Locke's tendency toward inconsistency can be seen in his definition of knowledge as "the perception of the connection and agreement, or disagreement and repugnancy, of any of our ideas" (*Essay*, IV.i.2). This is plainly incompatible with his later contention that we have intuitive knowledge of our own existence, demonstrative knowledge of God's existence, and sensitive knowledge of the existence of particular things. Nonetheless, Locke would not abandon his position for the sake of consistency alone. He was persuaded that common sense and the facts justified his conviction and that whatever faults there were in his position lay in the difficulty of stating a coherent theory of knowledge, not in the reality of things. If this made him an easy prey to a skillful dialectician, like Berkeley, it also left him closer to the common conviction of most of us when we think about anything other than epistemology. It is this viewpoint, almost unique in philosophy, that accounts for the abiding interest in Locke's thought and the great extent of his influence despite the shortcomings of his work.

**PURPOSE OF AN ESSAY.** In "Epistle to the Reader" Locke related that some friends meeting in his chamber became perplexed about certain difficulties that arose in their discourse about a subject (left unnamed). He proposed that before they could inquire further, "it was necessary to examine our own abilities and see what objects our understandings were, or were not, fitted to deal with." This discussion in 1670 or 1671 first started Locke on the inquiries that were to continue intermittently for twenty years. What Locke first set down for the next meeting is not known, unless it was Draft A (1671) of *An Essay con-*

*cerning Human Understanding*. That the initial suggestion became the abiding purpose of *Essay* is clear from Locke's assertion that his purpose was "to inquire into the original, certainty, and extent of human knowledge, together with the grounds and degrees of belief, opinion, and assent" (I.i.2). At the same time he disavowed any intention to examine "the physical consideration of the mind, ... wherein its essence consists, or by what motions of our spirits or alterations of our bodies we come to have any sensation by our organs or any ideas in our understandings, and whether those ideas do in their formation any or all of them depend on matter or no" (I.i.2).

Locke did not, in fact, offer any detailed or explicit accounts of these matters. He would have considered that a subject for natural philosophy. Nonetheless, he did, as indeed he had to, deal with the physical considerations of the mind, as well as all the other matters mentioned.

From the outset Locke was persuaded that our understanding and knowledge fall far short of all that exists; yet he was equally certain that men have a capacity for knowledge sufficient for their purposes and matters enough to inquire into. These convictions, pragmatic and utilitarian, set Locke apart from most of the other major philosophers of the seventeenth century, who, impressed by the new developments in mathematics and the new physical sciences, boldly plunged ahead with a rationalistic realism in the belief that their new methods would enable them in large measure to grasp reality. Locke saw that the very advances made in the new sciences put reality farther from the reach of the human mind. This did not make Locke a nominalist or an idealist in any modern sense; rather, he persistently affirmed the real objective existence of things or substances. What he denied was that the human understanding could know with certainty the real essences of substances. If "ideas" stand between reality and the understanding, it is to link them, even if only under the form of appearances. It is not to obliterate any connection between them or to justify a negation of substance—God, mind, or matter.

IDEAS. The key term in Locke's *Essay* is "idea," which he defined as "... whatsoever is the object of the understanding when a man thinks, ... whatever is meant by phantasm, notion, species, or whatever it is which the mind can be employed about in thinking" (I.i.8). Any object of awareness or of consciousness must be an idea. But then how can we have any knowledge of anything other than ideas and their relationships? It is true that Locke spoke of ideas as the "materials of knowledge." Yet knowledge itself, when possessed and made the object of

the mind, must be an idea. For example, to perceive that *A* is equal to *B* is to perceive the agreement between *A* and *B*. This agreement as perceived must be an idea, or it cannot be an object of the mind when it thinks. Despite this difficulty Locke clung tenaciously to his term "idea" in his disputes with Stillingfleet. He actually intended something other than he stated, namely, that knowledge is an operation, an activity of the mind, not initially one of its objects. It would have served his purpose better had he spoken of "knowing" rather than of "knowledge," even though this would not have entirely removed the difficulty, since to set the mind at a distance where we may look at it, in order to know what knowledge is, is still to have an idea.

Locke, however, went beyond ideas to assume the real existence of things, substances, actions, processes, and operations. Ideas, except when they are the free constructs of the mind itself, signify and represent, however imperfectly, real existences and events. So deep was Locke's conviction on this point that no argument could shake him, although he constantly tried to remove the difficulties implicit in his definitions of "ideas" and "knowledge." This conviction is evident in the first two books of *Essay*, in which Locke inquired into the origin of our ideas.

NO INNATE IDEAS. It was Locke's central thesis, developed extensively in Book II of *Essay*, that we get all our ideas from experience. The whole of the first book is given to an overlong criticism, at times not germane to the subject, of the doctrine that we have innate ideas and innate knowledge.

Locke contended that there are no innate principles stamped upon the mind of man and brought into the world by the soul. In the first place, the argument that people have generally agreed that there are innate ideas, even if true, would not demonstrate the innateness of ideas. Moreover, there are no principles to which all give assent, since principles such as "Whatever is, is" and "It is impossible for the same thing to be and not to be" are not known to children, idiots, and a great part of mankind, who never heard or thought of them. Locke here assumed that innateness was equivalent to conscious perceiving and argued that to be in the mind is to be perceived or to be readily recalled to perception. Locke allowed that there is a capacity in us to know several truths but contended that this lent no support to the argument that they are innate.

To argue that all men know and assent to certain truths when they come to the use of reason proves noth-

ing, since they will also come to know many truths that are not innate. It would appear, then, that all truth is either innate or adventitious. Again, why should the use of reason be necessary to discover truths already innately in the mind? Locke allowed that the knowledge of some truths is in the mind very early, but observation shows such truths are about particular ideas furnished by the senses; for example, a child knows the difference between the ideas of sweet and bitter before it can speak and before it knows abstract ideas. Even assent at first hearing is no proof of innateness, for many truths not innate will be assented to as soon as understood.

On the contrary, the senses first furnish us with particular ideas, which the mind by degrees becomes familiar with, remembers, and names. The mind subsequently abstracts from these particular ideas and gives names to general ideas. Thus, general ideas, general words, and the use of reason grow together, and assent to the truth of propositions depends on having clear and distinct ideas of the meaning of terms. Locke held it to be evident that particular propositions are known before the more universal and with as much certainty.

We have natural faculties or capacities to think and to reason. This is not, however, the same thing as having innate ideas, for if anyone means by innate ideas nothing but this natural capacity, he uses terms, according to Locke, in a manner plainly contrary to common usage.

In a similar fashion, Locke argued that we have no innate moral or practical principles, for there is no universal agreement about such principles; great varieties of human vice have been at one time or place considered virtues. We all have a desire for happiness and an aversion to misery, but these inclinations give us no knowledge or truth. Locke was persuaded that there are eternal principles of morality, which men may come to know through the use of reason about experience. This, however, is far from proving them innate.

In the third chapter of Book I Locke argued that no principles can be innate unless the ideas contained in them are innate, that is, unless men can be conscious of them. Impossibility and identity are hardly innate, yet without them we cannot understand the supposedly innate principle of identity, that it is impossible for the same thing both to be and not be. Similarly, the proposition that God is to be worshipped cannot be innate, for the notion of God is so diverse that men have great difficulty agreeing on it, while some men have no conception of God whatsoever.

*Locke's target.* Who was Locke criticizing in his long and repetitious attack on the doctrine of innate ideas? Was the position he denounced held by anyone in the form in which he presented the theory? Why did he examine the question at such length?

Since *Essay* was first published tradition has held that Locke's target was Descartes and the Cartesians. Certainly Leibniz thought so, as did others after him. In the late nineteenth century, critics pointed to Locke's own rationalism and noted that his recognition of men's natural faculties and innate powers to think and reason is not far from the position of Descartes, who wrote, "Innate ideas proceed from the capacity of thought itself," and "I never wrote or concluded that the mind required innate ideas which were in some sort different from its faculty of thinking." Various other possible objects of Locke's attacks were suggested, the Cambridge Platonists, certain groups in the universities, and various clergymen. Recently R. I. Aaron has argued persuasively that the older tradition, that Descartes, the Cartesians, and certain English thinkers were the targets of Locke's attack, is the correct one and that Locke was not simply striking at a straw man of his own making.

*Reasons for attacking innate ideas.* Locke suggested that the doctrine of innate ideas lends itself to a certain authoritarianism and encourages laziness of thought, so that the foundations of knowledge are not likely to be examined. The expression "innate ideas" is an unfortunate one and admittedly extremely vague. It carries with it the suggestion that certain ideas and knowledge are, in Locke's sense, imprinted on the mind and are in no way dependent on experience. Certainly there are passages in Descartes which strongly suggest that certain ideas are innately in the mind, and more than a few thinkers took this to be Descartes's meaning. Furthermore, Locke wished to prepare the ground for his own thesis that all ideas and all knowledge are acquired. If he overemphasized the crude sense of the theory of innate ideas, he also showed that even the refined doctrine is unnecessary in accounting for knowledge.

There is another point that Locke discussed later in *Essay*. Descartes asserted that the essence of the mind is to think. To Locke this meant that the mind could not both be and not think. He argued that the mind does not think always and that its real essence cannot be thinking. If the mind thinks always, either some ideas must be innate or the mind comes into being only after it has been furnished with ideas by experience. Neither alternative was acceptable to Locke.

**SOURCE OF IDEAS.** Locke, in his positive thesis in Book II, valiantly and sometimes awkwardly endeavored to show that every idea we have is ultimately derived from experience, either from sensation or reflection. Locke began by asserting that a man is conscious of two things, the fact “that he thinks” and “the ideas” in the mind about which he thinks. Locke’s initial concern was with the question of how a man comes by his ideas; and he made an assumption in terms of several similes. “Let us then suppose the mind to be, as we say, white paper, void of all characters, without any ideas. How comes it to be furnished? ... Whence has it all the materials of reason and knowledge?” (II.i.2). Locke replied to his own questions that we get all our ideas from experience, the two fountainheads of which are sensation and reflection. Our senses are affected by external objects (bodies) and afford us ideas, such as yellow, white, heat, cold, soft, hard, bitter, and sweet. Perceiving the operations of our own minds when we reflect, we are furnished with ideas of perception, thinking, doubting, believing, reasoning, knowing, and willing.

The ideas that are furnished by experience are the materials of reason and knowledge. These materials are either the immediate objects of sense, such as color, or the unexamined but direct awareness of such acts as doubting or knowing. Locke’s meaning becomes explicitly clear in his account of solidity. He held that we get the idea of solidity by touch. “That which ... hinders the approach of two bodies, when they are moving one towards another, I call solidity” (II.iv.1). He sharply distinguished this sense from the purely mathematical use of the term. Impenetrability is an acceptable alternative name for solidity. It is clearly distinct from space and hardness. After an extensive discussion Locke stated, “If anyone asks me what this solidity is, I send him to his senses to inform him. Let him put a flint or a football between his hands and then endeavour to join them, and he will know” (II.iv.6). All philosophical and scientific discourse about solidity, however complex and sophisticated it may be, must ultimately refer back to that from which it began, namely the experience or sensation we have when we put something such as a flint or a football between our hands. Similarly, we cannot by discourse give a blind man the idea of color or make known what pain is to one who never felt it. All knowledge about the physics of light and color or sound refers back to what we perceive when we see and hear. It is in this sense, then, that we get all our ideas from sensation and reflection. Locke nowhere, however, suggested that we can or should stop there. Once the mind is furnished with ideas, it may perform various operations with them.

**IDEAS AND THE REAL WORLD.** Throughout the first book of *Essay* Locke assumed the real existence of an external physical world and the substantial unity of a man in body and mind. He undoubtedly accepted the thesis that the external physical world is corpuscular and acts by bodies in motion that possess only those qualities which Locke called primary. Locke spoke of secondary qualities as powers in bodies to produce in our minds ideas that are signs of these powers but that in no way resemble the powers that produce them. Often he suggested that if we had the means of observing the minute motions of the particles making up gross bodies, we might have a clearer notion of what we mean when we call secondary qualities powers. Locke’s position here is physical realism. It is not simply a manner of speaking. The ideas we have do represent real things outside of us and do constitute the links by which we know something of the external physical world.

*Identity.* Among the bodies that exist are those of plants, animals, and men. Existence itself constitutes the principle of individuation. Identity is not applied in the same way to a mass of matter and a living body. The identity of an oak lies in the organization of its parts, which partake of one common life. So it is with animals. Again, “the identity of the same man consists: viz. in nothing but a participation of the same continued life, by constantly fleeting particles of matter, in succession vitally united to the same organized body” (II.xxvii.6).

*Origin of sensation.* With these controlling hypotheses in *Essay* in view, we may return to Locke’s invitation to consider the mind as a blank sheet of paper without any ideas. Is a mind without ideas anything but a bare capacity to receive ideas? If we ask what a man is without ideas, we can say he is an organized body existing in a world of other bodies and interacting with them. Experience is a matter of contact of the organized human body with other bodies before it is a matter of sensation or perception. Not every body impinging on our body gives rise to sensation; if it does not, we take no notice of it. However, if some external bodies strike our senses and produce the appropriate motions therein, then our senses convey into the mind several distinct perceptions. How this takes place Locke avoided considering, but that it takes place he was certain; a man, he asserted, first begins to think “when he first has any sensation” (II.i.23).

**SIMPLE AND COMPLEX IDEAS.** Locke proceeded to distinguish between simple and complex ideas. A simple idea is “nothing but one uniform appearance or conception in the mind, and is not distinguishable into different

ideas” (II.ii.1). A color seen, a sound heard, warmth felt, an odor smelled, are all simple ideas of sense. Once it is furnished with a number of simple ideas, the mind has the power to repeat, compare, and unite them into an almost infinite variety of combinations; but it is utterly incapable of inventing or framing a new simple idea. Thus, with respect to simple ideas the mind is mostly passive; they are simply given in experience. The ideas are given not in isolation from each other but in combinations, as when we simultaneously feel the warmth and softness of wax or the coldness and hardness of ice; nevertheless, simple ideas are distinct from each other in that the mind may mark off each from the other, however united the qualities may be in the things that cause the simple ideas in the mind. Moreover, only those qualities in things that produce ideas in us can ever be imagined at all. Thus, our knowledge of existence is limited by the ideas furnished by experience. Had we one sense less or more than we now do, our experience and knowledge would be respectively decreased or increased.

We have certain ideas, such as color or odor, from one sense only; others, like figure and number, from more than one sense. Reflection alone provides us with experience of thinking and willing. Other ideas, such as pleasure, pain, power, existence, and unity, we have from both sensation and reflection.

**PRIMARY AND SECONDARY QUALITIES.** Locke made a second basic distinction—between primary and secondary qualities. In doing so he clearly went beyond ideas. He wrote, “Whatsoever the mind perceives in itself, or is the immediate object of perception, thought, or understanding, that I call idea; and the power to produce any idea in our mind, I call quality of the subject wherein that power is” (II.viii.8). Primary qualities, he argued, are utterly inseparable from body. They are known to be primary because sense constantly finds them there if body can be perceived at all, and the mind by critical reflection finds them inseparable from every particle of matter. Solidity, extension, figure, and mobility are all primary qualities. Our ideas of these qualities resemble the qualities themselves, and these qualities really exist in body, whether or not they are perceived. Berkeley was to show that to speak of resemblance supposes that a comparison, an observation, can be made. Locke was aware of the difficulty, as is shown in his *Examination of Malebranche*. Apparently he believed it was the only explanation plausible in spite of its difficulties.

Secondary qualities, in Locke’s terms, were nothing but powers to produce various sensations. Bodies do so

by the action of their bulk, figure, and texture, and by the motion of their insensible parts on our senses. Somehow they produce in us such ideas as color, odor, sound, warmth, and smell. These ideas in no way resemble the qualities of bodies themselves. They are but signs of events in real bodies. Locke also frequently called these ideas secondary qualities. He would have been clearer had he called them sensory ideas of secondary qualities, preserving the distinction between qualities as attributes of a subject and ideas as objects in the mind. A third class of qualities (sometimes called tertiary) is the power of a body to produce a change in another body, for example, the power of the sun to melt wax.

Nowhere is Locke’s physical realism more evident than in his distinction between primary and secondary qualities. Whatever epistemological difficulties the distinction might entail, Locke was persuaded that the new physics required it. Indeed, the distinction was made by Boyle, Descartes, Galileo, and others before him and was thoroughly familiar in his day. Admittedly there is a problem in the assertion that a certain motion in body produces in us the idea of a particular color. Nevertheless, Locke was persuaded that it was so. In such difficult cases Locke fell back upon the omnipotence and wisdom of God and the fact that our knowledge is suited to our purpose.

**IDEAS OF REFLECTION.** Locke observed that perception is the first faculty of the mind and without it we know nothing else. Hence, the idea of perception is the first and simplest idea we have from reflection. What perception is, is best discovered by observing what we do when we see, hear, or think. Locke added that judgment may alter the interpretation we make of the ideas we receive from sensation. Thus, if a man born blind gains his sight, he must learn to distinguish between a sphere and a cube visually, though he can do so readily by touch. By habit the ideas of sensation are gradually integrated into the unified experience of complex ideas, and by judgment we come to expect things that look a certain way to also feel or smell a certain way. It is worth noting that Locke was persuaded that animals have perception and are not, as Descartes held, mere automatons.

**Memory and contemplation.** The second faculty of the mind that Locke held indispensable to knowledge is the retention manifested in both contemplation and memory. Contemplation consists in holding an idea before the mind for some time. Memory, however, gave Locke some difficulties. He asserted that “our ideas being nothing but actual perceptions in the mind—this laying

up of our ideas in the repository of the memory signifies no more but this: that the mind has a power in many cases to revive perceptions which it has once had, with this additional perception annexed to them, that it has had them before" (II.x.2). The inadequacy of this statement is at once evident. It proposes no more than a kind of subjective conviction that may often be in error. Locke's analysis of memory was more psychological than philosophical. He passed over the consideration of how memory is possible at all and the criteria by which a true memory may be distinguished from a false memory. He did say, however, that attention, repetition, pleasure, and pain aid memory and are the conditions under which memory is strengthened or weakened. Again he asserted that animals have memory.

*Other ideas of reflection.* Other faculties of the mind are discerning and distinguishing one idea from another, comparing and compounding, naming, and abstracting. Locke considered each point also in respect to animals, holding, for example, that animals compare and compound ideas only to a slight extent and do not abstract ideas at all. At the conclusion of this chapter (II.xi.15) Locke asserted that he thought he had given a "true history of the first beginnings of human knowledge."

**COMPLEX IDEAS.** Locke next considered complex ideas. Just as the mind observes that several combinations of simple ideas are found together, so too, it can by its own action voluntarily join several simple ideas together into one complex idea. There are three categories of complex ideas—modes, substances, and relations. Modes are dependencies or affections of substances. Simple modes are variations or different combinations of one simple idea, whereas in mixed modes several distinct ideas are joined to make a complex idea. Ideas of substances represent distinct particular things subsisting in themselves. Complex ideas of relation consist in comparing one idea with another.

This classification is not entirely satisfactory because ideas of modes invariably entail relations in the broadest sense. Locke seems to have been closer to Aristotle than to modern usage in his employment of the term "relation." Under modes Locke included space, duration and time, number, infinity, motion, sense qualities, thinking, pleasure and pain, power, and certain mixed modes. Under substance he placed the idea of substance in general, the ideas of particular substances, and collective ideas of substances. In the category of relation, he considered a number of ideas, including cause and effect, relations of place

and time, identity and diversity, and others that he classified as proportional, natural, instituted, and moral.

The greater number of these concepts have in other philosophies been credited with some a priori and extraempirical character. They are not direct objects of sensory experience; and they appear to have a certainty not found in the mere coexistence of sensory ideas. They are more abstract and universal than the simple ideas of sensation and reflection. Locke's broad use of the term "ideas" tends to confuse and obscure the distinction between sensory percept and concept. Nevertheless, Locke undertook to show how the mind actively constructs these complex ideas, abstract and conceptual though they may be, out of the materials of knowledge, the simple ideas of sensation and reflection. In this undertaking Locke's rationalism was most evident, for he held that while the mind constructs complex ideas, it cannot do so arbitrarily. In this sense, Locke could claim for them an objective reality.

*The mode of space.* Examination here will be limited to only those complex ideas that are most important and difficult. Among modes, only space, duration, number, thinking, and power will be considered. Locke contended that the modifications of a simple idea are as much distinct ideas as any two ideas can be. Space in its first manifestation is a simple idea, since in seeing and touching we immediately perceive a distance between bodies and the parts of bodies. Though the idea of space constantly accompanies other sensory ideas, it is distinguishable from them. All our modes of the idea of space derive from the initial sensory experience. Thus space considered as length is called distance, considered three-dimensionally is capacity, considered in any manner is termed extension. Each different distance, especially when measured by stated lengths, is a distinct idea, including the idea of immensity, which consists in adding distance to distance without ever reaching a terminus. So too, figure allows an endless variety of modifications of the simple idea of space. Place is distance considered relative to some particular bodies or frame of reference.

Locke disagreed with Descartes's assertion that extension is the essence of matter, although he agreed that we cannot conceive of a body that is not extended. But a body has solidity, and solidity is distinct from the notion of space; for the parts of space are inseparable in thought and in actuality and are immovable, whereas a solid body may move and its parts are separable. Descartes's argument that the physical universe is a plenum was dismissed by Locke as unsound, for there is no contradiction in the conception of a vacuum. If body is not infinite, we can

conceive of reaching out beyond the physical limits of the universe to a place unoccupied by matter. The idea of pure space is necessarily infinite, for we can conceive of no limit or terminus to it. Locke professed not to know whether space was a substance or an accident and offered to answer the question when the ideas of substance and accident were clarified. He was more confident of the idea of pure space than he was of the traditional philosophical categories. Locke placed a great load on the simple idea of space, and by the activity of his reason he went beyond the bounds of possible experience.

**Duration and time.** The idea of duration is broader than that of time. If we consider the train of ideas that passes through our minds, we observe that one idea constantly succeeds another, and so we come by the idea of succession. By reflection we acquire the idea of duration, which we may then apply to motion and sensory ideas. Where there is no perception of the succession of ideas in our minds, there is no sense of time. Locke insisted that motion does not furnish us with the idea of duration, and he directly opposed Aristotle's definition that "time is the measure of motion with respect to before and after."

Once we have the idea of duration, we need a measure of common duration. Time is the consideration of duration marked by certain measures such as minutes, hours, and days. The most convenient measures of time must be capable of division into equal portions of constantly repeated periods. We cannot be certain of the constancy of motions or of the time spans they measure. Locke was concerned with liberating time from motion. Consequently, he argued that we must consider duration itself as "going on in one constant, equal, uniform course; but none of the measures of it which we make use of can be known to do so" (II.xiv.21). Once time is liberated from motion, Locke held, we can conceive of infinite duration even beyond creation. Thus we can expand by endless addition the idea of duration to come to the notion of eternity.

Were it not for the implicit realism of Locke's arguments, it would be possible to agree with those scholars who have seen in his arguments about duration and expansion a vague groping for a position somewhat similar to Kant's a priori aesthetic. For both men, space becomes the framework of body, and duration or time the structure of the mind, or the inner sense.

**Number.** The idea of unity is everywhere suggested to the mind, and no idea is more simple. By repeating it we come to the complex modes of number. Once we have learned to perform this operation, we cannot stop short of the idea of infinity. Locke regarded both finite and infi-

nite as modes of quantity. Because we are able to apply the idea of number to space and time, we are capable of conceiving of them as infinite. The idea of infinity is essentially negative, since we come to it by enlarging our ideas of number as much as we please and discover that there is no reason ever to stop. We may know that number, space, and duration are infinite, but we cannot positively know infinity itself. Locke insisted that however remote from the simple ideas of sensation and reflection these ideas may be, they have their origin in those simple ideas.

**The modes of thinking.** Locke gave only casual and formal attention to the modes of thinking, such as sensation, remembrance, recollection, contemplation, attention, dreaming, reasoning, judging, willing, and knowing. Equally superficial was his consideration of modes of pleasure and pain, which consisted of little more than definitions of various emotions.

**Power.** The chapter on power is the longest in *Essay*, and Locke felt obliged to rewrite portions of it time and again, for each new edition. It is evident that power is not perceived as such. Locke observed that the mind, taking note of the changes and sequences of our ideas and "concluding from what it has so constantly observed to have been, that the like changes will for the future be made in the same things, by like agents, and by the like ways ... comes by that idea which we call power" (II.xxi.1). From this it hardly seems that the idea of power is a simple idea, unless Locke meant no more than that the idea of power is only the observation of the regular order and connection of our ideas. But Locke wrote that "since whatever change is observed, the mind must collect a power somewhere able to make that change, as well as a possibility in the thing itself to receive it" (II.xxi.4). Here the idea of power is a necessary idea of reason, grounded in certain other experiences. Locke never made clear this distinction. He admitted that the idea of power included some kind of relation but insisted that it was a simple idea.

Power is both passive and active. Whether or not matter has any active power, Locke pointed out, we have our idea of active power from the operations of the mind itself. We find by direct observation that we have the power to begin, continue, or stop certain actions of our minds and motions of our bodies. This power we call will, and the actual exercise of this power, volition, or willing. Action is voluntary or involuntary insofar as it is or is not consequent upon the order or command of the mind.

Locke proceeded to explore the ideas of will, desire, and freedom in terms of the idea of power. "The idea of

liberty is the idea of a power in any agent to do or forbear any particular action, according to the determination or thought of the mind, whereby either of them is preferred to the other" (II.xxi.8). Where this power is absent, a man is under necessity. Locke consequently dismissed as unintelligible the question of whether or not the will is free. The only intelligible question is whether or not a man is free. Freedom is one power of an agent and will is another; one power cannot be the power of another. "As far as this power reaches, of acting or not acting, by the determination of his own thought preferring either, so far is a man free" (II.xxi.21). Freedom then, for Locke, was the absence of constraint. If we distinguish will from desire, we cannot make the mistake of thinking the will is free.

What then determines the will with respect to action is some uneasiness in a man that may be called the uneasiness of desire. Good and evil work on the mind but do not determine the will to particular actions. The only thing that can overcome the uneasiness of one desire is the greater uneasiness of another. The removal of uneasiness is the first and necessary step to happiness. Since it is present desire that moves the will to action, good and evil contemplated and known in the mind can move us to action only when that knowledge is accompanied by a greater uneasiness than any other. Since we have many desires and can have knowledge of desired good in the future as well as feared evil, we can suspend the pursuit of any desire until we have judged it. Thus, government of our passions is possible whenever there is a greater uneasiness in not doing so. This power is the ground on which we hold men responsible for their actions. Good and bad are nothing but pleasure or pain, present or future. Error in choice is usually due to the greater strength of present pleasure or pain in comparison with future pleasure and pain. A true knowledge of what contributes to our happiness can influence a choice only when to deviate from that choice would give greater uneasiness than would any other action. Thus it is possible to change the pleasantness and unpleasantness of various actions by consideration, practice, application, and custom.

Locke's conception of power, like his ideas of cause and effect, was inadequate and vague. It was both a simple idea and a complex one; it was the notion of regular sequence and that of efficacious cause; and it was at once given and a priori. The rational and empirical elements in Locke were at war here. Locke was at his best in showing how the word "power" is commonly used. His analysis of the will and freedom was likewise involved in difficulties.

The will is not free and thus man's actions are determined; but at the same time we can suspend the execution of any desire by our judgment. Locke was aware of these difficulties, but he saw no satisfactory alternative.

*Mixed modes.* Mixed modes are made by the mind and are exemplified by drunkenness, a lie, obligation, sacrilege, or murder. To a great degree we get these ideas by the explanation of the words that stand for them.

SUBSTANCE. Of all the ideas considered by Locke none gave him more difficulty than that of substance, and nowhere was his empiricism more in conflict with his rationalism. The diverse trends of Locke's thought concerning substance and the problems he raised prepared the ground for Berkeley, Hume, Kant, and many others who struggled with the same questions. At every opportunity throughout *Essay* he returned to consider particular substances and the general idea of substance. Locke held that we are conversant only with particular substances through experience; yet his rationalism and realism would not permit him to abandon the general idea of substance.

The mind is furnished with many simple ideas by the senses, and it observes by reflection that certain of them are constantly together. It then presumes that these belong to one thing and for convenience gives them one name. In this way the mind arrives at the complex idea of particular substances, such as gold, which we observe to be yellow and malleable, to dissolve in aqua regia, to melt, and not to be used up in fire. A substance so defined gives us only a nominal definition.

Locke added that "not imagining how these simple ideas can subsist by themselves, we accustom ourselves to suppose some substratum wherein they do subsist, and from which they do result; which therefore we call substance" (II.xxiii.1). This idea of a substratum is extremely vague, and Locke called it a "something we know not what." Our ideas do not reach, and we cannot have, a knowledge of the real essence of substances. Nonetheless, Locke continued to believe that real essences do exist, although our knowledge comes short of them.

Our knowledge of corporeal substances consists of ideas of the primary and secondary qualities perceived by the senses and of the powers we observe in them to affect or be affected by other things. We have as clear an idea of spirit as of body, but we are not capable of knowing the real essence of either. Locke observed that we know as little of how the parts of a body cohere as of how our spirits perceive ideas or move our bodies, since we know nothing of either except our simple ideas of them. Locke

even suggested that God could if he wished, as far as we know, add to matter the power to think, just as easily as he could add to matter a separate substance with the power to think.

Even our idea of God is based on simple ideas that are enlarged with the idea of infinity. God's infinite essence is unknown to us. We can only know that he exists.

**RELATIONS.** The mind can consider any idea as it stands in relation to any other; and thus we come by ideas of relation, such as father, whiter, older. Frequently, the lack of a correlative term leads us to mistake a relative term for an absolute one. Locke distinguished the relation from the things related and appears to have made all relations external. Indeed, he held that many ideas of relation are clearer than ideas of substances; for example, the idea of brothers is clearer than the perfect idea of man.

Though there are many ideas and words signifying relations, they all terminate in simple ideas. There is a difficulty here. If the idea of relation is not a simple idea or a combination of simple ideas, then it is distinct from them. Like the general idea of substance, it is a concept derived from reason. No doubt the mind is capable of comparing the relation of one idea with another, but our perception of this operation must have for its object either a simple idea or the operation itself. On this point Locke was obscure and evasive and avoided the difficulties by the vague assertion that all relations terminate in simple ideas.

**Causation.** The relation to which Locke first turned was cause and effect. His discussion was inadequate and marked by the duality found in his consideration of other ideas. We observe the order and connection of our ideas and the coming into existence of things and qualities. In pointing this out Locke was on strictly empirical grounds. When, however, he defined cause as "that which produces any simple or complex idea," and "that which is produced, effect" (II.xxvi.1), he went beyond experience and rested his argument on reason. Locke undoubtedly saw the difficulties of his position. He was concerned, on the one hand, to show how we have the ideas of cause and effect from experience. On the other hand, he was not satisfied with a mere sequence theory. The difficulty arose, as it did with power and substance, because he was persuaded that there is a reality beyond the ideas manifest to us. It is a reality, however, about which he could say little in terms of his representationalism.

**Identity and diversity.** Under relation Locke also examined identity and diversity, by which he meant the

relation of a thing to itself, particularly with respect to different times and places. As was stated above, the identity of a plant, an animal, or a man consists in a participation in the same continued life. To this Locke added an examination of personal identity. He argued that personal identity is consciousness of being the same thinking self at different times and places. Locke also discussed other relations, such as proportional, natural, instituted, and moral, which are not essential to the main argument of *Essay* and which will, therefore, not be discussed here.

The remaining chapters of Book II of *Essay* are devoted to "Clear and Obscure, Distinct and Confused Ideas," "Real and Fantastical Ideas," "Adequate and Inadequate Ideas," "True and False Ideas," and "The Association of Ideas." All of them have merit in clarifying other parts of *Essay* but add little that is new and not discussed elsewhere. Consequently, they will be passed over.

**LANGUAGE.** At the end of Book II of *Essay* Locke related that he had originally intended to pass on to a consideration of knowledge. He found, however, such a close connection between words and ideas, particularly between abstract ideas and general words, that he had first to examine the "nature, use, and signification" of language, since all knowledge consists of propositions. Book III, therefore, was incorporated into *Essay*.

The merits of Book III are the subject of some controversy. Most scholars have dismissed it as unimportant and confused. Some, such as Aaron, see many merits in it despite its manifest inadequacies.

The primary functions of language are to communicate with our fellow men, to make signs for ourselves of internal conceptions, and to stand as marks for ideas. Language is most useful when general names stand for general ideas and operations of the mind. Since all except proper names are general, a consideration of what kinds of things words stand for is in order. "Words, in their primary' or immediate signification, stand for nothing but the ideas in the mind of him that uses them" (III.ii.2). We suppose they stand for the same ideas in the minds of others. Words stand for things only indirectly. General words stand for general ideas, which become general by separation from other ideas and from particular circumstances. This process Locke called abstraction.

**Definition.** Definition by genus and differentia is merely a convenience by which we avoid enumerating various simple ideas for which the genus stands. (In this, Locke prepared the way for descriptive definition, which makes no pretense of defining the real essence of things.) It follows that general or universal ideas are made by the

understanding for its own use. Thus the essences of so-called species are nothing but abstract ideas. Locke asserted that every distinct abstract idea is a distinct essence. This must not be taken in a Platonic sense, for it is the mind itself that makes these abstract ideas. If essences are distinguished into nominal and real, then with respect to simple ideas and modes there is no difference between nominal and real essence. In substances, they are decidedly different, in that the real essence of substance is unknowable to us.

**Names.** Locke asserted that the names of simple ideas are not definable. One wonders, Is blue a general idea? If so, what is this blue as against that blue? What is separated out? What retained? Locke never examined these questions, with the result that his conception of abstraction is vague and vacillating. Locke gave several distinct meanings to such terms as “general ideas” and “universal ideas,” shifting from one meaning to another and never clarifying them.

Complex ideas consisting of several simple ideas are definable and intelligible provided one has experience of the simple ideas that compose them. Without experience how can a blind man understand the definition of a rainbow?

Simple ideas are “perfectly taken from the existence of things and are not arbitrary at all” (III.iv.17). Ideas of substances refer to a pattern with some latitude, whereas ideas of mixed modes are absolutely arbitrary and refer to no real existence. They are not, however, made at random or without reason. It is the name that ties these ideas together, and each such idea is its own prototype.

Since names for substances stand for complex ideas perceived regularly to go together and supposed to belong to one thing, we necessarily come short of the real essences, if there are any. One may use the word “gold” to signify the coexistence of several ideas. One man may use the term to signify the complex idea of A and B and C. Another man of more experience may add D, or add D and leave out A. Thus, these essences are of our own making without being entirely arbitrary. In any case, the boundaries of the species of substances are drawn by men.

**Connective words** In a brief chapter, “Of Particles,” Locke pointed out that we need words signifying the connections that the mind makes between ideas or propositions. These show what connection, restriction, distinction, opposition, or emphasis is given to the parts of discourse. These words signify, not ideas, but an action of the mind. Again a difficulty arises. If “is” and “is not”

stand for the mind’s act of affirming or denying, then either the mind directly apprehends its own actions in some way or we do have ideas of affirmation or denial. If we do have ideas of the mind’s acts, then these words ought to signify the ideas of these acts; if we do not have ideas that these words signify, then either we do not apprehend them or something besides ideas is the object of the mind when it thinks. The remainder of Book III concerns Locke’s thoughts on the imperfection of words, the abuse of words, and his suggested remedies for these imperfections and abuses.

**KNOWLEDGE.** The first three books of *Essay* are largely a preparation for the fourth. Many scholars see a fundamental cleavage between Book II and Book IV. Yet Locke saw no conflict between the two books, and whatever split existed in Locke’s thought runs throughout *Essay*, as J. W. Yolton and others have pointed out. An effort can be made to reconcile Locke’s empiricism and his rationalism, his grounding of all ideas and knowledge in experience and his going beyond experience to the existence of things.

Many of Locke’s difficulties stem from his definition of “idea.” It is so broad that anything perceived or known must be an idea. But Locke showed, in Books I and II, that we get all our ideas from experience, not in order to claim that nothing exists except ideas, but to show that there is an alternative to the theory of innate ideas. For Locke, experience is initially a contact of bodies and subsequently a reflection of the mind. He never doubted the existence of an external physical world, the inner workings of which are unknown to us.

**Sources of knowledge.** There are two sources of knowledge—sensation and reflection. The ideas we have from reflection are in some important ways quite different from those we have from sensation. In Book II Locke asserted that the mind “turns its view inward upon itself and observes its own actions about those ideas it has (and) takes from thence other ideas” (II.vi.1). The important point here is that in reflection the mind observes its own action. It is true that Locke spoke of modes of the simple ideas of reflection, such as remembering, discerning, reasoning, and judging. Nonetheless, if the mind does observe its own action, then something more than ideas are the object of the mind in reflection, or else ideas of reflection are somehow importantly different from the ideas of sensation. This point will show up in a consideration of Locke’s theory of knowledge.

**Propositions.** Locke defined knowledge as “the perception of the connection and agreement, or disagree-

ment and repugnancy, of any of our ideas” (IV.i.2). This agreement or disagreement is in respect to four types: identity and diversity, relation, coexistence or necessary connection, and real existence. Perceiving agreement or disagreement is quite different from just barely perceiving the ideas that are said to agree or disagree. Strictly speaking, this perception must be a distinct idea of either agreement or disagreement. Yet this was not Locke’s meaning. Where there is knowledge, there is judgment, since there can be no knowledge without a proposition, mental or verbal. Locke defined truth as “the joining or separating of signs, as the things signified by them do agree or disagree one with another” (IV.v.2). There are two sorts of propositions: mental, “wherein the ideas in our understandings are, without the use of words, put together or separated by the mind perceiving or judging of their agreement or disagreement” (IV.v.5); and verbal, which stand for mental propositions.

**Judgments.** In this view, ideas are the materials of knowledge, the terms of mental propositions. They are, insofar as they are given in sensation and reflection, the subject matter of reflection. If perception of agreement or disagreement in identity and diversity is the first act of the mind, then that act is a judgment. If we infallibly know, as soon as we have it in our minds, that the idea of white is identical with itself and different from that of red, and that the idea of round is identical with itself and different from that of square, we must distinguish between the bare having of these ideas and the knowledge of their identity and diversity. The knowledge of their identity and diversity is a judgment. It is reflective, and in it the mind perceives its own action or operation. There can be no distinction between the judgment and the idea of it. This is perhaps Locke’s meaning, which is unfortunately obscured by his broad use of the term “idea.” This perception of its own action is quite distinct from the abstract idea of the power of judgment. We may be uncertain as to how the mind makes judgments, what determines it to judge, or in what kind of a substance this power inheres, but we may be sure that in the actual making of a true judgment the mind perceives its own act. This position may be beset with difficulties, but it makes some sense out of Locke’s definition of knowledge.

**Degrees of knowledge.** Locke recognized two degrees of knowledge, in the strict sense of the term—intuition and demonstration. Of the two, intuition is more fundamental and certain. “The mind perceives the agreement or disagreement of two ideas immediately by themselves, without the intervention of any other” (IV.ii.1). Such knowledge is irresistible and leaves no room for hesita-

tion, doubt, or examination. Upon it depends all the certainty and evidence of all our knowledge. Here, clearly, what the mind perceives is not any third idea, but its own act. In demonstration the mind perceives agreement or disagreement, not immediately, but through other mediating ideas. Each step in demonstration rests upon an intuition. This kind of knowledge is most evident in, but is not limited to, mathematics.

A third degree of knowledge is “employed about the particular existence of finite beings without us, which going beyond bare probability and yet not reaching perfectly to either of the foregoing degrees of certainty, passes under the name of knowledge” (IV.ii.14). Locke called this sensitive knowledge. Fully aware of the dialectical difficulty entailed in this position, he grounded his reply to critics on common sense. The differences between dreaming and waking, imagining and sensing, are strong enough to justify this conviction. Hunger and thirst should bring a skeptic to his senses. For Locke, it was enough that common sense supported him, for he always took sensory ideas to be signs or representations of something beyond themselves.

**Limits of knowledge.** Locke asserted that knowledge extends no farther than our ideas and, specifically, no further than the perception of the agreement or disagreement of our ideas. We cannot have knowledge of all the relations of our ideas or rational knowledge of the necessary relations between many of our ideas. Sensitive knowledge goes only as far as the existence of things, not to their real essence, or reality. Two examples were given. In the first, Locke argued that though we have the ideas of circle, square, and equality, we may never find a circle equal to a square and know them to be equal. In the second, he observed that we have ideas of matter and thinking but may never know whether mere material being thinks. This has been discussed earlier.

In his controversy with Stillingfleet, Locke never abandoned this latter thesis. And throughout this section (IV.iii) Locke showed that many relations of coexistence give us no certainty that they will or must continue to be so. He seemed persuaded that the continued discovery of new knowledge suggests that there are vast horizons of reality that we may advance upon but can never reach. With respect to the relations between abstract ideas we may hope to advance very far, as in mathematics. To this he added the belief that a demonstrable science of morality is possible. On the other hand, he held that we can have no certain knowledge of bodies or of unembodied spirits.

*Knowledge of existents.* Locke argued that though our knowledge terminates in our ideas, our knowledge is real. “Simple ideas are not fictions of our fancies, but the natural and regular productions of things without us, really operating upon us; and so carry with them all the conformity which is intended; or which our state requires” (IV.iv.4). On the other hand, he argued: “All our complex ideas, except those of substances, being archetypes of the mind’s own making, not intended to be copies of anything, nor referred to the existence of anything, as to their originals, cannot want any conformity necessary to real knowledge” (IV.iv.5).

Universal propositions, the truth of which may be known with certainty, are not concerned directly with existence. Nonetheless, Locke argued that we have intuitive knowledge of our own existence. Here the argument is much the same as Descartes’s, and it is valid only if we accept the view that the mind in reflection perceives its own acts. This knowledge of our own existence has the highest degree of certainty, according to Locke.

We have a demonstrable knowledge of God’s existence, Locke held. He used a form of the Cosmological Argument: Starting with the certainty of his own existence, he argued to the necessary existence of a being adequate to produce all the effects manifest in experience. The argument assumed the reality of cause, the necessity of order, and the intelligibility of existence.

Of the existence of other things, as has been shown, we have sensitive knowledge. Locke felt the inconsistency of his position on this matter, yet accepted what he believed common sense required. We know of the coexistence of certain qualities and powers, and reason and sense require that they proceed from something outside themselves. Throughout these arguments about existence Locke went beyond his own first definition of knowledge.

**PROBABILITY.** The remaining portions of *Essay* are concerned with probability, degrees of assent, reason and faith, enthusiasm, error, and the division of the sciences. Though Locke’s treatment of probability is inadequate, he recognized its importance. The grounds of probability lie in the apparent conformity of propositions with our experience and the testimony of others. Practical experience shows us that our knowledge is slight, and action requires that we proceed in our affairs with something less than certainty.

Faith was, for Locke, the acceptance of revelation. It must be sharply distinguished from reason, which is “the discovery of the certainty or probability of such propositions or truths, which the mind arrives at by deduction

made from such ideas which it has got by the use of its natural faculties, viz. by sensation or reflection” (IV.xviii.2). Though reason is not able to discover the truth of revelation, nevertheless, something claimed to be revelation cannot be accepted against the clear evidence of the understanding. Thus, enthusiasm sets reason aside and substitutes for it bare fancies born of conceit and blind impulse.

*Error.* Error cannot lie in intuition. Locke found four sources of error: the want of proofs, inability to use them, unwillingness to use them, and wrong measures of probability. Locke concluded *Essay* with a brief division of science, or human knowledge, into three classes—natural philosophy, or φυσική practical action and ethics, or προκτική, and οημιωτική, or the doctrine of signs.

**INFLUENCE OF ESSAY.** Many minds of the seventeenth century contributed to the overthrow of the School philosophies and the development of the new sciences and philosophies. Descartes and Locke between them, however, set the tone and direction for what was to follow. Certainly Locke was the most prominent figure in the early eighteenth century, the indispensable precursor of Berkeley and Hume as well as a fountainhead for the French Encyclopedists. If it is said that the two strains of Cartesian rationalism and Lockian empiricism met in Kant, it can be added that Hume built on Locke’s foundation and Kant formalized much that was first a vague groping in Locke. Though Locke was not a wholly satisfactory thinker, his influence on thought in England and America has never completely abated, and even now there appears to be a revived interest in *Essay*.

## POLITICAL THOUGHT

Locke’s earliest known political writings were *Essays on the Law of Nature*, written in Latin between 1660 and 1664 but not known until the Lovelace Collection was examined in 1946. They were first published in 1954 with a translation by W. von Leyden. Though much in these essays appears in *An Essay concerning Human Understanding* and *Two Treatises of Government*, there remain many points at which the early essays are in conflict with parts of both later works. This fact and the bother of translating them may have deterred Locke from publishing them, despite the urging of Tyrrell. Since von Leyden can find no evidence of direct influence of these essays on anyone other than Tyrrell and Gabriel Towerson, the student of Locke is referred to von Leyden’s publication for additional information.

**TWO TREATISES.** *Two Treatises of Government* appeared anonymously in 1690, written, it is said, to justify the revolution of 1688, or, according to the preface, “to establish the Throne of Our Great Restorer, our present King William; to make good his Title, in the Consent of the People.” Locke acknowledged his authorship only in a codicil in his will listing his anonymous works and giving to the Bodleian Library a corrected copy of *Two Treatises*. He never felt that any of the editions printed during his lifetime had satisfactorily rendered his work. Only in 1960 did Peter Laslett publish a critical edition based on the Coste master copy of *Two Treatises*.

**THE FIRST TREATISE.** It has long been suspected that the first treatise was written in 1683 and that the second treatise was written in 1689. Laslett has presented much evidence to show that the second treatise was the earlier work, written between 1679 and 1681. If his thesis is correct, it was a revolutionary document, whose purpose was not primarily to philosophize but to furnish a theoretical foundation for the political aims and maneuvers of Shaftesbury and his followers in their struggle with Charles II. Only further scholarly probing will resolve this question.

In his preface, Locke stated that the greater part of the original work had been lost. He was satisfied that what remained was sufficient, since he had neither the time nor the inclination to rewrite the missing sections. The evidence is clear that it was portions of the first treatise that were lost.

The first treatise is a sarcastic and harsh criticism of Sir Robert Filmer’s *Patriarcha*, which argued for the divine right of kings. Locke’s treatise is more of historical than philosophical importance. It argued that Adam was not, as Filmer claimed, divinely appointed monarch of the world and all his descendants. Neither was the power of absolute monarchy inherited from Adam. Adam had no absolute rights over Eve or over his children. Parents have authority over children who are dependent upon them and who must learn obedience as well as many other things for life. The function of the parent is to protect the child and to help him mature. When the child comes to maturity, parental authority ends. In any case, the relation of parent and child is not the same as that of sovereign and subject. Were Filmer right, one would have to conclude that every man is born a slave, a notion that was utterly repugnant to Locke. Even if Filmer were correct, it would be impossible to show that existing rulers, especially the English kings, possess legitimate claims to

their sovereignty by tracing it back to lawful descent from Adam.

**THE SECOND TREATISE.** Locke began the second treatise with the proposition that all men are originally in a state of nature, “a state of perfect freedom to order their actions, and dispose of their possessions, and persons as they think fit, within the bounds of the Law of Nature, without asking leave, or depending upon the Will of any other man” (II.ii.4). Although Locke sometimes wrote as if the state of nature were some period in history, it must be taken largely as a philosophical fiction, an assumption made to show the nature and foundation of political power, a fiction at least as old as Plato’s treatment of the Prometheus myth in the *Protagoras*. It is a state of equality but not of unbounded license. Being rational and being a creature bound by God, man must be governed by the law of nature.

**Natural law.** Though the concept of the law of nature is as old as antiquity, it flourished in the seventeenth century in the minds of a considerable number of ethical and political thinkers. In general it supposed that man by the use of reason could know in the main the fundamental principles of morality, which he otherwise knew through Christian revelation. Locke was extremely vague about the law of nature, but in his *Essays on the Law of Nature* he held that that law rests ultimately on God’s will. Reason discovers it. It is not innate. When, however, Locke spoke of it as “writ in the hearts of all mankind,” he suggested some kind of innateness. There are obvious difficulties here, for sense and reason may fail men, even though the law of nature is binding on all. Moreover, the various exponents of the law of nature differ on what it consists of, except that it presupposes the brotherhood of man and human benevolence.

**State of nature.** In a state of nature, according to Locke, all men are bound to preserve peace, preserve mankind, and refrain from hurt to one another. The execution of the law of nature is the responsibility of each individual. If any man violates this law, he thereby puts himself in a state of war with the others, who may then punish the offender. The power that one man may hold over another is neither absolute nor arbitrary and must be restrained by proportion. The state of nature was for Locke a society of men, as distinct from a state of government, or a political society.

**Social contract.** There are certain inconveniences in a state of nature, such as men’s partiality and the inclination on the part of some men to violate the rights of others. The remedy for this is civil government, wherein men

by common consent form a social contract and create a single body politic. This contract is not between ruler and ruled, but between equally free men. The aim of the contract is to preserve the lives, freedom, and property of all, as they belong to each under natural law. Whoever, therefore, attempts to gain absolute power over another puts himself at war with the other. This holds in the political state as well as the state of nature. When a ruler becomes a tyrant, he puts himself in a state of war with the people, who then, if no redress be found, may make an appeal to heaven, that is, may revolt. This power is but an extension of the right of each to punish an aggressor in the state of nature. Unlike Hobbes, Locke was persuaded that men are capable of judging whether they are cruelly subjected and unjustly treated. Since one reason for men entering into the social contract is to avoid a state of war, the contract is broken when the sovereign puts himself into a state of war with the people by becoming a tyrant.

*Slavery.* Curiously, Locke justified slavery on the grounds that those who became slaves were originally in a state of wrongful war with those who conquered them and, being captive, forfeited their freedom. Apart from being bad history, this argument ignores the rights of the children of slaves. Locke's inconsistency here may mercifully be passed over.

*Property.* Property was an idea that Locke used in both a broad and a narrow sense. Men have a right to self-preservation and therefore to such things as they need for their subsistence. Each man possesses himself absolutely, and therefore that with which he mixes his labor becomes his property. "God has given the earth to mankind in common." No man has original, exclusive rights to the fruits and beasts of the earth. Nevertheless, man must have some means with which to appropriate them. This consists of the labor of his body and the work of his hand. By labor, man removes things from a state of nature and makes them his property. Without labor, the earth and things in general have but little value. However, only so much as a man improves and can use belongs to him, nor may a man deprive another of the means of self-preservation by overextending his reach for property.

Though the right to property is grounded in nature, it is not secured therein. It is one of the primary ends of the state to preserve the rights of property, as well as to make laws governing the use, distribution, and transference of property. In communities or countries under government, there are fixed boundaries to the common territory, and there is land and property held in common which no one may appropriate to himself and to which those not members of the community have no right at all.

Money, being something that does not spoil, came into use by mutual consent, serving as a useful means of exchange. At the same time it made possible the accumulation of wealth greater than warranted by need or use.

*Political society.* Having established several rights and duties belonging to men by nature and having shown certain inconveniences and disadvantages of the state of nature, Locke turned to political society. The first society consists of the family, whose aims are not initially or primarily those of political society, but which may be included under political society.

In political society "any number of men are so united into one Society, as to quit everyone his Executive power of the law of nature, and to resign it to the public" (II.vii.89). The legislative and executive powers are "a right of making laws with penalties of Death, and consequently all less Penalties, for the regulating and preserving of property, and of employing the force of the community, in the execution of such laws, and in the defense of the commonwealth from foreign injury, and all this only for the public good" (II.i.3). By the social contract men give up, not all their rights, but only the legislative and executive right they originally had under the law of nature. This transference of power is always subordinate to the proper and true ends of the commonwealth, which are "the mutual preservation of their lives, liberties and estates."

Each man must voluntarily consent to the compact either explicitly or implicitly. An individual who at age of discretion remains a member of the community tacitly consents to the compact.

Since the compact is made between the members of the community, sovereignty ultimately remains with the people. The sovereign, in the form of a legislative body, and executive, or both, is the agent and executor of the sovereignty of the people. The community can act only by the rule of the majority, and everyone is bound by it, because an agreement of unanimity is virtually impossible. It is the people who establish the legislative, executive, and judiciary powers. Thus, an absolute monarch is incompatible with civil society.

Locke's theories so far are compatible with either monarchy, oligarchy, or democracy so long as it is recognized that ultimate sovereignty lies with the people. He believed that a constitutional monarchy with executive power, including the judiciary, in the hands of the monarch, and legislative powers in a parliamentary assembly elected by the people was the most satisfactory form of government. The supreme power he held to be

the legislative, for it makes the laws that the executive must carry out and enforce. Whenever the executive violates the trust that he holds, no obligation is owed him and he may be deposed. The legislature may also violate its trust, though Locke believed it less likely to do so. Whenever this occurs, the people have a right to dissolve it and establish a new government. For this reason a regularly elected legislative body is desirable.

**Rebellion.** Locke explicitly recognized, as the events during his lifetime had shown, that men may become tyrants to those whom they were bound to serve. It may be a king, an assembly, or a usurper that claims absolute power. In such cases the people have a right to rebellion if no other redress is possible. Locke was not unmindful of the fact that the executive needs latitude and prerogative so that he may govern, and that the legislative body must deliberate and make laws that they believe to be in the public good. The right to rebellion is warranted only in the most extreme conditions, where all other means fail. Locke did not believe that men would lightly avail themselves of this power, for men will suffer and endure much before they resort to rebellion.

In transferring to the government the right to make and execute law and make war and peace, men do not give up the natural light of reason, by which they judge good and evil, right and wrong, justice and injustice. In specific laws or executive decisions judgment must be allowed to the legislature and the executive. If, however, a long train of acts shows a tyrannical course, then men, judging that the sovereign has put himself into a state of war with them, may justly dethrone the tyrant. On the other hand, the legislative and executive power can never revert to the people unless there is a breach of trust.

The dissolution of government is not the dissolution of society. The aim of revolution is the establishment of a new government, not a return to a state of nature. The dissolution of a government may occur under many circumstances, but foremost among them are when the arbitrary will of a single person or prince is set in place of the law; when the prince hinders the legislature from due and lawful assembly; when there is arbitrary change in elections; when the people are delivered into subjection by a foreign power; and when the executive neglects and abandons his charge. In all such cases sovereignty reverts to the society, and the people have a right to act as the supreme power and continue the legislature in themselves, or erect a new form, or under the old form place sovereignty in new hands, whichever they think best. On the other hand, “the power that every individual gave the society, ... can never revert to the individuals again, as

long as the society lasts” (II.xix.243). As theory, Locke’s second treatise is full of inadequacies, but its magnificent sweep of ideas prepared the ground for popular and democratic government.

## EDUCATION AND RELIGION

Locke’s thought on education and religion was not presented in strictly philosophical terms. It was, however, deeply rooted in the fundamental concepts of *Essay* and *Two Treatises*. His works in these areas display clearly the liberal bent of his mind as well as his love of freedom, tolerance, and truth. His attitude was pragmatic and based on considerable psychological insight into the motives, needs, passions, and follies of men. *Some Thoughts concerning Education*, several letters on toleration, and *The Reasonableness of Christianity* profoundly affected educational and religious thought in the eighteenth century and after. Two of these works, *Some Thoughts concerning Education* and the first *Letter on Toleration*, continue to be fresh and relevant.

**EDUCATION.** When Locke was in Holland, he wrote a number of letters to Edward Clark advising him on the education of his son, a young man of no particular distinction. Locke had in mind the education of a gentleman who would one day be a squire. In 1693 Locke modified these letters somewhat and published the contents as *Some Thoughts concerning Education* in response to “so many, who profess themselves at a loss how to breed their children.” His thought was marked by a ready understanding of, and warm sympathy with, children. Three main thoughts dominate the work. First, the individual aptitudes, capacities, and idiosyncrasies of the child should govern learning, not arbitrary curricular or rote learning taught by the rod. Second, Locke placed the health of the body and the development of a sound character ahead of intellectual learning. In the third place, he saw that play, high spirits, and the “gamesome humor” natural to children should govern the business of learning wherever possible. Compulsory learning is irksome; where there is play in learning, there will be joy in it. Throughout he placed emphasis on good example, practice, and use rather than on precepts, rules, and punishment. The work was an implicit criticism of his own education at Westminster and Oxford, which he found unpleasant and largely useless.

Writing almost as a physician, Locke advised “plenty of open air, exercise, and sleep; plain diet, no wine or strong drink, and very little or no physic; not too warm and strait clothing; especially the head and feet kept cold,

and the feet often used to cold water and exposed to wet.” The aim in all was to keep the body in strength and vigor, able to endure hardships.

Locke urged that early training must establish the authority of the parents so that good habits may be established. The prime purpose is the development of virtue, the principle of which is the power of denying ourselves the satisfaction of our desires. The child should be taught to submit to reason when young. Parents teach by their own example. They should avoid severe punishments and beatings as well as artificial rewards. Rules should be few when a child is young, but those few should be obeyed. Mild, firm, and rational approval or disapproval are most effective in curbing bad behavior. Children should be frequently in the company of their parents, who should in turn study the disposition of the child and endeavor to use the child’s natural desire for freedom and play to make learning as much like recreation as possible. High spirits should not be curbed, but turned to creative use. Curiosity too should be encouraged, and questions should be heard and fairly answered. Cruelty must always be discouraged and courageousness approved.

As the child grows, familiarity should be increased so that the parent has a friend in the mature child. Virtue, breeding, and a free liberal spirit as well as wisdom and truthfulness were the goals set by Locke in all his advice. Affection and friendship were for him both means and ends of good education.

Learning, though important, Locke put last. First, he would have the child learn to speak and read his own language well by example and practice, not by grammar. In the study of all languages, he would put off the study of grammar until they can be spoken well. He would begin the learning of a second modern language early. Reluctantly he would allow a gentleman’s son to learn Latin, but he did not recommend much time on Greek, Hebrew, Arabic, rhetoric, or logic, which constituted the curricula of the universities of his day. Rather, time should be given to the study of geography, arithmetic, astronomy, geometry, history, ethics, and civil law. Dancing he encouraged, and music as well, in moderation. He was less sympathetic to poetry. Remarkably, he urged that everyone learn at least one manual trade and make some study of accounting. Finally, travel was valuable if not done before one could profit by it.

If much of this is familiar and even trite, it must be remembered that Locke was among the first to formulate these ideas. His influence on educational thought and practice was enormous and is still very much with us in its fundamental outlook and method.

RELIGION. Locke saw some merits in all the competing claims of various religious groups. He also saw the destructive force that was released when these claims sought exclusive public dominion at the expense of individual conscience. He looked in several directions at once. This tendency has earned for him the reputation of being timorous and compromising. Nonetheless, it is on this trait of mind that much of his great influence and reputation rests. For Locke, fidelity to the evidence at hand always outweighed cleverness, consistency, and dialectic. It is the chief testimony to his claim that truth was always his aim, even when he might have won an easy victory by dogmatic consistency.

Locke’s writings on religion are voluminous. When he died he was working on extensive commentaries on the *Epistles of St. Paul*, as well as a draft of a fourth *Letter on Toleration*. Earlier he had written and published three letters on toleration, *The Reasonableness of Christianity* (1695), and two *Vindications* (1695 and 1697) of the latter work. Moreover, Locke’s three letters to Stillingfleet, the bishop of Worcester, are concerned with religious questions as well as epistemological ones.

*Religious tolerance.* Locke’s first *Letter concerning Toleration* stated his position clearly, and he never deviated from it substantially. It was originally written in Latin as a letter to his Dutch friend Philip van Limborch. In 1689 it was published on the Continent in Latin, and in the same year a translation of it by William Popple appeared in English.

Locke was not the first to write in advocacy of religious toleration. His was, however, a powerful, direct, and passionate plea. It was linked with *Essay* by its recognition of the limits of human knowledge and human fallibility, and with *Two Treatises* by his deep commitment to individual rights and freedom.

Locke took toleration to be the chief characteristic mark of the true church, for religious belief is primarily a relation between each man and God. True religion regulates men’s lives according to virtue and piety, and without charity and love religion is false to itself. Those who persecute others in the name of Christ abjure his teachings, seeking only outward conformity, not peace and holiness. Who can believe that in torture and execution the fanatic truly seeks the salvation of the soul of his victim? Moreover, the mind cannot be forced or belief compelled. All efforts to force or compel belief breed only hypocrisy and contempt of God. Persuasion is the only lever that can truly move the mind.

