolitional knowledge of the choice he himself would make in various possible circumstances. Such knowledge, Molina believes, would destroy divine freedom.

The publication of Molina's *Concordia* aroused bitter controversy between the Molinists and the defenders of the standard view, primarily Domingo Báñez, Diego Alvarez, and other members of the influential Dominican order. The Dominicans accused the Molinists of undermining God's sovereignty over the created world by maintaining that God has no direct control over the choices of free creatures. The Molinists accused the Dominicans of destroying human freedom and making God morally responsible for sinful actions. The Vatican, anxious to avoid another divisive clash over the issues of grace and free will, called the factions to Rome to examine the matter. In 1597, Pope Clement VIII convened the *Congregatio de auxiliis*, and over the next ten years the Molinist position was scrutinized in eighty-five hearings and forty-seven debates. Initially things did not go well for the Molinists, and Molina died fearing that the censure of his views was imminent. However, the theory of middle knowledge ultimately escaped condemnation. In 1607, Pope Paul V closed the proceedings. He allowed both parties to continue teaching their doctrines and ordered the sides to refrain from accusing each other of contradicting the faith.

Though Molina's best known contributions are to speculative theology, he also authored a seven-volume treatise in moral and political philosophy entitled *De Justitia et jure* (published posthumously at Venice in 1614). This work discusses the source of legitimate political authority, the permissibility of slavery, and the justification of war, as well as economic issues such as taxation, free markets and monetary policy.

## MOLINA GARMENDIA, ENRIQUE (1871–1962)

Enrique Molina Garmendia, the Chilean spiritualist philosopher, was born at La Serena, Chile. After several years of practicing law and teaching on the faculty of the Liceo de Chillán, he became the first rector of the University of Concepción in 1919. He was one of the leading members of the generation of Latin American intellectuals who, under the influence of William James, Henri Bergson, and the French spiritualists, reacted against the positivism that had dominated the political and cultural life of Latin America for half a century.

Throughout the eleven books that he published between 1912 and 1952, Molina was basically concerned with philosophical anthropology and with offering "an interpretation of [the human spirit], acceptable even to the skeptics, formulating a consideration of the spiritual in human life where it is constructive and creative, and where it is involved with ethical exigencies" (*De lo espiritual en la vida humana*). This concern raised the problem of the nature of consciousness and its relation to being, as well as the problem of the origin and status of values in the natural order.

Rejecting both idealistic and materialistic ontologies, Molina maintained the priority of being over consciousness, although he noted that the emergence of the latter within natural processes indicates the potentiality for consciousness within being. Following the German philosopher Edmund Husserl, Molina declared that being

and consciousness are integrally united within experience. The priority of being “is affirmed, because it is first *lived* by consciousness as a totality of which consciousness forms a part” (*De lo espiritual en la vida humana*). Molina restated René Descartes’s basic premise as “I think, therefore I exist *and Being exists*.” An adequate conception of being must incorporate both the subjective and the objective poles of experience.

It is in man that spirit has become most fully actualized. Closely associated with consciousness, spirit is the locus of values and is characterized by the freedom that makes activity leading toward the realization of value possible. The realm of the spirit embraces all the realms that are the result of human creativity—morality, religion, the sciences, the arts, “all the work of enlightened intelligence.” Spirit is that element within each of these realms which aspires to be, which strives to perfect itself and to go beyond itself. Reason is the highest structure of spirit. Through reason, the presence of being is recognized, mere automatic functioning of the organism is overcome, and the horizons of consciousness are opened to the possibilities for creative advance.

## MONAD AND MONADOLGY

The Greek term *μονάς*, from which the word *monad* is derived, means a “unit” or a “one.” In Pythagorean writings it is the unity from which the entire number system, and therefore—as a consequence of the doctrine that “everything is number”—all things, are derived. Through Plato, who applied the Pythagorean term to the Ideas or Forms (*Philebus* V, 15B), it entered the tradition of Neoplatonism and Christian Platonism to mean a simple, irreducible, self-determining entity whose activity is the source of all composite beings. In this sense it was sometimes used to designate God as the simple source of all being and sometimes to signify the simplest irreducible entities in the created order out of whose harmonious action all existence is compounded.

A monadology is a metaphysical system that interprets the world as a harmonious unity encompassing a plurality of such self-determining simple entities. The term was first used in the early eighteenth century of the metaphysics of Gottfried Wilhelm Leibniz.

In its modern meaning since Leibniz, a monad is held to be (1) a simple, irreducible, and sometimes indestructible entity; and (2) the minimal unity into which the cosmos and all composite things in it can be resolved; yet (3) containing within itself, in contrast to material atoms, powers and relations of which it is itself the source. It is therefore conceived after the analogy of a mind or a *res cogitans* rather than a material substance. It is held to constitute, along with other monads, an all-inclusive unity or harmony of the cosmos as a whole.

A monadology may thus entail a theory of cosmic harmony, based upon a mathematical or scientific functionalism or upon a psychology of intersubjective relations, as well as a theory of relations, in which the relations constituting this cosmic harmony are brought into being through monadic action, although they do not affect the monads or organizations of monads that are the objects of the acts (Leibniz’s perceptions and Alfred North Whitehead’s prehensions are examples of such relations).

This intermonadic harmony may itself be regarded as a unity, or cosmic Monad, and this view may involve pantheism or a theistic theory of creation. The relation of the minimal monads to the supreme Monad is one of mirroring rather than being a part of; since the supreme Monad must itself be simple, each monad may be held to be a finite (unclear and indistinct) reflection of the attrib-

utes of the supreme Monad. (The metaphors of mirroring, of echoing, and of the infinite circle whose center is everywhere have commonly been used in monadologies.)

Monadologies may disagree in their fundamental categories. Monads are active substances and, therefore, also processes; Leibniz attempted, but with incomplete success, to unite a logical and a psychological analysis of the monad by applying the notions of intensionality and extensionality. The finite monads may be of a temporal nature; the cosmic order may be either eternal or temporal, or—as Whitehead and Charles Hartshorne held—both eternal and temporal. The finite monads themselves may be eternal changeless souls (John McTaggart). The cosmic harmony may be thought of as a divine Person or merely as the unitary society of monads.

In the history of modern monadologies, three conceptions have been operative: the Christian Platonist tradition of the soul as a simple substance possessing self-certainty in immediate unity (Augustine, *De Trinitate*, IX, 3; X, 9, 10); the Neoplatonic-Stoic conception of the One that is essentially represented in each of its parts; and a spiritualized form of atomism ultimately derived from this Neoplatonic-Stoic conception. The first tradition, mediated by Boethius, the Franciscans, and other medieval Platonists, became prominent in the seventeenth century in Francisco Suárez, René Descartes, and others. The second tradition emerged in the Renaissance in the concepts of the microcosm and macrocosm after a long history during which the Stoic doctrine of the Logos had been combined with the Neoplatonic theory of the One and the subordinate intelligences. This tradition involved the principle of plenitude, according to which the universe can achieve its maximal being only when God multiplies or reduplicates his nature in every created being. This principle was suggested by Meister Eckhart and explicated by Nicholas of Cusa in his doctrine of the coincidence of maximum and minimum in God. Giordano Bruno developed the principle of plenitude into a theory of material monads as spherical atoms that are spiritual reflections of the Divine Nature (*De triplice minimo et mensura ... Libri quinque*, 1591; *De monade, numero, et figura Liber*, 1591).

Leibniz's concept of monad is variously ascribed to Bruno, Henry More, or Franciscus Mercurius van Helmont, all of whom had made use of the term. But the terms *Monas* and *monadica* appear in the early papers of Leibniz, written long before he had come to know any of these thinkers or had developed his mature metaphysics.

Leibniz's monadology involves a harmonious universe composed of an infinite number of monads, each of

which was an infinite series of perceptive acts defined by a unique point of view or a unique law of series; each such law, in turn, was a particular finite combination of the perfections of God expressed in his creation. Leibniz presented a succinct but incomplete account of this system in his *Principles of Nature and of Grace* and the so-called *Monadology*, both written in 1714; he then devoted the last twenty years of his philosophical activity to a defense and amplification of his monadology through various papers and a vast correspondence. His system and that of Whitehead, who ascribed greater spontaneity and creativity to the monads and interpreted them as mind-like entities of limited duration, are the most detailed modern monadologies.

Trained in the Leibniz-Wolff tradition, Immanuel Kant wrote *Physical Monadology* in his precritical period (1756), in which the monads were treated as sources of motion in a Newtonian space. In the *Critique of Pure Reason* (1781), Kant called his second antinomy “the dialectic principle of monadology” (1st ed., p. 442). This antinomy is directed at the metaphysical claims for a monadology made by the Wolffian school. In their development of a realistic, spiritualistic metaphysics, Johann Friedrich Herbart, Hermann Lotze, and Gustav Theodor Fechner developed monadologies on a Kantian basis. In his third *Essai de critique générale* (Paris, 1859), and in *La nouvelle monadologie* (Paris, 1899), Charles Renouvier built a monadology upon his relativized interpretation of Kant, making the highest attainable harmony in “the best of all possible worlds” depend upon the freedom of human monads or persons. In contrast to this relativized monadism, Edmund Husserl, in his *Cartesian Meditations* (1929–1931), suggested a monadic completion of his transcendental phenomenology, describing a type of “indirect experience that possesses its own modes of verification” within one's own monadic experience and that also provides “the transcendental base” for an objective natural order; implied in this is a “sphere of monadological intersubjectivity.” Other recent monadologies include Dietrich Mahnke's attempt to reconcile Leibniz's monadology with recent science and philosophy; H. Wildon Carr's *Theory of Monads* (London, 1922), influenced by the British personalistic tradition; and William Stern's hierarchical system of persons and things, inspired by Benedict de Spinoza, Fechner, and Lotze.

## MONISM AND PLURALISM

How many things are there? Or how many kinds of thing? Monism is the doctrine that the answer to one or other of these questions is “Only one.” Opposed to monism is the doctrine of pluralism, which is that there are many kinds of thing, or that there are many things. It will be apparent, on reflection, that this weaker form of pluralism, that there are many things, is quite consistent with the weaker form of monism, that there is only one *kind* of thing to which the many particular things belong. For instance, materialism, in the sense that everything existent is material, is a form of monism because it insists that all existent things are of a single *kind*, the material kind. Thus monism and pluralism, though opposed, do not always exclude each other.

A doctrine that might be regarded as a form of pluralism, possibly the most important form of it, is dualism, the belief that there are two things or two types of thing. In view of its importance, it will be treated below in a separate section.

## MONISM

“Monism” is a name for a group of views in metaphysics that stress the oneness or unity of reality in some sense. It has been characteristic of monism, from the earliest times, to insist on the unity of things in time (their freedom from change) or in space (their indivisibility) or in quality (their undifferentiatedness). Such a view of the world is already found in a developed form in the pre-Socratic philosopher Parmenides and was nicknamed the “block universe” (by Thomas Davidson, a friend of William James), that is, the universe thought of as a single closed system of interlocking parts in which there is no genuine plurality and no room for alternative possibilities. Although this world view and similar ones are now classified as forms of monism, they may not have been seen as falling into a single category at all until the term *monism* had itself been invented. The term was coined by Christian Wolff (1679–1754), and he used it only in a narrow sense, applying it to the two opposite theories that everything is mental (idealism or mentalism) and that everything is material (materialism). The term was subsequently applied to a particular doctrine of the relation between mind and matter, namely, the theory of their absolute identity (the *Identitätsphilosophie* so often mentioned by William James). The main proponents of this doctrine were Friedrich Schelling and G. W. F. Hegel, although it actually originated with Benedict de Spinoza and is sometimes known as the double-aspect theory. It holds that mind and body are only modes of the same substance, and it is this substance to which they are both reducible, not one to the other. A more recent version of this theory is the “neutral monism” of William James, which Bertrand Russell at one time also adopted. On the other hand, it should be noted that the *Identitätsphilosophie* and neutral monism differ from the “identity theory,” which is a form of materialism recently set forth by J. J. C. Smart, Herbert Feigl, and others. The identity theory holds that the mind is not some third thing, some “neutral stuff” like sensation, but is literally identical with the brain.

In the nineteenth century the word *monism* came to be given wider application and so to have a systematic ambiguity, that is, a consistent variation of meaning according to context. Since then any theory that tries to reduce all phenomena to a single principle, or to explain them by one principle, or to make statements about reality as a whole, has been labeled “monism.” The ambiguity is not harmful, provided that theories about how many substances there are (substantial monism) are distinguished from theories about what *kinds* of substance exist

(attributive monism). This distinction also needs to be observed in the case of pluralism (see below).

Substantial and attributive monism are logically independent views, and the various possible combinations of attitude to these questions are actually found in the doctrines of major philosophers. Thus if by “substantial monism” we mean the theory that the apparent multiplicity of substances is really a manifestation of only a single substance in different states or from different points of view, then Spinoza, with his God-or-Nature, and Francis Herbert Bradley, with his Absolute, are typical substantial monists. Indeed, Part I of Spinoza’s *Ethics* is the classic exposition of substantial monism, offering a proof that there can be only one self-subsistent and independent thing. But Spinoza rejected attributive monism, which maintains that all the substances that there are, whether one or many, are ultimately of a single kind. He believed in an infinity of real attributes. An opposite case is that of Gottfried Wilhelm Leibniz, who rejected substantial monism but accepted a monism of attributes, for in his philosophy all the monads are of one kind, being souls.

A further possible doctrine, that might be called partial monism, is the belief that even if there is more than one realm of being, there is only one substance within some particular realm. For example, René Descartes, who is the classic dualist insofar as he divides the world into the two realms of mind and matter, accepted partial monism about matter, which he treated as a unitary substance, while he rejected partial monism about minds.

If monism in one or other of these various senses keeps on turning up in quite diverse philosophical systems, that is not really surprising. A striving for unity in a world description, perhaps for the sake of easier comprehensibility and greater economy of explanation, perhaps resulting from the direct appeal of simplicity, is a perennial urge in human thought. Even a substantial pluralist, Leibniz for instance, usually maintains that the plurality of substances in his world do form a systematic unity “ideally” or when looked at from the viewpoint of an omniscient being. To many minds, a monistic theory is always the most attractive option if the obstacles to holding it can be removed.

## DUALISM

Dualism is the position of those thinkers who find some radical and irreducible difference in the world, an insuperable gulf between two realms of being. Any philosophical system that divides the world into two categories or types of thing, or uses two ultimate principles of expla-

nation, or insists that there are two substances or kinds of substance, is a form of dualism. (The same ambiguity is found here as with the other labels.) Even the presence of a cardinal though not all-embracing contrast in a philosophical system may justify calling it a dualism in a looser sense, as when we speak of the dualism of Plato, in whose works the world of flux presented to the senses is sharply contrasted with the world of Forms known by the intellect, or when we consider the corresponding dualism of phenomena and noumena in Immanuel Kant.

Although superficially dualism can be seen as a special case of pluralism, it should be clear from the foregoing that it has often been, so to speak, the expression of failed monism. Nor is it merely that monism has to many minds the attractiveness described earlier; the dualistic position is inherently unstable and puzzle-generating. Once we have divided the world into two—for example, into natural and supernatural, temporal and eternal, material and mental, particular and universal—we have on our hands the problem of the relation between the two resulting worlds. These bridging problems have bulked large in both ancient and modern philosophy. Even though dualism of mind and body, for instance, may be said to reflect the time-honored view of common sense and was adopted by philosophers at least as early as Anaxagoras, Descartes’s version of it, with thinking substances operating mysteriously on bits of extended substance, set the problem for all subsequent philosophers until Gilbert Ryle, in *The Concept of Mind* (1949), dismissed it as a “category-mistake.”

There may be thinkers for whom oppositions themselves have an attraction, just as triads certainly do for some others. If so, the series of opposites set up by the Pythagoreans may have had this motivation. Since, however, they reduced the two sets to two fundamental principles, the Limit and the Unlimited, they may have been forced by their mathematical discoveries to acknowledge a difference that blocked the way to monism. Whatever the correct interpretation in their case, it is plain that no philosopher would in advance adopt dualism as an ideal at which to *aim*, in creating his world picture.

What in fact drew attention to dualism as a type of theory was theology, where doctrines like Manichaeism, with its two ultimate principles of good and evil, or darkness and light, are found. Those who put forward such doctrines were labeled “dualists” by Thomas Hyde, writing in Latin about 1700. Later the term found its way into philosophy in various languages.

## PLURALISM

If there is more than one kind of existent, why not any number instead of just two? The unsuccessful would-be monist may, through thinking in this way, lapse into pluralism. Others, like William James, may find they have a temperamental objection to monism, with its emphasis on the totality and its exclusion of individuality and quirkiness. Yet others may from the start see the world as having some kind of disconnectedness as an essential feature, without which motion, change, and free will, for example, would be impossible. The rejection of any form of monism of course entails adopting the corresponding pluralist viewpoint. There may, however, be different types of rejection. Pluralism may arise from the rejection of the metaphysical conception of the "block universe" or of the logical doctrine that all true statements are, in the last analysis, logically necessary. For if there are some truths of a merely contingent nature, the doctrine of internal relations, that all relations are grounded in the natures of the related terms, must be false, and this doctrine is fundamental to the idealist versions of monism. The case of Leibniz, who is often taken as a standard pluralist, does not illustrate this point, but an instance of this sort of conversion to pluralism is afforded by Russell, who writes of his early position, "I came to disbelieve Bradley's arguments against relations, and to distrust the logical bases of monism" (*The Philosophy of Bertrand Russell*, edited by P. A. Schilpp, Evanston, IL, 1944, pp. 11–12). Russell later adopted a full-blown pluralism associated with logic: For instance, "When I say that my logic is atomistic, I mean that I share the common-sense belief that there are many separate things" ("The Philosophy of Logical Atomism," 1918; reprinted in his *Logic and Knowledge*, New York, 1956, p. 178). Though this phase of Russell's philosophy is usually known as logical atomism, he also described it himself as "absolute pluralism." Even after abandoning logical atomism, Russell remained an enthusiastic pluralist; in 1931 he wrote of the proposition that the world is a unity, "the most fundamental of my intellectual beliefs is that this is rubbish. I think the universe is all spots and jumps, without unity, without continuity, without coherence or orderliness or any of the other properties that governesses love" (*The Scientific Outlook*, New York, 1931, p. 98).

**Bibliography**

Helpful general discussions of monism, dualism, and pluralism are rather few in number. The only good general account of all three is A. M. Quinton, "Pluralism and Monism," in the *Encyclopaedia Britannica*. The best sources, though more difficult to use, are the actual works of the philosophers mentioned as proponents of the various doctrines.

## MONISM

On monism see the works of philosophers named in the text, such as Parmenides, Spinoza, and Bradley. A useful discussion is C. E. M. Joad, "Monism in the Light of Recent Developments in Philosophy," in *PAS* 17 (1916–1917): 95–116. Now somewhat antiquated is A. Worsley, *Concepts of Monism* (London, 1907). A typical short account from the heyday of monism in British philosophy is A. E. Taylor, *Elements of Metaphysics* (London: Methuen, 1903), Chs. 2–3. Compare J. A. Smith, "The Issue between Monism and Pluralism," in *PAS* 26 (1925–1926): 1–24. See also Marvin Farber, "Types of Unity and the Problem of Monism," in *Philosophy and Phenomenological Research* 4 (1943–1944): 37–58, and postscript, *ibid.*, 6 (1945–1946): 547–583; Raphael Demos, "Types of Unity According to Plato and Aristotle," *ibid.*, 534–545; Abraham Edel, "Monism and Pluralism," in *Journal of Philosophy* 31 (21) (October 1934): 561–571; and Jonathan Bennett, "A Note on Descartes and Spinoza," in *Philosophical Review* 74 (3) (July 1965): 379–380. Such nineteenth-century works as Ernst Haeckel, *Der Monismus als Band zwischen Religion und Wissenschaft* (Bonn: E. Strauss, 1893; translated by J. Gilchrist as *Monism as Connecting Religion and Science*, London: A. and C. Black, 1895), are not now of much philosophical interest, for they are not about monism in general but are presentations of an outdated type of materialism.

## DUALISM

On dualism see the main works of Descartes. The difficulties of the dualist position in general are well brought out by John Passmore in his *Philosophical Reasoning* (London: Duckworth, 1961), Ch. 3. See also Simone Pétrement, *Le dualisme chez Platon, les gnostiques, et les manichéens* (Paris: Presses Universitaires de France, 1947).

## PLURALISM

The most readable book on pluralism and other theories is William James's *A Pluralistic Universe* (London: Longman, 1909). For further reading, there is James Ward, *The Realm of Ends, or Pluralism and Theism* (Cambridge, U.K.: Cambridge University Press, 1911). A dry but clear account is to be found in C. D. Broad, *The Mind and Its Place in Nature* (London: Kegan Paul, 1925), introduction. More difficult and technical but classic is G. E. Moore, "External and Internal Relations," in *PAS* 20 (1919–1920): 40–62, reprinted in his *Philosophical Studies* (New York: Harcourt Brace, 1922). Compare Bertrand Russell, "The Nature of Truth," in *Mind* 15 (1906): 528–533, reprinted as "The Monistic Theory of Truth," in Russell's *Philosophical Essays*

(London: Allen and Unwin, 1910). See also J. H. Muirhead, F. C. S. Schiller, and A. E. Taylor, "Why Pluralism?," in *PAS* 9 (1908–1909): 183–225; and P. Laner, *Pluralismus oder Monismus* (1905).

## MONTAGUE, RICHARD (1930–1971)

Richard M. Montague, a logician who taught in the Philosophy Department at the University of California at Los Angeles from 1955 until his premature death in 1971, is probably best known for his contributions to linguistic semantics, although he also made important contributions to mathematical logic and philosophy.

Montague was born in 1930. He attended the University of California at Berkeley both as an undergraduate and a graduate student, concentrating not only in mathematics and philosophy, but in Semitic languages. Working with Alfred Tarski, he completed a doctoral dissertation in 1957 entitled "Contributions to the foundations of axiomatic set theory." By that time he had published a large number of papers in various areas of mathematical logic.

Montague's interests in mathematical logic were general and included set theory, proof theory, model theory, and abstract recursion theory. One early theme in his work in mathematical logic concerned the consequences of semantic reflection for axiomatic versions of set theory and other mathematical theories. That work has been widely cited and is still important.

The work for which Montague is best known was carried out late in his life (beginning with the 1968 publication of "Pragmatics") and dealt with the development of logics intended to serve as vehicles for the interpretation of natural language and the formalization of philosophy. From Tarski, Montague inherited the view that semantical theories could and should be formulated with mathematical precision. However, his project of applying Tarski's techniques to natural language seems to derive more naturally from the work of Rudolf Carnap and Alonzo Church.

Both Carnap and Church worked with a framework for logical formalization, which, although it was developed in connection with the language of mathematical theories, was clearly more broadly applicable. Carnap was mainly interested in using formalization as a tool for clarifying philosophy. Church considered what he called the "logistic method"—that is, the method of logical formal-

ization developed in the first half of the twentieth century—to be applicable in a more general linguistic setting.

Carnap and Church both addressed a major obstacle standing in the way of generalizing Tarskian semantic theories to natural language—the problem of intensionality (which had already been raised by Gottlob Frege). Carnap explored how what are now called possible worlds could be used to model intensionality, while Church sought to formalize Frege's theory of sense and denotation. Influences of both can be seen in Montague's logical framework for interpreting natural language. Like Carnap, Montague appealed to possible worlds, and, like Church, he used higher-order logic. Montague's insight that a logic combining possible worlds with higher-order logic provided a flexible and powerful tool for natural language semantics proved to be fundamentally important.

All of Montague's publications concerning "Montague Grammar" are collected together in *Formal Philosophy: Selected Papers of Richard Montague* (1974). These papers develop the logical framework of "intensional logic." This is a higher-order logic involving on a system of types based on three primitive domains: entities (type  $e$ ), possible worlds, and the two truth values T and F (type  $t$ ). If  $\sigma$  and  $\tau$  are types, then  $\langle\sigma, \tau\rangle$  is also a type and corresponds to the set of functions from the domain of  $\sigma$  to the domain of  $\tau$ . Thus, for instance,  $\langle e, t\rangle$  is the type of functions from entities to truth values. If  $\sigma$  is a type, then  $\langle s, \sigma\rangle$  is also a type and corresponds to the set of functions from possible worlds to the domain of  $\sigma$ :  $\langle s, \langle e, t\rangle\rangle$ , then, is the type of intensions of sets of entities. For a book-length, systematic treatment of intensional logic, see Daniel Gallin's *Intensional and Higher-Order Logic* (1975).

A Montague grammar for a fragment of a language consists of a syntactic account of that fragment, which defines a set of syntactic structures showing how complex phrases are decomposed into components, and a semantic component that shows how a semantic value can be assigned to the structure given an assignment of values to the lexical items occurring in the structure. These values belong to the domains of a model of intensional logic. Intensional logic can serve as an intermediary in the mapping of syntactic structures to values, and as a vehicle for formulating postulates about the meanings of lexical items. This mapping conforms to a correspondence between grammatical categories like "Sentence" and "Noun-Phrase" and the types of intensional logic.

To see how the idea might work, consider the sentence “John wants a car.” The noun phrase ‘a car’ has type  $\langle\langle e, t \rangle, t \rangle$ ; it denotes the set of sets containing at least one car. (The insight that noun phrases denote sets of sets goes back to Frege’s 1884 work, *The Foundations of Arithmetic*.) The verb ‘wants’ corresponds to a function that inputs the intension of a Noun-Phrase denotation and returns a function from entities to truth values. Give this function the intension of ‘a car’ and it returns a function saying of each entity whether that entity wants a car. The type of ‘wants’ is therefore  $\langle\langle s, \langle\langle e, t \rangle, t \rangle \rangle, \langle e, t \rangle \rangle$ . Barbara Partee and Herman L. W. Hendriks provide a useful extended survey of Montague’s semantic framework and its subsequent influences in their 1996 essay “Montague Grammar.”

Montague himself saw intensional logic and his theory of language as a basis of formalizing philosophy, but the most important direct influence of his work was on the development of linguistic semantics, where its impact was enormous. Montague’s semantic techniques can be associated with any generative syntactic framework; his syntactic approach has been less influential, outside of subsequent work in the categorial grammar framework. (See Jacobson 1996, for example.)

Although few philosophers would agree that the goal of formalizing philosophy is enabled by Montague’s work, foundational questions raised by his approach have preoccupied and shaped subsequent work in analytic metaphysics and philosophy of language. Much of this influence is indirect, occurring through the work of David Lewis, who attended Montague’s courses at UCLA and was influenced by his ideas.

Because of Montague’s uncompromising emphasis on the technical dimension, his papers are difficult reading. But even now, they repay careful study. The linguistic papers and other philosophically relevant work were compiled in 1974 in *Formal Philosophy: Selected Papers of Richard Montague*. Further biographical information concerning Montague can be found in Anita and Solomon Feferman’s biography of Tarski, *Alfred Tarski: Life and Logic* (2004).

## MONTAGUE, WILLIAM PEPPERELL (1873–1953)

William Pepperell Montague, an American realist philosopher, received his BA from Harvard in 1896, his MA the following year, and his PhD in 1898. He taught briefly at Radcliffe, Harvard, and the University of California. In 1903 he began teaching at Barnard and from 1907 to 1910 was an adjunct professor and a member of the Columbia University graduate faculty of philosophy. He became associate professor in 1910, professor in 1920, and was the Johnsonian professor of philosophy from 1920 to 1941. In 1928 he was Carnegie visiting professor

in Japan, Czechoslovakia, and Italy. He served as chairman of several delegations to the International Congress of Philosophy (1920, 1934, 1937) and as president of the eastern division of the American Philosophical Association in 1923.

## REALISM

Montague advocated a frankly Platonic “subsistential realism.” He called it a right-wing realism, in contrast with left-wing realism, whose adherents included the behaviorists, objective relativists, and—to some extent—pragmatists. At the turn of the twentieth century, the idealist claim that the object of knowledge was dependent on the knower and thus was “ideal” had come increasingly under attack in England and America. Montague, in “Professor Royce’s Refutation of Realism” (1902), was one of the first to attack idealism by means of the realist theory of independence. This theory—that the object of knowledge is not dependent for its reality on the knowing relation—became one of the cardinal tenets of the New Realist movement, of which Montague was a charter member. However, by itself it was not enough to establish that the known is independent of the knower. It also had to be shown how a conscious, knowing organism could be in such a unique kind of rapport with events whose loci and dates were different from its own. Thus the central issue in epistemology for Montague was to establish the independence and the immanence of the object of knowledge.

Montague proposed his “subsistential realism” as a resolution of this issue. Subsistence included everything that could be made an object of discourse. The objects of knowledge then are subsistently real, that is, propositions and terms rather than commonsense objects, and as such they are directly present to mind (immanent), though independent of it. Montague thus brought the things of the earth into the realm of ideas by interpreting existence as a subclass of subsistence, hence also as a set of propositions.

With his idea of subsistent and existential propositions, Montague could distinguish nonveridical and unreal objects from the veridical and real. Existential propositions are the objects of true or real knowledge, and the “merely subsistent” propositions are the objects of false or unreal knowledge. Thus there is a tendency in Montague’s thinking to identify the true, real, and existent on the one hand, and the false, unreal, and nonexistent on the other.

What, then, is the cause of error? Truth and falsity attach to our judgments, Montague said, because of their

content, not because they are stated or believed. Error is the result of the selective action of sense perception and conception. He attributed error to these factors of the “personal equation” (as realists called the subjective aspect of knowledge) because he had said existential subsistent propositions cause themselves to be known in a way the “merely subsistent” cannot. But how can a proposition cause itself to be known?

The answer apparently was in the difference between the “merely subsistent” propositions and the existential subsistent propositions. Montague identified existential propositions with facts, and he described a fact as “something done,” a *fait accompli*. But this was as far as he went.

## ANIMISTIC MATERIALISM

Epistemology was secondary, however, to Montague’s preoccupation with the psychophysical problem of the nature of mind and its relation to the body. Naturalistic monism, strongly supported by science, could not, Montague claimed, adequately account for such characteristics of mind as purpose, privacy, duration, and integration. Traditional dualism could account for them, but it was scientifically sterile in its reliance on concepts of spirit. Montague’s answer, which he called “animistic materialism,” was the hypothesis of a physical soul possessing all of the traits of mind although still physically describable.

Throughout his career, Montague considered the soul to be the only answer to the psychophysical problem. After proposing the idea of a substantial soul in his first published writing, Montague soon rejected it in favor of considering the soul as a new kind of energy, purely private, and internally observable as sensation. This “potential” energy comes into existence when and where the kinetic energy of a stimulus ceases to be externally observable as motion. Sensations (or consciousness) and their externally observable causes are thus qualitatively identical. The potentiality of the physical is the actuality of the psychical, and vice versa. Just as when successive twists are imposed upon a coiled spring there is left unobservable potential energy, so too the potential energies of sensations leave traces superposed on one another. These traces constitute the memory system and modify the organism’s responses to later stimuli.

Thus, within the organism there arises a field of potential energy that is externally unobservable yet is causally effective upon the visible cerebral matrix; this inner organism possesses all the characteristics of mind. In Montague’s relational dualism, therefore, mind and body are in radical contrast as relations but not as sub-

stances. The truths of psychophysical dualism were thus saved without departing from material categories. Montague in general maintained this materialistic dualism, yet at one point (in "A Realistic Theory of Truth and Error," 1912) he admitted to what he called a qualified panpsychism: Matter had something psychical about it.

### RELIGIOUS VIEWS

Montague's "Promethean challenge to religion" (as he called it in *Belief Unbound*) was a challenge to authoritarianism, supernaturalism, and asceticism in religion. Montague denied what he termed the "pseudo creativeness" that idealism and pragmatism attribute to humans. Man has no transcendent power to legislate for nature, or to support infinite space and time by his consciousness. Realism instead gives to man an even greater responsibility of membership in the independent order of nature. Realism also adds to existent things the "quiet and infinitely great immensities of the realm of subsistence" where mind gains access to new and imperishable sources of joy and peace. Philosophy's one certainty is that ideals are eternal things, and the life that incarnates them attains an absolute value that time alone could not create and that death is powerless to destroy.

Ideals are not dependent on God's will. God is neither finite nor infinite in all things. He is infinite and eternal like the universe that is his body, all-perfect in himself and in his will but limited in power by that totality of actual and possible things which is within him yet not himself. God is to be loved because he is good, not because he is powerful.

Montague had a genuinely speculative and daring mind that explored not only the fields of philosophy but also such areas as time perception, mathematics, relativity theory, and quantum mechanics. At the beginning of Montague's career, philosophy suffered from what he called "internalism," a subjectivism sometimes carried to the point of solipsism, which, if it perhaps contained a grain of truth, was sterile. By the end of his life Montague feared that philosophy had gone to the other extreme. In "The Modern Distemper of Philosophy" (1951), he expressed his concern that it now suffered from an "externalism," a "distemper" that was eliminating important philosophical problems from discussion because they were insufficiently empirical.

## MONTAIGNE, MICHEL EYQUEM DE (1533–1592)

Michel Eyquem De Montaigne, French essayist and skeptical philosopher, was born near Bordeaux. His father was an important merchant, and his mother belonged to a wealthy Spanish-Portuguese Jewish family that had fled to Toulouse. Montaigne was raised a Catholic and was given special training by his father, who would not allow him to hear any language other than Latin until he was six. At this time he was sent to the Collège de Guyenne at Bordeaux, where he studied with some of the leading humanistic teachers of the time, among them the learned Latin poet George Buchanan (1505–1582), who would later be arrested and charged by the Portuguese Inquisition for "judaizing" and skepticism. Montaigne also apparently studied at the University of Toulouse, a leading center of humanism and unorthodox religious ideas. For thirteen years he was a member of the *parlement* of Bordeaux and made several trips to Paris and the court seeking a more important position. His closest friend at this time was the stoic humanist and poet Étienne de La

Boétie (1530–1563). Montaigne's first significant writing was a letter describing La Boétie's death, published at the end of the latter's *Oeuvres* in 1570.

In 1568 Montaigne published his French translation of *Theologia Naturalis sive Liber Creaturarum* ("Natural Theology or the Book of Creatures") by Raimond Sebond (Raymond of Sabunde, d. 1436), a fifteenth-century Spanish theologian who had taught at Toulouse. In Montaigne's translation he somewhat modified Sebond's rationalistic claims that unaided human reason could comprehend the universe and establish the existence and nature of God. Montaigne also published La Boétie's works before retiring from public life in 1571. The following year he began writing his most important work, the *Essays*, a series of rambling, erudite, witty discussions on a variety of topics, serving as a self-portrait. The longest of the essays, the "Apology for Raimond Sebond," was written about 1576 while Montaigne was studying the recently rediscovered treasury of Greek skepticism—the works of Sextus Empiricus—and undergoing a personal skeptical crisis. He had mottoes from Sextus carved into the rafter beams of his study and adopted as his own motto, "Que sais-je?" ("What do I know?"). In 1580 the first two books of the *Essays* were published. Besides writing, Montaigne tried in vain during the 1570s to mediate between the Catholics and the Protestant leader, Henri of Navarre (later Henri IV).