A church is “a voluntary society of men, joining themselves together of their own accord in order to the public worshipping of God in such manner as they judge acceptable to Him, and effectual to the salvation of their souls.” It is sharply distinct from a state, or commonwealth. The state is concerned with the public good, protecting life, liberty, and property. It has no authority in matters of the spirit. “Whatever is lawful in the commonwealth cannot be prohibited by the magistrate in the church.”

It is to be doubted that any man or group of men possess the truth about the one true way to salvation. In the Scriptures we have all that may reasonably be claimed by Christians to be the word of God. The rest are the speculations and beliefs of men concerning articles of faith and forms of worship. Sincere and honest men differ in these matters, and only tolerance of these differences can bring about public peace and Christian charity. Jews, pagans, and Muslims are all equally confident in their religious faith. Mutual tolerance is essential where such diversity exists. This is most evident when we observe that it is the most powerful party that persecutes others in the name of religion. Yet in different countries and at different times power has lain in the hands of different religious groups. It is physical power, not true faith, which decides who is persecuted and who persecutes.

Throughout Locke’s argument the liberty of person and the liberty of conscience are decisive. He limited this liberty only by denying to religion the right to harm directly another person or group or to practice clearly immoral rites. By a curious and probably prudential exception, he denied tolerance to atheists, because promises, covenants, and oaths would not bind them, and to any church so constituted “that all those who enter into it do thereby *ipso facto* deliver themselves up to the protection and service of another prince.”

Despite these limitations, Locke’s letter moved subsequent generations to a greater spirit of tolerance in religious matters. It is still part of the liberal democratic ideal and transcends the time of its composition.

**Faith and reason.** *The Reasonableness of Christianity* and *Vindications* are works more bound to Locke’s own time. Locke was probably neither a Socinian nor a deist, even though certain deists and Unitarians found comfort and inspiration in his work. He was a sincere Christian, who tried to diminish the flourishing schisms and sects by proposing a return to the Scriptures and an abandonment of the interminable theological disputes of his day. He accepted the divine inspiration of the Bible. Nevertheless, he held that even revelation must be tested by reason. In

the New Testament, Christianity is rational and simple. The core of Christian faith lies in the belief in the fatherhood of God, the divinity of Christ the Messiah, and the morality of charity, love, and divine mercy. Justification by faith means faith in Christ, whose essential revelation is that God is merciful and forgives the sinner who truly repents and strives to live a life of Christian morality. The Mosaic law, God’s mercy, and Christian morality are all consonant with human reason. Revelation discloses to man what unaided reason could not discover—the mysteries, the Virgin Birth, the Resurrection, the divinity of Christ. But when disclosed, these do not violate the canons of reason. Here as elsewhere, Locke’s emphasis on reason was circumscribed, reason must be followed where possible, but it does not carry us far enough by itself.

Locke’s influence was wide and deep. In political, religious, educational, and philosophical thought he inspired the leading minds of England, France, America, and to some extent, Germany. He disposed of the exaggerated rationalism of Descartes and Spinoza; he laid the groundwork for a new empiricism and advanced the claims for experimentalism. Voltaire, Montesquieu, and the French Encyclopedists found in Locke the philosophical, political, educational, and moral basis that enabled them to prepare and advance the ideas that eventuated in the French Revolution. In America, his influence on Jonathan Edwards, Hamilton, and Jefferson was decisive. Locke’s zeal for truth as he saw it was stronger than his passion for dialectical and logical niceness, and this may account for the fact that his works prepared the ground for action as well as thought.

### **Bibliography**

#### WORKS BY LOCKE

*Essays on the Law of Nature.* Translated from the Latin and edited by W. von Leyden. Oxford, 1954. Also gives an account of the Lovelace Collection.

- An Early Draft of Locke's Essay* (Draft A). Edited by R. I. Aaron and J. Gibb. Oxford, 1936. Valuable as a study of the development of *Essay*.
- An Essay concerning the Understanding, Knowledge, Opinion and Assent* (Draft B). Edited by B. Rand. Cambridge, MA: 1931. Valuable, but superseded by manuscript in Bodleian Library.
- Epistola de Tolerantia*. Gouda, 1689. Translated by William Popple as *A Letter concerning Toleration*. London, 1689. Several defenses appeared in the 1690s and fragments of a fourth in 1706.
- An Essay concerning Human Understanding*. London, 1690; 2nd ed. with large additions, London, 1694; 3rd ed., London, 1695; 4th ed., with large additions, London, 1700; 5th ed., with many large additions, London, 1706. Best modern edition, from which all quotes in this article are taken, is a reprint of the fifth edition, J. W. Yolton, ed., 2 vols. New York and London, 1961.
- Two Treatises of Government*. London, 1690. The critical and collated edition of Locke's corrected copy by Peter Laslett (Cambridge, 1960) surpasses all previous editions.
- Some Considerations of the Consequences of the Lowering of Interest and the Raising of the Value of Money*. London, 1692. Two additional papers on money appeared in 1695.
- Some Thoughts concerning Education*. London, 1693.
- The Reasonableness of Christianity*. London, 1695. Defenses of this work were published in 1695 and 1697.
- A Letter to the Right Rev. Edward Ld. Bishop of Worcester, concerning Some Passages relating to Mr. Locke's Essay of Humane Understanding*. London, 1697. Two further letters appeared, in 1697 and 1699.
- A Paraphrase and Notes on the Epistles of St. Paul to the Galatians* [etc.]. London, 1705.
- Posthumous Works of Mr. John Locke*, 6 vols. London, 1706.
- The Remains of John Locke*. Edited by E. Curl. London, 1714.
- Works of John Locke*. 3 vols. London, 1714; 10th ed., 10 vols., London, 1801.
- The Correspondence of John Locke and Edward Clarke*. Edited by B. Rand. Oxford, 1927.
- For the remainder of Locke's published and unpublished papers, consult the works listed below by Aaron, Christopherson, von Leyden, Long, Ollion, and Yolton. See von Leyden and Long particularly for the Lovelace Collection.
- WORKS ON LOCKE**
- Biographies**
- Bourne, H. R. Fox. *Life of John Locke*. 2 vols. London: H. S. King, 1876. Excellent, but inadequate since Lovelace Collection became available.
- Cranston, Maurice. *John Locke, a Biography*. London and New York: Longmans, Green, 1957. A thorough study of the life of Locke, using all materials available at present.
- King, Lord Peter. *The Life and Letters of John Locke*. London: H. Coburn, 1829. Not good, but contains original material.
- Critical Commentaries**
- Aaron, R. I. "Locke's Theory of Universals." *PAS*, Vol. 33 (1932/1933). Useful and enlightening.
- Aaron, R. I. *John Locke*. Oxford: Oxford University Press, 1937; rev. ed., Oxford, 1955. Best general commentary.
- Adamson, J. W. *The Educational Writings of John Locke*. Cambridge, U.K.: 1922.
- Bastide, C. *John Locke, ses théories politiques et leur influence en Angleterre*. Paris: Leroux, 1906. Still valuable work on Locke's political philosophy.
- Christopherson, H. O. *A Bibliographical Introduction to the Study of John Locke*. Oslo, 1930. Incomplete.
- Clapp, J. G. *Locke's Conception of the Mind*. PhD diss., Columbia University. New York, 1937.
- Cranston, Maurice. "Men and Ideas; John Locke." *Encounter* 7 (1956): 46–54.
- Czajkowski, C. J. *The Theory of Private Property in Locke's Political Philosophy*. Notre Dame, IN, 1941. Useful on the labor theory of value.
- DeMarchi, E. "Locke's Atlantis." *Political Studies* 3 (1955): 164–165.
- Gibson, James. *Locke's Theory of Knowledge*. Cambridge, U.K.: Cambridge University Press, 1917. Emphasizes Locke's rationalism.
- Gibson, James. *John Locke*. British Academy, Henriette Hertz Lecture, 1933.
- Gierke, Otto von. *Naturrecht und deutsches Recht*. Translated and edited by Ernest Barker as *Natural Law and the Theory of Society*. 2 vols. Cambridge, U.K.: 1934. A major study.
- Gough, J. W. *John Locke's Political Philosophy. Eight Studies*. Oxford, 1950. Important.
- Jackson, Reginald. "Locke's Distinction Between Primary and Secondary Qualities." *Mind* 38 (1929): 56–76.
- Jackson, Reginald. "Locke's Version of the Doctrine of Representative Perception." *Mind* 39 (1930): 1–25.
- James, D. G. *The Life of Reason: Hobbes, Locke, Bolingbroke*. London and New York: Longman, Green, 1949.
- Krakowski, E. *Les sources médiévales de la philosophie de Locke*. Paris: Jouve, 1915. One of the few studies of influences on Locke.
- Lamprecht, S. P. *The Moral and Political Philosophy of John Locke*. New York: Columbia University Press, 1918.
- Laslett, Peter. "The English Revolution and Locke's Two Treatises of Government." *Cambridge Historical Journal* 12 (1956). Interesting and controversial.
- Leibniz, G. W. *Nouveaux essais sur l'entendement humain*. Leipzig and Amsterdam, 1765. Translated by A. G. Langley as *New Essays concerning Human Understanding*. New York and London: Macmillan, 1896. An important critique of Locke by a contemporary.
- Leyden, W. von. "John Locke and Natural Law." *Philosophy* 31 (1956). A useful examination.
- Long, P. *A Summary Catalogue of the Lovelace Collection of Papers of John Locke in the Bodleian Library*. Oxford, 1959.
- O'Connor, D. J. *John Locke*. Harmondsworth, U.K.: Penguin, 1952.
- Ollion, H. *Notes sur la correspondance de John Locke*. Paris: A. Picard, 1908.
- Polin, R. *La politique de John Locke*. Paris, 1960. Interesting contrast to Laslett.
- Pollock, Sir Frederick. "Locke's Theory of the State." In his *Essays in the Law*. London: H. M. Stationery Office, 1922. Ch. 3.
- Ryle, Gilbert. *Locke on the Human Understanding*. Oxford: Oxford University Press, 1933.

- Smith, N. K. *John Locke*. Manchester, U.K.: Manchester University Press, 1933.
- Ware, C. S. "The Influence of Descartes on John Locke." *Revue internationale de philosophie* (1950): 210–230.
- Webb, T. E. *The Intellectualism of Locke. An Essay*. Dublin: W. McGee, 1857. Presents Locke as a precursor to Kant.
- Yolton, J. W. "Locke's Unpublished Marginal Replies to John Sergeant." *Journal of the History of Ideas* 12 (1951): 528–559.

## LOCKE, JOHN [ADDENDUM]

John Locke has been, for the last three decades, the subject of a rapid expansion of interest, stimulated by Oxford University Press's Clarendon edition of his works. The eight-volume edition of Locke's correspondence has opened new areas of information and exploration. So far in that series, we have definitive editions of *Essay* (including editions of the drafts and other relevant writings), the work on education, his paraphrases of St. Paul's epistles, and the papers on money, and well as *The Reasonableness of Christianity*, and the journals (again, opening a vast and important insight into Locke's reading, book buying, travels, opinions), and other works will follow. These editions, and the research that went into their production, have provided new resources for work on almost all aspects of Locke's life and writings, as well as material relating to his intellectual environment.

Antedating the Clarendon series was another medium for interest in Locke: *The Locke Newsletter*, founded and edited by Roland Hall. Beginning in 1970, published once per year (more or less), the newsletter has published articles on all aspects of Locke's thought. Included in each number is a list of recent (as of 1996) books and articles on Locke in many languages. This is a valuable source for keeping up to date on the publications about Locke. Another source of information on publications about Locke is the *Reference Guide* by Yolton and Yolton. Two other bibliographic resources are Attig's listings of Locke editions and the much fuller descriptive

bibliography of all editions of Locke's publications by Jean S. Yolton. The latter, a work long overdue, describes many different copies of Locke editions, which were located and examined in many different libraries and countries.

Among the topics in Locke's *Essay*, three have received special attention: the representative theory of perception, personal identity, and matter theory. The first of these in recent discussions has involved a debate over the nature of ideas: Are they special entities (e.g., images) standing between perceivers and objects, or are they simply the means for our access to the physical world? On the second topic it is becoming increasingly recognized that memory is not the crux of Locke's concept of person; it is consciousness, a wider and richer process (one with clear moral overtones) that focuses our awareness of self. A person for Locke is a moral being composed of the thoughts, feelings, and actions performed throughout a life. Consciousness is not a property of some immaterial substance, at least not so far as we can discover. The third topic has been given detailed attention via Locke's use of the corpuscular theory (see Alexander 1985). Some recognition has been given to Locke's movement toward the Newtonian concept of matter as force and power. Locke anticipated this development in his talk of the qualities of body being primarily powers. The substantiality of matter begins to fade under Locke's analysis of primary and secondary qualities. The chapter on power in *Essay*, the power of persons and the power of matter, is the longest and most complex chapter in that work (see J. W. Yolton 1993).

Locke's social and political thought has received even more attention throughout the decades, especially during the 1980s and 1990s. Laslett's early dating of *Two Treatises* and his locating that work in its historical context have been developed by writers such as Dunn, Harris, and Marshall. The central role of property and the relation of that concept to the person is generally recognized (see Tully 1980). His *Two Treatises* elaborates a concept of property that starts with each person's having property in his person. Acquisition of other possessions is a function of that original self-property. The tension between the interests and rights of the individual and those of society (or the community of mankind) is much discussed (see especially Gobetti 1992). The focus on consciousness as defining the person in his *Essay* indicated the central place of the individual in Locke's civil society. At the same time majority decisions were allowed to restrain individual actions. The power of the people is sanctioned by a social contract that obliges the ruler or legislative body to

act for the good of the citizens, in conformity with the laws of nature. The interconnections between Locke's moral views and his social and political thought have been discussed by Marshall (1984). The issue of religious toleration has focused some of the recent treatments of Locke's political and religious writings, but all of the toleration writings by Locke await their inclusion in the Clarendon editions.

Locke's religious interests in the Bible and in what is required of a Christian have been clarified by recent studies (e.g., Wainwright's edition of the *Paraphrases*, 1987), but this area will be further illuminated when the Clarendon edition of *Reasonableness* appears. Locke's relation to the Latitudinarians and the role of original sin in his thinking have been explored by Spellman (1988). Coleman's (1983) systematic study of Locke's moral theory set the stage for some of the recent attention to this aspect of Locke's thought.

Another newly developing area of Locke studies concerns the reception of his doctrines in Europe, especially in France. The difficulties the French had with the term "consciousness" when translating this English term have been interestingly analyzed by Davies (1990). Reactions to Locke's books in French-language journals and the impact of his doctrines (especially thinking matter) on Enlightenment thinkers have been presented by several writers (Hutchison 1991; Schøsler 1985, 1994; J. W. Yolton 1991). The full story of the reception of Locke's doctrines in Europe (especially in Germany, Portugal, and Holland) in the eighteenth century has yet to be written. Fruitful research programs are waiting for scholars. A number of collections of articles can be consulted to fill out this brief sketch of newer developments in Locke studies (Chappell 1994, Harpham 1992, Thompson 1991).

## LOGIC, HISTORY OF

*The mainstream of the history of logic begins in ancient Greece and comes down through the Arabian and European logic of the Middle Ages and through a number of post-Renaissance thinkers to the more or less mathematical developments in logic in the nineteenth and twentieth centuries. In the period after the fall of Rome many of the ancient achievements were forgotten and had to be relearned; the same thing happened at the end of the Middle Ages. Otherwise this Western tradition has been fairly continuous. Indian and Chinese logic developed separately. Today logic, like other sciences, is studied internationally, and the same problems are treated in the Americas, western and eastern Europe, and Asia and Australasia. The story of the development of logic will be told here under the following headings:*

ANCIENT LOGIC  
 LOGIC AND INFERENCE IN INDIAN  
 PHILOSOPHY  
 CHINESE LOGIC  
 LOGIC IN THE ISLAMIC WORLD  
 MEDIEVAL (EUROPEAN) LOGIC  
 THE INTERREGNUM (BETWEEN MEDIEVAL  
 AND MODERN LOGIC)  
 PRECURSORS OF MODERN LOGIC  
 MODERN LOGIC: THE BOOLEAN PERIOD  
 MODERN LOGIC: FROM FREGE TO GOËDEL  
 MODERN LOGIC: SINCE GOËDEL

### **Bibliography**

#### HISTORY OF LOGIC

(In general, texts by and studies on individual logicians are listed only if they do not appear in the bibliographies to the separate entries on these people. Most works cited in the body of this entry are not repeated below.)

#### *General Works*

Bocheński, I. M. *Formale Logik*. Freiburg: Alber, 1956.

Translated and edited by Ivo Thomas as *History of Formal Logic*. Notre Dame, IN, 1961. Contains extensive bibliographies.

Enriques, Federigo. *L'évolution de la logique*. Paris, 1926.

Kneale, William C., and Martha Kneale. *The Development of Logic*. Oxford: Clarendon Press, 1962.

Kotarbiński, Tadeusz. *Wykłady z Dziejów Logiki* (Lectures on the history of logic). Lodz: Zakład Narodowy im Ossolinskich we Wrocławiu, 1957. Translated into French as *Leçons sur l'histoire de la logique*. Paris: Presses Universitaires de France, 1964.

Prantl, Carl. *Geschichte der Logik im Abendlande*. 4 vols.

Leipzig: Hirzel, 1855–1870; reprinted (3 vols.), Graz, 1955. Covers the history up to 1600, with numerous quotations from the sources.

Scholz, Heinrich. *Abriss der Geschichte der Logik*. Berlin, 1931.

Translated by K. F. Leidecker as *Concise History of Logic*. New York: Philosophical Library, 1961.

#### *Works on Post-Medieval and Later Developments*

Jørgensen, Jørgen. *A Treatise of Formal Logic*, Vol. I: *Historical Development*. Copenhagen: Levin and Munksgaard, 1931.

Jourdain, P. E. B. "The Development of the Theories of Mathematical Logic and the Principles of Mathematics." *Quarterly Journal of Pure and Applied Mathematics* 41 (1910): 324–352; 43 (1912): 219–314; 44 (1913): 113–128.

Lewis, C. I. *A Survey of Symbolic Logic*. Berkeley: University of California Press, 1918; reprinted, New York, 1960.

Nidditch, P. H. *The Development of Mathematical Logic*. New York: Free Press of Glencoe, 1962.

Prior, A. N. *Formal Logic*, 2nd ed. Oxford: Clarendon Press, 1962.

Shearman, A. T. *Development of Symbolic Logic*. London: Williams and Norgate, 1906.

## ANCIENT LOGIC

### THE BEGINNINGS

Logic as a discipline starts with the transition from the customary use of certain logical methods and argument patterns to the reflection on and inquiry into these and their elements, including the syntax and semantics of sentences. In antiquity, logic as a systematic discipline begins with Aristotle. However, discussions of some elements of logic and a focus on methods of inference can be traced back to the late fifth century BCE.

**SYNTAX AND SEMANTICS.** Some of the Sophists classified types of sentences (*logoi*) according to their force. So Protagoras (485–415), who included wish, question, answer, and command (Diels-Kranz 80.A1, Diogenes Laertius 9.53–4), and Alcidamas (pupil of Gorgias, fl. fourth century BCE), who distinguished assertion (*phasis*), denial (*apophasis*), question, and appellation (Diogenes Laertius 9.54). Antisthenes (mid-5th–mid-4th cent.) defined a sentence as "that which indicates what a thing was or is" (Diogenes Laertius 6.3, Diels-Kranz 45) and stated that someone who says what is speaks truly (Diels-Kranz 49). Perhaps the earliest surviving passage on logic is found in the *Dissoi Logoi* or Double arguments (Diels-Kranz 90.4, c.400 BCE). It is evidence for a debate over truth and falsehood. Opposed were the views that: (1) truth is a—temporal—property of sentences, and that a sentence is true (when it is said), if and only if things are as the sentence says they are when it is said, and false if they are not; and (2) truth is an atemporal property of what is said, and that what is said is true if and only if the things are the case, and false if they are not the case. These are rudimentary formulations of two alternative corre-

spondence theories of truth. The same passage also displays awareness of the fact that self-referential use of the truth-predicate can be problematic—an insight also documented by the discovery of the Liar paradox by Eubulides of Miletus (mid fourth century BCE) shortly thereafter.

Some Platonic dialogues contain passages whose topic is indubitably logic. In the *Sophist*, Plato analyzes simple statements as containing a verb (*rhēma*, which indicates action) and a name (*onoma*, which indicates the agent) (Soph.261E–262A). Anticipating the modern distinction of logical types, he argues that neither a series of names nor a series of verbs can combine into a statement (Soph.262A–D). Plato also divorces syntax (*what is a statement?*) from semantics (*when is it true?*). Something (e.g., *Theaetetus is sitting*) is a statement if it both succeeds in specifying a subject and says something about this subject. Plato thus determines subject and predicate as relational elements in a statement and excludes statements containing empty subject expressions. Something is a true statement if with reference to its subject (*Theaetetus*) it says of what is (e.g., sitting) that it is. Something is a false statement if with reference to its subject it says of something other than what is (e.g., flying) that it is. Here Plato produces a sketch of a reductionist theory of truth (Soph.262E–263D; cf. also Crat. xxx). He also distinguishes negations from affirmations and takes the negation particle to have narrow scope: It negates the predicate, not the whole sentence (Soph.257B–C). There are many passages in Plato where he struggles with explaining certain logical relations. For example, his theory that things participate in Forms corresponds to a rudimentary theory of predication; in the *Sophist* and elsewhere, he grapples with the class relations of exclusion, union, and coextension; also with the difference between the *is* of predication (being) and the *is* of identity (sameness); and in *Republic* 4 he anticipates the law of noncontradiction. But his explications of these logical questions are cast in metaphysical terms and so can, at most, be regarded as protological.

**ARGUMENT PATTERNS AND VALID INFERENCE.** Pre-Aristotelian evidence for reflection on argument forms and valid inference are harder to come by. Both Zeno of Elea (c.490 BCE) and Socrates (470–399) were famous for the ways in which they refuted an opponent's view. Their methods display similarities with *reductio ad absurdum*, but neither of them seems to have theorized about their logical procedures. Zeno produced arguments (*logoi*) that manifest variations of the pattern *this* (that is, the opponent's view) *only if that*. *But that is impossible*. *So this is*

*impossible*. Socratic refutation was an exchange of questions and answers in which the opponents would be led, on the basis of their answers, to a conclusion incompatible with their original claim. Plato institutionalized such disputations into structured, rule-governed, verbal contests that became known as dialectical argument. The development of a basic logical vocabulary for such contests indicates some reflection upon the patterns of argumentation.

The fifth and fourth centuries BCE also see great interest in fallacies and logical paradoxes. Besides the Liar, Eubulides is said to have been the originator of several other logical paradoxes, including the Sorites. Plato's *Euthydemus* contains a large collection of contemporary fallacies. In attempts to solve such logical puzzles, a logical terminology develops here, too, and the focus on the difference between valid and invalid arguments sets the scene for the searching for a criterion of valid inference. Finally, it is possible that the shaping of deduction and proof in Greek mathematics that begins in the later fifth century BCE served as an inspiration for Aristotle's syllogistic.

## ARISTOTLE

Aristotle is the first great logician in the history of logic. His logic was taught by and large without rival from the fourth to the nineteenth centuries CE. Aristotle's logical works were collected and put in a systematic order by later Peripatetics who titled them the *Organon* or *tool* because they considered logic not as a part but rather an instrument of philosophy. The *Organon* contains, in traditional order, the *Categories*, *De Interpretatione*, *Prior Analytics*, *Posterior Analytics*, *Topics*, and *Sophistical Refutations*. In addition, *Metaphysics* Γ is a logical treatise that discusses the principle of noncontradiction, and some further logical insights are found scattered throughout Aristotle's other works. Some parts of the *Categories* and *Posterior Analytics* would today be regarded as metaphysics, epistemology, or philosophy of science rather than logic. The traditional arrangement of works in the *Organon* is neither chronological nor Aristotle's own. The original chronology cannot be fully recovered since Aristotle often inserted supplements into earlier writings at a later time. However, by using logical advances as criterion, we can conjecture that most of the *Topics*, *Sophistical Refutations*, *Categories*, and *Metaphysics* Γ predate the *De Interpretatione*, which in turn precedes the *Prior Analytics* and parts of the *Posterior Analytics*.

**DIALECTICS.** The *Topics* provide a manual for participants in the contests of dialectical argument as instituted in the Academy by Plato. Books 2–7 provide general procedures or rules (*topoi*) about how to find an argument to establish or refute a given thesis. The descriptions of these procedures—some of which are so general that they resemble logical laws—clearly presuppose a notion of logical form, and Aristotle’s *Topics* may thus count as the earliest surviving logical treatise. The *Sophistical Refutations* are the first systematic classification of fallacies, sorted by what logical flaw each type manifests (e.g., equivocation, begging the question, affirming the consequent, *secundum quid*) and how to expose them.

**SUB-SENTENTIAL CLASSIFICATIONS** Aristotle distinguishes things that have sentential unity through a combination of expressions (a horse runs) from those that do not (horse, runs); the latter are dealt with in the *Categories* (the title really means Predications). They have no truth value and signify one of the following: substance (*ousia*), quantity (*poson*), quality (*poion*), relation (*prosti*), location (*pou*), time (*pote*), position (*keisthai*), possession (*echein*), doing (*poiein*), and undergoing (*paschein*). It is unclear whether Aristotle considers this classification to be one of linguistic expressions that can be predicated of something else, or of kinds of predication, or of highest genera. In *Topics* 1 Aristotle distinguishes four relationships a predicate may have to the subject: It may give its definition, genus, unique property, or accidental property. These are known as predicables.

**SYNTAX AND SEMANTICS OF SENTENCES.** When writing the *De Interpretatione*, Aristotle had worked out the following theory of simple sentences: A (declarative) sentence (*apophantikos logos*) or declaration (*apophansis*) is delimited from other pieces of discourse such as prayer, command, and question by its having a truth value. The truth bearers that feature in Aristotle’s logic are thus linguistic items. They are spoken sentences that directly signify thoughts (shared by all humans) and, through these, indirectly, things. Written sentences in turn signify spoken ones. Sentences are constructed from two signifying expressions that stand in subject-predicate relation to each other: a name and a verb (Callias walks) or two names connected by the copula *is*, which cosignifies the connection (Pleasure is good) (*Int.* 3). Names are either singular terms or common nouns. Both can be empty (Cat. 10, *Int.* 1). Singular terms can only take subject position. Verbs cosignify time. A name-verb sentence can be rephrased with the copula (Callias is [a] walking [thing]) (*Int.* 12). As to their quality, a sentence is either an affir-

mation or a negation, depending on whether it affirms or negates its predicate of its subject. The negation particle in a negation has wide scope (Cat. 10). Aristotle defines truth separately for affirmations and negations: An affirmation is true if it says of that which is that it is; a negation is true if it says of that which is not that it is not (Met.Γ. 7((1011b25ff)). These formulations can be interpreted as expressing either a correspondence or a reductionist conception of truth. Either way, truth is a property that belongs to a sentence *at a time*. As to their quantity, sentences are singular, universal, particular, or indefinite. Thus Aristotle obtains eight types of sentences, which are later dubbed *categorical sentences*; the following are examples, paired by quality:

Singular:	Callias is just.	Callias is not just.
Universal:	Every human is just.	No human is just.
Particular:	Some human is just.	Some human is not just.
Indefinite:	(A) human is just.	(A) human is not just.

Universal and particular sentences contain a quantifier, and both universal and particular affirmatives are taken to have existential import. The logical status of the indefinites is ambiguous and controversial (*Int.* 6–7).

Aristotle distinguishes between two types of sentential opposition: contraries and contradictories. A contradictory pair of sentences (*antiphrasis*) consists of an affirmation and its negation (that is, the negation that negates of the subject what the affirmation affirms of it). Aristotle assumes that—normally—one of these must be true, the other false. Contrary sentences are such that they cannot both be true. The contradictory of a universal affirmative is the corresponding particular negative; that of the universal negative the corresponding particular affirmative. A universal affirmative and its corresponding universal negative are contraries. Aristotle thus has captured the basic logical relations between monadic quantifiers (*Int.* 7).

Since Aristotle regards tense as part of the truth bearer (as opposed to merely a grammatical feature), he detects a problem regarding future tense sentences about contingent matters and discusses it in the famous chapter nine of his *De Interpretatione*: Does the principle that, of an affirmation and its negation one must be false, the other true, apply to these? What, for example, is the truth value now of the sentence *There will be a sea battle tomorrow*? Aristotle may have suggested that the sentence has no truth value now and that bivalence thus does not hold—despite the fact that it is necessary for there either to be or not to be a sea battle tomorrow, so that the principle of excluded middle is preserved.

**NONMODAL SYLLOGISTIC.** Aristotle’s nonmodal syllogistic, the core of which he develops in the first seven chapters of Book One of his *Prior Analytics*, is the pinnacle of his logic. Aristotle defines a syllogism as “an argument (*logos*) in which, certain things having been laid down, something different from what has been laid down follows of necessity because these things are so.” This definition appears to require that (1) a syllogism consists of at least two premises and a conclusion, (2) the conclusion follows of necessity from the premises, and (3) the conclusion differs from the premises. Aristotle’s syllogistic covers only a small part of all arguments that satisfy these conditions.

Aristotle restricts and regiments the types of categorical sentence that may feature in a syllogism. The admissible truth bearers are now defined as each containing two different terms (*horoi*) conjoined by the copula, of which one (the predicate term) is said of the other (the subject term) either affirmatively or negatively. Aristotle never comes clear on the question whether terms are things (nonempty classes) or linguistic expressions for these things. Only universal and particular sentences are discussed. Singular sentences seem excluded, and indefinite sentences are mostly ignored.

Another innovation in the syllogistic is Aristotle’s use of letters in place of terms. The letters may originally have served simply as abbreviations for terms, as we can see for example in his *Posterior Analytics*, but in the syllogistic they seem mostly to have the function either of schematic term letters or of term variables with universal quantifiers assumed but not stated. Where he uses letters, Aristotle tends to express the four types of categorical sentences in the following way (with common later abbreviations in brackets):

- “A holds of every B” (AaB)
- “A holds of no B” (AeB)
- “A holds of some B” (AiB)
- “A does not hold of some B” (AoB)

Instead of *holds* he also uses *is predicated*.

All basic syllogisms consist of three categorical sentences in which the two premises share exactly one term, called the middle term, and the conclusion contains the other two terms, sometimes called the extremes. Based on the position of the middle term, Aristotle classified all possible premise combinations into three figures (*schemata*): The first figure has the middle term (B) as subject in the first premise and predicated in the second;

the second figure has it predicated in both premises; the third has it as subject in both premises:

A holds of B	B holds of A	A holds of B
B holds of C	B holds of C	C holds of B

A is also called the major term and C the minor term. Each figure can further be classified according to whether or not both premises are universal. Aristotle went systematically through the fifty-eight possible premise combinations and showed that fourteen have a conclusion following of necessity from them. His procedure was this: He assumed that the syllogisms of the first figure are complete and not in need of proof since they are evident. By contrast, the syllogisms of the second and third figures are incomplete and in need of proof. He proves them by reducing them to syllogisms of the first figure and thereby *completing* them. For this he makes use of three methods: (1) Conversion (*antistrophē*)—a categorical sentence is converted by interchanging its terms. Aristotle recognizes and establishes three conversion rules: “from AeB infer BeA”; “from AiB infer BiA”; and “from AaB infer BiA.” All second- and third-figure syllogisms but two can be proved by premise conversion. (2) *Reductio ad impossibile* (*apagōgē*)—the remaining two are proved by reduction to the impossible, where the contradictory of an assumed conclusion together with one of the premises is used to deduce by a first-figure syllogism a conclusion that is incompatible with the other premise. Using the semantic relations between opposites established earlier, the assumed conclusion is thus established. (3) Exposition (*ekthesis*)—this method, which Aristotle uses additionally to (1) and (2), is controvertible both as to what exactly it was and as to whether it is proof.

For each of the thirty-four premise combinations that allow no conclusion, Aristotle proves by counterexample that they allow no conclusion. As overall result, he acknowledges four first-figure syllogisms (later called Barbara, Celarent, Darii, Ferio), four second-figure syllogisms (Camestres, Cesare, Festino, Baroco), and six third-figure syllogisms (Darapti, Felapton, Disamis, Datisi, Bocardo, Ferison); these were later called the modes or moods of the figures. (The names are mnemonics: e.g., each vowel indicates in order whether the first and second premises and the conclusion were sentences of type *a*, *e*, *i*, or *o*.) Aristotle implicitly recognized that by using the conversion rules on the conclusions we obtain eight further syllogisms (AnPr. 53a3–14), and that of the premise combinations rejected as nonsyllogistic, some (five, in fact) will yield a conclusion in which the minor term is predicated of the major (AnPr. 29a19–27, Fapesmo, Fris-

esomorum, Firesmo, Fapemo, Frisemo). Moreover, in the *Topics*, Aristotle accepted the rules “from  $AaB$  infer  $AiB$ ” and “from  $AeB$  infer  $AoB$ .” By using these on the conclusions, five further syllogisms could be proved though Aristotle did not mention this.

Going beyond his basic syllogistic, Aristotle reduced the third and fourth first-figure syllogisms to second-figure syllogisms, thus de facto reducing all syllogisms to Barbara and Celarent; later, in the *Prior Analytics*, he invokes a type of cut-rule by which a multipremise syllogism can be reduced to two or more basic syllogisms. From a modern perspective, Aristotle’s system can be represented as an argumental natural deduction system *en miniature*. It has been shown to be sound and complete if one interprets the relations expressed by the categorical sentences set theoretically as a system of nonempty classes as follows:  $AaB$  is true iff the class A contains the class B.  $AeB$  is true iff the classes A and B are disjoint.  $AiB$  is true iff the classes A and B are not disjoint.  $AoB$  is true iff the class A does not contain the class B. The vexing textual question of what exactly Aristotle meant by *syllogisms* has received several rival interpretations, including one that they are a certain type of conditional propositional form. Most plausibly, perhaps, Aristotle’s complete and *incomplete* syllogisms taken together are understood as formally valid premise-conclusion arguments; and his complete and *completed* syllogisms taken together as (sound) deductions.

**MODAL LOGIC.** Aristotle is also the originator of modal logic. In addition to quality and quantity, he takes categorical sentences to have a mode; this consists of the fact that the predicate is said to hold of the subject either actually or necessarily or possibly or contingently or impossibility. The latter four are expressed by modal operators that modify the predicate, for example: “It is possible for A to hold of some B”; “A necessarily holds of every B.”

In *De Interpretatione* (12–13), Aristotle:

- (1) Concludes that modal operators modify the whole predicate (or the copula, as he puts it), not just the predicate term of a sentence;
- (2) States the logical relations that hold between modal operators, such as that “it is not possible for A not to hold of B” implies “it is necessary for A to hold of B”;
- (3) Investigates what the contradictories of modalized sentences are and decides that they are obtained by placing the negator in front of the modal operator.

(4) Equates the expressions *possible* and *contingent*, but wavers between a one-sided interpretation (where necessity implies possibility) and a two-sided interpretation (where possibility implies nonnecessity).

Aristotle develops his modal syllogistic in chapters eight to twenty-two of the first book of his *Prior Analytics*. He settles on two-sided possibility (contingency) and tests for syllogismhood all possible combinations of premise pairs of sentences with necessity (N), contingency (C), or no (U) modal operator: NN, CC, NU/UN, CU/UC, and NC/CN. Syllogisms with the last three types of premise combinations are called mixed modal syllogisms. Apart from the NN category, which mirrors unmodalized syllogisms, all categories contain dubious cases. For instance, Aristotle accepts:

A necessarily holds of all B.

B holds of all C.

Therefore A necessarily holds of all C.

This and other problematic cases were already disputed in antiquity, and since the mid-1930s, they have sparked a host of complex, formalized reconstructions of Aristotle’s modal syllogistic. As Aristotle’s theory is conceivably internally inconsistent, the formal models that have been suggested may all be unsuccessful.

## THE EARLY PERIPATETICS: THEOPHRASTUS AND EUDEMUS

Aristotle’s pupil and successor Theophrastus of Eresus (c. 371–c. 287 BCE) wrote more logical treatises than his teacher, with a large overlap in topics. Eudemus of Rhodes (later fourth century BCE) wrote books titled *Categories*, *Analytics*, and *On Speech*. Of all these works only a number of fragments and later testimonies survive, mostly in Aristotle commentators. Theophrastus and Eudemus simplified some aspects of Aristotle’s logic and developed others where Aristotle left us only hints.

**IMPROVEMENTS AND MODIFICATIONS OF ARISTOTLE’S LOGIC.** The two Peripatetics seem to have redefined Aristotle’s first figure so that it includes every syllogism in which the middle term is subject of one premise and predicate of the other. In this way, five types of nonmodal syllogisms only intimated by Aristotle later in his *Prior Analytics* (Baralipon, Celantes, Datibis, Fapesmo, and Frisesomorum) are included, but Aristotle’s criterion that first-figure syllogisms are evident is given up (fr. 91). Theophrastus and Eudemus also improved Aristotle’s modal theory. Theophrastus

replaced Aristotle's two-sided contingency by one-sided possibility so that possibility no longer entails nonnecessity. Both recognized that the problematic universal negative ("A possibly holds of no B") is simply convertible (fr. 102A). Moreover, they introduced the principle that in mixed modal syllogisms the conclusion always has the same modal character as the weaker of the premises (frs.106 and 107), where possibility is weaker than actuality, and actuality than necessity. In this way Aristotle's modal syllogistic is notably simplified, and many unsatisfactory theses, like the one mentioned above, disappear.

**PROSLEPTIC SYLLOGISMS.** Theophrastus introduced the so-called prosleptic premises and syllogisms (fr. 110). A prosleptic premise is of the form:

For all X, if  $\Phi(X)$ , then  $\Psi(X)$

where  $\Phi(X)$  and  $\Psi(X)$  stand for categorical sentences in which the variable X occurs in place of one of the terms. For example:

- 1) A <holds> of all of that of all of which B <holds>.
- 2) A <holds> of none of that which <holds> of all B.

Theophrastus considered such premises to contain three terms, two of which are definite (A, B) and one indefinite (*that*, or the bound variable X). We can represent (1) and (2) as:

$\forall X \text{ BaX} \rightarrow \text{AaX}$

$\forall X \text{ XaB} \rightarrow \text{AeX}$

Prosleptic syllogisms then come about as follows: They are comprised of a prosleptic premise and the categorical premise obtained by instantiating a term (C) in the antecedent *open categorical sentence* as premises, and the categorical sentences one obtains by putting in the same term (C) in the consequent *open categorical sentence* as conclusion. For example:

A <holds> of all of that of all of which B <holds>.

B holds of all C.

Therefore, A holds of all C.

Theophrastus distinguished three figures of these syllogisms, depending on the position of the indefinite term (also called *middle term*) in the prosleptic premise; for example (1) produces a third-figure syllogism, (2) a first-figure syllogism. The number of prosleptic syllogisms was presumably equal to that of types of prosleptic sentences: With Theophrastus's concept of the first figure, these would be sixty-four (that is, 32+16+16).

Theophrastus held that certain prosleptic premises were equivalent to certain categorical sentences, for example, (1) to "A is predicated of all B." However, for many, including (2), no such equivalent can be found, and prosleptic syllogisms thus increased the inferential power of Peripatetic logic.

**FORERUNNERS OF MODUS PONENS AND TOLLENS.** Theophrastus and Eudemus considered complex premises that they called *hypothetical premise* and that had one of the following two forms (or similar):

If something is F, it is G.

Either something is F or it is G. (with exclusive *or*)

They developed arguments with them that they called "mixed from a hypothetical premise and a probative premise" (fr. 112A) These arguments were inspired by Aristotle's syllogisms from a hypothesis (*An.Pr.* 1.44); they were forerunners of *modus ponens* and *modus tollens* and had the following forms: (frs.111 and 112):

If something is F, it is G.

*a* is F.

Therefore, *a* is G.

Either something is F or it is G.

*a* is F.

Therefore, *a* is not G.

If something is F, it is G.

*a* is not G.

Therefore, *a* is not F.

Either something is F or it is G.

*a* is not F.

Therefore, *a* is G.

Theophrastus also recognized that the connective particle *or* can be inclusive (fr. 82A); and he considered relative quantified sentences such as those containing *more*, *fewer*, and *the same* (fr. 89), and seems to have discussed syllogisms built from such sentences, again following up upon what Aristotle said about syllogisms from a hypothesis (fr. 111E).

**WHOLLY HYPOTHETICAL SYLLOGISMS.** Theophrastus is further credited with the invention of a system of the later so-called *wholly hypothetical syllogisms* (fr. 113). These syllogisms were originally abbreviated term-logical arguments of the kind:

If [something is] A, [it is] B.

If [something is] B, [it is] C.

Therefore, if [something is] A, [it is] C.

and at least some of them were regarded as reducible to Aristotle's categorical syllogisms, presumably by way of the equivalences to "Every A is B," and so on. In parallel to Aristotle's syllogistic, Theophrastus distinguished three

figures, each of which had sixteen modes. The first eight modes of the first figure are obtained by going through all permutations with “not X” instead of “X” (with X for A, B, C); the second eight modes are obtained by using a rule of contraposition on the conclusion:

(CR) From “if X, Y” infer “if the contradictory of Y then the contradictory of X”

The sixteen modes of the second figure were obtained by using (CR) on the schema of the first premise of the first figure arguments, for example:

If [something is] not B, [it is] not A.

If [something is] B, [it is] C.

Therefore, if [something is] A, [it is] C.

The sixteen modes of the third figure were obtained by using (CR) on the schema of the second premise of the first figure arguments, for example:

If [something is] A, [it is] B.

If [something is] not C, [it is] not B.

Therefore, if [something is] A, [it is] C.

Theophrastus claimed that all second- and third-figure syllogisms could be reduced to first-figure syllogisms. If Alexander of Aphrodisias reports faithfully, any use of (CR) that transforms a syllogism into a first-figure syllogism was such a reduction. The large number of modes and reductions can be explained by the fact that Theophrastus did not have the logical means for substituting negative for positive components in an argument. In later antiquity, after some intermediate stages, and possibly under Stoic influence, the wholly hypothetical syllogisms were interpreted as propositional-logical arguments of the kind:

If p, then q.

If q, then r.

Therefore, if p, then r.

## DIODORUS CRONUS AND PHILO THE LOGICIAN

In the later fourth to mid third centuries BCE, a loosely connected group of philosophers, sometimes referred to as dialecticians and possibly influenced by Eubulides, conceived of logic as a logic of propositions. Their best-known exponents were Diodorus Cronus and his pupil Philo (sometimes called Philo of Megara) although no writings of theirs are preserved. They each made groundbreaking contributions to the development of proposi-

tional logic, in particular to the theories of conditionals and modalities.

A conditional (*sunēmnenon*) was considered as a nonsimple proposition comprised of two propositions and the connecting particle *if*. Philo, who may be credited with introducing truth-functionality into logic, provided the following criterion for their truth: A conditional is false *when* and only *when* its antecedent is true and its consequent is false, and it is true in the three remaining truth-value combinations. The Philonian conditional resembles material implication except that—since propositions were conceived of as functions of time that can have different truth values at different times—it may change its truth value over time. For Diodorus, a conditional proposition is true if it neither was nor is possible that its antecedent is true and its consequent false. The temporal elements in this account suggest that the possibility of a truth-value change in Philo’s conditionals was meant to be improved on. With his own modal notions (see below) applied, a conditional is Diodorean true now if and only if it is Philonian true at all times. Diodorus’s conditional is thus reminiscent of strict implication. Philo’s and Diodorus’s conceptions of conditionals led to variants of the *paradoxes* of material and strict implication—a fact the ancients were aware of (S.E.M. 109–117).

Philo and Diodorus each considered the four modalities possibility, impossibility, necessity, and nonnecessity. These were conceived of as modal properties or modal values of propositions, not as modal operators. Philo defined them as follows:

Possible is that which is capable of being true by the proposition’s own nature ... necessary is that which is true, and which, as far as it is in itself, is not capable of being false. Non-necessary is that which as far as it is in itself, is capable of being false, and impossible is that which by its own nature is not capable of being true (Boethius, *In librum Aristotelis De interpretatione: secunda editio*, p. 234).

Diodorus’s definitions were these: “Possible is that which either is or will be <true>; impossible that which is false and will not be true; necessary that which is true and will not be false; non-necessary that which either is false already or will be false” (Boethius, *In librum Aristotelis De interpretatione: secunda editio*, p. 234). Both sets of definitions satisfy the following standard requirements of modal logic:

(1) Necessity entails truth and truth entails possibility;

- (2) Possibility and impossibility are contradictories, and so are necessity and nonnecessity;
- (3) Necessity and possibility are interdefinable;
- (4) Every proposition is either necessary or impossible or both possible and nonnecessary.

Philo's definitions appear to introduce mere conceptual modalities whereas with Diodorus's definitions, some propositions may change their modal value. Diodorus's definition of possibility rules out future contingents and implies the counterintuitive thesis that only the actual is possible. Diodorus tried to prove this claim with his famous Master Argument, which sets out to show the incompatibility of (1) "every past truth is necessary," (2) "the impossible does not follow from the possible," and (3) "something is possible which neither is nor will be true" (Epictetus *Discourses* II.19). The argument has not survived, but various reconstructions have been suggested. Some affinity with the arguments for logical determinism in Aristotle's *De Interpretatione* 9 is likely.

## THE STOICS

The founder of the Stoa, Zeno of Citium (335–263 BCE), studied with Diodorus. His successor, Cleanthes, (331–232) tried to solve the Master Argument by denying that every past truth is necessary and wrote books—now lost—on paradoxes, dialectics, argument modes, and predicates. Both philosophers considered logic as a virtue and held it in high esteem, but they seem not to have been creative logicians. By contrast, Cleanthes's successor, Chrysippus of Soli (c.280–207), is without doubt the second great logician in the history of logic. It was said of him that if the gods used any logic, it would be that of Chrysippus, and his reputation as a brilliant logician is amply testified. Chrysippus wrote more than 300 books on logic, on virtually any topic contemporary logic concerns itself with, including speech act theory, sentence analysis, singular and plural expressions, types of predicates, demonstratives, existential propositions, sentential connectives, negations, disjunctions, conditionals, logical consequence, valid argument forms, theory of deduction, propositional logic, modal logic, tense logic, logic of suppositions, logic of imperatives, ambiguity, and logical paradoxes—in particular, the Liar and the Sorites (Diogenes Laertius 7.189–199). Of all these, only two badly damaged papyri have survived, luckily supplemented by a considerable number of fragments and testimonies in later texts, in particular in Diogenes Laertius, book 7, sections 55–83; and Sextus Empiricus, *Outlines of Pyrrhonism*, book 2, and *Against the Mathematicians*, book 8

(both of which appear in *Works*). Chrysippus's successors, including Diogenes of Babylon (c.240–152) and Antipater of Tarsus, appear to have systematized and simplified some of his ideas, but their original contributions to logic seem small. Many testimonies of Stoic logic do not name any particular Stoic. Hence the following paragraphs simply talk about the Stoics in general; but we can be confident that a large part of what has survived goes back to Chrysippus.

**LOGICAL ACHIEVEMENTS BESIDES PROPOSITIONAL LOGIC.** The subject matter of Stoic logic are the so-called sayables (*lekta*): They are the underlying meanings in everything we say and think, but—like Gottlob Frege's senses—subsist also independently of us. They are distinguished from linguistic expressions: What we *utter* are those expressions, but what we *say* are the sayables (Diogenes Laertius 7.57). There are complete and deficient sayables. Complete sayables, if said, do not make the hearer feel prompted to ask a question (Diogenes Laertius 7.63). They include assertibles (the Stoic equivalent for propositions), interrogatives, imperatives, inquiries, hypotheses, and more. The accounts of the different complete sayables all had the general form *a so-and-so sayable is one in saying which we perform an act of such-and-such*. For instance: An imperative sayable is one in saying which we issue a command; an interrogative sayable is one in saying which we ask a question; a declaratory sayable (that is, an assertible) is one in saying which we make an assertion. Thus, according to the Stoics, each time we say a complete sayable, we perform three different acts: we utter a linguistic expression, we say the sayable, and we perform a speech-act.

Assertibles (*axiōmata*) differ from all other complete sayables by having a truth value: At any one time they are either true or false. Truth is temporal and assertibles may change their truth value. The Stoic principle of bivalence is hence temporalized, too. Truth is introduced by example: the assertible "it is day" is true *when* it is day, and at all other times false (Diogenes Laertius 7.65). This suggests a reductionist view of truth, as does the fact that the Stoics identify true assertibles with facts but define false assertibles simply as the contradictories of true ones (S.E.M. 8.85).

Assertibles are simple or nonsimple. A simple *predicative* assertible, such as *Dion is walking*, is generated from the predicate *is walking*, which is a deficient assertible since it elicits the question *who*, and a nominative case (Dion's individual quality or the correlated sayable), which falls under the predicate (Diogenes Laertius 7.63

and 70). There is thus no interchangeability of predicate and subject terms as in Aristotle; rather, predicates—but not the things that fall under them—are defined as deficient and thus resemble propositional functions. It seems that whereas some Stoics took the Fregean approach that singular terms had correlated sayables, others anticipated the notion of direct reference. Concerning demonstratives, the Stoics took a simple *definite* assertible such as *this one is walking* to be true when the person pointed at by the speaker is walking (S.E.M. 100). When the thing pointed at ceases to be, so does the assertible though the sentence used to express it remains (Alex.Aphr.An.Pr. 177–8). A simple *indefinite* assertible such as *someone is walking* is said to be true when a corresponding definite assertible is true (S.E.M. 98). Aristotelian universal affirmatives (“Every A is B”) were to be rephrased as “If something is A, it is B” (S.E.M. 9.8–11). The past tense assertible *Dion walked* is true when there is at least one past time at which *Dion is walking* was true. The negation of *Dion is walking* is *(It is) not (the case that) Dion is walking*, and not *Dion is not walking*. The latter is analyzed in a Russellian manner as *Both Dion exists and not: Dion is walking*’ (Alex.Aphr.An.Pr. 402).

**SYNTAX AND SEMANTICS OF COMPLEX PROPOSITIONS.** Thus the Stoics concerned themselves with several issues we would place under the heading of predicate logic; but their main achievement was the development of a propositional logic, that is, of a system of deduction in which the smallest substantial unanalyzed expressions are propositions, or rather, assertibles.

The Stoics defined negations as assertibles that consist of a negative particle and an assertible controlled by this particle (S.E.M. 103). Similarly, nonsimple assertibles were defined as assertibles that either consist of more than one assertible or of one assertible taken more than once (Diogenes Laertius 7.68–9) and that are controlled by a connective particle. Both definitions are recursive and allow for assertibles of indeterminate complexity. Three types of nonsimple assertions feature in Stoic syllogistic. Conjunctions are nonsimple assertibles put together by the conjunctive connective *both ... and ... and ...*. They have two or more conjuncts, all on a par. Disjunctions are nonsimple assertibles put together by the disjunctive connective *either ... or ... or ...*. They have two or more disjuncts, all on a par. Conditionals are nonsimple assertibles formed with the connective *if ..., ...*; they consist of antecedent and consequent (Diogenes Laertius 7.71–2). What type of assertible an assertible is is determined by the connective particle that controls it, that is, that is, that has the largest scope. *Both not p and q*

is a conjunction; *Not both p and q* a negation. Stoic language regimentation asks that sentences expressing assertibles always start with the logical particle or expression characteristic for the assertible. Thus the Stoics introduced an implicit bracketing device similar to that used in Jan Łukasiewicz’s (1878–1956) Polish notation.

Stoic negations and conjunctions are truth-functional. Stoic (or at least Chrysippean) conditionals are true when the contradictory of the consequent is incompatible with its antecedent (Diogenes Laertius 7.73). Two assertibles are contradictories of each other if one is the negation of the other (Diogenes Laertius 7.73) or when one exceeds the other by a pre-fixed negation particle (SE M 8.89). The truth-functional Philonian conditional was expressed as a negation of a conjunction: that is, that is, not as *if p, q* but as *not both p and not q*. Stoic disjunction is exclusive and non-truth-functional. It is true when necessarily precisely one of its disjuncts is true. Later Stoics introduced a non-truth-functional inclusive disjunction (Gellius.N.A. 16.8.13–14).

Like Philo and Diodorus, Chrysippus distinguished four modalities and considered them as modal values of propositions rather than modal operators; they satisfy the same standard requirements of modal logic. Chrysippus’s definitions are: An assertible is possible when it is both capable of being true and not hindered by external things from being true. An assertible is impossible when it is either not capable of being true <or is capable of being true, but hindered by external things from being true>. An assertible is necessary when, being true, it either is not capable of being false or is capable of being false but hindered by external things from being false. An assertible is nonnecessary when it is both capable of being false and not hindered by external things <from being false> (Diogenes Laertius 7.75). Chrysippus’s modal notions differ from Diodorus’s in that they allow for future contingents and from Philo’s in that they go beyond mere conceptual possibility.

**ARGUMENTS.** Arguments are—normally—compounds of assertibles. They are defined as a system of at least two premisses and a conclusion (Diogenes Laertius 7.45). Syntactically, every premise but the first is introduced by *now* or *but*, and the conclusion by *therefore*. An argument is valid if the (Chrysippean) conditional formed with the conjunction of its premisses as antecedent and its conclusion as consequent is correct (S.E.P.H. 2.137, DL 7.77). An argument is *sound* (literally: *true*) when in addition to being valid, it has true premisses. The Stoics defined so-called argument modes as a sort of schema of an argu-

ment (Diogenes Laertius 7.76). A mode of an argument differs from the argument itself by having ordinal numbers taking the place of propositions. A mode of the argument:

If it is day, it is light.  
 But it is not the case that it is light.  
 Therefore it is not the case that it is day.

is

If the 1<sup>st</sup>, the 2<sup>nd</sup>.  
 But not: the 2<sup>nd</sup>.  
 Therefore not: the 1<sup>st</sup>.

The modes functioned first as abbreviations of arguments that brought out their logically relevant form and second, it seems, as representatives of the form of a class of arguments.

**STOIC SYLLOGISTIC.** Stoic syllogistic is an argumental deductive system consisting of five types of indemonstrables or axiomatic arguments and four inference rules, called *themata*. An argument is a syllogism precisely if it either is an indemonstrable or can be reduced to one by means of the *themata* (Diogenes Laertius 7.78). Syllogisms are thus certain types of formally valid arguments. The Stoics explicitly acknowledged that there are valid arguments that are not syllogisms but assumed that they could be somehow transformed into syllogisms.

All basic indemonstrables consist of a nonsimple assertible as leading premiss and a simple assertible as coassumption and have another simple assertible as conclusion. They were defined by five standardized metalinguistic descriptions of the forms of the arguments (S.E. M. 8.224–5; D.L.7.80–81):

- (1) A first indemonstrable is an argument composed of a conditional and its antecedent as premisses, having the consequent of the conditional as conclusion.
- (2) A second indemonstrable is an argument composed of a conditional and the contradictory of its consequent as premisses, having the contradictory of its antecedent as conclusion.
- (3) A third indemonstrable is an argument composed of a negated conjunction and one of its conjuncts as premisses, having the contradictory of the other conjunct as conclusion.
- (4) A fourth indemonstrable is an argument composed of a disjunctive assertible and one of its disjuncts as premisses, having the contradictory of the remaining disjunct as conclusion.

(5) A fifth indemonstrable, finally, is an argument composed of a disjunctive assertible and the contradictory of one of its disjuncts as premisses, having the remaining disjunct as conclusion.

Whether an argument is an indemonstrable can be tested by comparing it with these metalinguistic descriptions. For instance:

If it is day, it is not the case that it is night.  
 But it is night.  
 Therefore it is not the case that it is day.

comes out as a second indemonstrable, and

If five is a number, then either five is odd or five is even.  
 But five is a number.  
 Therefore either five is odd or five is even.

as a first indemonstrable. For testing, a suitable mode of an argument can also be used as a stand-in. A mode is syllogistic, if a corresponding argument with the same form is a syllogism (because of that form). However, there are no five modes that can be used as inference schemata that represent the five types of indemonstrables. For example, the following are two of the many modes of fourth indemonstrables:

Either the 1 <sup>st</sup> or the 2 <sup>nd</sup> .	Either the 1 <sup>st</sup> or not the 2 <sup>nd</sup> .
But the 2 <sup>nd</sup> .	But the 1 <sup>st</sup> .
Therefore not the 1 <sup>st</sup> .	Therefore the 2 <sup>nd</sup> .

Although both are covered by the metalinguistic description, neither can be singled out as *the* mode of the fourth indemonstrables: If we disregard complex arguments, there are thirty-two modes corresponding to the five metalinguistic descriptions; the latter thus prove noticeably more economical.

Of the four *themata* only the first and third are extant. They, too, were metalinguistically formulated. The first *thema*, in its basic form, was:

When from two <assertibles> a third follows, then from either of them together with the contradictory of the conclusion the contradictory of the other follows (Apul.Int. 209.9–14).

This is an inference rule of the kind today called antilogism. The third *thema*, in one formulation, was:

When from two <assertibles> a third follows, and from the one that follows <that is, the third> together with another, external assumption, another follows, then this other follows

from the first two and the externally coassumed one (Simp.Cael. 237.2–4).

This is an inference rule of the kind today called cut rule. It is used to reduce chain syllogisms. (The second and fourth *themata* are also cut rules, and reconstructions of them can be provided since we know what arguments they, together with the third *thema*, were thought to be able to reduce.) A reduction shows the formal validity of an argument by applying to it the *themata* in one or more steps in such a way that all resultant arguments are indemonstrables. This can be done either with the arguments or their modes (S.E. M. 8.230–8). For instance, the argument mode:

If the 1<sup>st</sup> and the 2<sup>nd</sup>, the 3<sup>rd</sup>.  
But not the 3<sup>rd</sup>.  
Moreover, the 1<sup>st</sup>.  
Therefore not: the 2<sup>nd</sup>.

can be reduced by the third *thema* to (the modes of) a second and a third indemonstrable as follows:

When from two assertibles (“If the 1<sup>st</sup> and the 2<sup>nd</sup>, the 3<sup>rd</sup>.” and “But not the 3<sup>rd</sup>.”) a third follows (“Not: both the 1<sup>st</sup> and the 2<sup>nd</sup>.”—by a second indemonstrable) and from the third and an external one (“The 1<sup>st</sup>.”) another follows (“Not: the 2<sup>nd</sup>.”—by a third indemonstrable), then this other (“Not: the 2<sup>nd</sup>.”) also follows from the two assertibles and the external one.

The second *thema* reduced, among others, arguments with the following modes (Alex.Aphr.An.Pr. 164.27–31):

Either the 1 <sup>st</sup> or not the 1 <sup>st</sup> .	If the 1 <sup>st</sup> , if the 1 <sup>st</sup> , the 2 <sup>nd</sup> .
But the 1 <sup>st</sup> .	But the 1 <sup>st</sup> .
Therefore the 1 <sup>st</sup> .	Therefore the 2 <sup>nd</sup> .

The Peripatetics chided the Stoics for allowing such useless arguments, but the Stoics rightly insisted that if they can be reduced, they are valid. The four *themata* can be used repeatedly and in any combination in a reduction. Thus propositional arguments of indeterminate length and complexity can be reduced. Stoic syllogistic has been formalized, and it has been shown that the Stoic deductive system shows strong similarities with relevance logical systems such as those by Storrs McCall. Like Aristotle, the Stoics aimed at proving nonevident, formally valid *arguments* by reducing them by means of accepted inference rules to evidently valid *arguments*. Thus, although their logic is a propositional logic, they did not intend to provide a system that allows for the deduction

of all propositional-logical truths but, rather, a system of valid propositional-logical arguments with at least two premises and a conclusion. Nonetheless, it is evidenced that the Stoics independently recognized many simple logical truths, including excluded middle, double negation, and contraposition.

**LOGICAL PARADOXES.** The Stoics recognized the importance of both the Liar and the Sorites paradoxes (Cic.Acad. 2.95–8, Plut.Comm.Not. 1059D–E, Chrys.Log. Zet.col.IX, S.E.M.1.68&7.244–246&7.416.). Chrysippus may have tried to solve the Liar as follows: There is an uneliminable ambiguity in the Liar sentence (“I am speaking falsely,” uttered in isolation) between the assertibles (1) ‘I falsely say I speak FALSELY’ and (2) ‘I *am* speaking falsely’ (that is, I am doing what I’m saying), of which at any time the Liar sentence is said precisely one is true, but it is arbitrary which one: (2) entails (3) ‘I *am* speaking truly’ and is incompatible with (2) and (4) I truly say I speak falsely’ (2) entails (4) and is incompatible with (1) and (3). Thus bivalence is preserved. Chrysippus’s stand on the Sorites seems to have been that vague borderline sentences uttered in the context of a Sorites series have no assertibles corresponding them, and that it is obscure to us where the borderline cases start, so that it is rational for us to stop answering while still on safe ground. The latter remark suggests Chrysippus was aware of the problem of higher-order vagueness. Again, bivalence of assertibles is preserved.

## LATER ANTIQUITY

Very little is known about the development of logic from c. 100 BCE to c. 250 CE. It is unclear when Peripatetics and the Stoics began taking notice of the logical achievements of each other. Sometime during that period, the terminological distinction between *categorical syllogisms*, used for Aristotelian syllogisms, and *hypothetical syllogisms*, used not only for those by Theophrastus and Eudemus but also for the Stoic propositional-logical syllogisms, gained a foothold. In the first century BCE, the Peripatetics Ariston of Alexandria and Boethus of Sidon wrote about syllogistic. Ariston is said to have introduced the so-called *subaltern* syllogisms (Barbari, Celaront, Cesaro, Camestrop and Camenop) into Aristotelian syllogistic (Apul.Int. 213.5–10), that is, the syllogisms one gains by applying the subalternation rules (that were acknowledged by Aristotle in his *Topics*):

From “A holds of every B” infer “A holds of some B”

From “A holds of no B” infer “A does not hold of some B”

to the conclusions of the relevant syllogisms. Boethius suggested substantial modifications to Aristotle’s theories: He claimed that all categorical syllogisms are complete and that hypothetical syllogistic is prior to categorical (Gal.Inst.Log. 7.2), although we are not told prior in which way. The Stoic Posidonius (c.135–c.51 BCE) defended the possibility of logical or mathematical deduction against the Epicureans and discussed some syllogisms he called *conclusive by the force of an axiom*, which apparently included arguments of the type “As the 1<sup>st</sup> is to the 2<sup>nd</sup>, so the 3<sup>rd</sup> is to the 4<sup>th</sup>; the ratio of the 1<sup>st</sup> to the 2<sup>nd</sup> is double; therefore the ratio of the 3<sup>rd</sup> to the 4<sup>th</sup> is double,” which was considered conclusive by the force of the axiom “things which are in general of the same ratio, are also of the same particular ratio” (Gal. Inst. Log.18.8). At least two Stoics in this period wrote a work on Aristotle’s *Categories*. From his writings we know that Cicero was knowledgeable about both Peripatetic and Stoic logic; and Epictetus’s discourses prove that he was acquainted with some of the more taxing parts of Chrysippus’s logic. In all likelihood there existed at least a few creative logicians in this period, but we do not know who they were and what they created.

The next logician of rank, if of lower rank, of whom we have sufficient evidence is Galen (129–199 or 216 CE), whose greater fame was as a physician. He studied logic with both Peripatetic and Stoic teachers and recommended to avail oneself of parts of either doctrine, as long as it could be used for scientific demonstration. He composed commentaries on logical works by Aristotle, Theophrastus, Eudemus, and Chrysippus, as well as treatises on various logical problems and a major work titled *On Demonstration*. All these are lost except for some information in later texts, but his *Introduction to Logic* has come down to us almost in full. In *On Demonstration*, Galen developed, among other things, a theory of compound categorical syllogisms with four terms, which fall into four figures, but we do not know the details. He also introduced the so-called relational syllogisms, examples of which are “A is equal to B, B is equal to C; therefore A is equal to C” and “Dio owns half as much as Theo; Theo owns half as much as Philo. Therefore Dio owns a quarter of what Philo owns.” (Gal. Inst. Log. 17–18). All relational syllogisms Galen mentions have in common that they are not reducible in either Aristotle’s or Stoic syllogistic, but it is difficult to find further formal characteristics that unite them all. In general, in his *Introduction to*

*Logic*, he merges Aristotelian Syllogistic with a strongly Peripatetic reinterpretation of Stoic propositional logic.

The second ancient introduction to logic that has survived is Apuleius’s (second century CE) *De Interpretatione*. This Latin text, too, displays knowledge of Stoic and Peripatetic logic; it contains the first full presentation of the square of opposition, which illustrates the logical relations between categorical sentences by diagram. Alcinoüs, in his *Handbook of Platonism* 5, is witness to the emergence of a specifically Platonist logic, constructed on the Platonic notions and procedures of division, definition, analysis, and hypothesis, but there is little that would make a logicians heart beat faster. Sometime between the third and sixth century CE, Stoic logic faded into oblivion to be resurrected only in the twentieth century in the wake of the (re)discovery of propositional logic.

The surviving, often voluminous, Greek commentaries on Aristotle’s logical works by Alexander of Aphrodisias (fl. c.200 CE), Porphyry (234–c.305), Ammonius Hermeiou (fifth century), John Philoponus (c. 500), and Simplicius (sixth century), and the Latin ones by Anicius Manlius Severinus Boethius (c.480–524) have their main importance as sources for lost Peripatetic and Stoic works. Still, two of the commentators deserve special mention: Porphyry, for writing the *Isagoge* or *Introduction* (that is, to Aristotle’s *Categories*), in which he discusses the five notions of genus, species, differentia, property, and accident as basic notions one needs to know to understand the *Categories*. For centuries, the *Isagogē* was the first logic text a student would tackle, and Porphyry’s five predicables (which differ from Aristotle’s four) formed the basis for the medieval doctrine of the *quinque voces*.

The second is Boethius. In addition to commentaries, he wrote a number of logical treatises, mostly simple explications of Aristotelian logic, but also two very interesting ones: (1) His *On Topical Differentiae* bears witness of the elaborated system of topical arguments that logicians of later antiquity had developed from Aristotle’s *Topics* under the influence of the needs of Roman lawyers. (2) His *On Hypothetical Syllogisms* systematically presents wholly hypothetical and mixed hypothetical syllogisms as they are known from the early Peripatetics; it may be derived from Porphyry. Boethius’s insistence that the negation of “If it is A, it is B” is “If it is A, it is not B” suggests a suppositional understanding of the conditional, a view for which there is also some evidence in Ammonius, but that is not attested for earlier logicians. Historically, Boethius is most important because he translated all of Aristotle’s *Organon* into Latin, and thus

these texts (except the *Posterior Analytics*) became available to philosophers of the medieval period.

## LOGIC AND INFERENCE IN INDIAN PHILOSOPHY

By the fifth century BCE great social change was taking place in India and a period of intense intellectual activity came into being. Rational inquiry into a wide range of topics was under way, including agriculture, architecture, astronomy, grammar, law, logic, mathematics, medicine, phonology, and statecraft. Aside from the world's earliest extant grammar, Pāṇini's (c. 400 BCE) *Aṣṭādhyāyī*, however, no works devoted to these topics actually date from

this period. Nonetheless, scholars agree that incipient versions of first extant texts on these topics were being formulated.

One text dating from this period and important to tracing the development of logic in classical India is a Buddhist work, Moggaliputta Tissa's *Kathā-vatthu* (Points of controversy; third century BCE), which exhibits awareness of the fact that the form of argument is crucial to its being good. The text gives the refutation of some 200 propositions over which the Sthavīravāda, one of the Buddhist schools, disagreed with various Buddhist schools. The treatment of each point comprises a debate between a proponent and opponent. Throughout book 1, chapter 1, one finds refutations of precisely the following form:

Proponent:	Is A B?
Opponent:	Yes.
Proponent:	Is C D?
Opponent:	No.
Proponent:	Acknowledge defeat, since if A is B, then C is D.

The author clearly presumes it to be self-evident, first, that it is wrong to hold inconsistent propositions and, second, that the propositions assented to—corresponding to the propositional schemata of  $\alpha$ ,  $\neg B$ ,  $\alpha \rightarrow B$ —are indeed inconsistent.

The first 500 years of the Common Era saw the redaction of treatises devoted to the systematic exposition of the technical subjects mentioned earlier, as well as of philosophical treatises in which proponents of diverse religious traditions put forth systematic versions of their worldview. These latter works bear witness, in a number of different ways, to the intense interest of the period in argumentation. To begin with, the authors of many of these texts submit arguments and, in doing so, explicitly appeal to such well-known logical principles as those of noncontradiction, of excluded middle and of double negation, though they adduce them, not as principles of logic, but as self-evident ontic facts. Thus, the Buddhist philosopher Nāgārjuna (c. 150–250) often invokes an ontic principle of noncontradiction, saying such things as “when something is a single thing, it cannot be both existent and non-existent” (*Mūlamadhyamakārikā* chapter 7, verse 30), which is clearly reminiscent of Aristotle's own ontic formulation of the principle of noncontradiction, namely, “that a thing cannot at the same time be and not be” (*Metaphysics* book 3, chapter 2996b29–30).

Next, many of the arguments formulated correspond to such well-recognized rules of inference as *modus ponens* (i.e., from  $\alpha$  and  $\alpha \rightarrow B$ , one infers  $B$ ), *modus tollens* (i.e., from  $\neg B$  and  $\alpha \rightarrow B$ , one infers  $\neg \alpha$ ), disjunctive syllogism (i.e., from  $\neg \alpha$  and  $\alpha \vee B$ , one infers  $B$ ), constructive dilemma (i.e., from  $\alpha \vee B$ ,  $\alpha \rightarrow \gamma$  and  $B \rightarrow \gamma$ , one infers  $\gamma$ ), categorical syllogism (i.e., from  $\alpha \rightarrow B$  and  $B \rightarrow \gamma$ , one infers  $\alpha \rightarrow \gamma$ ), and *reductio ad absurdum* (i.e., if something false follows from an assumption, then the assumption is false). This last form of argument, termed *prasaṅga* in Sanskrit, is extremely common. Indeed, so common are such arguments in Nāgārjuna's works that his follower, Buddhapālita (470–540), took all of Nāgārjuna's arguments to be *prasaṅga* arguments. As a result, Buddhapālita and his followers were and are referred to as *prāsaṅgikas* (absurdists).

Finally, many of the texts are either devoted to, or have passages devoted to, the enumeration, definition, and classification of public discussion, or debate (*vāda*). The same texts or passages also identify the parts of argument, the flaws found in poor arguments, including such fallacies as circularity (*anyonya-āśraya*, reciprocal dependence) and infinite regress (*an-avasthā*, ungroundedness), as well as quibbles (*chala*) and sophistical refutations (*jāti*) (see Solomon 1976, vol. 1, chapter 5). They also set down ways in which a discussant's behavior warrant his or her being judged the loser of the debate (*nigraha-sthāna*) (see Solomon 1976, vol. 1, chapter 6).

One of the earliest examples of an argument in a form that clearly adumbrates the canonical form the classical Indian inference eventually takes is found in a passage in the *Caraka-saṃhitā* (CS book 2, chapter 8, section 31), a medical text, which defines an argument to have five parts: the proposition (*pratijñā*), the ground or reason (*hetu*), the corroboration (*dṛṣṭānta*), the application (*upanaya*), and the conclusion (*nigamana*). The following is an example:

Proposition:	The soul is noneternal
Ground:	because it is detectable by the senses.
Corroboration:	It is like a pot.
Application:	As a pot is detectable by the senses, and is noneternal, so is the soul detectable by the senses.
Conclusion:	Therefore, the soul is noneternal.

This form of the argument clearly reflects the debate situation. First, one propounds a proposition, that is, one sets forth a proposition to be proved. One then states the ground, or reason, for the proposition one is propound-

ing. Next, one corroborates with an example the connection implicit between the property mentioned in the proposition and the property adduced as its ground. The immediately ensuing step, the application, spells out the analogy between the example and the subject of the proposition. Notice that this part of the argument retains the vestiges of the analogical reasoning that is no doubt its predecessor. Finally, one asserts the proposition.

As was obvious to the thinkers of this period, not all arguments of this form are good arguments. However, no clear criteria are set forth whereby good arguments or inferences can be distinguished from bad ones. At best, some authors simply list good arguments, as does the Buddhist idealist Asanga (flourish fourth–fifth century CE) in a section at the end of a chapter of his *Yogācārabhūmi-śāstra* (Treatise on the stages of yogic practice). Other works provide lists of both good and bad arguments, the latter often referred to as nongrounds (*a-hetu*) or pseudogrounds (*hetu-ābhāsa*) (see Solomon 1976, vol. 1, chapter 7). It is difficult to be sure what the basis for the classification is in these early texts. In the *Nyāya-sūtra* (Aphorisms on logic), a work attributed to Gautama Akṣapāda (flourished second century CE), the author gives neither a definition nor an example. Even in cases where definitions and examples are given, as in the *Caraka-saṃhitā* mentioned earlier, the modern reader is rarely sure of what is intended.

Other passages from these earliest texts treat inference. In these passages inference is taken to be knowledge of one fact arising from knowledge of another. Often, as in the passages of the *Caraka-saṃhitā* (CS book 1, chapter 11, sections 21–22) and the *Nyāya-sūtra* (NS book 1, chapter 1, aphorism 5), no mention is made of any knowledge of what links the two facts. Moreover, the classification of inference in these two texts seems to be based on characteristics completely extrinsic to the logical features of the inferences adduced, for example, according to whether the property permitting the inference precedes, is simultaneous with, or succeeds the property to be inferred.

In contrast, passages from other texts of this period provide definitions of inference that require, besides knowledge of the two states of affairs, knowledge of the relation linking the two. However, instead of providing a formal relation, they provide a miscellany of material relations. The *Ṣaṣṭi-tantra* (Sixty doctrines), which is attributed by some to Pāñcaśikha (flourished second century BCE) and by others to Varṣaṇya (fl. after the second century CE), enumerates seven such relations, while the *Vaiśeṣika-sūtra* (Aphorisms pertaining to individuation;

VS book 9, aphora 20), a text attributed to Kaṇāda (flourished first century CE), enumerates five: the relation of cause to effect, of effect to cause, of contact, of exclusion, and of inherence. In each of these texts the miscellany of material relations serves to classify inferences. Thus, although in these two works the parts of an inference have been made explicit, the formal connection among these parts remained implicit.

The works of the Buddhist philosopher Vasubandhu (flourished fourth century CE) seem to be the earliest extant works that provide a formal characterization of the inference. He holds that inference has only three parts: a subject (*pakṣa*) and two properties, the property to be established (*sādhya*) in the subject and another that is the ground (*hetu*). Exploiting an idea ascribed by his coreligionist Asanga in his *Shùn Zhèng Lùn* to an unknown school (thought by at least one scholar to be the Sāṃkhya school), Vasubandhu maintained that a ground in an inference is a proper one if, and only if, it satisfies three conditions—the so-called *tri-rūpa-hetu* (the grounding property *hetu* in its three forms). The first form is that the grounding property (*hetu*; H) should occur in the subject of an inference (*pakṣa*; p). The second is that the grounding property (H) should occur in those things similar to the subject insofar as they have the property to be established (*sādhya*; S). And third, the grounding property (H) should not occur in any of those things dissimilar from the subject insofar as they lack the property to be established (S). These conditions can be viewed as a partial specification of the validity of inferences of this form:

Thesis:	p has S.
Ground:	p has H.
Indispensability:	Whatever has H has S.

The first condition corresponds to the premise labeled *ground* in the schema above, while the second two correspond to the premise labeled *indispensability*. In his *Vāda-vidhi* (Rules of debate) Vasubandhu makes clear that the relation, knowledge of which is necessary for inference, is not just any in a miscellany of material relations, but a formal relation, which he designates, in some places, as *a-vinā-bhāva*—literally, not being without (compare to the Latin expression *sine qua non*)—and in others, as *nāntarīyakatva*—literally, being unmediated.

The following are two examples of inferences satisfying the previous schema:

Thesis:	p has fire.
Ground:	p has smoke.
Pervasion:	Whatever has smoke has fire.
Thesis:	p is a tree (i.e., has tree-ness).
Ground:	p is an oak (i.e., has oak-ness).
Pervasion:	Whatever is an oak (i.e., has oak-ness) is a tree (i.e., has tree-ness).

The previous schema is the one that Buddhist thinkers insisted on for all sound inference or argument. Brahmanical thinkers came to insist on a the form found in the *Caraka-saṃhitā*, but with the form of the application modified to express a universal claim, thereby giving it the same logical core as the form accepted by the Buddhists.

It is important to note that, no matter how different the metaphysical assumptions of the various philosophical schools, they all used a naive realist's ontology to specify the states of affairs used to study inference. According to this view, the world consists of individual substances or things (*dravya*), universals (*sāmānya*), and relations between them. The fundamental relation is the one of occurrence (*vṛtti*). The relata of this relation are known as substratum (*dharmin*) and superstratum (*dharma*), respectively. The relation has two forms: contact (*saṃyoga*) and inherence (*samavāya*). So, for example, one individual substance, a pot, may occur on another, say the ground, by the relation of contact. In this case the pot is the superstratum and the ground is the substratum. Or, a universal, say brownness, may occur in an individual substance, say a pot, by the relation of inherence. Here, brownness, the superstratum, inheres in the pot, the substratum. The converse of the relation of occurrence is the relation of possession.

Another important relation is the relation that one superstratum bears to another. This relation, known as pervasion (*vyāpti*), can be defined in terms of the occurrence relation. One superstratum pervades another just in case where ever the second occurs the first occurs. The converse of the pervasion relation is the concomitance relation.

As a result of these relations, the world embodies a structure: If one superstratum, designated as H, is concomitant with another superstratum, designated as S, and if a particular substratum, say p, possesses the former superstratum, then it possesses the second. This structure is captured by both the inferential schema for Buddhist thinkers and the inferential schema for Brahmanical thinkers.

Dignāga (flourished fifth century CE), another Buddhist philosopher, consolidated and systematized the insights into the formal basis of inference found in Vasubandhu's works. First, distinguishing between inference for oneself and inference for another, he made explicit what had previously been only implicit, namely, that inference, the cognitive process whereby one increases one's knowledge, and argument, the device of persuasion, are but two sides of a single coin. Second, he undertook to make the three forms of the grounding property (*tri-rūpa-hetu*) more precise, pressing into service the Sanskrit particle *eva* (only). And third, and perhaps most strikingly, he created the *hetu-cakra* (wheel of reasons), a three-by-three matrix, set up to classify pseudogrounds in light of the last two forms of the three forms of a proper ground. On the one hand, there are the three cases of the grounding property (H) occurring in some, none, or all of substrata where the property to be established (S) occurs. On the other hand, there are the three cases of the grounding property (H) occurring in some, none, or all of substrata where the property to be established (S) does not occur. Letting S be the substrata in which S occurs and  $\bar{S}$  be the substrata in which S does not occur, one arrives at the following table:

H occurs in:	all S all $\bar{S}$	all S no $\bar{S}$	all S some $\bar{S}$
H occurs in:	no S all $\bar{S}$	no S no $\bar{S}$	no S some $\bar{S}$
H occurs in:	some S all $\bar{S}$	some S no $\bar{S}$	some S some $\bar{S}$

Dignāga's works set the framework within which subsequent Buddhist thinkers addressed philosophical issues pertaining to inference and debate. Thus, Śāṅkarasvāmīn (flourished sixth century CE) wrote a brief manual of inference for Buddhists, called the *Nyāya-praveśa* (Beginning logic), based directly on Dignāga's work. Not long thereafter, Dharmakīrti (flourished seventh century CE), the great Buddhist metaphysician, also elaborated his views on inference and debate within the framework found in Dignāga.

Dharmakīrti made at least two contributions to the treatment of inference. Recall that one of the developments found in Vasubandhu's work was the identification of the formal contribution of what corresponds with the premise labeled indispensability in the inferential schema above making explicit that the corresponding relation is a formal one. One of Vasubandhu's terms for it, namely, *avinābhāva* (not being without), made it clear that infer-

ence involves some form of necessity. The question raised by Dharmakīrti is: What is the basis for the necessity? Recognizing that the necessity does not arise from a simple enumeration of cases, Dharmakīrti postulated two relations to vouchsafe the necessity of inference: causation (*tadutpatti*) and identity (*tādātmya*). A second contribution was his attempt to bring knowledge of absences, or roughly negative facts, within the purview of inference.

Another important Buddhist thinker who treated inference was Dharmottara (flourished eighth century CE), who wrote a useful commentary on Dharmakīrti's widely read *Nyāya-bindu*.

Dignāga not only had a profound influence on his Buddhist followers but he also influenced his non-Buddhist contemporaries and their followers. It would be wrong, however, to conclude that every adoption of ideas similar to those used by Dignāga in his works should be attributed to him. After all, one cannot be certain that Dignāga's contemporaries did not arrive at similar ideas independently or that they might not have got their ideas from sources common to them and Dignāga. In any event, Praśastapāda (flourished sixth century CE), an adherent of the Vaiśeṣika school and a near contemporary of Dignāga, also defined inference in a way that not only made clear its formal nature but also used the quantificational adjective *sarva* (all) to make the formal connection precise.

At the same time, some authors of this period seem to have retained a view of inference akin to the one found in the *Ṣaṣṭi-tantra* and the *Vaiśeṣika-sūtra*, in which the formal role of what corresponds with the inferential schema's pervasion (*vyāpti*) had yet to have been identified. This is true both of Vātsyāyana (flourished fifth century CE), the author of the earliest extant commentary on the *Nyāya-sūtra* and of Śābara (flourished sixth century CE), the author of the earliest extant commentary on Jaimini's *Mīmāṃsā-sūtra*. However, it was not long before the advocates of both *Nyāya* and *Mīmāṃsā* adapted to the formal view of inference. On the one hand, one finds that the *Mīmāṃsā* thinker Kumārila Bhaṭṭa (flourished 730 CE), adopted, without special comment, the formal perspective. On the other hand, one also finds that, though the *Nyāya* thinker Uddyotakara (flourished late sixth century CE) argued vigorously against many of Dignāga's views, he nonetheless advocated a view that presupposed the formalization found in Dignāga's works. Thus, Uddyotakara classified grounds (*hetu*) as: concomitant (*anvaya*), where nothing distinct from particular substratum *p* (in the inferential schema) fails to have the property *S*; exclusive (*vyatireka*), where nothing distinct from

*p* (in the inferential schema) has the property *S*; and both concomitant and exclusive, where some things distinct from *p* have the property *S* and some fail to have the property *S*. This classification becomes the standard classification for the adherents of *Nyāya* during the scholastic period.

## CHINESE LOGIC

Systematic argument in Chinese philosophy began with the Moist school, founded in the fifth century BCE by the first anti-Confucian thinker, Mozi (c. 470–c. 391 BCE). He laid down three tests for the validity of a doctrine: ancient authority, common observation, and practical

effect. At first the controversies of the various schools over moral and political principles led to increasing rigor in argument; then to an interest in dialectic for its own sake, as evidenced in Hui Shih's paradoxes of infinity and in Kung-sun Lung's sophism "A (white) horse is not a horse"; and still later to the antirationalism of the Daoist Zhuangzi (born c. 369 BCE), who rejected all dialectic on the grounds that names have only an arbitrary connection with objects and that any point of view is right for those who accept the choice of names it assumes.

### LOGIC OF MOISM

In the third century BCE the Moists responded to Zhuangzi's skepticism by systematizing dialectic in the "Moist Canons" and the slightly later *Ta-ch'ü* and *Hsiao-ch'ü*.

"MOIST CANONS." The "Canons" confined dialectic to questions of the form "Is it this or is it not?" or, since they assumed that the proposition is merely a complex name for a complex object, "Is it or is it not the case that ...?" (The form is distinguished in Chinese by a verbless sentence with a final particle, not by a verb "to be.") In true dialectic the alternatives are paired ("Is it an ox or not?") so that one and only one fits the object. Dialectic excludes such questions as "Is it an ox or a horse?" (it may be neither) and "Is it a puppy or a dog?" (it may be both). Its solutions are absolutely right or wrong; being or not being "this," unlike being long or short, is not a matter of degree, since nothing is more "this" than this is. The Moists further argued that it is self-contradictory to deny or to affirm all propositions: the statement "All statements are mistaken" implies that it is itself mistaken, and one cannot "reject rejection" without refusing to reject one's own rejection.

Names are of three types, distinguished by their relations to "objects," which are assumed to be particular. "Unrestricted" names (such as "thing") apply to every object. Names "of kinds" (such as "horse") apply to every object resembling the one in question. "Private" names (for example, the proper name "Tsang") apply to one object. Whether a name fits an object is decided by appeal to a "standard." There may be more than one standard for an object; for "circle" the standard may be a circle, one's mental picture of a circle, or a compass. Some standards fit without qualification: A circle has no straight lines. Some fit only partially: In deciding whether someone is a "black man" it is not enough to point out his black eyes and hair. The "Canons" began with seventy-five definitions, evidently offered as "standards," of moral, psycho-

logical, geometrical, and occasionally logical terms. An example of a definition of a logical term is "All' is 'none not so'" (supplemented in the *Hsiao-ch'ü* by "'Some' is 'not all'"). The first of the series is "The 'cause' is what is required for something to happen." ("Minor cause: With this it will not necessarily be so; without this it necessarily will not be so. Major cause: With this it will necessarily be so.") The "Canons" also distinguish the senses of twelve ambiguous terms. Thus, "same" is (1) identical ("two names for one object"), (2) belonging to one body, (3) together, and (4) of a kind ("the same in some respects").

"TA-CH'Ü" AND "HSIAO-CH'Ü." The Moist *Ta-ch'ü* further refined the classification of names. Names indicating "number and measure" cease to apply when their objects are reduced in size; when a white stone is broken up it ceases to be "big," although it is still "white." Names indicating "residence and migration" do not apply when the population moves, as in the case of names of particular states ("Ch'i") or of kinds of administrative divisions ("country"). The claim that one knows *X* only if one knows that an object is *X* applies only to names indicating "shape and appearance" ("mountain," but not "Ch'i" or "county").

The *Ta-ch'ü*, and still more the *Hsiao-ch'ü*, also showed a shift of interest from the name to the sentence and to the deduction of one sentence from another. The Chinese never analyzed deductive forms, but the Moists noticed that the formal parallelism of sentences does not necessarily entitle us to infer from one in the same way as from another, and they developed a procedure for testing parallelism by the addition or substitution of words. For example, "Asking about a man's illness is asking about the man," but "Disliking the man's illness is not disliking the man"; "The ghost of a man is not a man," but "The ghost of my brother is my brother." In order to reconcile the execution of robbers with love for all men some Moists maintained that although a robber is a man, "killing robbers is not killing men." Enemies of Moism rejected this as sophistry, on the assumption that one can argue from "A robber is a man" to "Killing robbers is killing men," just as one can argue from "A white horse is a horse" to "Riding white horses is riding horses." The *Hsiao-ch'ü* replied that there are second and third sentence types of the same form, which do not allow such an inference—for example, "Her brother is a handsome man," but "Loving her brother is not loving a handsome man"; "Cockfights are not cocks," but "Having a taste for cockfights is having a taste for cocks." A four-stage procedure

was used to establish that “A robber is a man” belongs to the second type:

(1) Illustrating the topic (“robber”) with things (“brother,” “boat”) of which formally similar statements may be made.

(2) Matching parallel sentences about the illustrations and the topic—for instance, “Her brother is a handsome man, but loving her brother is not loving a handsome man”; “A boat is wood, but entering a boat is not entering wood”; “A robber is a man, but abounding in robbers is not abounding in men, nor is being without robbers being without men.”

(3) Adducing supporting arguments for the last and most relevant parallels by expanding them and showing that the parallelism still holds: “Disliking the abundance of robbers is not disliking the abundance of men; wishing to be without robbers is not wishing to be without men.”

(4) Inferring, defined as “using its [the topic’s] similarity to what he [the person being argued with] accepts in order to propose what he does not accept”: “Although a robber is a man, loving robbers is not loving men, not loving robbers is not loving men, and killing robbers is not killing men.”

## XUNZI

Outside the Moist school only the Confucian Xunzi (c. 313–c. 238 BCE) left a consecutive treatise on logical questions. According to his “Correct Use of Names” the purpose of names is to point out objects, thereby distinguishing the noble from the base and the similar from the different. Names are fixed by convention and are mutable, but to use them idiosyncratically when their usage is fixed is a crime akin to falsifying weights and measures. Objects are different if they differ in place although not in form; they remain the same if they change in form without dividing. Objects of the same kind are perceived by the senses as similar and are given the same name. Names may be of any degree of generality; we may assimilate objects under the name “thing” or distinguish them as “bird” and “beast.” (Like the Moists, Xunzi took for granted a nominalist position.) The sentence is a series of names conveying one idea, and a name is understood when we grasp both the object to which it points and its interconnections in the sentence.

Xunzi distinguished three sorts of fallacies, which he illustrated with unexplained examples (two are explained by his refutations of them in his “Treatise of Corrections”). Fallacies that abuse names are exposed by an

appeal to established usage, and fallacies that abuse objects are exposed by an appeal to the evidence of the senses. The first fallacy, “confusing names by misuse of names,” Xunzi illustrated by “To be insulted is not disgraceful.” This is a violation of the established use of “disgrace” in two senses, for social and for moral degradation. The second fallacy, “confusing names by misuse of objects,” was exemplified by “Our genuine desires are few.” Xunzi criticized this as a factual error about humankind. The third fallacy is “confusing objects by misuse of names.” Kung-sun Lung (born 380 BCE) had defended the sophism “A (white) horse is not a horse” on grounds which assume that the question is one of identity, not one of class membership. Xunzi would presumably have replied simply that a white horse is commonly called a “horse.”

## LATER LOGICAL THOUGHT

The classical period of Chinese philosophy ended about 200 BCE. The next important movement, the neo-Daoism of the third and fourth centuries CE, revived the study of the sophists and the Moist “Canons.” Indian treatises on logic were available in translation from the seventh century on; Buddhists wrote commentaries on them during the Tang dynasty (618–907), and in Japan they have continued to do so. But there is little evidence of progress by either Daoists or Buddhists. Neo-Confucianism, the main philosophical movement after the Song dynasty (960–1279), entirely neglected logical inquiry.

## CHINESE NEGLECT OF LOGIC

It is well known that almost all Chinese philosophical “systems” are practical, moral, or mystical philosophies of life, indifferent to abstract speculation. It is therefore not surprising that Chinese thinkers have cared little for the forms of reasoning, except under the pressure of the acute controversies of the third century BCE. What is surprising is the almost exclusive interest of Chinese philosophers in the problem of names and the fact that even those who advanced from the name to the sentence studied the parallelism of sentences rather than their analysis.

A reason for this interest can be found in the Chinese language, which organizes uninflected words solely according to word order and the placing of particles. Without the inflections that expose the structure of Sanskrit, Greek, or Arabic sentences and encourage the simultaneous growth of grammar and logic the Chinese sentence, until recently, almost defied analysis; the Chinese have been lexicographers but not grammarians. On the other hand, strict parallelism of clauses—in which

noun is matched with noun, adjective with adjective, adverb with adverb, verb with verb—is part of the ordinary resources of the Chinese language and easily calls attention to the logical dangers of formal parallelism.

**LOGIC IN THE ISLAMIC WORLD**

Arabic logic, like the rest of medieval Arabic science and philosophy, is entirely Western and has nothing to do with Oriental philosophy. It developed wholly in the wake

of the classical Greek tradition as preserved in and transmitted through late Greek Aristotelianism. The present account briefly traces the evolution of Arabic logic from its inception in the late eighth century to its stultification in the sixteenth century, mentioning only the most important trends, figures, and achievements. Information on individual writers can be found in Carl Brockelmann’s monumental *Geschichte der arabischen Litteratur*, cited hereafter as *GAL* (2 vols.—I, II—Weimar, 1890; Berlin, 1902; 2nd ed., Leiden, 1943–1949; 3 supp. vols.—SI, SII, SIII—Leiden, 1937–1942).

**TRANSMISSION OF GREEK LOGIC TO THE ARABS**

After their conquest of Syria-Iraq the Arabs came into contact with Greek learning as it continued to be nursed by various Christian sects—primarily the Nestorians and the Monophysites, or Jacobites—that had transplanted there (via such centers as Antioch, Edessa, and Nisibis) the Hellenistic scholarship of Alexandria. Thus, the first writers on logic in Arabic were Syrian Christian scholars, and their tradition of logical studies—closely linked to medicine—was transferred to an Arabic-language setting and laid the foundation for the development of Arabic logic.

The Syriac expositors of Aristotelian logic arrived at the following standard arrangement of logical works: *Isagoge* (by Porphyry), *Categories*, *De Interpretatione*, *Prior Analytics*, *Posterior Analytics*, *Topics*, *De Sophisticis Elenchis*, *Rhetoric*, and *Poetics*. These nine works were thought of as dealing with nine distinct branches of logic, each based on its own canonical text. This construction of Aristotelian logic was taken over by the Arabs, resulting in the following organization of the subject matter of logic:

Branch	Arabic Name	Basic Text
(1) Introduction	<i>al-ʿisāghūjī</i>	<i>Isagoge</i>
(2) Categories	<i>al-maqūlāt</i>	<i>Categories</i>
(3) Hermeneutics	<i>al-ʿibārah</i>	<i>De Interpretatione</i>
(4) Analytics	<i>al-qiyās</i>	<i>Prior Analytics</i>
(5) Apodictics	<i>al-burhān</i>	<i>Posterior Analytics</i>
(6) Topics	<i>al-jadal</i>	<i>Topics</i>
(7) Sophistics	<i>al-mughālahah</i> (or <i>al-safsatah</i> )	<i>De Sophisticis Elenchis</i>
(8) Rhetoric	<i>al-khitābah</i>	<i>Rhetoric</i>
(9) Poetics	<i>al-shiʿr</i>	<i>Poetics</i>

The totality of this organon was referred to as the nine books of logic, or as the eight books with the *Poetics* (or sometimes *Isagoge*) excluded. The first four of these logical treatises were apparently the only ones translated into Syriac prior to 800 and into Arabic prior to 850. They were called the four books of logic, and they constituted

the object of logical studies in the basic curriculum of the Syrian academies.

Arabic translations of Aristotle's logical treatises and of several Greek studies and commentaries on them prepared the ground for the first indigenous Arabic writer on logic, the philosopher Abū-Yūsuf Ya'qūb ibn Ishāq al-Kindī (c. 805–873; *GAL*, I, pp. 209–210). His logical writings, however, probably amounted to little more than summaries of the writings of others about the Aristotelian texts.

## SCHOOL OF BAGHDAD

In the late ninth and the tenth centuries Arabic logic was virtually the monopoly of a single school of logicians centered at Baghdad. The founders of this school belonged to a closely knit group of Syrian Christians, including the teachers of Abū Bishr Mattā ibn Yūnus and the teachers of these teachers. Its principal continuators were the pupils of Abū Bishr's pupil Yaḥyā ibn 'Adī and the pupils of these pupils. Virtually all of these men—with the notable exception of al-Fārābī, a Muslim—were Nestorian Christians.

Abū Bishr Mattā ibn Yūnus (c. 870–c. 940; *GAL*, I, p. 207) was the first specialist in logical studies to write in Arabic. He produced the first Arabic translations of *Posterior Analytics* and *Poetics* and translated several Greek commentaries on Aristotelian works (such as Themistius on *Posterior Analytics*). In addition he wrote logical commentaries and treatises of his own, which unfortunately have not survived.

Abū Naṣr al-Fārābī (c. 873–950; *GAL*, I, pp. 210–213) was perhaps the most important logician of Islam. His commentaries, only a fraction of which survive, covered the entire Aristotelian *Organon* in great detail. All later Arabic logicians—even those who, like Avicenna, have opposed al-Fārābī's influence—have seen Aristotle through his eyes. Among the points of special interest in the commentaries of al-Fārābī are (1) a strong emphasis on *ecthesis* (the setting out of terms) as a principle of syllogistic reduction, (2) an increased resort to noncategorical (for instance, hypothetical and disjunctive) types of syllogism, (3) an elaborate treatment of inductive uses of syllogistic reasoning, especially the application of the categorical syllogism in argument by analogy, and (4) a detailed treatment of the problem of future contingency, providing for a reading of Chapter 9 of *De Interpretatione* that does not deny prior truth status to future contingents (anticipating the position of Peter Abelard).

Yaḥyā ibn 'Adī (893–974; *GAL*, I, p. 207), who studied logic and philosophy with both Abū Bishr and al-Fārābī, not only translated Greek works from Syriac into Arabic but also taught virtually half of the Arabic logicians of the tenth century. He wrote various independent works (including a commentary on *Prior Analytics* that devoted special attention to modal syllogisms), almost none of which have survived.

The three principal achievements of this school of Baghdad are (1) completion of the series of Arabic translations of Greek logical works, (2) the masterly commentaries of al-Fārābī (and possibly others) on the logical treatises of Aristotle, and (3) the elaborate study of certain extra-Aristotelian topics by Abū Bishr Mattā and al-Fārābī (for instance, theory of “conditional,” or hypothetical and disjunctive, syllogisms along lines already found in Boethius, and the syllogistic reduction of inductive modes of argument).

## AVICENNA AND HIS INFLUENCE

Despite the demise of the school of Baghdad around 1050, the ultimate survival of logical studies in Islam was assured by the fact that logic had, through the mediation of medicine, become an integral constituent of the Arabic medicophilosophical tradition as taken over from the Syrian Christians. From a quantitative standpoint the eleventh century was a low ebb in the history of Arabic logic. Yet this period produced perhaps the most creative logician of Islam, the great Persian scholar Abū ibn Sīnā, known as Avicenna (980–1037; *GAL*, I, pp. 452–458).

Avicenna made a daring innovation. Although greatly indebted to the school of Baghdad, he had nothing but contempt for it because it regarded logic as the study of the Aristotelian texts. Avicenna disapproved of this orientation toward the text rather than the subject. For him, and for the tradition he dominated, a logic book was no longer a commentary on Aristotle but an independent, self-sufficient treatise or handbook that covered the ground after its own fashion. Avicenna's masterpiece is a series of treatises in his monumental *Kitāb al-shifā'* dealing with the nine parts of the Arabic logical organon.

An example of Avicenna's originality is the following: In Aristotle and in the Stoics one finds a temporal construction of the modality of necessity that construes “All *X*'s are necessarily *Y*'s” as “At any time *t* all *X*'s-at-*t* are *Y*'s-at-*t*.” This construction works well for, say, “All men are necessarily animals” but clearly not for “All men necessarily die.” Avicenna distinguished between such cases as:

(1) At every time during its existence every *X* is a *Y* (“All men are necessarily animals”).

(2) At most times during its existence every *X* is a *Y* (“All men are necessarily breathing beings”).

(3) At some time during its existence every *X* is a *Y* (“All men are necessarily dying beings”).

He then constructed a detailed theory of syllogistic inference from temporally modalized propositions of this sort.

Avicenna styled his own work in logic (and philosophy) as Eastern, in deliberate contrast with the Western approach of the school of Baghdad. This Eastern logic espoused by Avicenna differs from that of, say, al-Fārābī not so much in matters of substance as in emphasis and in willingness to depart from Aristotelian precedent. Thus, Avicenna imported into his logic a certain amount of material derived probably from Galen (including an at least grudging recognition of the fourth figure of the categorical syllogism) and certainly from the Stoics (for example, quantification of the predicate of categorical propositions, elaboration of quality and quantity for “conditional” propositions, and a treatment of singular propositions in the manner of the Stoics).

Avicenna’s call to study logic from independent treatises rather than via the Aristotelian texts met with complete success in Eastern Islam. Only in Muslim Spain did the tradition of Aristotelian studies of the school of Baghdad manage—for a time—to survive.

## LOGICIANS OF ANDALUSIA

During the late eleventh and the twelfth centuries Andalusia (Muslim Spain) was the principal center of logical studies in Islam. Muḥammad ibn ‘Abdūn (c. 930–c. 995; Heinrich Suter, *Die Mathematiker und Astronomen der Araber und ihre Werke*, Leipzig, 1900–1902, no. 161; not in *GAL*), a Spanish Muslim who studied medicine and philosophy in Baghdad, was instrumental in transplanting to Córdoba the teachings of the school of Baghdad in Aristotelian logic. In the medico-logical tradition of Andalusia these teachings stayed alive for more than two and a half centuries, surviving well past their extinction in Eastern Islam.

Abū’l-Ṣalt (1068–1134; *GAL*, I, pp. 486–487) wrote an influential logic compendium that follows al-Fārābī closely; like most other Spanish Arab logicians, he seems to have had special interest in modal syllogisms. The detailed study of the writings of Aristotle was revitalized by Ibn Bājja (or Avempace; c. 1090–1138; *GAL*, I, p. 460),

who wrote an important series (extant but unpublished) of discussions of Aristotle’s works based on the commentaries of al-Fārābī.

Ibn Rushd (or Averroes; c. 1126–c. 1198; *GAL*, I, pp. 461–462) was unquestionably the most important of the Arabic logicians of Spain. His elaborate commentaries on the treatises of Aristotle’s logical *Organon* rival (and conceivably surpass) those of al-Fārābī in their detailed understanding of Aristotle’s logic. Averroes stands, as he considered himself to stand, heir to the masters of the school of Baghdad and successor to the heritage of al-Fārābī.

Among the points of special interest in the Aristotelian commentaries of Averroes are (1) certain historical data—for instance, regarding Galen’s origination of the fourth syllogistic figure—taken from the last writings of al-Fārābī, (2) anti-Avicennist polemics that afford us a view of the points of dispute between Avicenna and his opponents, (3) the detailed account of the Aristotelian theory of modal syllogisms, and (4) in general, his effort to systematize as unified doctrine the teachings of the Aristotelian *Organon*.

After Averroes the logical tradition of Muslim Spain entered a period of decline. Arabic logic became extinct in Spain because there—in contrast to Eastern Islam, where logic achieved a *modus vivendi* with religious orthodoxy—popular and theological hostility toward logic and philosophy as an integral part of “alien learning” continued unabated.

## QUARREL OF THE EASTERN AND WESTERN SCHOOLS

Avicenna’s criticisms of the school of Baghdad and his shift away from Aristotelian orthodoxy were not received with universal acceptance. A Western school arose to oppose Avicenna’s innovations. Its principal exponents were the prolific Persian scholar Fakhr al-Dīn al-Rāzī (1148–1209; *GAL*, I, pp. 506–508) and his followers al-Khūnajī (1194–1249; *GAL*, I, p. 463) and al-Urmawī (1198–1283; *GAL*, I, p. 467). These logicians not only offered detailed criticisms of Avicenna’s departures from Aristotle but also wrote handbooks of logic that became standard textbooks both during the lifetime of their school and later.

Opposed to these Westerners, the school of the Easterners, which supported Avicenna, continued to be active throughout the thirteenth century. Its leading exponent was the eminent and versatile Persian scholar Kamāl al-Dīn ibn Yūnus (1156–1242; *GAL*, SI, p. 859). His position

was supported by his pupils al-Abharī (1200–1264; *GAL*, I, pp. 464–465) and Naṣīr al-Dīn al-Ṭūsī (1201–1274; *GAL*, I, pp. 508–512), as well as by the pupils of the last-named scholar, especially the logician al-Qazwinī al-Kātībī (c. 1220–c. 1280; *GAL*, I, pp. 466–467). These logicians produced polemical treatises to attack the theses of the Westerners, as well as textbooks and handbooks to facilitate the teaching of logic according to their conceptions.

Amid this disputation and textbook writing the logical treatises of Aristotle were completely lost sight of. In effect, Avicenna carried the field before him; in Eastern Islam, Aristotle's logical writings were utterly abandoned. Ibn Khaldūn (1332–1406) could lament, “The books and methods of the ancients are avoided, as if they had never been, although they are full of the results and useful aspects of logic.” The handbooks of the two thirteenth-century schools provided a basis for all future study in Islam, completely replacing the works of Aristotle. But very little produced at this stage has any significance for logic as a science rather than as a field of instruction.

## FINAL PERIOD

The period 1300–1500 may be characterized as the final period of Arabic logic, when its ossification became complete. It was a time not of creative logicians but of teachers of logic writing expository commentaries and supercommentaries on the thirteenth-century handbooks, now basic to all Arabic instruction in logic.

Underlying this development was the effort of al-Tustarī (c. 1270–c. 1330; *GAL*, SI, p. 816) and his disciple al-Taḥṭānī (c. 1290–1365; *GAL*, II, pp. 209–210) to effect an arbitration between the Eastern and Western schools. As a result, later Arabic logicians were free to draw on both sectors of the tradition and to use the handbooks of both schools for the teaching of logic. The flood of glosses and supercommentaries on commentaries on the thirteenth-century logic handbooks marks the final, disintegrative phase of the evolution of logic in Islam.

## CONTRIBUTIONS OF ARABIC LOGIC

Some of the original contributions made by the Arabic logicians to logic as a science are (1) al-Fārābī's syllogistic theory of inductive argumentation, (2) al-Fārābī's doctrine of future contingency, (3) Avicenna's theory of “conditional” propositions, (4) Avicenna's temporal construction of modal propositions, and (5) Averroes's careful reconstruction of Aristotle's theory of modal syllogistic. Many of the prominent “innovations” of medieval Latin logic are in effect borrowings or elabora-

tions of borrowings of Arabic ideas (for example, the distinction between the various modes of *suppositio* and the distinction between modality *de dicto* and *de re*).

However, in speaking of the “original contributions” of Arabic logic two qualifications are necessary. In the first place, our knowledge of late Greek logic is so incomplete that any “original” item of Arabic work could turn out to be a mere elaboration of a Greek innovation. Second, an emphasis on originality in discussing Arabic logic is somewhat misplaced in that all the Arabic logicians—even Avicenna, the most original of them all—viewed their logical work as the reconstruction of a Greek teaching rather than as an enterprise of innovation.

## Bibliography

### ARABIC LOGIC

A complete bibliography of Arabic logic can be found in Nicholas Rescher, *The Development of Arabic Logic* (Pittsburgh: University of Pittsburgh Press, 1964). On the transmission of Greek logic to the Arabs, see Max Meyerhof, “Von Alexandrien nach Baghdad,” in *Sitzungsberichte der Preussischen Akademie der Wissenschaften, Philosophisch-historische Klasse* 23 (1930): 389–429. The conflict between logic and Islamic religion is detailed in Ignaz Goldziher, “Stellung der alten islamischen Orthodoxie zu den antiken Wissenschaften,” in *Abhandlungen der Königlichen Preussischen Akademie der Wissenschaften, Philosophisch-historische Klasse, Jahrgang 1915* (Berlin, 1916). For the Arabs' familiarity with Aristotle's logical works, see R. Walzer, “Aristū” (Aristotle), in *Encyclopedia of Islam* (London, 1960), Vol. I; and Ibrahim Madkour, *L'organon d'Aristote dans le monde arabe* (Paris: Vrin, 1934).

Some representative Arabic logical texts accessible in European languages are D. M. Dunlop, translations of several logical *opuscula* of al-Fārābī in *Islamic Quarterly*, 2 (1955)–5 (1959); Nicholas Rescher, *Al-Fārābī's Short Commentary on Aristotle's "Prior Analytics"* (Pittsburgh, 1963); A. M. Goichon, *Avicenne: Livre de directives et remarques* (Paris, 1951); Mohammad Achena and Henri Massé, *Avicenne: Le livre de science*, Vol. I (Paris, 1955); *Aristotelis Opera cum Averrois Commentariis* (Venice, 1550 and later; 1562–1574 ed. reprinted photographically, Frankfurt: Minerva, 1962). Substantive study of the contributions of Arabic logicians has only begun. In addition to Prantl, *Geschichte der Logik im Abendlande*, Vol. II, above, consult T. J. de Boer, “Mantiq,” in *Encyclopedia of Islam*, 1st ed.; and Nicholas Rescher, *Studies in the History of Arabic Logic* (Pittsburgh: University of Pittsburgh Press, 1963).

## LOGIC IN THE ISLAMIC WORLD [ADDENDUM]

For more on everything in the entry, see especially Hans Daiber's *Bibliography of Islamic Philosophy* (1999). Few scholars would now accept that Arabic logic is "entirely Western"; it grew out of Greek texts, but developed differently from both Hellenistic and Latin logic.

### TRANSMISSION OF GREEK LOGIC TO THE ARABS

Research on the translation of the books of the *Organon* and their attendant commentaries is presented in summary essays in Goulet (1989–2003, pp. 502ff).

### THE SCHOOL OF BAGHDAD

The leading representative of the textual Aristotelianism of Baghdad was al-Fārābī, and much of his extant work is now either edited or translated (see Lameer 1994).

### AVICENNA AND HIS INFLUENCE

The many new editions, translations, and studies of Avicenna are listed by Jules L. Janssens (1999). An attempt to deal philosophically with his modal syllogistic is made by Paul Thom (2003, chapter 4 and idem). See also his essay "Logic and Metaphysics in Avicenna's Modal Syllogistic" (forthcoming).

### LOGICIANS OF ANDALUSIA

Averroes, though without much influence in the Islamic world, is the most acute of the Andalusian logicians. See Thom (2003, chapter 5) for a philosophical treatment of his later modal syllogistic.

### QUARREL OF THE EASTERN AND WESTERN SCHOOLS

There certainly were major differences among the post-Avicennan logicians, but Nicholas Rescher's use of "Eastern" and "Western" schools to gather them into opposing camps is misleading (see Street 2004, pp. 567ff).

### FINAL PERIOD

One cannot assume the tradition ossified because its most common genre became the commentary. The task ahead is to read and appraise the profusion of texts written from the 900s until after the colonial invasions of the nineteenth century. For a study of the attitudes to logic in this period, see Khaled El-Rouayheb's "Sunni Muslim Scholars on the Status of Logic, 1500–1800" (2004).

## MEDIEVAL (EUROPEAN) LOGIC

Although some elementary work was done in the ninth and tenth centuries it was not until the end of the eleventh century that medieval logic really began to develop a character of its own. It started as glosses and commentaries on some of a small number of texts that had survived from antiquity. These included Boethius's translations of Porphyry's *Isagoge*, Aristotle's *Categories* and *De interpretatione*, and two works written by Boethius himself, a treatise, *De Topicis Differentiis*, on topical inference based on the work of Themistius and Cicero, and another, *De divisione*, devoted to the various forms of division employed in logic. In the thirteenth century these works were collectively known as the *logica vetus*.

In addition logicians at the beginning of the twelfth century possessed Boethius's very extensive commentaries on the *Isagoge*, *Categories*, and *De interpretatione*, his two-part epitome of Aristotle's *Prior Analytics*, 1–7, *Introductio ad syllogismos categoricos* and *De syllogismo categorico*, his treatise on hypothetical syllogisms, *De*

*hypotheticis syllogismis*, and his commentary on Cicero's *Topica*, *In Topica Ciceronis*.

Also important in the early development of logic were Marius Victorinus's *De diffinitionibus*, Saint Augustine's *De dialectica*, and, at least in the ninth and tenth centuries, *De decem categoriis*, a fourth-century Latin translation of a Greek paraphrase of Aristotle's *Categoris* attributed to Augustine. In addition, Priscian's *Institutiones grammaticae*, with the eleventh- and twelfth-century glosses on it known as the *Glossulae*, were an important influence in the twelfth century on the development of philosophical semantics and in particular of theories of the substantive verb *to be*.

Boethius's translations of Aristotle's *Sophistical Refutations*, *Topics*, and *Prior Analytics* were recovered before the middle of the twelfth century. Along with the translation of the *Posterior Analytics* made then by James of Venice they provided logicians with what was distinguished from the *logica vetus* as the *logica nova*. Apart from the *Sophistical Refutations*, however, it was not until the beginning of the thirteenth century that the works of the *logica nova* had a significant impact on the development of logic. Although some parts of Avicenna's logical works were translated into Latin, unlike other areas of philosophy, Arabic writing had little impact on the development of logic.

From the middle of the twelfth century logicians developed their discipline in various ways and produced works characteristic of what would much later be referred to as the *logica modernorum*. These dealt, for example, with the properties of terms, and in particular the theory of supposition, syncategorematic words, modality, *obligationes*, *insolubilia*, consequences, and sophisms of various kinds, each of which is discussed in this entry.

## THE BOETHIAN BACKGROUND

Based as it was upon the texts of the *logica vetus* medieval logic included a great deal that has to do with ontology and philosophical semantics rather than with logic more narrowly construed as the theory of valid argumentation. Boethius gave medieval logicians much of their terminology but his commentaries on Aristotle and even more so his own works are essentially elementary, often confused, and sometimes inconsistent. It was these, however, which provided twelfth-century logicians with the material from which they constructed their new formal and philosophical logics. In particular, the remarkable developments they made in theory of inference had their beginnings in reflection on Boethius's *De Topicis Differentiis* and *De hypotheticis syllogismis*.

**TOPICAL INFERENCE.** Medieval logic at least in the first half of the twelfth century was characterized by an intense interest in conditional propositions and in the nature of topical inference as formulated by Boethius in *De Topicis Differentiis*. Logicians at this time were not generally concerned to regiment arguments into the modes and figures of the categorical syllogism but everywhere they classified inferences in accordance with lists of topics, based upon those given by Boethius.

In his treatise Boethius proposes to show how arguments may be discovered to settle any given question. What has to be found, he claims, is what Cicero, in his *Topica*, calls an "*argumentum*"—defined as a "reason which brings conviction where something is in doubt." An argument (*argumentatio*) is the expression in speech or writing of the proof of a conclusion constructed with the required *argumentum*. A *locus*, or topic, is the "site," or "source," of *argumenta* (*Diff. Top.* I, 1174D).

*Argumenta* are invoked by Boethius to warrant the enthymematic inference of a categorical conclusion from categorical premisses or the direct proof of a conditional proposition. In each case what is needed is a principle that is not itself provable, called by Boethius a *maximal proposition*, and a relevant fact about the items mentioned in the conclusion. For example, by appealing to the maximal proposition "a genus is predicated of whatever its species is predicated" and the truth that animal is the genus of human being we may either infer from the premiss that Socrates is a human being the conclusion that he is an animal or, directly, the corresponding conditional.

The various relationships which Boethius holds may exist between the predicate and subject of a true categorical proposition or between the antecedent and consequent of a true conditional provide him with his *loci* (*Diff. Top.* II, 1186C). With each *locus* there are associated all the maximal propositions warranting inferences which may be made on the basis of that relationship. The enthymeme above, for example, would be characterized as holding "from species," that is, in virtue of the relationship in which a species stands to its genus.

Boethius gives the lists and classifications of the *loci* provided by both Themistius and Cicero. They are divided into those which are intrinsic, that is, having to do only with the things themselves about which a question is asked, and those which are extrinsic, having no such connection with them. (*Diff. Top.* II, 1186D) Examples of intrinsic *loci* are that from species, given above, and that from what is defined, for which one maximal proposition is: "of that of which what is defined is not

predicated, the definition is not predicated.” Examples of extrinsic *loci* are that from authority, which justifies inferences from the authority of the majority of people, or the relevant experts, and *loci* from various kinds of opposition.

*Argumenta* drawn from the locus from authority are not necessary according to Boethius but they are probable in the sense of being generally convincing. Where Aristotle had taken probability and necessity to be properties of the premises and conclusion of a dialectical syllogism, however, Boethius takes them to characterize the nature of the inference from the premiss, or premisses, to the conclusion of an argument and the corresponding connection between the antecedent and consequent of a conditional (*Diff. Top.* I, 1180C).

THE THEORY OF CONDITIONAL PROPOSITIONS. In *De Topicis Differentiis*, Boethius classifies conditional propositions according to the quality of the antecedent and consequent. He accepts what we would now call a principle of contraposition and so maintains that a topical relationship warrants a conditional of the form “if something’s an *A*, then it’s a *B*” if and only if it warrants one of the form “if something’s not a *B*, then it’s not an *A*,” where *A* and *B* are general terms such as “human being” and “animal.” Conditionals of the form “if something’s an *A*, then it’s not a *B*” are true, he maintains, only for items which are “opposites,” that is, opposed exclusively but not exhaustively. For example, “if something’s a human being, then it’s not a donkey.” Those of the form “if something’s not an *A*, then it’s a *B*” hold only for items which are “immediates,” that is, opposed exclusively and exhaustively. For example, “if something’s not well, then it’s ill” (*Diff. Top.* I, 1179C).

With *De hypotheticis syllogismis* Boethius provided twelfth-century logicians with an account of the logic of certain conditional and disjunctive propositions but neither he nor any other ancient source provided them with what we would recognize as a propositional logic. Boethius had no clear understanding of the nature of either propositionality or propositional operation (Martin 1991).

In his general treatment of compound propositions in his long commentary on *De interpretatione*, Boethius thus denies that the copulative conjunction “and” does anything other than punctuate a list (*2 In Peri. Herm.*, 5, 109). In the same work he also explicitly rejects the Stoic practice of preposing a negative particle to a categorical proposition as ambiguous between the negation of the subject and predicate terms (*2 In Peri. Herm.*, 10, 261–2).

Without a notion of propositionality, Boethius has no notion a propositional form or of the substitution of propositional contents into propositional contexts to obtain new contents of arbitrary complexity. In *De hypotheticis syllogismis* he thus lists all the various kinds of hypothetical syllogism which he accepts for each different quality of the component categorical propositions. There, just as everywhere else where Boethius employs it, the negative particle preposed to a conditional never takes the whole of the following conditional proposition for its scope but always acts only on the consequent.

Boethius designates a conditional as affirmative if its consequent is affirmative and negative if it is negative no matter what the quality of the antecedent (*Hyp. Syll.* 1.9.6). The only compound propositions he considers are simple conditionals and disjunctions, that is those whose components are both categorical, and compound conditionals of which one or more component is a simple conditional. The most complex form of conditional he considers has simple conditionals for both its antecedent and consequent. These compound conditionals, again, have nothing to do with propositional logic as it is now understood. Conditionalized instances of contraposition, for example, are not true instances of the form since Boethius requires for the truth of “if (if something’s an *A*, then it’s a *B*), then (if something’s a *C*, then it’s a *D*)” that both “if something’s an *A*, then it’s a *C*” and “if something’s a *B*, then it’s a *D*” are true (*Hyp. Syll.* 3.9.1).

In *De hypotheticis syllogismis* Boethius gives the basic truth-condition for a conditional proposition, or consequence (*consequential*), which will be accepted throughout the middle ages. To “destroy” such a proposition, that is, to show that it is false, he says, one must show that it is possible for the consequent to be false when the antecedent is true. A conditional is thus true only if the truth of the antecedent is inseparable from that of the consequent. A simple disjunction, “something’s an *A* or it’s a *B*,” is equivalent, according to Boethius, to a simple conditional with a negative antecedent and affirmative consequent and so holds only for terms connected to one another as immediates (*Hyp. Syll.* 1.3.3).

In addition to stating the inseparability condition for their truth Boethius makes a distinction between conditionals which has profound consequences for the development of medieval logic and metaphysics. He claims that a relation of consequence may be indicated with either “*si*” (“if”) or equivalently with “*cum*.” The latter, however, usually means *when*, or *whenever* in Latin and that is how it is translated here.

The truth of an antecedent, Boethius notes, will be inseparable from that of a consequent if both are necessarily true even if there is no explanatory connection between them as, for example, “whenever (*cum*) fire is hot, then the heavens are spherical.” Boethius does not notice, however, nor does any other ancient source available in the twelfth century, that the inseparability requirement is apparently also satisfied by any conditional whose antecedent is impossible, or whose consequent is necessary.

Boethius designates as “accidental consequences” conditionals formed with “whenever” which meet the inseparability requirement merely on account of the truth-value of their components. He contrasts them with “natural consequences,” formed with “if,” in which the truth of the antecedent is inseparable from that of the consequent in virtue of an explanatory connection between them. For example “if something’s a human being, then its an animal” (*Hyp. Syll.* 1.3.6).

Finally, although Boethius correctly observes that Aristotle wrote nothing about hypothetical syllogisms, he takes from *Prior Analytics*, II. 4, as basic for the logic of conditional propositions what has been called Aristotle’s Principle: No two conditionals of the form “if something’s *A*, then its *B*” and “if something’s not *A*, then its *B*” can both be true (*Hyp. Syll.* 1.4.1).

## ABELARD AND THE DISCOVERY OF PROPOSITIONALITY

Peter Abelard, the first significant, and arguably the greatest, of all medieval logicians taught in Paris at various times between 1101 and 1140. Although most logical writing which we have from the twelfth century has been transmitted anonymously and with no certainty about its date of production, very fortunately both Abelard’s own survey of logic, the *Dialectica*, written probably around 1116, his *Logica*, consisting of commentaries on Porphyry, Aristotle, and Boethius, written around 1120, and his *Glossulae* on Porphyry, written in the 1120s, have survived more or less intact. The following account of logic in the first half of the twelfth century is thus mainly an account of Abelard’s work. He was, however, certainly not the only logician active at the time and much of his writing consists of arguments against sophisticated but unnamed opponents.