In 1580 Montaigne went to Paris to present a copy of his *Essays* to the king; he then set out on a trip to Germany, Switzerland, and Italy, which he describes in his *Travel Journal*. The following year he was called back from Italy to become mayor of Bordeaux, a post he held for four years. He then added material to his earlier *Essays* and wrote a third volume of them; the complete edition was first published in 1588 in Paris. Montaigne went to Paris and probably negotiated on behalf of Henri of Navarre concerning his succession to the throne, his conversion to Catholicism, and the temporary settlement of the religious wars, which was later incorporated into the Edict of Nantes. Illness apparently prevented Montaigne from joining Henri IV's court, but he continued to revise his *Essays*. The final version was published posthumously in 1595.

#### "APOLOGY FOR RAIMOND SEBOND"

Montaigne's most important philosophical work, the "Apology for Raimond Sebond," had an enormous influence on the subsequent history of thought. A superbly written presentation of skepticism, it formulated a challenge that affected Descartes, Pierre Gassendi, Bacon, and

many others and inspired monumental efforts to meet the challenge. The "Apology" gradually reveals a series of waves of doubt, continuously coupled with a new type of Christian fideism.

The essay begins with an account—probably not very accurate—of Montaigne's reasons for translating Sebond's *Theologia Naturalis*. Pierre Bunel, a Renaissance scholar, gave Montaigne's father a copy of the book, saying that it had saved him from Lutheranism. Long afterward, Montaigne's father asked his son to render it into French (from what Montaigne claimed was Spanish with Latin endings). After the translation appeared, Montaigne reported that some readers—mainly female—needed help in comprehending Sebond's contention that all the articles of the Christian faith could be established by reason. Two major objections to this thesis had been raised: the first held that Christianity should rest on faith rather than reason, and the second maintained that Sebond's reasons were not good ones. Montaigne purported to defend Sebond by showing that because all reasoning is unsound, Sebond's is no worse than anyone else's and, therefore, religion should rest on faith alone.

Montaigne held that people are vain, stupid, and immoral, and he pointed out that they and their achievements do not appear impressive when compared with animals and their abilities. The "noble savage" of the New World seemed to possess an admirable simplicity and ignorance that did not involve him in the intellectual, legal, political, and religious problems of the civilized European.

Montaigne suggested that our sole contact with the truth was due not to our intellect or reason, but rather to the grace of God; he agreed with St. Paul that ignorance is more useful than learning in acquiring truth. To show this, Montaigne examined the teachings of the ancient schools of philosophy and argued that those of the Pyrrhonists were the best and the most compatible with the Christian religion. All of the other philosophies were in conflict with one another, contained contradictions and absurdities, and relied on fallible human faculties and questionable premises to reach their conclusions. Only Pyrrhonists showed humans as naked and empty, portrayed their natural weaknesses, and by ridding them of their false or dubious opinions, left their minds a blank tablet, ready to receive whatever God might wish to write upon them. The modern Pyrrhonist would not be led into heresy, because he or she would accept no reasons or arguments that are open to question. In contrast to the Pyrrhonists, who suspended judgment on all matters, other philosophers offered their own opinions as genuine

truths. They thought that they had discovered the real nature of things and had measured the universe in terms of their own systems; they were only deceiving themselves.

In the later portions of the “Apology,” Montaigne presented the Pyrrhonic evidence that everything is dubious and that genuine knowledge must be gained either by experience or by reasoning. We do not, however, know the essence of what we experience (for example, the real nature of heat), and we do not even know the nature of our own faculties. We are constantly changing as our physical and emotional conditions alter, and the judgments we make and accept at one time, we find doubtful at another. Not only does this seem to happen to each of us, but it also appears to be the fate of humans in general. Each alleged scientific discovery is superseded by another, and what is thought true at one time is regarded as false or silly at another.

The new sciences of Copernicus and Paracelsus claimed that the ancient sciences of Aristotle, Ptolemy, and others were false. How could we know, Montaigne asked, that some future scientist would not make similar claims, on equally firm grounds, about these new discoveries? These same variations and disagreements occur in every area of human concern.

Montaigne then presented the more theoretical objections that Sextus Empiricus had raised about the possibility of gaining knowledge. All of our alleged knowledge, he argued, appears to come from sense experience, but perhaps we do not possess the requisite number of senses for gaining knowledge. Even if we do possess all of them, the information we gain through them is deceptive and uncertain. Illusions lead us to wonder when our senses are accurate. Dreams are often so similar to sense experiences that we cannot tell if sense experience itself is not really a dream. Each of our experiences differs from that of animals, from that of other human beings, and even from our other experiences; we cannot, therefore, know when to accept an experience as accurate. Such conditions as illness or drunkenness distort what we perceive. Perhaps normal experience itself is a kind of distortion.

In order to determine the accuracy of our experiences, we require a criterion. But we need some way of testing that criterion, and this requires a second criterion to establish how to test it, and so on. If reason is to be the judge of our experiences, then we need reasons to justify our reason, and so on, to infinity. Thus, if our ideas come from our sense experiences, we are hardly in a position to use our ideas to judge the nature of objects. Our experi-

ences and our ideas tell us only how things seem to be, but not necessarily how they are in themselves. Trying to know reality, Montaigne concluded, is like trying to clutch water. We can deal with the world only in terms of appearances, unless and until God decides to enlighten us. In our present state, we can only try to follow nature, living as best we can.

## INTENTIONS AND INFLUENCE

Montaigne questioned and cast doubt upon almost all of humankind’s beliefs in philosophy, theology, science, religion, and morality, and criticized almost every superstition and accepted view. He insisted that he was merely showing the human inability to find truth by means of natural capacities and the human need to rely on faith as the sole access to truth. Montaigne’s own portrayal of the human predicament succeeded in intensifying the doubts already produced by the religious crisis of the Reformation, the humanistic crisis of the Renaissance, and the philosophical-scientific crisis of revived Pyrrhonism. The three currents were fused into a massive and forceful onslaught in this “Apology.” Montaigne’s formulation of skepticism and the more didactic one of his disciple, Pierre Charron, provided the issues for seventeenth-century thought. Some, such as François de La Mothe Le Vayer, were to follow out the more destructive and anti-intellectual tendencies of Montaigne’s doubt. Others, such as Marin Mersenne and Gassendi, were to formulate a mitigated skepticism that could accept its doubts while seeking information about the world of appearances. Still others, such as Bacon, Herbert of Cherbury, and Descartes, were to seek new philosophical systems to provide for human knowledge a basis impervious to Montaigne’s doubts.

Some have seen Montaigne as a skeptic, questioning religion with everything else, and as the founder of the critical spirit of the Enlightenment. They have taken his fideism as a mask for his actual views and have portrayed him as a genuine freethinker and free spirit. Others have interpreted his fideism as an expression of his own resolution of his doubts. Although Montaigne lacked the religious fervor of Pascal, who regarded him as a skeptical nonbeliever, many of his contemporaries and later admirers took his skepticism as part of the Counter-Reformation, because it opposed the reasons and arguments of the Reformers by undermining the validity of all reasoning.

Montaigne played a vital role in the development of both Christian skeptical fideism and of the so-called *libertinage*, a later movement of critical freethinking that

preceded the Age of Reason. His views are compatible with both roles, in that his doubts neither imply nor contradict either a religious or an irreligious conclusion. He was probably mildly religious, accepting Catholicism in the light of the religious wars of his time. He apparently opposed fanaticism and wished for toleration of all sides, recognizing man as a fallible, limited creature struggling to live and comprehend with weak and uncertain capacities. Without God's assistance, man could only try to understand himself, guided by the past and the present. To understand himself and his situation would at least make him doubtful of radical proposals for solving everything, make him more tolerant, and—most important—make him capable of accepting himself and his fate. To philosophize, Montaigne said, was to learn to die.

## Bibliography

### WORKS BY MONTAIGNE

*The Essayes*. Translated by John Florio. London, 1603. New York: Modern Library, 1933. The first English edition, probably known to Shakespeare and Francis Bacon.

*The Essays*. Translated by Jacob Zeitlin. 3 vols. New York: Knopf, 1934–1936. Good introduction and notes.

*The Complete Essays of Montaigne*. Translated by Donald M. Frame. Stanford, CA: Stanford University Press, 1958. The best modern translation, containing the essays, journals, and letters, plus an excellent introduction and annotated bibliography.

*Œuvres complètes*. Paris: Gallimard, 1976.

*Apologie de Raimond Sebond de la Theologia à la Théologie*. Paris: Librairie Honoré Champion, 1990.

### WORKS ABOUT MONTAIGNE

Allen, Don Cameron. *Doubt's Boundless Sea: Skepticism and Faith in the Renaissance*. Baltimore, MD: Johns Hopkins Press, 1964. Reasserts the irreligious interpretation of Montaigne. See chapter 3.

Boase, Alan M. *The Fortunes of Montaigne: A History of the Essays in France, 1580–1669*. London: Methuen, 1935. A study of Montaigne's impact.

Brahami, Frédéric. *Le scepticisme de Montaigne*. Paris: Presses universitaires de France, 1997.

Brunschwig, Léon. *Descartes et Pascal, lecteurs de Montaigne*. New York: Brentano's, 1944. Shows the influence of Montaigne on both Descartes and Pascal.

Brush, Craig B. *Montaigne and Bayle: Variations on the Theme of Skepticism*. The Hague: Nijhoff, 1966. See chapter 3.

Busson, Henri. *Le Rationalisme dans la littérature française de la renaissance (1533–1601)*. Paris: J. Vrin, 1957. Interprets Montaigne as a freethinker and as part of an irreligious, rationalistic milieu.

Frame, Donald M. *Montaigne: A Biography*. New York: Harcourt, Brace, 1965.

Frame, Donald M. *Montaigne's Discovery of Man: The Humanization of a Humanist*. New York: Columbia

University Press, 1955. A study of the development of Montaigne's thought.

Frame, Donald M. "What Next in Montaigne Studies?" *French Review* 36 (1963): 577–587. A survey of the state of scholarship on Montaigne and an evaluation of various interpretations.

Giocanti, Sylvia. *Penser l'irrésolution: Montaigne, Pascal, La Mothe Le Vayer, Trois itinéraires sceptiques*. Paris: Honoré Champion éditeur, 2001.

Laursen, John Christian. *The Politics of Skepticism in the Ancients, Montaigne, Hume, and Kant*. Leiden, Netherlands: Brill, 1992. See chapters 4 and 5.

## MONTESQUIEU, BARON DE (1689–1755)

The philosopher and political theorist Charles-Louis de Secondat, Baron de Montesquieu, afterward Baron de la Brède et de Montesquieu, was born at Labrède, near Bordeaux, in the year of the English revolutionary settlement that established the preeminence of Parliament. He was a follower of John Locke and the outstanding champion in France of the supposedly "English" notions of freedom, toleration, moderation, and constitutional government. He was also a pioneer in the philosophy of history and in the sociological approach to problems of politics and law. Honored in his own country, Montesquieu was even more revered in the English-speaking world. He described the constitution of England as "the mirror of liberty," and although his analysis of the English principles of government was generally considered defective by later historians, it was hailed as marvelously penetrating

by English readers of his own time. Charles Yorke, the future lord chancellor, told Montesquieu, “You have understood us better than we understand ourselves.” Moreover, the founders of several new political societies, notably that of the United States, were profoundly affected by Montesquieu’s teaching. Especially influential was his theory that the freedom of the individual could best be guaranteed by the division of the powers of the state between three distinct organs that could balance and check one another—a separation of powers Montesquieu, rightly or wrongly, believed to be characteristic of the English system.

Montesquieu belonged to the *noblesse de robe*. Part of his design in recommending the separation of powers in France was to elevate the French aristocracy to a position comparable to that of the English, for whereas Rousseau believed that political liberty could be achieved only in a democracy and Voltaire believed it could best be achieved by a philosopher-king, Montesquieu held that liberty was most secure where there was a potent aristocracy to limit the despotic tendency of both the monarch and the common people. He believed that the way to preserve freedom was to set “power against power.”

No one wrote with greater eloquence against despotism than did Montesquieu, yet he was far from sharing the conventional liberal outlook of the eighteenth-century *philosophes*. He had all the conservatism characteristic of the landowner and the lawyer. In many respects he was positively reactionary; for instance, he wished to strengthen rather than diminish hereditary privileges. But like Edmund Burke, whom he influenced considerably, Montesquieu was able to reconcile his reforming and reactionary sentiments by insisting that he sought to restore old freedoms, not promote new ones. He argued that the centralizing monarchistic policy of Louis XIV had robbed Frenchmen of their ancient liberties and privileges. The only kind of revolution Montesquieu advocated was one that would give back to the French Estates—and to the nobility and the *parlements* in particular—the rights they had enjoyed before the seventeenth century. The actual French Revolution, which sought to enfranchise the bourgeoisie and the common people and to bring about a variety of other innovations, was far from the sort of change that Montesquieu had favored, although he inadvertently did help to inspire the events of 1789 and after.

Montesquieu’s parents were not well off. He inherited his title and much of his wealth from an uncle who at the same time bequeathed him the office of *président à mortier* of the *parlement* at Bordeaux. About the same

time his worldly position was further secured by a prudent marriage to a Protestant named Jeanne de Lartigue, who, although exceedingly plain in appearance, was heiress to a considerable fortune. Even so, Montesquieu remained an ambitious man, and, after twelve years as *président* in Bordeaux, he forsook his chateau and vineyards, to which he was deeply attached, and his wife, whom he loved perhaps rather less, to seek fame in Paris and to travel to other countries collecting material for his books. He was a success in the Paris salons, and although there seem to be no recorded examples of his wit in talking, he was celebrated as a conversationalist. He made friends with influential people and became the lover of the Marquise de Grave, among others. She inspired one of his early anonymous works, *Le temple de Gnide*, a mildly indecent erotic fantasy that was also a satire on the court of the infant Louis XV. After some difficulties Montesquieu was admitted to the French Academy in 1728.

He was on the whole a popular, but certainly not a generous, man. As a landowner he was most rigorous in the collection of even the smallest debts; at the same time he was slow to pay money he owed to others. In Paris he had a reputation for parsimony; more than one contemporary remarked that he “never ate at his own table.” At his chateau, La Brède, English guests were struck by what they politely called the “plainness” of the fare, and Montesquieu even economized on the arrangements for the wedding of his daughter Denise. He once warned his grandson, “La fortune est un état et non pas un bien.”

### LES LETTRES PERSANES

Montesquieu made his name as a writer at the age of thirty-two with the publication of *Les lettres persanes* (1721). Presented in the guise of a series of letters sent from France by two Persian visitors, Usbek and Rica, and translated into French by Montesquieu, this book is a satirical attack on French values and institutions. It is written with great wit and skill. The Persian visitors begin by remarking on the strange customs of the French in such matters as cutting their hair and wearing wigs and reversing the Persian rule of giving trousers to women and skirts to men. They then proceed by degrees to express delicate amazement at the things the French choose to respect or hold sacred. They comment on the mixture of grossness and extravagance in the manners of Parisian society. Their sly digs at French politics are even more telling. They describe Louis XIV as a “magician” who “makes people kill one another even when they have no quarrel.” The Persians also speak of “another conjuror who is called the Pope ... who makes people believe that

three are only one, and that the bread one eats is not bread or that the wine one drinks is not wine, and a thousand other things of the same sort.” The Spanish Inquisitors are described as a “cheerful species of dervishes who burnt to death people who disagreed with them on points of the utmost triviality.” The revocation of the Edict of Nantes is likewise mocked, Louis XIV being said to have contrived “to increase the numbers of the faithful by diminishing the numbers of his subjects.”

In the same book Montesquieu sought to establish two important principles of political theory—first, that all societies rest on the solidarity of interests and, second, that a free society can exist only on the basis of the general diffusion of civic virtue, as in the republics of antiquity.

Although Montesquieu attacked the manners of polite society in France, he did not fail to give *Les lettres persanes* a fashionable appeal. The two Persian travelers offer piquant descriptions of the pleasures of the harem and the sufferings of the women they have left behind them. Satire is nicely spiced with wit and the wit with impropriety, although this book is not quite so risqué as *Le temple de Gnide*. Montesquieu was said by Rutledge, one of his many admirers, to have “conquered his public like a lover; amusing it, flattering its taste, and proceeding thus step by step to the innermost sanctuary of its intelligence.”

### DE L'ESPRIT DES LOIS

Montesquieu's *Considérations sur les causes de la grandeur des Romains et de leur décadence* (1734), is a brilliantly written attempt to apply a scientific method to “historical understanding,” to set forth—admittedly in a distinctly literary style—a sociological explanation of one phase of historical experience as a model for a new kind of positivistic history. This book is perhaps best read as a prolegomenon to Montesquieu's masterpiece, *De l'esprit des lois*, on which he worked for seventeen years.

*De l'esprit des lois* was first published in Geneva in 1748 against the advice of all the friends to whom Montesquieu had shown the manuscript. It was promptly placed on the Index, but it sold twenty-two editions in less than two years. It was a resounding success. Even so, it is a long, rambling, ill-arranged book that reflects the developments and changes in the author's point of view in the seventeen years he took to write it. But like *Les lettres persanes* and the *Considérations*, it is the work of an unmistakable master of French prose and of a man who knows how to entertain his readers as well as to instruct them.

By the *esprit des lois*, Montesquieu meant the *raison d'être* for laws, or the rational basis for their existence. Like Locke, he believed in natural law, but he was a much more thoroughgoing empiricist in his method than was Locke. Montesquieu believed that the way to learn about law was to look at the actual legal systems in operation in various states. Formal recognition of natural rights did not mean that men had positive rights. Mere a priori principles have little real value; it is important, he argued, to have the actual verifiable facts of the situations in which men find themselves.

Similarly, in his approach to the question of freedom, Montesquieu was less interested in abstract assertions of a general concept than in the concrete circumstances in which freedom had been or was being enjoyed. “Liberty,” he wrote, “has its roots in the soil.” He noted that freedom is more easily maintained in mountainous countries, such as Switzerland, than in fertile plains, and on islands, such as England, than on continents. Island and mountainous states find it easier to defend themselves from foreign invasion; in mountainous countries the very poverty of the soil encourages industry, frugality, and independence and so promotes individualism among the people. Another condition of freedom, he suggested, is that tranquility which comes from security. This can be enjoyed only where the constitution sets inviolable limits to the action of the state and where the law itself guarantees the rights of the individual.

Montesquieu always insisted that political liberty could never be absolute. “Freedom,” he wrote, “is the right of doing whatever the laws permit.” For example, he maintained that free trade did not mean that traders should do what they liked, for that would be to enslave the nation. Restrictions on traders were not necessarily restrictions on trade but might well be measures conducive to the liberty of all. Good laws were those that protected the common interest, and it was the mark of a free society that all the people be allowed to follow their own inclinations as long as they did not disobey the laws.

### THE CONCEPT OF LAW

Montesquieu gives a rather bewildering definition of laws as “necessary relations,” or “the relations which necessarily follow from the nature of things.” Like most philosophers before David Hume, he failed to distinguish clearly between the normative laws of morals and the descriptive laws of science, but he was nevertheless conscious of having two tasks in seeking the *raison d'être* of laws. On the one hand, he was embarking on a sociological study of existing legal and political institutions, including the

institutions of positive law. Here Montesquieu the empiricist came to the front. On the other hand, Montesquieu the rationalist and the votary of natural law was seeking beyond his inductive generalizations for some general principles of justice and conduct, which he believed to be founded on reason.

I first of all examined men, and I came to the conclusion that in the infinite diversity of their laws and customs they were not guided solely by their whims. I formulated principles, and I saw particular cases naturally fitting these principles: and thus I saw the histories of all nations as the consequence of these principles, with every particular law bound to another law and dependent on a further more general law.

At the highest level of abstraction, Montesquieu saw a uniform law—"Men have always been subject to the same passions"—but in various societies this higher natural law is expressed in differing systems of positive law. The systems differ because the external conditions differ. Montesquieu made much of the differences of climate and attempted to describe how different climates promote different customs, habits, economic arrangements, and religions. Much of political wisdom consists in adapting general principles to local circumstances. Solon was right to give people "the best laws they could bear."

The measure of relativism in Montesquieu affronted his friends among the *philosophes*, who believed in a kind of abstract universal individualism, but Montesquieu's method proved the more acceptable to social theorists of later generations. Émile Durkheim said it was Montesquieu who gave modern sociology both its method and its field of study. Montesquieu was ahead of his time in regarding social facts as valid objects of science, subject to laws like the rest of nature; he was also ahead of his time in seeing social facts as related parts of a whole, always to be judged in their specific contexts.

## VIEWS ON RELIGION

Montesquieu resisted the notion that a "scientific" approach to problems of human conduct entailed determinism. He believed that God existed and that God had given men free will. "Could anything be more absurd," he asked, "than to pretend that a blind fatality could ever produce intelligent beings?" Assuredly, God had laid down the laws that govern the physical world, and "man, as a physical being, is, like all other bodies, governed by immutable laws." On the other hand, precisely because he is a rational, intelligent being, man is capable of transgressing certain laws to which he is subject. Some of the

laws he transgresses are his own laws, namely positive laws, but governing the conduct of men are other laws antecedent to positive laws, and these are the general "relations of justice" or, in a more conventional term, natural law.

Montesquieu's attitude toward religion was very like that of Locke. He did not believe in more than a few simple dogmas about the existence of God and God's benevolence, but to that minimal creed he clung with the utmost assurance. On the other hand, Montesquieu grew to be much more cautious than Locke in his criticisms of religious institutions. In *Les lettres persanes*, Montesquieu did not hesitate to mock the Roman Catholic Church and clergy, but in later years he took care to avoid provocative utterances on the subject. In his biography of Montesquieu, Robert Shackleton gives an example of the philosopher's increasing wariness as revealed in successive drafts of the *Esprit des lois*. In the first draft of the chapter on religion, Montesquieu wrote, "Under moderate governments, men are more attached to morals and less to religion; in despotic countries, they are more attached to religion and less to morals." In the second draft Montesquieu introduced at the beginning of that sentence, "One might perhaps say that ...." In the published version he cut out the remark altogether.

Much has been made of the fact that Montesquieu was reconciled to the Church of Rome on his deathbed. An Irish Jesuit named Bernard Routh got into the chateau at La Brède during Montesquieu's last illness, and in spite of the efforts of the Duchess d'Aiguillon to prevent him from "tormenting a dying man," the priest succeeded (or, at any rate, claimed to have succeeded) in leading the philosopher back to the path of devotion and repentance. The pope himself read Father Routh's account of Montesquieu's death "with the deepest reverence and ordered it to be circulated." Madame d'Aiguillon was able to rescue from the clutches of the Jesuits only one manuscript, that of the *Lettres persanes*. "I will sacrifice everything for the sake of reason and religion," Montesquieu had told the duchess, "but nothing to the Society of Jesus."

These dramatic scenes are perhaps less important to an understanding of Montesquieu's religious sentiments than is his behavior in less emotional times. He never asked his wife to give up her Protestantism, and he was always a fervent champion of religious toleration. At the same time, he remained on the best of terms with his several relations who were in holy orders in the Catholic Church. Besides, according to his "sociological" principle that every country had the religion its geographical and climatic conditions demanded, Montesquieu held that

Catholicism was the “right” religion for France, just as Anglicanism was the “right” religion for England. This is not to say that Montesquieu inwardly believed in more than a fraction of the teachings of the Catholic Church or that—until his deathbed repentance—the church regarded him as a true son. But he always detested atheism. To him the idea of a universe without God was *effroyable*. The concept of a loving creator played as prominent a part in his political theory as it did in that of Locke; indeed, whereas Locke had been content to see the church apart from the state, Montesquieu favored an alliance of organized religion with the government. In *Esprit des lois* he suggested that Christian principles, well engraved in the minds of the people, would be far more conducive to a good political order than either the monarchist notion of honor or the republican notion of civic virtue. Montesquieu was thus a deist in his heart and an Erastian in his politics.

## MONTGOMERY, EDMUND DUNCAN

(1835–1911)

Edmund Duncan Montgomery, a Scottish-American philosopher, anticipated in his “philosophy of vital organization” ideas of emergent evolution, the energetic nature of matter, and the pragmatic functioning of knowledge. Born in Edinburgh, he studied medicine in Germany in the 1850s, did research on cell pathology in London in the 1860s, and emigrated to America in 1870 with his sculptor wife, Elisabet Ney.

After a short-lived communitarian experiment at Thomasville, Georgia, the Montgomerys settled on Liendo Plantation, near Hempstead, Texas. There Montgomery wrote most of his philosophical articles and, in his later years, took an active role in community affairs. As chairman of the Waller County Democratic Party in the 1896 Bryan-McKinley campaign, he argued the dependence of political liberty upon economic reforms.

By 1867 Montgomery saw life as a power of certain compounds to reintegrate their chemical unity after damage, a power evolved by the inherent creativity of matter interacting in new combinations. He tested views of matter, mentality, selfhood, knowledge, and morality by this touchstone in over sixty articles in such journals as *Mind*, *Monist*, *Index*, *Open Court*, and the *International Journal of Ethics* and in five books. His major book was *Philosophical Problems in the Light of Vital Organization*.

Even inorganic compounds, Montgomery said, are inherently reactive, evolving in unpredictable ways by virtue of their peculiar composition and organization. Conservation of energy is thus wrongly viewed as requiring inertness of matter. Mentality is not dependent on a separate substance but is a capacity of certain complex organisms (chemical unities of a high order), heirs of evolution through foregone ages. Human knowledge and action are products of man's interplay with environment; they are instruments in preserving and enhancing well-being.

Some data of consciousness, such as kinesthetic and emotive states, seem to derive in each of us only from his own body, even though the body's activity thus perceived is in turn activated by outside stimuli. Others of our conscious states (such as visual data) are occasioned by features of either our own bodies or of external objects. Montgomery denied that this difference warrants the inference that there are two distinct kinds of substance, mental and material. All inferences from sensory data are conjectural. Data do not copy things but give "hieroglyphic signs" that permit discovery, prediction, and testing of natural relations among things.

Montgomery argued for a "naturalistic humanitarianism," a "religion of life," stressing ethical self-determination in a struggle against indifferent and hostile forces, to convey to the next generation a heritage nobler than the one received. Making common cause with those who wanted a religion and an ethic consistent with scientifically established knowledge, he added to classic criticisms of prevailing theologies and moral systems his own emphasis upon their failure to heed the full potentialities of men, the preeminent heirs of an evolution far from completed.

## MOORE, GEORGE EDWARD

(1873–1958)

George Edward Moore was born into moderately affluent circumstances in Upper Norwood (a suburb of London), the third son of D. Moore, M.D., and Henrietta Sturge Moore. The Sturges were prominent Quaker merchants and philanthropists. On his father's side there had been some tendency toward, and some prominence in, the practice of medicine.

Upon reaching eight, George Edward Moore commenced attendance at Dulwich College, a boarding and day school of excellent reputation located within walking distance of his home. In the ten years of his attendance there he acquired a thorough mastery of the classics. It was also at this time that he underwent a very painful experience. Having been converted around the age of twelve to "ultra-evangelism," he felt it his duty to preach the word of Jesus and to distribute religious tracts. He found these activities extremely repugnant and suffered much inward torment in carrying them out. This experience, which lasted two years or more, may account in some measure for his subsequent coolness to religious enthusiasms of any sort. Before leaving Dulwich College he was persuaded, through discussions with his eldest brother, the poet Thomas Sturge Moore, to adopt the view that was then known as "complete agnosticism." This seems to have been the view that there is no evidence in support of a belief in God's existence and almost as little in support of a belief in his nonexistence. So far as can be determined from his writings, Moore never departed from this view.

In 1892 Moore entered Trinity College, Cambridge, as a student in classics. At the beginning of his third year he changed his major concentration to philosophy and completed the moral science tripos in 1896. On the basis of a dissertation treating Immanuel Kant's ethics he was elected in 1898 a fellow for a term of six years. During the period 1898–1904 he carried on frequent and consequential discussions with Bertrand Russell, wrote *Principia Ethica*, presented several papers to the Aristotelian Society (to which he had been elected), and published a number of reviews and articles.

With the termination of his fellowship in 1904, Moore left Cambridge. Because of an inheritance he was still able to pursue his philosophical activities. He wrote articles, papers, and reviews, as well as the small volume *Ethics*, and gave a series of private lectures at Richmond. In 1911 he was invited to return to Cambridge as university lecturer. He lectured regularly at Cambridge from 1911 to 1925, first on philosophical psychology and later on metaphysics. In 1925 he succeeded James Ward as professor of mental philosophy and logic. His courses appear to have enjoyed a good deal of popularity among the more serious students of philosophy and had an immense influence upon the philosophizing going on in England at the time, as did his publications (notwithstanding that they consisted entirely of articles and papers).

In 1939, having reached the mandatory age of retirement, Moore gave up his professorship at Cambridge, though not his philosophical activities. These, with a few interruptions due to illness, he carried on to almost the very last years of his life, writing articles, editing his previous writings, working on problems, and holding discussions with friends and students. He died at Cambridge at eighty-five, survived by his wife, Dorothy Ely, whom he had married in 1916, and two sons, Nicholas, a poet, and Timothy.

Although Moore's life was extremely active in academic and philosophic spheres, it was almost without incident otherwise. Except for a brief sojourn in Germany in the summer of 1895, a somewhat longer stay in Scotland from around 1904 to 1908, and a couple of years spent during World War II lecturing in the United States, he resided entirely in England, mainly in or near Cambridge. His most noticeable personal trait appears to have been his intense and passionate absorption in philosophy. It is said, for example, that when discussing a question, whether with his professional peers or with a student, he gave himself wholly to the inquiry and viewed its progress with the constant fresh surprise of one considering a matter for the first time. Another trait that has been com-

mented on was his lack of any intellectual pretensions (in spite of a formidable erudition) and an almost childlike naïveté concerning ordinary affairs.

Moore served as editor of the philosophical journal *Mind* from 1921 to 1947. The major honors that he received during his lifetime were the Litt.D. from Cambridge (1913), the honorary degree of LL.D. from the University of St. Andrews and election as a fellow of the British Academy (1918), and appointment to the Order of Merit (1951).

## FORMATIVE PERIOD OF MOORE'S PHILOSOPHY

Moore's published philosophy falls into two distinct parts, divided by the year 1903. Although the writings published prior to 1903 are few and cover no more than five years, at least three different philosophical positions can be detected in them. In his first publication, a paper titled "In What Sense, if Any, Do Past and Future Time Exist?" (1897), Moore agreed wholly with F. H. Bradley. He argued that time does not exist, and he did so using Bradley's methods and premises, in particular the dogmas of internal relations and concrete universals and the principle that identifies reality with the absence of contradiction. When his conclusions, like the one that time does not exist, proved to outrage common sense, Moore was prepared to say that common sense is simply wrong, and he did so more than once.

One year later, in the essay "Freedom," Moore replaced Bradley with Kant as the philosopher with whom he was "in most agreement." What he agreed with most in Kant was the method of the transcendental exposition and the doctrine of synthetic necessary truths. He did not agree with the critical restrictions of Kant's philosophy or with what he took to be its psychological bias. He contended, for instance, that Kant was wrong in trying to conceive freedom in terms of the will (a psychological concept); freedom is rather to be understood and explained in terms of the idea of Transcendental Freedom, into which temporal relations do not enter. Thus, while accepting much of Kant's system and terminology, Moore continued to speculate in the critically unrestricted manner of the absolute idealists, maintaining that a reality transcending time and the senses is something that can be theoretically known and that must be theoretically known before the major problems of philosophy can be solved.

The next year, 1899, in the article "The Nature of Judgment," Moore adopted a third position. As part of his continuing attack upon psychologism in philosophy (an

attack he shared at the time with Russell), he proposed the doctrine, adumbrated in Thomas Reid, that mental acts and their objects are entirely separate existences. Applying this doctrine to Bradley's analysis of judgment, Moore concluded that the entire world—everything we can either think of or perceive with our senses—consists in qualitative universals, or what he called “adjectival concepts.” These universals compose propositions, material objects, minds, and all other “complex objects.” Not only do some universals (for example, red) exist through time, but some propositions also exist through time and are even objects of perception (for instance, the proposition that this book is red). Such universals and propositions are designated “empirical universals and propositions,” as opposed to those that do not exist through time, such as the concepts *two* and *attribute*, which are called “a priori.” This bizarre metaphysics, which might be termed “absolute realism” because according to it universals not only exist but, in fact, comprise everything that does exist, obviously repudiates all the major philosophical tenets to which Moore subscribed in his first essay: the dogmas of the nonreality of time, internal relations, concrete universals, and the transcendent monism that springs from them. Just as obviously it cannot be harmonized with the two-story world of phenomena and noumena that is attributed to Kant or with Kant's critical conclusions. Moore did, however, attempt to show that his realistic principles were compatible with, and even substantiated, Kant's method of transcendental exposition and distinction between a priori and empirical propositions and the doctrine of synthetic necessity. This Moore did by attempting to show that the possibility of a priori and empirical propositions, along with synthetic necessary truths, can be accounted for in terms of the realistic distinction between temporally existing (empirical) universals and nontemporal (a priori) universals and by shaping some of the arguments supporting this demonstration along the lines of a transcendental exposition. On the whole, though, the argumentation of “The Nature of Judgment,” as well as of the articles and reviews that immediately followed (1899–1902), proceeds in the legislative, dogmatic manner of Bradley.

With this unstable amalgam of Bradley, Kant, and absolute realism, the first period of Moore's philosophizing came to a close. Marked by abrupt changes of doctrine, by either derivativeness (as in the first two positions adopted) or bizarreness (as in the third), it is recognizably an effort to find, rather than to express, a philosophy. It is therefore with some justice that these writings have been generally ignored by succeeding generations of philosophers, as they were ignored by Moore himself in his sub-

sequent summations and compilations of his work. On the other hand, a complete understanding of Moore's later philosophy is difficult to arrive at without some familiarity with these earlier works. It will then be understood, for instance, that the charge sometimes leveled against Moore that he criticized the metaphysical theses of philosophers like Bradley piecemeal, without attempting to comprehend them fairly and in their entirety, is groundless. It will be understood, for instance, that in attacking items of Bradley's metaphysics Moore was attacking not only a system of thought with which he was thoroughly conversant but one to which he had himself once been most strongly attracted.

### MOORE'S PHILOSOPHY PROPER

The system of philosophical thought and method that has come to be associated with Moore's name and that he was alone concerned to defend issued fully formed in the volume *Principia Ethica* and the essay “The Refutation of Idealism” in 1903. This is not to say that no alterations thenceforth took place in the body of Moore's philosophical doctrines and aims. They did. For example, with the passage of time Moore became increasingly concerned with eliminating from the world various entities, such as propositions, that his principles generate. The theory proposed in “The Refutation of Idealism,” that we directly perceive material things, was replaced by a disjunction of theories respecting the relation between sense data and material things. And the note of philosophical optimism that expressed itself in *Principia Ethica* and “The Refutation of Idealism” in the view that solutions to the problems under discussion have either been completed in their pages or are on the brink of completion finally gave way to a note of philosophical pessimism and puzzlement. But in its main outlines what might be called Moore's philosophy proper was now permanently formed.

As will be seen in subsequent discussion, the tenets of this philosophy are largely based on the principle that sentences such as “I think of *X*” describe (*a*) mental acts and (*b*) objects related to but distinct from those acts. From 1903 until the late 1930s Moore almost invariably interpreted this principle realistically, and even after the late 1930s, when he was prepared to admit that the *esse* of sense data is *percipi*, this realist tendency continued to make itself felt in his philosophizing, especially with respect to universals. Moore's philosophy proper resembles, therefore, the absolute realism of “The Nature of Judgment.” There exists, however, a fundamental metaphysical difference between the two positions. This differ-

ence lies in the fact that Moore's absolute realism of 1899 is reductionistic, being the view that everything can be resolved into qualitative universals, whereas the realism he enunciated in 1903 and afterward is, in intention at least, nonreductionistic. Thus, within the compass of things that are, Moore now included both particulars—for example, material things—and universals, and though he was not perfectly clear about just what a universal or a particular is, he wanted to maintain neither that universals can be resolved into particulars nor that particulars can be resolved into universals. His new view was that each sort of thing is what it is and nothing else (or, in the words of Bishop Butler, quoted on the frontispiece of *Principia Ethica*, "Everything is what it is, and not another thing").

The most striking and significant difference between Moore's philosophizing prior to 1903 and his philosophy proper lies not, however, in doctrine or even in the mechanics of method (though differences here are pronounced) but in the attitude and style of his philosophizing. These now project the familiar picture of Moore: the picture of a cautious and probing observer, attempting by the patient dissection and scrutiny of minute and hardly distinguishable objects to set straight the confused descriptions by philosophers of what is the case. This posture of Moore's lends to his philosophizing the appearance of a completely empirical inquiry whose conclusions represent only what is found or not found to be the case, as opposed to what is merely thought to be or not to be the case. It is in the solvent of this empiricist posture that Moore's initial philosophical optimism, as one might predict, evaporated into pessimism and puzzlement. For the principle from which it originated, that sentences such as "I perceive *X*" describe acts of mind and distinct objects, is itself something no amount of observation would seem to confirm or lend substance to.

In the first of the lectures that he delivered in 1910–1911, some forty years later published under the title *Some Main Problems of Philosophy*, Moore listed the main topics of philosophy as three. The first and primary aim of philosophy, he said, is to provide a metaphysical inventory of the universe, that is, "a general description of the *whole* of this universe, mentioning all the most important kinds of things which we *know* to be in it, considering how far it is likely that there are in it important kinds of things which we do not absolutely *know* to be in it." The second aim is epistemological: to classify the ways in which we can know things. The third topic of philosophy is ethics.

In "A Reply to My Critics," published in 1942, Moore again divided his philosophical discussion into three parts: ethics, theory of perception, and method. Although this alteration in the classification of topics indicates certain real alterations in Moore's interests and views, it will be convenient to treat his philosophy proper under the five heads mentioned: method, metaphysics, general epistemology, theory of perception, and ethics.

**METHOD.** By Moore's "method" will be understood the topics encompassed by the following: (1) The question: What did Moore believe he was doing in philosophizing, that is, what project did he think he was engaged in? (2) The question: How did he attempt to carry out this project? (3) Certain questions that are often raised in specific connection with Moore's method, such as: What is the role of common sense in his method? What is the role of analysis?

*Moore's intentions.* It has been suggested by some of his commentators that what Moore was trying to do was to analyze ordinary language, to defend common sense, or to recommend ways of speaking. As an answer to the question What was Moore *actually* doing? it is possible that one or all of these suggestions may be true. But it is clear that none of them describes what Moore believed he was doing.

Moore's conception of what he was doing originated in the following two principles, to which he consistently subscribed: the principle that sentences like "I think that *P*" and "I perceive *X*" designate acts of consciousness, on the one hand, and objects related to but distinct from those acts, on the other; and the principle that every object of consciousness is either a simple, in which case it is unanalyzable, or a complex, in which case it always possesses a definable essence in terms of which it is the sort of thing it is and not some other sort of thing. The first principle makes it appear as if there should be discoverable as the objects of consciousness a great many more kinds of entities and properties than persons ordinarily envisage, and these entities and properties should comprise, at least in part, what is objectively in the universe. When applied to these entities, the second principle makes it appear as if every complex object should be unequivocally reducible to simples. But this picture of things raises a question: If the constitution of the universe is both so determinate and so open to consciousness, why is it that there has been so much disagreement and confusion in the attempts of philosophers to describe it? And to this question the most obvious answer seems to be that past errors and confusion in philosophy have arisen

either from inattention on the part of philosophers to the objects of their consciousness or from a lack of clarity and preciseness in their statements and questions.

In fact, the two major concerns of Moore through the period 1903–1911 directly correspond to the above outline of subject matter. Primarily, Moore wished to determine what sorts of entities or properties fall within the province of his particular inquiry, for example, ethics, theory of perception; to classify these entities (where deemed necessary) as simples or complexes; and to analyze the essences of the complexes. Second, and always as a project subordinate to the first, he wished either to direct the reader's attention to the objects of consciousness that pertain to the inquiry at hand or to lay bare the ambiguities and unclarity of the terms customarily used by philosophers in conjunction with the inquiry at hand, and to supply "precising" definitions of the terms that he intended to use.

After the lectures of 1910–1911 an increasing concern with terminological questions was detectable in Moore's writing. This concern is traceable to an apparently growing conviction on his part (as well as on the part of his contemporaries) that the terminological sources of philosophical error and confusion are much more subtle, deeply rooted, and pervasive than he had originally thought and much more intimately connected with the logical grammar of ordinary language. In the last connection it is worth recalling that certain of Moore's contemporaries eventually decided that the root and cure of all philosophical problems lay in terminological confusion and clarification.

Moore never went so far as to assent to the last conclusion. He did, however, relinquish his earlier view that the primary concern of philosophy is to observe and delineate the entities objectively making up the universe. By 1940, when he composed his "Reply to My Critics," he described himself as engaged, not in the analysis of facts, but in the analysis of concepts. Although he was unclear about what the relation is between concepts, the entities objectively making up the universe, and verbal expressions, he appears to have thought that concepts are not only distinct from and (at least from their side) independent of their verbal expressions but also distinct from the entities objectively making up the universe (for otherwise, in analyzing concepts, he would be resolving philosophical doubts and questions in a way that he agreed that one cannot do and that he was not doing). But just what, then, are concepts according to Moore? In "A Reply to My Critics" he did not say. It is not improbable, however, that Moore had come full circle, back to

something like Bradley's psychologically grounded view of concepts, which, ironically, served in "The Nature of Judgment" as the launching platform for Moore's philosophy of realism.

*Moore's procedure.* In much the same way that Moore's doctrine of mental acts and objects dictated his conception of what he was trying to do, it also dictated his conception of how to accomplish what he was trying to do. It is evident, for instance, that once sentences like "I think that *P*" and "I perceive *X*" are interpreted according to that doctrine, it must seem unjustified to argue in the legislative manner of Bradley, which Moore employed in "The Nature of Judgment" and the essays previous to it. If the objects of acts of judging, perceiving, and thinking are entities distinct from, and indeed independent of, those acts, then whatever we can learn about those objects must be by means of synthetic observations, not a priori thought. Moore throughout his philosophy proper adhered to this viewpoint. Where he conceived himself as primarily engaged in reporting, classifying, and analyzing the entities objectively constituting the universe, he assumed that he was basing his reports and analyses on observation. Where, as in "A Reply to My Critics," he conceived himself as engaged rather in analyzing concepts, it is evident that he thought of concepts as comprising some sort of object he was engaged in observing.

As was noted previously, this picture of philosophical inquiry suggests that philosophical questions have determinate and easy solutions that it might be expected all philosophers will agree on. Moore's explanation of this discrepancy between expectation and fact—that the disagreements and failures of philosophers stem either from a lack of attention to what is present to their consciousness or from terminological unclarity—suggests, in turn, that in order to be certain we are observing what we think we are we must make sure both that our attention is directed to the right objects and that we know the precise meanings of the terms we are employing in our thoughts.

It turns out, however, that even with this supplement observation fails to bring about the results that Moore anticipated or that his assumptions might have led him to anticipate. The answers to philosophical questions remain stubbornly shrouded in obscurity and disagreement. Moore was therefore compelled to add to his methods and procedures. In cases where he felt there was no conclusive answer to a question, he resorted to what might be termed the principle of weighted certainties. If, for instance, he felt that proposition *A* possessed more certainty than proposition *B*, or if he felt that he knew the

truth of *A* with more certainty than that of *B*, he would refuse to deny the truth of *A* on account of some argument based on *B*. In short, a lesser certainty (according to this principle) cannot rationally overturn a greater certainty per se (though a number of lesser certainties, cohering together, may). Moore also employed, in the same connection, the scholastic method of citing all the plausible arguments that can be advanced for or against a thesis in order to indicate its degree of credibility. And finally, in order to discredit a thesis (usually a thesis of skepticism), he employed either a *reductio ad absurdum* argument or what might be called a paradigm argument. He pointed out, for example, that the skeptic who maintains that we cannot know there are other persons is already contradicting himself by supposition in referring to the plural, *we*. Or he argued that if such-and-such is not an instance of knowing, then no one has ever known anything and there cannot be such a thing as knowing.

When these norms for evaluating philosophical conclusions are arranged in order of their indefeasibility, it would seem that where observation unequivocally reveals just what a thesis represents to be the case, according to Moore the thesis is indefeasible. Thus, Moore maintained that when we look at an inkwell we directly perceive a sense datum and that this claim is indefeasible in that observation unequivocally presents us with a sense datum. Where a thesis can be shown to contain an evident contradiction, according to Moore it is conclusively disproved. Thus, one can affirm with certainty that the skeptic who maintains that *we* cannot know other persons exist is wrong. Where the principle of weighted certainties or the method of citing plausible arguments has to be invoked, Moore would generally grant that answers are not conclusive or indefeasible, although there may be more to be said in favor of one answer than another. In certain cases, however, it would appear that the certainties or feelings of certainty (Moore rarely distinguished between the two) attaching themselves to a thesis are so absolute or overpowering that no denial of the thesis is either psychologically or rationally (in view of the principle of weighted certainties) possible.

**Common sense.** It is tempting, but wrong, to suppose that because Moore defended common sense, common sense constitutes a court of last appeal in his philosophy. Indeed, the very fact that he described himself as defending common sense indicates that it cannot.

In his works Moore used the term *common sense* to refer to two different, but related, things. He sometimes meant by it, he said, simply those beliefs that men universally or almost universally subscribe to at some partic-

ular epoch. At other times he meant either those beliefs that we are naturally inclined to hold or the propensity that issues in such beliefs.

Although there may exist a very intimate causal connection between these two forms of common sense, they are not one and the same thing. As the “universal” belief of men at a particular epoch, common sense can change, and Moore in fact argued that it can. As a natural tendency to believe something, common sense would not seem susceptible of change. It must be remarked, however, that Moore never explicitly drew the above distinction or attempted to “analyze” the notion of common sense beyond saying that it consists in the universal belief of men at a particular time. In practice, however, he would seem to have maintained that although both forms of common sense possess a certain amount of presumptive credibility, it is essentially as a natural tendency that common sense provides a foundation for philosophical conclusions. It does this in two ways. When we try to deny the latter form of common sense we find it virtually impossible to do so because what we naturally tend to believe keeps slipping into our assertions. We thus find ourselves contradicting ourselves by supposition, like the skeptic who says that *we* cannot know persons exist. On the other hand, what we naturally tend to believe will have attached to it some degree of certainty. This degree varies, it seems, from an absolute quantity, which makes dissent really impossible, to a quantity that only inhibits dissent. For example, Moore said he was naturally disposed to think that what he always saw directly when viewing a material thing was the surface, or part of the surface, of the material thing, but he finally decided it would be nonsense to maintain that he did.

Moore, then, defended common sense by showing that certain beliefs that we are naturally inclined to hold, and consequently that most men do hold, are supported by the principle of weighted certainties or by showing that the traditional counterclaims of skeptics are self-contradictory. He did not argue conversely that because a certain belief is a belief of common sense it is ipso facto indisputably true or need not be subjected to assessment.

**Analysis.** When Moore described himself as “analyzing,” he conceived of himself as picking out and naming the essential constituents of complex objects. In his earlier works he viewed himself, when analyzing, as picking out and naming the essential constituents of various objective entities and facts; in his later works, as picking out and naming essential constituents of various complex concepts. In his reply to C. H. Langford in “A Reply to My

Critics," he explicitly denied that he ever engaged in the analysis of verbal expressions.

This last denial may not be disingenuous, but it is misleading. Moore maintained that the only proper meaning of the term *analyzing verbal expressions* is merely counting the letters in a sentence, noting the order of the letters, and so on. If this is true, then obviously Moore never engaged in analyzing verbal expressions, and just as obviously his denial that he did is trivial.

It may therefore be more significant to ask whether Moore engaged in linguistic analysis, where "linguistic analysis" is used as a technical term designating the following practices or inquiries: the determination of the meaning of a word or expression (not excepting the determination of its dictionary meaning); the determination of the various senses of a word or expression; the determination of the ordinary use of a word or expression; and the determination of discrepancies between the philosophical and ordinary uses of a word or expression. In all these senses of the technical term *linguistic analysis*, Moore, it is clear, engaged frequently in linguistic analysis. However, as was pointed out previously, he engaged in linguistic analysis never as an end in itself but always as an inquiry subordinate to the ascertainment of facts or the determination of the essential constituents of things or concepts.

**METAPHYSICS.** By the term *metaphysical* Moore sometimes meant to refer to nonnatural objects or qualities, that is, objects or qualities that are constituents of the universe but not of temporal events (or nature); sometimes he meant to refer to the sort of philosophical inquiry that concerns itself with the overall constitution of the universe. It is in the latter sense that the term *metaphysics* is being used here.

Although not without expressing some doubts on the matter, Moore inclined to the view that the things to be *found* in the universe are broadly of two sorts: those things that exist and those that simply *are* but do not exist. A third class of things consists of those that neither exist nor are; they simply are not. As Moore conceived of these categories, the main ontological division is between the things that are and those that are not. For the former, whether they exist or simply are, comprise the objective constituents of the universe and have equal claim to philosophical investigation. The latter are merely "chimeras" or "imaginary objects."

Moore suggested at least three ways of distinguishing between things that are and things that are not. First, the former possess the property of being; the latter do not.

Second, borrowing from Russell's theory of descriptions, Moore claimed that whereas an object that *is* or possesses *being* can be the bearer of a name, imaginary objects can be described only by incomplete symbols. Thus, for example, "centaur" is not the name of anything (for there is nothing to bear the name), whereas "chair" is a name. Third, if a thing's *esse* is *percipi*, then it is an imaginary object and actually *is not*. There are only thoughts of centaurs, for example; there are not centaurs independent of our thoughts. Hence, centaurs are imaginary objects. Moore, however, discovered difficulties with the last description in that he thought it likely that the *esse* of acts of consciousness and sense data is *percipi*, and at the same time he did not want to say that acts of consciousness and sense data *are not*.

Where he did distinguish between mere being and existence (and in places he did not), Moore generally cited two grounds as the basis for the distinction. Sometimes he argued that whatever endures through parts of time exists; what does not endure through parts of time does not exist. He also sometimes argued that whatever can be an object of sensory perception exists. Although he never discussed the connection between these two criteria for existence, it seems from what he said on other matters that the temporal criterion states both a necessary and a sufficient condition for existence, whereas the sensory criterion states but a sufficient condition. For in Moore's system it is possible that material things are never the contents of sensory perception, but they are, *par excellence*, things that exist.

In addition to existence, being, and nonbeing, Moore treated at length and in detail the category of *reality*. Although painstakingly carried out, his thoughts on this subject possessed little overall coherence. In *Principia Ethica* he equated reality with existence; in the lectures of 1910–1911 he equated it simply with *being*. In the same lectures he referred to reality as a property; on the other hand, in *Philosophical Studies*, in the essay "The Conception of Reality" (1917), he denied that reality is a property. What he consistently maintained is expressed in his rejection of Bradley's view that reality possesses degrees and that the highest degree of reality is at an extreme remove from material things. Moore denied that reality possesses degrees. But if it does, he said, then he wanted to maintain, in opposition to Bradley, that material things possess the highest degree of it.

Within the category of *being* Moore distinguished between three kinds of objects: particulars, truths or facts, and universals. He generally, though not always, argued as if particulars may be divided into five sorts:

material things, sense data (for instance, *patches* of yellow), acts of consciousness, volumes of space, and intervals of time. He did not appear to think that the term *mind* refers to a particular substance in which acts of consciousness inhere. The theory he seemed to favor is that acts of consciousness are located in material bodies and are properties of material bodies and that the word *mind* stands for something like a logical construction from acts of consciousness. Truths or facts are the objects of true beliefs and comprise such things as mathematical equations—for example,  $2 + 2 = 4$ —and the references of indicative sentences, such as “Tom stood to the left of Henry.” Universals are again divisible into three sorts: relations, relational properties, and a third sort of universal that is neither a relation nor a relational property. Moore never provided an essential description of this third sort of universal, but he cited as clear-cut examples of it numbers and nonnatural qualities or objects, such as *good*, and as possible examples of it shades of color.

Of the three sorts of *being*—that is, particulars, facts, and universals—particulars alone exist; facts and universals merely *are*: This, at least, was Moore’s view when he was prepared to grant that a significant distinction holds between existence and mere being. It was also his view that the only *substantial* things we are acquainted with are material bodies and acts of consciousness.

It should be remarked that the above inventory of the universe was not considered by Moore to be exhaustive. There may be things in the universe that we are in fact ignorant of or must even necessarily remain ignorant of. For example, Moore thought it is not impossible that God exists but found no evidence for maintaining that he does. Moore described himself as being certain, though, that all the things that have been mentioned as *being* or *existing* do constitute at least some of the constituents of the universe.

GENERAL EPISTEMOLOGY. Although a number of the topics that have been treated under the heading of Moore’s methodology might as reasonably be considered under the heading of his general epistemology, and vice versa, under his methodology it was asked what Moore in his philosophizing was attempting to do and how he was attempting to achieve his aims, whereas under his epistemology these quite different questions are being asked: (1) What, according to Moore’s philosophic account, does knowledge consist in? (2) Does knowledge, as so conceived, exist, and if it does, what is it knowledge of?

(1) What does knowledge consist in? Moore’s basic metaphysical and methodological principles dictate that

in order to discover what knowledge is, it is necessary to distinguish between the different senses (if there are different senses) of the verb “to know” and then to pick out and analyze the particular objects denoted by these senses of “to know” and the relations (if any) that hold between them.

Throughout his earlier writings and the lectures of 1910–1911, Moore was convinced that careful observation of facts and careful differentiation of terms provide us with the following results. First, every instance of cognition ultimately consists in an act of consciousness and, distinct from the latter, in an object. Second, an act of consciousness can exist only as long as the corresponding instance of cognition exists. Thus, when I cease to see a sense datum, my *seeing* of it ceases to exist. The object of cognition, however, may or may not exist after the act of consciousness to which it is related ceases. This is a matter to be decided by empirical considerations. Third, it is conceivable that an act of consciousness and its related object—for example, a sense datum—exist in two different locations. “It seems to me conceivable,” wrote Moore in *Some Main Problems of Philosophy*, “that this whitish colour is really on the surface of the material envelope.... My seeing of it is in another place—somewhere within my body.”

Reflecting this analysis of cognition and its objects, Moore thought that he could pick out four different ways of knowing and, corresponding to them, four different senses of the verb “to know.” First and basic to an understanding of any other sense of “to know” is the sense in which “to know” stands for cases in which the relation between the object cognized and its correspondent act of consciousness is similar to or identical with the relation that a patch of color has to the consciousness of a person seeing that patch of color. This is knowledge by direct apprehension or knowledge by acquaintance. A second sense of “to know” represents cases in which the relation between the object cognized and the correspondent act of consciousness is similar to or identical with the relation that, for example, a hat on a table has to the act of consciousness of a person who is remembering that his hat was on the table. Thus, he knows that his hat was on the table, but neither the hat and table nor any sense data that were connected with the hat and table are directly present to his consciousness. This is knowledge by indirect apprehension. At least until 1911, Moore described himself as uncertain whether knowledge by indirect apprehension always necessitates direct apprehension of a proposition, by means of which, following Russell’s theory of knowledge by description, one is made aware of the object indi-

rectly apprehended, but he was inclined to think it does. Third, there is a sense of “to know” that represents cases in which the following complex relation between acts of consciousness and objects holds: there is an act of consciousness; there is a proposition directly apprehended; this proposition is in fact true; we believe that it is true; and we believe that it is true because of some further relation or condition that it satisfies. What this further condition is Moore left undecided, though one might plausibly suppose that it had to do with conclusive evidence. In any event, Moore termed this way of knowing “knowledge proper.” Last, and involving the previous senses of “to know,” is that sense of “to know” in which we describe a person as knowing something, such as the multiplication table, even though he may not at the time be conscious of anything. We imply, in such cases, that the person in question has at some time known, in one of the other three senses of “to know,” the multiplication table.

Moore also distinguished between what he termed “immediate knowledge” and “knowledge by direct apprehension.” Immediate knowledge is a species of “knowledge proper.” Thus, immediate knowledge is distinguished from knowledge by direct apprehension in that the latter does not require the presence of a proposition (for instance, I can directly apprehend sense data), whereas the former does. It is specifically the “kind of way in which you know a proposition to be true—really know it, not directly apprehend it—when you *do not* know any other proposition from which it follows” (*Some Main Problems of Philosophy*).

(2) Does knowledge exist? and of what things? Since Moore, purportedly on the basis of observation, resolved knowledge into a certain complex of objects, it is evident that knowledge, or “acts of knowing,” exists in his view. The question of its existence becomes, indeed, a psychological or introspective question (it would seem) rather than an epistemological one.

In dealing with the question of what sorts of things are known, Moore generally, however, treated it as a *de jure* or epistemological, rather than a *de facto* or psychological, question. Thus, in defense of asserting that such-and-such a sort of thing can be known, he would sometimes appeal to the principle of weighted certainties (for example, he would ask, “Which is more certain—that I know that I am holding a pencil in my hand or that the principles of the skeptic are true?”) and sometimes to paradigm arguments of the sort “If I do not know that *P*, then I can know nothing.” In this connection, it is worth noting that Moore sometimes argued *de jure* that we know such-and-such a sort of thing exists although he

was unable to discover by introspection the way in which we know it. For instance, he insisted that we know the existence of material things, such as the earth and our own body and other bodies like it, but he was unable to determine with any certainty in just what way we know their existence.

Moore claimed that in addition to the existence of material things, we know the existence of our own acts of consciousness and our own sense data, past events in our lives, the being of universals and nonnatural qualities or entities (such as good), the existence of other minds, synthetic necessary truths, and practically all matters of fact that are commonly thought to be known—for instance, that Caesar crossed the Rubicon, that Earth goes around the sun, and so on. Thus, in contrast to the skeptic, who traditionally maintains that the circumference of knowledge is much smaller than people ordinarily think, Moore appears to have maintained that it is much larger than people ordinarily think. For it is doubtful that people ordinarily think they know the existence of some things called sense data and acts of consciousness or the being of some things called nonnatural qualities or universals.

**THEORY OF PERCEPTION.** It is apparent that Moore’s general epistemological principles and the premises that he operated with in his methodology enforce an empiricist approach to knowledge. They imply that all knowledge must finally be based on the observation of objects presented in experience. In three respects, however, Moore consistently parted company with traditional empiricists. He refused to limit the term *experience* to mean simply sensory experience. That is, he wanted to maintain that many sorts of objects other than those discovered by the senses are the objects of acts of consciousness—for example, timeless facts, relational universals, and nonnatural qualities. He also wanted to maintain (following Kant) that there are necessary synthetic truths and that we can apprehend these truths. And finally, he was never willing to reject what seemed to him a certain truth—for instance, that he was holding a pencil—because some less certainly true analyses or philosophical principles were incompatible with it. Thus, he consistently refused to acquiesce in the skeptical conclusions that traditional empiricism and indeed, it seems, his own empiricist principles tend to establish.

At the same time, these principles seem to have had two distinct effects on Moore’s overall philosophizing. First, as time passed his interests converged on theory of perception and questions concerning our knowledge of an external, material world. Second, the skeptical conclu-

sions that empiricism appears to foster produced a constantly widening cleavage in his philosophy between what he wanted to assert preanalytically to be certainly true and what his analyses permitted him to assert to be certainly true. This ever-growing cleavage is nowhere more apparent than in his theory of perception.

In his essay of 1903, "The Refutation of Idealism," Moore maintained that material things can be directly apprehended and therefore can be known to exist with as much certainty as one's own acts of consciousness. Soon afterward, however, Moore was led to change his mind on this crucial point, apparently by what has sometimes been referred to as the argument from synthetic incompatibility. This argument assumes that the looks of things are the objects a person directly perceives, and then, because the looks of things change when the thing itself is not presumed to be changing, the argument concludes that what a person directly perceives is not the material thing or a part of its surface but some other kind of object that possibly exists only when he is perceiving it. This "other kind of object" is called by Moore a sense datum.

Moore had trouble in deciding just what a sense datum is: whether it is a particular or a universal, whether it is something like a color (in the case of visual sense data) or some other sort of thing. His final position on this question would seem to be that a visual sense datum is a *patch* of some color: The patch, which is a particular, is related to the color, which is a universal of the third sort (that is, it is neither a relation nor a relational property) in the way something is related to that which, in part, is spread over it.

The main problem concerning Moore in his theory of perception was not this, however, but the question of the relation between sense data and the material things to which they "belong." Although Moore concerned himself with this question in a series of remarkably closely reasoned essays, commencing with "The Status of Sense-Data" (1914) and concluding with his last published article, "Visual Sense-Data" (1958), he was never able to arrive at a definite or even a very plausible answer. Throughout most of these essays he presented three alternative theories as possibly true: phenomenalism, or what he termed the Mill-Russell theory—that is, the view that a material thing is simply a "logical construction" of sense data; some form of representational theory (varying from the theory that the relation between sense data and material things is an unanalyzable relation of "appearing" to causal theories resembling John Locke's); and the theory that visual sense data are identical with parts of the surfaces of material things. With all these alternatives he

found grave difficulties and, indeed, was led in the end to dismiss the last as constituting, at least in most cases of perception, nonsense. But if we do not directly perceive material things or their surfaces (and Moore was willing to grant that perhaps we never do), and if by "material things" is meant nothing so Pickwickian as a logical construction of sense data (and Moore would have tended to agree that nothing so Pickwickian is meant), how can we possibly know that material things exist? Moore, in one of his last lectures, "Four Forms of Scepticism," suggested none too plausibly that we know their existence by analogical or inductive arguments.

ETHICS. As in the other branches of his philosophy, Moore was confident in his earlier works on ethics of the correctness and finality of the results he set forth; this confidence diminished constantly in the solvent of his empiricist methods of inquiry and was replaced in his later works by no more than tentative agreement with his earlier views. Also, as in the other branches of his philosophy proper, Moore's viewpoint toward both the proper method of ethical inquiry and the nature of the findings to be anticipated stemmed directly from his originally realist presuppositions.

Ethics, as Moore conceived of the discipline, takes the form of a partly definitional, partly descriptive science, resting on observation and induction. His theory is not, however, naturalistic. The fundamental object of observation for ethics, goodness, is a nonnatural quality or entity, according to Moore, and thus is one that neither exists through parts of time nor presents itself through sensory experience. On the other hand, his theory is not "metaphysical": it does not purport to *define* this fundamental entity or quality of ethics in terms of some *other* nonnatural entity or quality. Indeed, a main point of Moore's theory is that the fundamental entity of ethics cannot be defined at all and that any attempt to define it must commit what he termed "the naturalistic fallacy." This is essentially the fallacy that results from construing the "is" of attribution as an "is" of identity, and thus supposing, for example, that because pleasure is (attributive "is") good, good is identical with pleasure.

The fundamental object of ethics is the simple quality or entity good; being simple, good is unanalyzable and indefinable. One can only say that good = good. This is the outcome of the first and most basic inquiry any science of ethics must engage in, the answer to the question What is good?, where this ambiguous question is understood to ask for a definition.

A second important inquiry that the science of ethics undertakes is to determine what are the preeminent goods obtainable by men. Since the term *good* is here being used substantively (and not adjectively) to refer to complex wholes to which the quality or entity *good* attaches, definitions or analyses of such goods are possible, in the sense that the parts making up the wholes in question can be set forth. On the other hand, because the quality “good” is indefinable, it is not possible to determine which things are and which are not good analytically. This can be determined only by perceiving which wholes possess good, and to what degree or amount. Since they do not rest on any external evidence, such perceptions were termed by Moore “intuitions,” and it is for this reason that his theory of ethics is sometimes called “intuitionistic.” A further character of these perceptions is that when we perceive that a certain whole possesses in itself a certain amount of good, we perceive at the same time that any similar whole must possess in itself an equal amount of good. Thus propositions of the sort “Such-and-such possesses in itself such-and-such amount of good” or “Such-and-such is intrinsically good” express truths that are both synthetic and necessary.

The determination of what things are preeminently good is complicated by two factors. First, substantive goods are organic unities or wholes; that is, the good of a whole is not simply equal to the sum of the goods of its parts. This makes it impossible to determine what things are good and in what amount merely by determining previously the amount of good attaching itself to basic units of experience and adding up these units. Second, it is in fact difficult to separate, in our perceptions or intuitions, organic wholes from their consequences; hence, in assessing goods-in-themselves we are likely to include the good accruing to causal consequences of those wholes. In order to avoid the last sort of error, Moore proposed that we isolate the organic unity we are concerned with by imagining it as alone existing in the universe and then asking whether it is better that it exists or does not.

Applying this method to the question What are the preeminent goods obtainable by men? Moore maintained that “it is obvious that personal affection and aesthetic enjoyments include by far the greatest goods with which we are acquainted.”

The third major inquiry of ethical science encompasses the questions of traditional casuistry: What are our duties? What is their order of precedence? What actions as a rule are right?, and so forth. The answers to all these questions are predicated, in Moore’s system, on the assumption that unlike the term *good*, the terms *right*,

*duty*, *virtue*, and so on are definable. They are all, in fact, definable in terms of good. When we say that a certain sort of action is right or our duty *we mean* that it is productive of the greatest amount of good in comparison with any possible alternative action. Thus, in determining duties and right actions we must not only determine what things are good in themselves but what causal effects actions will have, and this is an almost impossible task, except when conceived in rather short-term measures. As so conceived, Moore generally argued that the rights and duties enjoined and sanctioned in conventional morality are indeed just what the science of ethics shows to be our rights and duties.

### CRITICISM OF MOORE’S PHILOSOPHY PROPER

Moore, in his last writings, confessed that he had not been a good answerer of questions, and if by a “good answerer to a philosophical question” is meant one who leaves the question settled or seemingly close to being settled, it is hard not to agree. In his ethics Moore provided simple, clear-cut answers to the problems and questions of traditional ethics, but their very simplicity (like saying the world is made of water) produces its own disbelief, and this disbelief is borne out by subsequent reflection. For example, if good is a simple objective quality of some sort, why should persons be concerned with maximizing it? In the other branch of inquiry with which he was primarily concerned, theory of perception, Moore failed even to provide clear-cut answers or decisions.

Again, if by “good philosophical answers” are meant answers that can be formed into a consistent system, it must be agreed that Moore is not a good answerer. In his philosophy there are a great many loose ends that he never tied together or attempted to tie together. For instance, he made no attempt to tie together his discussions of the two questions What is the relation of sense data (i.e., patches) to universals? and What is their relation to material things? In the same connection, Moore sometimes admitted that he was inclined to hold at one and the same time two incompatible views (as on the question whether the surfaces of material things are directly seen) and was unable to choose between them.

On the other hand, if a good philosophical answer is conceived as one that is closely reasoned and demands and instills close reasoning on the part of its auditor or reader, then Moore was a good answerer. Studying Moore, it can be fairly said, is like holding one’s mind to a whetstone: A mind composed of good stuff is bound to be sharpened (and one of poor stuff to be dulled).

Further, if philosophy is conceived as an inquiry rather than a closed system, Moore was a good answerer. It is the essence of inquiry that every problem considered be freshly considered, that pat answers be abjured, that truth be placed ahead of remaining consistent or reaching conclusions, and that alternatives be given a hearing and their merits weighed. These are precisely the virtues of Moore's philosophizing.

A more serious objection that can be urged against Moore is that there are a certain number of philosophical prejudices that he adopted without question, but that he ought to have questioned. It is arguable, for instance, that he adopted without question the principle that there is something called an act of consciousness and something called an object of that act. Applied to the various topics of philosophy, this principle produces all sorts of obvious nonsense: a ridiculous proliferation of entities, and so on. Why, it may be asked, did Moore not seriously question this presupposition and remove it? And if he had, might he not have arrived at sound conclusions instead of the perplexity that he does in fact arrive at?

There is unquestionably a good deal of justice in this last objection. Yet, with some justice too, one may retort on Moore's behalf: "What other principle *seems* as certainly true as the above principle? Has some alternative assumption permitted philosophers to arrive at indisputably true conclusions? And if not, why should Moore not explore the resources of this principle, which seems true to him, just as other philosophers explore the resources of the principles they have accepted, which seem equally true to them?"

## Bibliography

### WORKS BY MOORE

Except in ethics, Moore's major published philosophical writings consist almost entirely of articles, papers (to be delivered), reviews, and compilations of articles and lectures. Exceptions would be his autobiography (a minor masterpiece in its genre) and "A Reply to My Critics," included in the collection of critical essays concerning Moore's philosophy titled *The Philosophy of G. E. Moore*. In

this bibliography, the more important or influential articles of Moore's are noted in the compilations in which they occur.