Most important, Abelard understood the distinction between the propositional content of a sentence and the force with which it is uttered (Martin 2004). The propositional content “that Socrates is running,” for example, may be asserted with an assertive utterance of “Socrates is

running” or it may contribute to the meaning without itself being asserted in an assertive utterance of the conditional “if Socrates is running, then he is moving.” Since Boethius treats “proposition” (*propositio*) and “assertion” (*enuntiatio*) as synonyms, however, it was rather difficult for Abelard to formulate clearly the distinction for an assertion between force and content.

Abelard uses the term “proposition” (*propositio*) to refer to a token propositional sentence. In his early writings he borrows from Priscian the expression “the being of the thing” (*essentia rei*) to speak about propositional content and identifies it with a state-of-affairs. In later writings he refers rather to the *dictum* of a proposition, that is, to “what is said” with it. For Abelard it is *dicta* which are in the first place the bearers of truth and falsity and so, for example, a conditional is true if and only if the truth of the *dictum* of the consequent follows from the truth of the *dictum* of the antecedent.

The distinction between force and content, which Peter Geach has called the *Frege Point* in deference to its supposed discoverer, is crucial for the development of genuinely propositional logics. Abelard saw this and consequently rejected Boethius’s views on copulative conjunction. To the contrary, he insists that a copulative conjunction of propositions is itself a single proposition and may thus be subject to a further propositional operation. “It’s not the case that (*p* and *q*)” where “*p*” and “*q*” are propositions is just as much a single proposition, he insists, as “it’s not the case that (if *p*, then *q*).”

**ABELARD’S TWO NEGATIONS.** Negation is the simplest propositional operation. If it is defined truth-functionally, it takes any propositional content and produces another, its contradictory, false if the first is true and true if it is false.

The invention of this operation in Latin logic cannot quite be claimed with certainty for Abelard. It is possible that it was used by his predecessors since it appears in very limited way in a discussion of the appropriate way to negate a simple conditional proposition in the *Dialectica* of Garlandus Compotista, apparently written in the second decade of the twelfth century roughly contemporary with Abelard’s *Dialectica*.

Abelard, however, is the first Latin writer known to us who discusses propositional negation in general and applies it both to simple and compound propositions (Martin 2004). He distinguishes, indeed, two kinds of negation. First, and principally, propositional negation, which he calls “destructive” negation, and which has the whole of the following propositional content for its

scope. Second, and derivatively, a negation, which he refers to as “separative” which in the case of affirmative categoricals is obtained by negating the predicate (*Dial.* II.2, 173 sq.). Abelard follows Boethius in classifying conditionals as affirmative according the quality of their consequents. The separative negation of a given affirmative conditional is obtained by negating its consequent either destructively or separatively.

A necessary condition for the truth of both an affirmative categorical and its separative negation is that the subject term is not empty. There is no such requirement for the truth of its destructive negation.

With this distinction between negations Abelard constructs an account of the relationships between quantified propositions which results in effect in a rectangle of opposition rather than the famous square of Aristotle as Boethius understood it. Aristotle gives “not every *A* is *B*” as the contradictory opposite of “every *A* is *B*” in *De interpretatione* but in the *Prior Analytics* “some *A* is not *B*” and according to Boethius the meaning is the same.

Abelard, however, argues that “some *A* is not *B*” is not the contradictory of “every *A* is *B*” but rather “it is not the case that every *A* is *B*.” He thus avoids the problem typically raised against Aristotle’s logic of quantified terms, that since it requires for the truth of a universal affirmation that the subject term is not empty, given there are no chimeras, an affirmation such as “every chimera is conversing” is false. It follows that its contradictory is true. Since “some chimera is not conversing” is true, however, only if the subject term is not empty, there must be some chimeras for it to be true of! For Abelard this is not a problem since on his account both propositions are false (*Log. “Ingrid.” sup. Perierm.* 7, 408–11).

**THE MANIPULATION OF MODALITY.** Once the notion of propositional content was available the difference between two different interpretations of modal propositions could be formulated precisely. In his *Dialectica* Abelard notes that a mode may appear in a categorical proposition either as an adverb or an adjective as, for example, in “Socrates is possibly a bishop” and “that Socrates is a bishop is possible” (Knuutila 1993). Abelard holds that though they differ syntactically these two propositions are semantically equivalent and it is the first which properly expresses the intended meaning since possibility is properly attributed to things (*de rebus*) (*Dial.* II.2, 191sq.). The adverb serves to indicate that the inherence of the predicate in the subject is modified in some way. Later medieval logicians will refer to this as the *de re* reading of the modal claim.

In the case of true *de re* claims about possibility there is of course no actual inherence to modify and Abelard holds that such propositions are true just in case the nature of the subject is compatible with the predicate. Human nature is compatible with being a bishop so “Socrates is possibly a bishop” is true even though he never has been nor never will be one (*Dial.* II.2, 193).

Abelard records that one of his masters proposed an alternative account of propositions with adjectival modes. They are to be understood, he held, as claims about the possibility, necessity, etc. of the sense (*de sensu*), that is the propositional content, of the simple propositions from which they “descend.” Against this interpretation Abelard, in effect, argues that if we substitute for a given propositional content an equivalent one, the truth-value of the proposition will remain the same. Since universal negatives convert simple, “no blind man is a seeing man” is equivalent to “no seeing man is a blind man.” While his opponents accept, however, that “no blind man is possibly a seeing man” is true, since they agree that the blind do not regain their sight, they claim that “no seeing man is possibly a blind man” is false. The *de sensu* reading, however, requires them to have the same truth value (*Dial.* II.2, 196).

Although he maintains in the *Dialectica* the *de sensu* reading is in general not the proper way to interpret modal propositions, Abelard does allow that it is correct for the adjectival modes “true” and “false” since these, he argues, they are properly predicated of propositional contents (*Dial.* II.2, 204–6).

Abelard discusses the same questions at length in his *Logica* in commenting on Aristotle’s account of the relations between modalities in *De interpretatione*, 12. He notes, in the first twelfth-century reference to the *Sophistical Refutations*, that the distinction he is interested corresponds to that made by Aristotle between reading a proposition such as “a standing man is possibly sitting” in a composite (*per compositionem*), or a divided way (*per divisionem*). Here, however, Abelard does not insist on the reading *de rebus* but rather works out in detail the relations between modal claims of both kinds (Abelard 1958, 13).

**ABELARD ON ENTAILMENT.** In his logical works Abelard sought to unify into a single theory of inference the disconnected remarks on topics and the consequence relation which he found in Boethius (Martin 2004). To do this he provides a new general definition of a *locus* as the force of, or as we would say, the warrant for an entailment (*vis inferentiae*) (*Dial.* III.1, 253). He then devotes hun-

dreds of pages of his logical works to investigating the role of *loci* thus conceived in proving conditionals and validating the corresponding enthymemes.

According to Abelard, a proposition *p* entails a proposition *q*, just in case the corresponding conditional, or consequence, *if p, then q* expresses a relationship of following, or “consecution” (*consecutio*). For this to be so, he holds, the sense of the antecedent, that is, its propositional content, must contain that of the consequent. Abelard characterizes this kind of connection as necessary but insists that it must be distinguished from the satisfaction of the inseparability condition which it guarantees, and which alone provides only the necessity of what he calls association (*comitatio*) (*Dial.* III.2, 459).

Entailments are divided by Abelard into the perfect and the imperfect. Perfect entailments satisfy the containment requirement in virtue of the form, or structure, of the propositions involved. Imperfect entailments are those in which the sense of the antecedent contains that of the consequent but does not do so in virtue of their form (*Dial.* III.1, 253).

Abelard makes the notion of perfection, and so form, more precise, and anticipates modern definitions of logical truth, by giving as a necessary condition for perfect entailment that consecution is preserved through all uniform substitutions of terms or propositional contents. He does not, however, regard the condition as sufficient and, in particular, although he classifies the conditionalizations of all valid categorical and hypothetical syllogisms as perfect, he holds that instances of the principle of reflexivity, *if p, then p*, are imperfect, presumably because they fail to have a canonical syllogistic form. Like all other imperfect entailments, according to Abelard, they must thus be warranted as instances of an appropriate maximal proposition (*Dial.* III.1, 255).

By far the greatest part of Abelard’s *Dialectica* is concerned with establishing just which conditional propositions express imperfect entailments. Boethius in *De Topicis Differentiis* says that he will explore which *loci* are suited to which syllogisms and according to Abelard this led some logicians to hold that even the canonical syllogistic figures needed topical warrants. He and his mid-twelfth century followers known, probably because of their views on universals, as the *Nominales*, rejected this. They held rather that putative principles cited to support categorical and hypothetical syllogism are simply their metalinguistic formulation as rules. They contain no term indicating a topical relationship, that is no *locus differentia*, upon which the inference in question rests (*Dial.* III.1, 256–263).

Imperfect entailments, according to Abelard, are conditionals and the corresponding enthymemes, which satisfy the two conditions necessary and sufficient for following for a restricted range of terms. The topical difference specifies the relevant substitution class and the maximal proposition warrants the inference for substitutions from that class. For example, the conditional “if Socrates is a human being, then Socrates is an animal” is true and so are all substitutions for “human being” and “animal” which stand in the relationship of species to genus. For example, “if Socrates is a pearl, then Socrates is a stone,” warranted by the maximal proposition “of whatever a species is predicated, so is its genus” (*Dial.* III.1, 315).

NECESSITY. Abelard’s main task in his discussion of topical inference is to establish just which topical relations and which maximal propositions warrant true conditionals. He argues in the *Dialectica* that since what is being proved are conditional propositions, even though their surface form may be categorical, maximal propositions must in fact be general conditionals “containing” each of the proved conditionals as their instances. His treatment of this question involves a sophisticated discussion of how relative pronouns function in quantified propositions and the rules for logically manipulating them.

Since Boethius had allowed that some *argumenta* are probable but not necessary certain of Abelard’s contemporaries had, he tells us, accepted as true any conditionalization of an enthymeme supported by a probable maximal proposition. In particular they took to be true conditionals warranted by maximal propositions which guarantee the inseparability of association but not the following or consecution which Abelard requires for entailment (*Dial.* III.1, 271 sq.).

Against them Abelard invokes the principle from the *Prior Analytics* mentioned above. His opponents accept conditionals warranted by appeal to the *locus* from immediates and the maximal proposition “of that from which one of a pair of immediates is removed the other is predicated.” They must thus accept the following argument: [I1] if something does not exist, then it is not well (by the *locus* from part to whole, since “not-well” is predicated of all non-existent things as well as all existing things which are not well); [I2] if something is not well, then it is sick (from immediates); [I3] if something is sick, then it exists (from part to whole); so, by transitivity, [I4] if something does not exist, then it is sick, and thus [I5] if something does not exist, then it exists. [I5], how-

ever, contradicts Aristotle's principle and, Abelard maintains, is obviously impossible (*Dial.* III.1, 276).

Abelard investigates in detail various proposals to modify [I2] to block the embarrassing inference while retaining its warrant from immediates. In particular he considers various ways of adding what he calls a "temporal" qualification, indicated with "when" (*cum*), to form propositions such as "if (when something's an animal, it's not well), then it's sick."

Boethius, as noted, claims that "if" and "when" are equivalent as indicators of a conditional connection and in *De hypotheticis syllogismis* he invariably gives the conditional components of compound conditionals with "when." For example, "if (when something's an *A*, it's a *B*), then it's a *C*." This practice allows Abelard to treat the embedded propositions as temporal rather than conditional in interpreting Boethius claims about the hypothetical syllogism (*Dial.* IV.1, 472 sq.).

The problem for Abelard is that having insisted that one destroys a conditional by showing that it is possible for the antecedent to hold without the consequent, Boethius apparently assumes that an affirmative simple conditional and the corresponding negative conditional are contradictory opposites. He thus claims to be valid, for example, syllogisms of the form "if (when something's an *A*, it's a *B*), then it's a *C*, but it's not a *C*; therefore when something's an *A*, it's not a *B*."

Abelard in the end rejects Boethius's account of the hypothetical syllogism. In this case, for example, he maintains, contrary to Boethius, that the valid argument is rather an instance of *modus tollens* (*if p, then q, not:q; therefore not:p*) which concludes with the propositional negation of the antecedent: "if (when something's an *A*, it's a *B*), then it's a *C*, but it's not a *C*; therefore it is not the case that (when something's an *A*, it's a *B*)." Abelard thus, in effect, replaces Boethius's account of the hypothetical syllogism with a genuinely propositional theory which takes *modus ponens* (*if p, then q, p; therefore q*) and transitivity (*if p, then q, if q, then r; therefore if p, then r*) as basic principles and *modus tollens* as a derived principle and holds that all uniform substitution instances, no matter how complex, are valid (*Dial.* IV.1, 498 sq.).

Abelard was unable to save Boethius's account of the hypothetical syllogism and so he replaced it with the correct one. Apparently no one else could to do any better and *De hypotheticis syllogismis* disappeared from the logic curriculum some time in the twelfth century. It is not until Walter Burley (1274–1344) published *De puritate artis logicae* in about 1325 that hypothetical syllogisms

were discussed in any detail again, and there the conditional premisses are always simple conditionals.

RELEVANCE. Abelard accepts that the *locus* from immediates and many others guarantee the inseparability of association, but he also requires a relevant connection between antecedent and consequent for the conditional to be true (Martin 2004). He does not, however, insist on relevance for the validity of an argument. So long as it is impossible for the premisses to be true and the conclusion at the same time false, true premisses will guarantee a true conclusion and that is all that an argument is asked to produce. Abelard thus denies as a general principle what we would now call the Deduction Theorem, that an argument *p; therefore q* is valid if and only if the corresponding conditional *if p, then q* is true (*Dial.* III.2, 455).

Abelard's distinction between association and following or consecution as two kinds of necessary connection is based on the account given in the *Isagoge* of the relationship between substances and their accidents. According to this a substance does not require a particular accident in order to exist and so accidents are separable from their subjects. The problem is that while a given substance may undergo a change with respect to certain of its accidental features there are others, according to Porphyry, which must always be present. Blackness, for example, in the case of crows, and the property of being able to laugh in the case of humans. Neither of these are included in the account of what it is to be a crow or to be human but there is no natural possibility of their subjects existing without them. Such "inseparable" accidents can, however, it is claimed, be removed in the sense that we can conceive of a crow without conceiving its blackness. They are thus contrasted with definitional features which are included as part of its essence, in the definitional account of what it is to be a particular kind of thing (*Log. "Ingrid." sup. Porph.* 6, 93).

Abelard's two necessities are a generalization of this distinction between actual and conceptual inseparability. He points out in his own discussion of inseparable accidents that although the antecedent and consequent of "if Socrates is a stone, then Socrates is a pearl," are inseparable, a pearl being classified as a kind of stone, nevertheless the conditional is false. The antecedent and consequent are inseparable, and Abelard is the first medieval logician we know of to make this point, merely because the antecedent is impossible. He goes to point out that if the inseparability of association were sufficient as well as necessary for following, then any conditional with an impos-

sible antecedent would be true. For example, “if Socrates is a stone, then Socrates is a donkey” (*Dial.* III.1, 285).

Abelard does not, however, formulate the famous principles that anything follows from an impossibility and that a necessity follows from anything. He could not be expected to do so, however, since given his definition of following they are false.

Abelard believes that his own account of the semantics of the conditional generates what we would today call a connexive logic, a logic, that is, for which no proposition can entail or be entailed by its contradictory opposite. These principles entail, Abelard recognizes, both the propositional version of Aristotle Principle and what we may call Abelard’s Principle: No two conditionals of the form *if p, then q* and *if p, then not:q*, can both be true.

Abelard accepts simplification (*if (p and q), then p* and *if (p and q), then q*), contraposition (*if (if p, then q), then (if not:q, then not:p)*), and transitivity (*if p, then q, if q, then r; therefore if p, then r* is valid). Suppose, then, that Abelard’s Principle is false for some *p* and *q*, that is both (1) *if p, then q* and (2) *if p, then not: q* are true. But then if (3) *if (p and not:q), then p* is true and likewise (4) *if q, then not:(p and not:q)*, we may infer by transitivity that *if (p and not:q), then not:(p and not:q)*, an instance of *if p, then not:p*, which Abelard insists is a paradigm of impossibility. Abelard’s Principle is thus necessarily true and he gives a similar argument to prove Aristotle’s Principle (*Dial.* III.1, 290).

From these principles there follows the most characteristic feature of the logical theory advocated by Abelard and the *Nominales*: No conditional can be true of which the antecedent and the consequent differ in quality. For example if *if p, then not: q* were true, for some *p* and *q*, then *if (p and q), then not:(p and q)* would true by transitivity and contraposition.

Most famously Abelard argued against the *locus* from opposites in this way. If the *locus* warranted a true conditional then the conditional “if Socrates a human being, then Socrates is not a donkey” would be true and we could infer the impossibility “if Socrates is a human being and a donkey, then it is not the case that Socrates is a human being and a donkey.” He sees too, and explicitly acknowledges, that it follows from the principles of his logic that the conditional principle of double negation (*p if and only if not:not:p*) is false in both directions (*Dial.* II.2, 179).

Unfortunately Abelard’s various intuitions about the propositional connectives are inconsistent (Martin 1987). In particular the principles which he holds to govern

negation are incompatible with simplification. This point seems to have been first noticed the 1130s by Alberic of Paris who confronted Abelard with the following argument: The conditional [A0] “if Socrates is a human being, then he is an animal” is a paradigm of entailment according to Abelard. He must also accept each of the following: By simplification [A1] if Socrates is human and Socrates is not an animal, then Socrates is not an animal; by contraposition, [A2] if Socrates is not an animal, then Socrates is not a human being; again by contraposition, [A3] if Socrates is not a human being, then it is not the case that Socrates is human being and Socrates is not an animal; so by transitivity, [A4] if Socrates is human being and Socrates is not an animal, then it is not the case that Socrates is a human being and not an animal—contradicting a fundamental principle of Abelard’s logic. Alberic’s proof of inconsistency precipitated a crisis in the history of logic.

## THE PARISIAN SCHOOLS AND THE CRISIS OVER THE CONDITIONAL

In middle decades of the twelfth century a number famous logicians were active at Paris and with each of was associated a school (Martin 1987). In some cases very substantial treatises have survived from these schools, illustrating that this was a period of intense activity in logic. Unfortunately most of these and certainly the most important are still unpublished. The schools may be distinguished by their response to Alberic’s proof of the inconsistency of Abelard’s system.

Abelard’s own followers, the *Nominales*, continued to maintain the correctness of his account of the conditional and the connexive principles. Their strategy seems to have been to take negation to be a cancellation of content so that nothing follows from *p and not:p* rather than both *p* and *not:p*.

The followers of Alberic, the *Montani*, so-called because their school was located on Mont Ste. Geneviève, held that the argument failed because the conjunction of contraries in [A1] undermined the relationship on which [A0] was based. In a different context Abelard himself anticipates this objection to impossible antecedents and argues at length against it that since the antecedent is not asserted, and the argument is formally valid, the conclusion follows.

The school of Gilbert of Poitiers, the *Porretani*, held that the problem lay in the unrestricted principle of simplification. They required, as do twentieth century connexive logics, that both conjuncts play a role in such an inference. The most surprising response was that of the

followers of Robert of Melun, the *Melidunenses*, who took as their basic principle for the logic of the conditional the rule “nothing follows from the false.”

The solution that eventually won the day, however, was that proposed by the followers of Adam of the Little Bridge, the *Parvipontani*, so called again because of the location of their school in Paris. They accepted that the argument was sound because they apparently held that inseparability alone is both necessary and sufficient for the truth of a conditional. Aristotle’s Principle thus fails when the consequent is necessary and Abelard’s when the antecedent is impossible.

John of Salisbury tells us in his *Metalogicon* (1159) that one of his students, William of Soissons, had gone on to join the *Parvipontani* and discovered the twelfth-century version of one of the twentieth century’s most famous arguments, the proof that *ex impossibili quodlibet*, the so-called paradox of strict implication, according to which anything follows from an impossibility (*Metalogicon* II.10).

In his *De naturis rerum* written at the end of the twelfth century Alexander Neckham gives the argument as follows: [S1] if Socrates is a human being and Socrates is not a human being, then Socrates is a human being; [S2] if Socrates is a human being, then Socrates is a human being or Socrates is a stone; [S3] if Socrates is a human being and Socrates is not a human being, then Socrates is not a human being; therefore [S4] if Socrates is a human being and Socrates is not a human being, then Socrates is a stone (*De Naturis Rerum* cixxiii, 288–89).

The outcome of the crisis provoked by Alberic was a complete change in the understanding of the logical connectives. John of Salisbury tells us that he could not conceive why any one would think that anything follows from an impossibility but according to Alexander Neckham nothing was more obvious.

Abelard had insisted that a genuine connection was required for the truth of conditionals and disjunctions. Alexander’s argument, on the other hand, assumes only inseparability for the conditional and much less for the disjunction. [S2] is the so-called Principle of Addition characteristic of the disjunction defined as true if one of the disjuncts is true. The disjuncts are no longer required to be related as immediates.

The conditional and disjunction were standardly defined in this way for the rest of the middle ages. Until the end of the thirteenth century, however, a contrast continued to be drawn between an accidental consequence which held wherever the inseparability condition

was met and a natural consequence in which the sense of the antecedent contained the consequent. This stronger connection was needed because it was necessary to reason about impossibilities.

## THE RECEPTION OF THE *LOGICA VETUS* AND THE DEVELOPMENT OF THE *LOGICA MODERNORUM*

Some time towards the end of the twelfth century the various different schools disappeared as the independent masters formed themselves into the corporation that became the University of Paris. Teaching and research in logic was the preserve there of the Faculty of Arts and its results appear in the introductory textbooks of the *logica modernorum*. To the traditional topics these add extensive discussions of fallacies and the properties of terms.

**FALLACIES.** Although Abelard had some limited access to the *Sophistical Refutations* it was not until around 1140 that the analysis of fallacies became a major concern for logicians. From the beginning, however, a short list was available in Boethius’s discussion of Aristotle’s remark in *De interpretatione* 6, that the putative negation of a given proposition may fail to have the required opposite truth value because the subject or predicate terms have different meanings in the two propositions (De Rijk 1962–1967).

Although Boethius’s list of the ways in which this might occur ceased to be of much interest once the *Sophistical Refutations* were easily available, one of his fallacies was particularly important for the later development of logic. With no further explanation Boethius gives as an example of what he calls *univocation* the propositions “*homo ambulat*” (“human being walks”) and “*homo non ambulat*” (“human being does not walk”). He claims that they are true together when the first is true of an individual, or particular man, and the second is true of “special man.”

Abelard notes that univocation arises because the context in which a term is used may affect its meaning. For example, since medieval Latin has no articles or quotation marks it cannot distinguish between the occurrences of “*homo*” in “*homo est albus*,” “*homo est vox*,” and “*homo est species*,” in the way in which we distinguish in their translations between “a human is white,” “‘human’ is a word,” and “human is a species” (De Rijk 1962–1967, I, pp. 51–56).

Logicians in the second half of the twelfth century commented at length on and refined Aristotle’s account

of fallacy in the *Sophistical Refutations*. By the end of the century the results of their work are clear in theology where the theory of fallacy is frequently invoked to explain and resolve errors in argumentation. In addition to the standard fallacies logicians also developed as a special form of argument the idea of counter instances (*instantiae*) which they found in the *Sophistical Refutations*, *Topics*, and *Prior Analytics*. With these the principles advocated by one or another of the schools were shown to lead to a conclusion which was unacceptable to it.

Once the works of the *logica nova* were available logicians seem to have turned their attention from the theory of consequences and topical inference to issues in philosophical semantics. Here a distinction was made between categorematic words, or terms, that is words which on their own can be the subject or predicate of a categorical proposition, and all other words which can occur in any kind proposition. The latter were called syncategorematic words.

**THE PROPERTIES OF TERMS.** Termist logic, so called because of its interest in the semantical properties of terms, seems to have developed in rather different ways in Paris and Oxford. The most famous Parisian termist was certainly Peter of Spain (c. 1205–1277), whose *Tractatus*, or *Summulae logicales*, written around 1235, was much commented on and remained the standard introductory text in logic in continental Europe and Scotland for the rest of the middle ages. It seems, however, not to have been greatly used in England, where the University of Oxford had its own textbooks. The *Introductiones in logicam* (c. 1245) by William of Sherwood (c. 1210–c. 1270) perhaps also belongs in the Oxford tradition. Another text belonging to the Parisian tradition is the *Summa Lamberti* (c. 1255) of Lambert of Auxerre (fl. 1250s) on which the following remarks are based.

**IMPOSITION AND SIGNIFICATION.** Medieval logicians developed their philosophical semantics in the first place from Boethius's commentaries on the first chapter of *De interpretatione*: Spoken words are introduced to bring to mind mental items, understandings (*intellectus*), which are obtained from the things which exist in the extra-mental world and are likenesses of them. For substantial common terms such as "human being" the corresponding understandings are the mental correlates of the forms which in the world make individuals to be the kinds of things that they are. For accidental terms such as "whiteness" they are the forms which cause individuals to have the accidental features that they do.

Words were held to acquire their meaning through acts of baptism, known as *imposition* (*impositio*), or *institution* (*institutio*) (Kretzmann et al. 1982, ch. 9). In the case of individual humans literally so. For general terms the impositor introduces a name in the presence of a paradigmatic sample with the intention that all and only individuals of the kind in question bear the same name. Adam's naming of the beasts of the field and the fowls of the air (Genesis 2:19) provided a suitable example. Although medieval accounts of imposition do not seem to have been very developed there are obvious similarities to modern causal theories of reference.

The immediate and proper signification of a common term is the understanding constituted when it uttered in the mind of a listener who speaks the language. Just what a given philosopher thought about the things understood and their relationship to individuals in the world depended on where he stood on the question of universals. Lambert, for example, was a realist. The term "human being," he claims, signifies immediately the understanding of the form which makes humans to be human and mediately the form itself. It does not signify individual human beings (*Logica*, 206).

**SUPPOSITION.** "Supposition" is used in the thirteenth century to refer to what earlier writers had called "appellation," it is a property which an already significant term has in virtue of its use. Corresponding to the three different contextual meanings recognized in the fallacy of univocation there are three forms of supposition. With no change in the signification established by its original imposition, the term "*homo*" thus supposits, or stands for three different kinds of things in the propositions "*homo est albus*," "*homo est vox*," and "*homo est species*."

In the first, according to Lambert, "*homo*" has personal supposition because it stands for the individuals "contained under" the form which it indirectly signifies. In the other two, he says, its supposition is simple (*Logica*, 209). In the second it stands for the thing which the term signifies indirectly—a form according to Lambert, and a "universal thing" according to Peter of Spain. In the third proposition the terms stands for itself.

William of Sherwood gives a slightly different classification. According to him in the third proposition "*homo*" has material supposition and in the other two formal supposition. In the first this formal supposition is personal and in the second it is simple (*Introductiones*, 75).

Personal supposition is the semantical property which most interested logicians since their task was to say

in general what determines the truth or falsity of a given proposition and to do so they needed to decide what the terms in the proposition stand for.

**THE DIVISIONS OF SUPPOSITION.** Treatises on the properties of terms make many distinctions and precisions within personal supposition. Supposition properly speaking is a property of a substantive noun which it has when it stands for something. An adjective in use, on the other hand, couples something and so is said to have the property of copulation.

Supposition in general, according to Lambert, is either natural and accidental. The imposition of a term connects it mediately with a form and, at a second remove, prior to any contextual determination to all the individuals which have done, do, or will share in that form. These are what it naturally supposits for (*Logica*, 208).

Accidental supposition is supposition determined by context and may, as noted, according to Lambert, be simple, or personal. Personal supposition is further divided into discrete supposition, the supposition had by proper names, and common supposition, the supposition of common terms.

The common supposition of a term such as “human being” is further determined by its interaction with the syncategorematic words of quantity and quality, and may be either determinate or confused. Logicians offered various accounts of these forms of supposition but by the fourteenth century typically explained them in terms of their inferential relations (Kretzmann et al. 1982, ch. 9)

Supposition is determinate when the term is the subject of an indefinite or particular affirmative, such as “a human being is running” and “some human being is running.” Here we may descend from the particular or indefinite proposition to the propositional disjunction of singulars whose subjects are the *supposita* of the common term and ascend from any one of those singulars to the general proposition. So from “some human being is running” we may infer “Socrates is running or Plato is running or ...” and from the truth of any one of the disjuncts we may infer that some human being is running.

In confused supposition, a common term stands for all its *supposita* together. It may do this in one of two ways, either as with the subject of a universal affirmative where the supposition is distributive, and one may descend to, and ascend from, the propositional conjunction of each of the corresponding singulars. For example from “every human being is running” to “Socrates is running and Plato is running and ...” and conversely.

The other form of confused supposition, merely confused supposition, is exemplified by a common term occurring as the predicate of a universal affirmative proposition. Here the term again stands for all *supposita* but taken together in such way that one can descend only to the predicate disjunction but ascend from any singular. For example from “every human being is an animal” to “every human being is (this animal or that animal or ...)” and from “every human being is this animal” to every man is an animal.

Negation distributes any simple term to which it is applied, so both the subject and predicate of no man is running, that is, every man is not running, have confused and determinate supposition (Lambert, *Logica*, 210).

Historians have puzzled about the relationship between supposition theory and modern quantification theory but this seems to miss the point. Supposition theory does not aim to state truth-conditions for propositions but to determine which of the *supposita* of a term occurring in a proposition someone uttering it should be understood as referring to and in what way.

**AMPLIATION AND RESTRICTION.** The propositions given above to illustrate the divisions of supposition all have simple subjects and predicates with the verb in the present tense and not modified in any way. A term is said to appellate those of its *supposita* which actually exist and in the case of all these propositions appellation and supposition coincide. The qualification of a substantive with an adjective restricts its supposition to suitably qualified things. In “a white human being is running,” for example, “human being” has determinate supposition only for those of its *appellate* which are white (Lambert, *Logica*, 226).

Tense affects the supposition of terms by ampliating them to stand for *supposita* other than their *appellate*, though these may also be included in the supposition. For example in “an old man was a young man” the predicate term has merely confused supposition for those of its *supposita* which existed in the past but do not now exist. The subject term has determinate supposition for its *appellate* and its past *supposita*.

There is no suggestion in the twelfth century termists named that a term might supposit for *possibilia* which never exist. Lambert and Peter of Spain hold, for example, that in the modal proposition “some man might be the Antichrist” “man” supposits for past and future men (Lambert, *Logica*, 228). Ampliation to pure *possibilia* is allowed, however, in the *Summa logicae* (c. 1324) of William of Ockham (c. 1285–1349) and *Summulae de*

*dialectica* (1330s) of John Buridan (c. 1300–c. 1360). The change in theory of ampliation reflects a radically new conception of possibility introduced in the work of John Duns Scotus (c. 1265–1308) at the beginning of the fourteenth century. Against the assumption that all possibilities must be realized in time Scotus famously argued for the logical possibility that things could now be otherwise than they in fact are and so that there are possibilities that are never realized.

**SYNCATEGOREMATIC WORDS.** Both Peter of Spain and William of Sherwood as well as other termist logicians produced treatises entirely devoted to syncategorematic words (Kretzmann et al. 1982, ch. 11). These treatises do not deal with all words that are not categorematic but only with a relatively small and fairly standard set. In addition to the definition by exclusion, syncategorematic words are further characterized as semantically incomplete in that they acquire a signification only by being combined in some way with categorematic terms. For this reason they are said to be *consignificant*.

It is in the treatises on *syncategoremata* that termist logicians deal with the difficult words whose presence may affect the validity of a principle of inference and allow the construction of sophisms. As, for example, in the proof by Sherwood that no man lectures at Paris unless he is an donkey: “A man lectures at Paris unless he is an donkey” is a false conditional since the antecedent “a man is not a donkey” is necessarily true and consequent may be false. Therefore the contradictory of the conditional is true (*Syncategoremata* 82–3). In the fourteenth century such puzzles and their resolutions were collected together in separate works devoted to grammatical, logical, including modal and epistemic, and physical sophisms. Their resolution often required that the inner structure of a syncategorematic term be exposed by what was called *exposition*. “Socrates is beginning to be white,” for example, might be expound as ‘Socrates is not now white and after now Socrates will be white’ leading on to a discussion of tense, change, and the structure of time.

Included among the *syncategoremata* in these treatises we find the propositional connectives and confirmation the twelfth century insight into their nature had not been lost. William of Sherwood, for example, discusses both negation and the copulative conjunction. He clearly distinguishes, extinctive, or propositional negation and argues that if the conjunction “Socrates is running and Plato is arguing” is negated with a preposed particle the result is true just in case one of the coupled propositions is false (*Syncategoremata* 86).

## MODISM

In the last quarter of the thirteenth century the termist semantics of supposition was replaced by what is known as modism, or speculative, that is, theoretical, grammar (Marmo 1994, Kelly 2002). The proponents of this theory, the *modisti*, for example Martin of Dacia (d. 1304), Boethius of Dacia (fl. 1275), and Thomas of Erfurt (fl. 1300) were concerned to say something more general about the meaning of both categorematic and syncategorematic terms than their termist predecessors. They held that all meaningful words are characterized by certain modes of signifying and that these correspond to the traditional parts of speech. Corresponding to each modes of signifying, is a mode of understanding, and a mode of being.

According to the modists a proper name like “Socrates” as well as signifying Socrates, carries information about the essential character of what it signifies. It signifies it as a substance, for example, in the *modus substantiae*, though not as an existent, since we use nouns to speak about presently non-existent and fictional items. A verb, on the other hand, signifies what it signifies in the mode of change and becoming. Grammatical features which were regarded as less fundamental, for example, number and tense, were held to correspond to accidental modes of signifying, understanding, and being (Kretzmann et al. 1982, ch. 13).

On the basis of their distinction between modes the *modisti* developed an account of grammatical congruity—the modes have to fit together in the right way. They sought to go beneath the surface structure of their language to locate the underlying relationship between the components of propositions. Their idea was that the order required by Latin grammar did not properly represent the real relationships between the things signified. Though twelfth century logicians had already explored some of these ideas especially with regard to pronouns, the *modisti* deserve credit for being the first to attempt to develop a systematic theory of syntax.

Although the modists distinguished between the full signification of a word including its mode of signifying and the things in the world to which it applies, they made no use of the idea of supposition. They seem not to have developed an account of the contextual dependence of reference to compete with that of termists and in the end it was the semantics of termism which won the day (Kretzmann et al. 1982, ch. 13).

## OBLIGATIONS

The earliest treatises on what were known as obligations (*obligations*) date from the second half of the twelfth century (Martin 1993). In obligational disputation one participant, the respondent, is required to agree to a hypothesis and to reply consistently with it in the face of questions put to him by the opponent. The aim of the opponent is make the respondent contradict himself.

The most important form of obligation was the one known as *positio*, in which the opponent posits to be true something which is in fact false. In the twelfth and thirteenth centuries it had two forms depending on whether the *positum* was false but possibly true, possible *positio*, or an impossibility, impossible *positio*. The original motivation for the latter seems to have been Boethius's proposal in *De hypotheticis syllogismis* that an impossibility be posited in order to see what follows (*Hyp. Syll.* I.2.6).

The earliest surviving treatise on impossible *positio*, the *Tractatus Emmeranus*, recognizes that no coherent argumentation is available under such an hypothesis if one accepts that anything follows from an impossibility. It stipulates instead that reasoning in impossible *positio* should rely only on consequences in which the consequent is contained in the antecedent and so not employ those with an affirmative antecedent and negative consequent—the theory uniquely characteristic of Abelard and the *Nominales* (De Rijk 1974). Later treatments of impossible *positio* require only that they be conducted using consequences satisfying the containment condition.

In accounts of possible *positio* written before 1330s the respondent's answers are required to be consistent with everything that has gone before. He must thus concede a *propositum* which follows from the conjunction of the *positum* with all *proposita* already conceded and the contradictories of those which have been denied and deny a *propositum* whose contradictory follows from this conjunction. A *propositum* is irrelevant if neither it nor its contradictory follows from the conjunction and the respondent is required, if it is true, to concede it and, if it is false, to deny it (Kretzmann et al. 1982, ch. 16A).

A well conducted *positio* thus yields a set of propositions cotenable with the original *positum* and so an account of how the world might be. In treatises on possible *positio* written before the beginning of the fourteenth century we find a rule to the effect that if *n* is the present time, the *propositum* “*n* is the present time” must be denied, since it is not possible for things now to be other than now they are. Duns Scotus rejects this principle in

setting out his new account of possibility and it is no longer found in fourteenth century accounts of *positio*.

Possible *positio* provides a way of testing the respondent's reasoning skills but also of constructing alternative possible world-histories. This application is common in fourteenth century treatments of reconciliation of divine foreknowledge with the possibility that things might be otherwise than they will be.

In the mid-1330s a group of logicians at Oxford proposed modifications to the principles of *positio*. Richard Kilvington (c. 1305–1361) in his *Sophismata* required that the respondent answer an irrelevant *positum* not in accordance with his beliefs about its actual truth-value but rather in accordance with the beliefs he would have if the *positum* were true. Kilvington noticed that these may well differ if the *positum* refers to the respondent's epistemic states (Kretzmann et al. 1982, ch. 16B).

Roger Swineshead (d. 1356) went much further in his *Obligaciones* (1340s?) and proposed what became known as the “new response” (Kretzmann et al. 1982, ch. 16B). For reasons which remain obscure he required the respondent simply to concede a *propositum* if it follows from the *positum* alone and to deny it if is incompatible. Everything else is irrelevant. This change, however, undermines the constructive character of *positio* since, for example, if some false proposition *p* is posited and *q* is an irrelevant truth, the respondent must concede both *p* and *q* when they are proposed but go on to deny their conjunction *p* and *q*. Swineshead's account of *positio* seems to have enjoyed some limited success but it is not mentioned after the end of the fourteenth century.

## INSOLUBLES

The most famous example of what medievals called insolubles, sentences difficult but not impossible to solve, is the Liar: “This sentence is false” (Spade 1988). The difficulty is to assign it a truth-value since it seems that if it is true, then it is false, and if it is false, then it is true. The problem is first noticed the middle ages in the *Ars disserendi* of Adam of the Little Bridge published in 1132 and its medieval origins may well lie in reflection on possible *positio*.

Both the *Tractatus Emmeranus* and another treatise from the second half of the twelfth century, the *Obligaciones Parisiensis* (De Rijk 1975), note that if a respondent accepts as a *positum* “the *positum* is false” or an equivalent, then the opponent will be able to force him to contradict himself (Martin 1993). Both works go on to discuss propositions such as “a falsehood is conceded”

which may be certainly be posited but cannot then be conceded as the rules of *position* require since if it is, it becomes a Liar. The appropriate response, they claim, is to reply “You are not saying anything” (*nugaris*).

The earliest known treatise entirely devoted to the Liar, the *Insolubilia Monacensis*, from roughly the same date, adopts the same solution, voiding (*cassatio*): A self-referential utterance of “this sentence is false” fails to assert anything (De Rijk 1966). This solution continued to be invoked in the thirteenth century but is no longer employed in the heyday of insoluble literature, the first half of the fourteenth century.

Many different solutions were proposed to the problem and Thomas Bradwardine (c. 1295–1349) lists eight others besides *cassatio* in his *Insolubilia* (Spade 1988). These include, for example:

- 1) *Secundum quid et simpliciter* (qualified and unqualified): Distinguish between the qualified and unqualified possession of a property as Aristotle does in the *Sophistical Refutations* discussing the puzzle of a man who takes an oath to break his oath. The Liar is false without qualification, but relatively true.
- 2) *Transcasus* (change of situation): The claim made in uttering the Liar refers to an instant before the utterance. The Liar is simply false since the speaker said nothing then.
- 3) *Restrictio* (restriction): The supposition of the term “false” in the Liar is restricted to standing only for sentences other than the Liar or sentences equivalent to it. Since uttering the Liar utters only that sentence, it is simply false.

Bradwardine rejected all the theories in his list and offered a new one which set the agenda for later discussions. He maintained, first, that a proposition is true if it signifies things *only* as they are but is false if it signifies things as other than they are—it may well also signify them as they are. Second, he held, and seems to have been the first to do so that a proposition signifies just what follows from it. Bradwardine concluded that if a proposition signifies itself to be false, then it signifies itself to be true. The Liar thus signifies itself to be both true and false and so is false (Roure 1970).

## CONSEQUENCES

Treatises devoted to consequences seem to be product of the fourteenth century and, although one was written by the great Parisian logician John Buridan, they are almost exclusively a British production. The second or third

decade of the fourteenth century marks a turning point in the history of consequences as important as the resolution of the twelfth-century crisis (Martin 2005).

Duns Scotus was not a logician but he put logic to the service of metaphysics when he located a formal distinction between any two items which are actually inseparable but conceptually separable. If being *B* follows accidentally but not naturally from being *A*, then being *A* is formally but not existentially distinct from being *A*.

Ockham’s rejection of the formal distinction seems to explain his introduction of an entirely new theory of consequences. In his *Summa logicae* rather than distinguishing between natural and accidental consequences by appealing to *loci* which guarantee containment in contrast to those which do not, he takes basic logical distinction to be between what he calls material and formal consequences (*Sum. Log.* III.3.1).

All consequences must satisfy the inseparability requirement. Material consequences satisfy it merely in virtue of truth-values of the antecedent and consequent and so include all the paradoxical consequences. Formal consequences hold in virtue of there being a connection between antecedent and consequent guaranteed by a middle, another name for a *locus*. The middle, however, is required only to guarantee non-trivial inseparability.

There is thus no logical distinction between consequences for Ockham corresponding to that between natural and accidental consequences. It is replaced by an appeal to the epistemological notion of evidence but this does not partition the class of true consequences in the way the natural—accidental distinction does. Nor, more importantly, can it be used to argue for the formal distinction.

In an alternative classification of consequences Ockham invokes a distinction already made the thirteenth century to consequences which satisfy the Inseparability condition in virtue of the necessity of the present. He holds that if the conjunction *p and not:q* is now false but at some time will be true, the truth of the antecedent is now inseparable from that of the consequent and so *if p, then q* is a consequence *ut nunc* (as-of-now). If *p and not:q* is false at all times, past, present, and future, according to Ockham, *if p, then q* is a simple consequence (*Sum. Log.* III.3.1).

Ockham’s new theory of consequences seems to have very rapidly supplanted the old one and natural consequences are not mentioned in logic texts after the first quarter of the fourteenth century. Nor for that matter is impossible *positio*.

While Ockham's examples of the middles which provide the guarantee of formal consequence are all what we would classify as formal in that they hold for all uniform substitution instances of terms, his practice indicates that some middles hold only for limited classes of terms. This possibility is absent in later writers such as Buridan who explicitly defines formal consequence in terms of the uniform substitution of any terms satisfying the inseparability conditions.

By the middle of the fourteenth century the logic of consequences is thus fully formal in the modern sense and treatises on the subject contain many of the rules recognized in classical modal propositional logic.

### THE LOGIC OF MODALITY

While the *Prior Analytics* offered logicians nothing on categorical syllogisms not already available in Boethius what Aristotle had to say about modal forms was extremely problematic (Lagerlund 2000). The difficulty is that he accepts modal conversion principles such as accidental conversion: *if every A is necessarily a B, then some B is necessarily an A* but also claims that while *every B is necessarily C and every A is B; therefore every A is necessarily C* is valid *every B is a C and every A is necessarily B; therefore every A is necessarily C* is not. The conversion seems only to hold only if the modality is understood in the composite sense while the claim about the syllogisms requires the divided sense.

The first known medieval solution is found in the commentary on the *Prior Analytics* written Robert Kilwardby (1215–1279) in the 1240s (Thom 2003). Aristotle had designated as *per se* predications in which the subject contains the predicate and Kilwardby claims that modality may be uniformly construed in the divided sense if the conversion principles are restricted to those in which the antecedents are *per se* predications. Thus “every man is necessarily an animal” converts accidentally with “some animal is necessarily human” but “every literate (man) is necessarily a man” does not convert in this way with “every man is necessarily literate.” Kilwardby thus makes just the distinction between modal claims that was made between natural and accidental consequences.

Ockham in his *Summa logicae* explores the relationship between divided and composite readings on the basis of his claim that these do not differ in the case singular propositions (Normore 1999). He derives syllogisms for composite modals by applying to categorical syllogism the principles of modal inference, for example “if the premisses are all necessary, then so is the conclusion.” Ockham goes on to examine syllogisms formed

with divided modals and with mixtures of both divided and composite (*Sum. Log.* III.1.20–46). He holds that divided claims are equivocal. Thus in “every *A* is possibly *B*,” according to Ockham, the predicate is always amplified by the mode but the supposition of subject may be understood to be only for what are now actually *A* or as amplified for what can be *A*.

The most important development in syllogistics in the middle ages is in the work of Buridan. Buridan goes beyond Ockham in taking the theory of the syllogism to be simply an instance of the general theory of formal consequence (King 1985). He shows how the validity of the moods of the categorical syllogism can be proved from basic principles governing the semantics of general terms. The theory of modal syllogism with composite modality is, as with Ockham, quite straightforward. Buridan's treatment of divided modals is complex and of great interest since it reveals his attitude to the iteration of modalities and seems to commit him to the same principles as that of the modern system of strict implication known as S5.

Treatises on each of the subjects mentioned above continued to be produced through the fourteenth and fifteenth centuries by vast numbers of logicians. None of them, however, were of the stature of Abelard, Ockham, or Buridan, and originality in logic gave way at the end of the period to mere pedantry.

## INTERREGNUM (BETWEEN MEDIEVAL AND MODERN)

The interregnum between medieval scholastic logic and modern mathematical logic may be taken as having begun about the middle of the fifteenth century. There is no clear mark of division; the change was a shift away from the characteristic interests of the twelfth to the fifteenth century, with nothing of comparable importance arising to take their place. At the same time, certain less desirable trends in scholastic logic were perpetuated. The result is that formal logic was reduced almost entirely to a very imperfectly presented syllogistic. Medieval influences continued to operate in the early years of the sixteenth century, and medieval authors were still sometimes read in the seventeenth, but by the time that William of Ockham's *Summa Logicae* was printed at Oxford in 1675, no one had written creatively in the idiom of scholastic logic for many years.

The interregnum was characteristically sterile, a cause for despondency when one thinks of the large place logic continued to occupy in the educational curriculum and of the innumerable writers who put manuals of logic on the market. The tendency to publish at all costs was encouraged by the post-Reformation and post-Tridentine growth of universities, colleges, and seminaries.

### VALLA

The first author to consider is the humanist Lorenzo Valla (1407–1457), best remembered for his writing on the forged donation of Constantine. In his *Dialecticarum Libri Tres* (1441), Valla gave no definitions of syllogistic figures and moods, evidently assuming that the reader would know about these. His aim was to confine the syllogistic to the first two figures, without the five moods of

Theophrastus and Eudemus. To do this he would have had to reject subalternation, conversion, and *reductio ad absurdum*. About subalternation he was inconsistent; conversion he rejected as lacking brevity, ease, pleasantness, and utility; *reductio ad absurdum* he largely neglected. The five offending moods were called "Agrippine births," and of them all the most monstrous was "Frise-momorum, forsooth!"

Here we see the common humanist objection to the barbarity of scholastic terminology, but of course Valla was not objecting merely to comparatively recent Scholastics. His fullest invective was saved for the six moods of the third figure, which he thought insane and never found in use, unlike the first-figure and second-figure moods, which he accepted as dictated by nature to everyone, "even peasants, even women, even children." The standard means of reduction are but "remedies for sick syllogisms." The standing of the third figure would remain a point of dispute for a hundred years, until Ramus undercut Valla's argument by declaring that the figure was in obvious fact very commonly used (*Institutionum Dialecticarum Libri Tres*, Paris, 1554). Thus, Philipp Melanchthon (*Compendiaria Dialectices Ratio*, Basel, 1521) could not make up his mind on the subject.

### MELANCHTHON

In Melanchthon (1497–1560), a most influential writer, the rhetorical approach to logic already appeared at a high state of development, although he retained some Aristotelian doctrine. The rhetorical tradition, derived from Cicero and Quintilian, had a place, albeit a very subordinate one, in scholastic logic. We can see it beginning to predominate in the *Dialectica ad Petrum de Medicis* (edited by D. M. Inguanez and D. G. Muller, Monte Cassino, 1943; composed about 1457), by Joannes Argypoulos, who held that the detail of the theory of *suppositio*, which was the distinctive and most original scholastic contribution to logic, offered almost nothing to oratorical practice.

Thus, scholastic logic, which in its origins had borrowed considerably from grammar, began to yield to the third member of the trivium, rhetoric. Accordingly Melanchthon declared the fruit of dialectic to be the ability to speak with propriety and exactness on any theme, and he expounded the Ciceronian syllogism, with its five parts—*propositio*, *approbatio*, *assumptio*, *assumptionis approbatio*, and *complexio*—before the Aristotelian. (A century later a similar five-part syllogism, with proposition, reason, example, application, and conclusion, came into favor in the New Nyāya school of Indian logic.) In

general, Melanchthon said, the natural reasoning common to the learned, children, and ordinary people is to be preferred to the “rancid commentaries of dialecticians.” From this time on it was often felt desirable to include comparative lists of terminology, ancient and modern, as was done by a commentator on Rodolphus Agricola in 1538, by John Seton in 1572, and by John Sanderson in 1589.

## RAMUS

The syllogistic as a deductive system underwent considerable attrition in the rhetorical treatment of logic, but this cannot be ascribed exclusively to the new interests. John Dolz’s *Sillogismi* (Paris, 1511), a work of purely scholastic inspiration, methodically examines arguments in the different moods and figures as though they had nothing to do with one another. Dolz gave thirty-two sets of objections to Barbara before going on to Celarent “to avoid prolixity.” Although logic applied to itself was by no means unknown in Scholasticism, the idea of a closed logical system was little developed, and hence the piecemeal treatment so characteristic of the scholastic *sophismata* was easily extended to encroach on the systematic character of syllogistic. The fact that Aristotle began by presenting syllogisms in lists probably also contributed to this encroachment.

The process of fragmentation was given new impetus by Pierre de la Ramée (Peter Ramus, 1515–1572). This great master of Latin rhetorical style and innovator of educational theory developed a massive attack on the Aristotelian tradition in logic and an alternative corpus of logical material that quickly gave rise to a widespread Ramist scholasticism.

**ATTACK ON ARISTOTELIAN TRADITION.** Ramus’s *Animadversiones Aristotelicae* (Paris, 1556) tells in twenty books how Ramus turned from the clarity of Plato to the comparative chaos of Aristotle. Pretending to be analytical, Aristotle was almost completely deficient in that (Ramist) analysis that consists in systematic definition and division, and his doctrines are not supported by examples (are not, in fact, established by rhetorical syllogisms!). These are the standards Ramus applied as he worked through the *Prior Analytics* in his Book VII, firing off a broadside at every detail of Aristotelian or scholastic doctrine that occurred to him on the way. The typically rhetorical teaching that experience, observation, and usage are the proper guides in logic is prominent. Variables seldom make their appearance in this milieu, but Ramus’s express attack on abecedarian examples—which,

being examples of nothing, can be adapted to nothing—is remarkable.

**RAMIST LOGIC.** The *Dialecticae Libri Duo* (Paris, 1556) is divided between invention, or discovery, and judgment, a distinction derived immediately from Agrippa and mediately from Cicero and Boethius. This distinction had been recalled among Scholastics—for example, at the opening of Kilwardby’s popular thirteenth-century commentary on the *Prior Analytics*, often printed under the name of Giles of Rome. Like Descartes, whose methodological ideas supplanted his own, Ramus could not escape his antecedents. The first book covers topics, or loci; the second expounds the Ramist syllogistic, divided into the contracted syllogism (an enthymematic version of the Aristotelian third figure) and the explicated syllogism (comprising the second and first figures, in that order). There are no signs of quantification, all unquantified propositions that are not singular being deemed universal. A mood is general if it contains no singular term, special if it contains one, and proper if it contains two. Examples are taken from classical rhetoric and poetry; the propriety of such sources was vigorously attacked by a little-known anti-Ramist, Thomas Oliver of Bury, in his *De Sophismatum Praestigiis Cavendis* (Cambridge, U.K., 1604), on the ground that logic has very little place in poetry or forensic oratory.

This whole early version of an ordinary-language approach to logic was admirably countered by Gisbertus Isendoorn (*Cursus Systematicus*, Oxford, 1658). Writing directly against the famous Cambridge Ramist George Downname, Isendoorn said (p. 613): *Observa ... orationem et popularem discurrendi usum non esse mensuram et normam Logicae, sed rectam rationem et accuratam artem viamque concludendi* (Mark that popular speech and usage are not the standard and norm of logic, but right reason and an exact method of reaching conclusions).

## MANUALS OF LOGIC

With all the effort of the mid-sixteenth century to simplify logic, it is not surprising that vernacular manuals began to appear, although sparsely, at that time. In England there were Thomas Wilson’s *The Rule of Reason* (London, 1551), Ralph Lever’s *The Arte of Reason rightly termed Witcraft* (London, 1573), Abraham Fraunce’s *The Lawiers Logike* (London, 1588), and Thomas Blundevile’s *The Arte of Logicke* (London, 1599); in France there was Philippes Canaye’s treatise *L’organe* (Paris, 1589). Little further seems to have been published in English until John Newton’s *The English Academy* (London, 1677).

Wilson's pioneer effort is interesting chiefly for its novel terminology; for example, the major, minor, and middle terms are called the "terme at large," the "several terme," and the "double reapeate." Blundevile introduced an arithmetical syllogism and used a catechetical method. This method had been used by Matthias Flacius Illyricus in *Paralipomena Dialectices* (Basel, 1558; composed 1550), which gives a very detailed treatment of the venerable *pons asinorum*. Canaye's book was also devoted largely to the *pons asinorum*, being distinguished by the dissection of the traditional rectangular figure into two circular ones. The same subject had been dealt with in Christopher Corner's *Ratio Inveniendi Medium Terminum* (Basel, 1549), which set a new standard of scholarship by appending a Greek text of relevant chapters of Aristotle. Thus, Aristotelian subjects were being pursued, in somewhat new ways, at the same time that the widespread Ramist innovations were taking hold.

Something of the same development can be seen in commentaries on the *Prior Analytics*, from the sixteenth-century editions of Kilwardby, through the work of Lefèvre d'Étaples (Faber Stapulensis), with his emphasis on tabular presentation; that of Agostino Nifo (Niphus Suessanus), who professed to follow the Greek commentators but wrote a long treatise on conversion in the scholastic manner; Burana's urbane commentary, with lengthy appendixes by his teacher Bagolinus and an interesting prefatory glimpse of the logical curriculum in a north Italian university; Monlorius's commentary, relatively brief but careful; to that of Pacius, with its businesslike presentation, schemes, and figures, a work praised by Sir David Ross in his own commentary. Within this developing tradition of Aristotelian scholarship we may also put the *Apparatus Syllogistici Synopsis* of Joannes Albanus (Bologna, 1620), which elaborately examined the crescent-shaped and triangular diagrams that descended from Greek sources to the Aristotelians of the Renaissance.

In a field in which syllogistic occupied so large a place one must note widespread incompetence in the matter of classification by figure. This is, of course, a point settled by definition, as Lorenzo Maiolo (*Epiphylides in Dialecticis*, Venice, 1497) and John Wallis (*Institutio Logicae*, Oxford, 1687) saw. These two were exceptional, however. Franciscus Titelmans (*De Consideratione Dialectica Libri Sex*, Paris, 1544) found the distinction between major and minor premises a hard thing for youths; Richard Crakanthorp (*Logicae Libri Quinque*, London, 1622) omitted the fourth figure without rejecting it and found it hard to determine the number of

moods. The basic trouble was that the later medievals, following a lead given by Boethius, defined the major premise as the first stated, the major term as the extreme therein, and so on, whereas Philoponus had defined the major term as the predicate of the conclusion, the major premise as the premise containing the major term, and so on. Each of the schemes can be worked out consistently, but they give different classifications and are mutually incompatible. This was seldom understood; it was a common fault to speak of indirect conclusions in connection with Philoponian definitions or to define with Philoponus and then take, for example, Balnama as fourth figure, instead of first figure with transposed premises.

In the Oxford logicians one does not find twenty-four moods in four figures correctly worked out on a Philoponian basis until Henry Aldrich (*Artis Logicae Compendium*, Oxford, 1691; this first edition was anonymous). The principles of the matter remained so little understood that even Augustus De Morgan (*Formal Logic*, 1847) could say, "Consider the fourth and first figures as coincident and the arbitrary notion of arrangement by major and minor vanishes," and W. S. Jevons (*Elementary Lessons in Formal Logic*, 1876) described fourth-figure syllogisms as ill arranged and imperfect and unnatural in form. "Unnatural" as a description of fourth-figure syllogisms was first used by Averroes, and his opinion was reinforced by Giacomo Zabarella (1533–1589); both meant to make a point of genuine formal logic, but they used some phrases that permitted a psychological interpretation. Sir William Hamilton's treatment of the matter (*Lectures on Logic*, 1860, Vol. IV), with lists of authors for and against the fourth figure and indirect moods of the second and third, is useless without knowledge of these authors' definitions and therefore of what they were favoring or opposing. A writer of a very different style was John Hospinianus (1515–1575), who proceeded on a combinatory basis and found that by admitting singular and indefinite propositions to the syllogistic and by identifying certain moods, he could obtain thirty-six valid moods out of a possible 512.

Extremely influential on manuals of the eighteenth and nineteenth centuries was *Logique, ou l'art de penser* (1662; *The Port-Royal Logic*), by Antoine Arnauld and Pierre Nicole. Even Aldrich, who disliked its novel terminology and Cartesian standpoint, may well have been prompted by it to his strict deductive treatment, for he shows no acquaintance with any other likely influence. The authors' epistemological interests certainly contributed much to the psychologism that was soon to infect logic, but such headings as conception, judgment,

and reasoning were not new in promoting this tendency. Canaye had already spoken of syllogism as the third operation of the mind, which *leaves* the premises and *arrives* at the conclusion. Such terminology is symptomatic of a change that occurred in the mid-seventeenth century. The Port-Royal section on method—a most popular subject in this period—more explicitly opened the way to the discursive excesses that would soon masquerade as logic, culminating, perhaps, in Henry Kett's *Logic Made Easy, or A Short View of the Aristotelic System of Reasoning, and Its Application to Literature, Science, and the General Improvement of the Mind* (Oxford, 1809).

A book praised by Leibniz and rather above the average, although not completely out of the common rut, is the *Logica Hamburgensis* (Hamburg, 1638), by Joachim Jung, or Jungius. One notable feature of this book is the marking of the lines of a syllogistic demonstration by letters, which are then used as references for showing by what principles which line follows from which others. Such a rather exact method of proof was very exceptional in logic before modern times, but contemporaneously with Jung, Pierre Hérigone introduced a similar method in mathematics (*Cursus Mathematicus*, Paris, 1634–1637). Jung was thoroughly acquainted with the possible use of contraposition as a means of syllogistic proof but was no more successful in his discussion of the fourth figure than so many others had been. Under the medieval heading of consequences he noted the argument *a recto ad obliquum*, which can be found in Aristotle's *Topics* II, 8, 114a18.

Some considerations, usually brief, of such standard medieval subjects as consequences and supposition theory continued to appear—for instance, those of Chrysostom Javellus (*Compendium Logicae*, Lyons, 1580), Robert Sanderson (*Logicae Artis Compendium*, Oxford, 1618), and Henry Aldrich—but these were exceptions. Arnold Geulincx hoped to repopularize such treatises by his *Logica Fundamentis Suis a Quibus Hactenus Collapsa Fuerat Restituta* (Leiden, 1662). He was able to relate alternation, conjunction, and negation by means of their truth conditions according to the laws that are often called after De Morgan or William of Ockham but that go back, at least in part, to the *Synkategoremata* of Peter of Spain. These laws were also known to the mathematician Gerolamo Saccheri, whose *Logica Demonstrativa* (Turin, 1697) is outstandingly original in its high degree of organization, its reflections on the assumptions necessary to logic, and its use of indirect proof, in the pattern of the so-called *mirabilis consequentia*, to the effect that what follows from its own negation is true. Unfortunately the few signs

of revival and advance discernible at the close of the seventeenth century did not produce any general or permanent result, and even the work of Leibniz met with little response.

## PRECURSORS OF MODERN LOGIC

Modern logic, or the logic that is loosely called "mathematical," began in a serious and systematic way with Augustus De Morgan's *Formal Logic* and George Boole's *Mathematical Analysis of Logic*, both published in 1847.

But a number of earlier writers were already "modern" in spirit, and of these, four stand out especially sharply—Leibniz, Euler, Lambert, and Bolzano.

(A. N. P.)

## LEIBNIZ

Gottfried Wilhelm Leibniz (1646–1716) was distinguished in many fields, but in none more than in logic. There, however, his worth was not fully appreciated until the twentieth century. He early began to investigate Aristotelian syllogistic and never completely escaped from the syllogistic point of view. In 1666 he wrote a *Dissertatio de Arte Combinatoria*, a juvenile work that was not free of mistakes, as he later realized, but that showed a new, high sense of organization and a genuine feeling for formal logic, very rare at the time. In one part of this book Leibniz worked out for himself the calculations of Hospinianus (1560) relative to the possible and the valid moods of syllogism. He differed from Hospinianus in making singular propositions equivalent to universal ones, as did Wallis and Euler. He arrived at twenty-four strictly Aristotelian syllogisms, six in each of four figures, which he arranged in a neat tableau suggestive of certain deductive relationships. Leibniz's standard method of proof in this context was *reductio ad absurdum*, as suggested to him by his teacher Jakob Thomasius (1622–1684), author of *Erotemata Logica* (Leipzig, 1670), but he also recognized the need for conversion. He wrongly credited Ramus with a method actually known in the thirteenth century, the device of proving laws of conversion and subalternation by means of syllogism and the laws of identity “All *a* is *a*” and “Some *a* is *a*.”

Leibniz often returned to syllogistic and was periodically vexed by semantic considerations, namely whether to think of the matter in extension or in intension—whether in “All *a* is *b*” it is the *a*'s which are said to be contained in the *b*'s or the property *a* which contains the property *b*. Leibniz had something of a fixation on the intensional approach, although he often suspected that extension was more effective and logically satisfactory. One thing that pushed him in the direction of extensionality was a fondness for experimenting with spatial interpretations. Thus, we find several attempts at diagrammatic representation, some using ruled and dotted lines and some using circles. He found it impossible to carry through such interpretations when thinking in intension.

**THEORY OF COMBINATIONS.** The theory of combinations is highly relevant to logic. Chrysippus is reported to

have shown some interest in combinations, Kilwardby and others in the thirteenth century repeatedly made combinatory summaries of assertoric and modal syllogistic, and semantic interpretations of logical formulas in finite domains employ the theory. Besides the syllogistic computations described, Leibniz considered how many predicates can be truly asserted of a given subject or how many subjects set under a given predicate. Such problems need some preliminary arrangements, and Leibniz supposed that a composite concept is analyzable into a number of ultimate simples, just as an integer is uniquely decomposable into its prime factors. Correlating the simple concepts with prime numbers, we can say that a predicate is truly attributable to its subject if the product associated with the predicate divides that associated with the subject. The essentials of this idea have been used in modern times to obtain a decision procedure for syllogistic, and unique decomposition into primes plays an essential part in Gödel numbering.

**UNIVERSAL LANGUAGE.** The idea of decomposing concepts into “prime factors” suggested to Leibniz the possibility of following up the initial steps toward a universal language taken by John Wilkins (1668), Jean Joachim Becher (1661), George Dalgarno (1661), Athanasius Kircher (1663), and others. He wanted such a language not merely to be practically or commercially useful, as were many of the pioneer efforts, but to be logically constructed so as to have general scientific import. Leibniz later distinguished a universal language from a logical calculus and desired to base his language on a thorough analysis of the communicative function of the various parts of speech, tenses, suffixes, and so on (an anticipation of modern theories of syntactical categories), and at one point (*Analysis Linguarum*, 1678) he envisaged a basic Latin rather in the style of C. K. Ogden and I. A. Richards's basic English.

In saying that nouns express ideas and verbs express propositions Leibniz radically altered the Aristotelian basis of the distinction and gave, in germ, the concept of a propositional function. Such reflections led him to a reductionist program, with adverbs reduced to (derived from) adjectives and adjectives to nouns, and with the copula taken as the only fundamental verb. He recognized that particles, connectives, and prepositions are of especial importance to linguistic structure. In taking us out of the syllogistic area this theory recalls the medieval doctrine of syncategorematic terms and Thomas Aquinas's analysis of many prepositions, while it adumbrates the logic of truth-functional connectives and of relations. Leibniz knew that not all arguments are syllogistic, in this

matter acknowledging a debt to Jung, but the dominance of a syllogistic point of view in Leibniz's thought is shown by his curious distinction between syllogistic and "grammatical" consequences.

This part of Leibniz's thought constitutes a distinct chapter in the history of the relations between grammar and logic. Grammar had been influential in the constitution of scholastic logic, but in the interregnum it had yielded to the third member of the medieval trivium, rhetoric, as a dominant power. In the projects for a universal and rational language we see grammar reasserting itself. But Leibniz was not content to confine logic to the "trivial" arts.

**LOGICAL CALCULUS.** The idea that logic might be quadrivial, and notably mathematical, was not new with Leibniz. Leibniz considered Aristotle to have been, in his logic, the first to write mathematically outside mathematics (letter to Gabriel Wagner, 1596). Roger Bacon (thirteenth century)—who also wished to reduce the trivial art of grammar to the quadrivial one of music—stated in his *Opus Maius* that "all the predicaments depend on the knowledge of quantity, with which mathematics deals, and therefore the whole of logic depends on mathematics." It is in the light of this that one should read the statement in his *Communia Mathematica* that "the mere logician cannot accomplish anything worthwhile in logical matters" (*nihil dignum potest purus logicus in logicalibus pertractare*). William of Ockham had been of the opposite opinion, and in *De Sacramento Altaris* he described mathematicians as among those less skilled in logic. Ramón Lull had written a combinatorial work, *Ars Magna* (which captured Leibniz's imagination, though he soon came to understand its deficiencies), and Thomas Hobbes had elaborated suggestively, if ineffectively, on the theme "by ratiocination I mean computation" ("Computatio Sive Logica," in *De Corpore*).

There is little doubt, however, that Leibniz's ideas, which far outstripped in detail and understanding any earlier hints, were his own spontaneous creation. "While I was yet a boy with a knowledge only of common logic, and without instruction in mathematics, the thought came to me, I know not by what instinct, that an analysis of ideas could be devised, whence in some combinatory way truths could arise and be estimated as though by numbers" (*Elementa Rationis*). He was thereafter constantly occupied with such notions and attempted to contrive an alphabet of thought, or *characteristica universalis*, which would represent ideas in a logical way, not things in a pictorial way, and would be mechanical in operation,

unambiguous, and nonquantitative; this alphabet of thought would be a means of discovery, a support to intuition, and an aid in ending disputes.

Leibniz regarded his great invention of the infinitesimal calculus (1675) as emerging from such researches, and the calculus led him to reflect still more intently on the properties desirable in such a characteristic. Exactly what he meant by "mechanical" and "calculation" is still in question, and he no doubt underestimated the task he set himself, but the imaginative fervor with which he always wrote of it reveals, as we can now appreciate, a true prophetic instinct. He often used an image from mythology to summarize his intentions, saying that his method was to be a *filum Ariadnes*, a thread of Ariadne. Many authors had long envisaged logic as a Cretan maze in need of such a clue—and that this should be so in an age when logic was scarcely existent does them little credit—but from the pen of Leibniz the allusion was more than a literary elegance and condensed a program of "palpable demonstrations, like the calculations of arithmeticians or the diagrams of geometers." (For Leibnizian references to the *filum*, see Louis Couturat, *La Logique de Leibniz*, pp. 90–92, 124; for other authors, see Ivo Thomas, "Medieval Aftermath.")

**ENCYCLOPEDIA.** One may ask what the theory of combinations was meant to combine, what the logical calculus was meant to calculate with, or where the analyses presupposed by the unified language of science were to be found. Leibniz was not content to leave such analysis in the state of a general project. The enormous range of his knowledge and interests, which included unity in religion, international relations, cooperation among scientists and scholars, and jurisprudence, as well as the not unrelated ordering of thought, prompted his lasting interest in the construction of an encyclopedia. T. Zwinger's *Theatrum Vitae Humanae* (1565) and Johann Heinrich Alsted's *Encyclopaedia* (1608) provided Leibniz with a basis for early schematisms, and sketches and fragments from about 1668 to the end of his life show an unceasing interest in the plan, which he believed had failed of completion through his own distractions and the lack of younger assistants. Appeals to monarchs and to learned societies met with little response. The project was, of course, a gigantic one, impossible of immediate fulfillment, but it should not be supposed that Leibniz thought it could be perfected quickly. Rather, its elaboration was to proceed gradually, along with that of the universal language and a calculus of logic. In later drafts this calculus took an ever more prominent place.

STRUCTURE OF THE CALCULUS. The main stages (1679, 1686, 1690) of Leibniz's many experiments in logical algebra have often been expounded and commented on. Here only some laws which were constant features will be mentioned.

- (1)  $a$  is  $a$ ;
- (2) If  $a$  is  $b$  and  $b$  is  $c$ , then  $a$  is  $c$ .

Propositions of the form " $a$  is  $b$ " are intended as universal affirmatives, "All  $a$  is  $b$ ," which Leibniz normally thought of as meaning that the property  $a$  contains the property  $b$ . Sometimes he wrote " $a$  contains  $b$ " instead of " $a$  is  $b$ ." Accordingly, rule (1) is one of the syllogistic laws of identity which, as was said above, he used from the start in syllogistic demonstrations, and rule (2) is the Barbara syllogism. Today we know that by means of the calculus of quantifiers and some definitions all asserted laws of the syllogistic can be obtained from rules (1) and (2) alone. Leibniz lacked those aids, but he admitted negative terms that obey the laws

- (3)  $a$  is interchangeable with not-not- $a$ ;
- (4)  $a$  is  $b$  if and only if not- $b$  is not- $a$ .

Rule (4) is the law of contraposition familiar to the Scholastics and, for Leibniz, most recently given prominence by Jung. From rules (1) to (4), with some definitions and Leibniz's favorite method of *reductio ad absurdum*, the whole syllogistic can be obtained. Leibniz did not use exactly that method but adopted at one time a rather similar one based on a restatement of rule (1),  $a = aa$ , and rule (5), below. Identity has the substitutive property described below; " $a$  is  $b$ " is made equivalent to " $a = ab$ "; and "Some  $a$  is  $b$ " is written " $Sa = b$ ." Compound terms such as  $ab$  were thought of as signifying the addition of properties  $a$  and  $b$ . They obey the laws

- (5)  $ab$  is  $a$ ;
- (6)  $ab$  is  $b$ ;
- (7) If  $a$  is  $b$  and  $a$  is  $c$ , then  $a$  is  $bc$ .

It has been pointed out by Karl Popper that if rules (5) and (6) are made the premises of the mood *Darapti*, we have the conclusion "Some  $a$  is  $b$ ." This does not render the system inconsistent, but it does show that the system is already more extensive and more trivial than Leibniz presumably intended. From rules (1), (2), (5), (6), and (7) it is easy to deduce, as Leibniz did,

- (8) If  $a$  is  $bc$ , then  $a$  is  $b$ , and  $a$  is  $c$ , which is the converse of (7), and
- (9) If  $a$  is  $b$ , then  $ac$  is  $bc$  (using rules 2, 5, 6, and 7);

- (10) If  $a$  is  $b$  and  $c$  is  $d$ , then  $ac$  is  $bd$  (using rule 9 twice and then rule 2).

Rule (10), which was known to Abelard in the twelfth century, Leibniz called *praeclarum theorema*, a very notable theorem.

Identity of terms was introduced in various ways, but always so that it was equivalent to the conjunction of " $a$  is  $b$ " and " $b$  is  $a$ " and so that identical terms could be substituted for one another in all contexts of the calculus. The first definition in the *Non Inelegans Specimen Demonstrandi in Abstractis*, for instance, posits that  $a = b$  holds if and only if  $a$  and  $b$  can be substituted for each other without altering the truth of any statement. The "only if" part is commonly called the principle of the identity of indiscernibles; for its converse W. V. Quine has suggested "the indiscernibility of identicals." As a principle of general application it has given rise to much discussion, although it is normally accepted in logic. While it is commonly attributed to Leibniz, Aristotle presented it in essentials in the *Topics* (VII, 1, 152a31 ff.) and *De Sophisticis Elenchis* (Ch. 24, 179a37 ff.).

An algebraic calculus requires that substitution for variables be possible, and Leibniz explicitly recognized this, in what was certainly the clearest statement in logic of the principle up to his time. Some medievals—Albert the Great, for instance—had shown their understanding of the generality conferred by variables when they called them "transcendental terms." Three more laws important for the calculus were known to Leibniz, following from rules (1), (5), (6), and (7):

- (11)  $ab$  is  $ba$  (using 5, 6, and 7);
- (12)  $a$  is  $aa$  (using 5);
- (13)  $aa$  is  $a$  (using 1 and 7).

In the course of his experiments Leibniz came to see that particular propositions have existential import, whereas universals may not, and it was a puzzle to him what the existential import might be—factual existence or logical possibility—and whether it was built into his system or had to be further provided for. This problem had been raised by medieval logicians from the time of Abelard. One of Leibniz's solutions—that subalternation is invalid if the universal states a relation of concepts and the particular states a matter of fact but holds if we stay in one of those domains—is essentially that of Paul of Venice, who required the subjects of both propositions to have the same *suppositio*.

At a late stage Leibniz used the addition sign in place of, and with the sense of, multiplication; that is, he used  $a$

+  $b$  instead of  $ab$ . But he knew that such expressions could be interpreted as logical disjunctions, and there is also an early hint that the calculus could be interpreted propositionally, the antecedent of a conditional being said to contain the consequent. This hint may serve as a summary indication of Leibniz's position in the history of logic. Aristotle had used "antecedent" and "consequent" for "subject" and "predicate"; among medievals (such as Abelard and Kilwardby) it is often hard to tell whether the words were used of propositions or of terms; Leibniz offered a glimpse of the two domains as distinct but analogous. If his work had not gone long unpublished (we still have no complete edition), we might not have had to wait so long for the full light of Boolean day.

### EULER

The noted mathematician Leonhard Euler (1707–1783) is remembered in logic chiefly for his geometrical illustrations of syllogistic, "Euler's diagrams" or "Euler's circles." Similar devices were used by J. C. Sturm (1661), Leibniz (see Bocheński, *History of Formal Logic*, plate facing p. 260), Joachim Lange (1712), and Gottfried Ploucquet (1759), and in a very general way the idea of spatial illustration goes back at least to Juan Luis Vives, who used triangles to illustrate the Barbara syllogism ("De Censura Veri," in *Opera*, Basel, 1555). But because of Euler's fame as a mathematician and the popularity of his charming *Lettres à une princesse d'Allemagne* (the relevant letters are CII ff., dated 1761) such diagrams are traditionally named for him.

Euler used proper inclusion for the universal affirmative proposition, exclusion for the universal negative, and intersection for both the particulars. If his interpretation is followed systematically, it correctly decides the validity or invalidity of all three-term syllogisms with all terms distinct but fails for the laws of identity and con-

tradition and for degenerate syllogisms depending on them. Apparently nobody developed full syllogistic along these lines until J. D. Gergonne (1816), whose five relations give a complete system and can indeed be defined by three of them (see Ivo Thomas, "Eulerian Syllogistic," and references supplied there), but not by Euler's three. The extensional approach evidenced by Euler's interpretation of the universal affirmative was a healthy influence.

Euler also lent his authority to the doctrine that singular propositions are equivalent to universal ones (*Lettres*, CVII), a thesis propounded by John Wallis (from 1638; see Appendix to his *Institutio Logica*, Oxford, 1687). Bertrand Russell severely criticized this doctrine as confusing class membership with inclusion, but of course we can get an inclusive proposition equivalent to a membership proposition by taking the unit class of the singular subject.

### LAMBERT AND PLOUCQUET

Johann Heinrich Lambert (1728–1777), German physicist, mathematician, and astronomer, devoted a number of essays to the enterprise of making a calculus of logic, which he evidently thought of in connection with the tree of Porphyry. His standpoint is, as is usual with the early investigators, intensional. Let  $a$  and  $b$  be any concepts,  $a + b$  their combination into a compound concept, and  $ab$  their common part. The letters  $\gamma$  and  $\delta$  can be multiplied with conceptual variables, so that  $a\gamma$  and  $a\delta$  are read as "the genus of  $a$ " and "the difference of  $a$ ." The intended meaning suggests that  $\gamma$  and  $\delta$  are descriptive operators;

yet Lambert sometimes treated them as though they were placeholders for generic or differential concepts. At any rate Lambert, following an elementary intuition, posited  $a = a\gamma + a\delta = a(\gamma + \delta)$ . Wanting to descend the tree to subordinate species as well as to ascend to superordinate genera and differences, he used the notation  $a\gamma^{-1}$  or  $a/\gamma$ , which should mean “the genus under  $a$ .” Waiving the fact that a concept containing  $a$  may be an ultimate species, we reflect that although  $a\gamma$  is unique,  $a\gamma^{-1}$  may not be so. This accounts for the trouble that Lambert found in applying multiplication and division, for  $(a/\gamma)\gamma$ , “the genus of a species of  $a$ ,” is identical with  $a$  whereas  $(a\gamma)/\gamma$ , “a species of the genus of  $a$ ,” need not be  $a$  itself. Lambert used subtraction to obtain the removal of a concept. He did not account for the appearance of coefficients and, in general, did not question the logical appropriateness of the algebraic operations to which his basic intuitions gave rise. Boole met with similar difficulties but reflected on them.

In syllogistic Lambert started not from the Aristotelian relations but from the five that are now attributed to Gergonne. This is feasible, but Lambert failed to achieve a satisfactory notion for the mutual exclusion of two terms. His most promising innovation lay in his attention to the relative product, but he did not develop this in any practical way.

Lambert, like Leibniz, experimented with sets of ruled and dotted lines to illustrate the relationships of syllogistic terms, in part trying to correct the defect in Euler’s circles of not allowing for  $a = b$ . Some stages of his investigations were criticized by his correspondents G. J. von Holland (whose extensional standpoint was remarkable for the time) and Gottfried Ploucquet (1716–1790), both of whom were making their own efforts to evolve a logical calculus. Ploucquet, who was a teacher of Hegel, claimed independence of Euler in his use of closed figures—he used squares (1759)—and seems to have been the first to base his syllogistic on thoroughgoing quantification of the predicate. One of his notations, “ $A \succ B$ ” for “No  $A$  is  $B$ ,” strangely, enjoyed some popularity.

### BOLZANO

The most important logician of the first half of the nineteenth century was Bernard Bolzano (1781–1848). His views are closest to those of Leibniz, who preceded him by more than a century (Bolzano was sometimes called the Bohemian Leibniz). Although he quoted often and extensively from philosophers and logicians of his own generation and the preceding one, among them Kant, Salomon Maimon, Hegel, J. F. Fries, J. G. E. Maass, and K. L. Reinhold, he did this almost always in order to criticize them, and rightly so from our modern point of view, because orders of magnitude separate Bolzano as a logician from his contemporaries.

One may doubt whether he deserves to be called a forerunner of mathematical logic and modern semantics. His approach is in many respects rather crude and old-fashioned in comparison with those of George Boole and Gottlob Frege, one and two generations later, respectively. But many points first made by Bolzano look strikingly modern. Unfortunately most of these were either not noticed or not understood during his lifetime or were forgotten by later generations.

For Bolzano logic was mainly the theory of science. To investigate science he used a partly formalized language consisting of ordinary German extended by various types of constants and variables, as well as by certain technical terms which for the most part he was at great pains to define as carefully as possible.

The fundamental entities with which logic has to deal, according to Bolzano, are terms and the propositions they constitute. These abstract entities are carefully distinguished from the corresponding linguistic and mental entities. Because a single proposition can be expressed in an indefinite number of ways, Bolzano’s first aim was to normalize such linguistic expressions, to reduce all of them to canonical forms prior to their purely formal treatment.

Bolzano’s solution was highly idiosyncratic. Deviating radically from tradition, he claimed that all sentences (complex and compound sentences as well as simple ones) are reducible to the single form “ $A$  has  $b$ ,” where “ $A$ ” is the subject term, “ $b$ ” the predicate term, and “has” the copula. Although this reduction works reasonably well with such sentences as “John is hungry,” which can easily be rendered as “John has hunger,” it sounds less

convincing in the case of reducing “This is gold” to “This has goldness” (although Bolzano presented reasons why such words as “goldness” had not been created in natural languages) and still less so when “John is not hungry” is reduced to “John has lack-of-hunger.” The reduction of the compound sentence “Either  $P$  or  $Q$ ” to “The-term-One-of- $P$ -and- $Q$ -is-true has the-property-of-being-a-singular-term” or “The-term-One-of- $P$ -or- $Q$ -is-true has nonemptiness” (depending on whether the original expression “Either ... or ...” is interpreted from its context as denoting exclusive or inclusive disjunction) looks rather strange in its verbal formulation, although it looks much less strange in some appropriate symbolism. And reducing “Some  $A$  is  $B$ ” to “The-term-An- $A$ -which-is- $B$  has nonemptiness” may appear fantastic at first sight, although it looks much more familiar when symbolized as  $A \cap B \neq \emptyset$ . Nevertheless, Bolzano did not attempt to present a full set of rules for such conversions and relied instead on the reader’s willingness to believe in the existence of such reductions after being shown how to perform them on certain representative samples, including some rather recalcitrant cases.

This reduction played a small role in the further development of Bolzano’s work in logic. His major innovation was his introduction of the technique of variation into what amounts essentially to the logical semantics of language, even though the semantic approach, in its modern sense, was foreign to him. Starting with a proposition, true or false, he investigated its behavior with regard to truth and falsehood under substitution for any of its terms of all other fitting (that is, propositionhood-preserving) terms. (In modern terminology, he investigated all models of sentential forms.) When the number of such variants was finite he defined the degree of validity of a proposition with respect to one or more of its constituent terms as the ratio of the number of its true variants to the number of all variants. When this ratio is 1, the proposition is universally valid; when 0, universally contravalid; when greater than 0, consistent.

After extending these notions to propositional classes Bolzano was able to define an amazing number of interesting, and sometimes highly original, metalogical notions, including compatibility, dependency, exclusion, contradictoriness, contrariety, exclusiveness, and disjointness. By far the most important notion introduced in this way is that of derivability with respect to a given class of terms, defined as holding between two propositions  $P$  and  $Q$  if and only if  $Q$  is consistent and every model of  $Q$  is a model of  $P$  with respect to this class of terms; with respect to propositional classes it is defined similarly. This

definition differs only in the unfortunate consistency clause from Tarski’s definition, given in 1937, of what he called the consequence relation.

Kant had defined an “analytic” affirmative judgment as one in which the predicate concept was already contained in the subject concept. Rejecting this definition as clearly inadequate for explicating logical truth, Bolzano defined a proposition to be analytically true when universally valid with respect to at least one of its constituent terms, analytically false when universally contravalid, etc., and as analytic when either analytically true or analytically false. Bolzano was aware that this definition of analytical truth was too broad as an explication of logical truth, and he therefore went on to define a proposition as being logically analytic when (again in modern terminology) all its descriptive (extralogical) constituent terms occur in it vacuously, an anticipation of a well-known definition by W. V. Quine (1940).

Bolzano’s views of probability are also strikingly modern. To define the probability of the proposition  $M$  on the assumptions  $A, B, C, D, \dots$  (with respect to certain terms  $i, j, \dots$ ) he used the relative degree of validity of  $M$  with respect to  $A, B, C, D, \dots$ , which he defined as the ratio of the number of true variants of the set  $M, A, B, C, D, \dots$  to the number of true variants of the set  $A, B, C, D, \dots$ . This conception, tenable, of course, only when the numbers involved are finite, is an important refinement of Laplace’s well-known conception of probability, standard in Bolzano’s time, in that it elegantly sidesteps the problem of circularity involved in the notion of equipossibility.

## MODERN LOGIC

### THE BOOLEAN PERIOD

The eighteenth-century and early nineteenth-century logicians considered in the preceding section were all Continental Europeans, and those who were also philosophers, namely Leibniz and Bolzano, were representatives of Continental rationalism. The British empiricism of the same period produced no logicians. On the contrary, it was antilogical. The empiricists attacked formal logic—by which they meant the attenuated syllogistic to which much of the science had shrunk during the interregnum—as trivial and sometimes as circular. This antilogicism largely echoed John Locke, whose scornful treatment of logic in his *Essay concerning Human Understanding* had provoked one of Leibniz's minor defenses of it, in the *Nouveaux Essais*. In the early nineteenth century the common logic was rescued from oblivion by Richard Whately but was not enlarged by him. Its enlargement, however, came soon after and, despite the British antilogical tradition, was at first largely a British affair, spreading later to the United States (C. S. Peirce) and then to Germany (Ernst Schröder).

### Bibliography

Appraisals of Hamilton's logic are to be found in John Venn, *Symbolic Logic*; C. I. Lewis, *A Survey of Symbolic Logic*; Jørgen Jørgensen, *A Treatise of Formal Logic*, Vol. I; and A. N. Prior, *Formal Logic*. Hamilton's principles, if not his practice, have found a recent defender in P. T. Geach, *Reference and Generality* (Ithaca, NY: Cornell University Press, 1962); his quantification has been analyzed in some detail by Władysław Bednarowski, "Hamilton's Quantification of the Predicate," in *PAS* 56 (1956): 217–240. Except for *Formal Logic*, all the works by De Morgan cited in the section on him are reprinted in *On the Syllogism, and Other Logical Writings*, edited by Peter Heath (London: Routledge and K. Paul, 1966). The best modern accounts of De Morgan are to be found in Lewis, op. cit.; Jørgensen, op. cit.; and Prior, op. cit.

On Boole, see Lewis, op. cit.; Jørgensen, op. cit.; and William C. Kneale and Martha Kneale, *The Development of Logic*. The best earlier expositions are by P. E. B. Jourdain, in "The Development of the Theories of Mathematical Logic and the Principles of Mathematics"; Venn, op. cit.; and Alexander MacFarlane, in *Principles of the Algebra of Logic* (Edinburgh: Douglas, 1879). A. T. Shearman, *Development of Symbolic Logic*, is also useful.

Jørgensen, Lewis, and Jourdain all give some account of Jevons. For earlier criticism, see Shearman, above, and F. H. Bradley, *Principles of Logic* (London: K. Paul, Trench, 1883).

On Jevons's machine, see Wolfe Mays and D. P. Henry, "Jevons and Logic," in *Mind* 62 (1953): 484–505; and Martin Gardner, *Logic Machines and Diagrams*.

There are appraisals of Venn in the works by Jørgensen, Jourdain, and Shearman. On Venn diagrams, see Lewis, op. cit.; Prior, op. cit.; Gardner, op. cit.; J. N. Keynes, *Studies and Exercises in Formal Logic*, 4th ed. (London: Macmillan, 1906); and almost any elementary logic text.

In addition to his book, MacColl published a series of seven papers, "The Calculus of Equivalent Statements," in *Proceedings of the London Mathematical Society* (1877–1898); a series of eight papers, "Symbolic Reasoning," in *Mind* (1880–1906); and "The Existential Import of Propositions," in *Mind* 30 (1905): 401–402, 578–580. On MacColl, see Jourdain, op. cit.; Prior, op. cit.; and Bertrand Russell's review of MacColl's *Symbolic Logic and Its Applications*, in *Mind* 30 (1906): 255–260.

Most of Peirce's logical writings are to be found in Vols. II, III, and IV of his *Collected Papers*, edited by Charles Hartshorne, Paul Weiss, and Arthur W. Burks, 8 vols. (Cambridge, MA: Harvard University Press, 1931–1958), but there is a discussion of logical paradoxes in Vol. V, Book 2, Paper 3, and one of the history of logic in Vol. VII, Book 2, Ch. 3, Sec. 10. His most developed and comprehensive logical paper is "On the Algebra of Logic: A Contribution to the Philosophy of Notation," Vol. III, Paper 13. "The Critic of Arguments," Paper 14 in the same volume, is comparatively easy reading and has a purple patch on rhemes and demonstratives. Peirce's existential graphs, which he thought were his most important contribution to logic, are the subject of Vol. IV, Book 2. *The Collected Papers* do not include some of Peirce's contributions to the *Century Dictionary*, such as the very suggestive article "Syllogism."

(A. N. P.)

**HAMILTON.** The nineteenth-century revival of logic in Britain, inaugurated by Whately and continued by, among others, George Bentham, chrétien, and Solly, owed much of its later impetus to the cosmopolitan learning and reforming zeal of Sir William Hamilton (1788–1856). A severely critical article by Hamilton on Whately and his followers, in the *Edinburgh Review* (1833; reprinted in his *Discussions*, London and Edinburgh, 1852), established his authority in the field, which was chiefly exercised thereafter in oral teaching from his Edinburgh chair. His scattered and largely polemical writings, including even the posthumous *Lectures on Logic* (Edinburgh and London, 1861), give a very imperfect account of his system, which acquired such order as it possessed from the works of his pupils and disciples: William Thomson and H. L. Mansel at Oxford; T. S. Baynes, John Veitch, and William Spalding in Scotland; and Francis Bowen in America. Hamilton's main service was to insist, following Kant, on the formal nature of logic and to break with the prevailing European tradition by exhibiting its forms primarily as relations of extension

between classes. He also attempted to maintain a parallel logic of intension (or comprehension) for concepts, as the inverse of extension, but this approach, like others of its kind, was a predictable, if pardonable, failure.

Hamilton's most celebrated innovation, though it was far from being his invention, was the "thoroughgoing quantification of the predicate." By attaching the quantifiers "all" ("any") and "some" to the predicate, he obtained eight propositional forms, in place of the AEIO of tradition:

- (1) All *A* is all *B*.
- (2) All *A* is some *B*.
- (3) Some *A* is all *B*.
- (4) Some *A* is some *B*.
- (5) Any *A* is not any *B*.
- (6) Any *A* is not some *B*.
- (7) Some *A* is not any *B*.
- (8) Some *A* is not some *B*.

If "some" is read as "some only," these are all simply convertible and can thus be represented as the affirmations or denials of equations. The syllogisms made up of such propositions arrange themselves, tidily enough, into 108 valid moods, 12 positive and 24 negative, in each of 3 figures (Hamilton rejected the fourth). With this arrangement, a consolidated rule of inference, and a quasi-geometrical symbolism to depict it all, Hamilton claimed to have effected a major simplification—indeed, completion—of the Aristotelian scheme.

These hopes were not borne out in the sequel. His own vacillations in the use of "some" and neglect of the differences between "all" and "any" threw even professed Hamiltonians into confusion, and the status of his propositional forms (not to mention the validity of some of his syllogisms) was much disputed. The first, for example, has no contradictory in the set and appears (on the ordinary view of "some") to be a compound of (2) and (3). The two particular affirmatives, (3) and (4), found acceptance with some writers, such as Thomson and Spalding; but of the new negatives, (6) made few friends, and (8) none at all; since it is compatible with any of the others, it says so little as to be well-nigh vacuous. A more serious objection is that since forms (1) to (5) represent all the possible ways in which two classes can be related in extension (that is, the Gergonne relations), the last three must necessarily be ambiguous or redundant.

*P. L. Heath (1967)*

DE MORGAN. The above criticisms of Hamilton's system are primarily due to Augustus De Morgan (1806–1871), whom Hamilton, in 1846, had misguidedly accused of plagiarizing his quantification. In the famous and protracted controversy that ensued, De Morgan was led into a thorough dissection of the whole system, and subsequent critics, from Mill, Peirce, and Venn onward, have taken most of their ammunition from him.

Though greatly superior as to insight and technical ability, the logic of De Morgan has affinities with that of his rival in that it, too, lays stress on the autonomy of logic and on the extensional point of view. It equally shares Hamilton's interest in reforming and enlarging the traditional syllogistic, an enterprise now outdated, which has caused it to fall into unmerited neglect. Apart from his early *Formal Logic* (London, 1847; 2nd ed., Chicago, 1926), the bulk of De Morgan's logical writings are to be found in five memoirs (plus a sixth, still unpublished) contributed to the *Cambridge Philosophical Transactions* between 1846 and 1862. The *Syllabus of a Proposed System of Logic* (London, 1860) gives a cursory account of his scheme, as does his article "Logic" in the *English Cyclopaedia (Arts and Science Division)*, V, London, 1860, pp. 340–354).

The basis of common logic, for De Morgan, consists in relations of partial or total inclusion, or exclusion, among classes. Where information about a majority of class members is available or where, as in the "numerically definite" syllogism, precise numbers are given, it is possible, as he shows, to draw valid conclusions of a non-Aristotelian type. But these conditions are seldom realized. A more radical departure is the admission into ordinary propositions of negative terms and class names (symbolized by lower-case letters), such that a term *X* and its "contrary" *x* between them exhaust the "universe of discourse" (a useful device that has since been generally adopted). Assuming these classes to have at least notional members, it follows that two classes and their contraries can be related in eight possible ways:

- (1) All *X*'s are *Y*'s.
- (2) All *x*'s are *y*'s.
- (3) All *X*'s are *y*'s.
- (4) All *x*'s are *Y*'s.
- (5) Some *X*'s are *Y*'s.

- (6) Some  $x$ 's are  $y$ 's.
- (7) Some  $X$ 's are  $y$ 's.
- (8) Some  $x$ 's are  $Y$ 's.

These can be rewritten without negative symbols as:

- (1) All  $X$ 's are  $Y$ 's.
- (2) All  $Y$ 's are  $X$ 's.
- (3) No  $X$ 's are  $Y$ 's.
- (4) Everything is either  $X$  or  $Y$ .
- (5) Some  $X$ 's are  $Y$ 's.
- (6) Some things are neither  $X$ 's nor  $Y$ 's.
- (7) Some  $X$ 's are not  $Y$ 's.
- (8) Some  $Y$ 's are not  $X$ 's.

Of these the contradictory pairs are (1) and (7), (2) and (8), (3) and (5), and (4) and (6). Since the distribution of terms is given or implied throughout, these forms are simply convertible by reading them in reverse. "Contraversion" (or obversion) is obtained by altering the distribution of a term, replacing it by its contrary, and denying the result. "All  $X$ 's are  $Y$ 's" becomes successively "No  $X$ 's are  $y$ 's," "All  $y$ 's are  $x$ 's," and "Everything is either  $x$  or  $Y$ ." The procedure is the same for the other seven forms, making 32 possibilities in all.

De Morgan's rule of syllogism is either that both premises should be universal or, when only one is, that the middle term should have different quantities in each. Inference takes place by erasing the middle term and its quantities. Since, including the syllogisms of weakened conclusion, there are 4 basic patterns, and since 3 terms and their contraries can be paired off, in premises and conclusion, in 8 different ways, there are 32 valid syllogisms, of which half have two universal premises and 8 a universal conclusion.

To remedy the "terminal ambiguity" whereby the undistributed term in the universal "All  $X$ 's are  $Y$ 's" may refer indifferently to some or all of the  $Y$ 's, De Morgan investigated the complex propositions produced by combining pairs of elementary forms. It is in this connection that he gives the well-known rules for negation of conjunctions which have since received his name—though he did not, in fact, invent them.

In endeavoring to patch up Hamilton's quantified system De Morgan made further distinctions between "cumular" (collective) and "exemplar" (distributive) forms of predication; struggled, unavailingly, to bring the intensional interpretation of terms (as attributes) into

line with the extensional and to subsume both under a pure logic of terms (the "onymatic" system); and explored in passing such nontraditional forms of inference as the syllogisms of "undecided assertion" and "transposed quantity." More important is his recognition that the copula performs its function in inference, not as a sign of identity, but only through its role as a transitive and convertible relation.

De Morgan's generalization of the copula leads on, in his fourth Cambridge memoir, to a pioneer investigation of relations in general, which is the foundation of all subsequent work in the field. He there distinguishes a relation (say, "lover of") from its denial, its contrary, and its converse ("loved by"); proceeds to compound relations, or relative products (" $L$  of  $M$  of"), and to quantified versions of these (" $L$  of every  $M$ ," "of none but  $M$ 's," etc.); and discusses a variety of equivalences that hold between these different sorts of relations and the rules for their discovery and manipulation. The purpose of this, typically enough, was to exhibit the syllogism in its most general form, as a series of combinations of relations. Despite the ingenuity and resource with which he treated it, this devotion to the syllogism was something of a weakness in De Morgan's work. It tethered him too closely to tradition, so that it was not until others exploited them that his own most fruitful discoveries were seen for what they were.

*P. L. Heath (1967)*

**BOOLE.** George Boole (1815–1864) was the founder of modern mathematical logic. Nevertheless, few of his ideas are currently accepted in mainstream logic in the forms originally proposed by him. His learned and fertile mind conceived of several important hypotheses, the testing and modification of which changed the face of logic irrevocably. One of his most important hypotheses was that every proposition can be expressed using an algebraic equation suitably reinterpreted: that logic and algebra share a common uninterpreted formal language and thus also that they have similar problem types and similar methods.

The universal affirmative, or A proposition, "Every square is a rectangle" was expressed by  $x = xy$ , where  $x$  is the class of squares,  $y$  the class of rectangles, and  $xy$  the "Boolean or logical product" of  $x$  with  $y$ , the class of common members of  $x$  and  $y$ . The universal negative, or E proposition, "No rectangle is a circle" was expressed by  $yz = 0$ , where  $z$  is the class of circles and 0 is the empty

class—an idea Boole introduced into logic. The conclusion “No square is a circle,”  $xz = 0$ , which Aristotle and previous logicians deduced in one “intuitive” step, was derived by Boole using a chain of algebraic manipulations—illustrating another of his hypotheses, namely that on some level reasoning was mechanical or algorithmic.

He used 1 for the universe, or “universe of discourse,” a ubiquitous expression in modern logic that Boole coined. He used the minus sign for “logical subtraction”:  $1 - x$  is the class of objects in the universe that are not in the class  $x$ . Using the above symbols, expression of the particular affirmative, or I proposition, “Some rectangle is a square” and the particular negative, or O proposition, “Some rectangle is not a square” as *inequalities* would have been easy:  $yx \neq 0$  and  $y(1 - x) \neq 0$ . This is a point that Boole never mentioned and probably did not notice—Boole’s hypothesis was that algebraic *equations* were sufficient. Instead, he conceived of a logical operator, now called Boole’s vee, or the vee, which was to produce from a class  $x$  a resultant class  $vx$  supposed by him to be “indefinite in every respect except that it contains some individuals of the class [ $x$  in this case] to whose expression it is prefixed.” Using the vee, Boole “expressed” the above  $vy = vx$  and  $vy = v(1 - x)$ . The vee itself as well as the two “translations” have been criticized by later logicians—mainstream logic has not adopted Boole’s vee, although its similarity to other more recent nonstandard operators has been noted—for example, the Hilbert epsilon.

Using the algebraic formal language, Boole was able to express several “laws of thought” analogous to laws of algebra; indeed some were expressed by the same equations used for laws of algebra—for example, the commutative law  $xy = yx$ . He employed his laws of thought in two unprecedented ways. First, regarding the equations as conditions on “unknowns,” he created a wholly new theory of logical equation-solving using the laws of thought the way laws of algebra are used in numerical equation-solving. Second, regarding the most basic of his laws of thought as laws of logic, he created an axiomatization of logic. Boole realized that no “class logic” as such could treat the arguments now dealt with in truth-functional propositional logic. To meet this deficiency he proposed an ingenious reinterpretation of his system that, in his view, transformed it into something akin to propositional logic. In the process, he discovered key ideas now incorporated into modern truth-function logic, establishing himself as the first modern figure in any history of propositional logic. These are but three of Boole’s many revolutionary innovations.

John Corcoran (2005)

JEVONS. It was the aim of William Stanley Jevons (1835–1882), himself a pupil of De Morgan, to render Boole’s calculus more simple and “logical” by removing those of its features that he found “mysterious” and by reducing its operations to mechanical routine. He also professed, officially, to reject the extensional standpoint in favor of a “pure logic” of terms, or “qualities,” though the result in practice was still effectively a class or propositional logic, conceived rather in the manner of De Morgan’s “onymatic” system. These views are set forth in two pamphlets, *Pure Logic* (London and New York, 1864) and *The Substitution of Similars* (London, 1869; both reprinted in *Pure Logic and Other Minor Works*, London, 1890), and at greater length in *The Principles of Science* (2nd ed., London, 1887) and *Studies and Exercises in Deductive Logic* (London, 1884).

Jevons takes over the Boolean notations for conjunction and identity ( $AB, A = B$ ) and admits negative classes, which he symbolizes, like De Morgan, by a small  $a$ , but makes no use of 1, the universal class, and dismisses as uninterpretable both the operations of subtraction and division and the various ill-favored symbols— $(1 - x), x/y, 0/0, 1/0$ , etc.—that result from their use. In the case of disjunction (written + or, more generally,  $\vee$ ) Jevons follows the minority view of De Morgan and a few others in proposing to read it inclusively, so that  $A + B$  is permitted to have common members, and  $A + A = A$  (law of unity). The importance of this reform, almost universally accepted since, is that it abolishes the need for numerical coefficients, establishes the symmetry between conjunction and disjunction exhibited, for example, in De Morgan’s laws,  $\overline{AB} = a + b$  and  $\overline{A + B} = ab$ , and makes possible such other useful rules of simplification as the “law of absorption,”  $A + AB = A$ .

Jevons conceives of classes as groups of individuals, and of propositions about such classes, or about qualities, as equations asserting a complete or partial identity between them. Thus, “All  $A$  is  $B$ ” identifies all  $A$ ’s with those that are  $B$ —that is,  $A = AB$ —and the corresponding E-proposition is  $A = Ab$ . He symbolizes particular propositions, on occasion, by an arbitrary prefix, but pays little attention to them—or, indeed, to the problems of quantification in general. Inference consists merely of what he calls the “substitution of similars”—that is, the replacement of any term by another, stated in a premise to be identical to it. Thus,  $A = AB$  and  $B = BC$  yield, by substitution,  $A = ABC = AC$ , the conclusion.

Of more interest is the Jevonian method of indirect inference, based on what he calls the “logical alphabet.” This alphabet, which amounts to no more than a Boolean expansion of 1, is constructed by listing all the possible combinations of the terms *A*, *B*, *C*, etc., together with their negatives, thus:

<i>ABC</i>	<i>aBC</i>
<i>ABc</i>	<i>aBc</i>
<i>AbC</i>	<i>abC</i>
<i>Abc</i>	<i>abc</i>

Any given premise, say  $A = BC$ , on being combined with each line in turn will be found inconsistent with some—that is, will yield an expression equal to 0. These lines being struck out, the remainder give the conclusion, though it still remains to consider the “inverse problem” (which Jevons saw but did not solve) of expressing the results in a single concise formula. Particular propositions are somewhat troublesome to handle on this scheme, which actually works better for propositions than for classes. But with many terms the process soon becomes tedious in either case, and it was to remedy this that Jevons invented his “logical abacus” and “logical piano,” contrivances which operate mechanically on the same principle, namely the employment of the premises to eliminate inconsistent combinations from a matrix already set up on the machine. The development of the modern computer has revived interest in Jevons’s pioneer device and in his very able description of its workings. For the rest, Jevons’s “equational logic,” though famous in its day, is now remembered chiefly for the technical improvements on Boole’s procedure that it helped to bring into use.

*P. L. Heath (1967)*

VENN. The logic of John Venn (1834–1923), sketched briefly in the *Princeton Review* (1880) and more fully elaborated in his *Symbolic Logic* (London, 1881), shows a greater understanding of George Boole’s intentions and a better acquaintance with the historical background than had yet been displayed by anyone else. Though he did not suppose the new methods to have any great practical advantage over the old, he saw no reason, either, to suspect them of being anything more than a generalization of traditional practices, couched, for convenience, in a mathematical form. He therefore resisted the Jevonian simplifications and was at pains to bring out the logical significance of such operations as subtraction and division, though the latter is admitted to merit inclusion

more on grounds of consistency than for any use made of it in the reasoning of everyday life.

Venn’s own account of the matter proceeds from what he calls the “compartmental,” or “existential,” view of logic, whose purpose is to set out the possible ways in which the four classes designated by *x*, *y*, and their negatives, in combination, may have one or more of their components empty. Omitting the case where all four compartments are unoccupied, this yields fifteen forms of proposition, compared with the four that arise on the traditional, or predication, view, whereby an attribute is asserted or denied of a class, and the five that emerge from diagrammatic consideration of the ways in which two nonempty classes may include, exclude, or overlap one another. Each view has its merits, in Venn’s opinion, the choice between them being ultimately a conventional one.

This leads Venn to the discussion of another vexed issue, the “existential import” of propositions. Traditional logic must in consistency assume that its classes have members and nonmembers alike, and its universal propositions are thereby rendered hypothetical. To Venn it was clearer what the universal denies than what it asserts, and he therefore proposed to write *A*, “All *x* is *y*,” as  $x\bar{y} = 0$  and *E*, “No *x* is *y*,” as  $xy = 0$ . These propositions are definite, yet they do not require members in *x* or *y* to make them true, since they deny only the existence of members in the common class. Particular propositions do, however, imply the presence of members in each class, since they contradict the universals; they are therefore to be written *I*,  $xy \neq 0$ , and *O*,  $x\bar{y} \neq 0$ , respectively. This was an improvement on Boole’s use of indefinite symbols and has since been generally adopted, though one consequence of it (also noted by Hugh MacColl) is that subalternation ceases to be valid and that the “syllogisms of weakened conclusion” which depend on it have therefore to be rejected.

Venn was not much enamored of the syllogism, but he deserves the gratitude of all beginners in the subject for what is probably his best-known contribution to logic, the diagrams that bear his name. These are, in effect, graphical representations of the algebraic processes introduced by Boole and mechanically illustrated in Jevons’s alphabet: The partitioning of a universe in terms of the possible combinations of *x*, *y*, and so on, and the elimination of those subdivisions inconsistent with the premises given. For two terms a pair of intersecting circles (*x* and *y*) on a ground give the four compartments  $xy + x\bar{y} + \bar{x}y + \bar{x}\bar{y} = 1$  (Figure 1). Three interlaced circles (Figure 2) depict the eight combinations of Jevons’s table,

**FIGURE 1**

given earlier. The effect of a universal premise is to declare one or more compartments to be empty, shown by shading the area in question. A particular premise indicates that one or more compartments have occupants, shown by a cross (which may lie ambiguously on the boundary between two areas). The conclusion can then be read off, in various ways, by inspection. By the use of ellipses the same principle can be employed for up to five terms, but it then becomes unwieldy, especially in the “inverse problem” of formulating the outcome, so that one or another of the square diagrams devised by later authors is at that stage generally preferable. With suitable modifications the method can also be extended to the calculus of propositions. Though Venn did not carry this extension far, he was led by it to an early realization of the truth-functional character of the relation of material implication.

The merit of Venn’s work lies not in its original departures, which are few, but rather in the light it throws on the obscurities of Boole’s procedure and in its very careful and fair discussion of opposing views.

*P. L. Heath (1967)*

**CARROLL.** The contributions of Lewis Carroll (Charles L. Dodgson, 1832–1898) to logic consist of several pieces published between 1887 and 1899. *The Game of Logic* (London, 1887) is a book written for young people to teach them to reason logically by solving syllogisms using diagrams and colored counters. His diagrammatic method is a visual logic system that we know now to be sound and complete.

In *Symbolic Logic, Part I* (London, 1896) Carroll developed two formal methods to solve syllogisms and

**FIGURE 2**

sorites. The first is the Method of Underscoring that is dependent on his idiosyncratic algebraic notation that he called the Method of Subscripts. The second is his Method of Diagrams, which he extended to handle more than three terms (classes), but without providing examples. However, his diagrammatic system is an improvement over that of his contemporary, John Venn, because first, unlike Venn’s system, Carroll’s can handle existential statements. Second, as A. Macaula showed in 1995, diagrams for ten terms (sets) or more can be drawn more easily than Venn diagrams for a large number of sets. Finally, the diagrams are self-similar and can be generated by a linear iterative process. Carroll used his method to reduce the nineteen or more valid forms of inference codified by medieval Aristotelian logicians first to fifteen forms and then to just three formulas.

Carroll published two pieces in the journal *Mind*. The first, “A Logical Paradox” (N. S. vol. 3, 1894, 436–438) is an example of hypothetical propositions. W. W. Bartley III remarks in the second edition of his book, *Lewis Carroll’s Symbolic Logic* (1986, p. 505) that for about eighty years eminent logicians and philosophers failed to see this problem as little more than a routine exercise in Boolean algebra. Of the eleven questions Dodgson sent to *The Educational Times* (ten on mathematical topics) the substance of one, Question 14122, (February 1, 1899, vol. lii, p. 93) on his logical paradox, had appeared as a “Note” to his 1894 *Mind* article. H. MacColl and H. W. Curjel provided (different) solutions. The second piece in *Mind*, “What the Tortoise Said to Achilles” (N. S. vol. 4, 1895, 278–280) is a humorous example of an important problem about logical inference that Carroll was perhaps the

first to recognize: the rule allowing a conclusion to be drawn from a set of premises cannot itself be treated as an additional premise without generating an infinite regress.

We see in Bartley's 1986 publication of Carroll's lost book, *Symbolic Logic, Part II*, that Carroll introduced two additional methods of formal logic. The first, the method of barred premises, a direct approach to the solution of problems involving multilateral statements is an extension of his Method of Underscoring. The second and most important, the Method of Trees, a mechanical test of validity using a *reductio ad absurdum* argument, is the earliest modern use of a truth tree to reason in the logic of classes. It uses one inference rule (binary resolution) and a restriction strategy (set of support) to improve the efficiency of the construction. His tree method is a sound and complete formal logic system for sorites.

PEIRCE. The logical work of Charles Sanders Peirce (1839–1914) was an unusual blend of the traditional and the modern. His early paper "Memoranda concerning the Aristotelian Syllogism," read and distributed in 1866, adapted to the second and third syllogistic figures Kant's description of first-figure reasoning as the subsumption of a case under a rule, and in later papers he exhibited analogy and induction as probabilistic weakenings of the second and third figures thus conceived. In 1867, independently of Jevons, Peirce improved Boole's logical algebra by identifying logical addition with the inclusive rather than the exclusive sense of "either-or." In 1870, inspired by De Morgan's pioneer work on the logic of relations, he extended Boole's method of algebraic analogy to this discipline, noticed that there are three-termed as well as two-termed relations, and introduced the sign " $\leftarrow$ " for class inclusion, considered an analogue of the arithmetical " $\leq$ ."

In 1880, Peirce began to use the symbol " $\leftarrow$ " indifferently for class inclusion, implication, and the "therefore" of inference. It became one of his persistent themes that the distinction between terms, propositions, and inferences is of little logical importance. For him all propositions are, in the end, implications (this thesis is bound up with his pragmatic theory of meaning) and as such are simply inferences deprived of an element of assertiveness; terms, at least general terms, are propositions deprived of a subject. General terms are "rhemes," or, as we would now say, "open sentences," sentences with gaps where names might go. Such sentences with gaps are in a broad sense relative terms, the number of gaps indicating what Peirce called the "adinity" of the relation. Thus, " $\text{— loves —}$ " represents a "dyadic" relation,"— gives — to —" a "triadic" one, and so on. Extending this conception downward, Peirce described an ordinary predicative term, such as " $\text{— is a man,}$ " as representing a "monadic" relation and a complete sentence, with no gaps at all, as representing a "medadic" one.

As Frege did with his "concepts," Peirce compared his "rhemes" to unsaturated chemical radicals having various valencies. Unlike Frege, however, he did not subsume rhemes under functions, like "The square of —," as the special case in which the value of the function for a given argument is a truth-value. Frege's procedure underlined the resemblance between a completed proposition and a name; for Peirce a completed proposition was rather a special case of a predicate. Nevertheless, Peirce pioneered (in 1885) the use of truth-value calculations in establishing logical laws and also foreshadowed many-valued logic by suggesting that there might be an infinity of degrees of falsehood, with truth as the zero.

A gap in a rheme may be filled, in the simplest case, by what Peirce called an "index." He divided signs into indices, which operate through some physical connection with what they signify; icons, which operate through some resemblance to what they signify; and symbols, which acquire their meaning by convention. An ordinary proper name is an "icon of an index"; it is (when uttered) a noise that resembles the noise that was made when we were introduced to the person named. A simple index would be, for example, a demonstrative pronoun accompanied by a pointing gesture. Peirce regarded the phrase "demonstrative pronouns" as an inaccurate description—it would be more appropriate to call a noun a "pro-demonstrative." A common noun, for Peirce, is only an inseparable element in a rheme (for example, "man" in "is a man").

Instead of directly filling a gap in a rheme with an index, we may say either “I can find you an object such that it—” (“is a man,” “loves Susan,” etc.) or “Take anything you like and it —” (“is mortal if human,” etc.). These are the particular and universal quantifiers, which Peirce introduced into his logic—independently of Frege, but with some debt to his own student O. H. Mitchell—in 1883. He represented them with the mathematical symbols “ $\Sigma$ ” and “ $\prod$ ” for continued sums and products. If we write “ $a = 0$ ” for “ $a$  is false” and “ $a \rightarrow 0$ ” for “ $a$  is true,”  $\Sigma_i a_i$  or “For some individual  $i$ ,  $a_i$ ” will have for its value the sum of the values of the possible  $a_i$ ’s and therefore will be  $\rightarrow 0$  (that is, true) if and only if at least one of the  $a_i$ ’s is  $\rightarrow 0$ , whereas  $\prod_i a_i$  or “For any individual  $i$ ,  $a_i$ ” will have for its value the product of the values of the possible  $a_i$ ’s and therefore will be  $\rightarrow 0$  if and only if all of the  $a_i$ ’s are  $\rightarrow 0$ . Peirce was aware of the possibility of putting any quantified expression into what is now called prenex normal form, with all the quantifiers at the beginning. He also, in what he called second-intentional logic, quantified over variables other than those standing for indices.

Every implication, Peirce came to believe, has an implicit or explicit initial quantifier—that is, is of the form  $\prod_i (a_i \prec b_i)$ , “For any  $i$ , if  $a_i$ , then  $b_i$ .” The  $i$ ’s may be either ordinary individuals of which our  $a$  and  $b$  may be true, or instants at which they may be true, or possible states of affairs in which they may be true; for example, “If it rains it pours” may mean “For any instant  $i$ , if it rains at  $i$ , it pours at  $i$ ” or “For any possible state of affairs  $i$ , if it rains in  $i$ , it pours in  $i$ .” But in the latter case we may consider wider or narrower ranges of possibility, and if we limit ourselves to the actual state of affairs, the quantifier may be dropped.

Peirce made several attempts to define negation in terms of implication, and in 1885 he produced a set of axioms for the propositional calculus with implication accepted as an undefined operator and negation defined as the implication of a proposition from which anything at all would follow. This was the second set of axioms sufficient for the propositional calculus to be produced in the history of the subject (the first being Frege’s of 1879) and the first set to use the curious law  $((a \prec b) \prec a) \prec a$ , now called Peirce’s law. But Peirce experimented with other types of systems also, and in 1880 he anticipated H. M. Sheffer in showing that all truth-functions can be defined in terms of “Neither — nor —” and “Not both — and —.” The “not” within a proposition (as opposed to “It is not the case that —,” governing the whole), which forms the “negative propositions” of traditional logic, he regarded as expressing the relation of otherness, and he

worked out what properties of this relation are reflected in traditional logical laws. For example, the law of contraposition, “Every  $A$  is a  $B$ ” entails that whatever is not a  $B$  is not an  $A$ ,” follows from the mere fact that otherness is a relation, for whatever relative term  $R$  may be, if every  $A$  is a  $B$ , then whatever is an  $R$  (for instance, an other) of every  $B$  is an  $R$  of every  $A$ .

Peirce thought it desirable that logical formulas should reflect the structure of the facts or thoughts which they express and so be, in his sense, “icons”—that is, signs operating by resemblance to what they signify—and he sought constantly to develop symbolism that were genuinely “iconic.” In his later years he came to regard this as best achieved by a system of diagrams which he called “existential graphs.” Typically, he attempted to represent his graph for “If  $A$  then  $B$ ” as basic, but in fact his diagrams are most easily understood as starting from the representation of “and” by juxtaposition and of “not” by enclosure in a bracket or circle or square.  $(A(B))$ , which is his graph for “If  $A$  then  $B$ ,” reads off naturally as “Not both  $A$  and not  $B$ .” Rules of inference are represented as permissions to alter the graphs by insertions and erasures; for example:

(R1) We may insert or remove double enclosures at will, provided that there is no symbol caught between the two enclosures; for instance, we may pass from  $A$  to  $((A))$ , i.e., to “Not not  $A$ ,” and back, but not from  $(A(B))$  to  $AB$ .

(R2) Any symbol may be removed from an evenly enclosed graph (including a completely unenclosed one) or added to an oddly enclosed one; for instance, we may pass from  $AB$ , i.e., “ $A$  and  $B$ ,” to  $A$ , or from  $(A(BC))$  to  $(A(B))$ , i.e., from “If  $A$  then both  $B$  and  $C$ ” to “If  $A$  then  $B$ ,” or from  $(A)$  to  $(AB)$ , i.e., from “Not  $A$ ” to “Not both  $A$  and  $B$ .”

(R3) We may repeat a symbol across an enclosure immediately interior to the symbol’s own, and if a symbol is already thus repeated, we may remove it from the inner enclosure; for instance, we may pass from  $(A(B))$  to  $(A(AB))$ , i.e., from “If  $A$  then  $B$ ” to “If  $A$  then both  $A$  and  $B$ ,” or from  $A(AB)$  to  $A(B)$ , i.e., from “ $A$  and not both  $A$  and  $B$ ” to “ $A$  and not  $B$ .”

If a graph is such that these permissions will enable us to transform it into any graph at all, that graph is “absurd” and its negation a logical truth. For example,  $A(A)$ , “Both  $A$  and not  $A$ ,” leads by R2 to  $A((B)A)$ , where  $B$  is any graph you please, and this leads by R3 to  $A((B))$ , this by R2 to  $((B))$ , and this by R1 to  $B$ . Hence,  $(A(A))$ , “If  $A$  then  $A$ ,” is a logical truth. For clarity Peirce suggested drawing rectangular enclosures, with evenly enclosed

symbols written on the left and oddly enclosed ones on the right. For example, Figure 3 is a representation of  $(A(B(C)))$ , “If  $A$  then ( $B$  but not  $C$ ).” This arrangement makes it clear that Peirce was, in effect, setting up what are nowadays called “semantic tableaux,” in the manner of E. W. Beth.

Peirce also thought of logical truth as represented by the blank sheet on which his graphs were drawn and absurdity by an enclosure with nothing but the blank graph sheet inside it. Since by R2 we may inscribe anything whatever in such an otherwise blank enclosure, this enclosure would in fact represent an absurdity in the previous sense of a graph that can be transformed into any graph whatsoever. “If  $A$  then absurdity,” Peirce’s favorite definition of “Not  $A$ ,” would then be strictly “ $(A(( )))$ ” (“If  $A$  then  $B$ ” is “ $(A(B))$ ,” and here we put “ $( )$ ” for  $B$ ), but this assumes that in representing the absurd as “ $( )$ ” we already understand simple enclosure as negation, and in attempting to modify his symbolism in ways which would avoid this assumption Peirce was led into occasional unnecessary trouble.

Although Peirce was one of the inventors of bound variables, in his graphs for quantified formulas he explicitly dispensed with them in favor of what he called “lines of identity,” a device recently put to the same purpose, though informally, by W. V. Quine and Peter Geach. A monadic rheme may be written as “—  $A$ ” or “ $A$  —,” the single valency line being close enough to be thought of as part of the symbol, and on its own this symbol is read as “Something is  $A$ .” If “—  $B$ ” is added to this, the whole, “ $A$  — —  $B$ ,” of course, means “Something is  $A$  and something is  $B$ .” But if the valency lines are joined by a “line of identity,” to give us “ $A$  ———  $B$ ,” this means “Something is  $A$  and *that same thing* is  $B$ ,” or “Something is at once  $A$  and  $B$ .” In the common systems this identification of the subjects of which  $A$  and  $B$  are predicated is effected by attaching these predicates to the same bound variable, thus: “For some  $x$ ,  $x$  is  $A$  and  $x$  is  $B$ .” Again, “If anything is  $A$  then *that same thing* is  $B$ ” is distinguished in the common systems from the more indefinite “If anything is  $A$  then something is  $B$ ” by writing the former with a common bound variable, thus: “For any  $x$ , if  $x$  is  $A$  then  $x$  is  $B$ .” In Peirce’s graphs this is done by tightening “ $(— A (— B))$ ” to “ $(\overline{A(B)})$ ” or “ $(A \text{ — } B)$ .” To give some examples with dyadic rhemes, “Every  $A$  is an  $R$  of some  $B$ ” comes out as “ $(A \text{ — } R \text{ — } B)$ ”; “Some  $B$  is  $R$ ’d by every  $A$ ” as “ $(A \text{ — } R \text{ — } B)$ ”; and “Every  $A$  is an  $R$  of itself” as “ $(A \text{ — } \overline{R})$ ” or “ $(A \text{ — } \overline{R})$ .”