*Principia Ethica*. London: Cambridge University Press, 1903.

*Ethics*. London: Williams and Norgate, 1912.

*Philosophical Studies*. London: Routledge, 1922. Collection of papers, including "The Refutation of Idealism" (1903), "The Status of Sense-Data" (1914), "The Conception of Reality" (1917), "Some Judgements of Perception" (1918), and "External and Internal Relations" (1919). It is in the last paper that the term *entailment* is first used and defined philosophically.

*The Philosophy of G. E. Moore*. Edited by P. A. Schilpp. Evanston, IL: Northwestern University Press, 1942; 2nd ed., New York, 1952. Contains "An Autobiography" and "A Reply to My Critics." In the second edition is the "Addendum to My 'Reply.'"

*Some Main Problems of Philosophy*. London: Allen and Unwin, 1953. Contains Moore's lectures of 1910 and 1911.

*Philosophical Papers*. London: Allen and Unwin, 1959. With an obituary notice by C. D. Broad. Includes "A Defense of Common Sense" (1923), "Is Existence a Predicate?" (1936), and "Proof of an External World" (1939).

*The Commonplace Book, 1919–1953*. Edited by Casimir Lewy. New York: Macmillan, 1962.

### WORKS ON MOORE

Bridge, Ursula, ed. *W. B. Yeats and T. Sturge Moore, Their Correspondence, 1901–1937*. London, 1953. In this correspondence the two well-known poets (one of them Moore's brother) refer at some length to Moore's philosophy and some of Moore's comments on their interpretations of his philosophy. Although of little philosophical interest, their references provide an amusing picture of nonphilosophers trying desperately to understand Moore. Typical is Yeats's remark "I find your brother extraordinarily obscure."

Keynes, John Maynard. *Two Memoirs*. London: Hart-Davis, 1949. In the second memoir, "My Early Beliefs" (pp. 78–103), Keynes describes the members and discussions of the "Bloomsbury Club," c. 1903–1914. This is a fascinating, witty, and informative account of the tremendous influence Moore's *Principia Ethica* had on some of the finer and younger intellectuals of the early twentieth century in England; of their attempts, largely verbal, to put Moore's ethical theories into some sort of practice; and of Moore's role in the group, his method of verbal argument, and the "pure and passionate intensity" of his realistic "vision."

Malcolm, Norman. *Knowledge and Certainty*. Englewood Cliffs, NJ: Prentice Hall, 1963. "George Edward Moore," pp. 163ff. In the first part of this important essay Malcolm presents a penetrating and intimate description of Moore's character as a man and as a philosopher, based in large part on personal recollections and impressions. In the remaining parts he discusses the relationship of certain of Moore's "common-sense propositions" to the concept of common sense, to traditional philosophy, and to Wittgenstein's views on the proper role of philosophy with respect to ordinary language. Included is a philosophic evaluation of Moore's purported defense of common sense. This essay is notable not only for the light it sheds on some central aspects of Moore's philosophizing but for the original philosophizing that it

contains on the topics of ordinary language, the concept of common sense, and traditional skepticism concerning perception.

Passmore, John. "Moore and Russell." In *A Hundred Years of Philosophy*. London: Duckworth, 1957. Passmore presents a very searching account of Moore's earlier philosophy (especially as set forth in the 1899 essay "The Nature of Judgment") and his later views on the "analysis of meaning." Passmore also discusses, in an interesting and illuminating way, Moore's theory of sense data and his essays "The Refutation of Idealism" and "Proof of an External World."

Schilpp, P. A., ed. *The Philosophy of G. E. Moore* (see above). Contains critical essays on Moore's ethics by C. D. Broad, Charles L. Stevenson, William K. Frankena, H. J. Paton, Abraham Edel, and A. Campbell Garnett; on his theory of perception by O. K. Bouwsma, C. J. Ducasse, Paul Marhenke, and C. A. Mace; on what might broadly be called his method by Arthur E. Murphy, C. H. Langford, Norman Malcolm, Morris Lazerowitz, Alice Ambrose, John Wisdom, Richard McKeon, and V. J. McGill; and on his influence by L. Susan Stebbing. A number of the essays referred to, such as Bouwsma's "Moore's Theory of Sense-Data," are in their own right important contributions to the topics under discussion. But even when not intrinsically important, these essays constitute a particularly valuable commentary on Moore's philosophy in that Moore, in his "Reply," entered into several detailed discussions of their contents in an attempt to clarify his views. See especially his replies to the essays by Broad, Stevenson, Frankena, Bouwsma, Ducasse, and Langford.

Urmson, J. O. *Philosophical Analysis, Its Development between the Two World Wars*. Oxford: Clarendon Press, 1956. A penetrating work on the "analytic movement" that helps one place Moore in his later philosophical setting. Although only fragmentary references are made to Moore's philosophy, many of the points of view and many of the topics that Moore was concerned with and that influenced his own philosophizing (from 1910 on) are brought into the open and clarified.

Warnock, G. J. "G. E. Moore." In *English Philosophy since 1900*. London, 1958. This thin commentary propagates the thesis that Moore's philosophy can best be understood and appreciated through an understanding and appreciation of his temperament and character. The claim is made that Moore was a "man with no metaphysical quirks of temperament."

White, A. R. *G. E. Moore, a Critical Exposition*. Oxford, 1958. This work—the only English work of book length devoted exclusively to commentary on the philosophy of Moore—collects and collates most of the things Moore had to say on method, theory of ethics, and theory of perception.

*John O. Nelson (1967)*

## MOORE, GEORGE EDWARD [ADDENDUM]

G. E. Moore's ethical writings, especially *Principia Ethica* of 1903, have long been regarded as philosophically revo-

lutionary. In fact, Moore shared his main ethical views—nonnaturalism in metaethics and ideal consequentialism in normative ethics—with such late-nineteenth-century writers as Henry Sidgwick and Hastings Rashdall. But Moore defended these views with unusual vigor and so had a disproportionate influence on later moral philosophy.

Moore's nonnaturalism comprised two main theses. One was the realist thesis that moral judgments are objectively true or false; the other was the autonomy-of-ethics thesis that moral judgments are *sui generis*, neither reducible to nor derivable from nonmoral judgments such as scientific or metaphysical ones. Our knowledge of them must therefore derive from intuitive judgments of self-evidence.

Moore did not argue extensively for realism. Like others of his era, he took it largely for granted. But his argument for the autonomy of ethics has come to be known as the "open-question argument." If goodness were identical to pleasure, the claim that pleasure is good would be equivalent to the empty statement that pleasure is pleasure, which it plainly is not. Rather, whether pleasure is good is always an open question. Since this argument generalizes to all nonmoral properties, goodness cannot be identical to any such property. Some later philosophers challenged this argument against the "naturalistic fallacy"; others took it to support antirealist conclusions quite different from Moore's. But it remains a central argument for the irreducibility of moral claims.

Though these main theses were familiar, Moore did introduce two innovations. One was his view that the central irreducible moral property is *good* rather than *ought* or *right*; the other was that the intrinsic goodness can depend only on its intrinsic properties, apart from any relations to other states. It follows that to judge whether a given state is good, we must imagine a world containing only that state and ask whether such a world is good.

Moore's ideal consequentialism likewise comprised two theses. One was that right acts always produce the most good. The other was that there is a plurality of goods, all ideal in the sense that their being good does not depend on people's attitudes to them. (Moore thought that the naturalistic fallacy led philosophers to identify goodness with some one natural property and so to miss this plurality.) In *Principia Ethica* he held that one intrinsic good is beauty apart from any consciousness of it; another is vicious people's deserved pain. But the chief goods in this work were the admiring contemplation of beauty and personal love, which for Moore involved the

admiring contemplation of others' good qualities. In characterizing both goods, he used his "principle of organic unities," according to which the value of a whole need not equal the sum of the values of its parts. Beauty on its own has little value, and the contemplation of merely imagined beauty just moderate value, but the contemplation of real beauty has great value, more than the sum of the values of those components.

*Principia Ethica* was written with a self-confidence bordering on arrogance. Moore thought most previous moral philosophers had made crude conceptual errors, and that once those were exposed, the moral truth would be self-evident to all. This tone helped make his presentation of nonnaturalism the canonical one. As a result, twentieth-century metaethics can be seen as a sequence of reactions to his views. His substantive views about the good received less attention, but at the beginning of the twenty-first century, interest has revived in his claims about, for example, appropriate attitudes and organic unities. His moral philosophy is again alive as a whole.

## MORAL ARGUMENTS FOR THE EXISTENCE OF GOD

From the time of Immanuel Kant to the present day, a great many attempts have been made to base arguments for God's existence not upon the mere fact that there is a world, nor on the general orderliness it manifests, but on a very special feature of that world—human moral experience. The popularity of moral arguments is not hard to understand. David Hume and Kant had produced powerful and apparently disabling criticisms of the traditional arguments of natural theology, criticisms that seemed decisive against any conceivable type of argument to God as the explanation of the world. Hume had no alternative theistic argument to offer and, insofar as theoretical reasoning is concerned, Kant had none either. The structure of Kant's ethical philosophy, however, accorded to "practical reason" privileges not shared by theoretical reason. If God was to retain any place in the Kantian system, the weight of apologetic had to be shifted from the theoretical to the practical, to exploring the implications of our moral situation. Between Kant's day and the middle of the twentieth century, skepticism about the theoretical arguments tended to deepen rather than to lighten; hence, there has been no lack of religious apologists following Kant's new "moral route" to God.

Another reason for the popularity of moral argument is religious rather than philosophical. Even if the argument to God as First Cause or "necessary being" were valid, these notions of deity can be more of an embarrassment than a help to the religious imagination. They present us with a divine object or superobject, whereas religion demands that God be primarily known as *person*. A moral argument offers hope of overcoming that external and thinglike character: It ensures that concepts of God will be, from the outset, personal concepts.

### TYPICAL MORAL ARGUMENTS

Among the many varieties of moral argument, the following are both historically important and recurrent patterns. Several of them may be found in a single author.

First, if one understands moral rules as "commands," one may argue to the existence of a "commander." The commander cannot be the individual human moral agent, for what today I command myself to do, I can tomorrow command myself not to do. I can have absolute moral obligations only if a God exists to command them. Because I do have absolute moral obligations, it follows that God exists.

Second, a minor variant of this moral argument claims that if we recognize moral authority, we must *ipso facto* recognize the existence of God as alone able to confer that authority. We judge that the moral law retains its authoritativeness whether particular human wills are at any time actually accepting its rules and principles or not; therefore, the source of its authority must lie altogether outside those human wills.

Third, the notion of “moral law” itself is said to be incomplete without reference to God, for law implies “lawgiver,” a divine legislator. Our very acknowledgment of a moral law, therefore, presupposes theism.

Fourth, it has been claimed that there is a remarkable degree of agreement among the moral judgments made by men in widely different cultures and historical periods. Many apparent disagreements can be attributed to differences in belief and thus held to be not fundamental. This impressive measure of agreement, it is argued, can be accounted for only on the supposition that God has written his law in the hearts of men.

Certain of the most interesting and influential moral arguments take as their premise some part of the content of the moral law itself. We are under moral obligation to perfect ourselves and to attain a “highest good” (*summum bonum*) that is manifestly unattainable in a life lived under the conditions we know here and now. We can, at best, make a start to a moral development that requires very different conditions for its completion. But since that complete development is demanded of us as duty, it must be attainable. God and immortality are thus presupposed in our actual moral experience.

## ANALYSIS OF MORAL ARGUMENTS

Let us briefly consider each of the varieties of moral arguments again and attempt to estimate their strengths and weaknesses.

Of the moral commander argument we can pertinently ask: Is the notion of command basic to ethics? Certainly not in the sense of parade-ground commands, commands passively received and acted upon unreflectively. Such obedience is a long way from moral deliberation and judgment. An immature moral agent may see his duties as commands (parental, for example); but the mark of mature moral judgment is self-commitment to a policy on which one has deliberated. This policy may or may not be in harmony with someone’s command; in any case, it does not owe its authenticity to its being commanded. “Here I stand,” one may say; and this can express

a settled resolution, one not to be made one day and rescinded the next.

Even if it were established that a celestial being unvaryingly commanded a certain policy as obligatory in an absolute sense, the unvaryingness of his command could not itself furnish the ground for the absoluteness of the obligation. For it is at least logically possible that this celestial being ought not to command unvaryingly what he does so command. If he commands what is right and obligatory, that is cause for thankfulness; but one could scarcely be thankful over a truth of logic. “Unvaryingly” must not equal “stubbornly” or “with chronic moral blindness”; these are unthinkable possibilities for Christian theism. But this does not affect the point being made: that absoluteness is not analyzable in terms of unvaryingness of command. Moreover, the Christian wishes to make one all-important moral judgment that could not possibly have its absoluteness reduced to commandedness by God—the judgment, namely, that God is morally perfect. But if a human being can make this moral judgment uncommanded, why can he not make others also?

Analogous criticisms can be made of the argument from the authority or authoritativeness of the moral law to the need for a divine source of authority. To put the main objection boldly: It is of the very nature of a fundamental moral judgment that it should be made on no authority but that of the agent who makes it. Certainly there are occasions when I may believe that another person has a superior measure of insight into the situation in which I have to act; I may then properly accept his judgment in lieu of my own. Yet if this is not to be a culpable moral abdication, I must have good grounds for trusting my temporary “authority”: I must judge him to be morally reliable. But this is itself a moral judgment—one that I can make on nobody’s authority but my own; or if on someone’s authority, then this new person must be judged reliable on my own authority, and so on. A legitimate appeal to authority presupposes that autonomous moral judgments have already been made. Our argument held that we must postulate God as the authorizer of all our moral judgments—otherwise they would carry no authority; but we find, contrariwise, that God can play the role of authority only if we are able to make certain moral judgments without appealing to any external authority whatsoever.

The third version alleged that the notion of “moral law” is incomplete unless God is postulated as lawgiver. *Law*, however, is a word with many strands to its meaning; and it is only by failing to distinguish certain of the

strands that this can appear to be a plausible line of argument. It is perfectly intelligible to say that some person or group of persons has laid down positive laws, rules for a community, backed by penal sanctions. The existence of a developed body of such laws normally implies the existence of lawmakers or codifiers. It is quite another thing (and not really intelligible) to speak of anyone, human or divine, “laying down” the moral law itself. Laws, rules, and regulations are of the right logical type to be laid down in accordance with, or in conflict with, the moral law. But the moral law itself is not the sort of thing that needs to be, or that logically can be, laid down or promulgated by anyone. No conceivable story about men or gods could be taken, without absurdity, to describe the inauguration (or the annulling) of the moral law. Commands might be uttered, inscriptions miraculously appear; but it would never become a trivial or tautological question to ask of their content, “Is this in fact morally binding?” The distinctively moral authority of a rule or law does not lie in the prestige or power of its initiator, nor in the circumstances of its first recognition.

The argument from the convergence of moral codes is most often set forth in an objectivist ethical context. The existence of objective moral qualities “seen” to be there, or “intuited,” by different moral agents in widely different places and times remains inexplicable unless we posit a God who creates and morally guides. It is less often noticed that the argument is perhaps stronger—certainly no weaker—if it is set forth in a subjectivist context instead. This was apparently noted by F. R. Tennant, who (in a conversation reported by R. B. Braithwaite) argued on the following lines. Failing the existence of any objective moral properties or moral relations, it is all the more remarkable that there should be such a measure of congruity among moral judgments or decisions: sufficiently remarkable to point the way, again, to divine activity. Yet this argument is not at all conclusive. The supernatural hypothesis that it puts forward is not the only hypothesis available to account for the data; and it has the disadvantage that it is not empirically confirmable or refutable. Powerful competitors would be arguments from the relative stability of basic human needs, desires, and aversions or from the pervasiveness of aggressive and social drives in the personality. These alone might well account for the actual agreements among moral judgments and would account for them without invoking the immensely problematic notion of divine causality.

## PRESUPPOSITION OF THE HIGHEST GOOD

Our last group of arguments began its history in modern philosophy with a statement of Kant: “The idea of the highest good ... cannot be realized by man himself ... ; yet he discovers within himself the duty to work for this end. Hence he finds himself impelled to believe in the cooperation or management of a moral Ruler of the world, by means of which alone this goal can be reached (*Religion within the Limits of Reason Alone*).

Kant was not betraying the austerity or rigor of his moral philosophy; he was not offering religious inducements to moral behavior. He would have denied distinctively moral worth to someone whose “dutiful” actions were aimed at securing his own postmortem happiness. The emphasis in his argument is wholly on the intelligibility and rationality of the moral demand; it was inconceivable to him that the categorical imperative should be a mocking voice, laying obligations upon us and at the same time denying the environment in which alone the obligations could be fulfilled. (It has been claimed that Kant had abandoned these moral arguments by the time he wrote the *Opus Postumum*, but the contrary view has been argued more forcibly; see G. A. Schrader, “Kant’s Presumed Repudiation ...”)

The strength of Kant’s moral argument is clearly dependent on the strength of his ethical theory as a whole. It is only because he saw moral judgment as the work of practical reason (not as a matter of emotive reactions or responses) that he was able to make plausible use of those judgments as a basis for theological demands. Any fundamental criticism of the Kantian ethic would ipso facto imperil the theology.

The argument is equally imperiled if we deny that we are under obligation to attain the highest good and our individual moral perfection, saying that we are obliged only to strive toward these unrealizable ends. We might indeed reverse Kant’s argument as follows. From our observation of the world we conclude that the highest good and our moral perfection are unattainable; therefore, we can have no obligation to attain these but, at best, only an obligation to strive toward them. We can interpret them in Kant’s own term, *regulatively*, as Kant himself sometimes did. (See John R. Silber, “Kant’s Conception of the Highest Good ...”)

The postulating of God and immortality is aimed at solving an antinomy—of making intelligible what, without the postulate, is inexplicable. But does the postulation of God in fact produce intelligibility, a lifting of mystery?

Or is there not so much mystery in the postulate itself that the final effect is a deepening, not a lightening, of perplexity? If independence, autonomy, and freedom are essential to a moral agent, that autonomy will presumably remain essential in a hereafter as well as in the here and now. But, if so, the postulation of God and immortality can by no means ensure that the ultimate moral goals will, in fact, be reached, even though it was precisely to ensure their attainment that the postulates were made.

Kant's theory of time as a "form of sensibility" makes it very dubious whether he could have spoken meaningfully of a continuing moral development and the attainment of the highest good in a hereafter. Granted that he disclaimed all theoretical insight into what such an existence would be like (this measure of agnosticism is part of the force of *postulate* as distinct from *demonstrate*), the notion of time still remains essential to Kant's moral argument. If we are unable to give meaning to it in that context, the argument cannot but suffer.

It is possible to reject some portions of Kant's detailed argumentation and yet to advance a moral argument of a definitely Kantian type. This was notably done in W. R. Sorley's *Moral Values and the Idea of God* and in A. E. Taylor's *The Faith of a Moralist*. Neither of these writers held the moral argument to be the sole and all-sufficient theistic proof, but they did believe that without it the case for theism is weak and dubious.

Sorley attempted first to show that "the moral order is an objectively valid order, that moral values belong to the nature of reality," and that "the history of the world-process is fitted to realise this order." If we were to assume that the goal of the world-process is the realizing of happiness, there would be the weightiest empirical evidence against us. With moral worth and goodness it is different. Conditions that work against happiness may work for, not against, the developing, trying, and testing of moral fiber. "The very imperfection of the world [is] an argument pointing to the theistic conclusion." There remains yet a gap between the claim that the universe works toward a moral purpose and the full claim that God exists: Sorley seeks to fill this gap by arguing that belief in God is presupposed by belief in an objective and "eternally valid" morality. If the moral law is eternally valid, and valid whether we recognize it or not, "how could this eternal validity stand alone, not embodied in matter and neither seen nor realized by finite minds, unless there were an eternal mind whose thought and will were therein expressed?"

One can readily agree that the world as we experience it is better adapted to be a vale of soul-making than a

hedonistic holiday camp. Yet there are difficulties about even the soul-making view. Some human suffering (the unmerited suffering of young children, for instance) cannot always be treated plausibly as developing moral fiber, or as realizing any other moral value. The natural environment can figure as the destroyer of moral personality as well as its preserver and nourisher. Sorley's further argument, from the validity of the law to an eternal mind, surely contains a confusion of the logical and the psychological. Questions about validity and about truth are logically independent of questions about the propositions that are actually entertained in someone's mind. Whether or not there exists a person who says (or thinks) *p*, has no bearing on the truth of *p* or, if *p* is a moral principle, upon its bindingness or validity in the relevant sense.

A. E. Taylor saw the moral life not as a mere conforming to given static principles and rules but as directing the moral agent along certain paths of self-development. There is development within the moral ideal: "We discover tomorrow that today's ideal 'had more in it' than we had supposed." The goal transforms itself as we approach it. The further we pursue it, the less able we become to conceive the human good in purely this-world, secular terms. There is development also within our awareness of time. Purposeful, valuable activity produces an extension of our "conscious present"; it delivers us from the dullness of "one thing after another." The limiting case in this development would be well expressed by Boethius's account of eternity—"the complete and simultaneous fruition of a life without bounds."

"We may argue," Taylor then claimed, "from the existence of a function to the reality of an environment in which the function can find adequate exercise." But no view of the world, short of theism, can guarantee the completion of these directions of development that Taylor has described.

Whatever is decided about the validity of the argument as an argument, Taylor's *The Faith of a Moralist* is a lastingly impressive and eloquent account of a religiously oriented morality. On validity, however, some searching criticisms were made by C. D. Broad in his review of Taylor's work published in *Mind* (1931). Taylor had taken as his premises certain moral judgments and certain trends of development in our experience of value. He then had asked what these entailed; whatever they entailed was to be added to our true beliefs about the universe. Broad argued that, in order to avoid a vicious circle, we must be sure that our premises do not already covertly assume the theistic conclusion. We must know that we have these duties and aspirations without already presupposing God

and immortality. Only in this way could the existence of God and immortality be the conclusion of our argument. It is hard to be sure that these value judgments and aspirations are not the *consequence* of a prior theism. And a further point must be added: Only such a previously held theism, or cryptotheism, could entitle us to argue, with Taylor, “from the existence of a function to the reality of an environment in which [it has] adequate exercise.” (Or, if this is true by definition of *function*, only such a theism can justify calling those value pursuits “functions.”) Once again it might be added that the directions of moral development, although unrealizable in toto, could still be taken as targets for ever-nearer approximation. That they can be taken in this way, however, tells against Taylor’s argument, for he wished to deny that we can be morally serious about these unless complete realization is possible.

Moral theories dominant in the mid-twentieth century did not tend to lead naturally into moral arguments for God. In Britain and the United States, at any rate, they were characteristically this-worldly. But exceptions do occur. Austin Farrer offered, if not a moral argument, then certainly a moral “persuasion” toward theism in the first chapter of *Faith and Logic*, “A Starting-Point for the Philosophical Examination of Theological Belief.” His argument is that we are incontestably under an obligation to love our neighbor—that is, to hold him in highest regard; and that this is not impossible if our neighbor is a lovable person. If our neighbor occasionally lapses from lovability and from goodness, we may still manage to love his “normal” self, although it is temporarily obscured. If, however, he lapses chronically and grossly, how are we to love him? To love what he might be is now to love a fiction only; but it is persons, not fictions, that we ought to love. Farrer claimed Christianity provides a uniquely helpful way in which we can see the unlovable neighbor, admit his deficiencies, and yet succeed in loving him. In praying for and about our neighbor, we bring our view of him into relation with God’s action—his action in creating our neighbor and his constant and costly redemptive action on our neighbor’s behalf. Farrer insisted that, if these reflections help to give plausibility and impressiveness to the Christian view itself, they are not to be taken as a refurbishing of strong Kantian claims to establish God’s existence.

Farrer appears to have assessed the capacity of this type of argument far more realistically than those who used it before him. If we judge that certain attitudes or evaluations are supremely worth realizing—for example, that “people ought to be held in the utmost regard”—then it is reasonable, even mandatory, to take up whatever

stance will best further our task of realizing them. In our present example, we are required to meditate upon those reflections that uniquely put our neighbor in a regard-furthering light. Of course, provisos must be added. There must, for instance, be no logical incoherence in the description of the stance or of the context that furthers our neighborly love; otherwise, what we called the light or the stance might be in fact only a fugitive, quasi-aesthetic movement of feeling. To provide a point of entry to traditional Christianity, the stance must be capable of being expressed in a set of meaningful affirmations about reality. Another obvious proviso is that our premises must be sound. We must in fact be under obligation to hold our neighbor in highest regard, and all non-Christian ways of seeing our neighbor must be less helpful than the Christian way. It is particularly upon the second of these premises that, in a fuller discussion, argument necessarily would concentrate.

### Bibliography

The chief sources for moral arguments to God are the following works of Kant: *Kritik der praktischen Vernunft* (Riga: J. F. Hartknoch, 1788), translated by T. K. Abbott (London and Dublin, 1879) and by L. W. Beck (Chicago, 1949), and *Die Religion innerhalb der Grenzen der blossen Vernunft* (Königsberg: Bey Friedrich Nicolovius, 1794), translated by T. M. Greene and H. H. Hudson as *Religion within the Limits of Reason Alone*, 2nd ed. (New York: Harper, 1960).

Post-Kantian works in which moral arguments to God play an important part are Austin Farrer, “A Starting-Point for the Philosophical Examination of Theological Belief,” in *Faith and Logic* edited by B. G. Mitchell (New York, 1957); John Henry Newman, *A Grammar of Assent* (London, 1901), especially pp. 109–110; Hastings Rashdall, *The Theory of Good and Evil*, 2 vols. (Oxford: Clarendon, 1907), and *God and Man* (Oxford, 1930); W. R. Sorley, *Moral Values and the Idea of God* (Cambridge, U.K.: Cambridge University Press, 1918); and A. E. Taylor, *The Faith of a Moralist* (London: Macmillan, 1930), reviewed by C. D. Broad in *Mind* 40 (1931): 364–375.

Among contemporary studies of the Kantian argument are the following: H. P. Owen, *The Moral Argument for Christian Theism* (London: Allen and Unwin, 1965); G. A. Schrader, “Kant’s Presumed Repudiation of the ‘Moral Argument’ in the Opus Postumum,” in *Philosophy* 26 (1951): 228–241; John R. Silber, “Kant’s Conception of the Highest Good as Immanent and Transcendent,” in *Philosophical Review* 68 (1959): 469ff.; and W. H. Walsh, “Kant’s Moral Theology,” in *Proceedings of the British Academy* 49 (1963): 263–289.

## MORAL ARGUMENTS FOR THE EXISTENCE OF GOD [ADDENDUM]

The moral argument purports to show that evidence from our moral experience supports the existence of God. From the 1970s onward, various forms of the moral argument have been developed by many philosophers. While defenders argue with increased sophistication, they also tend to make more modest claims about the force of the moral argument.

### MORAL ARGUMENTS AS ABDUCTIVE AND CUMULATIVE ARGUMENTS

If the moral argument is construed as a deductive argument that moves from, say, the objectivity of moral values to the existence of God, then to rebut the argument, the critic needs to show only that the objectivity of moral values and the nonexistence of God are logically compatible. This is a relatively easy task. However, developments in epistemology and philosophy of science since the 1960s lead many to think that it is more realistic to look, in most areas of inquiry, for an abductive argument, an inference to the best explanation. We can formulate the moral argument too as an abductive argument, that is, argue that among diverse worldviews, the theistic worldview is the best explanation of, say, the objectivity of morals, especially in contrast with naturalism.

Since abductive arguments are by nature cumulative arguments, the force of an abductive moral argument will depend not on any single feature of morality, but rather on how well it can explain the whole gamut of moral experience, both its form and its content. For example, Louis Pojman argues, “Given the assumption of standard contemporary secular moral philosophy: I. The notion of *moral obligation* becomes seriously problematic; II. The notion of the *supremacy of morality* either becomes problematically analytic or it vanishes; III. The problem of morality and self-interest becomes insoluble; IV. The idea that human beings have intrinsic value ceases to make sense.” Hence, “most contemporary secular ethical systems offer no hope of guiding human conduct, and should be abandoned” (1992b, p. 4).

In contrast, ethical systems that proceed from transcendent assumptions can offer resources unavailable to secular ethical systems. For example, the Christian tradition can appeal to a perfectly good, omnipotent God who created humanity in his image. Each person is endowed with a specific *telos*, which the individual must seek to

realize. Within this framework, all humans have equal intrinsic worth, free will, and eternal destiny (see also Pojman 1991, 1992a). Morality consists of obeying God’s commands, which promote human flourishing and are backed by rewards and punishments. All these provide a solid foundation for the existence of moral obligation and responsibility.

### ARE MORAL TRUTHS ANALYTIC?

Not all theistic philosophers accept the moral argument. For example, Richard Swinburne (1974) believes that fundamental moral truths are necessary truths and do not need to be explained. Defenders have several ways to respond. First, they may flatly deny Swinburne’s claim by pointing out that moral nihilism and moral relativism at least appear to be logically coherent positions. Second, even if many moral principles are necessary truths, it does not follow that they cannot be explained by more basic necessary truths about God’s essential moral nature and logically necessary existence. Charles Taliaferro even suggests a cosmological-ethical argument that utilizes “the resources of a theistic metaphysics in providing a singular, comprehensive explanatory account of moral truths as well as other essential truths,” in addition to explaining the existence of the cosmos. In this way, theism may exhibit “a marked simplicity and force missing from its competitors” (1996, p. 290).

Third, the realm of necessary moral truths appears to be mysterious and odd from a naturalistic perspective. It is puzzling why we should be aware of these truths and why moral consciousness features so prominently in human existence. Necessary moral truths by themselves do not have any power to endow agents with morality, and a naturalistic universe cannot have any causal interaction with these abstract truths. Why, then, should we suppose that a morally blind world would endow us with correct moral intuitions? The case is different with sense experience, whose reliability is to some extent tied with our survival. It is not without reason that most naturalists prefer moral skepticism. As John Mackie admits, “There can be a secular morality, not indeed as a system of objective values or prescriptions, but rather as something to be made [that is, invented]” (1977, p. 227; see also Harman 1984).

### THE ODDITY OF MORAL OBLIGATION

For Mackie, another reason why morality is so odd is that moral claims are authoritative and objectively prescriptive: “Any wrong (possible) course of action would have not-to-be-doneness somehow built into it” (1977, p. 40).

George Mavrodes (1986) points out that naturalistic evolution may well produce creatures with moral sentiments conducive to survival. However, the existence of *actual* moral obligations appears to be strange, especially because moral obligations often come into conflict with self-interest.

Some atheists (David Gauthier [1986], Gregory S. Kavka [1984]) try to reconcile moral obligations with self-interest, and claim that in the long run it is in the best interests of everyone for every individual to act morally. The viability of this kind of contractual project depends on whether it can satisfactorily answer questions like these: Should one still be moral when in fact not everyone else will act morally? What about the moral free-rider? Do extremely powerful people really need to act morally? Why should we sacrifice our own interests for the benefits of people who cannot reciprocate, such as future generations, extremely marginalized people in one's own society, and people in distant countries? Is it rational to sacrifice one's life for the sake of morality?

### THE MORAL GAP

A broadly Kantian moral argument continues to find defenders. Ronald Green (1978) starts from the question "Why should I be moral?" John Hare (1996) focuses on the gap between the demand that one act morally and our capacities to meet this demand, according to most moral theories. Since "ought" implies "can," the description of the moral life in this moral gap is incoherent. To resolve this incoherence, secular moralists either exaggerate our moral capacity, reduce the moral demand, or try to find some substitute for God to help bridge the gap. Hare criticizes many of these options and argues that the Christian doctrines of atonement and incorporation in Christ can solve the problem. Debates surround whether Hare's criticisms of the secular options are cogent and whether the Christian faith can really offer something that other options cannot (see Zagzebski 1999).

### THE EUTHYPHRO DILEMMA

Atheistic philosophers such as Kai Nielsen (1990) and Michael Martin (2002) have produced sustained replies to the moral argument. They think that the *Euthyphro* dilemma (are morally good acts commanded by God because they are morally good, or are they morally good because they are commanded by God?) shows that morality has to be independent of God. If morality depends on God's command, then morality will be arbitrary, because God might command cruelty for its own

sake. If one denies this possibility, one already commits to an independent standard of the good apart from God.

Some theists reply by saying that God's essential nature, from which the divine will flows, provides the ultimate standard of goodness, and this is neither independent of God nor arbitrary. Robert M. Adams has proposed a modified divine-command ethics that, as a postulate, equates being contrary to the commands of a *loving* God with the *essence* of being wrong (Adams 1987). This is not an analysis of the *meaning* of "right" and "wrong," because Adams grants that our moral practice gives us some basic understanding of morality apart from religion. However, it does not follow, he thinks, that, on the basis of this basic understanding, we can understand the *essence* of being wrong. (Someone who understands the meaning of "water," can further discover that the nature, or essence, of water is H<sub>2</sub>O.) On Adams's view, the answer to the *Euthyphro* dilemma is that a *loving* God would not command cruelty for its own sake.

### A CRITICAL DIALOGUE BETWEEN ETHICAL SYSTEMS

The success of the moral argument in the long run depends on the relative merits of the theistic and atheistic accounts of morality. (We should also include, say, Confucian ethics and Buddhist ethics among the contenders.) Adams (1999) has developed his theistic ethics into a comprehensive theory of the good and the right. Michael Moore (1996) and Michael Martin (2002) have used naturalistic moral realism (Brink 1989) to show that naturalistic ethics is superior and that theistic ethics is superfluous (see also Copan 2003, 2004). The moral argument does not appear to be conclusive. Its significance mainly lies in its contribution to a cumulative case for God's existence and its capacity to stimulate a lively debate on the implications of different worldviews on morality.

## MORAL DILEMMAS

The label *moral dilemma* is commonly applied to any difficult moral problem. Several introductory anthologies in ethics have been titled *Moral Dilemmas*, suggesting that all of the issues discussed therein are moral dilemmas, regardless of their structure, simply because they raise

hard moral questions. Many people even talk about moral dilemmas when it is not clear whether or not morality is relevant at all.

Moral philosophers, in contrast, usually have in mind something more specific. Minimally, they count a situation as a moral dilemma only if one moral reason conflicts with another (moral or nonmoral) reason. Reasons conflict in a situation if the agent is not able in that situation to comply with all of the reasons. For example, if it is in Ann's interest to lie to a potential employer, then Ann's prudential reason to lie conflicts with Ann's moral reason not to lie. Similarly, moral reasons can conflict with religious reasons (as on one interpretation of the biblical story of Abraham being commanded by God to sacrifice his son, Isaac) or with aesthetic reasons (as on one understanding of Gauguin's decision to leave his family to pursue his art).