This “Beta part” of Peirce’s graphs, of course, contains special rules for the transformation of lines of iden-

**FIGURE 3**

tity. For example, the additions and erasures of terms permitted by R2 may be extended to terms attached to others by lines of identity; thus, we may pass from “ $A$  ———  $B$ ,” “Something is at once  $A$  and  $B$ ,” to the plain “—  $B$ ,” “Something is  $B$ .” Peirce said that the blank sheet—which is left here when “ $A$  —” with its line of identity is removed and which represents accepted truth when considered as a medad—represents an accepted existent when considered as a monad.

Since lines of identity may themselves be treated as dyadic rhemes and subjected to enclosure, the graphs cover identity theory and, therefore, the arithmetic of specific integers, as well as the theory of first-order quantification. For example, “There are at least two  $A$ ’s” will be “ $A \text{ — } (—) A$ ”—that is, “Something is an  $A$ , and something that *is not* that thing is also an  $A$ .” But the graphs do not readily lend themselves to the representation of higher-order quantifications, such as “Some qualities belong to everything and others to some things only,” although Peirce made some rather clumsy efforts in this direction. More successful, but only adumbrated in outline, was his extension of his method to modal logic by using separate sheets for different possible worlds. This procedure is very like that now adopted by S. A. Kripke) and also echoes medieval theories of “ampliation.”

There is probably no logical writer who has been more rich in original suggestions than Peirce, and his papers are a mine that has still to be fully worked. He was, at the same time, more aware than any of his contemporaries of the contributions made by their ancient and medieval predecessors. He held and persuasively supported a theory that Aristotle had anticipated (in a chapter of the *Prior Analytics* (now missing) later derivations of simple conversion from the laws of identity and syllogism, and he saw the significance of the Megarian controversy over the nature of implication and of the distinctions drawn by the Schoolmen in their theory of *consequentiae*.

Peirce's immediate circle in America included two logicians of some distinction: O. H. Mitchell, from whom Peirce derived the germ of his device of quantification, and Christine Ladd Franklin (1847–1930), who used eight “copulae” to construct De Morgan's eight categorical forms and exhibited syllogisms in different figures as derivable from “inconsistent triads,” or “antilogisms.” An antilogism states that a certain three propositions—for example, “Every  $Y$  is a  $Z$ ,” “Every  $X$  is a  $Y$ ,” and “Not every  $X$  is a  $Z$ ”—cannot all be true: hence (syllogism 1), the first and second jointly imply the denial of the third; also (syllogism 2), the first and third jointly imply the denial of the second; also (syllogism 3), the third and second jointly imply the denial of the first.

**THE HERITAGE OF KANT AND MILL.** The development of logic, at least of formal logic, in the nineteenth century was largely independent of the general development of philosophy during the same period. Of the logicians considered in the preceding section only C. S. Peirce and perhaps William Hamilton were of importance in branches of philosophy other than logic, and the persons who were of most importance in other branches of philosophy contributed nothing whatsoever to technical developments of the sort here described. These persons did not ignore logic altogether, however, nor did competent logicians entirely ignore them. It will be helpful, therefore, to break the chronological order at this point and to glance back at these philosophical developments and influences.

In the nineteenth century, as in the eighteenth, there were divergent Continental and British philosophical influences, but the Continental stream, stemming from Immanuel Kant (1724–1804), was now not so much rationalistic as idealistic, and in logic it was increasingly antiformal, antimathematical, and antitechnical. Kant himself could not be described as antiformal; he had a quite exalted view of the place of formal logic in philosophy. Unfortunately, however, he thought of formal logic not as a field for new developments but as the first science to have reached perfection—it had reached perfection, he said, with the work of Aristotle. Even Kant's “Aristotelianism” was of the sadly truncated variety that had been characteristic of the interregnum. Slightly systematizing what he took to be Aristotelian logic, he divided “judgments” according to their “quantity” into universal, par-

ticular, and singular; according to their quality into affirmative ( $X$  is  $Y$ ), negative ( $X$  is-not  $Y$ ) and infinite ( $X$  is not- $Y$ ); according to what he called “relation” into categorical, hypothetical (that is, conditional), and disjunctive; and according to modality into apodictic (asserting necessity or impossibility), assertoric, and problematic (asserting possibility). The division according to quality is particularly absurd; where would one put, for example, the forms “ $X$  is-not not- $Y$ ” and “Not- $X$  is  $Y$ ”? More influential was his subdivision of affirmative categoricals into “analytic,” in which the predicate concept is implicitly contained in the subject concept, and “synthetic,” in which it is not. “Body is extended,” for example, is analytic because what is meant by a body is precisely an extended substance.

The empiricism that had characterized British philosophy in the eighteenth century was still in evidence in the nineteenth in the work of John Stuart Mill (1806–1873), but Mill was not, as the eighteenth-century British empiricists had been, antilogical or antimathematical. He did not personally advance the young science of mathematical logic, but he was not hostile to it, and in the later nineteenth century it was possible for J. N. Keynes and W. E. Johnson to develop a logical style that was indebted almost equally to Mill and to the mathematicians.

Mill's own formal logic, like Kant's, was rather thin, and for details he referred his readers to Richard Whately; the greater part of his *System of Logic* (London, 1843) is devoted to what would now be called scientific method. Its first two books, however, contain well-developed theories about the meaning of various types of words and sentences and about the nature of syllogistic reasoning. It may be added here that the propositions corresponding to what Kant called analytic judgments were described by Mill as “merely verbal.”

In the later nineteenth century there was considerable crossing of geographical and philosophical boundaries. Christoph Sigwart (1830–1904), in Germany, was indebted to Mill as well as to Kant; Franz Brentano (1838–1917), in Austria, owed much to Mill and nothing at all to Kant. The antimathematical logical tradition of Kant and G. W. F. Hegel was carried further in England by F. H. Bradley and Bernard Bosanquet, just when logic as an exact science was being given in Germany a new impetus by Gottlob Frege.

A. N. Prior (1967)

KEYNES. John Neville Keynes (1852–1949) was for a large part of his long life registrar of the University of Cambridge. His first contribution to logic was an article in *Mind* in 1879, in which he defended formal logic as a substantial discipline distinguishable alike from the philosophical logic being pursued by the heirs of Kant and Hegel, from the “empirical” (largely inductive) logic developed by the heirs of J. S. Mill, and from the mathematical logic lately started on its career by Boole and De Morgan.

In 1884, Keynes’s view of the subject was exhibited in greater detail in the first edition of his *Studies and Exercises in Formal Logic*. This work dealt, in the traditional manner, successively with terms, judgments, and syllogisms, but it had a fourth part in which essentially Boolean material was presented as a logic of categorical propositions with conjunctive, disjunctive, and negative terms and conjunctive and disjunctive compounds of these propositions. Each chapter in the book consisted of a number of well-constructed exercises, sometimes with introductory remarks and often with lengthy comments. Part I, on terms, was much influenced by the treatment of names in Book I of Mill’s *System of Logic*. Part II was distinguished by a very judicious discussion, in Chapter 8, of the problems raised by Brentano and Venn about the existential import of categorical propositions.

In successive revisions and enlargements in 1887, 1894, and 1906 the chapters took on the more normal shape of extended discussions with exercises at the end.

Part IV (on compound and complex propositions) was transformed into a long appendix, and much new material was incorporated. W. E. Johnson, in the preface to his own logic, was able to refer to the final product as “Dr. Keynes’s classical work, in which the last word has been said on most of the fundamental problems of the subject.” To this result Johnson himself generously contributed; he and Keynes had frequent and regular discussions of logical problems, and many of the footnotes in Keynes’s third and fourth editions express his indebtedness to Johnson. For example, Keynes owed to Johnson the distinction between “conditional” and “true hypothetical” propositions that Russell later dealt with more precisely as one between formal and material implication.

Keynes’s literary style was of singular clarity and distinction, and he dealt urbanely but decisively with the many sophistries and confusions that were current, especially among logical writers of a broadly idealist stamp, such as Bosanquet and Bradley. At the same time, he paid attention, particularly in his final edition, to the broadly “intensional” considerations to which these writers were perhaps more sensitive than many whose standards of logical rigor were higher. He handled modal distinctions, for example, with the same neatness and skill which he brought to other topics, and he anticipated C. I. Lewis in drawing attention to what are now called the paradoxes of strict implication.

The development of Keynes’s thought from edition to edition, as he brought it to bear on one topic after another, is fascinating to examine. For instance in dealing with what Mill called the connotation and denotation of general names he distinguished even in the first edition between (1) the connotation proper—that is, the set of attributes that we select by convention as those that an object must have if we are to give the name to it—and (2) the totality of attributes possessed in common by all the attributes to which the name applies. In the second edition he suggested that for (2) we might use the Port-Royalists’s term “comprehension.” Thus, the connotation being selected by convention, objective facts determine the name’s denotation, that is, which objects have the attributes entitling them to the name, and further objective facts determine the comprehension, that is, which attributes beyond the connotation these objects have in common. But in the third edition Keynes noted that we might alternatively fix the application of a name by an “exemplification,” a selection not of attributes but of objects, with respect to which we decide that we will give a certain name to anything which possesses all the attrib-

utes that these objects have in common (making an exception, as Johnson reminded Keynes that we would have to do, of such attributes as that of having been selected for this purpose). When we proceed this way convention fixes the exemplification, and the facts determine the comprehension and then the denotation.

JOHNSON. Keynes's collaborator William Ernest Johnson (1858–1931) did not publish Part I of his own *Logic* until 1921 (Part II, 1922; Part III, 1924), although he had published a series of three articles titled “The Logical Calculus” in *Mind* in 1892 (17: 3–30, 235–250, 340–357) and two titled “The Analysis of Thinking” in *Mind* in 1918 (27: 1–21, 133–151). In the first series the variables in Boolean equations were explicitly given the propositional interpretation, the logical product (“ $x$  and  $y$ ”) being represented by juxtaposition and negation by a superimposed bar. The logical product and negation being taken as primitive, “If  $x$  then  $y$ ” is defined as “Not ( $x$  and not  $y$ )”—that is,  $\overline{xy}$ —the logical sum “ $x$  or  $y$ ” as “Not (not  $x$  and not  $y$ ),” and universal and particular quantification as continued logical multiplication and addition. “The Analysis of Thinking” is more philosophical and seems to reflect the influence of G. F. Stout's *Analytic Psychology*.

Johnson's *Logic* exhibits an attractive combination of the formal elegance of his 1892 articles with the philosophical penetration of those of 1918. In some ways—for example, in his extensive discussion of “problematic induction” (that is, scientific generalization)—he played Mill to Keynes's Whately. His book is now best known for its development of the distinction between “determinables” and “determinates,” in Part I, Chapter 11. A “determinable” is one of the broad bases of distinction that may be found in objects, such as color, shape, size. Under each of these fall more or less determinate characteristics, such as red, blue, and so on, under color (and scarlet, crimson, etc. as more determinate forms of red). Johnson used this distinction as the basis of many further developments. In Part II, Chapter 10, for example, Johnson discussed what he called “demonstrative induction,” in which a universal conclusion is deduced from a singular premise by the help of an “all-or-nothing” proposition. From “Either every  $S$  is  $P$  or every  $S$  is not  $P$ ” and

“This  $S$  is  $P$ ” we can infer “Every  $S$  is  $P$ .” A natural extension is the form of reasoning in which the major premise asserts that every  $S$  exhibits the same determinate form of the determinable  $P$  (for instance, every specimen of a given element has the same atomic number) and the minor that this  $S$  exhibits the determinate form  $p$  of this determinable; hence, every  $S$  is  $p$ . (Cf. Mill on “uniform uniformities” in his *System of Logic*, Book III, Ch. 4, Sec. 2.)

Johnson presented many critical asides concerning Russell's *Principles of Mathematics*, the most valuable being in Part II, Chapter 3, “Symbolism and Functions.”

## Bibliography

### WORKS ON JOHNSON

Acute and careful, as well as captious, criticism of Johnson is contained in H. W. B. Joseph's “What Does Mr. W. E. Johnson Mean by a Proposition?,” in *Mind* 36 (1927): 448–466, and 37 (1928): 21–39. Johnson's views are also discussed in A. N. Prior's “Determinables, Determinates and Determinants,” in *Mind* 58 (1949): 1–20, 178–194. There is a fine informative obituary of Johnson by C. D. Broad in *Ethics and the History of Philosophy* (London: Routledge, 1952).

## FROM FREGE TO GÖDEL

Twentieth-century logic, and even late nineteenth-century logic, cannot be properly understood without some acquaintance not only with earlier nineteenth-century logic but also with nineteenth-century mathematics. The final section of our survey therefore begins with a sketch of the influence of nineteenth-century mathematics on the major logical developments of both the Boolean and the more recent periods. This will be followed by discussions of particular logicians.

(A. N. P.)

NINETEENTH-CENTURY MATHEMATICS. Mathematics in the nineteenth century was characterized by reorganization in every field, effected both by generalization, which led to the viewing of areas once considered discrete as special instances of the same general case, and by the examination of foundations, either in terms of basic concepts or by an axiomatic approach. Apart, therefore, from any specific contributions that mathematicians made to modern logic, the atmosphere was highly favorable to an explicitly logical investigation both of mathematics in general and of its various branches, including, by the end of the century, mathematical logic itself. At the same time, the growth of abstract algebra encouraged the persistence of Leibniz's ideal of mathematizing deductive logic; his ideas, although most were unpublished, maintained a steady, if at first tenuous, foothold. Thus, the early mathematical logicians, having caught the idea of a new kind of algebra, tended to work on it as a specialized branch of mathematics. By the end of the nineteenth century it had become an instrument sufficiently perfected to be able to discard its traditional algebraic appearance, even to forget momentarily its self-concern, and to apply itself to the articulation of the increasingly well-organized mathematical material. Only in the twentieth century did it catch up to its own axiomatic origins and fruitfully rejoin its algebraic ones.

*Peacock*. As early as 1821, A. L. Cauchy (1789–1857), in his influential *Cours d'analyse* (Paris, 1821, introduction, p. ii), attacked the current use of algebraic reasonings in geometry because "they tend to make one

attribute an indefinite range to the algebraic formulas, while in reality most of these formulas hold uniquely under certain conditions, and for certain values of the quantities concerned.” This thought was adopted, in a more positive version, by George Peacock (1791–1858) in *A Treatise on Algebra* (2 vols., London, 1842–1845), elaborating a work of 1830. Instead of merely rejecting such illegitimate, or at any rate unjustified, extensions of the ranges of algebraic formulas, he distinguished between two kinds of algebra, arithmetical and symbolic.

Arithmetical algebra is the science which results from the use of symbols and signs to denote numbers and the operations to which they may be subjected; those numbers or their representatives, and the operations upon them, being used in the same sense and with the same limitations as in common arithmetic. [In symbolical algebra] the symbols which are used are perfectly general in their representation, and perfectly unlimited in their values; and the operations upon them, in whatever manner they are denoted, or by whatever name they are called, are universal in their application. (Vol. I, Ch. 1)

The relationship of the two is more fully explained in the introduction:

The generalizations of arithmetical algebra are generalizations of reasoning not of form. ... Symbolical algebra adopts the rules of arithmetical algebra, but removes altogether their restrictions. ... It is this adoption of the rules of the operations of arithmetical algebra as the rules for performing the operations which *bear the same names* in symbolical algebra, which secures the absolute identity of the results in the two sciences so far as they exist in common. ... This principle, in my former *Treatise on Algebra*, I denominated the “principle of the permanence of equivalent forms.”

Peacock expressed his conviction that the convention by which such permanence had been commonly assumed had both delayed the emergence of his symbolical algebra as a science in its own right and resulted in consequent confusion and false reasoning such as Cauchy had complained of. By contrast to arithmetical algebra, “the results of symbolical algebra, which are not common to arithmetical algebra, are generalizations of form, and not necessary consequences of the definitions” which introduce special conditions according as the variables denote lines, forces, periods of time, and so on.

*Boole.* It is not hard to see the influence of Peacock’s thoughts on George Boole. In the introduction to *The Mathematical Analysis of Logic* (1847), Boole wrote:

Those who are acquainted with the present state of the theory of symbolical algebra, are aware, that the validity of the process of analysis does not depend upon the interpretation of the symbols which are employed, but solely upon the laws of their combination. Every system of interpretation which does not affect the truth of the relation supposed, is equally admissible. ... That to the existing forms of analysis a quantitative interpretation is assigned, is the result of the circumstances by which those forms were determined, and is not to be construed into a universal condition of analysis. It is upon the foundation of this general principle, that I purpose to establish the calculus of logic, and that I claim for it a place among the acknowledged forms of mathematical analysis, regardless that in its object and in its instruments it must at present stand alone.

In this passage we see mathematical logic struggling to be born, aware of its parentage, but still uncertain, as it continued to be for some time, of its status. Boole himself interpreted his calculus in relation to both classes and propositions. Thus, “The symbol  $1 - x$  selects those cases in which the proposition  $X$  is false” (*The Mathematical Analysis of Logic*, “Of Hypotheticals”), and “Let us for simplicity of conception give to the symbol  $x$  the particular interpretation of *men*, then  $1 - x$  will represent the class of ‘not-men’” (*An Investigation of the Laws of Thought*, London, 1854, Ch. 3 in Prop. iv).

Peacock’s work drew increased attention to the formal properties of operations, and Boole regarded his subject from this point of view.

The laws we have established ... are sufficient for the base of a calculus. From the first of them it appears that the elective symbols are *distributive*, from the second that they are *commutative*; properties which they possess in common with symbols of *quantity*, and in virtue of which, all the processes of common algebra are applicable to the present system.” (*The Mathematical Analysis of Logic*, “First Principles”)

These terms actually antedate Peacock; they may have been introduced by F. J. Servois (see *Annales des mathématiques*, 5 [1814]: 93). “Associativity” has been ascribed

to Sir William Rowan Hamilton (see Hermann Hankel's *Theorie der complexen Zahlensysteme*, Leipzig, 1867).

**Gergonne.** The new trend in algebra was already evidenced by the “Essai de dialectique rationnelle” (in *Annales des mathématiques* 7 [1816–1817]: 189–228) of J. D. Gergonne (1771–1859). In this he wrote:

In the same way that an algebraic calculation can be carried out without one having the least idea about the meaning of the symbols on which one is operating, it is possible to follow a course of reasoning without any knowledge of the meaning of the terms in which it is expressed, or without adverting to it if one knows it.

Such a formalistic approach would have been more in order when fields of application were better charted, and Karl Weierstrass was still fighting for this point of view many years later. Gergonne later did important work on duality in geometry, which shows again his ability to distinguish structure from interpretation. He offered a new analysis of the fundamental ideas of syllogistic and used an inverted *C* for inclusion, now standardized as the hook, *C*.

**De Morgan.** Augustus De Morgan, a contemporary of Peacock and Boole, took a special interest in the organization of mathematics for didactic purposes. After *Elements of Arithmetic* (1830) he wrote *On the Study and Difficulties of Mathematics* (1831), *First Notions of Logic* (1839), which was designed to help beginning students of geometry, and *Formal Logic* (1847). In *Trigonometry and Double Algebra* he investigated symbolic calculuses. A remarkable text (“On the Syllogism, III”) shows De Morgan striking out element after element in the material proposition “Every man is animal” till he is left with  $X—Y$ , showing the “pure form of the judgment”; thus, he made a start on the extension of the mathematical notion of function, to which Boole, Peirce, and most notably Frege also contributed. De Morgan’s right parenthesis, as used in “ $X$ ” to mean “every  $X$ ,” yielding “ $X$ ” $Y$ —that is, every  $X$  is  $Y$ —is reminiscent of Gergonne’s inverted *C*, although Gergonne’s symbol means “is contained in” and operates on two terms rather than one.

**Grassmann.** One of the creators of a new form of algebra was H. G. Grassmann (1809–1877). Grassmann’s *Ausdehnungslehre* (Leipzig, 1844; rev. ed., 1862), fundamental to vector analysis, anticipated W. R. Hamilton’s work through its greater generality and influenced Alfred North Whitehead’s *A Treatise on Universal Algebra with Applications* (Cambridge, U.K., 1898). Giuseppe Peano’s *Calcolo geometrico* (Turin, 1888) was written “according

to the *Ausdehnungslehre* of H. Grassmann, preceded by the operations of deductive logic.”

**Non-Euclidean geometry.** In geometry the great breakthrough was the effective creation of non-Euclidean systems. The chief figures were János Bolyai (1802–1860), Nikolai Ivanovich Lobachevski (1793–1856), and Bernhard Riemann (1826–1866). Bolyai’s work on non-Euclidean geometry was titled *Appendix Scientiam Spatii Absolute Veram Exhibens; A Veritate aut Falsitate Axiomaticis XI Euclidei (A Priori Haud Unquam Decidenda) Independentem*. Written in 1823, it was published in 1833 at Maros-Vásárhely in the second volume of the *Tentamen* of his father, F. Bolyai. Lobachevski wrote *Geometrische Untersuchungen zur Theorie der Parallellinien* (Berlin, 1840), an elaboration of ideas first presented in a lecture delivered at Kazan in 1826. Riemann’s inaugural lecture *Ueber die Hypothesen, welche der Geometrie zu Grunde liegen* (1854) was published at Göttingen in 1867. Each seems to have done his work independently of the others, but behind all of them appears the great, although in this matter somewhat enigmatic, figure of Karl Friedrich Gauss (1777–1855), friend of Bolyai’s father and of Lobachevski’s teacher Bartels and teacher of Riemann. Gauss’s correspondence shows him long to have had ideas on the subject, and to him we owe the word *non-Euclidean* (in a letter to Taurinus, 1824).

Bolyai, as the title of his work indicates, simply dropped Euclid’s axiom of parallels; Lobachevski adopted its denial. Both required the infinity of the straight line. Riemann, approaching the matter from an analytic point of view, wished to determine the general conditions of spaces in which the measure of distance would remain everywhere constant and figures could move freely without deformation. He was thus led to consider spaces of constant curvature and more than three dimensions, with Euclidean space a special case. Riemann’s work was immediately taken up by Hermann von Helmholtz (1821–1894), in *Über die thatsächlichen Grundlagen der Geometrie* (1868–1869) and *Über die Thatsachen, die der Geometrie zu Grunde liegen* (1868), and was further refined by Sophus Lie (1842–1899). Lie was one of the principal developers of the theory of groups, which Felix Klein (1849–1925) applied to geometry in his *Erlanger Programm, Vergleichende Betrachtungen über neuere geometrische Forschungen* (Erlangen, 1872; translated by M. W. Haskell as “A Comparative Review of Recent Researches in Geometry,” in *Bulletin of the New York Mathematical Society* 2 [1892–1893]: 215–249).

**Independence.** Though Bertrand Russell (in 1897), Whitehead (in 1898), and David Hilbert (in 1899) all

wrote on geometry, and Hilbert's later foundational work (*Grundlagenforschung*) provided the basis for all subsequent investigations, these pioneers of mature mathematical logic failed to secure independence for their propositional axioms. This is remarkable after all the attention that had been devoted to the independence of Euclid's axiom of parallels. Frege, too, failed in this matter. Alessandro Padoa, in 1901, gave directives for establishing the independence of concepts within an axiom system—an idea that influenced Peano—but no general method for securing the independence of propositional axioms was attained until Jan Łukasiewicz (1925) and Paul Bernays (1926), independently, found the method of interpretation by matrices.

*Many-valued logics and proof theory.* Non-Euclidean geometries are often mentioned in discussions of the status of many-valued logics, but they appear to have had no direct influence. (Łukasiewicz was brought to the idea by Aristotle's *Peri Hermeneias*.) It is likely that the theory of groups (closed systems of operations)—which was already finding widespread application by the end of the nineteenth century—and the rise of different algebras did much to create the climate of thought in which proof theory, and in general the metalogical investigation of the properties of entire deductive systems, could be developed. Such investigation seems to be one of the most notable characteristics differentiating mathematical logic from the logic of any other period. Proof theory stems mainly from Hilbert.

*Schröder.* The early, algebraic period of mathematical logic ended with Ernst Schröder (1841–1902). After a paper on algorithms for solving equations (1870) and a textbook on arithmetic and algebra, Schröder devoted himself more and more to the algebra of logic, his two chief works being *Der Operationskreis des Logikkalküls* (Leipzig, 1877) and *Vorlesungen über die Algebra der Logik* (3 vols., Leipzig, 1890–1905). Much of his work was a tidying up of the past. He discarded Boole's subtraction and division, which were subject to too many restrictions to be satisfactory inverse operations; used (as had W. S. Jevons) the sign of addition in the sense of inclusive rather than exclusive alternation; and introduced at the beginning a sign for inclusion. In this last matter he independently duplicated Frege's abandonment of the algebraic form in *Begriffsschrift* (Halle, 1879), which later became standard with *Principia Mathematica* (3 vols. Cambridge, U.K., 1910–1913). But Schröder remained interested in the solution of equations; his results for the Boolean system were taken over by Whitehead in *A Treatise on Universal Algebra*. Like Peirce, Schröder noticed a

duality between logical multiplication and addition and similarly between the null and the universal classes. Duality in geometry had been brought to the fore by J. V. Poncelet (1822), enunciated with greater generality by Gergonne (1827), and skillfully exploited by Jakob Steiner (1830).

Schröder explicitly rejected those syllogisms that are invalid when the terms are null, Boole having merely passed them over. Besides using the method of  $1 - 0$  evaluation, which goes back to Boole, he developed a process of reduction to normal form. Schröder introduced two novelties. Unlike those of his contemporaries mentioned above, he was interested in independence, wishing particularly to have the distributive law independent of his other axioms, and he was thus brought to perhaps the first idea of a nondistributive lattice. He also had a clear view of the need for a theory of logical types:

By that process of arbitrary selection of classes of individuals of the manifold originally envisaged, there arises a new, much more extensive manifold, namely that of the domains or classes of the previous one. ... [It] is necessary from the start that among the elements given as individuals there should be no classes comprising as elements individuals of the same manifold. (*Vorlesungen*, Vol. I, p. 247)

This foreshadows Russell's vicious-circle principle.

Schröder worked on Peirce's algebra of dyadic relatives as an extension of Boole's algebra, but the result was unsatisfactory, and, indeed, by the time Peirce reviewed it Schröder had already abandoned the algebraic form (though not the name) in favor of what is essentially first-order functional calculus. The Schröder-Bernstein theorem, to the effect that if each of two classes is similar to a part of the other, then they are similar to each other, was proved by Schröder in 1896 and independently by Felix Bernstein in 1898.

*Peano.* Schröder deplored the lack of use for the logical tool he had developed and experimented with the application of his theory of relation to Dedekind's chains. Giuseppe Peano, primarily interested in the rigor of mathematical proof, applied Schröder's instrument to comprehensive mathematical material in successive volumes of his *Formulaire de mathématiques* (5 vols., Turin, 1892–1908). He prefaced the work with a section on mathematical logic (a phrase that he originated), distinguished class membership from inclusion, which Schröder had not done, and expressed all theorems as implications rather than as equations. He still did not iso-

late propositional logic as a deductive preliminary, but he stated a generalized form of *modus ponens*, to the effect that a true proposition could be suppressed when it occurred as an antecedent or as part of a conjunction of antecedents in a theorem.

Peano had already obtained his five axioms of arithmetic, which contain the principle of mathematical induction, by 1889, when he published *Arithmetices Principia Nova Methodo Exposita*. The year before, J. W. R. Dedekind had reached substantially the same result in *Was sind und was sollen die Zahlen?* (Brunswick, Germany, 1888) with the induction principle provable, however, owing to his having started further back in logic, with sets and projections, rather than with sets, number, and successor. Frege, as Dedekind did not know at that time, had gone still further in the same direction. The fact that Peano, even in 1908, did not refer to either Frege or Dedekind but explicitly left the possibility of defining “number” an open question may indicate that he continued to be interested in logic more as a means of attaining brevity and rigor, and an occasional new insight, than as material from which the basic arithmetical notions might be constructed.

**Cantor.** Peano did draw on the theory of sets of Georg Cantor (1845–1918), including Cantor’s proofs that the algebraic numbers can be put in one-to-one correspondence with the positive integers and that the real numbers cannot be so made to correspond (the “diagonal” proof). Cantor’s work had grown out of a reorganization of analysis parallel to that of algebra and geometry. He was influenced, of course, by the work of Cauchy, Riemann, and Hankel on functions of complex variables, but his principal predecessor was Karl Weierstrass (1815–1897), who was greatly interested in foundational matters, especially in regard to irrational numbers and points of condensation of infinite sets. Cantor became convinced that without extending the concept of number to actually infinite sets it would hardly be possible to make the least step forward without constraint. The arithmetic that he thus created was welcomed by Frege; its influence is widely apparent and was acknowledged in Russell’s *Principles of Mathematics* (Cambridge, U.K., 1903), which plotted the future progress of *Principia Mathematica*.

Ivo Thomas (1967)

FREGE. Modern logic began with the publication in 1879 of the *Begriffsschrift* of Gottlob Frege (1848–1925). In the *Begriffsschrift* we find for the first time a comprehensive treatment of the ideas of generality and existence, because sentence forms which were hitherto accommodated only by complicated ad hoc theories are here provided with an adequate symbolization by the device of quantification, rules for which are adjoined to the first complete formalization of the classical propositional calculus. The result closely approximates a modern formal axiomatic theory. It meets Frege’s aim of a codification of the logical principles used in mathematical reasoning, although the rules of inference (substitution and *modus ponens*) and the definition of other logical constants in terms of the primitives (negation, implication, the universal quantifier, and identity) are not explicitly formalized but are mentioned as obviously justified by reference to the intended interpretation. A proof of completeness was not to be had in Frege’s day, but he demonstrated the power of his system by deriving a large number of logical principles from his basic postulates and took an important step toward the formulation of arithmetical principles by showing, with the aid of second-order quantification, how the notion of serial order may be formalized.

After the *Begriffsschrift*, Frege’s next major work was *Die Grundlagen der Arithmetik* (Breslau, 1884), an analysis of the concept of cardinal number presented largely in nontechnical terms. It opens the way for Frege’s theories with a devastating criticism of the views of various writers on the nature of numbers and the laws of arithmetic. Difficulties encountered in the analyses of number find

explanation and resolution in the celebrated claim that a statement of number contains an assertion about a concept. To say, for instance, that there are three letters in the word *but* is not, on Frege's view, to attribute a property to the actual letters; it is to assign the number 3 to the concept "letter in the word 'but'." If we now say that two concepts  $F$  and  $G$  are numerically equivalent (*gleichzahlig*) if and only if there is a one-to-one correspondence between those things which fall under  $F$  and those which fall under  $G$ , we can define the number that belongs to a concept  $F$  as the extension of the concept "numerically equivalent to the concept  $F$ ."

In terms of this definition any two numerically equivalent concepts, such as "letter in the word 'but'" and "letter in the word 'big,'" can be seen to determine the same extension, and therefore the same number, and it remains only to specify concepts to which the individual numbers belong. In sketching this and subsequent developments Frege found that the notions used appear to allow of resolution into purely logical terms. He concluded that it is probable that arithmetic has an a priori, analytic status, a view that places him in opposition to Immanuel Kant, who held that propositions of arithmetic were synthetic a priori, and to J. S. Mill, who regarded them as inductive generalizations.

In papers published after the *Grundlagen*, Frege turned his attention to problems of a more general philosophical nature, and the development of his thought in this period led to a revised account of his logic, which is incorporated in his most ambitious work, *Die Grundgesetze der Arithmetik* (2 vols., Jena, Germany, 1893–1903), in which he extended and formalized the theory of number adumbrated in the *Grundlagen*. In the *Begriffsschrift* he had rejected the traditional subject-predicate distinction but had retained one predicate, "is a fact" (symbolized "⊢"), which indicated that the judgment which it prefaced was being asserted. In his essay "Über Sinn und Bedeutung" this view was abandoned on the ground that the addition of such a sign, conceived as a predicate, merely results in a reformulation of the same thought, a reformulation which in turn may or may not be asserted.

The logic of the *Grundgesetze* is based on Frege's theory of sense and reference, the interpretation of the symbolism of the *Begriffsschrift* being modified accordingly. The formal system of the *Begriffsschrift* is further changed by replacing certain of the axioms with transformation rules, but a more important innovation is the extension of the earlier symbols to cover classes. Corresponding to any well-defined function  $\Phi(\xi)$  is the range, or course of values (*Wertverlauf*), of that function, written  $\dot{\epsilon}\Phi(\epsilon)$ ,

which Frege introduced via an axiom stipulating that  $\dot{\epsilon}\Phi(\epsilon)$  is identical with  $\epsilon\psi(\epsilon)$  if and only if the two associated functions  $\Phi(\xi)$  and  $\psi(\xi)$  agree in the values which they take on for all possible arguments  $\xi$ . In particular, this axiom licenses the passage from a concept to its extension, the course-of-values notation providing a means of representing classes and foreshadowing Bertrand Russell's class-abstraction operator,  $\hat{z}(\phi z)$ . Another device that found a close analogue in Russell's logic is Frege's symbol  $\backslash\xi$ . If a course of values  $\xi$  has a unique member, then  $\backslash\xi$  is this member; otherwise  $\backslash\xi$  is the course of values  $\xi$  itself. In the first case  $\backslash\xi$  provides a translation of expressions of the form "the  $F$ " and so corresponds to Russell's description operator,  $(\iota x)(\phi x)$ ; the second case ensures that when  $\xi$  has no unique member,  $\backslash\xi$  is nevertheless well defined.

The preliminary development of logic and the theory of classes is followed by the main subject of the *Grundgesetze*, the theory of cardinal number, developed with respect to both finite and infinite cardinals. The theory of real numbers is begun in the second volume but the treatment is incomplete, and Frege was probably loath to advance further in this direction after learning, while the second volume was in the press, that the very beginnings of his theory harbored a contradiction. This contradiction, discovered by Russell, resulted from the axiom allowing the transition from concept to class, an axiom in which Frege had not had the fullest confidence. Russell's communication is discussed in an appendix to the second volume, where an emended version of the axiom is put forward. This emendation was not, in fact, satisfactory, and although Frege apparently did not know that a contradiction could still be derived, he eventually abandoned his belief that the program of the *Grundgesetze* could be carried out successfully and claimed that geometry, not logic, must provide a basis for number theory.

PEANO. Giuseppe Peano (1858–1932), professor of infinitesimal analysis at Turin and a prolific writer on a wide range of mathematical topics, contributed to the early development of both logicism and the formalism to which it is partly opposed. His first book, published under the name of a former teacher, Angelo Genocchi, was devoted to the calculus and featured a careful, systematic treatment of the subject that contrasted favorably with customary texts in rejecting loosely phrased defini-

tions and theorems and in substituting rigorous proof for appeals to intuition. Peano was particularly insistent that the acceptability of a mathematical proposition should depend not on its intuitive plausibility but on its derivability from stated premises and definitions, and he devised a remarkable illustration of the way in which what appears evident to intuition may nonetheless be contradicted by formally incontrovertible considerations. This is his well-known space-filling curve, introduced in 1890 in the paper “Sur une Courbe, qui remplit toute une aire plane” (*Mathematische Annalen* 36 [1890]: 157–160). About ten years earlier Camille Jordan had defined a curve as a continuous and single-valued image of the unit segment. This definition accords well enough with our intuitive conception of a curve, but Peano showed that a curve in conformity with this definition could in fact pass through every point in a square based on the unit segment and so would appear as a uniformly shaded surface if plotted on a graph.

Convinced that the development of mathematics must proceed independently of intuitive considerations, Peano embarked upon a program of refounding the various branches of mathematics. Not only geometry and analysis, where we are particularly inclined to make an appeal to what can be grasped pictorially, but even elementary number theory was to be purified of common-sense preconceptions. The entities of a mathematical theory (numbers, points, and so forth) would have to enter into the theory not as idealizations of objects given to intuition but as postulated or defined entities, having only those properties which are explicitly listed or which can be grounded on the initial definitions. To ensure the exclusion of misleading intuitive associations, Peano devised a new symbolic language in which to formalize definitions and other postulates. Principles of reasoning employed within mathematics, as well as conceptions forming the substance of mathematical theories, are transcribed into the new notation. It is at this point that mathematical logic enters into Peano’s work, and although he did not carry the development of his system very far, the basic ideas and notation were taken over by Whitehead and Russell as a starting point for the system of logic presented in great detail in *Principia Mathematica*.

Also important for subsequent developments was Peano’s presentation of arithmetic. It is based on a set of postulates known as the Peano axioms, although, as has been noted, Richard Dedekind had published them earlier. The axioms were intended to free the concept of

number from dependence on intuition. The essentials of Peano’s treatment are embodied in these five axioms:

- (1) 0 is a number.
- (2) The successor of any number is a number.
- (3) No two numbers have the same successor.
- (4) 0 is not the successor of any number.
- (5) Any class which contains 0 and which contains the successor of  $n$  whenever it contains  $n$  includes the class of numbers.

The Peano axioms are commonly taken as a basis for the arithmetic of the natural numbers, supplemented by recursive definitions of such arithmetical operations as addition, multiplication, and exponentiation. Peano himself made considerable use of recursive definition, an analogue, for definitions, of the axiom of mathematical induction given by (5), which allows us to calculate the value of a function  $f(n)$  step by step, given an explicit definition of  $f(0)$  along with a definition of  $f(n')$  in terms of  $f(n)$ —here “ $n$ ” means “the successor of  $n$ .” Thus, for addition Peano provided the two recursion equations  $a + 0 = a$  and  $a + n' = (a + n)'$ . Rewriting the second of these as  $a + (n + 1) = (a + n) + 1$ , we can see that we have here a particular case of the associative law for addition,  $x + (y + z) = (x + y) + z$ , which can in fact be derived from the recursion equations by means of axiom (5). Multiplication is defined in similar fashion by means of the equations  $a \cdot 0 = 0$  and  $a \cdot b' = a \cdot b + a$ , and once more familiar arithmetical laws can be extracted by means of induction.

With the assistance of a number of colleagues, including Cesare Burali-Forti, Peano succeeded in reformulating much of existing mathematical theory in accordance with his criteria of rigor and precision, the results of these investigations appearing in the journal *Rivista di Matematica* (later also *Revue de mathématiques* and *Revista de mathematica*) from 1891 to 1906 and in Peano’s *Formulaire de mathématiques* (5 vols., Turin 1892–1908). The detailed coverage of algebra, arithmetic, set theory, geometry, and other branches of mathematics argues convincingly for Peano’s approach, but it is questionable whether it vindicates a formalist philosophy of mathematics, since further metamathematical investigation, notably by Thoralf Skolem, has shown that if Peano’s axioms are embedded in an axiomatization of set theory, they do not serve to characterize the natural numbers to the exclusion of other progressions. At the same time, it should be noted that Peano was not himself concerned with advancing either a formalist or a logicist philosophy; his approach was determined by a desire for

technical improvements in the presentation of mathematics.

WHITEHEAD AND RUSSELL. In *The Principles of Mathematics*, published in 1903, Bertrand Russell (1872–1970) set out to establish the logicist view that “all pure mathematics deals exclusively with concepts definable in terms of a very small number of fundamental logical concepts, and that all its propositions are deducible from a very small number of logical principles” (2nd ed., p. xv) and also to explain “the fundamental concepts which mathematics accepts as indefinable” (*ibid.*). In the *Principles* this program is pursued with minimal recourse to symbolism, the systematic formal presentation being reserved for a proposed second volume. What in fact appeared as the sequel was the classic *Principia Mathematica* (3 vols., Cambridge, U.K., 1910–1913), written in collaboration with Alfred North Whitehead. The subject matter of *Principia Mathematica* considerably overlaps that covered by Frege in his *Grundgesetze der Arithmetik*, a work to which the authors acknowledge their chief debt on questions of logical analysis; in some respects, such as the demarcation between logical and metalogical theses, *Principia Mathematica* falls short of the standards of rigor observed in Frege’s masterpiece. The symbolism adopted in *Principia Mathematica* derives largely from Peano, and the development of arithmetic and the theory of series is based on the work of Cantor.

We shall concentrate on the most important feature distinguishing *Principia Mathematica* from Frege’s work, the attempt to avoid the contradictions which Russell found implicit in the fifth axiom of the *Grundgesetze*. This axiom licensed the transition from a concept to its extension and from an extension to the concept, a transition that appears to do no more than give formal expression to a platitude. For instance, the proposition “Stravinsky is a member of the class of composers” appears to be no more than a circumlocution for “Stravinsky is a composer.” In general, it would seem reasonable to lay down as a law that  $x$  is a member of the class of  $\phi$ ’s if and only if  $x$  is  $\phi$ —in Russellian notation,  $x \in \bar{z}(\phi z) \equiv \phi x$ . But despite its platitudinous appearance, this principle turns out to harbor a contradiction, since corresponding to the concept “is not a member of itself” we have the class of all such things—that is, the class of all classes which are not members of themselves—and if we

now ask whether this class is or is not a member of itself, we find that either way a contradiction arises: If it is a member of itself, then it satisfies the defining condition of such members, so it is not a member of itself, and if it is not a member of itself, it belongs to the class of such classes and so is a member of itself.

This contradiction was noted by Russell in 1901, and in subsequent years finding ways to avoid it formed one of his major concerns. His final analysis, incorporated into *Principia Mathematica*, attributed the contradiction, along with a number of analogous paradoxes, to a mode of reasoning involving a vicious circle, a circle that arises when we postulate a collection of objects containing members definable only by means of the collection as a whole. Russell regarded such collections as illegitimate totalities, to be avoided by observing his “vicious-circle” principle, “Whatever involves *all* of a collection must not be one of the collection.” Appealing to this principle, Russell claimed that the values of a function cannot contain terms definable only by means of the function, and in place of an indiscriminate application of functions to arbitrary arguments he defined an ascending hierarchy of types, beginning with individuals and progressing through functions of individuals, functions of functions of individuals, and so forth, the only arguments which a function can significantly take being those of the immediately preceding type. In particular, a class cannot significantly be taken as an argument to its defining function, and the derivation of Russell’s paradox is accordingly obstructed by ruling out both “ $x \in x$ ” and its negation as ill-formed.

Apart from enabling us to block the derivation of paradoxes, Russell claimed, the theory of types based on the vicious-circle principle has a certain consonance with common sense. However, the principle itself (in the various nonequivalent forms given by Russell) can be challenged on the ground that it rules out circular procedures which are in no way vicious.

If the vicious-circle principle is rejected, it is natural to regard Russell’s paradox as no more than a straightforward contradiction, the absurdities resulting from the abstraction schema  $(\exists x)(y)(y \in x \equiv \phi(y))$  being no different in kind and requiring no different an explanation from those yielded by  $(\exists x)(y)(Fyx \equiv \phi(y))$ , where the membership relation is replaced by an arbitrary dyadic predicate. On this view the problem of finding consistent instances of the abstraction schema reduces to the analogous problem for the uninterpreted version, but although such an approach has its merits, it loses sight of an important feature of the system which the vicious-circle

principle shapes via the theory of types. That is, the form of theory which the principle determines conforms to a natural conception of classes according to which they are, or at least could be, generated by a step-by-step procedure, the superstructure of classes of classes of classes, and so on, resting ultimately on the initial elements of lowest type. On the other hand, although it is natural to conceive of a domain of classes as initially secured by such a procedure, it would seem equally natural to relax this constructivist approach to the extent of allowing the specification of particular classes in the domain to proceed by characterizations in terms of the given totality, provided only that the consequent reflexivity does not embody a contradiction.

POST. Besides provoking reactions in the form of rival philosophies of mathematics, the work of Whitehead and Russell stimulated new technical developments. For example, although Whitehead and Russell made free use, in *Principia Mathematica*, of the notions of truth-value and truth-function, they failed to incorporate these notions into a systematic technique for evaluating formulas of the propositional calculus. Such a technique, the method of truth tables, was presented by Emil Post (1897–1954) in his dissertation of 1920, published as “Introduction to a General Theory of Elementary Propositions” in the *American Journal of Mathematics* (43: 163–185) in 1921, the year in which Wittgenstein independently presented the same method in his *Tractatus Logico-Philosophicus*. The method dates back, in fact, to Peirce, but Post considered truth tables in their application not only to classical logic but also to systems in which any number of values are allowed, the primitive connectives of *Principia Mathematica*, “ $\sim$ ” and “ $\vee$ ,” having in these systems the generalized analogues “ $\sim_m$ ” and “ $\vee_m$ ,” where  $\sim_m P$  takes the values  $t_2, t_3, \dots, t_m, t_1$  as  $P$  takes the values  $t_1, t_2, \dots, t_m$ , and  $P \vee_m Q$  takes that of the two values assigned to  $P$  and  $Q$  which bears the lesser subscript. Classical two-valued logic is accordingly a particular case of the many-valued logics so constructed. Post provided definitions of consistency and completeness, and for the first time a formulation of the propositional calculus was proved to have these properties, the method of truth tables providing a basis for the proofs.

In his 1920 dissertation Post showed how both truth tables for classical logic and associated postulate sets may

be generalized. These postulate sets were treated as uninterpreted formal systems, an approach which Post maintained and extended in the direction of even greater generality in later works, where the derivation of theorems from axioms is represented as the production of strings—that is, finite sequences of symbols—from certain other strings of specified form. Most mathematical theories can be transcribed into the canonical forms admitted by Post, and he was able to show that the rules of any theory so expressed can be reduced to productions of a particularly simple type, a reduction that greatly simplifies investigations into the syntax of formal systems.

This approach leads directly to a formulation of recursive enumerability (a set is recursively enumerable if its members can be generated as the values of an effectively calculable function) and thence to one of recursiveness (a set is recursive if both it and its complement are recursively enumerable); Post provided illuminating proofs of results concerning decidability and related topics and introduced and developed a number of important concepts in this field. In 1947 he showed the recursive unsolvability of the word problem for semigroups. That is, he proved that it is impossible to determine whether or not two arbitrarily given strings are equivalent (where  $A$  and  $B$  are equivalent if  $B$  can be obtained from  $A$  by starting with  $A$  and applying a finite sequence of specified operations prescribing the production of one string from another). This result, published independently and in the same year by A. A. Markov, is an interesting example of the resolution, by techniques of mathematical logic, of an outstanding problem in the field of mathematics proper.

RAMSEY. Frank Plumpton Ramsey (1903–1930), a brilliant Cambridge philosopher and logician, attempted to give a satisfactory account of the foundations of mathematics in accordance with the method of Frege, Russell, and Whitehead, defending their view that mathematics is logic while proposing revisions in the system of *Principia Mathematica* suggested by the work of Wittgenstein.

According to Russell, pure mathematics consists of “the class of all propositions of the form ‘ $p$  implies  $q$ ’ where  $p$  and  $q$  are propositions containing one or more variables, the same in the two propositions, and neither  $p$  nor  $q$  contains any constants except logical constants” (*The Principles of Mathematics*, p. 3). Ramsey agreed with this definition insofar as it characterizes the generality

that is a feature of pure mathematics, but he claimed that it takes no account of an equally important mark of mathematics, its tautological character. The term *tautological* in the relevant sense derives from Wittgenstein, who applied it to formulas of the propositional calculus which come out true no matter what combinations of the values *true* and *false* are assigned to the component propositions. Ramsey extended the term to apply to valid formulas of the predicate calculus. Thus, the formula “ $(x) . \phi x : \supset : \phi a$ ” is tautological, since “ $\phi a$ ” expresses one of the possibilities which go to make up the possibly infinite conjunction abbreviated by “ $(x) . \phi x$ .”

Admittedly we cannot write down the fully expanded versions of quantified formulas, but this inability does not affect the tautological character of truths formulated in the compressed notation. Similarly, Ramsey maintained, the inability of human beings to list the members of an infinite class is no bar to our conceiving of classes whose members could be indicated only in this way and not via the specification of a defining predicate. Indeed, the possibility of such indefinable classes is an essential part of the extensional attitude of modern mathematics, and Ramsey regarded the neglect of this possibility in *Principia Mathematica* as one of the work’s three major defects. Thus, as interpreted in the system of *Principia Mathematica* the multiplicative axiom (axiom of choice) is logically doubtful, but on an extensional view of classes it is, according to Ramsey, an evident tautology.

The second major defect that Ramsey found in *Principia Mathematica* concerns Russell’s attempt to overcome the paradoxes, in particular his postulation of the axiom of reducibility. Ramsey accepted the simple theory of types as an unquestionably correct measure for avoiding the logical contradictions, such as Russell’s paradox and the Burali-Forti paradox, but he claimed that the contradictions that the hierarchy of orders had been introduced to avoid are of no concern either to logic or to mathematics. These contradictions—for instance, the Richard paradox and Weyl’s contradiction concerning the word *heterological*—cannot be stated in logical terms alone but contain some further reference to thought, language, or symbolism. Rejecting Russell’s conception of orders, Ramsey put forward a less restrictive theory based on his extensional view of propositional functions. Just as “ $(x) . \phi x$ ” represents an infinite conjunction of atomic propositions “ $\phi a . \phi b . . .$ ” so “ $(\phi)\phi a$ ” expands to “ $\phi_1 a . \phi_2 a . . .$ ” and similarly with disjunctions replacing conjunctions for existential quantifiers. Accordingly, if we start with truth-functions of atomic formulas, then no matter how often or in what respect we generalize upon

them, we shall never pass to propositions significantly different from these elementary truth-functions; the only difference will lie in the notation introduced with the quantifiers. There is consequently no need for the axiom of reducibility—which, Ramsey claimed, could anyhow be false—and although the resultant theory countenances definitions of propositions in terms of totalities to which they belong, such definitions are in Ramsey’s eyes no more vicious than an identification of a man as the tallest in a group of which he is a member.

The third great defect in *Principia Mathematica* which Ramsey proposed to rectify concerns Russell’s definition of identity, according to which it is impossible for two objects to have all their properties in common. Ramsey held that this consequence shows that identity has been wrongly defined, and he advanced a definition of “ $x = y$ ” designed to render the phrase tautological when  $x$  and  $y$  have the same value and contradictory otherwise.

**BROUWER AND INTUITIONISM.** The intuitionist conception of mathematics was developed by the Dutch mathematician Luitzen Egbertus Jan Brouwer (1881–1966). According to Brouwer mathematics is not a system of formulas and rules but a fundamental form of human activity, an activity that has its basis in our ability to abstract a conception of “twoness” from successive phases of human experience and to see how this operation may be indefinitely repeated to generate the infinitely proceeding sequence of the natural numbers. In the system of mathematics based on this primordial intuition, language serves merely as an aid to memory and communication and cannot of itself create a new mathematical system; our words and formulas have significance only insofar as they are backed by an essentially languageless activity of the mind. In particular, the wording of a theorem is meaningful only if it indicates the mental construction of some mathematical entity or shows the impossibility of the entity in question. Brouwer’s conception of proof as essentially mental is useful as a corrective to a narrow formalist account that would construe proof as proof in a given formal system, although his psychologism is philosophically questionable—Wittgenstein’s work has rendered more than doubtful the thesis that language is only an incidental accompaniment to thought, required solely for purposes of memory and

communication. What is important in intuitionism is not so much its psychologistic features as its emphasis on constructibility and the form of mathematics which its criterion of meaningfulness determines.

Implicit in classical mathematics is the notion that to know the meaning of a statement it is sufficient to know the conditions under which the statement is true or false, even though these conditions may be such that we could never be in a position to determine whether or not they held. The possibility of a gap between what can be meaningfully stated and what can be recognized either as true or as false is not admitted by the intuitionists. On their theory we can know the meaning of a statement only when we can recognize a proof of it; indeed, to understand a statement simply is to know what constitutes a proof or verification of that statement.

This emphasis on verification leads to an explanation of the logical constants and of a number of mathematical concepts that results in the rejection or reinterpretation of large parts of classical mathematics. Thus, whereas in classical mathematics the truth-table definition is adequate to giving the meaning of the constant “ $\vee$ ” (“or”), for the intuitionist we can explain the meaning of a statement of the form “ $A \vee B$ ” only by indicating under what conditions we should be warranted in asserting such a statement. These conditions are that we should be warranted in asserting  $A$  or that we should be warranted in asserting  $B$ , and it is clear that neither condition may hold, even when  $A$  is the negation of  $B$ .

Assume, for instance, that  $A$  is an existentially quantified statement,  $\exists xP(x)$ , with the quantifier ranging over the natural numbers. To suppose that this holds is to suppose that we can actually construct a number with the required property. On the other hand, what is it to suppose that  $\exists xP(x)$  is false? It cannot mean that a case-by-case examination of the numbers will provide a refutation of the statement, since a case-by-case investigation of an infinite totality is not a real possibility—it is a picture to which the classical mathematician is wedded by a mistaken analogy with finite totalities. But if  $\sim\exists xP(x)$  is to have a meaning which we can grasp, it can mean only that there is a contradiction in the idea of a number’s having the property  $P$ . Given this explanation of the sense of the proposition and its negation, we are obliged to abandon Aristotelian logic as no longer trustworthy in this context, for asserting the disjunction  $\exists xP(x) \vee \sim\exists xP(x)$  is tantamount to asserting that we either are in a position to construct a suitable number or can show the impossibility of such a construction. We are not entitled to assert a priori that at least one of these possibilities must obtain,

but to do so would simply be to commit ourselves to the unfounded belief that all mathematical problems are solvable.

This insistence on the identification of existence with constructibility can be traced back to Leopold Kronecker (1823–1891), and a precise formulation of principles of intuitionist logic was carried out in 1930 by a pupil of Brouwer’s, Arend Heyting (1898–1980). Several branches of mathematics have been redeveloped from the intuitionist standpoint, but the reconstructions are often complicated, and in some cases, particularly where set-theoretic notions are involved, there has been a question of outright rejection, rather than reconstruction, of classical mathematics. Thus, impredicative definitions, hierarchies of transfinite numbers, and nonconstructive postulates such as the axiom of choice (and hence the well-ordering theorem), while important classically, are rejected in toto by the intuitionists, a rejection which has led many mathematicians to discount the claims of intuitionism without giving sufficient attention to the arguments, admittedly often obscurely expressed, on which they are based.

*Bede Rundle (1967)*

**HILBERT AND FORMALISM.** The leading exponent of the formalist philosophy of mathematics was David Hilbert (1862–1943), who pioneered in a development of logic known as proof theory or metamathematics. From the time of his first papers on the foundations of mathematics, Hilbert stressed the importance of the axiomatic method and its superiority over the genetic approach, by which concepts are extended piecemeal as the need arises. Once a theory is axiomatized, however, it invites a number of general questions concerning the logical relations holding between its propositions, and Hilbert was soon to consider as central among such questions the problem of establishing consistency, or freedom from contradiction. Hilbert did not himself think that there was any support for the allegations of inconsistency in analysis, as made by Hermann Weyl. Nevertheless, he wished to consolidate once and for all the foundations of mathematics and to give them such clarity that the axiom of choice would be as perspicuous as the simplest arithmetical truth. To this end he needed to devise consistency proofs. He had, in 1899, shown the consistency of Euclidean geometry relative to the theory of real numbers, but proofs of this form do no more than shift the problem of consistency to the

system to which the original theory has been reduced. Some new, more direct method seemed to be called for.

Despite his confidence in the consistency of classical mathematics, Hilbert contended that operating in an abstract way with mathematical concepts had proved insecure, and his remedy was to interpret number theory as relating to the observable domain of such signs as 1, 11, 111. Elementary number theory is thereby assured of a concrete interpretation—"3 > 2," for example, can be understood as asserting that the concatenation of three strokes extends beyond the concatenation of two strokes. However, the possibility of such an interpretation does not extend to all branches of classical mathematics, for such entities as transfinite cardinals do not allow of representation as sequences of strokes.

Hilbert's solution to this difficulty was to treat such numbers as "ideal" elements. Thus, appealing to Kant, he argued that one precondition for the application of logical laws is a domain of extralogical concrete objects, given in actual perception and capable of being exhaustively surveyed. Nowhere in nature is an actual infinity to be found; therefore, whereas for finite numbers a perceptually given basis could be given, transfinite numbers had a place in mathematics only as ideal elements, much like the ideal factors introduced to preserve the simple laws of divisibility for algebraic whole numbers. Such a reduction was, Hilbert claimed, a natural extension of the work of Weierstrass, who had shown that reference to infinity in the context of calculus involved merely a *façon de parler*, replaceable by a theory of limits requiring a potential infinite rather than an actual one. Similarly, the infinities introduced by Cantor, though apparently irreducible, had to be shown to be indispensable, and arguments proceeding via the infinite had to be replaced by finite methods that achieve the same goal. Again, since the transfinite enters with the use of unbounded quantifiers, statements containing these had to be regarded as ideal statements.

With this approach Hilbert hoped to partially vindicate classical mathematics against the attacks of the intuitionists. Complete vindication, however, required a proof of consistency, and the method that Hilbert proposed for obtaining such a proof is closely related to his method for providing elementary number theory with a sound basis. That is, just as he had considered numbers as sequences of strokes, so he now regarded formulas and proofs as sequences of uninterpreted signs. In this way he provided a concrete subject matter for a proof of consistency, a proof that was to invoke only logical principles whose security and perspicuity are equal to the security

and perspicuity of the perceptually given domain on which they are to operate.

Thus, the consistency of some given formalization of a branch of mathematics could be unquestionably established if it could be shown by finite combinatorial methods that no manipulation of the symbols which represents a passage from axioms to theorems could result in the derivation of the expression " $0 = 1$ " or of some other concatenation of symbols which, when interpreted, is seen to be an absurdity. The theory itself might contain symbols for transfinite cardinals and other ideal elements, but this would be no obstacle to a consistency proof, since in such a proof we are required only to treat these symbols as perceptually given objects and to show that they will never figure in a formula whose negation is also provable. On the other hand, Hilbert believed that although nonfinitary concepts are allowable within mathematics proper, they are not to be countenanced in the theory of proof that is to ensure consistency.

The formalist school, which included Wilhelm Ackermann, Paul Bernays, and John von Neumann, succeeded in establishing a number of metamathematical results of considerable significance, but without completing Hilbert's original program, for although successively stronger systems of arithmetic were proved consistent, no proof was forthcoming for the full system required by classical number theory. And, indeed, results obtained by Kurt Gödel in 1931 indicate that no finitary consistency proof is possible, since any proof of consistency must make an appeal to principles which are more general than those provided by the system and accordingly are as much open to question as those principles whose consistency we wish to establish. Attempts were subsequently made to prove consistency by means which were as close to being finitary as possible, notably by Gerhard Gentzen in 1936, but even if "finitary" were thought to apply to the methods used—in this case an application of transfinite induction—it would not follow that classical mathematics had been vindicated against the intuitionists, since to their way of thinking the mere consistency of mathematics would not suffice to confer a clear meaning on the crucial concepts of classical mathematics.

*Bede Rundle (1967)*

**LÖWENHEIM.** A number of significant results concerning the first-order functional or predicate calculus (with

identity) date from a paper published in 1915 by Leopold Löwenheim (1878–1957), a mathematician of Schröder’s school. In this paper, “Über Möglichkeiten im Relativkalkül” (*Mathematische Annalen* 76 [1915]: 447–470), Löwenheim showed how the problem of deciding the validity of formulas in this calculus reduces to the problem of determining the validity of formulas in which only two-place predicate letters occur. Since (from the point of view of decidability) such formulas are accordingly no less general than arbitrary formulas of the calculus, we know from a later result, by Alonzo Church, that the decision problem for this class is unsolvable. However, Löwenheim was able to provide a decision procedure for a more restricted class of formulas, those in which only one-place predicate letters occur. He also showed that no formula of this restricted class could be valid in every finite domain, yet not be valid in an infinite domain, and his most famous result, known as Löwenheim’s theorem, states that any formula of the full calculus which is valid in a denumerable domain is valid in every nonempty domain.

Although it is not difficult to show that if a formula is valid in a given domain, it is valid in any smaller domain, we cannot in general claim that validity in a given domain establishes validity in a larger domain. But as Löwenheim recognized, a formula may be valid in every domain comprising only finitely many of the natural numbers, yet not be valid in the domain of all natural numbers. The significance of Löwenheim’s result is thus that validity in a denumerable domain guarantees validity not simply in any smaller domain but in domains which, like that of the real numbers, are of even greater cardinality than the set of natural numbers.

*Bede Rundle (1967)*

**SKOLEM.** The Norwegian mathematician Thoralf Skolem (1887–1963) made extensive contributions to the development of logic, maintaining a steady output of important papers from 1920 until his death. Skolem’s first major result was an extension of the above-mentioned theorem of Löwenheim that if a formula of the first-order functional calculus (with identity) is valid in a denumerably infinite domain, it is valid in every nonempty domain and that, equivalently, if such a formula is satisfiable at all, then it is satisfiable in a domain comprising at most a denumerable infinity of elements. In 1920, Skolem generalized this theorem to the case of classes (possibly infinite) of formulas, establishing that if a class of formulas is simultaneously satisfiable, then it is satisfiable in a denumerably infinite domain. Skolem’s proof makes use of the axiom of choice and the Skolem normal form of a

formula—a type of prenex normal form in which no universal quantifier precedes an existential quantifier—but both these devices were subsequently dropped, and a more constructive version of the proof was given in 1928, a version which led to the developments of Herbrand and to Gödel’s completeness proof.

Skolem was led by his work on Löwenheim’s theorem to consider set-theoretic concepts as in a certain sense relative. This view derives from the fact that suitable axiomatizations of set theory can be written in the notation of first-order logic, the only symbol foreign to this logic—the epsilon of membership—being replaced by a dyadic predicate letter. The result is a set of formulas which, if consistent, has by Löwenheim’s theorem an interpretation within a denumerably infinite domain. At the same time, within the system of set theory we can establish, by Cantor’s theorem, the existence of nondenumerably infinite sets. This apparent conflict between the magnitude of the sets in the axiomatic theory and the more limited domain in which it is modeled is known as the Löwenheim–Skolem paradox. Skolem’s way out of this paradox was to suggest that the distinction between denumerable and nondenumerable be taken as relative to an axiom system, a set which is nondenumerable in a given axiomatization perhaps being denumerable in another.

The possibility of an enumeration not available within the original axiom system has led to the description of Löwenheim’s theorem as the first of the modern incompleteness theorems, but Skolem’s resolution of his paradox does not represent the only possibility. In the first place, it is not clear how the required enumeration could be devised even outside the system in question. To take an analogous case, Cantor’s theorem shows that the members of a set containing three elements cannot be paired off with the members of the power set of this set. Since the power set in this case contains eight elements, Cantor’s result is in no way surprising, but there is no inclination to say that further mappings might be devised which would yield a one-to-one correspondence between the three-member set and the eight-member set. In the second place, Löwenheim’s theorem does not require us to suppose that the axiomatized theory guarantees an enumeration of the sets, since the reinterpretation of the original symbolism with respect to a denumerable domain results in a revision of the propositions implying or asserting the existence of a nondenumerable infinity of sets. By hypothesis, such propositions go over into propositions which hold in the denumerable model, but although their truth is preserved, their original meaning

is altered: they could not without contradiction assert the nondenumerability of the new model.

The set-theoretic relativism that Skolem inferred from the Löwenheim–Skolem theorem led him to doubt whether mathematical concepts could be completely characterized axiomatically, and in 1934 he published a result confirming these doubts by demonstrating that no categorical system of postulates for the natural numbers can be expressed in the notation of quantification theory. Any attempt to give a unique characterization of the natural numbers by means of propositions expressed in this notation is bound to fail, even if a denumerable infinity of such propositions is allowed, since there will always be other systems of entities conforming to the structure so defined. Although this result was uncongenial to those who had hoped to delineate the numbers from a formalist standpoint, the nonstandard models which are yielded by such proofs have become increasingly important, and their application to such topics as independence proofs and mathematical analysis promises to be fruitful.

Skolem also made important contributions to the theory of recursive functions. His work in this field dates from a pioneering paper of 1923, in which he sought to develop arithmetic in a logic-free calculus. Essentially this meant the elimination of quantifiers, an elimination that Skolem proposed to effect by the extensive use of recursive definitions. For instance, instead of defining “ $a < b$ ” as “ $(\exists x)(a + x = b)$ ,” we can avoid the use of the existential quantifier by means of the joint stipulation of (i)  $-(a < 1)$  and (ii)  $a < (b + 1) \leftrightarrow (a < b) \vee (a = b)$ . In this and subsequent papers Skolem advanced such reductions as part of a finitistic program for securing the basis of arithmetic.

Also important are Skolem’s contributions to set theory. The Zermelo–Fraenkel system is commonly presented with his modifications, and in his last years he took up the study of set-theoretic contradictions from the standpoint of systems of many-valued logic.

*Bede Rundle (1967)*

**HERBRAND.** Despite a tragically short life—he was killed in a mountaineering accident in 1931 at the age of twenty-three—Jacques Herbrand made substantial contributions to the development of mathematical logic, especially to investigations in the metatheory of logic that were the particular concern of Hilbert and his school. The bulk of Herbrand’s contributions is to be found in his University of Paris dissertation of 1930, *Recherches sur la*

*théorie de la démonstration* (published in *Travaux de la Société des Sciences et des Lettres de Varsovie*, Classe III (33) [1930]: 33–160). This work has much in common with the later “*Untersuchungen über das logische Schliessen*” of Gerhard Gentzen, but the presentation of proofs and explanations is much less perspicuous than Gentzen’s, and even now some aspects of Herbrand’s work await further clarification and elaboration.

Herbrand’s starting point is the system of classical propositional logic presented in Whitehead and Russell’s *Principia Mathematica*, but the extension of this to functional calculi of first and higher orders is effected by the addition of further rules in place of axioms. The resultant calculi, in which mathematical theories may be embedded, are investigated from a Hilbertian proof-theoretic viewpoint, with emphasis on such syntactic notions as derivability and to the exclusion of semantic questions that cannot be given a finitistic interpretation. New proofs are given of a number of results already known, such as those concerning solvable cases of the decision problem, and for the first time the idea and proof of the deduction theorem is presented for a particular system of logic. That is, Herbrand showed that a necessary and sufficient condition for the derivability of a proposition  $P$  in his theory with hypotheses  $H$  is that  $H \supset P$  should be derivable in the logic without hypotheses.

Herbrand’s most powerful result concerns the necessity and sufficiency of certain conditions for the provability of a quantificational schema. He showed, in fact, that such a schema is provable if and only if a quantifier-free tautology of a prescribed form is constructible from it. The proofs of the various theses that go to make up this result are somewhat complicated, but the form of tautology which is associated with a provable formula can be indicated in the following way: First, a given quantificational schema is so transformed that each quantifier has its minimum scope or, alternatively, each has its maximum scope. Taking just the first case, then, all the quantifiers are placed initially and have a scope that extends to the far right of the formula.

Suppose we are given a schema in this form—for example,  $\exists x \exists y \forall z [Fx \rightarrow (Fy \ \& \ Fz)]$ —which we shall call “ $A$ .” The necessary and sufficient condition of  $A$ ’s holding is that it be false that for any  $x$  and  $y$  there is a value of  $z$  for which the matrix of  $A$  is false. Accordingly, if  $x$  and  $y$  both take the value  $a_1$ , say, there must be some value  $a_2$  of  $z$  that results in the falsity of the matrix if  $A$  is to be false; further, if  $x$  takes the value  $a_1$  and  $y$  takes the value  $a_2$ , then for some value  $a_3$  of  $z$  the matrix must be false; again, if  $x$  takes the value  $a_2$  and  $y$  takes the value  $a_1$ , the matrix must

be false for some value  $a_i$  of  $z$ , and so on. But if we find that at least one of the substitution instances of the matrix so generated must be true, we have shown the failure of a necessary condition for the falsity of  $A$ . In fact, this is the outcome of the present example, since the disjunction of the cases so far considered,  $[Fa_1 \rightarrow (Fa_1 \& Fa_2)] \vee [Fa_1 \rightarrow (Fa_2 \& Fa_3)] \vee [Fa_2 \rightarrow (Fa_1 \& Fa_4)]$ , is a tautology—thus, if  $Fa_2$  is true, the first disjunct is true, and if  $Fa_2$  is false, the last disjunct is true.

Herbrand showed how such disjunctions can be constructed from a formula in prenex normal form with the quantifiers occurring in any number and order. He showed, too, that the original formula can be retrieved from such a disjunction by the application of a few simple rules, without use of *modus ponens*. And, indeed, it is clear from the example given that the only rules required for the derivation of the original formula from the tautology are rules allowing for the insertion of quantifiers before the disjuncts and a rule allowing us to erase repetitions of identical disjuncts. The final result allows us to assert that the constructibility of a tautologous disjunction is both a necessary and a sufficient condition for the provability of the associated quantified schema.

In addition to shedding considerable light on the structure of quantification theory, Herbrand's theorem is the source of a number of important metatheoretic results. Löwenheim's theorem is an immediate consequence—accepted by Herbrand only when reinterpreted finitistically—and certain cases of the decision problem allow of simple resolution. Important for Herbrand's aims was the application of his theorem to the question of the consistency of arithmetic, and he was able to show that if we have a model for a set of hypotheses, an interpretation with respect to some domain under which all these hypotheses are true, then no contradiction can arise in the theory deduced from the axioms. Suppose hypotheses  $H_1, H_2, \dots, H_n$  give rise to a contradiction while having a true interpretation within the model. Since  $H_1 \& H_2 \& \dots \& H_n$  comes out true in the model, the model brings the negation of this conjunction out false, and if a formula is false in some domain, it is not associated with a quantifier-free tautology. If, on the other hand,  $H_1, H_2, \dots, H_n$  yield a contradiction, then  $\sim(H_1 \& H_2 \& \dots \& H_n)$  is provable and thus is associated with a tautologous disjunction. This form of consistency proof was discussed further by Herbrand in his later article "Sur la Non-contradiction de l'arithmétique" (*Journal für die reine und angewandte Mathematik* 166 [1931]: 1–8), and the same idea appears in Gentzen's "Untersuchungen über das logische Schliessen."

**GÖDEL.** Kurt Gödel (1906–1978), a major figure in the history of logic, is best known for his celebrated incompleteness theorem presented in "Über formal unentscheidbare Sätze der Principia Mathematica und verwandter Systeme I" (*Monatshefte für Mathematik und Physik* 38 [1931]: 173–198) and his associated proof of the impossibility of establishing the consistency of customary formulations of arithmetic by methods formalizable within the systems themselves. In addition to these results (discussed in the entry Gödel's Theorem), Gödel made important contributions to several other branches of logic, and prior to his 1931 paper he had already presented the first completeness proof for the first-order functional calculus (in "Die Vollständigkeit der Axiome des logischen Funktionkalküls," *Monatshefte für Mathematik und Physik* 37[1930]: 349–360). Making use of a normal form devised by Thoralf Skolem, Gödel elaborated a proof along lines that were followed by Jacques Herbrand to a similar end in a publication of the same year (*Recherches sur la théorie de la démonstration*, in *Travaux de la Société des Sciences et des Lettres de Varsovie*, Classe III [33] [1930]: 33–160), but he went further than Herbrand in his method for showing how any unprovable formula may be falsified.

Intuitionistic as well as classical logic has been one of Gödel's major concerns, and his results in this field are of importance to an understanding of the formalizations of this logic initiated by Arend Heyting in 1930. The intuitionist propositional calculus is naturally thought of as a subsystem of classical logic, obtained by omitting from the latter those theses that are intuitionistically unacceptable. Gödel indicated that this picture could in a sense be reversed, since it is possible to define all two-valued truth-functions by means of the connectives for negation and conjunction, and he was able to show that any formula involving only these connectives is provable within intuitionistic logic if it is provable classically. Gödel showed, further, that even classical number theory, if suitably interpreted, can be thought of as included within intuitionistic number theory. He also proved that the intuitionist propositional calculus has no finite characteristic matrix. That is, although the two-valued truth tables for classical logic serve to verify all and only those theses provable in this logic, it is impossible, according to Gödel's result, to devise truth tables having any finite number of values that will perform the same service for the intuitionist system.

Two propositions that have been at the center of much investigation and controversy are the axiom of choice and Cantor's generalized continuum hypothesis. It was Gödel who proved that both are consistent with the axioms of set theory provided only that these axioms are themselves consistent. The axiom of choice is a highly nonconstructive axiom licensing the selection of an unspecified element from each of a (possibly infinite) family of sets and the formation of a set comprising just the elements so selected. The generalized continuum hypothesis, which in fact implies the axiom of choice, states that  $2^{\aleph_\alpha} = \aleph_{\alpha+1}$ ; that is, starting with  $\aleph_0$ , which is the number of the natural numbers, the series of increasingly higher cardinals is successively generated by raising 2 to the power of the preceding aleph. The system  $\Sigma$  of set theory that Gödel used derives from John von Neumann and Paul Bernays. Gödel showed that if it were possible to derive a contradiction from the axiom of choice and the continuum hypothesis in  $\Sigma$ , then the axioms of  $\Sigma$  alone would suffice for the derivation of a contradiction. This result is obtained by constructing a model  $\Delta$  within  $\Sigma$  itself, where  $\Delta$  is such that the propositions asserting that the axioms of  $\Sigma$  hold for  $\Delta$  are demonstrable in  $\Sigma$  and the similar relativizations to  $\Delta$  of the axiom of choice and the generalized continuum hypothesis are likewise demonstrable in  $\Sigma$ . Paul J. Cohen showed, in 1963, that the negations of these propositions are also consistent with the axioms of set theory. In other words, the axiom of choice and the generalized continuum hypothesis are now known to be independent of the other axioms of set theory.

## SINCE GÖDEL

The pace of development in logic picked up rapidly after Gödel's incompleteness theorems, and five branches emerged: set theory, model theory, proof theory, computability theory, and nonclassical logics.

Gödel's theorems were formulated for type theory, but this was soon displaced as the framework for mathematics by Zermelo-Frankel set theory with choice (ZFC). Gödel's theorems still apply, and imply the existence of set-theoretic statements that can be neither proved nor disproved. Gödel himself showed that Cantor's continuum hypothesis cannot be disproved, and conjectured that it cannot be proved, as was established in the 1960s

by Paul Cohen. Since then the search for new axioms to settle questions left open by ZFC has flourished.

Gödel's results on the unprovability of the consistency of a formal theory within the theory itself were followed by Tarski's work on the undefinability of truth for a formal language within the language itself. Tarski's work also for the first time gave a rigorous definition, in a *meta-language*, of truth for a sentence of formal language, relative to an interpretation, which is needed for a fully rigorous statement even of Gödel's earlier *completeness* theorem. With his truth definition Tarski laid the foundations for a general theory of models, a model of a formal theory being an interpretation that makes it true.

Gödel showed the unachievability of the original aim of proof theory: to establish the consistency of infinitistic mathematics by finitist means; but this leaves open the possibility of establishing *relative* consistency through the interpretation of ostensibly stronger in ostensibly weaker theories. Gödel himself contributed to this program, and in the mid-1930s the powerful new methods were introduced by Gerhard Gentzen (1909–1945).

Gödel used in his work the auxiliary notion of a primitive recursive function, which include many but not all functions that are effectively computable in an intuitive sense. Two equivalent proposed characterizations of the full class of effectively computable functions followed. Recursive function theory was developed in collaboration with his student S. C. Kleene (1909–1994) by Alonzo Church, who proved there is no effectively computable function that will tell whether a given formula is logically valid. Turing machines were developed by Alan Turing, who proved the possibility in principle of a universal programmable computer, a possibility that began to be realized during the Second World War.

Gödel contributed not only to the areas just enumerated, which together constitute *mathematical logic*, but also to the study of modal and other nonclassical logics, often called *philosophical logic*. Mathematical logic was characterized by explosive growth after 1945. Philosophical logic grew more slowly until the development of a usable model theory for nonclassical logics with the work of Saul Kripke and others circa 1960, after which development speeded up and important connections with theoretical computer science emerged.

Much of the growth in all five branches has occurred in areas far removed from philosophy, but if the volume of philosophically oriented work has decreased in relative terms, still it has increased in absolute terms owing to the overall growth of logic.

**GENTZEN.** The first systematic formulations of the propositional and predicate calculi were presented axiomatically, on the analogy of certain branches of mathematics. In 1934, Gerhard Gentzen (1909–1945), a logician of Hilbert’s school, published a formalization of logical principles more in accordance with the way in which these principles are customarily applied. (A similar approach was developed independently by S. Jaśkowski; see below, section on Polish logicians.) In illustrating his technique Gentzen considered how we might establish as valid the schema  $(X \vee (Y \& Z)) \supset (X \vee Y) \& (X \vee Z)$ . Assuming that the antecedent holds, either  $X$  is true, or  $Y \& Z$  is true. In the former case we can pass to each of  $X \vee Y$  and  $X \vee Z$  and hence to their joint assertion. Assuming now  $Y \& Z$ , we may infer  $Y$ , whence  $X \vee Y$ , and likewise  $Z$ , whence  $X \vee Z$ . In this case the conjunction is once more derivable. Since it is derivable from each disjunct of the original assumption, we may assert the implication unconditionally.

In this simple form of argument the justification of the schema has been broken down into a series of uncomplicated steps, each involving either the introduction or the elimination of a logical connective. Extracting the rules that were applied and supplementing them with similar rules governing the use of the other connectives, we arrive at a system of “natural” deduction—either *NJ* (intuitionist logic) or *NK* (classical logic). Gentzen considered the former more natural than the latter, but whichever we opt for, it appears that the resultant codification of logical principles is more natural, on at least two counts, than a codification presented in axiomatic fashion.

In the first place, we avoid the devious moves that may be necessary to establish a logical principle from an axiomatic basis and follow more closely a pattern of reasoning that we should intuitively adopt. In the second place, the conception of logic as a system of axioms and theorems adjoined to some given subject matter appears inappropriate, since, in their application to, say, a branch of mathematics, principles of logic function not as true statements forming part of the theory in question but as rules of inference allowing us to establish relations of consequence between propositions of the theory.

In addition to the systems *NJ* and *NK*, Gentzen devised related formalizations of logic, the *L*-systems, in

which derivable formulas are shown to possess a particularly direct form of proof. These systems contain the “cut” rule, a generalized form of *modus ponens* that, like *modus ponens*, has the disadvantage that we cannot work back from a schema to premises from which it could have been derived. However, although the cut rule is crucial in showing the equivalence of the *L*-systems with the earlier *N*-systems, Gentzen showed that the cut rule can be eliminated from any proof in the *L*-systems. This powerful metatheorem simplifies the reconstruction of proofs of valid formulas, yielding a decision procedure for the propositional fragments of *LJ* and *LK* and greatly facilitating the search for proofs in the full calculi. Gentzen further applied his *Hauptsatz* to proofs of consistency; in particular, he showed one formalization of arithmetic to be noncontradictory. The formalization in question does not contain a schema of unrestricted induction, but in later works Gentzen remedied this defect, overcoming the obstacle to such proofs presented by Gödel’s results by making use of a principle of transfinite induction which cannot be reduced to ordinary induction within the system. It is a matter of controversy whether such a proof represents the attainment of one of Hilbert’s goals, a finitary consistency proof for classical number theory.

*Bede Rundle (1967)*

**CHURCH.** From the beginning of the twentieth century questions concerning the decidability of logical and mathematical theories have held a special interest for logicians, mathematicians, and philosophers. A number of important concepts and far-reaching results in this field have come from Alonzo Church (1903–1995), author of a definitive text on logic and noted writer on the history of logic.

The notion of decidability is not one which a beginner in mathematics could explicitly formulate, but both this and related notions, such as that of effective calculability, have a place in the description of the most elementary mathematical concepts. Often our understanding of a particular numerical predicate is inextricably tied to our ability to determine whether or not an arbitrary number satisfies that predicate, and in many cases terms expressing the result of a calculation or computation can be fully grasped only by one who has the ability to carry out the sorts of computation in question. Thus, with the division of numbers into odd and even there is intimately associated a technique for determining which of these predicates applies to an arbitrary whole number; similarly, a person’s grasp of the concepts of sum and product is

measured by his ability to calculate sums and products. But although the grasp of concepts and the mastering of techniques may go hand in hand in many cases, the symbolism of arithmetic allows us to formulate propositions whose truth-value may resist determination by any obvious methods of computing or reasoning in general, a situation that frequently arises with the introduction of unrestricted quantification.

Consider, for instance, the proposition  $P$ , "There is at least one odd perfect number." A perfect number is a number that is equal to the sum of its divisors, itself excluded. Thus, 6 is perfect, being equal to the sum of 1, 2, and 3; so is 28, being equal to the sum of 1, 2, 4, 7, and 14. Like "x is odd," the predicate "x is perfect" is a decidable predicate, in the sense that given any number  $n$ , we can, after a finite number of steps, respond with an unambiguous *yes* or *no* to the question "Is  $n$  perfect?" But although both of the predicates entering into  $P$  are decidable, the infinitude of the positive integers is an obstacle to an immediate determination of the truth-value of  $P$  which would make use of the decidability of these predicates together with a case-by-case examination of the integers. Indeed, proposition  $P$ , along with Fermat's last theorem, Goldbach's conjecture, and many other propositions of elementary number theory, has as yet been neither proved nor disproved. Accordingly we may well wonder whether it is possible to devise a technique that, when applied to an arbitrary proposition of this class, would enable us to determine the truth or provability of the proposition. Now, for all we know, any one of these outstanding problems may eventually be resolved, but Church showed that no general technique could be devised which would allow us to ascertain in an effective manner the truth or provability of an arbitrary arithmetical proposition.

By a direct application of the method of diagonalization (a procedure whereby a hypothesized function is shown to differ from each member of a class of functions of which it must be a member if it is to exist), Church demonstrated not simply that such a technique has proved elusive but that the supposition of its existence involves an absurdity. In this respect arithmetic contrasts with the propositional calculus, but although the propositional calculus does have a decision procedure—the method of truth-tables—Church showed that the first-order functional calculus fares no better than arithmetic, it being impossible to find a method that allows us to recognize as provable or refutable an arbitrary formula of this calculus. It may prove—indeed, in many cases it has already been shown—that fragments of these systems are

decidable, but Hilbert's aim of a general technique which would banish ignorance from mathematics appears to be unattainable.

In demonstrating his theorem Church was obliged to provide a formal counterpart of the intuitive notion of effective calculability, and he proposed that this notion be identified with that of recursiveness. The notion of a recursive function (of positive integers) was introduced by Gödel, acting on a suggestion of Herbrand, and was analyzed in detail by S. C. Kleene. A function is said to be (general) recursive (a generalization of the notion of primitive recursive) if, roughly speaking, its value for given arguments can be calculated from a set of equations by means of two rules, one allowing the replacement of variables by numerals, the other allowing the substitution of equals for equals. As Church remarks, the intuitive status of effective calculability rules out any complete justification of his proposal (since known as Church's thesis), but he adduces reasons for regarding the identification as plausible, and the plausibility of his thesis has subsequently been reinforced by the discovery that despite their apparent dissimilarity, various alternative attempts to characterize the intuitive concept have all proved equivalent to that of general recursiveness.

Thus, at the time Church put forward his thesis the Church-Kleene notion of  $\lambda$ -definability was already known to provide an equivalent, and Turing's "computability," Post's "1-definability" and "binormality," and Markov's "computability" provide alternatives defined with respect to machines and combinatorial operations. It should be mentioned, however, that Church's thesis has not met with universal support; a summary and criticism of a number of objections can be found in Elliot Mendelson's "On Some Recent Criticism of Church's Thesis" (in *Notre Dame Journal of Formal Logic* 4 [1963]: 201–205).

*Bede Rundle (1967)*

**TURING AND COMPUTABILITY THEORY.** In the late 1930s Alan M. Turing was one of the founders of computability theory. His main contributions to this field were published in three papers that appeared in the span of a few years, and especially in his ground-breaking 1936–1937 paper, published when he was twenty-four years old.

As indicated by its title, "On Computable Numbers, with an Application to the Entscheidungsproblem," Turing's paper deals ostensibly with real numbers that are

computable in the sense that their decimal expansion “can be written down by a machine.” As he pointed out, however, the ideas carry over easily to computable functions on the integers or to computable predicates.

The paper was based on work that Turing had carried out as a Cambridge graduate student, under the direction of Maxwell Newman (1897–1984). When Turing first saw a 1936 paper by Alonzo Church, he realized at once that the two of them were tackling the same problem—making computability precise—albeit from different points of view. Turing wrote to Church and then traveled to Princeton University to meet with him. The final form of the paper was submitted from Princeton.

In a space of thirty-six pages, the paper manages to accomplish the following six goals:

(1) A formalization of what it means to be “calculable by finite means,” in terms of an idealized computing device—now known of course as a Turing machine.

(2) The construction of a “universal computing machine,” which when supplied with the “standard description” of a machine  $M$  on its tape, will simulate the operation of  $M$ .

(3) The proof of the unsolvability of the halting problem and proofs of the unsolvability of other problems, such as the problem of deciding, given a machine  $M$ , whether or not  $M$  will ever print the symbol 0.

(4) Three kinds of arguments for Turing’s thesis, that is, the claim that his formulation in terms of machines is successful in capturing the idea of “processes which can be carried out in computing” (249). It should be noted that Kurt Gödel and others have found Turing’s arguments here completely convincing.

(5) A proof of Church’s theorem that David Hilbert’s Entscheidungsproblem can have no solution, that is, the problem of deciding whether or not a given formula is derivable in the predicate calculus is unsolvable.

(6) An outline, in an appendix, of the equivalence of computability by Turing machines to computability as formulated by Church in terms of the  $\lambda$ -calculus. (This proof was given in further detail in Turing’s 1937 paper, “Computability and  $\lambda$ -Definability.”)

Turing’s paper remains a readable introduction to his ideas. How might a diligent clerk carry out a calculation by following instructions? The clerk might organize the

work in a notebook. At any given moment his or her attention is focused on a particular page. Following the instructions, he or she might alter that page, and then might turn to another page. And the notebook is large enough that he or she never comes to the last page.

The alphabet of symbols available to the clerk must finite; if there were infinitely many symbols, then there would be two that were arbitrarily similar and so might be confused. One can then, without loss of generality, regard what can be written on one page of notebook as a single symbol. And one can envision the notebook pages as being placed side by side, forming a paper tape, consisting of squares, each square being either blank or printed with a symbol. At each stage of the work, the clerk—or the mechanical machine—can alter the square under examination, can turn attention to the next square or the previous one, and can look to the instructions to see what part of them to follow next. Turing describes the latter as a change of state of mind.

Turing writes, “We may now construct a machine to do the work” (251). Such a machine is of course now called a Turing machine, a phrase first used by Church in his review of Turing’s paper in *The Journal of Symbolic Logic*. The machine has a potentially infinite tape, marked into squares. Initially, the tape is blank. (Alternatively, if one wants to compute some function, the input word or number can be written on the tape.) The machine is capable of being in any one of finitely many states (the phrase of *mind* being inappropriate for a machine).

At each step of the calculation, depending on its state at the time, the machine can change the symbol in the square under examination at that time, can turn its attention to the square to the left or to the right, and can then change its state to another state.

The program for this Turing machine can be given by a table. Where the possible states of the machine are  $q_1, \dots, q_r$ , each line of the table is a quintuple  $(q_i, S_j, S_k, D, q_m)$  that is to be interpreted as directing that whenever the machine is in state  $q_i$  and the square under examination contains the symbol  $S_j$ , then that symbol should be altered to  $S_k$  and the machine should shift its attention to the square on the left (if  $D = L$ ) or on the right (if  $D = R$ ), and should change its state to  $q_m$ . For the program to be unambiguous, it should have no two different quintuples with the same first two components. One of the states, say  $q_1$ , is designated as the initial state—the state in which the machine begins its calculation. If one starts the machine running in this state, it might (or might not), after some number of steps, reach a state and a symbol for which its

table lacks a quintuple having that state and symbol for its first two components. At that point the machine halts.

In particular, where 0 and 1 are among the symbols in the alphabet, the machine might run on and on, sometimes printing a 0 or 1 on the tape (besides printing whatever other markers are needed for the computation). In this way, the machine might generate an infinite binary string. One can interpret this binary string as giving the binary expansion of a real number in the unit interval. Say that a real number is computable if it differs by an integer from a number in the unit interval whose binary expansion can be generated by some Turing machine.

Alternatively, if one wants the machine to compute a function, one can, after starting the machine with the input word or number on the tape, wait for it to halt and then look at the tape (starting with the square then under examination) to see what the output word or number is.

Turing shows how to construct a “universal computing machine” that, when supplied with the “standard description” of a machine  $M$  on its tape, will simulate the operation of  $M$ . This allows him to apply a diagonal argument to show that there can be no computable way to determine whether or not a given machine will continue to print 0’s and 1’s forever. In effect, he shows the unsolvability of the halting problem.

Turing argues that his formulation of the computability concept includes all sequences that would informally be considered to be computable. That is, he argues for what is now called Turing’s thesis, the Church-Turing thesis, or Church’s thesis, depending on the context. He gives three kinds of arguments: First, he shows how his machines can capture the informal idea of a step-by-step process, as indicated briefly earlier. Second, he shows that certain changes to his definition of a machine would have no effect at all on what sequences would be computable. And third, he gives examples of large classes of numbers that are computable: the real algebraic numbers,  $e$ ,  $\pi$ , the real zeros of the Bessel functions, and so forth. Of course, as he emphasizes, only countably many real numbers can be computable.

Turing’s 1939 paper, “Systems of Logic Based on Ordinals,” is based on his PhD dissertation, written under Church’s supervision during Turing’s two-year stay at Princeton.

Gödel’s incompleteness theorems had shown that any sufficiently strong formal system was incomplete, and in particular could not prove its own consistency. One can then add to this formal system the sentence expressing its consistency, thereby obtaining a stronger system.

And this process can be iterated. The iteration can be transfinite, making use of ordinal notations for the constructive ordinals. This topic, which was later taken up by Solomon Feferman (1928–) in the 1950s, does not directly pertain to computability theory.

In the process, however, Turing introduced the important concept of computability relative to an oracle. He gave the basic definitions and indicated how his work on computability could be adapted to incorporate the idea of calculations that, at any stage, could utilize a hypothetical fixed body of information. This idea later led to work on the classification (of problems or of sets or of functions) according to degree of unsolvability. Moreover, the degrees of unsolvability are partially ordered, under what is now called Turing reducibility.

After 1939 Turing’s work on computability stopped while Turing, now back in England, threw himself into wartime cryptographic work. There was an urgent need to break the German battlefield Enigma code. The success of Turing and the British cryptographic team was of enormous military importance throughout World War II. But nothing was known publicly about this work until it was declassified several years after Turing’s suicide in 1954.

After the war Turing turned to computation topics, both practical and theoretical, outside the field of computability theory. On the practical side, he was involved in hardware and software design for early digital computers. On the theoretical side, he published important work on artificial intelligence.

**DECIDABLE AND UNDECIDABLE THEORIES.** Suppose  $T$  is a theory (i.e., a set of sentences) in a formal language

$L$  of logic. A decision procedure for  $T$  is a mechanical procedure for calculating whether any given sentence of  $L$  is a logical consequence of  $T$ . We say that  $T$  is decidable if it has a decision procedure and undecidable if not. The decision problem for  $T$  is to determine whether or not  $T$  is decidable. (One can avoid the slightly vague notion of a mechanical procedure by noting that a theory  $T$  is decidable if and only if the set of its logical consequences is computable.)

Quantifier elimination and related model-theoretic techniques have yielded proofs that many important first-order theories are decidable. Examples are the theory of addition of integers (Presburger 1930), the theories of real-closed fields and algebraically closed fields (Tarski 1951), the theory of abelian groups (Szmielew 1955), and—if a number-theoretic conjecture of Schanuel is true—the theory of the field of real numbers with exponentiation (Macintyre and Wilkie 1996). The first theory shown to be undecidable was first-order Peano arithmetic; Kurt Gödel proved its undecidability in 1931. Many other undecidable theories are known, but the proofs of undecidability are all based directly or indirectly on Gödel's ideas. In 1970 Yuri V. Matiyasevich (1993) improved Gödel's result by showing that the set of diophantine sentences true in the natural numbers is not computable (a diophantine sentence is one of the form "There are natural numbers  $m, n$ , and so on such that  $E$  is true," where  $E$  is an arithmetical equation using  $m, n$ , and so on). Part 3 of "Decidable and Undecidable Theories" of J. Donald Monk (1976) gives many examples.

We say that a formal language  $L$  of logic is decidable if the empty theory in  $L$  is decidable—in other words, if there is a mechanical test to determine which sentences of  $L$  are valid. Gödel's ideas led to a proof that if  $L$  is a non-trivial first-order language, for example, with at least one binary relation symbol besides equality, then  $L$  is undecidable (Church 1936). Later research extended this result to various important sublanguages of first-order languages. But there are also decidable languages, for example, languages of propositional logic and a number of languages with monadic predicate symbols (e.g., the language of syllogisms). See Egon Börger, Erich Grädel, and Yuri Gurevich (1997) for full information on decidable and undecidable languages. After their book appeared, a new family of decidable languages was discovered, the guarded languages, whose decidability implies the decidability of various modal logics (see Grädel, Hirsch, and Otto 2002).

The decision problem for logical languages is also known as the Entscheidungsproblem. See Paulo Mancosu

(1999, §8) on the place of this problem in early twentieth-century thinking about the foundations of mathematics, particularly within the school of David Hilbert.

### MODEL THEORY

**Tarski.** The Polish-American logician Alfred Tarski (1901–1983) was born Alfred Teitelbaum in Warsaw; he changed his surname to Tarski in 1924. That same year he obtained his doctorate at the University of Warsaw for a thesis in logic under the supervision of Stanisław Leśniewski; he had also studied under Tadeusz Kotarbiński, Kazimierz Kuratowski, Jan Łukasiewicz, Stefan Mazurkiewicz and Waław Sierpiński. At the University of Warsaw he was Docent and then Adjunct Professor from

1924 to 1939; simultaneously he taught in a high school from 1925 to 1939. From 1942 to his retirement in 1969 he held posts at the University of California at Berkeley.

Through his own work and that of his students, Tarski stands along with Aristotle and Frege as one of the creators of the discipline of logic. Andrzej Mostowski, Julia Robinson, Robert Vaught, Chen-Chung Chang, Solomon Feferman, Richard Montague, Jerome Keisler, and Haim Gaifman, among others, wrote their theses under his supervision.

In print Tarski was reluctant to place himself in any philosophical tradition. He described himself as “perhaps a philosopher of a sort.” In 1930 he said that he agreed in principle with Leśniewski’s “intuitionistic formalism,” but in 1954 he reported that this was no longer his attitude. His philosophical reticence was certainly deliberate and reflected a view that careful formalization can resolve or at least avoid problems thrown up by philosophical speculation.

Tarski had many research interests within logic. He maintained most of them throughout his career and integrated them to an extraordinary degree. The setting of most of his work in Warsaw from 1926 to 1938 was the notion of a deductive theory. Such a theory develops a certain subject matter, starting from primitive terms together with axioms and proceeding by definition and logical deduction, all within a formally defined language. Tarski saw these theories as a paradigm for research in mathematical subjects. Like David Hilbert with his metamathematics, Tarski proposed to take the theories themselves as subject matter. But unlike Hilbert, Tarski did so by developing metatheories (that is, deductive theories about deductive theories) without any restriction to finitary means. For example the notion of “true sentence of the deductive theory  $T$ ” must be defined in a metatheory  $T'$ . Tarski chose as primitive notions of  $T'$  those of  $T$  together with notions from set theory and syntax, and he showed how to write a definition in the metatheory which exactly characterizes the class of true sentences of  $T$ . He proposed similar metatheoretic definitions of “satisfies,” “definable,” and (with less confidence) “logical consequence.” His later characterization of “logical notion” was published posthumously. His influential English exposition of his definition of truth in 1944 is still the best nontechnical introduction.

At the same time Tarski developed methodologies for creating deductive theories of particular topics, and for settling the decision problem for particular deductive theories. His method of elimination of quantifiers, based on work of Thoralf Skolem and others, guided him to an

axiomatisation of the first-order theory of the field of real numbers. As a byproduct he found an algorithm for deciding the truth of first-order statements about the field of real numbers (or, as he later realized, any real-closed field). Responding to the work of Alonzo Church and Alan Turing on undecidability, Tarski developed methods for proving the undecidability of a deductive theory  $T$  by interpreting a known undecidable theory within  $T$ .

In the 1940s Tarski turned his attention to the application of metatheorems of logic in mathematics. In parallel with Anatolii Mal'tsev and Abraham Robinson, he showed that the compactness theorem of first-order logic could be used to prove purely mathematical facts. During the early 1950s he recast his notion of deductive theory to fit the new program. A deductive theory was no longer about a particular subject matter. Rather it was in a formal language with primitive symbols that could be interpreted as one pleases. An interpretation that makes all the axioms of the theory true is called a *model* of the theory. We can study those classes of structures which consist of all the models of a particular theory; in 1954 Tarski proposed the name *theory of models* for this line of research. Tarski adapted his definition of truth to define the relation “Sentence  $\phi$  is true in structure  $A$ .” He published this new model-theoretic truth definition in a joint paper with Vaught, which also included fundamental theorems about elementary embeddings between structures.

Particular theories that Tarski had studied in connection with quantifier elimination or undecidability became central to model-theoretic research. Some of them, such as the theories of real-closed fields and algebraically closed fields, remained central fifty years on. Tarski also stated several problems that strongly influenced the direction of model-theoretic research. For example he asked for a quantifier elimination for the field of reals with an exponentiation function, and for algebraic necessary and sufficient conditions for two structures to be elementarily equivalent.

Tarski’s further contributions during his American period were perhaps more scattered but no less important. He was closely involved in the theory of large cardinals. He also worked with students and colleagues on relation algebras and cylindrical algebras. During the 1960s he studied finite axiomatisations of equational classes, picking up a theme from his work with Łukasiewicz during the 1920s on propositional logics. He never lost his interest in formal theories of geometry. Students of his recall that he looked back with particular pride to the work that he did during the 1940s with Bjarni

Jónsson on decompositions of finite algebras. With the help of colleagues in Europe and the United States, he was instrumental in the setting up of the series of International Congresses in Logic, Methodology and Philosophy of Science, which first met at Stanford in 1960.

**Robinson.** Abraham Robinson (1918–1974) was a logician and mathematician. Born in Waldenburg (Silesia), he moved to Palestine in 1933, where he studied mathematics at the Hebrew University in Jerusalem and also joined the Haganah. In 1940 he fled to Britain as a wartime refugee and enlisted with the Free French Air Force. He took his PhD in London in 1949 while teaching aerodynamics at the Cranfield College of Aeronautics. He held posts successively in Toronto, Jerusalem, Los Angeles, and finally Yale, where he died of cancer. His eventful life is described by Joseph W. Dauben (1995).

Robinson's PhD thesis on applications of logic in mathematics led to an invitation to speak at the International Congress of Mathematicians in 1950. The talks of Robinson and Alfred Tarski at this congress became founding documents of the new discipline that Tarski named model theory. Throughout his career Robinson was one of the most fertile contributors of programs, techniques, and results to model theory.

Robinson's thesis contains his independent discovery of the compactness theorem for first-order languages of any cardinality. In the proof he introduced constant symbols to stand for the elements of the model to be constructed. He noticed that if these constant symbols corresponded to the elements of a given structure  $A$ , and the theory contained sentences expressing all the relations of the structure  $A$ , then any model of the theory would contain an isomorphic copy of  $A$ . This observation became the method of diagrams, which Robinson used systematically as a way of creating models of a theory with prescribed embeddings between them. Diagrams immediately became one of the fundamental techniques of model theory (for many applications, see Robinson 1963).

Robinson switched from one branch of mathematics to another with extraordinary ease. There were certain topics that he kept returning to from different angles. Two in particular were elementary embeddings and algebraically closed fields. Combining the two, he noted that every embedding between algebraically closed fields is elementary. He coined the term *model-complete* for theories whose models have this property and devised tests to show when a theory is model-complete.

Observing the role of algebraically closed fields in field theory, he looked for analogous structures within other classes. Model completions, model companions, infinite forcing companions, and finite forcing companions were notions that he proposed at various times as generalizations of algebraic closure. He identified the classes of real-closed fields and differentially closed fields as the model completions of the ordered fields and the differential fields, respectively, and axiomatized the class of differentially closed fields (though the usual axioms are an improved version due to Lenore Blum). In 1965 the notion of model completion played a central role in the proofs by James Ax and Simon Kochen, and independently by Yuri Ershov, of a number-theoretic conjecture of Emil Artin.

Around 1960 he noticed that any proper elementary extension of the field of real numbers contains infinitesimals. He quickly developed this insight into a powerful

and intuitively natural approach to mathematical analysis that he named nonstandard analysis. Nonstandard analysis is one of the few innovations in logic that were entirely the work of a single individual.

Not long before his death, Robinson collaborated with the number theorist Peter Roquette to apply model-theoretic methods in number theory. This work gave a first hint of the deep interactions between model theory and diophantine geometry that came to light in the 1990s, sadly too late for Robinson to contribute. In fact, Robinson died before he could take on board the stability theory pioneered by Michael Morley and Saharon Shelah, though his students, Greg Cherlin and Carol Wood, did contribute to this field, bringing with them Robinson's lifelong eagerness to apply model theory to algebra, algebraic geometry, and mathematics in general.

Though unable himself to believe in any kind of existence for infinite totalities, he strongly defended the right of mathematicians to proceed as if such totalities exist. His discussion (Robinson 1965) of mathematical and epistemological considerations that favor one or another of the traditional views in philosophy of mathematics is thoughtful but seems not to reveal a thoroughly worked out position. His anti-Platonistic attitude may have helped him to create nonstandard analysis by allowing him to be relaxed about what the “real” real numbers are.

In Robinson's *Selected Papers* (1979), the bibliography lists ten books, more than a hundred papers, and a film. One in seven of his papers are in wing theory and aeronautics.

SET THEORY SINCE GÖDEL See *Set Theory*

### THE PROLIFERATION OF NONCLASSICAL LOGICS.

The twentieth century, and especially its second half, was marked by a fairly spectacular proliferation of what are sometimes called nonclassical logics. To understand this, one needs to see the matter in its historical context. There have been three great periods in the history of European logic: ancient Greece, medieval Europe, and, starting toward the end of the nineteenth century, the current period. Each period has been marked by the production of novel theories of the nature and extent of logical validity. Thus, in the ancient period, Aristotle, the Megarian, and the Stoic logicians offered different accounts of validity, the conditional, and modality. The medieval period tried to reconcile some of the differences in their heritage, and in the process produced numerous different accounts of the nature of the connectives, consequence, and supposition. Not surprisingly, in both periods there was active and lively debate concerning the theories that were produced.

The periods between the great periods were characterized not just by a lack of interest in logic, but by a forgetting of much of the significant prior developments. In particular, all that remained of logic in about the middle of the nineteenth century—so-called traditional logic—was a somewhat bowdlerized form of the theory of the syllogism and some of its medieval accompaniments. It was at this time that mathematical logic came into existence. It was mathematical in two senses. The first is that the logicians who produced it were interested in the analysis of the reasoning of the mathematics of their time (and its foundations). The second is that they applied mathematical techniques to the subject in a novel way, such as those of abstract algebraic, set theory, and combinatorics.

Out of this, principally at the hands of Gottlob Frege and Bertrand Russell, developed a novel theory of logic. This was streamlined, organized, and simplified by a number of logicians in the first part of the twentieth century—notably, David Hilbert, Alfred Tarski, and Gerhard Gentzen. The result was an account of inference that was so much more powerful than traditional logic that is soon superseded it as the standard canon. This is so-called classical logic.

It had hardly appeared, however, before some logicians realized that a number of assumptions that were packed into it were contentious—especially once one goes beyond the kind of mathematical reasoning out of which classical logic arose. One of these was the principle of bivalence: that every (declarative) sentence is either true or false. In the 1920s the first many-valued logics

were produced by Jan Łukasiewicz, Emil Post, Tarski, and others. In many-valued logics, sentences can be assumed to be neither true nor false, both true and false, have an infinity of degrees of truth, and so on.

Another assumption that is packed into classical logic is truth-functionality: that the truth value of a compound sentence is a function of the truth values of its parts. This is obviously not true of modal notions, and in the 1920s Clarence Irving Lewis presented in axiomatic form the first modern systems of modal logic. Modal logic was given an enormous boost with the discovery of world-semantics by, in particular, Saul Kripke in the 1960s. This allowed for the production of logics for other non-truth-functional notions (so called intentional logics), such as tense-operators (by Arthur Prior), epistemic and doxastic notions (by Jaako Hintikka), and deontic notions (by Henrik von Wright).

Another early critique of classical logic was provided by mathematical intuitionists, such as Luitzen Brouwer and Arend Heyting, who, driven by the view that existence should not be asserted unless people can construct the object in question, produced a system of formal logic in which a number of propositional and quantifier inferences that are valid in classical logic fail.

In the second half of the century, various critics of classical logic attacked the account of the (material) conditional it employs (as had Lewis). This produced the relevant logics of Alan Anderson and Nuel Belnap, and the conditional logics of Robert Stalnaker and David Lewis. These logics both have world-semantics. The world semantics for relevant logics were produced by, in particular, Richard Routley (later Sylvan) and Robert Meyer. The central feature of such semantics (it can be seen in retrospect) is the deployment of the notion of an impossible world.

The principle of inference of classical logic that everything entails a contradiction came under attack in its own right by logicians in the same period, including Stanisław Jaśkowski, Newton da Costa, and Graham Priest. This produced a number of paraconsistent logics, which may be many-valued, modal, relevant, or of other kinds.

The development of nonclassical logics received further momentum from the advent of computer science and information technology after the 1960s. This produced new constructivist systems (such as linear logic), intentional logics (such as dynamic logic), and paraconsistent logics (such as various resolution systems). Research in Artificial Intelligence has also produced new

epistemic logics, as well as the whole new area of formal non-monotonic (i.e., non-deductive) inference.

Thus, at the start of the twenty-first century there is a wide range of logics embodying different metaphysical presuppositions and potential applications. What to make of this is another matter. Perhaps most obvious is that the revolution in logic that occurred around the turn of the twentieth century was not so much the production of a novel logical theory—important though this was. It was instead the deployment of mathematical techniques to logic in a novel way. This allowed the development of classical logic, but the techniques were so powerful and versatile that they could be used to produce many other logics as well.

Which of all these logics is right, and, indeed, the meaning of that question, are matters to be determined only by detailed philosophical argument. Such arguments have been much part of the philosophical landscape since about the middle of the twentieth century. Indeed, the twenty-first century is seeing disputes in philosophical logic of a depth and acuity not seen since medieval logic. Whatever their outcome, the presence of the multitude of logical systems serves to remind that logic is not a set of received truths, but a discipline in which competing theories concerning validity vie with each other. The case for each theory—including a received theory—has to be investigated on its merits.

KRIPKE AND KRIPKE MODELS. See *Kripke, Saul*

FRIEDMAN AND REVERSE MATHEMATICS. During the second half of the twentieth century, many mathematicians lost interest in the foundations of mathematics. One of the reasons for this decline was an increasingly popular view that general set theory and Gödel-style incompleteness and independence results do not have much effect on mathematics as it is actually practiced. That is, as long as mathematicians study relatively concrete mathematical objects, they can avoid all foundational issues by appealing to a vague hybrid of philosophical positions including Platonism, formalism, and sometimes even social constructivism. Harvey Friedman (born 1948) has continually fought this trend, and in 1984 he received the National Science Foundation's Alan T. Waterman Award for his work on revitalizing the foundations of mathematics.

One of Friedman's methods of illustrating the importance of foundational issues is to isolate pieces of mathematics that either display the incompleteness phenomenon or require substantial set theoretic assumptions and which most mathematicians would agree fall within the scope of the central areas of mathematics. For example, he has created numerous algebraic and geometric systems that make no explicit reference to logic but which, under a suitable coding, contain a logical system to which Gödel's incompleteness theorems apply. Furthermore, these systems look similar to many systems used by mathematicians in their everyday work. Friedman uses these examples to argue that incompleteness cannot be dismissed as a phenomenon that occurs only in overly general foundational frameworks contrived by logicians and philosophers.

Friedman has also done a large amount of work concerning the necessary use of seemingly esoteric parts of Zermelo-Frankel set theory and its extensions. He has found theorems concerning concrete objects in mathematics that require the use of uncountably many iterations of the power set axiom and others that require the use of large cardinal axioms. These investigations have culminated in what Friedman calls Boolean relation theory.

In his 1974 address to the International Congress of Mathematicians, Friedman started the field of reverse

mathematics by suggesting a three-step method for measuring the complexity of the set theoretic axioms required to prove any given theorem  $T$ . First, formalize the theorem  $T$  in some version of set theory. (Typically a formal system called second order arithmetic is used.) Second, find a collection of set theoretic axioms  $S$  which suffices to prove  $T$ . Third, prove the axioms in  $S$  from the theorem  $T$  (while working in a suitably weak base theory). If the third step is successful, then the equivalence between  $S$  and  $T$  shows that  $S$  is the weakest collection of axioms which suffices to prove  $T$ . If the third step fails, then the second step must be repeated until a proof of  $T$  is found using only axioms that can be proved from  $T$ . Because the third step involves proving axioms from theorems as opposed to the usual action of proving theorems from axioms, this type of analysis is now called reverse mathematics. It is frequently possible to draw a number of foundational conclusions concerning a theorem  $T$  once the equivalent collection  $S$  of set theoretic axioms has been isolated.

## LOGIC, NON-CLASSICAL

The purpose of this entry is to survey those modern logics that are often called “non-classical,” classical logic being the theory of validity concerning truth functions and first-order quantifiers likely to be found in introductory textbooks of formal logic at the end of the twentieth century.

For the sake of uniformity I will give a model-theoretic account of the logics. All of the logics also have proof-theoretic characterizations, and in some cases (such as linear logic) these characterizations are somewhat more natural. I will not discuss combinatory logic, which is not so much a non-classical logic as it is a way of expressing inferences that may be deployed for both classical and non-classical logics. I will use  $A, B, \dots$  for arbitrary sentences;  $\wedge, \vee, \neg,$  and  $\rightarrow,$  for the standard conjunction, disjunction, negation, and conditional operators for whichever logic is at issue. “Iff” means “if and only if.” For references see the last section of this article.

### EXTENSIONS VERSUS RIVALS

An important distinction is that between those non-classical logics that take classical logic to be alright as far as it goes, but to need extension by the addition of new connectives, and those which take classical logic to be incorrect, even for the connectives it employs. Call the former *extensions* of classical logic, and the latter *rivals*. Thus modal logics, as now usually conceived, are extensions of classical logic. They agree with classical logic on the extensional connectives (and quantifiers if these are present) but augment them with modal operators. By contrast, intuitionist and relevant logics are more plausibly thought of as rivals. Thus  $A \vee \neg A$  is valid in classical logic but not intuitionist logic, and  $A \rightarrow (B \rightarrow A)$  is valid in classical logic but not relevant logic.

The distinction must be handled with care however. Modern modal logics can be formulated, not with the modal operators, but with the strict conditional,  $\Rightarrow$  (from which modal operators can be defined), as primitive; and  $A \Rightarrow (B \Rightarrow A)$  is not valid. From this perspective modal logic is a rival to classical logic (which is the way it was originally intended). Similarly it is (arguably) possible to add a negation operator,  $\$,$  to relevant logics which behaves as does classical negation. Classical logic is, then, just a part of this logic, identifying the classical  $\neg A$  and  $A \rightarrow B$  with the relevant  $\$A$  and  $\$A \vee B,$  respectively. From this perspective, in a relevant logic,  $\rightarrow$  and  $\neg$  are operators additional to the classical ones, and relevant logic is an extension of classical logic.

What these examples show is that whether or not something is an extension or a rival of classical logic is not a purely formal matter but a matter of how the logic is taken to be applied to informal reasoning. If, in a modal logic, one reads  $A \Rightarrow B$  as “if  $A$  then  $B$ ” then the logic is a rival of classical logic. If one reads  $A \rightarrow B$  as “if  $A$  then  $B$ ” and  $A \Rightarrow B$  as “necessarily, if  $A$  then  $B$ ,” it is an extension. If, in a relevant logic, one reads  $A \rightarrow B$  as “if  $A$  then  $B$ ,” and  $\neg A$  as “it is not the case that  $A$ ,” the logic is a rival to classical logic; if one reads  $\$A \vee B$  as “if  $A$  then  $B$ ” and  $\$A$  as “it is not the case  $A$ ,” it is an extension. (The examples also raise substantial philosophical issues. Thus both a relevant logician and an intuitionist are liable to deny that  $\$$  is a connective with any determinate meaning.)

### MANY-VALUED LOGICS

A central feature of classical logic is its bivalence. Every sentence is exclusively either true (1) or false (0). In *many-valued logics*, normally thought of as rivals to classical logic, there are more than two semantic values. Truth-functionality is, however, maintained; thus the value of a compound formula is determined by the values of its components. Some of the semantic values are *designated*, and a valid inference is one in which, whenever the premises are *designated*, so is the conclusion.

A simple example of a many-valued logic is that in which there are three truth values, 1,  $i,$  0; and the truth functions for the standard connectives may be depicted as follows:

	$\neg$				
*1	0	$\rightarrow$	1	$i$	0
$i$	$i$	1	1	$i$	0
0	1	$i$	1	1	$i$
		0	1	1	1

$\vee$	1	$i$	0	$\wedge$	1	$i$	0
1	1	1	1	1	1	$i$	0
$i$	1	$i$	$i$	$i$	$i$	$i$	0
0	1	$i$	1	0	0	0	0

The only designated value is 1 (which is what the asterisk indicates). This is the Łukaziewicz 3-valued logic,  $\mathcal{L}_3.$  If the middle value of the table for  $\rightarrow$  is changed from

1 to  $i$  we get the Kleene 3-valued logic  $K_3$ . The standard interpretation for  $i$  in this logic is *neither true nor false*. If in addition  $i$  is added as a designated value, we get the paraconsistent logic  $LP$ . The standard interpretation for  $i$  in this is *both true and false*.

$\mathbb{L}_3$  can be generalized to a logic,  $\mathbb{L}_n$ , with  $n$  values, for any finite  $n$ , and even to one with infinitely many values. Thus the continuum-valued Łukasiewicz logic,  $\mathbb{L}_\mathbb{R}$ , has as semantic values all real numbers between 0 and 1 (inclusive). Normally only 1 is designated. If we write the value of  $A$  as  $v(A)$ ,  $v(A \vee B)$  and  $v(A \wedge B)$  are the maximum and minimum of  $v(A)$  and  $v(B)$ , respectively;  $v(\neg A) = 1 - v(A)$ ;  $v(A \rightarrow B) = 1$  if  $v(A) \leq v(B)$  and  $v(A \rightarrow B) = 1 - (v(A) - v(B))$  otherwise. Standardly the semantic values are thought of as degrees of truth (so that 1 is *completely true*). Interpreted in this way  $\mathbb{L}_\mathbb{R}$  is one of a family of many-valued logics called *fuzzy logics*.

**MODAL LOGICS**

Another family of non-classical logics maintains bivalence, but rejects truth-functionality. *Modal logics* augment the connectives of classical logic with the operators  $\Box$  (it is necessarily the case) and  $\Diamond$  (it is possibly the case). The truth-values of  $\Box A$  and  $\Diamond A$  depend on more than just the truth value of  $A$ .

Standard semantics for modal logics invoke a set of (possible) worlds, augmented with a binary relation,  $R$ .  $wRw'$  means, intuitively, that from the state of affairs as it is at  $w$ , the state of affairs as it is at  $w'$  is possible. (In first-order modal logics each world comes also with a domain of quantification.) The extensional connectives are given their usual truth conditions with respect to a world, but if we write the value of  $A$  at world  $w$  as  $v_w(A)$ :

$$v_w(\Box A) = 1, \text{ iff for all } w' \text{ such that } wRw', v_{w'}(A) = 1$$

$$v_w(\Diamond A) = 1, \text{ iff for some } w' \text{ such that } wRw', v_{w'}(A) = 1$$

Validity is defined in terms of truth preservation at all worlds. (This is for *normal* modal logics. *Non-normal* modal logics have also a class of non-normal worlds, at which the truth conditions of the modal operators are different.)

Different modal logics are obtained by putting constraints on  $R$ . If  $R$  is arbitrary we have the system  $K$ . If it is reflexive (validating  $\Box A \rightarrow A$ ), we have  $T$ ; if transitivity is also required (validating  $\Box A \rightarrow \Box \Box A$ ), we have  $S4$ ; if symmetry is added (validating  $A \rightarrow \Diamond \Box A$ ), we have  $S5$ . (Alternatively, in this case,  $R$  may be universal: For all  $w$  and  $w'$ ,  $wRw'$ .) If we have just the condition that every world is related to some world or other (validating  $\Box A \rightarrow \Diamond A$ ), we have  $D$ .

The notion of possibility is highly ambiguous (logical, physical, epistemic, etc.). Arguably, different constraints on  $R$  are appropriate for different notions.

**INTENSIONAL LOGICS**

World semantics have turned out to be one of the most versatile techniques in contemporary logic. Generally speaking, logics that have world-semantics are called *intensional logics* (and are normally thought of as extensions of classical logic). There are many of these in addition to standard modal logics.

$\Box$  may be interpreted as “it is known that”, in which context it is usually written as  $K$  and the logic is called *epistemic logic*. (The most plausible epistemic logic is  $T$ .) It may be interpreted as “it is believed that”, in which case it is usually written as  $B$ , and the logic is called *doxastic logic*. (Though even the logic  $K$  seems rather too strong here, except as an idealization to logically omniscient beings.)  $\Box$  may be interpreted as “it is obligatory to bring it about that”, in which case it is written as  $O$ , and the logic is called *deontic logic*. The standard deontic logic is  $D$ .

One can also interpret  $\Box$  as “it is provable that.” The best-known system in this regard is usually known as  $GL$  and called *provability logic*. This logic imposes just two constraints on the accessibility relation. One is transitivity; the other is that there are no infinite  $R$ -chains, that is, no sequences of the form  $w_0Rw_1, w_1Rw_2, w_2Rw_3, \dots$ . This constraint verifies the principle  $\Box(\Box A \rightarrow A) \rightarrow \Box A$ , but not  $\Box A \rightarrow A$ . The interest of this system lies in its close connection with the way that a provability predicate,  $Prov$ , works in standard systems of formal arithmetic. By Gödel’s second incompleteness theorem, in such logics one cannot prove  $Prov(\langle A \rangle) \rightarrow A$  (where  $\langle A \rangle$  is the numeral for the gödel number of  $A$ ); but Löb’s theorem assures us that if we can prove  $Prov(\langle A \rangle) \rightarrow A$  we can prove  $A$ , and so  $Prov(\langle A \rangle)$ . It is this idea that is captured in the characteristic principle of  $GL$ .

Another possibility is to interpret  $\Box$  and  $\Diamond$  as, respectively, ‘it will always be the case that,’ and ‘it will be the case at some time that.’ In this context the operators are normally written as  $G$  and  $F$ , and the logic is called *tense logic*. In the world-semantics for tense logics, worlds are thought of as times, and the accessibility relation,  $R$ , is interpreted as a temporal ordering. In these logics there are also past-tense operators:  $H$  and  $P$  (“it has always been the case that” and “it was the case at some time that,” respectively). These are given the reverse truth conditions. Thus for example:

$$v_w(HA)=1, \text{ iff for all } w' \text{ such that } w'Rw, v_w(A)=1$$

The past and future tense operators interact in characteristic ways (e.g.,  $A \rightarrow HFA$  is logically valid). The basic tense logic,  $K_p$ , is that obtained when  $R$  is arbitrary. As with modal logics, stronger systems are obtained by adding constraints on  $R$ , which can now represent the ideas that time is dense, has no last moment, and so on.