Moral philosophers normally restrict the class of moral dilemmas further to include only conflicts between one moral reason and another reason that is also moral in nature. In Plato's example, if Brad holds a weapon for a friend and promises to return it when that friend asks for it, then Brad has a moral reason to return it when the friend asks. But if Brad knows that this friend is going to use the weapon to commit a harmful crime, then Brad has a moral reason not to return the weapon to the friend (at least at that time).

Many philosophers would not classify this conflict as a moral dilemma because it is resolvable—the moral reasons against returning the weapon override the moral reasons in favor of returning the weapon, so overall Brad morally ought not to return the weapon, assuming that the harmful crime is serious enough. In contrast, even if moral dilemmas must be unresolvable, Carol is in a moral dilemma on this account if Carol has a moral reason to help the needy but can help only one of two equally needy people.

Some philosophers limit moral dilemmas even further to include only conflicts among certain kinds of moral reasons. A moral reason is a moral requirement just in case it would be morally wrong not to act on it without an adequate justification or excuse. Carol's moral reason to help a particular needy person, for example, is not a moral requirement if it would not be morally wrong for Carol to refuse to help this needy person (as long as Carol helps enough other needy people at other times). Then, if moral dilemmas are limited to unresolvable conflicts between moral requirements, Carol is not in a moral dilemma when she can help only one of two equally needy people. In contrast, if David can keep only one of

two conflicting promises, assuming that David has a moral requirement to keep his promises, then David is in a moral dilemma, even if moral dilemmas are defined as unresolvable conflicts of moral requirements.

Other moral theorists define moral dilemmas in different terms, for instance, as situations where every alternative is morally wrong. The term *wrong*, however, is unclear in this context. If an act is called morally wrong when, and only when, it violates a non-overridden moral requirement, then this definition reduces to the previous one. In contrast, if an act is called morally wrong only when it violates an overriding moral requirement, then this definition makes moral dilemmas obviously impossible. That obviousness suggests that philosophers who claim that moral dilemmas are possible do not use this strong definition of moral dilemmas. Instead, they seem to identify moral dilemmas with unresolvable moral requirement conflicts.

To show that a situation fits that definition, it is not enough to cite nonmoral facts, such as that the agent cannot do both acts or even that each act is necessary to fulfill a promise. The situation is not a moral dilemma unless there are moral requirements for conflicting alternatives and neither moral requirement overrides the other. In support of the claim that there is a real moral requirement on each side, philosophers who see the situation as a moral dilemma cite the counterfactual that it would be morally wrong not to choose a particular alternative if there were no moral reason to choose the conflicting alternative. They also often argue that moral requirements on each side provide the best explanation of why remorse (or guilt, but not just regret), an apology, compensation, or some other moral residue is appropriate after either choice.

In support of the claim that neither moral requirement overrides the other, philosophers who assert the possibility of moral dilemmas can argue that some situations are so symmetrical that neither moral requirement could override the other. A common symmetrical example is Sophie's choice between her two children when a Nazi guard threatens to kill her and both of her children if she does not pick one child to be killed. In nonsymmetrical cases, some philosophers also argue that conflicting moral requirements can be incomparable, in which case neither moral requirement overrides the other (although they are also not exactly equal).

Opponents who deny the possibility of (even resolvable) conflicts between moral requirements sometimes object that if one conflicting moral requirement overrides the other, then the other is no longer a moral require-

ment. This objection conflates overriding with cancellation. Like physical forces, moral requirements that are overridden by stronger moral requirements can still retain some moral force, as shown by their ability to justify remorse, apologies, compensation, and other forms of moral residue.

Another common objection to the possibility of moral dilemmas charges that, if neither moral requirement overrides the other, then the agent is morally permitted to choose either alternative and, hence, is not in a moral dilemma. However, if an act is not morally permitted only when it violates an overriding moral requirement, then the claim that both acts are morally permitted is compatible with the situation being a conflict between non-overridden moral requirements and, hence, a moral dilemma on the above definition. In contrast, if an act is not morally permitted when it violates a non-overridden moral requirement, then neither act is morally permitted in an irresolvable moral requirement conflict. Either way, the notion of permission does not rule out moral dilemmas.

Additional arguments against the possibility of moral dilemmas try to derive a contradiction from the definition of moral dilemmas. If the agent in a moral dilemma morally ought to adopt each alternative separately, then the agent morally ought to adopt both alternatives together, according to the agglomeration principle. If the agent morally ought to adopt both alternatives, then the agent must be able to adopt both alternatives, according to the principle that *ought* implies *can*. The agent cannot adopt both alternatives in a moral dilemma, by definition. Thus, the definition of moral dilemmas plus agglomeration and *ought* implies *can* imply a contradiction. Defenders of moral dilemmas respond by denying either agglomeration or *ought* implies *can*, or both.

Another formal argument applies a closure principle: An agent has a moral requirement not to do whatever prevents that agent from fulfilling a moral requirement. This closure principle implies that an agent in a moral dilemma has a moral requirement to adopt and also not to adopt each alternative. This is supposed to be absurd, because an agent cannot be required not to do what that agent is required to do. Defenders of moral dilemmas respond by denying either the closure principle or the claim that *required* implies *not required*, or both.

More arguments have been given against the possibility of moral dilemmas. Some philosophers claim that moral theories that yield moral dilemmas must be inconsistent or must fail to fulfill some purpose of moral theo-

ries, such as to prescribe particular decisions. Others argue that it would be unfair to blame or hold the agent responsible for failing to adopt one alternative when the agent adopted the other alternative in order to fulfill a non-overridden moral requirement. Defenders of moral dilemmas, of course, have responses to such arguments, but it remains controversial whether their responses are adequate.

## MORAL EPISTEMOLOGY

It is easy to find examples of moral claims. People often say or write such things as: (a) Deliberate targeting of innocent civilians in war is wrong. (b) Women should get equal pay for equal work. I shall refer to the contents of moral claims as moral statements. I presuppose nothing controversial regarding the real nature of moral statements. The first two examples of moral statements are general, but many are particular, for example: (c) George Bush should not have invaded Iraq. (d) I ought to make a contribution to tsunami relief. Not all moral statements concern what is right or wrong, or what we should or should not do. Some concern our rights: (e) Everyone has a right to his or her own opinion. (f) The KKK has a right to adopt a highway just as any other group does. Other moral claims concern what is morally good or bad, what is virtuous or vicious, what is praiseworthy, when morally significant feelings such as guilt, remorse or gratitude, are appropriate, and so on. I hope this makes it sufficiently clear what I mean to count as moral statements.

Just as a person can be insincere in making a non-moral claim, such as an ordinary factual claim, so a person can make a moral claim insincerely. It is not hard to imagine someone expressing agreement with others about some moral statement just to avoid confrontation, argument, or ridicule. In addition, we all recognize that what we say or write about morality does not exhaust our moral views, just as our factual beliefs can be more extensive than what we choose to make public. Let us therefore distinguish between people's moral judgments—that is, what they really think—and the public moral claims they make. I take no controversial stand regarding the nature of moral judgments.

### A NARROW AND A BROAD UNDERSTANDING OF MORAL EPISTEMOLOGY

According to one traditional understanding, epistemology is the theory of knowledge. It is concerned with analyzing knowledge or specifying the conditions that must be satisfied for something to count as knowledge, with determining what we know and accounting for how we know it. Accordingly, moral epistemology would be concerned with moral knowledge. It would seek to determine whether any of our moral judgments count as knowledge and to provide an account of whatever moral knowledge we do have. Unfortunately this traditional understanding puts moral epistemology at risk of being a field with which many ethical theorists can have no substantial engagement.

Although there is a great deal of debate regarding the proper analysis of knowledge, nearly everyone agrees that for a person to know a statement (or proposition), that statement must be true. There is almost as wide agreement that a person must believe something in order to know it. In spite of the consensus that knowledge requires true belief, epistemologists do not work much on accounts of either truth or belief. They instead focus on figuring out what knowledge requires in addition to true belief and at understanding the precise nature of whatever else is required. Epistemologists do not agree about exactly what more is required for knowledge, but nearly all would accept that for a true belief to be knowledge it must be *good* in some yet to be specified but particularly epistemic sense. Epistemologists are, therefore, primarily concerned with understanding something normative or, more broadly, evaluative. When they attempt to determine whether we know something or how we might know it, they are engaged in an evaluative enterprise, seeking to address such questions as whether we ought to

hold the belief in question, whether we are justified or responsible or warranted in holding it, or simply whether the belief has some special positive epistemic status. Philosophically significant debates about skepticism regarding some type of belief rarely begin with the skeptics arguing that the beliefs are false. They typically charge that the beliefs are deficient in some other way—that they are unjustified or unwarranted—whereas nonskeptics try to show that the beliefs are legitimate or up to standard.

If we adopt the traditional knowledge-centered understanding of moral epistemology, many ethicists cannot take moral epistemology seriously; if they allow that there are any significant evaluative questions regarding moral judgments, they must take them to fall outside moral epistemology. One reason for this is that a great many ethical theorists accept some version of noncognitivism. This was the dominant metaethical position for a large part of the twentieth century, and it may still be the majority view. In spite of the apparent similarities between moral statements such as “Murder is wrong” and descriptive statements such as “The cat is black,” noncognitivism holds that moral statements are not descriptive, that they do not state facts. Noncognitivists variously hold that moral statements instead do such things as vent emotions, state how one feels about certain actions and call upon others to feel the same way, make universal prescriptions, or express one’s acceptance of norms.

Hence, according to noncognitivism, moral judgments blatantly fail to satisfy the most obvious necessary conditions for knowledge. No moral judgments are true for the simple reason that they are not the sort of thing that could possibly be true; like questions or commands, they are neither true nor false. We could put the point in other ways by saying that moral claims do not really make statements at all or that moral judgments do not have propositions—things that carry truth values—as their objects or contents. Hence, even when we sincerely make a moral claim, we are not really expressing a belief. If moral statements such as “Theft is wrong” are not descriptive but have some sort of noncognitive content—if they are, for example, ventings of emotion (“Theft: big time yucko!”) or prescriptions (“Don’t steal!”)—then clearly their contents are not the sorts of things that one could possibly believe or, for that matter, disbelieve.

So noncognitivism entails the impossibility of moral knowledge. Regardless of how interesting the various versions of noncognitivism might be or how subtle and deep are the arguments that support them, no interesting normative epistemology is necessary to see this entailment. We need not get involved in any sort of epistemic evalua-

tion of moral judgments to reach the skeptical conclusion. One need not do anything like reconstruct the evidence we have for our moral judgments and evaluate it to see how strong it is. One need not investigate the cognitive processes that produce moral judgments and attempt to determine how reliable they are. Since moral judgments just are not, according to noncognitivism, the sorts of things that could possibly be knowledge, there is no reason to get involved in the distinctive kind of evaluation of belief or judgment that is the special business of epistemology. Indeed, it would seem that epistemic evaluation of moral judgments could not really make any sense for a noncognitivist. Moral epistemology as an area of serious inquiry is left open only to cognitivists.

But of course this is not the way things are. Most people, regardless of their metaethical views, evaluate moral judgments, and they evaluate them in ways that seem no different from straightforward epistemic evaluations of ordinary factual judgments. They take some moral judgments to be epistemically better and others worse. People are dubious, for example, of moral judgments made on the basis of incomplete information or made when someone is tired or emotionally distraught, just as one would doubt factual judgments made in such circumstances.

We think we can at least sometimes provide reasons or evidence for or against moral judgments and that the reasons or evidence can be evaluated. We sometimes seek reasons for moral judgments we have already made, and at other times we try to find reasons that would allow us to make a moral judgment when we are unsure. In certain cases we ask others about their reasons for moral judgments and look askance upon their judgments if they can provide no adequate reasons. We are perfectly comfortable applying terms of epistemic evaluation such as *reasonable* and *unreasonable*, *rational* and *irrational*, *warranted* and *unwarranted*, or *justified* and *unjustified* to moral judgments. When we apply these terms to moral judgments, it seems that we use them in the same way as when we apply them to other kinds of judgments.

There are two hard lines that affirm the restrictive understanding of epistemology as concerned exclusively with knowledge and accept that the conjunction of this conception with noncognitivism entails that the epistemic evaluation of moral judgments makes no sense. The one hard line concludes that epistemic evaluation of moral judgments, that is, moral epistemology, makes no sense. The other accepts the epistemic evaluation of moral judgments and rejects noncognitivism. I expect the first hard line approach would be more popular than the

second. But I prefer a third alternative. It maintains that epistemic evaluation of moral judgments makes perfectly good sense, as common practice suggests, and that most metaethical positions, including most versions of noncognitivism, can recognize this; it instead rejects the narrow understanding of epistemology. One advantage of this approach is that there are independent reasons for preferring a broader conception of epistemology.

We can extend the conception of epistemology, and specifically epistemic evaluation, in two ways. First, we should allow that epistemology is concerned with more than knowledge and its constituents. There are significant concepts of epistemic evaluation that do not figure in the analysis of knowledge. Some epistemologists account for knowledge in terms of reliable belief formation. Others disagree because a person's reliability may not be subjectively accessible to that person. They hold that knowing requires responsible belief, and that belief is irresponsible unless we have reason to think the belief is likely to be true. Others hold that to be known a belief must be properly based or grounded, while others hold that to be known a belief must be part of an extensive coherent system of beliefs. Yet others think a belief must be formed by a properly functioning cognitive mechanism. There are still more contenders: for example, those who analyze knowledge in terms of the exercise of intellectual virtues. Presumably at most one of these accounts provides a correct analysis of knowledge, but even those accounts that fail as analyses of knowledge may still succeed in identifying something that has epistemic value.

Whether reliable belief is necessary for knowledge, it is a good thing to be reliable in forming beliefs. The same holds for subjectively accessible reasons: It is clearly a good thing to have such reasons for a belief, regardless of whether they are necessary for knowledge—and so on for the various other evaluative characteristics of belief that have been put forward as necessary for knowledge. A strong case can be made that each is a real epistemic good. There are also concepts of epistemic evaluation that do not even seem to be required for knowledge. According to one account, rational beliefs are those that would stand up upon thorough reflection because they satisfy the believer's own deep epistemic standards. This is a highly subjective sense of rationality and therefore it is probably not required for knowledge. Nevertheless, it is epistemically good to have beliefs that satisfy one's own epistemic standards rather than beliefs that one would, upon careful consideration, regard as epistemically flawed. There are doubtless still more concepts of epistemic evaluation.

The second way to broaden epistemology is by abandoning the dominant monistic view of epistemic evaluation that regards truth as sole intrinsic epistemic good and all other epistemic goods as valuable because of some connection to truth such as being a means to true belief. There have been attempts to show that some features, such as coherence, make truth more likely, but these attempts have not met with much success. It has seemed obvious all along that other features, such as subjective rationality, do not make true belief objectively likely. We need not conclude that no such features are epistemically valuable. It is better to allow that some things we value epistemically do not make true belief likely. In the case of something like reliable belief, at least on some understandings, the connection with truth is obvious. But even here we should take a broader view, at least for moral judgments. As we have seen, noncognitivism entails that moral judgments have no truth values and hence cannot be reliable.

Nevertheless, it seems obvious that some moral judgments are more reliable than others. For example, moral judgments made by a person who is emotionally distraught or who has selfish interests at stake are less than reliable. Most noncognitivists can easily accept such seemingly obvious examples, since most draw some sort of distinction between correct and incorrect moral judgments. Hence a notion of reliability is available that is an extension of the familiar, truth-connected notion. It makes more sense to recognize judgments that are reliable in this extended sense as epistemically valuable than to think that we are making an epistemic evaluation when we criticize a factual belief because a person formed it, say, when in a rage, but some totally different kind of evaluation when we criticize a moral judgment for exactly the same reason.

## EPISTEMIC EVALUATION OF MORAL JUDGMENTS

If the broad conception of moral epistemology is basically correct, we should not ask simply whether any moral judgments are known or justified. Recognizing that there are various significant concepts of epistemic evaluation, we should ask what, if any, positive epistemic statuses moral judgments might have and also whether moral judgments suffer from any epistemic flaws so severe that we should regard them with a robust skepticism—a skepticism that holds not merely that no moral statements are known, but that moral judgments are so flawed that it makes no sense to use them either in moral theorizing or as a guide to life and action.

Some moral judgments are bound to be epistemically flawed for straightforward reasons—for example, because they were formed by a person who was emotionally distraught or who stood to gain or lose depending upon the judgment, or because they were made on the basis of an incomplete or incorrect understanding of the facts of the case, or because the person judging feels unsure or has no stable opinion. We know that judgments like these run a significant risk of error, regardless of their content. Let us set aside such obviously flawed judgments and focus on those that are free of all such well recognized sources of error. Such moral judgments already have some positive epistemic status—they have managed to avoid some significant pitfalls. But this is not, perhaps, a very impressive status, so let us consider what more might be said on behalf of moral judgments.

Among the remaining moral judgments, we can distinguish between those formed or not formed on the basis of inference. We obviously cannot have formed all of our judgments by inferring them from other judgments. Some of our judgments must be noninferential. It might be that all moral judgments are inferred from nonmoral judgments, either immediately or by means of inferential chains that eventually terminate exclusively in nonmoral judgments. Certain ethicists have tried to ground moral judgments in something like this way, deriving them from theses regarding the meanings of moral terms in conjunction with purely empirical claims. But it seems highly unlikely that anything like this will work out, and near certain that the moral judgments of ordinary people are not grounded in this way. Ordinary people, and even philosophers when they are being ordinary, form many noninferential moral judgments, and when they do infer moral judgments, the inferences have moral premises that are, or eventually trace to, noninferential moral judgments. So let us focus on noninferential moral judgments.

Consider the widely shared judgment that it is wrong to cause animals suffering for no good reason. Those who share this general judgment will also make judgments regarding the wrongness of many particular cases of animal torture. It is certainly possible to reach the general judgment via inference or to infer the particular judgments from it. But it is also possible to make both judgments noninferentially. Even where the judgments are noninferential, it is quite obvious that they do not come from nowhere. We were taught to make such judgments as children. At some time or other when we were children, our parents or some other adult caught us, or perhaps a sibling or a friend tormenting some helpless small

animal and scolded us. Maybe one incident was enough; maybe similar incidents were repeated, but eventually the lesson stuck.

Perhaps, then, our noninferential moral judgments get their epistemic status in the same way as our beliefs in other things we were taught as children. I believe that my maternal grandfather was killed in World War II, before I was born. This belief is noninferential, but it does not just pop into my head from I know not where. I know full well that it arises from testimony and memory. When I was a child my mother told me this. I believed her. Although I never received any objective confirmation of the belief—for example, by reading a letter from the War Department—neither did I encounter any reason to doubt what I was told. And I still remember what I was told. This is sufficient for my belief to have some fairly impressive epistemic credentials. My belief is rational or reasonable. You could say that I am epistemically responsible in believing. The belief coheres with other things I believe, although I would have to admit that most of the relevant beliefs are also things I remember being told by my parents. My mother has usually been reliable, and I know this to be so because in many cases what she told me has been borne out by the future course of experience. And I know my memory is fairly reliable as well, at least about things like this.

As good as all this is, however, it is still possible that my belief is seriously flawed. Suppose my grandfather mysteriously disappeared around the start of the war, and, although my mother knew he was involved with organized crime, she deceived herself into believing he had gone off to the war. When he didn't return at the end of the war, she came to believe he had been killed in action. Under this scenario, given the fact that my mother's original belief about her father's fate had little positive epistemic status—indeed, was flawed—my belief would be seriously flawed. It is significant that in such cases a testimonial belief can have a higher epistemic status than the belief of the testifier. Nevertheless, the epistemic status attainable by beliefs that are (solely) grounded in testimony and memory is constrained by the epistemic status of the testifier's belief. The epistemic status of memorial beliefs is similarly constrained by the status of the original belief.

Of course, the adults who taught us about morality when we were children probably did not fabricate their own moral views in some strange way. They were taught about morality by their parents, who were taught by theirs, and so on. This suggests a somewhat different problem: In the case of beliefs that have their source in

chains of testimony and memory involving a series of people, somewhere along the line someone must have formed the relevant beliefs in some other way. And if the beliefs that come later in the chain are to be free from significant epistemic defect, somewhere along the line some beliefs must have attained some fairly strong positive epistemic status in virtue of something other than testimony and memory.

In the case of historical beliefs, which presumably trace back to persons who witnessed the events in question, it might make sense to suppose that the original source beliefs had the requisite epistemic credentials. But in the case of moral judgments it is hard to credit such a view, unless one takes something like the biblical narrative of Moses quite literally and holds that all our moral judgments can be traced through a long chain of testimony and memory all the way back to Moses or some other prophet whose moral judgments came straight from God. My guess is that even many theists will find such a supposition incredible.

How, then, might noninferential moral judgments attain a significant positive epistemic status? Here is a possibility: We were also taught to make simple arithmetical judgments. I can well remember trying to memorize multiplication and division tables. But although testimony and memory are surely somehow involved in the arithmetical judgments we now make, these judgments do not get their epistemic status primarily from testimony and memory. Indeed, I doubt that our simple arithmetical judgments are even produced by memory and testimony any longer. Somewhere along the line, no doubt as a result of our training, we reached a point where we could simply see for ourselves that simple arithmetical propositions are true. Simple mathematical and logical propositions, and perhaps some few others, are special. Any person with the conceptual resources to really understand the propositions can simply see that they are true, or at least this is one venerable and still widely held view. Some ethicists have wanted to say that certain ethical statements are like this as well. So the first part of the current proposal is that although we were taught to make moral judgments when we were children, such judgments are no longer merely products of testimony and memory. Rather, when we understand and consider certain moral statements, they simply seem to us as though they are true, so we form the moral judgment. The second, explicitly epistemic part of the proposal is that such moral judgments have the same positive epistemic status as simple arithmetical judgments and come to have this status in the same way.

There are reasons for being suspicious that things are quite so simple. Before I explain why, here are a couple of terminological notes. Contemporary discussions of moral epistemology and methodology frequently are conducted in terms of considered moral judgments and moral intuitions. Considered moral judgments are typically characterized simply as noninferential moral judgments that are not subject to obvious sources of error. When we narrowed our focus to such judgments above, however, I did not refer to them as considered moral judgments because judgments formed through testimony are not inferential in their origin, and neither are memorial judgments. Nevertheless, moral judgments formed via testimony or memory are not considered moral judgments even if they have avoided the usual sources of error. In the first part of the proposal regarding moral judgments we have restricted our attention to judgments that are free of the usual sources of error and are not only noninferential but are also held simply because it seems to the believer that they are true. Such judgments are appropriately regarded as considered moral judgments.

The term *intuition* can be used in a stronger, epistemically loaded sense or a weaker, nonepistemic sense. In the weaker sense, intuitions are simply noninferential judgments that do not arise from any of the traditionally recognized sources of knowledge: Intuitions are not produced by sense perception, introspection, memory, or testimony. A person makes an intuitive judgment simply because the proposition seems true upon due consideration. Considered moral judgments are, therefore, a subset of moral intuitions, namely, those that have avoided obvious causes or error. Limiting ourselves to the first part of the current proposal regarding moral judgments, we could say these judgments are moral intuitions in the weak sense. There are various stronger concepts of intuition that add to the weak notion a claim to some positive epistemic status—often some strong status such as certainty or infallibility or incorrigibility. Critical discussions of intuitionism often assume a strong notion of intuition, most frequently one involving a very strong epistemic status. The second part of the current proposal takes moral judgments to be moral intuitions in a very strong sense.

I would like to consider two significant grounds for doubting that our considered moral judgments are epistemically similar to simple mathematical judgments. They also may seem to be grounds for doubting that considered moral judgments are intuitions in any strong sense and even that considered moral judgments could have a significant positive epistemic status. The first

ground for doubt is based on the fact that our considered moral judgments seem to be revisable; the second is based on the fact that there is considerable disagreement regarding these judgments.

Most people who reflect on their moral views encounter conflicts among their considered moral judgments. Many of us find certain moral principles intuitively obvious, particularly midlevel principles such as “It is right to keep one’s promises” and “It is wrong to lie.” One need not reflect very long to come up with cases where application of an intuitive principle produces a judgment at odds with our considered moral judgment regarding the case. (This is just what one does when arguing by counterexample.) Conflicts can also emerge if we make different intuitive moral judgments about different particular cases and there is no difference between the cases that we judge sufficient to justify our different moral judgments. When we encounter conflicts among our considered moral judgments, moral reflection obviously does not halt. We decide what to revise and move on. But the existence, or more properly, the frequency of such conflicts does seem to count against the claim that our considered moral judgments are epistemically similar to simple mathematical beliefs.

The problem is not that our intuitive judgments about simple logical and mathematical propositions could never come into conflict and can never be revised. There are mathematical propositions that seem intuitively obvious but lead to paradox—that is, they come into conflict with other intuitive mathematical propositions. In such cases we are led to revise some intuitive judgments. But such occurrences are the rare exception in mathematics and logic, however, and vastly more common with moral judgments. Hence, although we might get away with claiming that simple mathematical propositions can be seen to be true by anyone who adequately understands them, even though we are forced to allow that those who adequately understand are sometimes mistaken when they think they see something to be true, the parallel claim regarding considered moral judgments seems much less plausible.

People seem to disagree a lot about morality. Some of the differences might not constitute conflicts—that is, cases where the judgments are inconsistent. Some of the differences might arise from misunderstanding on the part of one or both parties, and some might not involve considered moral judgments. But even setting aside such disagreements, there are many real conflicts between the considered moral judgments of mature adults who fully understand. Not only does the existence and extent of

these conflicts render untenable the claim that considered moral judgments have the same epistemic status as simple mathematical judgments, but it also could be taken to block the claim that considered moral judgments have any significant positive epistemic status. One reason is that, in many cases of conflict, the parties to the different sides come from different societies or cultures, a circumstance that seems to support the idea that moral judgments are some sort of social or cultural construct. They might then be reliable guides to the taboos or mores of the judge’s own culture but not to anything more substantial or objective. When conflicts among considered moral judgments within cultures are added to the mix, we seem to have ample reason to doubt whether they are reliable guides to anything at all.

Actually, the fact that a single person’s considered moral judgments can conflict and require revision is not a bad thing. Indeed, it is a fundamental element of the most influential approach to the construction and justification of moral theories. According to the method of reflective equilibrium, we should strive to mold our considered moral judgments and a set of moral principles that account for them into a coherent system via a series of mutual adjustments to principles and judgments, with revisions guided only by what seems most likely to be true upon due consideration. If only considered moral judgments and moral principles are involved, a narrow reflective equilibrium emerges. Inquirers should next strive to bring their judgments into a wide equilibrium, which also includes background theories and judgments—for example, views regarding the nature of persons or the role of morality in society. Once again, in the search for a wide reflective equilibrium, no type of judgment has a privileged status. Coherence is attained by a series of mutual adjustments.

The method of reflective equilibrium is an idealization of the kind of moral inquiry carried on by many philosophers and presumably by at least some reflective nonspecialists. We might, then, shift away from the considered moral judgments of ordinary people and ask about the epistemic status of the moral judgments we would hold if we brought our moral judgments into wide reflective equilibrium. It might be all but impossible for us ever to attain such equilibrium, but perhaps we can approach it ever more closely. The moral judgments a person holds in reflective equilibrium would have a number of epistemically good features: they would have been formed after careful and thorough reflection, they would not conflict with either the person’s other moral judgments or any of the person’s other beliefs, and they would

be part of a highly coherent system of beliefs and judgments. Moreover, we might hope that there would be fewer conflicts between the moral judgments of different people who had brought their beliefs into reflective equilibrium. One reason for this hope is that part of the method explicitly involves considering alternatives to one's own moral system.

Unfortunately, I fear we cannot expect that inquirers will converge upon a single system of moral judgments in wide reflective equilibrium. It is too easy to imagine people who begin with radically different moral perspectives being led to revise their judgments in different ways to overcome the conflicts internal to their own moral perspectives, and so at the end of their inquiries being led to accept very different, incompatible moral systems in reflective equilibrium. So questions about the reliability of moral judgments persist.

I will close by briefly describing one possible way of addressing such questions. Suppose that people differ in their capacities for making moral judgments. Suppose that this capacity needs to be developed through experience and possibly even training, but that it can also be corrupted. (For what it is worth, common sense strongly supports these suppositions.) Let's call a person with a well-developed capacity for moral judgment a competent moral judge. If two people with unequally developed capacities for moral judgment were to bring their moral judgments into reflective equilibrium, they would probably disagree to some extent. Such disagreement would not establish that the moral judgments of both inquirers were unreliable, however, for it might be that only one of the inquirers is a competent moral judge. Presumably the moral judgments the competent judge would make in reflective equilibrium would be quite reliable. Since the other person's moral judgments would also be in reflective equilibrium, it would not be possible to prove to that person that his or her judgments are unreliable or that the competent judge's moral judgments are reliable. But this would not change the fact that the competent judge's moral judgments would be reliable.

One might require that, in order for a person's moral judgments to have a significant positive epistemic status, a person must be able to prove that his or her moral judgments are reliable or that he or she is a competent moral judge. If this is right, then we will have to grant that even the moral judgments competent judges hold in reflective equilibrium have no significant positive epistemic status. We should note, however, that if similar requirements were imposed across the board, we would be forced to conclude that almost none of our beliefs or judgments

have a significant positive epistemic status. On the other hand, if actually being reliable is sufficient for having a significant positive epistemic status, at least in conjunction with all the other epistemic goods we have identified, then it seems that the moral judgments competent judges would make in reflective equilibrium will have such a status. One might doubt whether there are any competent judges, but I do not think we know that there are not. So there is reason to hope that moral judgments can attain a strong positive epistemic status.

## MORAL PRINCIPLES: THEIR JUSTIFICATION

The problem of how, if at all, we could set about justifying assertions about what we ought to do in various practical situations is one that has been the major concern of moral philosophers. Such basic questions are indeed endemic in most branches of philosophy. We ask not only if we can ever know what we ought to do but whether we can justify our claims to knowledge of an external world, how we can know the truth of statements about the past, or whether we can ever be sure of the existence of minds other than our own. But in ethics the problem seems more recalcitrant and, indeed, to many nonphilosophers at least, more real. For while skepticism about the existence of an external world or of other minds may seem difficult to refute, to most it is impossible to embrace, whereas skepticism about the possibility of claiming knowledge of any objective truths about what we ought to do is not so rare, either among men in general or those who would wish to characterize themselves as philosophers.

It is not, of course, surprising that this should be so. Ethical attitudes vary much more, from society to society and even between individuals, than do our beliefs about the external world or other people's feelings. The patent fact of ethical disagreement forces us to reexamine the bases of our moral beliefs. Furthermore, the disagreements we encounter concerning moral issues often seem to involve deep matters of principle that leave no common ground between the disputants. This is sometimes referred to as the problem of disagreement about ultimate moral principles. It is this problem—whether ultimate moral principles are susceptible of rational justification—that will be examined in this article.

Most philosophers would agree that the particular way in which a philosophical problem is formulated will make a great deal of difference to what solution is possible to it or, indeed, whether any solution is possible. It will be necessary therefore to set out in detail what is meant by a disagreement about ultimate moral principles and to defend this way of expressing the issue against certain objections before a possible solution is set out.

## MORAL PRINCIPLES

A “man of principle” is sometimes thought of, with distaste, as a man who acts in accordance with a fixed set of rules, ignoring the complexities of the situation and failing to adapt his behavior to changing circumstances. The morality of principles and rules is sometimes contrasted with the morality of sensibility, which emphasizes such virtues as sympathy and integrity as against a rigid code of behavior. In either kind of morality, however, particular judgments will have to be made, based on a view of the situation in which the agent acts, and some factors in the situation will have to be regarded as reasons for acting in one way rather than another. There is, therefore, a more general sense of “moral principle,” which can be regarded as common to both views, in which a moral principle indicates some factor that is generally relevant to what ought to be done.

Moral principles can then be regarded as statements picking out those factors of situations that can be appealed to as moral reasons. “Lying is wrong” suggests that the fact that a statement is known to be false is a reason for not making it to someone. “Adultery is wrong” suggests that the fact that someone is married is a reason for his refraining from sexual intercourse with any person who is not his spouse. And, again, “One ought to be kind” suggests that there are reasons for performing kind actions rather than unkind ones. Asserting a moral principle of this kind and denying the suggestion about reasons results in paradox. Thus, for example, if somebody says “Lying is wrong, but the fact that a statement constitutes a lie is no reason whatsoever for not making it,” he seems to have taken back in the second half of his sentence what he asserted in the first.

If saying that someone ought to do something commits one to claiming that there is some fact in the situation that is a reason for doing the thing in question, then this reason must be subject to the requirement that reasons in general must satisfy: that anything that is a reason in any one case must be a reason in every case unless there are other special reasons for ignoring it. This applies to reasons generally, not just to moral reasons. For example,

if the fact that it is raining is a reason for saying Smith will get wet, it is a reason for saying anyone else will unless there are some relevant differences in their cases, such as being indoors or carrying an umbrella. It is this that leads to the claim that moral principles must be universal, at least to the degree that they pick out factors that are universally relevant to what we ought to do, although not necessarily universally determining what we ought to do in every particular case. Thus it would seem that the correctness of the universal moral principle involved—or, in other words, that what is appealed to as a reason should indeed be a reason—is a necessary although not a sufficient condition of the correctness of the particular judgment about what ought to be done.

**JUSTIFICATION OF MORAL JUDGMENTS.** If the correctness of universal moral principles is a condition of the correctness of particular moral judgments, then obviously the first question we must ask in investigating how our particular moral judgments can be justified is, How can we justify claiming that certain moral principles are correct? There are, however, some objections to this way of treating the problem that must be considered.

It may be pointed out that value judgments in other areas do not seem to require justification by reference to some universally relevant factors. And if we are willing to allow that in other realms of value there are judgments that do not require to be backed by universal principles, why not in morals? For example, there are very considerable difficulties in representing judgments about the value of a work of art as being backed by or dependent on principles at all. It may be impossible, when we say some work of art is good, to indicate any feature the possession of which is bound to make any other work of art good. (One might be tempted to say that beauty is such a feature. But this is unconvincing because one is using the term either narrowly, in which case there are plenty of good works of art that one would never describe as beautiful, or so widely that it means only “good in the way that a work of art is good.”) Surely, however, it must be agreed that the goodness of anything, including a work of art, depends on what qualities it has, however difficult it may be to say in a given case precisely what qualities it has that make it good. And in order to begin to justify the judgment that something is good, one must refer to its qualities; one cannot draw anyone’s attention to the goodness itself. If it is proper to refer to these qualities to back one’s claim that the object is good, then it is at least to the point to ask why something else, which has the same qualities, is not good. If such a question is to the point, it shows that we accept that the possession of certain qualities is

being put forward as a general reason for saying that the object is good.

Even if this is correct, however, it is clear that the features by virtue of which any given work of art is judged to be good tend to be many, complicated, and organically related. Although any feature pointed to in support of a judgment that a work of art is good must also be relevant to the criticism of other works of art, there may be in every other case many other relevant factors that alter the situation completely. The same thing might be claimed for moral cases. It may be said that every human situation is infinitely complicated, so that however many relevant features one may pick out in a particular case, there will always be a host of others that can be set against them. Such considerations would lead not so much to a denial of the universality of morally relevant features as to doubt about the utility of stating the problem in terms of principles. To this there are two answers.

First, it would be against common sense to claim, for example, that the wanton murder of children is not wrong. Even where other features that are regarded as morally relevant are also present—such as that one had promised one's old mother on her deathbed to try to exterminate the Jews—few would regard them as justifying child murder. So anyone who persists in claiming that it is always possible that such actions as child murder may be justified because of the complex character of every particular human situation is, at best, someone who has an unusual moral outlook, and this means that his very claim that every situation is so complicated that no general principles can be admitted is dependent on his having a different set of moral principles from most people's. So even to consider whether this objection is correct, we still have to ask which general principles are justifiable.

Second, we have already remarked that moral principles will be a necessary but not a sufficient condition of the correctness of our particular moral judgments. Although on their own they may never be sufficient to solving all moral problems, they will certainly be necessary to our having any moral problems at all. This may be illustrated in terms of a case mentioned by Jean-Paul Sartre. A young man has a dilemma. Should he join the French Resistance, or should he stay at home and look after his aging mother? Sartre points out that no rehearsal of general principles would ever serve to solve such a problem. This is no doubt true, but it does not show that the correctness of such principles is not relevant. For why is the young man worried about only those two possibilities? There are plenty of other things he could do. He could learn tightrope walking or set up as an ice-cream

vendor or enlarge his earlobes with brass rings. But these are obviously of no importance, whereas looking after the old mother and joining the resistance are important. Why is Sartre's case serious and dramatic and the other suggestions frivolous and silly? Why does it matter what the young man does, to himself or to anyone? There can surely be no problem at all unless such things as joining the resistance (defending one's country) or looking after the old mother (kindness to a dependent) are morally relevant features of the situation—unless they are things that it is reasonable to consider in deciding what to do. And if there are morally relevant features in the situation, there are corresponding moral principles. If these principles are not correct (and, indeed, there are those who would question patriotic principles), then there is no problem, or at least not the same problem.

A different kind of objection can be disposed of very briefly. It is that as a matter of experience, we do not think in terms of principles. Rather, on particular occasions we simply know instinctively what is right. Now this may very well be true or perhaps true for a number of people. However, the question at issue is not a psychological one about the kind of process that goes on before a moral judgment is made; it is a philosophical one about how we may justify making the moral judgments we do make, by whatever psychological process we make them. Whatever goes on in the heads of mathematicians, it is still Euclid's proofs alone that can justify Euclid's theorems.

### ULTIMATE MORAL PRINCIPLES

Moral principles in the sense adumbrated above will be of varying degrees of generality, and some will be held to be more fundamental than others. For example, the principle that one ought not to commit adultery may be defended on the ground that adultery is inimical to the stability of the family. In terms of reasons for acting, this can be put as follows. The fact that someone is married is held to be a reason for his refraining from sexual intercourse with anyone other than his spouse. But why is this a reason? Because, it might be said, *in fact* sexual infidelity is apt to break up the unity of the family. Such an argument would, of course, presuppose that the fact that something is apt to disrupt the family is a reason for avoiding it or, in other words, that one ought not to disrupt the family. Thus the principle "One ought not to commit adultery" would be regarded as less fundamental than the principle "One ought not to disrupt the unity of the family." In the process of trying to justify particular moral judgments, we will usually find ourselves trying to show that certain necessary conditions of their correct-

ness, our moral principles, have further necessary conditions in terms of more fundamental moral principles. The process will usually be much more complicated than I have represented it; in justifying a less fundamental moral principle, we will usually find a variety of more fundamental moral principles coming into play. But however complicated such a process may be, it is obvious that we cannot suppose it to go on forever. At some point we should reach some principles that we regard as the most fundamental. For example, we might want to say that we do not claim that one ought to be kind because this follows from some further principle; we ought to be kind because we ought, and that is an end to the matter. These we may call ultimate moral principles, and their correctness is a necessary condition of the correctness of all other moral judgments. Unless some such ultimate moral principles can be shown to be justifiable, no other moral judgments can be shown to be justifiable.

Some philosophers hold that this representation of the matter is utterly mistaken and, indeed, that it is precisely because of this “justificationist” view that so many philosophers despair of finding an answer and become ethical skeptics. If, it is argued, moral principles are regarded not as first premises from which a moral system is deduced but as conjectures that can be altered and amended by subsequent moral experience, we at least have a method of correcting our moral attitudes that will justify us in claiming that they are more or less rationally defensible. It will not be possible to do this view justice in a small space. It can only be said here that the major difficulty with this view is that the test of the moral principle is taken to be the particular judgments we are inclined to make, particular judgments that conflict with the supposed principle and thus refute it. But what is now the test of the correctness of the particular judgment? The suggested method would seem to be a way of finding out, by examining someone’s particular judgments, what his moral principles are rather than a way of finding out which moral principles are correct. Furthermore, it has not been claimed in this article that moral principles are first premises from which whole moral systems can be deduced but only that moral principles are statements of relevant moral factors. Their correctness is a necessary, not a sufficient, condition of the correctness of moral judgments.

Nevertheless, the charge is certainly well founded that this way of setting out the problem is a most plausible invitation to ethical skepticism. For it would on the face of it appear that the very statement of the problem precludes its solution. If we look on more and more gen-

eral moral principles as representing a regress of necessary conditions of the correctness of moral judgments, then either this regress is viciously infinite or there is a point at which it must stop. But any attempt to justify some principle as a stopping point would appear to start the whole process off again. To acquiesce in some stopping point would be to accept an ultimate principle and, it would seem, to accept that nothing further could be said in its justification. It looks then as if this way of putting the problem makes inevitable the conclusion that ultimate principles are unjustifiable.

## AUTONOMY AND OBJECTIVITY OF MORAL PRINCIPLES

One way to put the problem is to regard it as a conflict between the autonomy and the objectivity of moral principles. The demand that ethics be regarded as autonomous originated with Immanuel Kant, in the view that an action is not moral unless it is determined by the agent’s rational will rather than by something external to that will, such as a desire, or the will of another (a king, a friend, the state, God). Here the concern is with the determination of action, not directly with the determination or, rather, justification of moral judgment. The autonomy of moral principles, with which we are concerned, is not, however, entirely unconnected with Kant’s sense of autonomy. It is the idea that a moral judgment can never depend for its correctness entirely on factors that are nonmoral; that is, that in the justification of any moral judgment one must have recourse to a moral principle, which must in turn be justified in terms of some more general moral principle and so on. In other words, a moral judgment or principle is never deducible from any set of premises that contain no moral judgment or principle.

The demand that morality be regarded as objective was also emphasized by Kant. A moral act for Kant was one that could be willed by an autonomous, rational will; its character as a moral act depended not on the particular nature or desires of the willing agent but on the nature of a rational will as such. For Kant a maxim is objective when it is valid for any rational being. Again, Kant’s concern was with the determination of action rather than the justification of judgment. But once again our sense of objectivity is not unconnected with Kant’s. When someone’s judgment is stigmatized as subjective rather than objective, this means that some idiosyncratic factors such as the hopes and fears or special interests of the speaker have affected his judgment; an objective judgment, however, is one not affected by such idiosyncratic factors but

one that any reasonable and unbiased person would form in the circumstances. Obviously, we can speak of objective matters only in respect of matters that are publicly determinable, where we can talk of what would be judged by any reasonable and careful observer rather than what appears to be the case to some individual because of some peculiarities of his own. Thus, we might say with Kant that objectively true judgments are those that are “valid for all rational beings” rather than what merely seems to be so to certain individuals. The demand of objectivity in ethics may then be put at its most minimal as the demand that the truth of any moral judgment shall not depend on the peculiarities of the person making it but, rather, that it shall be determinable by any rational observer who is apprised of the facts. Its truth will not depend on the fact that it is judged so by some one person rather than another but on objective considerations.

The conflict between the demands of objectivity and autonomy is now not difficult to see. For how can ultimate principles, which cannot be based on any further considerations, be based on objective considerations? How can we claim that they are matters that are publicly determinable when it would seem that, if they were autonomous, no considerations beyond themselves would make their truth determinable at all?

Henry Sidgwick, impressed by the utilitarian moral system but despairing of the kinds of argument put forward by earlier utilitarians such as Jeremy Bentham and John Stuart Mill to justify their ultimate principle, substituted instead the doctrine of intuition, a doctrine that was accepted by many other philosophers who were very far from being utilitarians. It was thought that the problem of justification in ethics was parallel to similar problems in other fields of knowledge and that in each case one would find oneself with incorrigible starting points, truths known directly, without inference or the necessity or possibility of further justification. Thus, in our knowledge of the world we might be thought to begin with direct awareness of our experience; in mathematics, with the direct perception of mathematical relationships. In ethics we begin simply with the perception of universal ethical relationships, between what is right or fitting and certain states of affairs. Whatever the difficulties in this general epistemological theory, in ethics there is the additional difficulty that the commonsense roots of the problem of justification—the inescapable fact of disagreement on fundamental ethical matters—are untouched by the doctrine of intuitionism. The appeal to intuition in the face of this disagreement leaves no way of rationally resolving it.

## TRANSCENDENTAL ARGUMENTS

It is possible, however, that an account of the justification of ultimate principles can be given that avoids both an infinite regress of justifying principles and any arbitrary stopping point. Kant’s demands for autonomy and objectivity amount to the requirement that a morally good action be rationally chosen in accord with a law that is valid for all rational beings universally and that is determined by nothing beyond itself. The difficulties in making the demands of autonomy and objectivity compatible, so that this requirement becomes a feasible one, seem capable of only one kind of solution, which was the one adopted by Kant. If moral principles cannot be justified by considerations outside themselves yet must be regarded as objectively justifiable, then it seems that certain moral principles must somehow be demanded by the formal character of morality itself; certain rules must be required by any morality that is to satisfy the two demands.

Kant’s particular solution has not seemed very satisfactory, but if a solution is to be found at all, it must be in the same direction. To put the point in more contemporary language, the only kind of solution that seems possible is one that shows that certain moral principles must be regarded as correct if moral discourse is to be possible at all, at least as an autonomous and objective form of practical discourse. An argument to this effect may be called a transcendental argument. If such arguments can be constructed, it should be easy to see how they solve the problem we have been considering. For a principle can be shown to be objectively true, without appealing to factors outside itself, if it can be shown that the form of discourse of which the principle is an example is impossible without presupposing the principle. That is, by showing that no one can claim to be using a form of autonomous, practical, and objective discourse unless he at the same time accepts the principle in question.

Three arguments of this kind can be advanced to establish three ultimate principles, which we may call the principles of impartiality, rational benevolence, and liberty. It is important that throughout it should be borne in mind that these arguments are intended to establish ultimate principles—that is, factors of the most general moral relevance, which will be necessary, but by no means sufficient, to establishing any correct moral theories, rules, or particular judgments. Even given that these arguments establish the ultimate principles of impartiality, rational benevolence, and liberty, there will still remain the difficult problem of their application in practice.

**IMPARTIALITY.** As far as we are concerned with a form of discourse in which we objectively judge actions right or wrong, so that a correct practical judgment is one that could in principle be reached by anybody, such judgments must be made in terms of features that the actions or the situations in which they are done possess and not on any other factors arbitrarily introduced by the person making the judgment. Thus, any feature picked out as relevant must be one that is always relevant unless there is some special explanation, for a feature that is relevant in one case and not in another, where there is no further difference, is one that is not relevant at all in any ordinary sense and forms no guide to action. It follows that any action that it is right or wrong for one person to do is right or wrong for every person to do unless there are some special factors present in the other cases. And from this demand of universality it follows, insofar as morality is practical, that one ought to act in accordance with it: What anyone ought to do in any given set of circumstances is what anyone else ought to do, as long as his case is not relevantly different, and anything one ought to do on any given occasion is what one ought to do on every occasion unless again there are factors present that are relevantly different. That one ought to treat similar cases similarly is obviously a general case of the particular requirement of justice toward men, that any form of treatment that is thought to be right for one man must be right for all others, unless the others are significantly different.

**RATIONAL BENEVOLENCE.** The principle of rational benevolence is that stated by Sidgwick, that one ought in action to consider the interests of all beings in the universe. That this is a most impractical injunction is important, but not fatal, for how in practical situations we may apply any ultimate principle is another, though admittedly difficult, question.

The principle may be justified as follows. The demand of objectivity is that what is right or wrong should be determinable at least in principle by all rational beings. This requires that moral discourse should be a form of public discourse, in which the relevance and force of any consideration is dependent on its content and not on the will or status of whoever puts it forward. That is, the remark of any rational being may be relevant to the question whether some action is right or wrong. The ideal of this form of discourse therefore requires that it should be possible for any rational being to participate in it as an interlocutor; if any is excluded arbitrarily then all may be, and the form of discourse as a public institution would be impossible. This does not mean that other forms of dis-

course may not be constructed in which certain possible interlocutors are excluded by fiat, but this would not then be the fully rational, autonomous, and objective form of discourse we require. A parallel may be found in scientific discourse. As far as it is objective, considerations must be dealt with on their merits and not in terms of the will or status of whoever puts them forward. If any arbitrary exclusion of possible interlocutors is made, then we do not have public objective scientific discourse but a sort of game in which arbitrarily selected players alone are entitled to make certain moves and in which what is determined in the outcome is who has won rather than what is true.

If moral discourse is to be public and objective, then it must allow for the participation of any possible rational interlocutor. Now let us define an interest as that which any rational being should seek for himself insofar as he considers the effects of his actions on himself and not on others except insofar as what affects others also affects him (for example, if it is rational for anyone to avoid pain, then it is in my interest to seek those actions that avoid pain to myself but not necessarily those that avoid pain to others except insofar as the pain of others causes pain to me or prevents my achieving some other end that it would be rational for me to choose for myself). Now it is by definition necessary that every rational being should seek his own interests as far as possible. It would be irrational for any being to participate in a form of discourse the practical effect of which would be to deny his interests; hence, it would be irrational for anyone to adopt moral discourse without further justification if from the beginning his interests were to be ruled out. But this means that anyone who wishes to adopt moral discourse must allow that any possible interlocutor must not have his interests ruled out of consideration from the beginning, and any rational being is in principle a possible interlocutor. It follows that as far as public objective moral discourse is to be possible, it is presupposed that what is determined by such means will not neglect the interests of any rational being—that is, that in deciding what I ought to do, or what anyone ought to do, the interests of all rational beings whatsoever must be taken into account.

**LIBERTY.** The principle of liberty is that one ought not to interfere, without special justification, in the chosen course of any rational being or impose on any rational being conditions that will prevent him from pursuing his chosen courses of action. Moral discourse is a form of discourse in which we try to guide action rationally. We try to determine action on the basis of a rational consid-

eration of the nature of the action and its context, not by some other means such as violence. Any interference with the chosen course of a rational being is a determination of his action by force or at least a limit imposed by force on the extent to which his actions may be rationally determined. Such interference must then be presupposed as absent in public objective practical discourse in which action is determined by reason, and hence in using such discourse, in participating in it as an institution, one is presupposing that one ought not to interfere by force, but only by rational persuasion, in the chosen course of any rational being.

The arguments given for these three principles are very much oversimplified, and it could not be claimed that they have the force of demonstrations. But enough has been said to show that the type of argument they represent is at least a possible one and hence that the apparent conflict between autonomy and objectivity is not a real one and that the problem of the justification of ultimate principles may not be insoluble.

#### COMPLETENESS AND APPLICATION OF PRINCIPLES.

Two important problems remain. The first we may deal with briefly. It is one that was very important to Kant, with regard to both theoretical and practical principles. How can we be sure that we have achieved completeness in any list of principles? If ultimate principles can be established only by transcendental arguments, we have at least some clue to the answer to this problem; for the rest it might be argued that the problem is not so urgent as some have thought.

A transcendental argument is one that depends on an account of what is necessary to a given form of discourse; in ethics we are concerned with what is necessary to a form of discourse that is practical, universal, objective, and autonomous. We are, that is, dependent on a consideration of the formal characteristics of the form of discourse. This gives at least some negative criterion for deciding what principles may be justified as ultimate. Thus, it would be most implausible to suggest, for example, that "One ought not to drink alcoholic liquor on Sundays" could be justified as an ultimate moral principle. For it is reasonably obvious that no direct connection could be established between the purely formal characteristics of any form of discourse and such particular matters as are picked out by the concepts of the principle in question. Such a principle would have to be, if justifiable at all, one that would depend on matters beyond the purely formal characteristics of practical reason. It is always possible, however, though in this case surely a fan-

tastic suggestion, that someone with sufficient ingenuity might show that some apparently low-level principle is in fact justifiable as an ultimate one by a transcendental argument. And this may disturb us, for how can we be sure that we are not failing to take account of such principles all the time? We should not, however, be much disturbed, for two reasons. First, if a principle is a necessary condition of the possibility of moral discourse, one would expect to find it as a pervasive explicit or implicit principle of most moral codes (allowing for the resources of human confusion), and this is true for the three principles—justice, benevolence, and liberty—we have mentioned. Second, when it is suggested that there is a reason for acting in one way rather than another, the suggestion requires justification, in the absence of which the suggestion may be reasonably ignored. The onus of proof is on anyone who suggests that a certain principle is correct; until such proof is at least suggested, the fear that there may be quite unknown principles, which are not generally accepted but which could, with sufficient ingenuity, be justified transcendently, is an idle one.

The second difficulty that we face at this point is of the utmost importance; indeed, one might fairly say that out of it all the really important and difficult questions of substance in ethics arise. It is the problem of the application of these principles to particular situations, both in themselves and in relation to one another. Unless it is possible to show that these principles can be rationally applied, then no amount of rational demonstration of the ultimate principles will enable us to show that the particular moral judgments we make can be rationally justified.

In this article it has been argued that any account of how particular judgments about what ought to be done can be justified will need to examine principles that are necessary but not sufficient to justify particular judgments. These principles will pick out factors of general moral relevance, and the principles in turn will require justification. This may then require reference to more general principles, but some principles that are incapable of further justification will be reached in this way, and these we have called ultimate principles. It would seem that ultimate principles could never be justified objectively, but it is suggested that arguments that show them to be necessary if objective practical discourse is to be possible would justify them and that such arguments are possible. It is, however, emphasized that since ultimate principles are necessary but not sufficient to the justification of particular judgments, we have not by this suggestion solved the whole problem of how ethical disagreement can be rationally resolved. We have only

removed one ground for saying that they can never be rationally resolved.

### **Bibliography**

For an account of objectivity and autonomy, and an attempt to justify certain factors as ethically relevant from a consideration of the formal character of practical reason, see Immanuel Kant, *The Moral Law: Kant's Groundwork of the Metaphysic of Morals*, translated by H. J. Paton (London, 1964).

Attempts to justify ultimate principles are to be found in Jeremy Bentham's *Introduction to the Principles of Morals and Legislation* in *A Fragment on Government, and an Introduction to the Principles of Morals and Legislation*, edited by W. Harrison (Oxford, 1948); J. S. Mill's *Utilitarianism in Utilitarianism, Liberty, and Representative Government*, No. 482A in *Everyman's Library*; Henry Sidgwick's *Methods of Ethics* (London, 1907; reprinted 1962).

More recent attempts to justify some factors as of ultimate ethical relevance are to be found in Kurt Baier's *The Moral Point of View: A Rational Basis for Ethics* (Ithaca, NY: Cornell University Press, 1958), especially Chs. 7–8, and Baier's two articles in *Philosophical Studies*, 4 (1953)—“Good Reasons,” 1–15, and “Proving a Moral Judgment,” 33–44; J. N. Findlay's *Values and Intentions* (London: Allen and Unwin, 1961), his “Morality by Convention,” in *Mind*, n.s., 53 (1944): 142–169, and his “Justification of Attitudes,” in *Mind*, n.s., 63 (1954): 145–161; Philippa Foot's “Moral Arguments,” in *Mind*, n.s., 67 (1958): 502–513, and her “Moral Beliefs,” in *PAS*, n.s., 59 (1958–1959): 85–104; A. P. Griffiths's “Justifying Moral Principles,” in *PAS*, n.s., 58 (1957–1958): 103–124; D. L. Pole's *The Conditions of Rational Inquiry* (London: University of London, Athlone Press, 1961), especially Ch. V; M. G. Singer's *Generalisation in Ethics* (London, 1963); S. E. Toulmin, *An Examination of the Place of Reason in Ethics* (Cambridge, U.K.: Cambridge University Press, 1950; reprinted 1958).

## MORAL PSYCHOLOGY

Moral psychology is the area of scholarship that investigates the nature of psychological states that are associated with morality—states such as intentions, motives, the will, reason, moral emotions (such as guilt and shame), and moral beliefs and attitudes. The purview of moral psychology also includes associated concepts of virtue, character trait, and autonomy. It has generally been

thought of as a descriptive enterprise rather than a normative one, though this is not always the case.

Traditionally we can see two different approaches to moral psychology. The first is the *a priori* approach to understanding moral psychology and the significance and function of psychological states. The second is the empirical approach that considers the evidence of their significance, function, and development. Both of these strands will take as their starting point common sense intuitions about how people think about morality, make moral decisions, and the circumstances under which they feel moral emotions. These intuitions may be based on a long history of observation of human behavior, or they may simply be the result of natural selection leading to similarity in thought which itself might be adaptive. Either way, common sense provides the baseline for research in moral psychology.

The *a priori* strand engages in conceptual analysis of the relevant psychological states and their connections. There is a debate, for example, about whether reason alone can motivate, or not. What *explains* our actions? Is it the case that when I give money to charity I do so simply because I believe it will help people who need help, or do I also need to desire to help them? This will engage us in a discussion of the distinction between belief and desire. A view, which can be traced back at least as far as David Hume, holds that beliefs are of matters of fact and can be true or false; desires, on the other hand, have no truth-value. And, it is desires that are essentially motivating.

Thus, whenever one wants to fully explain an action one needs to be able to identify the belief/desire combination that gives rise to it. But this seems to present a puzzle for moral action: often, morality requires us to act against our desires. I am required to keep my promises, even if I don't want to. But how can I keep my promises if I don't want to, when desire is necessary for action? So there is also a *normative* question that can be raised. Presumably I am giving money to charity because I think that it is a good thing to do. I accept the norms of giving. So, is it the case that if I think that giving to charity is good, it *necessarily* provides me a motivating reason for giving? Is there a necessary connection, or conceptual tie, between the normative reason (the recognition that giving is good) and my motivation to perform the action of giving? If I think there is, then I am an “internalist”; if, however, I do not believe that there is a necessary connection, then I am an “externalist.” The acceptance of the norm, the recognition that giving to charity is a good thing, will then necessarily mean that I have at least a

weak desire to act on the reason. This could, of course, be defeasible.

But there are those who disagree. Those who are externalists, such as David Brink, argue that amoralists can recognize moral reasons—for example, the amoralist can recognize that it is good to give to charity—yet utterly fail to be moved by this recognition. Indeed, that is what it is to be an amoralist. They are defective not because they fail to see moral reasons as moral, but precisely because they recognize them and yet fail to be moved by them at all. Internalists argue that amoralists, when they articulate a belief that “*x* is good” and then fail to be moved, do not *really* believe what they have articulated. They are trying to make moral judgments, but they are failing to actually do so. Michael Smith also allows that such agents may be practically irrational.

A related feature of Hume’s view of moral psychology is its commitment to the view that desire is a given. That is, one cannot reason oneself into a *basic* desire. One can reason about non-basic desires—for example, perhaps I would like to eat ice cream today. Then someone points out that ice cream really isn’t very healthy. Since I would rather eat healthy food, I now no longer desire to eat the ice cream. But the desire to eat the ice cream is not basic. Rather, I would like to feel good—and once someone points out to me that a habit of eating ice cream will make me less likely to keep feeling good in the long run, that desire to eat ice cream falls away. But I have not been reasoned out of the basic desire. Indeed, it is its conflict with this desire that makes me ready to jettison the other.

But other writers disagree with this Humean conception of desire, and the reason/desire dichotomy. They believe that we can rationally reflect on basic desires and come to change them through the force of this rational reflection alone. For example, one might argue that desires, even some fundamental ones, are based in part on beliefs that we have. If I desire, for example, to avoid treating persons as means, it may be that I have this desire because I think that being respectful toward others requires this, and I believe, with good reason, that respecting others is obligatory. This desire could be basic in that it cannot be reduced to another desire. If this case is plausible, then we have a basic desire supported by reason.

One way to view this case is as that of a commitment one has. The desire to avoid treating others disrespectfully is more than just a strong basic desire that I have, which happens to be stronger than the other desires I have that might conflict with it. It is a commitment, a normative commitment that I have, and I have it for rea-

sons that are motivating reasons. These reasons carry the desire to be respectful of others with them. Further, there are reasons for this desire having to do with my beliefs about, perhaps, what it is to be a flourishing human being. Presumably I could be argued out of the desire, then. A Humean might try to respond to this, however, by pointing out that any “argument” one would give would in turn depend upon some stronger desire for its force. Desires are not themselves true or false, but they can loosely be considered irrational if based on false beliefs. Beliefs exposed as false would then presumably lead to an alteration of the desire one had based on that belief. In the example that I cited above, then, the Humean would probably say that my desire to be respectful of others is based on the belief that this is good and obligatory—so that simply shows that I have a more basic desire to live up to my obligations.

The field of moral psychology also has a more empirical side. Aristotle believed that the observation of human beings could reveal to us what, for human beings, was *eudaimonia*. Thomas Hobbes believed that an astute observer of human nature would find support for psychological egoism. Charles Darwin believed that natural selection could account for the sorts of emotions that human beings feel, including the moral emotions. Data that psychologists have gathered about human behavior have influenced the way some think about morality. For example, the work of psychologist Carol Gilligan raised the issue of gender differences in approaches to thinking about moral problems, which in turn influenced writers in feminist ethics.

More recently, empirical psychological research has been brought into moral theory to shed light on a host of issues, ranging from the issue of what, exactly, goes on in a person’s brain when she thinks about moral issues, to the issue of the innateness of our moral cognition, to the seemingly basic commitment human beings have to moral objectivity. There is also the extremely interesting and important issue of how natural selection has shaped our sense of morality and moral practices, as well as our moral intuitions. For example, Jesse Prinz has done work in comparative psychology that offers evidence against moral nativism. He believes that the evidence best supports the view that there is not even a minimal innate moral competence—instead it is culture that guides the formation of our moral capacities.

The work of Shaun Nichols draws on literature in developmental psychology to investigate the claim, widely argued in meta-ethics, that people are generally moral objectivists. That is, that people accept the view

that there are some true moral judgments, and when a moral judgment is true, it is non-relativistically true. Nichols points out that experiments in developmental psychology, though not at this point in time conclusive, point to the view that for persons, generally, moral objectivism is the “default position” when it comes to commonsense, or lay, meta-ethics.

There is also a trend in moral philosophy of exploring the significance of emotion in moral judgment. This has a counterpart in the psychological research. Joshua Greene and Jonathan Haidt refer to this as the “affective revolution.” The interest in this area of psychological research was sparked by Antonio Damasio’s work showing that good reasoners needed affect. When portions of the brain that regulate affect are damaged, agents do not perform very well on follow-through in practical reasoning tasks. The classic case, discussed by Damasio, is Phineas Gage. Gage was a railway worker who suffered damage to his frontal lobe in an accident in 1848. This caused an apparently extreme personality change that involved inappropriate emotional responses and a disposition to impulsive behavior. He became unreliable and untrustworthy. He was able to reason in the abstract but was not able to carry through. Affect thus at least seems crucial to effective moral motivation. This conclusion was supported by studies involving more recent cases of frontal lobe damage.

Greene’s own work explores brain activity when persons consider moral dilemmas. He and his colleagues discovered that when personal dilemmas were presented to subjects—that is, situations in which those being harmed are close to the subject—there is far more brain activity in the emotional areas of the brain, and those areas of the brain underlying social cognition, than when the problem cases were impersonal. We do seem moved to help in personal cases to a greater extent than impersonal cases. This research supports what charitable organizations have long realized. To promote giving there is a need to make the plight of the suffering personal to potential givers—through photographs and letters, for example. Of course, this leaves untouched the question of what people ought to do. While it is true that our emotions are engaged more in these personal situations, that has no implications for what our obligations are in these cases. This is where we need normative ethics.

Still, this line of research supports the descriptive view that when we behave morally, or at least think about moral issues, in a way that has more motivating force, there is considerable engagement of our affective capacities. Further, when those affective capacities are impaired,

we are left with agents whom we would describe as morally defective. Phineas Gage was widely considered to be a deadbeat after his accident. That is a moral judgment of his character, and the appropriateness of that judgment has something to do with the fact that he lacked the correct emotional responses, those appropriate for the circumstances in which he found himself.

Empirical psychological research has also influenced literature on virtue ethics. Virtue ethics is a type of normative ethical theory that bases moral evaluation on virtue concepts. The approach has been attacked for its failure to reflect psychological reality. For example, Gilbert Harman’s work on virtues makes use of situationist literature in social psychology. He argues, citing situationist experiments, that there are no character traits. Rather, the best explanation for a person’s behavior is his situation—so, if one would like a reliable way to predict behavior, one needs simply to look at the person’s situation. Persons who are in a hurry will be less likely to help than persons who are not. Persons who smell fresh cookies baking are more likely to act benevolently than those who are not smelling the cookies, and so forth.

Thus, character traits need not be cited at all in reliable predictions or explanations. There is no reason to think they exist. Further, if there are no character traits, then there are no character traits that are virtues. It would follow then that virtue ethics is a non-viable normative ethical theory, since it assumes what does not in fact exist. There are no stable character traits, at least, no stable and robust moral character traits. John Doris has softened Harman’s claim somewhat, also by bringing in evidence from empirical psychology. On Doris’s view all that is warranted by the empirical data is the view that character traits are not “global”—that they are more narrowly prescribed and local than intuition would have it. Thus, there may not be a general robust trait of benevolence, but there may be a trait of “benevolence when one smells cookies” and “benevolence when one is not in a hurry,” and so forth. Doris still views even this weaker position as a threat to virtue ethics since it cuts against the assumption that there are robust, global character traits. A virtue ethicist is free to respond that even if Doris is correct, virtue ethics may still offer a regulative ideal. After all, it is a theory of how we ought to be, not how we are.

Assuming, with common sense intuitions, that there are character traits that qualify as virtues, is there any particular psychology that characterizes moral virtue? Here we move away from use of evidence from experimental psychology and back to philosophical analysis of normative concepts that is, nevertheless, sensitive to our views of

psychological reality. In my own work I argue there is no special psychology that characterizes moral virtue, and that what counts as a moral virtue is characterized by externalities such as the consequences that the traits systematically produce. Other writers, such as Rosalind Hursthouse, disagree. Taking Aristotle as her inspiration, she holds that virtue states require that the agent have certain psychological states, such as a kind of practical wisdom that is needed for deliberating well about what to do—presumably, one needs to deliberate well in order to be a good person. Another writer who has attacked this moral psychology of the virtues is Nomy Arpaly, who argues that all that is needed is that the agent be responsive to the right sorts of reasons.

It is true that one thing that we hold people responsible for is their failure to be responsive to the right sorts of reasons. If one observes an agent acting with a callous disregard for the well-being of others, this can give rise to feelings of outrage. Thus, these failures of appropriate responsiveness can generate moral emotions that are indicative of our moral commitments. For example, we have a commitment to a norm of honesty. This norm is important to regulating our social interactions. In a person of reasonably good character, a failure to be honest will lead to feelings of remorse. Also, in a person of reasonably good character, seeing another behave dishonestly will give rise to a reactive attitude of outrage or resentment. When such feelings are appropriately felt, this may serve as good evidence that there has been a moral failure.

Reactive attitudes, then, can figure into accounts of moral responsibility and moral accountability. R. Jay Wallace, for example, has developed an account of what it is to hold someone responsible, morally—it is an attitudinal stance toward someone, a third-person stance that crucially involves reactive attitudes. If one holds someone responsible for having done something bad, then it is appropriate to feel something like resentment toward that person. Note that this is not a descriptive claim. It is true that normal persons do feel resentment under these circumstances. It is also the case that this indignation or resentment is *appropriate* when one has been wronged. Thus, though there is some disagreement over this, the sphere of moral psychology does involve an investigation of some normative issues having to do with the normative status of some of the mental states and character traits central to moral evaluation.

## MORAL REALISM

Moral realism is a metaethical view committed to robust objectivity in ethics. No single description is likely to capture all realist views, but a reasonably accurate rule is to understand moral realism as the conjunction of three theses:

The semantic thesis: The primary semantic role of moral predicates (such as "right" and "wrong") is to refer to moral properties (such as rightness and wrongness), so that moral statements (such as "honesty is good" and "slavery is unjust") purport to represent moral facts, and express propositions that are true or false (or approximately true, largely false, and so on).

The alethic thesis: Some moral propositions are in fact true.

The metaphysical thesis: Moral propositions are true when actions and other objects of moral assessment

have the relevant moral properties (so that the relevant moral facts obtain), where these facts and properties are robust: their metaphysical status, whatever it is, is not relevantly different from that of (certain types of) ordinary non-moral facts and properties.

To deny any one of these three theses is to embrace some form of moral irrealism. Many philosophers consider moral realism the default position because it appears best to capture many central features of ordinary moral thought: the assertoric surface character of ordinary moral discourse, the phenomenology of moral experience, our claim to have moral knowledge, and the possibility (and nature) of genuine moral error, progress, and disagreement even among sincere, open-minded, and well-informed people (Dancy 1986, Brink 1989, Shafer-Landau 2003).

The semantic thesis is (for better or worse) often associated with the related psychological thesis called cognitivism, according to which the primary role of moral judgments is to express beliefs. One form of irrealism, non-cognitivism, holds that their primary role is to express motivational “non-cognitive” states of mind, such as approving, prescribing, commending, or planning, but can assign moral predicates and judgments a secondary role of referring to (non-moral) properties and expressing (non-moral) beliefs (Copp 2001). How well realists can explain the reliable connection between moral judgment and moral motivation is a matter of some dispute (Smith 1994).

The alethic thesis says that some moral propositions are robustly true only if we combine it with the realist’s metaphysical thesis. The irrealists’ attitude to the alethic thesis depends on their conception of truth. Error theory accepts a robust reading of the semantic thesis but rejects the alethic thesis on this robust reading. It holds that ordinary moral thought presupposes the existence of robust moral facts and properties but is systematically in error: every moral judgment with existential import is mistaken because there are no robust moral facts to make any such judgment true (Mackie 1977). Non-cognitivist irrealists can accept a non-robust reading of the alethic thesis if they endorse minimalism about truth (but see Dreier 2004). This move may eventually earn them the right to speak of moral facts and truths, and to say all the same things that any morally decent person would say about what is right or wrong, good or bad, just or unjust, and so on, even though they reject the realist’s metaphysical thesis (Blackburn 1993).

The metaphysical thesis is central to moral realism because realism is primarily a view about metaphysics,

not about truth or semantics. It holds that moral facts and properties are not metaphysically inferior in kind to many ordinary sorts of non-moral facts and properties. What is it for a fact or property to be metaphysically robust, though? One sense in which ordinary non-moral properties are robust is that they enter into explanations of real phenomena; water has its surface properties because it is H<sub>2</sub>O, for example. In this sense, the realist’s metaphysical thesis says that moral properties enter into explanations of phenomena that irrealists would explain by other means (Dreier 2004). An irrealist might take the fact that one believes that inequality is unjust to consist in some such fact as that one has decided to include the reduction of inequality among one’s aims. A realist might instead say it consists in standing in a certain belief-like relation to the properties of inequality and injustice. Likewise, the realist might say, whether such a belief is correct or mistaken is just a matter of whether the two properties are related as the belief represents them as being related. The realist’s explanation of the assertoric features of ordinary moral discourse, possession of moral knowledge, and nature of moral disagreement would be analogous.

Understanding the metaphysical thesis as above affords one (albeit not the only) way of capturing many realists’ conviction that ethics concerns objective matters of fact whose existence and nature are independent of anyone’s sentiments, opinions, evidence, or theories about what is right or wrong, obligatory, permissible, or impermissible, good or bad, and so on. So understood, the thesis also classifies as irrealist any view according to which explanations of moral phenomena involve no essential reference to moral facts or properties, but only to such factors as our individual tastes, cultural or social conventions and agreements, basic human sentiments, or the beliefs or plans we would have if we were fully informed and rational. Thus ethical subjectivism, ethical relativism, projectivism, and most forms of constructivism in ethics rightly count as irrealist even though they accept the realist’s semantic and alethic theses.

Disputes within the realist camp concern primarily the nature of moral facts and properties. Non-naturalist realists hold that moral properties are robust properties that are distinct from but supervene (see below) on natural properties (Moore 1903, Shafer-Landau 2003). Naturalist realists hold that moral properties are robust natural properties. Reductive naturalists hold that moral properties are identical to natural properties that we can represent in austere non-moral terms (Railton 1986). Non-reductive naturalists hold that moral properties are an irreducible subclass of the class of natural properties,

which we may be unable to represent in austere non-moral terms (Boyd 1988, Brink 1989).

Arguments for and against different forms of moral realism differ also depending on whether we take true statements of property identity to be analytic (true in virtue of the meanings of their constituent terms) or synthetic, and what we think qualifies a property as natural. If, for example, natural properties are just those that we can investigate empirically, then naturalism will hold that knowledge of any synthetic moral proposition is answerable to empirical evidence, whereas non-naturalism will hold that knowledge of some synthetic moral propositions is empirically infeasible (Copp 2003, Shafer-Landau 2003). An issue for synthetic naturalists in particular is what determines the reference of moral predicates to the supposedly natural moral properties. Given their view of the matter, can they explain the intelligibility of such “open questions” as whether something that satisfies a given naturalistic non-moral predicate (such as “is pleasant”) also satisfies a given moral predicate (such as “is good”) (Moore 1903, Horgan and Timmons 1992)?

According to the supervenience argument against moral realism, we can distinguish between a weaker, true claim and a stronger, false claim about the supervenience of the moral on the natural. (*Supervenience* is a technical name for a relation of necessary covariance.) The alleged problem for the realist is that she cannot, but the irrealist can, explain why the weaker supervenience claim should be true, given that the stronger claim is false (Blackburn 1993). According to one clear version of the argument (Dreier 1992), the true claim is that it is analytically necessary that, for each moral property *M* that an object *O* has, there is a (possibly complex) natural property *N* that *O* has, and it is metaphysically necessary that *M* always accompanies *N*. The stronger, putatively false claim differs in saying that *M* always accompanies *N* as a matter of analytic necessity. (Variations of the argument concern predicates rather than properties and involve different types of necessity.) The objection is that if realists are committed to the thesis called “lack of entailment,” according to which no set of non-moral naturalistic truths entails any particular moral truth, then they must admit (falsely) that it is possible for *M* sometimes not to accompany *N*.

Different forms of moral realism respond differently to the supervenience argument. Analytic naturalists may regard the argument as question-begging, for they deny that the stronger supervenience claim is false (Jackson 1998). Non-naturalists may accept a lack of analytical entailment but claim that duly specified sets of naturalis-

tic truths metaphysically entail particular moral truths because the facts which the former concern exhaustively constitute (in some sense to be explained) the facts which the latter concern (Shafer-Landau 2003). Some synthetic naturalists may say that their theory explains why the weaker supervenience claim is true (since moral properties are natural ones), but entails that no set of non-moral naturalistic truths analytically entails any particular moral truth (since any connection between non-moral and moral truths is synthetic). Others may express doubts as to whether the relevant supervenience claims are formulated so as to make them both interesting and acceptable to synthetic naturalists.

According to the explanatory argument against moral realism, properties of a certain kind are metaphysically robust only if they make a distinctive contribution to our overall explanatory picture of the world (the “explanatory requirement”), but moral properties make no such contribution; therefore, moral properties are not metaphysically robust. A prominent version of this argument claims that mentioning moral properties such as wrongness makes no distinctive contribution to causal explanations of such occurrences as a person’s indignation or her judgment “that’s wrong” upon seeing some hoodlums set a cat on fire, above and beyond the contribution of mentioning the person’s prior beliefs, aversions, and moral principles (Harman 1977). If so, the causal version of the explanatory requirement gives us good reason to deny that there are robust moral facts.

One realist response is to argue that the causal requirement is dubious; for if it is, then it would be no objection to moral realism if moral properties violated that requirement (Shafer-Landau 2003). Moral properties could still play non-causal explanatory roles. A very different response is to accept the causal requirement, but argue that mentioning moral properties can make a distinctive contribution to causal explanations of both intentional occurrences, such as moral judgments, and non-intentional ones (Sturgeon 1988, Brink 1989). On the latter score, one may argue that a person’s kindness can cause her to help others or that injustice or oppression can provoke resistance, and that these properties can play such causal-explanatory roles only if they are real, and indeed natural, properties. Here the intricate question arises whether moral properties are epiphenomenal, in that they play no causal-explanatory role over and above the causal-explanatory role of the non-moral properties on which they supervene, or by which they are realized (Miller 2003, Sturgeon 2005).

What unites these debates about moral realism is the concern whether, and how, robust moral facts and properties enter into accounts of various phenomena that irrealists would explain by other means. One general moral may be that arguments in metaethics often are arguments about the best explanation of the phenomena in question. Other important debates between realists and irrealists and within the realist camp concern the rational authority of morality, the extent to which moral realism affords a rational basis for resolving moral disagreements, the existence of an internal connection between moral judgment and moral motivation and whether such “motivational internalism” would make moral properties metaphysically strange, and questions about moral methodology and moral epistemology, such as the place of ethics in a naturalistic worldview and the parity or continuity of ethics with empirical inquiry and the sciences.

*See Responsibility, Moral and Legal*

## MORAL RULES AND PRINCIPLES

Normative rules and principles say what things are required or permitted or good or bad. In other words, normative rules and principles say what agents ought to do or what agents are allowed to do; or what deserves to be promoted, praised, or approved; or what deserves to be opposed, criticized, or disapproved. Moral rules or principles differ from normative ones of other kinds (such as rules or principles of law, etiquette, or clubs) in that moral rules or principles indicate what agents morally ought to do or are morally allowed to do, or what deserves moral praise and admiration.

Rules and principles are (to at least some extent) general—that is, they are about kinds of situations or about classes of cases, not about individual instances. So rules or principles are juxtaposed with judgments about a particular instance. The judgment that Martin Elgin-brodde ought to feed his hamster at 8 a.m. on July 7, 2007, does not articulate a rule. Rather, it articulates a judgment about what a particular person should do on a particular occasion. Because rules and principles are about kinds of situations or classes of cases, rules or principles entail judgments about particular instances. The

principle that people ought to feed their pets entails that Miguel ought to feed his cat, that Janet ought to feed her dog, that Rahul ought to feed his bird, that Jo ought to feed his ferret, and so on for as many pet owners as there are.

Many philosophers have held that moral rules and principles must apply universally. What it is right for one person to do must be right for anyone else to do unless there is some morally relevant difference between the cases. This thought is reflected in the Golden Rule and serves as a cornerstone of the moral philosophies of Immanuel Kant and Richard M. Hare. But one important difference between Kant and Hare concerns the degree of detail and complexity they allow into moral principles. Kant thought moral principles had to be quite simple; Hare thought they could be highly detailed and complex as long as they were formulated in completely universal terms.

How stringent are moral rules and principles? Most people must take moral rules and principles to be very important—in particular, to generate very strong reasons for action. Otherwise, the degree of social cooperation and solidarity that moral rules and principles are supposed to provide is unlikely to be achieved. Some philosophers—for example, Ronald Dworkin (1977)—have held that moral rules can be more specific and less stringent than moral principles. A moral rule might be: “Be especially kind to your parents.” A more general and stringent principle might be: “Be especially kind to your benefactors.” In a case where a parent has not been a benefactor, for example, a father who always ignores the plight of his offspring, the rule “Be especially kind to your parents” might fade to nothing.

Admittedly, even the rule “Be especially kind to your benefactors” can be overridden. To take an extreme example, being kind to benefactors might conflict in some situation with saving many innocent lives. Suppose that for some reason one can either go to thank benefactors or devote the time to saving innocent lives, but not both of these things. With respect to such a case, the principle “Be especially kind to benefactors” seems morally less important than the principle “Prevent harm to others.” Many other moral rules or principles are likewise capable of being outweighed or overridden in certain cases by other moral rules or principles.

Are there any rules or principles that always outweigh any opposing moral considerations? Consider the principles “Do not do what is morally wrong” and “Do what you morally ought to do.” Such principles concern compliance with all-things-considered moral verdicts.

These principles tell us to do whatever is, all things considered, morally required. They give us no indication which moral considerations win out over others to generate all-things-considered moral verdicts.

Are there any rules or principles that both provide information about what morality requires and always outweigh any opposing moral considerations? Two kinds of principles have been suggested. One of these kinds consists of moral principles outlawing evil purposes, such as “Do not, for its own sake, harm others” and “Do not, for its own sake, deceive others.” The other kind consists of principles offered as the most general and basic principle of morality, such as Kant’s “Act only on maxims that you can will to be universal laws” and the act-utilitarian’s “Do whatever acts promote aggregate well-being.”

There are other moral theories that put forward other foundational principles. For example, T. M. Scanlon’s (1982) contractualist theory of morality claims that moral wrongness is determined by rules for the general regulation of behavior that no one could reasonably reject as the basis of informed, unforced, general agreement. Richard B. Brandt’s (1967) rule-utilitarian theory holds that moral wrongness is determined by rules that have the highest expected impartial utility. Rosalind Hursthouse’s (1999) virtue ethics holds that an act is wrong if it is one that would not be done by someone with a full set of the character traits that benefit others or the agent.

Some philosophers think that the theories just mentioned are mistaken to claim that morality is so unified. For example, pluralists such as William David Ross (1930) think that there is a plurality of basic moral principles that identify the features that count morally in favor of actions that have them (moral pros) and other features that count morally against the actions that have them (moral cons). These moral pros and cons are the appropriate inputs to moral assessment; a verdict about all-things-considered moral rightness or wrongness is the appropriate output. Rossian pluralists think that these moral principles (and thus the moral pros and cons that the principles identify) can conflict. For example, the fact that an act would benefit others counts in its favor, and the fact that an act would keep one’s promise counts in its favor. Sometimes, however, keeping one’s promise is not what would benefit others.

Rossian pluralists also think that the principles do not come in a strict hierarchy of importance that would resolve all the possible conflicts among them. This presents the question of what is the right thing to do when the Rossian principles conflict. Rossian pluralists hold that

which principle wins when there is conflict among them cannot be captured in a correct, informative, general principle. For example, a general principle that benefiting others always trumps keeping promises is not correct. Neither is a general principle that keeping promises always trumps benefiting others. Instead, in some situations it is right to keep a promise though one could benefit others more if one broke the promise, but in other situations it is right to break a promise if this is necessary in order to benefit others. So Rossian pluralists admit that moral verdicts about right and wrong cannot be systematized in correct informative general principles. They maintain that, when basic principles conflict, the right thing to do is a matter of judgment rather than a further principle. Still, Rossian pluralists think that moral principles have an important place, namely, in identifying the moral pros and cons.

Some philosophers think even principles about what counts as a moral pro or a moral con are incorrect. These philosophers are called moral particularists. Particularists hold that, for any feature of an action or its consequence that is a moral pro in one situation, that same feature might be a moral con in another situation. Whereas Rossians think that the fact that an act would benefit someone is always a reason in favor of the act, particularists think that, in some situations, the fact that an act would benefit someone is morally positive but in other situations it is morally negative. Wiping sweat from a torturer's brow, for example, would benefit the torturer but would not count in favor of the action. More generally, particularists maintain that features of actions can switch moral "polarity," depending on the context. Most will agree that one should try to help the person being tortured rather than wiping the torturer's brow. The question is how to explain what the inputs to that verdict are. Particularists say that the fact that wiping the torturer's brow would benefit him is no reason to do it, but rather, a reason against doing it.

On this issue, antiparticularists divide into two groups. Antiparticularists in one group say that the potential benefit to the torturer is massively outweighed by the importance of trying to help the person being tortured. But antiparticularists in this group hold that the fact that wiping the torturer's brow would benefit him counts at least a little bit in favor of wiping his brow. Antiparticularists in the other group agree with particularists that the fact that wiping the torturer's brow would benefit him is no moral reason to wipe his brow. Antiparticularists in this second group thus agree with particularists that the example about wiping the torturer's brow

refutes the claim that benefiting someone is always a moral pro. But these antiparticularists oppose particularism by claiming there is some other feature that does always have the same moral polarity. For example, these antiparticularists might claim that any act with the feature of benefiting an innocent person has at least this in its moral favor. In other words, antiparticularists in this second group abandon the more general claim that benefiting a person is always a morally positive feature, but they insist on the somewhat less general claim that benefiting an innocent person is always a morally positive feature.

The debate over particularism is mostly about whether there are any correct informative general principles, either that specify all-things-considered moral rightness or that indicate which features always operate as moral pros or cons. Antiparticularists win the debate if they come up with correct informative general principles of one or both kinds. Particularists win if they show that every informative general principle put forward is incorrect.

The debate over particularism has other elements as well. On the one hand, particularists say that one can often see not only which features count in which way in a particular situation but also what is all-things-considered morally right in that situation. If particularists are right about that, the question is posed: What is the point of trying to formulate general principles if we can see which particular acts are right without them?

On the other hand, antiparticularists point out that we commonly take being unprincipled as a serious moral flaw. Why is being unprincipled such a moral flaw if acting on principles is not part of being moral? Furthermore, why does moral education start with learning rules and principles if these end up playing no role in determining moral rightness? And why does moral reasoning so often consist in comparing different cases if correct moral judgments are always about particular cases rather than about classes of cases or types of situations?

Particularists pose a challenge to the idea that principles play an essential role in morality. This challenge has forced other moral philosophers to be more specific about which principles they defend and about what roles they think principles must play. Rossian pluralists think correct informative principles are only about moral pros and cons. Many other philosophers—for example, utilitarians, Kantians, contractualists, and virtue ethicists—think that there is a correct informative general principle specifying a foundational principle of right and wrong,

yet there is persisting disagreement among them over what this principle is.

## MORAL SENSE

In the first half of the eighteenth century certain British philosophers argued that the "moral sense" is the faculty by which we distinguish between moral right and wrong. The deliverances of this faculty are feelings or sentiments; hence, it is counted as a sense. Our observation of an instance of virtuous action is the occasion for a feeling of pleasure or satisfaction, which enables us to distinguish that action as virtuous. Similarly, our observation of an instance of vicious action is the occasion for a feeling of pain or uneasiness, which enables us to distinguish that action as vicious. The moral sense is also an influencing motive in our pursuit of virtue and our avoidance of vicious behavior, and it plays a part in our bestowal of praise and blame.

### HISTORICAL BACKGROUND

Arguments for and against the moral sense take their character from the larger social and intellectual context in which they were advanced. The late seventeenth century and early eighteenth century in Europe saw the culmination of certain lines of thought that had their origin in earlier times. The Protestant insistence on individual conviction in purely religious matters had an effect on other areas of thought as well. The rejection of external authority as the guarantor of religious truth and the consequent reliance of each believer on his own inner light led to a full-blown theory of knowledge in which the different ways a person can know different kinds of subject matter were definitively cataloged. The way of knowing a given subject was appealed to as the foundation or guarantee of truth. The first account of this theory of knowledge was John Locke's *Essay concerning Human Understanding* in the late seventeenth century. The most comprehensive statement of it was the *Treatise of Human Nature* by David Hume in the eighteenth century. These developments in theory of knowledge were closely related to a growing interest in feelings and their expression. The new theory of knowledge was also closely connected with changes in beliefs about God's relation to the world. Speculations about the will of God were no longer a necessary preliminary to doing physics. When the notion of a physics without God met in men's minds with a resistance to religious authority in all matters, including morals, the problem was posed of the possibility of accounting for morality without an appeal to a divine source. But if morality is not founded on God's will, where is the foundation laid? In line with the new theory of knowledge, the most promising direction for a search appeared to be in human nature itself.

The first Englishman to search for the foundation of morals in human nature, Thomas Hobbes, returned with a brilliantly stated but outrageous report. He found that *good* and *evil* are relative to the person who uses these words; and when people are joined together in a commonwealth, then good and evil are subject to the determinations of the commonwealth. As for our motives for pursuing good and avoiding evil, they may be summed up as self-interest. Were it to our own interest to pursue what others, or the commonwealth, have designated as evil, we certainly would; but, for the most part, our appreciation of the convenience that follows from everyone's following the same rules and, at the worst, our fear of punishment on being caught deter us from the practice of evil.

Hobbes's unflattering picture of human nature and his relativistic account of morals, which he presented in *Leviathan*, are the ominous and ever-present background of all discussions of moral philosophy for the next hundred years. They called forth their contradictory counterpart in the writings of the third earl of Shaftesbury. Shaftesbury argued that Hobbes had made a shortsighted survey of human nature. There is benevolence in human nature, as well as selfishness; and indeed, if men were not originally endowed with a disposition to be sociable, the formation of a commonwealth would be impossible. Shaftesbury was the first to attribute to a moral sense our ability to distinguish between good and evil, virtue and vice. This sense, along with our natural affection for virtue, accounts for the possibility of morality. Shaftesbury, however, did not make clear how the possession of a moral sense enables us to avoid relativism in moral judgments; and indeed the specter of relativism must inevitably haunt the proponents of the moral sense.

#### DEVELOPMENT OF THE DOCTRINE

The systematic development of the doctrine of a moral sense was left to Shaftesbury's successors: first Francis Hutcheson and later Hume. Their first move was to fit the moral sense into the mainstream of eighteenth-century philosophy by finding a place for it in Locke's theory of knowledge. Looking into the human mind, Locke found that all knowledge consists of perceptions, which must arrive in the mind by one of two routes, either sensation or reflection. Whatever can be known must be accounted for as a perception; and whatever cannot be accounted for in this way is not knowledge. The proponents of the moral sense accounted for our knowledge of moral right and wrong as Lockean reflexive perceptions. When someone observes a given action or considers a certain charac-

ter trait, these first perceptions are immediately followed by a secondary set of feelings of either pleasure or uneasiness, according to whether the action or character is virtuous or vicious. By consulting these secondary perceptions, we can make our moral judgments. The proponents of the moral sense were careful to point out that actions are not virtuous *because* they please. Rather we know them to be virtuous because we are pleased in a *certain manner*. Thus, moral pleasures and pains are distinctive feelings. Hume argued for the possibility of distinguishing different kinds of pleasure by pointing out, for example, that someone may be pleased both by a good musical composition and by a good bottle of wine, and their goodness is determined merely by the pleasure they give; but we do not say on that account that the wine is harmonious or the music of good flavor.

Besides accounting for our knowledge of right and wrong, the moral sense closes the gap between moral knowledge and moral behavior by providing a motive for moral behavior. Since moral knowledge consists of feelings of pleasure and uneasiness, the prospect of enjoying or avoiding these feelings is a sufficient motive for pursuing virtue and avoiding vice. If moral knowledge were not ultimately a matter of feelings, it would be possible for someone to know that a certain kind of action is virtuous but still have no motive for doing it. The moral sense also enables us to account for our approval and condemnation of actions and characters as following from our being pleased or pained by them.

#### CRITICISM

The moral sense was subjected to two sorts of criticism. The first sort was directed against supposed defects in the doctrine of the moral sense itself. The second sort of criticism advanced the claims of rival candidates for the title of moral faculty.

**DEFECTS IN THE DOCTRINE.** The bluntest form of the first sort of criticism was to interpret the proponents of the moral sense as talking about an extra organ of sense, "a moral nose" or "a moral ear." How acute they were to have discovered a new human organ which no one had noticed until they came along! Merely to mention the possibility was enough to show the nonexistence of such an organ and to render the doctrine of a moral sense laughable. Hutcheson was especially plagued with this kind of criticism. But he spoke of the moral sense as a determination of the mind, which left the way open for viewing the moral sense not as an organ but as a faculty that can be looked for only in the way memory or will can

be looked for. Hume's defenses against this criticism were somewhat better. He boldly asserted the principle that our acquaintance with our senses or faculties can never be anything but an acquaintance with their characteristic perceptions. Hence, he was justified in confining himself to talk of moral feelings and sentiments; and indeed, he never actually used the phrase "moral sense" in any argument but relegated it to a section title.

The next most severe criticism was to point out that although all men are said to be endowed with a moral sense, there is no universal agreement about moral right and wrong. Hutcheson turned aside this criticism by arguing that the moral sense may be inoperative or defective, just as human eyes may be. Hume added that differences in moral judgments may be attributed to differences in experience and education and to a failure to pass judgment from a disinterested point of view; and he hoped that by additional experience or by a greater effort to achieve disinterestedness moral disputants might be able to reach agreement.

But the critics of the moral sense thought that by far the most serious fault in the doctrine was its apparent foundation of the distinction between moral right and wrong on human nature itself. This opened the door to Hobbesian relativism: Whatever action pleases is virtuous, and whatever displeases, vicious. Actually, Hutcheson based the distinction between virtue and vice on the will of God, one step removed from human nature. It just so happens, he held, that God determined us to be pleased by benevolent actions; and when nothing interferes with the moral sense, we count benevolence a virtue and malevolence a vice. But, his opponents argued, to base the distinction between moral good and evil on God's will is no less arbitrary than to base it on human nature itself. If, by divine fiat, we count benevolence a virtue, we might very well have done the opposite, had God so pleased. What is more, the distinction between good and evil cannot possibly rest on God's will, for if good and evil have not some real character in themselves, what is there to determine his will in the first place?

Hume based the distinction between moral right and wrong directly on human nature—that is, our power to be pleased and displeased by different ways of acting—without an appeal to any divine determination of this power. But if there is to be a stability in the distinction between moral right and wrong, then there must be a consistency in human nature. This is no easy thing to show, for the slightest inspection of human affairs appears to tell against it. Yet Hume argued that, on balance, man is more of a social being than not. Indeed, this

contention had always been strongly supported by proponents of the moral sense; but Hume added the refinement that man's very inclination to be social leads him to be pleased by those actions and character traits which tend to make society possible and to be displeased by those which tend to disrupt society. Thus, while the distinction between virtue and vice does indeed rest on human nature, it is not an arbitrary distinction. We do have a good reason for preferring one sort of action to another, namely the action's tendency to maintain society. Should someone ask, "And why should I prefer the maintenance of society to its destruction?" Hume had no answer in the form of a logical argument. He certainly recognized the possibility of someone's preferring the destruction of society over its maintenance; but on such a fundamental issue, he held, there can be no arguments pro or con, but only an appeal to feelings. Society exists because, as a matter of fact, by far the greater number of people have the kind of feelings that make it possible.

**RIVAL MORAL FACULTIES.** Another set of objections to the moral sense was advanced by those who argued that the faculty by which we discern moral right and wrong must be reason, or the understanding. The most notable members of this school were Samuel Clarke, John Balguy, and Richard Price. Their most characteristic doctrine was that moral right and wrong are unchanging and unchangeable and, thus, independent of any human, or even divine, determination. This school accepted Locke's theory of knowledge with the modification that the understanding is capable of originating new simple ideas for itself by considering those it gets by way of the two great avenues of sensation and reflection. Thus, according to Clarke, the understanding can discern a certain eternal fitness that things and actions bear to one another in their natures. He likened these moral discoveries to mathematical reasoning in which one discovers the consistency of certain concepts. The implication is that the absolute and immutable character of moral distinctions is such that they can be known only by reason. Therefore, the moral faculty could not possibly be a sense.

Hume endeavored to answer these arguments by pointing out that, strictly considered, reason is capable only of comparing ideas. Since moral knowledge is a sentiment or feeling that arises on the observation of an action or character trait, it is not the result of comparing ideas, and thus it cannot be a conclusion of reason. What is more, since our moral sentiments about certain actions may excite us to perform or to avoid these actions, it is even more doubtful that our moral knowledge comes from reason, for, according to Hume, the conclusions of

reason alone can never be an exciting motive to action. A person may know that a certain way of acting may have a certain result, but in order for him to act to achieve that result, he must first find it pleasing.

The moral sense and reason were not the only candidates for a moral faculty proposed at that time. Joseph Butler argued for conscience; and Adam Smith chose to argue for sympathy—which had also figured in Hume’s moral philosophy—as the source of moral distinctions. Considering the arguments advanced on behalf of the different candidates for the moral faculty, one can see that the issue was never one that could be settled by empirical investigation. The search for a moral faculty had its origin in the general acceptance of a faculty psychology, supplemented with the Lockean assumption that the acts attributed to our mental faculties are to be accounted for as the occurrence of various sorts of perceptions. When one recognizes the ad hoc character of the conceptual framework in which the disputes over the nature of the moral faculty took place, one can see why there was no resolving them. When one no longer finds a need for a faculty psychology, the need to search for a moral faculty goes too.

The present-day moral philosopher no longer casts his study as an investigation of the deliverances of a moral faculty, but rather as a study of the logic of moral discourse. Despite their central preoccupation, the proponents of the moral sense have made a contribution to the development of modern moral philosophy. In particular, they contributed the points that morality assumes the value of society and is incomprehensible apart from this presupposition; that conduct must be judged by general rules; and that a general rule of definitive importance to morality is the injunction to act for the greatest good of the greatest number. But perhaps the most important contribution to moral philosophy by the proponents of the moral sense was their insistence that feeling has a place in morals and that to miss this fact is to omit a distinctive element in moral discourse.

## MORAL SENTIMENTS

One’s sentiments are the contents of one’s sensed, or felt, experience—in contrast to the contents of simply one’s thoughts. Whatever else they are, then, sentiments are affective phenomena. In common parlance, talk of sentiments refers alternatively to occurrent feelings, affective dispositions, and emotional attitudes taken toward people and objects. Moral sentiments, where the adjective *moral* is used in a descriptive sense, would then be some subset of these feelings, dispositions, and attitudes: those that are more or less intimately related to moral phenomena. Whether any of the moral sentiments thus understood are moral in a normative sense, that is, whether one morally may or should experience or express any of these sentiments in relevant circumstances, is a further question.

One problem that immediately confronts any philosophical account of moral sentiments is the question whether such affective phenomena in fact form a unified category. Affective responses vary widely with respect to their causes, phenomenology, duration, intentional objects (if any), and mode of expression, as well as their susceptibility to rational assessment and control. This variability is no less present in the case of that subset of affective phenomena related in some way to morals. Contrast, for example, rationally impervious and visceral disgust to resentment, a comparatively subdued attitude that arguably is a response fitting only to moral wrongs. Both disgust and resentment, however, are moral sentiments in the sense that people commonly experience these affective reactions in response to moral phenomena.

Just which phenomena one admits to the category of moral sentiments depends, of course, on the specific theory of the sentiments one accepts. Consideration of con-

temporary theories of the emotions is instructive here. Although such theories are quite varied, a common taxonomy distinguishes between cognitivist and noncognitivist theories of emotion. Cognitivist theories of emotion hold that emotions necessarily involve thoughts, beliefs, or judgments ascribing properties to their objects. Some cognitivists (Nussbaum 2001) identify emotions with evaluative judgments, for example, identifying fear with the evaluative judgment that the object of fear somehow threatens one's welfare or identifying one's resenting another's action with the judgment that the other wrongs one in so acting. Sentiments, understood as essentially affective phenomena, apparently play at best a peripheral role on some such theories of emotion.

Noncognitivist theories of emotion, in contrast, embrace a view of emotions as essentially felt experiences different in kind from thoughts beliefs or judgments. William James (1842-1910), famously identified emotions with the perception of bodily changes—or feelings—caused by external stimuli. Contemporary followers of James (Prinz 2004) have built on his emotional noncognitivism to avoid what they view as shortcomings of the cognitivist alternatives. Some noncognitivists object that emotions, unlike beliefs or judgments, are not properly subject to assessment in terms of truth or falsehood. Noncognitivists also object that cognitivist theories require that those subject to emotions possess a conceptual or propositional repertoire that obvious subjects of emotion—human infants and animals, for example—do not, in fact, possess. In response to such objections, some philosophers opt for mixed theories according to which emotions are some amalgam of cognition and affect (Oakley 1992).

Clarity about the correct theory of affective responses is a prerequisite for progress in the longstanding philosophical debate over the role of moral sentiments in moral agency. Philosophers have long debated the role of moral sentiments in, for example, (1) moral deliberation and judgment, (2) moral motivation, and (3) moral responsibility.

In examining the role of moral sentiments in moral deliberation and judgment, moral motivation, and moral responsibility, modern moral philosophers have been concerned especially with the role one should attribute to moral sensibility—generally understood as a capacity for experiencing, or disposition to experience, feelings, emotions, and attitudes that include guilt, resentment, respect, esteem, honor, pride, and shame—relative to the role of reason, understood as a cognitive capacity whose objects (e.g., thoughts or propositions) are amenable to

evaluation in terms of truth or falsehood. Moral philosophers committed to treating moral judgments as bona fide judgments, whether by taking them to refer to causally explanatory moral properties or by regarding them as subject to similarly robust standards of truth and falsehood as is descriptive discourse, are often known as metaethical cognitivists. Metaethical noncognitivists, in contrast, deny that moral evaluations identify irreducibly moral properties or report truth-evaluable beliefs. The distinction between cognitivism and noncognitivism in one's metaethical theory is independent of the distinction between cognitivism and noncognitivism about emotions. However, differences among philosophers concerning the relative role of sentiment and reason in the moral domain reflect philosophical differences in the specific theory of sentiment, or emotion, they accept.

## HISTORICAL CONTEXT

Although contemporary moral philosophers might be inclined to trace the term *moral sentiments* to developments in eighteenth-century British moral philosophy, philosophical interest in the affective aspects of one's moral experience is not limited to any specific epoch. Already in ancient Hellenistic philosophy, one finds a concern with the place of feelings, emotions, and affective attitudes generally in the constitution and care of the psyche, or soul.

For Plato (c. 429–347 BCE) and Aristotle (384–322 BCE), for example, human excellence (for them the subject of ethics) required that one's soul be properly constituted in the relation of its rational, desiderative, and appetitive parts—the latter comprising the domain of sentiments or emotions. For Plato, the proper constitution of the soul was an achievement of an upbringing where one's appetites (e.g., natural urges for food and sex), desires (e.g., aspirations for the goods of honor and victory), and rational judgments were in harmony. Absent a proper upbringing, the desiderative and appetitive parts of the soul were bound to prove unruly and psychically divisive, thereby making a good life unattainable. On such a view, arguably, all affects of the soul have ethical import, whether or not they have ethical content.

Aristotle further developed an account of the education of the soul where the parts concerned with feeling pleasures and pains functioned, at least in persons properly reared, as important guides for choosing and acting well. Affective dispositions of the soul could play this role for Aristotle because he understood the feeling part of the soul according to a perceptual model on which it could provide one with knowledge of the objects it perceived

through pleasure and pain, much as one's visual perceptions provide knowledge of the objects of sight. On this view, to possess virtues of character such as courage and justice consists in part in being disposed to experience the appropriate emotions in response to, respectively, fearful circumstances and the unfair distribution of goods.

The Stoic school of Hellenistic philosophers (of which Zeno of Citium [335–263 BCE] is an example) combined a rich cognitivist theory of the emotions as judgments concerning value with the prescription that the wise person, or sage, should ultimately expurgate himself of emotion altogether. The motivation for the prescription derived from the Stoic view that virtue is the only good. Other things of value (e.g., health, and wealth), while typically choice-worthy, are things about which the Stoic sage is properly indifferent. To the extent that emotions give importance to things other than virtue by judging them good, then, they implicate one in false judgments about the good. As such, emotions are antagonistic to reason, by whose power one should strive to eliminate them.

This antagonistic divide between sentiment and reason reappears in the early modern period, fueled by changes brought by the advance of Newtonian science, religious strife, and philosophy itself (e.g., John Locke's [1632–1704] philosophy of mind). It is in this, the early modern period, beset by changes that sustained doubt about the status of morality as a deliverance of revelation or of reason alone, that one first encounters the school of moral philosophers known as the *sentimentalists*: Anthony Ashley Cooper (the third Earl of Shaftesbury [1671–1713]) Frances Hutcheson (1694–1746), David Hume (1711–1776), and Adam Smith (1723–1790).

Shaftesbury is perhaps most often credited with having first used the phrase *moral sense*, defending it as a sense, quite literally, of moral right and wrong. According to Shaftesbury, the moral sense enables all persons to experience affections of approval or disapproval upon reflection on the first-order affections, or motives, of oneself and others. Judgments about what is morally right and morally wrong, as well as the motivations to action that they support, are on this view expressions of the reflective approval or disapproval that is fitting for one's and others' motives.

Hutcheson adapted Shaftesbury's theory of a moral sense that apprehended with approval virtuous motives, which Hutcheson understood as forms of benevolence, and responded with disapproval to the vicious. However, Hutcheson abandoned Shaftesbury's metaphysical views, among them the view that the immutable order of nature

guarantees the fittingness of these moral affections for their objects. Hutcheson also viewed reason, as opposed to sentiment, as a purely theoretical and, so, motivationally inert faculty. These two features of Hutcheson's philosophy are echoed in the empiricist sentimentalism of Hume.

An admirer of Cicero (106–143 BCE) and Tacitus (c. 56–120 CE), Hume inverted the Stoic hierarchy of reason and sentiment when he announced that “Reason is, and ought only to be the slave of the passions” (Hume 1973, II. iii. 3, p. 415). To be sure, Hume's slogan conceals a more nuanced Humean view of moral evaluation and moral motivation. Humans are naturally constituted, on Hume's view, to feel certain passions, or sentiments, in response to certain causes. Reason, exclusively concerned as it is with matters of fact and relations of ideas, cannot oppose passion in the sense that reason cannot cause us to form moral beliefs or motivate us to act in the absence of some affective input. Hume nonetheless distinguishes between better and worse ways of forming evaluative beliefs and between better and worse motives. He does so by privileging moral assessments made from what he calls the common or general point of view, a point of view one succeeds in occupying when one evaluates motives or character traits in terms of their typical effects. Such evaluation proceeds not through the operations of a moral sense but through the influence of the general point of view on what Hume identifies as the mechanism of sympathy. For sympathetic creatures occupying the general point of view, moral evaluation consists in apprehending whether the motives or character traits being evaluated are immediately agreeable or useful to oneself or others. In this way, Hume concludes “Morality...is more properly felt than judg'd of” (Hume 1973, III. i. 2, p. 470).

Smith developed his brand of moral sentimentalism in his *The Theory of Moral Sentiments* (1759/1982). Smith's sentimentalism resembled Hume's in privileging sympathy as a psychological process by means of which one comes to take pleasure in virtue and be pained by vice. Significantly, however, the two differed in their conceptions of precisely how sympathy operates on the sentiments. Whereas Hume envisaged moral evaluation being made from an observer's point of view on the motives or character traits of others, Smith's sympathetic exercise required one to consider motives and character traits by projecting oneself into the point of view of the possessor or those affected by that point of view. By thus imagining oneself in another's situation, Smith maintained, one comes to share in the feelings that the other person experiences. Sympathy, understood as an imagi-

native capacity for fellow-feeling, in this way provides one a motive toward benevolence, according to Smith.

The antagonistic sentiment–reason divide that some early modern philosophers championed is transposed into a semantic key in the work of some twentieth-century Anglo-American philosophers. The work of metaethical noncognitivists such as Charles Stevenson (1908–1979) and Alfred Jules Ayer (1910–1989) especially influenced the development of contemporary philosophical debate over the respective roles of sentiment and reason in morals. Ayer notably argued for a distinction between cognitive meaning (possessed by descriptive statements and analytic statements) and emotive meaning (possessed by moral statements). On Ayer’s view, moral utterances, appearances notwithstanding, serve not to assert facts but to express the emotions of the speaker. “In saying that a certain type of action is right or wrong,” he wrote in *Language, Truth, and Logic* (1936/1952), “I am not making any factual statement, not even a statement about my own state of mind. I am merely expressing certain moral sentiments.” Thus, on Ayer’s view, ethical utterances are not candidates for assessment in terms of truth or falsity. Stevenson endorsed Ayer’s so-called emotive view of moral language, though he was careful to stress the interconnections between descriptive and emotive meaning, as well as a meaning of *true* that might appropriately (albeit emotively) be applied to ethical statements. Caveats notwithstanding, Ayer’s philosophy of language, combined with the view that the proper task of philosophy is analysis of cognitively meaningful language, issued in an era when the work of the moral philosopher was limited to that of metaethical reflection on moral language and phenomena.

## CONTEMPORARY DEBATE

Although the days when Anglo-American moral philosophers limited their task to metaethical reflection have ended, the debate about the respective roles of sentiment and reason in moral deliberation and judgment, moral motivation, and moral responsibility lives on.

In the area of moral deliberation and judgment, the expressivists are the noncognitivist inheritors of emotivism. Like the emotivists, expressivists (e.g., Allan Gibbard and Simon Blackburn) distinguish between descriptive and evaluative discourse. Whereas emotivists such as Ayer hold that ethical utterances express the speaker’s sentiments, however, the expressivists defend a more complicated account of the affective phenomena expressed in ethical utterance. They do so in an attempt

to avoid now-familiar problems with emotivism; for, example, its difficulties accommodating ethical disagreement and explaining the behavior of ethical expressions in the embedded contexts and inferences common to moral deliberation.

More recently, a form of sentimentalism about ethical judgment has become popular that holds that ethical utterances that predicate some evaluative property *P* (such as, “murder is wrong”) do not express emotion but, rather, express the speaker’s endorsement of the having of certain emotions in response to property *P*. Following on the work of Gibbard, Daniel Jacobson and Justin D’Arms have begun to develop a form of *rational sentimentalism* that clarifies the kind of endorsement that is at issue in evaluative judgments generally. Making use of a generic relationship of *fittingness*, they offer an account of when one’s moral sentiments are fitting to their objects, which distinguishes this question from other appraisals of the sentiments (such as prudential and moral appraisals of these responses). Correcting past philosophers’ conflation of the claim that an emotion is fitting its object with the claim that it is morally appropriate to its object, their work promises to reinvigorate philosophical study of moral emotions that, while arguably fitting to their objects in certain circumstances, nonetheless have suffered neglect due to their perception as being somehow morally undesirable. Contempt and moralized disgust are examples.

Neosentimentalism about ethical judgment of the D’Arms/Jacobson variety is a form of emotional rationalism that bridges the metaethical noncognitivism/cognitivism divide. In some ways this neosentimentalism resembles the so-called sensibility theories of moral judgment espoused by metaethical cognitivists such as John McDowell. McDowell holds that moral sensibility functions much like perceptual ability: One’s moral sensibility enables one to apprehend and form beliefs whose contents are irreducibly moral properties, much as one’s visual perception allows one to apprehend color properties. Some contemporary moral philosophers rely on metaethical cognitivism, such as McDowell’s, to urge a return to an Aristotelian view of moral sentiment that rejects an inherently antagonistic divide between reason and sentiment. On such an Aristotelian view, ethical deliberation and judgment primarily differ from deliberation and judgment about nonmoral phenomena, not in any metaphysical or epistemological peculiarities pertaining to their content but in the necessarily practical nature of their progeny.

In stressing the obviously practical nature of moral deliberation and judgment (that is, the way in which it engages with intention, action, and affect), however, the metaethical cognitivist risks unwittingly fueling the metaethical noncognitivist program. If one holds, with the metaethical noncognitivists, that propositional attitudes such as beliefs are motivationally impotent in themselves, then acknowledging the practical character of moral deliberation and judgment requires one to reject a view of moral deliberation and judgment as exclusively cognitive phenomena. The metaethical noncognitivist's rejection is complete in denying that they are even partly so, a rejection supported by the noncognitivist tendency to understand mental phenomena in terms exclusively of beliefs or desires.

One response to this denial proceeds from arguing that such a mental repertoire is impoverished in failing to admit that certain mental phenomena, emotions among them, may possess the representational character of beliefs while also possessing the motivational force of desires. In this way, a more nuanced moral psychology might advance contemporary debate.

Finally, it is worth noting that although the necessarily practical character of moral deliberation and judgment typically is raised as a challenge for the metaethical cognitivist, cognitivism in the theory of emotion—at least those versions that simply equate emotions with evaluative beliefs—also invites the question of how to account for the motivational potency of emotions.

As this brief taxonomy suggests, different theoretical commitments—whether in moral theory or the theory of emotions—support different conceptions of how sentiments figure in moral experience. These commitments also support different views concerning responsibility for one's moral emotions. If emotions are akin to urges and desires, to pleasures and pains, or to perceptions of some sort—with respect to which individuals arguably are passive—is it even intelligible to regard oneself and others as accountable for emotions? If, alternatively, emotions are judgments, are individuals thereby any closer to locating a form of control one exercises over them that would justify holding oneself and others accountable for them? Or should one challenge the assumption, as do some philosophers, that such control is necessary for justifying attributions of responsibility?

The philosopher P. F. Strawson famously argued that even should the metaphysical thesis of determinism hold true, individuals could not avoid holding themselves and others in general responsible for what he called the reactive attitudes (for example, gratitude, resentment, for-

givenness, love, and hurt feelings). To be sure, he recognized, one often suspends these attitudes in special cases: the cases of children; the incapacitated. In the case of typical mature agents, however, susceptibility to the reactive attitudes is a condition of membership in a common humanity. On such a view, the theoretical question whether one possesses the freedom to control one's emotions is abandoned in favor of attending to the necessity of regarding oneself and others as responsible for emotions if one is to regard oneself and others as moral agents at all. The alternative, Strawson argued, is not a rational expurgation of such attitudes in deference to the determinist thesis but an objective stance toward oneself and others that amounts to viewing humans as perpetual patients, appropriate objects not of emotional engagement but of treatment. If Strawson is correct, philosophical interest in the moral sentiments is likely to continue to evade constraint to any single historical epoch, central as they are to moral personhood.

## MORAL SKEPTICISM

The two main forms of skepticism about morality are skepticism about moral truths and skepticism about reasons to comply with moral considerations. These doc-

trines challenge the cognitive significance or rational authority of morality.

Skepticism about moral truths denies that there are—or that we can know that there are—true moral propositions (or facts) that entail that something has a moral attribute. This form of skepticism seems to imply that rational and informed agents would give moral claims no credence. It has been supported by a variety of arguments, including arguments about moral disagreement. One deep motivation for it is the difficulty of explaining the normativity or action-guiding nature of moral claims.

Noncognitivists attempt to explain the normativity of moral judgments by supposing that their function is to express states of the speaker and to affect behavior rather than to express propositions. Noncognitivists would agree that there are no true moral propositions, since they hold that moral claims do not express propositions. Yet they do not view moral claims as defective. According to noncognitivists, one who makes a claim, such as "Truthfulness is morally required," expresses a moral attitude or acceptance of a moral norm (Ayer, [1936] 1946; Gibbard, 1990; cf. Hume, [1739–1740] 1978).

Cognitivists object that our moral thinking cannot be understood except on the assumption that moral claims express propositions. To avoid skepticism, cognitivists must believe that there are moral properties that are sometimes exemplified. For if no moral property exists, or if none is exemplified, it follows that there are no moral requirements, no moral goods or bads, no moral virtues or vices. It may follow that there are no *honest* persons, for example, although there may be truthfulness persons.

A skeptic might hold that moral properties exist but that none is exemplified. This position seems implausible, however, for if there is the property of wrongness, it would be astonishing if nothing were ever wrong. Alternatively, a skeptic might argue that there are no moral properties. According to widely accepted views about propositions, however, the proposition that lying is wrong, for example, would attribute the property wrongness to acts of lying. The property would be a constituent of the proposition. Hence, if there are no moral properties, these views about propositions may lead to the conclusion that no proposition is expressed by sentences such as "Lying is wrong."

J. L. Mackie argued that there are no moral properties (1977). We conceive of moral properties as intrinsic; if an action is wrong, it is wrong "as it is in itself." But we

also conceive of moral properties as intrinsically action guiding; we can be motivated to act in an appropriate way simply by coming to know that an action would be wrong, regardless of any antecedent motivations. Yet, Mackie thought, it is not intelligible that it be intrinsic to an action's having an intrinsic property that the mere recognition that the action has the property could motivate a person. The idea of a moral property is not intelligible; moral properties would be metaphysically "queer."

Gilbert Harman (1977) argued for an epistemic version of skepticism about moral truths. He argued that there seems to be no good reason to affirm any moral proposition, for moral hypotheses are never part of the best explanation of any observation. There is always a better nonmoral explanation. The belief that there are true moral propositions is therefore unwarranted.

Skepticism about moral truth appears to have a life of its own in secular cultures, independent of skeptical arguments. Some people believe that moral truths are grounded in God's commands. A secular culture would tend to think, however, that all substantive facts are empirical and "natural." And natural facts do not seem to be normative in the way moral facts are normative. It is therefore difficult to see how a natural fact could be a moral fact.

The second skeptical doctrine is the thesis that there need be no reason to comply with moral considerations. According to this thesis, rational agents would not give attention to moral considerations, as such, in deciding how to live their lives. To be sure, we may desire to live morally, and this desire may give us a reason to live morally. Or we may find ourselves in a context in which living morally is in our interest. Yet these possibilities do not show that there is necessarily a reason to comply with moral considerations (Nielsen, 1974); they do not distinguish moral considerations from considerations of etiquette, for example.

Skepticism about compliance is typically motivated by the idea that morality can require actions that are not to the agent's advantage. Assuming that there are reasons for one to do something just in case it would be to one's advantage, this idea implies that there may be no reason to comply with morality.

The two main skeptical doctrines are closely linked, on certain ways of thinking. First, it may seem, we cannot be guaranteed to have reasons to comply with moral considerations unless there are moral truths of which we have knowledge. Second, a kind of "internalist" theory holds that moral facts are "constituted" by reasons. On

this view there are no moral facts unless there are reasons of a relevant kind.

Internalist antiskeptical theories attempt to defeat both skeptical doctrines at once. Immanuel Kant held, in effect, that if a moral imperative corresponds to a truth, it does so in virtue of the fact that it would be complied with by any fully rational agent (Kant, [1785] 1981). "Externalist" theories attempt to deal with skepticism about moral truths independently from skepticism about compliance (Sturgeon, 1985). Those who believe that moral truths are grounded in God's commands may suppose, for example, that God necessarily gives us reasons to comply.

Philosophers who accept one of the skeptical doctrines typically try to defuse it. Skeptics about rational compliance may argue that people with normal psychologies invariably have reasons to comply with morality. Skeptics about moral truth may argue that there nevertheless are reasons to engage in the practice of judging things morally.

## MORE, HENRY

(1614–1687)

Henry More, the philosopher, poet, and Cambridge Platonist, was born at Grantham, Lincolnshire. His father, “a gentleman of fair estate and fortune,” was a strict Calvinist but supported church and king against the Puritans. He introduced his son to Edmund Spenser’s *Faerie Queene*, and Spenser’s Platonism, allegorizing, and moral attitudes persist in More’s own writings. At Eton, where More was educated, the religious atmosphere was latitudinarian; More abandoned the Calvinist doctrine of predestination without losing what he called “an inward sense of the divine presence.” In December 1631 he entered Christ’s College, Cambridge, where he was elected to a fellowship in 1639. He remained at Cambridge until his death, refusing preferments, except those he could pass on to such fellow Platonists as Edward Fowler and John Worthington. Unlike most of the Platonists he took no part in public affairs or in university administration. In *An Explanation of the Grand Mystery of Godliness* (1660) he defended what he called a “neutrality and cold indifference in public affairs.”

When More entered Christ’s College, it was split into three factions—the high church party, the Calvinistic Puritans, and the Medians, so called because they stood for a moderate church and had as their leader Joseph Mede, or Mead (1586–1638), author of *Clavis Apocalyp-tica* (1627), an allegorical interpretation of the Scriptures. More’s tutor Robert Gell, whose *Remaines* were published in 1676, was a member of Mede’s party; he emphasized even more strongly than Mede that salvation depended upon “good works,” not on blind faith, and he shared Mede’s fascination with demonology and Scriptural interpretation. More himself described Mede as an “incomparable interpreter of Prophecies,” and in *The Grand Mystery of Godliness* defends his biblical interpretations against the criticisms of Hugo Grotius.

### NEOPLATONISM

Developing a passion for philosophy, More read widely in Aristotle and the Scholastics. However, he became impatient with their failure, as he thought, to provide a satisfactory account of the relation between God and the individual self. He therefore turned to the Neoplatonists and to mystical writings, especially the *Theologia Germanica*, an anonymous fourteenth-century mystical handbook that Martin Luther republished in 1516. From the mystics and Neoplatonists More derived his belief that to acquire knowledge, one must first seek moral per-

fection and his definition of perfection as the process of becoming godlike by subduing egoism. More did not refer to Benjamin Whichcote, none of whose writings was published until just before More’s death, but he told his biographer that 1637 was the date of his conversion to his “new way of thinking”; this was the year of Whichcote’s appointment as Sunday lecturer at Trinity Church. More shared certain fundamental epistemological and metaphysical ideas with Ralph Cudworth. These were ultimately derived from Platonism, and how far Cudworth’s formulation of them influenced More or vice versa is impossible to determine.

More’s first philosophical writings were allegories in Spenser’s manner, collected in 1647 as *Philosophical Poems*. They present a complicated world view in which the basic concepts of Neoplatonism are interpreted in Trinitarian terms. Christ is presented as a living demonstration that a human being can be wholly possessed by God, rather than as a Calvinistic redeemer. More’s poems preach the lesson common to Cambridge Platonism that the life we live, not the creed we preach, is our path to salvation, but their obscure allegorical manner is quite remote from Whichcote’s direct, epigrammatic style.

### METAPHYSICS

In atmosphere the *Philosophical Poems* carry us back to the Renaissance. More saw Plato through the eyes of Plotinus and Plotinus through the eyes of Renaissance humanists such as Marsilio Ficino, who set out with the help of allegory to Christianize Neoplatonic metaphysics. Yet on December 11, 1648, More wrote the first of four Latin letters to René Descartes, in which he not only expressed the highest admiration for Descartes’s work but added that Descartes’s views “appear indeed to be my own—so entirely have my own thoughts run along the channels in which your fertile mind has anticipated me.” Nor was this a merely transient enthusiasm. In the general preface to his *A Collection of Several Philosophical Writings* (1662), he still spoke with admiration of Descartes. Yet in the *Divine Dialogues* (1668) and even more severely in *Enchiridion Metaphysicum* (1671) More criticized “the superstitious admiration” for Descartes and alleged that his views led to atheism, a charge against which he had previously defended Descartes.

Not surprisingly, More’s French critics accuse him of irresponsible fickleness. But if *Enchiridion Metaphysicum* is the first of More’s writings to be officially an anti-Cartesian tract, the fact remains, as Descartes realized from the beginning but More only slowly, that More’s leading ideas had always been in complete opposition to

Cartesianism. The central point in More's metaphysics as it is developed in *The Immortality of the Soul* (1659) and the metaphysical sections of *Divine Dialogues* and *Enchiridion Metaphysicum* is that extension is a characteristic of all substances and not, as Descartes had argued, a peculiarity of matter. Substances fall into two classes—spirits and material objects. Spirits are physically indivisible, can penetrate both other spirits and material objects, and can initiate motion; material objects are physically divisible, impenetrable, and capable of motion only when it has been communicated to them. But both spirits and material objects are extended. There are familiar objections to such an ontology; these concern, particularly, the compatibility of the two properties of being extended and being spiritual. In meeting these objections, More began by making two logical points. The first is that since we are never acquainted with essences but only with attributes, it is no objection to the extendedness of thinking beings that we “cannot see why” a being which thinks should also be extended. The second is that the intellectual separability of the properties of being extended and being spiritual is no proof of their incompatibility.

More's opponents have to show, he argued, that it is logically impossible for anything to be extended and yet to think. Most of the arguments that are supposed to establish this impossibility depend, according to More, upon the tacit identification of extension and materiality; the rest can be met by distinguishing between two forms of extension—metaphysical and physical. Metaphysical extension—pure space—is eternal, infinite, physically indivisible; physical extensions are finite, physically divisible, mutable. We can break up a particular cylinder, and we can easily imagine it not to exist, but we cannot take a piece out of space or imagine it not to exist. These properties it shares with God; indeed, space is an “obscure representation of the essence or essential presence of the divine being.”

More came to see in Descartes the leader of what he calls the nullibists, who deny extension to spirits. And although Descartes had set out to defend God and immortality—this was one main reason why More approved of him—More finally concluded that nullibism is atheistic in tendency. For More the essential feature of the soul is that it initiates movement. To do this, however, it must be where body is. This is possible because unlike material objects spirits can penetrate both other spirits and material objects, contracting or expanding like Isaac Newton's “aether,” as the occasion makes necessary. Thus, God, an individual mind, and a material object can all be present in the one place without losing their independ-

ence as substances. Spirit can be regarded, More argued, as a sort of fourth dimension; a body that contains a spirit has a certain “spissitude,” or density of substances.

More's criticism of mechanical explanation is along the same general lines. At first, he had welcomed Descartes's mechanical explanations; by carrying ingenuity, so More thought, as far as it could be carried, they made it clear just what the limits of mechanical explanation were. But his conclusion is that mechanical explanation is never possible and that to suppose otherwise leads to atheism. (The emergence of Benedict de Spinoza from the Cartesian school encouraged More in this belief.)

A material object, he said, is nothing but a “congeries of physical monads”—that is, a collection of atomic particles. To explain how these particles are held together in solid objects, we have to introduce a nonmaterial, although spatial, spiritual agent. Equally, he argued, gravity is inexplicable in mechanical terms; mechanics—he meant, of course, Cartesian mechanics—cannot explain why a bullet once fired from a gun should ever return to Earth's surface. Even more obviously, the behavior of living organisms cannot be derived from a collection of particles.

Indeed, in order to explain any natural process, we have to refer to spirit as something additional to material particles; spirits are the true cause of all activity. This does not mean that all activity is the work of conscious rational beings. Spirit exists at various levels; “seminal forms,” which are neither sensitive nor rational but are still capable of initiating motion, are responsible for actions at a level lower than animal feeling.

## RELIGION AND ETHICS

More's metaphysical theories are not worked out in detail. His main interests, indeed, were religious rather than metaphysical: to defend Christianity against its three main enemies—namely, atheists, Roman Catholics, and “enthusiasts.” *An Antidote against Atheism* (1653) reformulates the Ontological Argument but mainly relies upon anecdotes about animals to establish an Argument from Design and upon anecdotes about witches and apparitions to establish that spiritual forces are at work in the world. *Conjectura Cabbalistica* (1653), with the aid of the Jewish kabbalah, discerns Platonism and Cartesianism in Genesis; indeed, More expressed his regret that he had ever wasted his time on philosophy seeing that all fundamental truths are contained in the Bible. *A Brief Discourse of the Nature, Causes, Kinds and Cure of Enthusiasm* (1656) is directed against “enthusiasm,” defined as “a full but false persuasion in a man that he is inspired.”

More found the origin of enthusiasm in “melancholy”—that is, in a manic–depressive constitution. *The Grand Mystery of Godliness* defends the Cambridge Platonist concept of religion against Calvinists, atheists, and Roman Catholics alike; *An Antidote against Idolatry* (1674) attacks Roman Catholics. More had a special animosity against Quakers that increased in intensity when his disciple and admirer Anne Finch, Lady Conway, at whose home in Ragley, Warwickshire, he had been a frequent guest, became a convert to Quakerism.

More’s *Enchiridion Ethicum* (1667), translated into English by Edward Southwell in 1690 with the appropriate title *An Account of Virtue*, was the most popular of More’s writings in his own time but has since been neglected. It can be most succinctly described as a Christian version of Aristotle’s *Nicomachean Ethics*, although the detail is influenced by Descartes’s account of the passions and by mathematical ideals. (More set out a number of “moral axioms,” which incorporate an ethical calculus.) Virtue, More argued, consists in pursuing what seems to be in accordance with right reason, but both our capacity to discover what actions accord with reason and our inclination toward those actions flow from a special “boniform” faculty. Reason itself cannot incite action; virtuous action can be instigated only by the passional side of our nature. The ultimate ground of all virtue is intellectual love. Thus, More hoped to weld the Christian doctrine of love and the Aristotelian doctrine of intellectual activity into a single ethical system.

## INFLUENCE

More devoted the last seven years of his life to translating his English works into Latin in the hope of attracting wider interest on the Continent. They caught the attention of Gottfried Wilhelm Leibniz, but although he took an occasional phrase from More, he was interested in him mainly as a representative of the sort of view he particularly wished to avoid. In fact, More, the only one of the Cambridge Platonists to publish at all extensively, quite failed in what he conceived as his main task—to halt the advance of the mechanical worldview. More’s metaphysics, however, had a considerable influence on Newton even if mathematicians, not metaphysicians, were Newton’s principal masters. Newton did not refer explicitly to More—the Cambridge group almost never referred to one another—but the resemblances are conspicuous. Newton was taught mathematics at Grantham, More’s birthplace, by a former pupil of More’s; Newton’s correspondence reveals that he and More stood close to one another.

## Bibliography

### WORKS BY MORE

More’s *Philosophical Poems* are reprinted in Alexander Balloch Grosart, *The Complete Poems of Henry More* (Blackburn, U.K., 1878). Geoffrey Bullough, *Philosophical Poems of Henry More* (Manchester, U.K.: University of Manchester, 1931), is a selection with a valuable introduction and notes. More’s main philosophical writings are included in *A Collection of Several Philosophical Writings* (London, 1662) and his theological writings in *Theological Works* (London, 1708); the Latin version, *Opera Omnia* (London, 1675–1679), contains in addition a number of controversial pamphlets. Sections of the *Enchiridion Metaphysicum* were translated by Joseph Glanvill in his *Saducismus Triumphatus* (London, 1681) and are included in Flora Isabel MacKinnon, *Philosophical Writings of Henry More* (New York: Oxford University Press, 1925), with a useful bibliography and expository essays. Edward Southwell’s translation of *Enchiridion Ethicum* has been reprinted by the Facsimile Text Society (New York, 1930). The correspondence with Descartes is partly translated by Leonora D. Cohen in *Annals of Science* 1 (1) (1936): 48–61, and is included in Geneviève (Rodis-)Lewis, *Correspondance avec Arnaud et Morus* (Paris, 1953).

### WORKS ON MORE

For works on More see the bibliography under the “Cambridge Platonists” entry. See also Richard Ward, *The Life of Dr. H. More* (London, 1710); M. F. Howard has edited this life, but his introduction is not reliable (London, 1911). See also Marjorie Nicolson, ed., *The Conway Letters* (London: Oxford University Press, 1930), and Paul Russell Anderson, *Science in Defense of Liberal Religion* (New York and London: Putnam, 1933). For More’s relation to Newton see Edwin Arthur Burt, *The Metaphysical Foundations of Modern Physical Science* (London: Kegan Paul Trench and Trubner, 1925; rev. ed., 1950), and Alexandre Koyré, *From the Closed World to the Infinite Universe* (Baltimore: Johns Hopkins Press, 1957). On the opposite side see Edward William Strong, *Procedures and Metaphysics* (Berkeley: University of California Press, 1936), and Stephen Edelston Toulmin, “Criticism in the History of Science: Newton on Absolute Space, Time and Motion,” in *Philosophical Review* 68 (1) (1959): 1–30, and (2) (1959): 203–228.

## MORE, THOMAS (1478–1535)

Sir Thomas More, later canonized St. Thomas More, was a lawyer and statesman rather than a philosopher. More was born the son of a London lawyer who later became a judge. He was educated at St. Anthony's School and was appointed a page in the household of Archbishop (later Cardinal) Morton, who sent him to Canterbury Hall, Oxford, in the early 1490s. More left without a degree to study at New Inn and Lincoln's Inn in London. His lectures dealt not only with law but also with St. Augustine's *City of God*. He early composed various English poems and Latin epigrams that were not printed for years. However, a Latin translation of four Greek dialogues of Lucian appeared in 1506, and an English translation of the Latin life of his model, Giovanni Pico della Mirandola, in 1510. Increasingly involved in public affairs, More became a member of Parliament in 1504, beginning the career that

led to the well-known events of his chancellorship and his martyrdom. By the time of the *Utopia* (1516), he had long since mastered Greek and enjoyed the friendship of such humanists as Desiderius Erasmus, Thomas Linacre, William Grocyn, John Colet, Cuthbert Tunstall, and St. John Fisher.

### PHILOSOPHICAL ORIENTATION

With respect to his philosophy, Thomas More belonged very much to the early or Erasmian period of the English Renaissance in his emotional and intellectual attitudes—toleration of eclecticism, search for simplicity, stress on ethics, return to Greek sources, and desire for reform: social, political, educational, religious, and philosophical. These traits appear not only in his highly imaginative and durably significant creation, *Utopia*, but also in his most pertinent pronouncements in real life. The latter may be divided into two philosophical periods, roughly separated by the year 1521, the year of publication of Henry VIII's *Defense of the Seven Sacraments (Assertio Septem Sacramentorum)*, which More undertook to defend by his pseudonymous diatribe (1523) against Martin Luther's strictures.

During his first period, in his justly famous letters to Martin Dorp (1515), to the University of Oxford (1518), and to a monk (1519–1520), More opted for a simplified logic, the study of all Aristotle's works in Greek with their classical Greek commentaries, and the mastery of the Greek New Testament and Greek Fathers as well as the pagan classics in the original language. He praised the Aristotelian paraphrases of Jacques Lefèvre d'Étaples and, in a letter to Erasmus (May 26, 1520), expressed complete agreement with Juan Luis Vives's *False Dialecticians (Pseudodialectici)*. His attack on contemporary Schoolmen centered on their preoccupation with logic, the universals, and a mere fragment of the Aristotelian corpus.

In his second, controversial period, More rose to the defense of Thomas Aquinas and the scholastic theologians, whose doctrine he showed to agree with that of the earlier church. However, since the interest of these works, even of *A Dialogue of Comfort against Tribulation* (1534), is almost entirely theological, there is no need to dwell on them, except to point out that he held the common scholastic views on the mutual relationship, harmony, and assistance between reason and revelation, with philosophy as the propaedeutic to theology and as the handmaid of theology. This synthesis appears in a fundamental form even on the island of Utopia, where ethical norms are bolstered by religious truths and where the

true religion can prevail in an atmosphere of free and calm reasoning.

## UTOPIA

Since *Utopia* is More's major, or at least most influential, writing, its philosophical elements will be discussed in detail.

**BACKGROUND.** Renaissance thinkers usually held that there were four great philosophical schools: Platonism, Aristotelianism, Stoicism, and Epicureanism, which differed mainly according to their opinions of the *summum bonum*. The Christianization of Aristotle was accomplished in the thirteenth and fourteenth centuries by the Schoolmen, and that of Plato in the fifteenth century by Marsilio Ficino and other humanists. Stoicism had found expression in almost boundless humanistic admiration for the writings of Seneca and especially Cicero before reaching definite formulation later in the Christian Stoicism of Justus Lipsius. It was therefore inevitable that humanistic attempts, if only rhetorical ones, should be made to Christianize Epicurus, too. The latter's rehabilitation had been much accelerated in the early fifteenth century by Ambrogio Traversari's Latin translation of his life by Diogenes Laërtius. Lorenzo Valla had set forth Epicurus's doctrine favorably in *De Voluptate ac de Vero Bono* (*Pleasure and the True Good*). Finally Erasmus undertook his thorough baptism in *De Contemptu Mundi* (*The Contempt of the World*, written c. 1490) and the colloquy *The Epicurean* (published 1533). In both these works, Erasmus manipulated the concept of pleasure and the principles of selection to establish a Christian Epicureanism.

**EPICUREANISM IN UTOPIA.** More's main sources for classical Epicureanism were undoubtedly the *Lives* of Diogenes Laërtius and the *De Finibus* of Cicero, with minor borrowings from Seneca, Quintilian, Lucian, and Aulus Gellius. The "Christian" modifications already introduced by such humanists as Lorenzo Valla and Erasmus should not be minimized. The preoccupation of Renaissance men with the problem of pleasure is evident from the many humanistic treatments of the subject, including that by Ficino. Consequently Epicurus and Epicureanism are here viewed not according to their historical reality but according to the light in which they appeared to Thomas More through his reading and conversation.

In spite of the great to-do in the *Utopia* about the philosophy of pleasure and in spite of the deliberate but superficial rejection of Stoicism, the emphasis on virtue

and virtuous living is disproportionate, even extraordinary, and therefore suspicious. This respect for Stoicism also becomes explicit in the stress on the guidance of nature, the assumed existence of natural law, and the natural community of humankind.

There are several contacts between Utopian and Epicurean hedonism. The most evident, naturally, is the exaltation of pleasure as the *summum bonum*, to which all human activities, including the operations of the virtues, are directed and subordinated. But the term *pleasure* (*coluptas*) is so manipulated in the *Utopia* that it embraces everything from scratching an itch to enjoying eternal bliss with God. Like Epicurus, the Utopians hold to both kinds of pleasure: pleasure as a state and pleasure as motion. Hence health for them is a true pleasure. Like Epicurus, they belittle neither the joy arising from conferral of a benefit, nor the testimony of a good conscience as the reward for just deeds, nor the importance of mental pleasures. There is a common emphasis with Epicurus on the simple life, which in Utopia leads to the ridicule of false, unnatural delight in fine clothing, noble ancestry, glittering jewelry, gold and silver, gambling, and hunting. Perhaps the most important connection is the enunciation of the principles of selection; the single positive criterion is that a pleasure be natural—a criterion recognized as so obscure that it is delimited by three negative norms: that no pain follow the pleasure chosen, that no greater pleasure be lost, and that no social harm result.

**DIVERGENCES FROM CLASSICAL EPICUREANISM.** The departures from the postulates of classical Epicureanism are so radical that the Utopian philosophy in action can be labeled Epicurean, or even hedonistic, only in the broadest sense. For example, good Utopians must believe in the providence of God, the immortality of man's soul, and divine retribution in a future life. These Utopian principles are taken not from Epicurus but from More's great favorite, Plato, especially his *Laws*. Utopian ascetics, with their hope of reward in a future life, would be ridiculous to Epicurus. The Platonic origin of Utopian communism also is evident, for Epicurus thought that the holding of property in common by friends implied mutual mistrust. Minor points of divergence are the emphasis upon marriage (in contrast with its disapproval by Epicurus in spite of his traditional devotion to his parents), upon euthanasia (in comparison with Epicurus's denial of suicide even to the blind), and upon learning (Epicurus urged his disciples to fly from learning in the swiftest ship available). Utopians love their gardens, but for practical rather than philosophical purposes, so that,

surprisingly, no reference is made in *Utopia* to the connection between Epicurus and gardens.