Of course it is not necessary to have just one family of intensional operators in a formal language: One can have, for example, modal and tense operators together. Each family will have its own accessibility relation, and these may interact in appropriate ways. Systems of logic with more than one family of modal operators are called *multi-modal*. One of the most important multi-modal logics is *dynamic logic*. In this there are operators of the form  $[\alpha]$  and  $\langle \alpha \rangle$ , each with its own accessibility relation,  $R_\alpha$ . In the semantics of dynamic logic, the worlds are thought of as states of affairs or of a computational device. The  $\alpha$ s are thought of as (non-deterministic) actions or programs, and  $wR_\alpha w'$  is interpreted to mean that starting in state  $w$  and performing the action  $\alpha$  (or running the program  $\alpha$ ) can take one to the state  $w'$ . Thus  $[\alpha] A$  ( $\langle \alpha \rangle A$ ) holds at state  $w$ , just if performing  $\alpha$  at  $w$  will always (may sometimes) lead to a state in which  $A$  holds. The actions themselves are closed under certain operations. In particular, if  $\alpha$  and  $\beta$  are actions, so are  $\alpha\beta$  (perform  $\alpha$  and then perform  $\beta$ );  $\alpha \cup \beta$  (perform  $\alpha$  or perform  $\beta$ , non-deterministically);  $\alpha^*$  (perform  $\alpha$  some finite number of times, non-deterministically). There is also an operator,  $?$  (“test whether”), which takes sentences into programs. The corresponding accessibility relations are:  $xR_{\alpha\beta}y$  iff for some  $z$ ,  $xR_\alpha z$  and  $zR_\beta y$ ;  $xR_{\alpha \cup \beta}y$  iff  $xR_\alpha y$  or  $xR_\beta y$ ;  $xR_{\alpha^*}y$  iff for some  $x=x_1, x_2, \dots, x_n=y$ ,  $x_0R_\alpha x_1, x_1R_\alpha x_2, \dots, x_{n-1}R_\alpha x_n$ ;  $xR_{A?}y$  iff ( $x=y$  and  $v_x(A)=1$ ). Because of the  $*$  operator, dynamic logic can express the notion of finitude in a certain sense. This gives it some of the expressive strength of second-order logic.

### CONDITIONAL LOGICS

Another family of logics of the intentional variety was triggered by some apparent counter-examples to the following inferences:

$$A \rightarrow B \vdash (A \wedge C) \rightarrow B$$

$$A \rightarrow B, B \rightarrow C \vdash A \rightarrow C$$

$$A \rightarrow B \vdash \neg B \rightarrow \neg A$$

which are valid for the material conditional. (For example: “If you strike this match it will light; hence if you strike this match and it is under water it will light.”) Log-

ics of the conditional that invalidate such principles are called *conditional logics*. Such logics add an intentional conditional operator,  $>$ , to the language. In the semantics there is an accessibility relation,  $R_A$ , for every sentence,  $A$  (or one,  $R_x$ , for every proposition, that is, set of worlds,  $X$ ). Intuitively  $wR_A w'$  iff  $w'$  is a world which  $A$  holds but is, *ceteris paribus*, the same as  $w$ . The truth conditions for  $>$  are:

$$v_w(A > B)=1 \text{ iff for all } w' \text{ such that } wR_A w', v_w(B)=1$$

The intuitive meaning of  $R$  motivates the following constraints:

$$wR_A w' \text{ then } v_w(A)=1$$

$$\text{if } v_w(A)=1, \text{ then } wR_A w$$

Stronger logics in the family are obtained by adding further constraints to the accessibility relations. A standard way of specifying these is in terms of “similarity spheres”—neighbourhoods of a world containing those worlds that have a certain degree of similarity to it.

The natural way of taking a conditional logic is as a rival to classical logic (giving a different account of the conditional). Some philosophers, however, distinguish between indicative conditionals and subjunctive/counterfactual conditionals. They take the indicative conditional to be the material conditional of classical logic, and  $>$  to be the subjunctive conditional. Looked at this way conditional logics can be thought of as extensions of classical logic.

### INTUITIONIST LOGIC

There are a number of other important non-classical logics that, though not presented originally as intentional logics, can be given world semantics. One of these is *intuitionist logic*. This logic arose out of a critique of Platonism in the philosophy of mathematics. The idea is that one cannot define truth in mathematics in terms of correspondence with some objective realm, as in a traditional approach. Rather one has to define it in terms of what can be proved, where a proof is something that one can effectively recognize as such. Thus, semantically, one has to replace standard truth-conditions with proof-conditions, of the following kind:

$$A \vee B \text{ is provable when } A \text{ is provable or } B \text{ is provable.}$$

$$\neg A \text{ is provable when it is provable that there is no proof of } A$$

$$\exists x A(x) \text{ is provable when we can effectively find an object, } n, \text{ such that } A(n) \text{ is provable}$$

Note that in the case of negation we cannot say that  $\neg A$  is provable when  $A$  is not provable: We have no effective way of recognizing what is not provable; similarly, in the case of the existential quantifier, we cannot say that  $\exists xA(x)$  is provable when there is some  $n$  such that  $A(n)$  is provable: we may have no effective way of knowing whether this obtains.

Proceeding in this way produces a logic that invalidates a number of the principles of inference that are valid in classical logic. Notable examples are:  $A \vee \neg A$ ,  $\neg \neg A \rightarrow A$ ,  $\neg \forall xA(x) \rightarrow \exists x \neg A(x)$ . For the first of these, there is no reason to suppose that for any  $A$  we can find a proof of  $A$  or a proof that there is no proof of  $A$ . For the last, the fact that we can show that there is no proof of  $\forall xA(x)$  does not mean that we can effectively find an  $n$  such that  $A(n)$  can be proved.

In the world-semantics for intuitionist logic, interpretations have essentially the structure of an S4 interpretation. The worlds are interpreted as states of information (things proved), and the accessibility relation represents the acquisition of new proofs. We also require that if  $v_w(A)=1$  and  $wRw'$ ,  $v_{w'}(A)=1$  (no information is lost), and if  $x$  is in the domain of quantification of  $w$  and  $wRw'$  then  $x$  is in the domain of quantification of  $w'$  (no objects are undiscovered). Corresponding to the provability conditions we have:

$$v_w(A \vee B) = 1 \text{ iff } v_w(A) = 1 \text{ or } v_w(B) = 1$$

$$v_w(\neg A) = 1 \text{ iff for all } w' \text{ such that } wRw', v_{w'}(A) = 0$$

$$v_w(\exists xA(x)) = 1 \text{ iff for all } n \text{ in the domain of } w, v_w(A(n)) = 1$$

Unsurprisingly, given the above semantics, there is a translation of the language of intuitionism into quantified S4 that preserves validity.

Another sort of semantics for intuitionism takes semantic values to be the open sets of some topology. If the value of  $A$  is  $x$ , the value of  $\neg A$  is the interior of the complement of  $x$ .

### RELEVANT LOGIC

Another logic standardly thought of as a rival to classical logic is *relevant* (or *relevance*) logic. This is motivated by the apparent incorrectness of classical validities such as:  $A \rightarrow (B \rightarrow B)$ ,  $(A \wedge \neg A) \rightarrow B$ . A (propositional) relevant logic is one in which if  $A \rightarrow B$  is a logical truth  $A$  and  $B$  share a propositional parameter. There are a number of different kinds of relevant logic, but the most common has a world-semantics. The semantics differs in two major ways from the world semantics we have so far met.

First it adds to the possible worlds a class of logically impossible worlds. (Though validity is still defined in terms of truth-preservation over possible worlds.) In possible worlds the truth conditions of  $\rightarrow$  are as for  $\rightarrow$  in S5:

$$v_w(A \rightarrow B) = 1 \text{ iff for all } w' \text{ (possible and impossible) such that } v_{w'}(A) = 1, v_{w'}(B) = 1$$

In impossible worlds the truth conditions are given differently, in such a way that logical laws such as  $B \rightarrow B$  may fail at the world. This may be done in various ways, but the most versatile technique employs a three-place relation,  $S$ , on worlds. If  $w$  is impossible, we then have:

$$v_w(A \rightarrow B) = 1 \text{ iff for all } x, y \text{ such that } Swxy, \text{ if } v_x(A) = 1, v_y(B) = 1$$

This clause can be taken to state the truth conditions of  $\rightarrow$  at all worlds, provided that we add the constraint that, for possible  $w$ ,  $Swxy$  iff  $x=y$ . With no other constraints on  $S$ , this gives the basic (positive) relevant logic,  $B$ . Additional constraints on  $S$  give stronger logics in the family. Typical constraints are:

$$\exists x(Sabx \text{ and } Sxcd) \Rightarrow \exists y(Sacy \text{ and } Sbyd)$$

$$Sabc \Rightarrow Sbac$$

$$Sabc \Rightarrow \exists x(Sabx \text{ and } Sxbc)$$

Adding all three gives the (positive) relevant logic,  $R$ . Adding the first two gives  $RW$ ,  $R$  minus Contraction ( $A \rightarrow (A \rightarrow B) \vdash A \rightarrow B$ ). The intuitive meaning of  $S$  is, at the time of this writing, philosophically moot.

The second novelty of the semantics is in its treatment of negation. It is necessary to arrange for worlds where  $A \wedge \neg A$  may hold. This may be done in a couple of ways. The first is to employ the Routley  $*$  operator. Each world,  $w$ , comes with a “mate,”  $w^*$  (subject to the constraint that  $w^{**}=w$ , to give Double Negation). We then have:

$$v_w(\neg A) = 1 \text{ iff } v_{w^*}(A) = 0$$

(If  $w=w^*$ , this just delivers the classical truth conditions.) Alternatively, we may move to a four-valued logic in which the values at a world are *true only*, *false only*, *both*, *neither* ( $\{1\}$ ,  $\{0\}$ ,  $\{1,0\}$ ,  $\emptyset$ ). We then have:

$$1 \in v_w(\neg A) \text{ iff } 0 \in v_w(A)$$

$$0 \in v_w(\neg A) \text{ iff } 1 \in v_w(A)$$

The semantics of relevant logic can be extended to produce a (relevant) *ceteris paribus* conditional,  $>$ , of the kind found in conditional logics, by adding the appropriate binary accessibility relations.

### DISTRIBUTION-FREE LOGICS

There are some logics in the family of relevant logics for which the principle of Distribution,  $A \wedge (B \vee C) \vdash (A \wedge B) \vee (A \wedge C)$ , fails. To achieve this the truth conditions for disjunction have to be changed. In an interpretation, let  $[A]$  be the set of worlds at which  $A$  holds. Then the usual truth conditions for disjunction can be written:

$$v_w(A \vee B) = 1 \text{ iff } w \in [A] \cup [B]$$

To invalidate Distribution, the semantics are augmented by a closure operator,  $\mathfrak{C}$ , on sets of worlds,  $x$ , satisfying the following conditions:

$$X \subseteq \mathfrak{C}(X)$$

$$\mathfrak{C}\mathfrak{C}(X) = \mathfrak{C}X$$

$$\text{if } X \subseteq Y \text{ then } \mathfrak{C}(X) \subseteq \mathfrak{C}(Y)$$

The truth conditions of disjunction can now be given as:

$$v_w(A \vee B) = 1 \text{ iff } w \in \mathfrak{C}([A] \cup [B])$$

Changing the truth conditions for disjunction in *RW* in this way (and using the Routley  $*$  for negation) gives linear logic (*LL*). *LL* is usually formulated with some extra intentional connectives, especially an intentional conjunction and disjunction. These connectives can be present in standard relevant logics too. Intuitionist, relevant, and linear logics all belong to the family of *substructural logics*. Proof-theoretically, these logics can be obtained from a sequent-calculus for classical logic by weakening the structural rules (especially Weakening and Contraction).

Another logic in which distribution fails is *quantum logic*. The thought here is that it may be true (verifiable) of a particle that it has a position and one of a range of momenta, but each disjunct attributing to it that position and a particular momentum is false (unverifiable). The states of a quantum system are canonically thought of as members of a Hilbert space. In the world-semantics for quantum logic, the space of worlds is taken to be such a space, and sentences are assigned closed subsets of this.  $[A \wedge B] = [A] \cap [B]$ ,  $[A \vee B] = \mathfrak{C}([A] \cup [B])$ , where  $\mathfrak{C}(X)$  is the smallest closed space containing  $X$ ; and  $[\neg A] = [A]^+$ .  $X^+$  is the space comprising all those states that are orthogonal to members of  $X$ . (It satisfies the conditions:  $X = X^{++}$ , if  $X \subseteq Y$  then  $Y^+ \subseteq X^+$ , and  $X \cap X^+ = \emptyset$ .) In quantum logic  $A \rightarrow B$  can be defined in various ways. Perhaps the most plausible is as  $\neg A \vee (A \wedge B)$ . (The subspaces of a Hilbert space also have the structure of a partial Boolean algebra. Such an algebra is determined by a family of Boolean algebras collapsed under a certain equivalence relation,

which is a congruence relation on the Boolean operators. Partial Boolean algebras can be used to provide a slightly different quantum logic.)

### PARACONSISTENT LOGICS

Before we turn to quantifiers there is one further kind of logic to be mentioned: *paraconsistent logic*. Paraconsistent logic is motivated by the thought we would often seem to have to reason sensibly from information, or about a situation, which is inconsistent. In such a case, the principle  $A, \neg A \vdash B$  (*ex falso quodlibet sequitur*, Explosion), which is valid in classical logic, clearly makes a mess of things. A paraconsistent logic is precisely one where this principle fails.

There are many different families of paraconsistent logics—as many as there are ways of breaking Explosion. Indeed many of the techniques we have already met in this article can be used to construct a paraconsistent logic. The 3-valued logic *LP* is paraconsistent, as is the Łukasiewicz continuum-valued logic, provided we take the designated values to contain 0.5. The ways that negation is handled in relevant logic also produce paraconsistent logics, as long as validity is defined over a class of worlds in which  $A$  and  $\neg A$  may both hold. Another approach (*discussive logic*) is to employ standard modal logic and to take  $A$  to hold in an interpretation iff  $A$  holds at some world of the interpretation. In this approach the principle of Adjunction ( $A, B \vdash A \wedge B$ ) will generally fail, since  $A$  and  $B$  may each hold at a world, whilst  $A \wedge B$  may not. Another approach (“positive plus”) is to take any standard positive (negation free) logic, and add a non-truth-functional negation—so that the values of  $A$  and  $\neg A$  are assigned independently. In these logics, the principle of Contraposition ( $A \leftrightarrow B \vdash \neg B \leftrightarrow \neg A$ ) will generally fail. Yet another is to dualise intuitionist logic. In particular one can take semantic values to be the closed sets in some topology. If the value of  $A$  is  $X$ , the value of  $\neg A$  is the closure of the complement of  $X$ .

### SECOND-ORDER QUANTIFICATION

We now turn to the issue of quantification. In classical logic there are quantifiers  $\forall$  and  $\exists$ . These range over a domain of objects, and  $\forall x A(x) \vdash \exists x A(x)$  holds if every [some] object in the domain of quantification satisfies  $A(x)$ . All the propositional logics we have looked at may be extended to first-order logics with such quantifiers. Other non-classical logics may be obtained by adding to these (or replacing these with) different kinds of quantifiers.

Perhaps the most notable of these is second-order logic. In this there are bindable variables ( $X, Y, \dots$ ) that can stand in the place where a monadic first-order predicate can stand and which range over sets of objects in the first-order domain—canonically all of them. (There can also be variables that range over the  $n$ -ary relations on that domain, for each  $n$ , as well as variables that range over  $n$ -place functions. The second-order extension of classical logic is much stronger than the first-order version. It can provide for a categorical axiomatization of arithmetic and consequently is not itself axiomatizable.

Monadic second-order quantifiers can also be given a rather different interpretation, as plural quantifiers. The idea here is to interpret  $\exists X Xa$  not as “There is a set such that  $a$  is a member of it,” but as “There are some things such that  $a$  is one of them.” The proponents of plural quantification argue that such quantification is not committed to the existence of sets.

### OTHER SORTS OF QUANTIFIERS

There are many other non-classical quantifiers. For example one can have a binary quantifier of the form  $Mx(A(x), B(x))$ , “most  $A$ s are  $B$ s.” This is true in a finite domain if more than half the things satisfying  $A(x)$  satisfy  $B(x)$ . It is not reducible to a monadic quantifier plus a propositional connective.

Another sort of quantifier is a cardinality quantifier. The quantifier “there exist exactly  $n$  things such that” can be defined in first-order logic with quantification and identity in a standard way. The quantifier “there is a countable number of things such that” (or its negation, “there is an uncountable number of things such that”) cannot be so defined—let alone the quantifier “there are  $\kappa$  things such that,” for an arbitrary cardinal,  $\kappa$ . Such quantifiers can be added, with the obvious semantics. These quantifiers extend the expressive power of the language towards that of second-order logic—and beyond.

Another kind of quantifier is the branching quantifier. When, in first-order logic, we write:

$$\forall x_1 \exists y_1 \forall x_2 \exists y_2 A(x_1, x_2, y_1, y_2)$$

$y_2$  is in the scope of  $x_1$ , and so its value depends on that of  $x_1$ . To express non-dependence one would normally need second-order quantification, thus:

$$\exists f_1 \forall x_1 \exists f_2 \forall x_2 A(x_1, x_2, f_1(x_1), f_2(x_2))$$

But we may express it equally by having the quantifiers non-linearly ordered, thus:

$$\forall x_1 \exists y_1 \forall x_2 \exists y_2 A(x_1, x_2, y_1, y_2)$$

As this would suggest, branching quantifiers have something of the power of second-order logic.

A quite different kind of quantifier is the substitutional quantifier. For this there is a certain class of names of the language,  $C$ .  $\Pi x A(x)$  [ $\Sigma x A(x)$ ] holds iff for every [some]  $c \in C$ ,  $A(c)$  holds. This is not the same as standard (objectual) quantification, since some objects in the domain may have no name in  $C$ ; but first-order substitutional quantifiers validate the same quantificational inferences as first-order objectual quantifiers. Note that the notion of substitutional quantification makes perfectly good sense for any syntactically well-defined class, including predicates (so we can have second-order substitutional quantification) or binary connectives (so that  $\Sigma x(AxB)$  can make perfectly good sense).

Finally in this category comes free quantifiers. It is standard to interpret the domain of objects of quantification (at a world) as comprising the objects that exist (at that world). It is quite possible, however, to think of the domain as containing a bunch of objects, some of which exist, and some of which do not. Obviously this does not change the formal properties of the quantifiers. But if one thinks of the domain in this way one must obviously not read  $\exists x$  as ‘there exists an  $x$  such that’; one has to read it simply as ‘for some  $x$ ’. Given this set-up, however, it makes sense to have existentially loaded quantifiers,  $\forall^E$  and  $\exists^E$ , such that  $\forall^E A(x)$  [ $\exists^E A(x)$ ] holds (at a world) iff all [some] of the existent objects (at the world) satisfy  $A(x)$ . If there is a monadic existence predicate,  $E$ , these quantifiers can be defined in the obvious way, as (respectively):  $\forall x(Ex \rightarrow A(x))$  and  $\exists x(Ex \wedge A(x))$ . Clearly, existentially loaded quantifiers will not satisfy some of the standard principles of quantification, such as  $\forall^E x A(x) \rightarrow A(c)$ ,  $A(c) \rightarrow \exists x^E A(x)$  (since the object denoted by ‘ $c$ ’ may not exist). Some logics do not have the existentially unloaded quantifiers, just the loaded ones. These are usually called *free logics*.

### NON-MONOTONIC LOGICS

It remains to say a word about one other kind of logic that is often categorized as non-classical. In all the logics we have been considering so far:

$$\text{if } \Sigma \vdash A \text{ then } \Sigma \cup \Delta \vdash A$$

(where  $\Sigma$  and  $\Delta$  are sets of formulas): Adding extra premises makes no difference. This is called *monotonicity*. Logics in which this principle fails are called *non-monotonic logics*. Non-monotonic inferences can be thought of as inferences that are made with certain default assumptions. Thus I am told that something is a bird, and I infer that it can fly. Since most birds fly this is a reasonable con-

clusion. If, however, I also learn that the bird weighs 20 kg. (and so is an emu or an ostrich), the conclusion is no longer a reasonable one.

There are many kinds of non-monotonic logics, depending on what kind of default assumption is implemented, but there is a common structure that covers many of them. Interpretations,  $I$ , of the language come with a strict partial ordering,  $>$  (often called a *preference ordering*). Intuitively,  $I_1 > I_2$  means that the situation represented by  $I_1$  is more normal (in whatever sense of normality is at issue) than that represented by  $I_2$ . (In particular cases it may be reasonable to suppose that  $>$  has additional properties.)  $I$  is a *most normal model* of  $\Sigma$  iff every  $B \in \Sigma$  holds in  $I$ , and there is no  $J > I$  for which this is true.  $A$  follows from  $\Sigma$  iff  $A$  holds in every most normal model of  $\Sigma$ . As is clear a most normal model of  $\Sigma$  is not guaranteed to be a most normal model of  $\Sigma \cup \Delta$ . Hence monotonicity will fail. As might be expected there is a close connection between non-monotonic logics and conditional logics, in which the inference  $A \rightarrow B \vdash (A \wedge C) \rightarrow B$  fails. Though non-monotonic logic has come to prominence in modern computational logic, it is just a novel and rigorous way of looking at the very traditional notion of non-deductive (inductive, ampliative) inference.

## HISTORY, PERSONS, REFERENCES

We conclude this review of non-classical logics by putting the investigations discussed above in their historical context. References that may be consulted for further details are also given at the end of each paragraph. For a general introduction to propositional non-classical logics, see Priest (2001). Haack (1996) is a discussion of some of the philosophical issues raised by non-classical logics.

The first modern many-valued logics, the  $\mathbb{L}_n$  family, were produced by Jan Łukasiewicz in the early 1920s. (Emil Post also produced some many-valued logics about the same time.) Łukasiewicz's major philosophical concern was Aristotle's argument for fatalism. In this context he suggested a many-valued analysis of modality. Logics of the both/neither kind were developed somewhat later. Canonical statements of  $K_3$  and  $LP$  were given (respectively) by Stephen Kleene in the 1950s and Graham Priest in the 1970s.  $\mathbb{L}_\infty$  was first published by Łukasiewicz and Alfred Tarski in 1930. The intensive investigation of fuzzy logics and their applications started in the 1970s. A notable player in this area was Lotfi Zadeh. (Rescher 1969, Urquhart 2001–, Hájek 1998, Yager and Zadeh 1992.)

Modern modal logics were created in an axiomatic form by Clarence Irving Lewis in the 1920s. Lewis's concern was the paradoxes of the material conditional, and he

suggested the strict conditional as an improvement. Possible-world semantics for modal logics were produced by a number of people in the 1960s, but principally Saul Kripke. The semantics made possible the systematic investigation of the rich family of modal logics. (Bull and Segerberg 2001–, Garson 2001–, Hughes and Cresswell 1996.)

The idea that the techniques of modal logics could be applied to notions other than necessity and possibility occurred to a number of people around the middle of the twentieth century. Tense logics were created by Arthur Prior, epistemic and doxastic logic were produced by Jaakko Hintikka, and deontic logics by Henrik von Wright. Investigations of provability logic were started in the 1970s by George Boolos and others. Dynamic logic was created by Vaughn Pratt and other logicians particularly interested in computation, including David Harrel, in the 1970s. (van Benthem 1988, Burgess 2001–, Thomason 2001–, Meyer 2001–, Åqvist 2001–, Boolos 1993, Harrel, Kozen, and Tiuryn 2001–.)

Conditional logics (with “sphere semantics”) were proposed by David Lewis and Robert Stalnaker in the 1970s. They were formulated as multi-modal logics by Brian Chellas and Krister Segerberg a few years later (Harper, Stalnaker, and Pearce 1981, Nute and Cross 2001–).

The intuitionist critique of classical mathematics was started by Luitzen Egbertus Jan Brouwer in the early years of the twentieth century. This generated a novel kind of mathematics: intuitionist mathematics. Intuitionist logic, as such, was formulated by Arend Heyting and Andrei Kolmogorov in the 1920s. The intuitionist critique of mathematical realism was extended to realism in general by Michael Dummett in the 1970s (Dummett 1977, van Dalen 2001–).

Systems of relevant logic, in axiomatic form, came to prominence in the 1960s because of the work of Alan Anderson, Nuel Belnap and their students. World-semantics were produced by a number of people in the 1970s, but principally Richard Routley (later Sylvan) and Robert Meyer. The semantics made possible the investigation of the rich family of relevant logics. The four-valued semantics for negation is due to J. Michael Dunn (Dunn and Restall 2001–, Mares 2004).

Linear logic was produced by Jean-Yves Girard in the 1980s. Although many members of the class of sub-structural logics had been studied before, the fact that they could be viewed in a uniform proof-theoretic way, was not appreciated until the late 1980s. The formulation of quantum logic in terms of Hilbert spaces is due, essentially, to George Birkhoff and John von Neumann in the

1930s. The use of an abstract closure operator to give the semantics for non-distributive logics is due to Greg Restall. (Troelstra 1992, Restall 2000, Paoli 2002, Chihara and Giuntini 2001, Hughes 1989).

The first paraconsistent logic (discussive logic) was published by Stanisław Jaskowski in 1948. Other non-adjunctive logics were later developed in the 1970s by Peter Schotch and Raymond Jennings. Newton da Costa produced a number of different paraconsistent logics and applications, starting with positive-plus logics in the 1960s. The paraconsistent aspects of relevant logic were developed by Priest and Routley in the 1970s. (Priest, Routley and Norman 1989, Priest 2001, Carnielli et al. 2001, Mortensen 1995).

Second-order quantification goes back to the origins of classical logic in the work of Gottlob Frege and Bertrand Russell. Its unaxiomatizability put it somewhat out of fashion for a number of years, but it made a strong come-back in the last years of the twentieth century. The notion of plural quantification was made popular by George Boolos in the 1980s. (Shapiro 1991, 2001–; Boolos 1984).

Quantifier phrases other than “some *A*” and “all *A*” are pervasive in natural language; and since Frege provided an analysis of the quantifier many different kinds have been investigated by linguists and logicians. Branching quantifiers were proposed by Jaakko Hintikka in the 1970s. Substitutional quantification came to prominence in the 1960s, put there particularly in connection with quantification into the scope of modal operators by Ruth Barcan Marcus. It was treated with suspicion for a long time, but was eventually given a clean bill of health by Kripke. Free logics were first proposed in the 1960s, by Karel Lambert and others (van der Does and van Eijck 1996, Barwise 1979, Kripke 1976, Bencivenga 2001–).

Non-monotonic logics started to appear in the logic/computer-science literature in the 1970s. There are many kinds. The fact that many of them could be seen as logics with normality orderings started to become clear in the 1980s (Shoham, 1988; Crocco, Fariñas del Cerro, and Herzig 1995; Brewka, Dix, and Konolige, 1997).

## LOGIC, TRADITIONAL

In logic, as in other fields, whenever there have been spectacular changes and advances, the logic that was current in the preceding period has been described as "old" or "traditional," and that embodying the new material has been called "new" or "modern." The Stoics described themselves as "moderns" and the Aristotelians as devotees of the "old" logic, in the later Middle Ages the more adventurous writers were called *moderni*, and since the latter part of the nineteenth century the immensely

expanded logic that has developed along more or less mathematical lines ("mathematical logic," "symbolic logic," "logistics") has been contrasted with the "traditional" logic inherited from the sixteenth and seventeenth centuries. In every case the logic termed "old" or "traditional" has been essentially Aristotelian, but with a certain concentration on the central portion of the Aristotelian *corpus*, the theory of categorical syllogism—the logic of Aristotle himself having been rather less circumscribed than that of the "tradition," especially of the sixteenth to the nineteenth century.

### THE LOGIC OF TERMS

To begin with the categorical syllogism, an inference, argument, or syllogism (traditionally, all arguments are assumed to be syllogistic) is a sequence of propositions (premises followed by a conclusion), such as "All animals are mortal; all men are animals; therefore, all men are mortal." Propositions, in turn, are built up from terms—for example, "animals," "mortals," "men." The traditional order of treatment, therefore, begins with the study of terms (or, in writers with a psychological or epistemological bias, ideas) and goes on to the study of propositions (or judgments), concluding with that of syllogisms (or inferences).

The terms from which the propositions principally studied in the traditional logic are built up are common nouns (*termini communes*), such as "man" and "horse," although some attention is also paid to singular terms, such as "Socrates," "this man," and "the man next door." Much of the traditional theory is devoted to the arrangement of common nouns in an order of comprehensiveness, and here a distinction is made between two aspects of their functioning—their "extension" (as the logicians of Port-Royal called it) or "denotation" (John Stuart Mill) and their "intension" (Sir William Hamilton), "comprehension" (Port-Royalists), or "connotation" (Mill). The extension or denotation of a common noun is the set of individuals to which it applies, its intension or connotation the set of attributes that an individual must possess for the common noun to be applicable to it. Thus, the connotation of the term *man* consists of the attributes of being an animal, being rational, and perhaps possessing a certain bodily form; its denotation consists of all objects that possess these attributes.

Broadly, the connotation of a term is its meaning, the denotation its application. The analysis of the meaning of a term is described as definition, and the breaking up of the set of objects to which it applies into subsets is described as division. The subsets of the set of individuals to which a

given term applies are called the species of the genus denoted by the given term. The attribute that marks off a particular species from others of the same genus is called its differentia. The species is said by scholastic logicians to “fall under” its genus, and the standard way of defining a species is by giving its genus and its differentia.

The ordering of terms into species and genera is often thought of as having an upper and a lower limit. The upper limit, or *summum genus*, will be a broad category such as “thing” (*substantia*)—horses are animals, animals are organisms, organisms are bodies, bodies are things. More abstract terms will come to an end in more abstract categories, such as “quality” or “relation” (scarlet is a species or kind of red, red is a color, color is a quality). The *infima species*, or lower limit, is a more difficult concept. Man, for example, is commonly given as an *infima species*, but are not men divisible into, for instance, dark-haired and fair-haired men? This is answered, from the point of view of intension, by dividing the attributes of an individual into those that constitute its essence or nature and those that are merely accidental, and genuine species are said to be marked off by “essential” attributes only; further subdivisions differentiated by “accidental” attributes, such as the color of a man’s hair, are not counted as genuine species. This distinction is not recognized by some writers. Gottfried Wilhelm Leibniz counted all attributes of an individual as essential, so that someone would not be *that* individual if he were in the least respect different from what he is. At the other extreme, Mill said that “individuals have no essences,” although he had a use for the term *essence* in connection with general terms: It is of the essence of being a man, for example, to be an animal, if being an animal is one of the attributes commonly employed in fixing the application of the word *man*.

An allied doctrine of Mill’s is that the proper names of individuals, by contrast with common nouns, have no connotation, only denotation. We may not be able to think of a named individual without thinking of him as having certain attributes, but the purpose of a proper name is not to convey the fact that he has those attributes but only to identify him as *that* individual. This view has been criticized by various writers, on the ground, among others, that we cannot identify an object at all without knowing at least its *infima species*. Mill has also been criticized for using the same term, “denotation,” both for the application of a common noun and for what is named by a proper name.

Common terms can be simple or complex. Some kinds of complexity are of logical interest—for example, the conjunctive combination exemplified by “blind man” (i.e., what is both blind and human) and the disjunctive

combination exemplified by “man-or-beast.” This kind of complexity is of interest because, for one thing, it links up with the previous topic, a blind man being a species (in the broad though not the narrow sense) of man and a man being a species (again in the broad sense) of man-or-beast (i.e., of animal). Again, the term “son-of-Philip” is compounded of the relative expression “son of” and the proper name “Philip,” and this, too, links with the preceding topic, a son of Philip being a species (in the broad sense) of son. But the logical behavior of complex terms of these types is a topic of modern rather than traditional logic. Even traditional logic, however, has something to say about negative terms, such as “non-man” (i.e., what is not human), as will be shown in what follows.

The distribution of terms is a subject that will be more intelligible after propositions and syllogisms have been considered.

## THE LOGIC OF PROPOSITIONS

**OPPOSITION.** The division of traditional logic called the logic of propositions is not to be confused with what is now called the propositional calculus. The propositional calculus studies the logical behavior of propositions formed from simpler propositions by means of various connectives (for example, “Either all men are liars or no men are”), as opposed to propositions formed not from other propositions but from terms (for example, “No men are liars”). The traditional logic of propositions or judgments, on the other hand, is chiefly concerned with the classification and simpler interrelations of precisely the second class of propositions, although it normally also touches on “compound” or “hypothetical” propositions, without going beyond their simplest types and the simplest inferences involving them.

Propositions not compounded of other propositions are called categorical. This word has the force of “unconditional,” the implied contrast being with forms like “If all that the Bible says is true, all men are mortal” or “Either not all that the Bible says is true, or all men are mortal.” Categoricals have a *subject term* and a *predicate term* (“men” is the subject term and “mortal” the predicate term of “All men are mortal”) and are subdivided in two main ways—according to quantity, into universals (“All men are mortal,” “No men are mortal”) and particulars (“Some men are mortal,” “Some men are not mortal”), and according to quality, into affirmatives (“All men are mortal,” “Some men are mortal”) and negatives (“No men are mortal,” “Some men are not mortal”). These are often displayed in a square, with universals at the top, particulars at the bottom, affirmatives on the left, negatives on the right:

Universal affirmatives are called A-propositions, particular affirmatives I-propositions, universal negatives E-propositions, and particular negatives O-propositions (the vowels being taken from the words *affirmo* and *nego*). Two other “quantities” are commonly mentioned, namely *singular* and *indefinite*. Singular propositions, such as “Socrates is mortal,” are a genuinely distinct type, which we shall touch upon at appropriate points; indefinites, such as “Men are mortal,” seem merely to be universals or particulars in which the quantity is left unstated. The expressions other than terms which enter into these forms are called “syncategorematic”; they are divided into the signs of quantity “all” and “some” and the copulas “is” or “are” and “is not” or “are not.” (“No” is both a sign of quantity and a sign of negation.)

These types of propositions—A, E, I, and O—are the traditional “four forms,” and as a preliminary to logical manipulation it is customary to restate given sentences in some standard way that will make their quantity and quality immediately evident. The forms given above, with “all,” etc., and with plural common nouns for terms, are the most widely used, but it is in some ways less misleading to use “every,” etc., and the terms in the singular—“Every X is a Y,” “No X is a Y,” “Some X is a Y,” “Some X is not a Y.” What is important is to understand that “some” means simply “at least one”; “Some men are mortals” or “Some man is a mortal” must be understood as neither affirming nor denying that more than one man is a mortal and as neither affirming nor denying that all men are (i.e., “some” does *not* mean “only some”).

A square of the type shown earlier is called a *square of opposition*, and propositions with the same terms in the same order may be “opposed” in four ways. Universals of opposite quality (“Every X is a Y,” “No X is a Y”) are said to be *contraries*; these cannot be jointly true. Particulars of opposite quality (“Some X is a Y,” “Some X is not a Y”) are said to be *subcontraries*; these cannot be jointly false. Propositions opposed only in quantity are said to be *subalterns*, the *subalternant* universal implying (without being implied by) the *subalternant* particular (“Every X is a Y” implies “Some X is a Y,” and “No X is a Y” implies “Some X is not a Y”). Propositions opposed in both quantity and quality (“Every X is a Y” and “Some X is not a Y,” and “No X is a Y” and “Some X is a Y”) are *contradictories*;

they cannot be jointly true or jointly false—the truth of a given proposition implies the falsehood of its contradictory; its falsehood implies the contradictory’s truth.

**EQUIPOLLENCE.** Closely connected with the theory of opposition is that of the equipollence of propositions with the same terms in the same order but with negative particles variously placed within them. Since contradictories are true and false under reversed conditions, any proposition may be equated with the simple denial of its contradictory. Thus, “Some X is not a Y” has the same logical force as “Not every X is a Y,” and, conversely, “Every X is a Y” has the force of “Not (some X is not a Y),” or, to give it a more normal English expression, “Not any X is not a Y.” Similarly, “Some X is a Y” has the force of “Not (no X is a Y)” and “No X is a Y” that of “Not (some X is a Y)—that is, “Not any X is a Y.” Also, since “no” conveys universality and negativeness at once, “No X is a Y” has the force of “Every X is not-a-Y,” and, conversely, “Every X is a Y” has the force of “No X is not-a-Y.” Writers with an interest in simplification have seen in these equivalences a means of dispensing with all but one of the signs “every,” “some,” and “no.” Thus the four forms may all be expressed in terms of “every,” as follows: “Every X is a Y” (A), “Every X is not-a-Y” (E), “Not every X is not-a-Y” (I), “Not every X is a Y” (O).

Of singular propositions all that need be said at this point is that they divide into affirmatives (“Socrates is mortal,” “This is a man,” “This man is mortal”) and negatives (“Socrates is not mortal,” etc.) and that when their subject is formed by prefixing “this” to a common noun (as in “This man is mortal”), the singular form is implied by the corresponding universal (“Every man is mortal”) and implies the corresponding particular (“Some man is mortal”). Some of the traditional logicians attempted to assimilate singular propositions to particulars, some to assimilate them to universals, but these attempts are not very impressive, and it is one of the few merits of the Renaissance logician Peter Ramus that he and his followers treated them consistently as a type of their own.

**CONVERSION OF PROPOSITIONS.** With regard to pairs of propositions of the same form and with the same terms, but in reverse order—for example, “No X is a Y” and “No Y is an X”—these are sometimes equivalent and sometimes not. Where they are, as in the case just given, they are said to be *converses* of one another, and the forms are said to be convertible. E and I are convertible; A and O are not. That every man is an animal, for example, does not imply that every animal is a man, and that some animal is not a horse does not imply that some horse is not

an animal. Conversion, the inference from a given proposition to its converse (“Some men are liars; therefore, some liars are men”), is a type of immediate inference—that is, inference involving only one premise (as opposed, for instance, to syllogisms, which have two). Other immediate inferences are those from a given proposition to an “equipollent” form in the sense of the preceding section (for example, “Every man is mortal; therefore, not any man is not”) and from a subalternant universal to its subalternant particular (“Every man is mortal; therefore, some man is mortal”).

The conversion just described is “simple” conversion; with universals (even A, though it is not “simply” convertible) there is also a conversion *per accidens*, or *subaltern conversion*—that is, a legitimate inference to the corresponding particular form with its terms transposed. Thus, although “Every man is an animal” does not imply that every animal is a man, it does imply that some animal is.

Other forms of immediate inference arise when negative terms are introduced. The simultaneous interchange and negation of subject and predicate is called *conversion by contraposition*, or simply *contraposition*. It is a valid process with A’s and O’s, not with E’s and I’s. (“Every man is an animal” implies “Every non-animal is a non-man”—whatever is not an animal is not a man—and “Not every animal is a man” implies “Not every non-man is a non-animal,” but “No horse is a man” does not imply “No non-man is a non-horse”; “Some X is a Y” is true and “Some non-Y is a non-X” false if the X’s and the Y’s overlap and between them exhaust the universe.) All of the four forms may be “obverted” (Alexander Bain’s term)—that is, have their quality changed and the predicate negated (“Every X is a Y” implies “No X is a non-Y,” “No X is a Y” implies “Every X is a non-Y,” and similarly with the particulars). A variety of names are given to the results of repeated successive obversion and conversion.

THE LOGIC OF SYLLOGISM

A categorical syllogism is the inference of one categorical proposition, the conclusion, from two others, the premises, each premise having one term in common with the conclusion and one term in common with the other premise—for example:

Every animal is mortal;  
 Every man is an animal;  
 Therefore, every man is mortal.

The predicate of the conclusion (here “mortal”) is called the major term, and the premise that contains it (here written first) the major premise. The subject of the

conclusion (“man”) is the minor term, and the premise that contains it (here written second) the minor premise. The term common to the two premises (“animal”) is the middle term.

FIGURES AND MOODS. Syllogisms are divided into four figures, according to the placing of the middle term in the two premises. In the first figure the middle term is subject in the major premise and predicate in the minor; in the second figure predicate in both; in the third figure subject in both; in the fourth predicate in the major and subject in the minor. The following schemata, with P for the major term, S for the minor, and M for the middle, sum up these distinctions:

Figure 1	Figure 2	Figure 3	Figure 4
$\frac{M-P}{S-M}$	$\frac{P-M}{S-M}$	$\frac{M-P}{M-S}$	$\frac{P-M}{M-S}$
$\frac{S-P}{S-P}$	$\frac{S-P}{S-P}$	$\frac{S-P}{S-P}$	$\frac{S-P}{S-P}$

Within each figure, syllogisms are further divided into *moods*, according to the quantity and quality of the propositions they contain.

Not all of the theoretically possible combinations of propositions related as above constitute valid syllogisms, sequences in which the third proposition really follows from the other two. For example, “Every man is an animal; some horse is an animal; therefore, no man is a horse” (mood AIE in Figure 2) is completely inconsequent (even though all three propositions happen in this case to be true). During the Middle Ages those syllogistic moods that are valid acquired certain short names, with the mood indicated by the vowels, and all of them were put together in a piece of mnemonic doggerel, of which one of the later versions is the following:

*Barbara, Celarent, Darii, Ferioque* prioris;  
*Cesare, Camestres, Festino, Baroco* secundae;  
*Tertia Darapti, Disamis, Datisi, Felapton,*  
*Bocardo, Ferison* habet. Quarta insuper addit  
*Bramantip, Camenes, Dimaris, Fesapo, Fresison.*

Here Bocardo, for example, means the mood OAO in Figure 3, of which an illustration (C. S. Peirce’s example) would be

Some patriarch (viz., Enoch) is not mortal;  
 Every patriarch is a man;  
 Therefore, some man is not mortal.

There is also a group of moods (Barbari and Celaront in Figure 1, Cesaro and Camestrop in Figure 2, Camenop in Figure 4) in which a merely particular conclusion is drawn although the premises would warrant our going further

and making the conclusion universal (the “subaltern” moods). The Ramists added special moods involving singulars (if we write S and N for affirmative and negative singulars, we have ASS and ESN in Figure 1, ANN and ESN in Figure 2 and SSI and NSO in Figure 3). It may be noted that every syllogism must have at least one universal premise, except for SSI and NSO in Figure 3—the so-called expository syllogisms, for example, “Enoch is not mortal; Enoch is a patriarch; therefore, not every patriarch is mortal.” Moreover, every syllogism must have at least one affirmative premise, and if either premise is negative or particular, the conclusion must be negative or particular, as the case may be (“the conclusion follows the weaker premise,” as Theophrastus put it, negatives and particulars being considered weaker than affirmatives and universals).

**REDUCTION.** The mnemonic verses serve to indicate how the valid moods of the later figures may be “reduced” to those of Figure 1—that is, how we may derive their conclusions from their premises without using any syllogistic reasoning of other than the first-figure type. (This amounts, in modern terms, to proving their validity from that of the first-figure moods taken as axiomatic.) In the second-figure mood Cesare, for example, the letter *s* after the first *e* indicates that if we *simply convert* the major premise we will have a pair of premises from which we can deduce the required conclusion in Figure 1, and the initial letter *C* indicates that the first-figure mood employed will be Celarent. An example of a syllogism in Cesare (EAE in Figure 2) would be

No horse is a man;  
Every psychopath is a man;  
Therefore, no psychopath is a horse.

This conclusion may equally be obtained from these premises by proceeding as follows:

No horse is a man—*s*—→No man is a horse;  
Every psychopath is a man → Every psychopath is a man;  
Therefore, no psychopath is a horse.

Here the right-hand syllogism, in which the first premise is obtained from the given major by simple conversion and the second is just the given minor unaltered, is in the mood Celarent in the first figure. Festino “reduces” similarly to Ferio, and Datisi and Ferison (in the third figure) reduce to Darii and Ferio, though in the third-figure cases it is the minor premise that must be simply converted. Darapti and Felapton reduce to Darii and Ferio by conversion of the minor premise, not simply, but *per accidens* (this is indicated by the *s* of the other moods being changed to *p*).

Camestres (Figure 2) and Disamis (Figure 3) are a little more complicated. Here we have not only an *s*, for the simple conversion of a premise, but also an *m*, indicating that the premises must be transposed, and a further *s* at the end because the transposed premises yield, in Figure 1, not the required conclusion but rather its converse, from which the required conclusion must be obtained by a further conversion at the end of the process. An example in Disamis would be the following:

Some men are liars;  
All men are automata;  
Therefore, some automata are liars.

If we convert the major premise and transpose the two, we obtain the new pair

All men are automata;  
Some liars are men,

and from these we may obtain in the first-figure mood Darii not immediately the conclusion “Some automata are liars” but rather “Some liars are automata,” from which, however, “Some automata are liars” does follow by simple conversion.

Baroco and Bocardo are different again. In both of them neither premise is capable of simple conversion, and if we convert the A premises *per accidens* we obtain pairs IO and OI, and there are no valid first-figure moods with such premises—in fact, no valid moods at all with two particular premises. We therefore show that the conclusion follows from the premises by the device called *reductio ad absurdum*. That is, we assume for the sake of argument that the conclusion does not follow from the premises—that is, that the premises can be true and the conclusion false—and from this assumption, using first-figure reasoning alone, we deduce impossible consequences. The assumption, therefore, cannot stand, so the conclusion does after all follow from its premises.

Take, for example, the following syllogism in Baroco (AOO in Figure 2):

Every man is mortal;  
Some patriarch (viz., Enoch) is not mortal;  
Therefore, some patriarch is not a man.

Suppose the premises are true and the conclusion is not. Then we have

- (1) Every man is mortal;
- (2) Some patriarch is not mortal;
- (3) Every patriarch is a man.

(This is the contradictory of the conclusion.) But from (1) and (3), in the first-figure mood Barbara, we may infer

(4) Every patriarch is mortal.

However, the combination of (2) and (4) is impossible. Hence, we can have both (1) and (2) only if we drop (3)—that is, if we accept the conclusion of the given second-figure syllogism.

It is possible to “reduce” all the second-figure and third-figure moods to Figure 1 by this last method, and although this procedure is a little complicated, it brings out better than the other reductions the essential character of second-figure and third-figure reasoning. Figure 1 is governed by what is called the *dictum de omni et nullo*, the principle that what applies to all or none of the objects in a given class will apply or not apply (as the case may be) to any given member or subclass of this class. As Immanuel Kant preferred to put it, first-figure reasoning expresses the subsumption of cases under a rule—the major premise states some affirmative or negative rule (“Every man is mortal,” “No man will live forever”), the minor asserts that something is a case, or some things are cases, to which this rule applies (“Enoch and Elijah are men”), and the conclusion states the result of applying the rule to the given case or cases (“Enoch and Elijah are mortal,” “Enoch and Elijah will not live forever”). Hence, in Figure 1 the major premise is always universal (that being how rules are expressed) and the minor affirmative (“Something is a case”).

Second-figure reasoning also begins with the statement of a rule (“Every man is mortal”) but in the minor premise denies that we have with a given example the result which the rule prescribes (“Enoch and Elijah are *not* mortal,” “Enoch and Elijah *will* live forever”) and concludes that we do not have a case to which the rule applies (“Enoch and Elijah cannot be men”). It combines, in effect, the first-figure major with the contradictory of the first-figure conclusion to obtain the contradictory of the first-figure minor (compare the “reduction” of Baroco). A second-figure syllogism, in consequence, must have a universal major, premises opposed in quality, and a negative conclusion. Its practical uses are in refuting hypotheses, as in medicine or detection (“Whoever has measles has spots, and this child has no spots, so he does not have measles”; “Whoever killed *X* was a person of great strength, and *Y* is not such a person, so *Y* did not kill *X*”).

In the third figure we begin by asserting that something or other does not exhibit the result which a proposed rule would give (“Enoch and Elijah are *not* mortal,” “Enoch and Elijah *will* live forever”), go on to say that we nevertheless do have here a case or cases to which the rule would apply if true (“Enoch and Elijah *are* men”), and

conclude that the rule is not true (“Not all men are mortal,” “Some men do live forever”). A third-figure syllogism, consequently, has an affirmative minor (the thing is a case) and a particular conclusion (the contradictory of a universal being a particular); its use is to confute rashly assumed rules, such as proposed scientific laws.

This rather neat system of interrelations (first clearly brought out by C. S. Peirce) concerns only the first three figures; it was not until the later Middle Ages, in fact, that a distinct fourth figure was recognized. The common division of figures assumes that we are considering completed syllogisms, with the conclusion (and its subject and predicate) already before us; however, the question Aristotle originally put to himself was not “Which completed syllogisms are valid?” but “Which pairs of premises will yield a syllogistic conclusion?” Starting at this end, we cannot distinguish major and minor premises as those containing, respectively, the predicate and subject of the conclusion. Aristotle distinguished them, in the first figure, by their comparative comprehensiveness and mentioned what we now call the fourth-figure moods as odd cases in which first-figure premises will yield a conclusion wherein the “minor” term is predicated of the “major.” Earlier versions of the mnemonic lines accordingly list the fourth-figure moods with the first-figure ones and (since the premises are thought of as being in the first-figure order) give them slightly different names (Baralip-ton, Celantes, Dabitis, Fapesmo, Frisesomorum).

**DISTRIBUTION OF TERMS.** Terms may occur in A-, E-, I-, and O-propositions as distributed or as undistributed. The rule is that universals distribute their subjects and particulars distribute their predicates, but what this means is seldom very satisfactorily explained. It is often said, for example, that a distributed term refers to all, and an undistributed term to only a part, of its extension. But in what way does “Some men are mortal,” for example, refer to only a part of the class of men? Any man whatever will do to verify it; if any man whatever turns out to be mortal, “Some men are mortal” is true. What the traditional writers were trying to express seems to be something of the following sort: A term *t* is distributed in a proposition *f(t)* if and only if it is replaceable in *f(t)*, without loss of truth, by any term “falling under it” in the way that a species falls under a genus. Thus, “man” is distributed in

Every man is an animal;  
No man is a horse;  
No horse is a man;  
Some animal is not a man,

since these respectively imply, say,

Every blind man is an animal;  
 No blind man is a horse;  
 No horse is a blind man;  
 Some animal is not a blind man.

On the other hand, it is undistributed in

Some man is keen-sighted;  
 Some man is not disabled;  
 Every Frenchman is a man;  
 Some keen-sighted animal is a man,

since these do not respectively imply

Some blind man is keen-sighted;  
 Some blind man is not disabled;  
 Every Frenchman is a blind man;  
 Some keen-sighted animal is a blind man.

In this sense A- and E- propositions do distribute their subjects and E- and O-propositions their predicates. John Anderson pointed out that the four positive results above may be established syllogistically, given that all the members of a species (using the term widely) are members of its genus—in the given case, that all blind men are men. From “Every man is an animal” and “Every blind man is a man,” “Every blind man is an animal” follows in Barbara; with the second example the syllogism is in Celarent, with the third in Camestres, with the fourth in Baroco. Note, however, that the mere prefixing of “every” to a term is not in itself sufficient to secure its “distribution” in the above sense; for example, “man” is not distributed in “Not every man is disabled,” since this does not imply “Not every blind man is disabled.”

For a syllogism to be valid the middle term must be distributed at least once, and any term distributed in the conclusion must be distributed in its premise (although there is no harm in a term’s being distributed in its premise but not in the conclusion). Many syllogisms can quickly be shown to be fallacious by the application of these rules. “Every man is an animal; every horse is an animal; therefore, every horse is a man,” for example, fails to distribute the middle term “animal,” and it is clear that any second-figure syllogism with two affirmative premises would have the same fault (since in the second figure the middle term is predicate twice, and affirmatives do not distribute their predicates). Other special rules for the different figures, such as that in Figures 1 and 3 the minor premise must be affirmative, can be similarly proved from the rules of distribution together with the rules of quality (that a valid syllogism does not have two negative premises, and that a conclusion is negative if and only if one premise is). Logicians have endeavored to prove some

of these rules from others and to reduce the number of unproved rules to a minimum.

**EULER’S DIAGRAMS.** One device for checking the validity of syllogistic inferences is the use of certain diagrams attributed to the seventeenth-century mathematician Leonhard Euler, although their accurate employment seems to date rather from J. D. Gergonne, in the early nineteenth century.

From the traditional laws of opposition and conversion it can be shown that the extensions of any pair of terms  $X$ ,  $Y$  will be related in one or another of five ways: ( $\alpha$ ) every  $X$  is a  $Y$  and every  $Y$  is an  $X$ , that is, their extensions coincide; or ( $\beta$ ) every  $X$  is a  $Y$ , but not every  $Y$  is an  $X$ , that is, the  $X$ ’s form a proper part of the  $Y$ ’s; or ( $\gamma$ ) every  $Y$  is an  $X$ , but not every  $X$  is a  $Y$ , that is, the  $Y$ ’s form a proper part of the  $X$ ’s; or ( $\delta$ ) some but not all  $X$ ’s are  $Y$ ’s and some but not all  $Y$ ’s are  $X$ ’s, that is, the  $X$ ’s and  $Y$ ’s overlap; or ( $\epsilon$ ) no  $X$ ’s are  $Y$ ’s and so no  $Y$ ’s are  $X$ ’s, that is, the  $X$ ’s and  $Y$ ’s are mutually exclusive. These five cases are represented by the following diagrams:

“Every  $X$  is a  $Y$ ” ( $A$ ) is true if and only if we have either ( $\alpha$ ) or ( $\beta$ ); “Some  $X$  is not a  $Y$ ” ( $O$ ) if and only if we have either ( $\gamma$ ) or ( $\delta$ ) or ( $\epsilon$ ); “No  $X$  is a  $Y$ ” ( $E$ ) if and only if we have ( $\epsilon$ ); and “Some  $X$  is a  $Y$ ” ( $I$ ) if and only if we have either ( $\alpha$ ) or ( $\beta$ ) or ( $\gamma$ ) or ( $\delta$ ). From these facts it follows that  $A$  and  $O$  are in no case true together and in no case false together, and similarly for  $E$  and  $I$ ; that  $I$  is true in every case in which  $A$  is and also in two cases in which  $A$  is not, and similarly for  $O$  and  $E$ ; that  $A$  and  $E$  are in no case true together but in two cases are both false; and that  $O$  and  $I$  are in no case both false but in two cases are both true. After working out analogous truth conditions for the forms with reversed terms, we will see that they are the same for the two  $I$ ’s and the two  $E$ ’s (showing that these are simply convertible) but not for the two  $A$ ’s and the two  $O$ ’s (showing that these are not). Given which of

the five relations holds between  $X$  and  $Y$  and which between  $Y$  and  $Z$ , we can work out by compounding diagrams what will be the possible relations between  $X$  and  $Z$ . For example, if we know that every  $X$  is a  $Y$  and every  $Y$  a  $Z$ , then we must have either  $(\alpha)XY$  and  $(\alpha)YZ$  or  $(\alpha)XY$  and  $(\beta)YZ$  or  $(\beta)XY$  and  $(\alpha)YZ$  or  $(\beta)XY$  and  $(\beta)YZ$ ; that is, we must have

Inspection will show that for  $X$  and  $Z$  we have in every case either

so in every case every  $X$  is a  $Z$ . Hence, Barbara is valid.

When employing this procedure it is essential to consider all the possible cases involved. Barbara is not validated, for example, by considering case (iv) alone, as popular expositions of this method sometimes suggest.

**POLYSYLOGISMS, ENTHYMEMES, AND INDUCTION.** In an extended argument the conclusion of one inference may be used as a premise of another, and the conclusion of that as premise of a third, and so on. In presenting such an argument we may simply omit the intermediate steps and list all the premises together. For example, the sequence of categorical syllogisms “Every  $X$  is a  $Y$ , and every  $Y$  is a  $Z$ , so every  $X$  is a  $Z$ ; and every  $Z$  is a  $T$ , so every  $X$  is a  $T$ ” may be condensed to “Every  $X$  is a  $Y$ , every  $Y$  is a  $Z$ , and every  $Z$  is a  $T$ ; therefore, every  $X$  is a  $T$ .” Such a condensed chain of syllogisms is called a polysyllogism or sorites. The theory of chains of two syllo-

gisms was thoroughly studied by Galen, as reported in an ancient passage unearthed by Jan Łukasiewicz. Galen showed that the only combinations of the Aristotelian three figures that could be thus used were 1 and 1, 1 and 2, 1 and 3, and 2 and 3. His discovery of these four types of compound syllogism was misunderstood by later writers as an anticipation of the view that single syllogisms may be of four figures.

Even when it is not a conclusion from other premises already stated, one of the premises of an inference may often be informally omitted (for example, “Enoch and Elijah are men; therefore, Enoch and Elijah are mortals”). Such a truncated inference is often called an enthymeme. This is not Aristotle’s own use of the term, though he did mention that a premise is often omitted in the statement of an enthymeme in his sense. An Aristotelian enthymeme is a merely probable argument—that is, one in which the conclusion does not strictly follow from the premises but is merely made more likely by them. When the claim made for an argument is thus reduced, the normal rules may be relaxed in certain directions; in particular, the second and third figures may be used to yield more than merely negative results. Thus, Figure 2 may be used not only to prove that something is not a case falling under a given rule but also to suggest that it is one—to use a modern example:

Any collection of particles whose movement is accelerated will occupy more space than it did;

A heated gas will occupy more space than it did;

Therefore, a heated gas may be a collection of particles whose movement is accelerated.

Figure 3 may be similarly used not only to prove that some rule does not hold universally but also to suggest that it does hold universally—for instance:

$X, Y, Z$  are all of them white;

$X, Y, Z$  are all of them swans;

Therefore, perhaps all swans are white.

If the second premise here is strengthened to “ $X, Y, Z$  are all the swans there are,” the conclusion will follow without any “perhaps” (of course, the new premise is in this case a false one, and the conclusion is also false). The form of inference

$X, Y, Z$ , etc., are all of them  $P$ ’s;

$X, Y, Z$ , etc., are all the  $S$ ’s there are;

Therefore, all  $S$ ’s are  $P$ ’s

was called by Aristotle “induction”; more accurately, he used this term for a similar passage from all the sub-

species to their genus (“The *X*’s, the *Y*’s, and the *Z*’s are all of them *P*’s and are all the *S*’s; therefore, ...”). He observed that the “conversion” of the second premise to “All the *S*’s are the *X*’s, the *Y*’s, and the *Z*’s” will turn such an induction into a syllogism in Barbara.

The term *induction* being extended in the more recent tradition to cover the merely probable inference given just previously, we distinguish Aristotelian induction by calling it “formal” or “perfect” induction or (as W. E. Johnson called it) “summary” induction. The Figure 2 type of merely probable inference is one of the things meant by the term “argument from”—or “by”—“analogy” (or just “analogy”); C. S. Peirce called it “hypothesis.”

**SKEPTICAL CRITICISMS OF SYLLOGISTIC REASONING.** In the latter part of the nineteenth century, under the influence of J. S. Mill, textbooks of the traditional type came to have two main divisions, “formal” or “deductive” logic (dealt with more or less as above) and “inductive” logic or “scientific method.” With the details of inductive logic we are not concerned here, but we may glance at the view of some writers that merely probable induction and analogy are the only genuine types of reasoning, “formal” or syllogistic reasoning being useless or spurious because it is inevitably circular, assuming in the premises what it sets out to prove as the conclusion.

The second-century skeptic Sextus Empiricus suggested that in the syllogism “Every man is an animal; Socrates is a man; therefore, Socrates is an animal,” the only way to establish the major premise is by induction; however, if the induction is incomplete the examination of a new instance—for example, of Socrates—might prove it false, and if it is complete the conclusion (“Socrates is an animal”) must already have been used in establishing it. This argument was repeated by such writers as George Campbell, in the eighteenth century, who supplemented it with another, to cover the case in which the major is established not by induction but simply by definition or linguistic convention: “Of course every man is an animal, for being an animal is part of what we mean by being a man.” In this case it is the minor premise, “Socrates is a man,” that cannot be established without first establishing the conclusion (that he is an animal). The same point was urged by another Scottish philosopher, Thomas Brown. It is allied to an argument used by Sextus to show not that syllogism is circular but that the major premise is superfluous. If, he said, every man is an animal because it follows from an object’s being a man that it is an animal, then the allegedly enthymematic

“Socrates is a man; therefore, Socrates is an animal” must be valid as it stands.

Richard Whately, answering Campbell’s arguments in the early nineteenth century, complained that Campbell had confined himself to examples in which the syllogistic argument was indeed superfluous and countered them with some in which it was not—for example, the case of some laborers, ignorant of the fact that all horned animals are ruminant, digging up a skeleton which they, but not a distant naturalist, could see to be horned, the laborers and the naturalist thus separately providing premises which were both required to obtain the conclusion that the skeleton was of a ruminant animal. Whately admitted that the sense in which we may make a “discovery” by drawing a syllogistic conclusion is different from that in which we make a discovery by observation, but it can be a genuine discovery none the less; there are “logical” as well as “physical” discoveries.

After Whately, J. S. Mill took up the argument, but it is not entirely clear what side he was on. Sometimes he treated a universal major as already asserting, among other things, the conclusion:

Whoever pronounces the words, All men are mortal, has affirmed that Socrates is mortal, though he may never have heard of Socrates; for since Socrates, whether known to be so or not, really is a man, he is included in the words, All men, and in every assertion of which they are the subject. (*System of Logic*, Book II, Ch. 3, p. 8, note)

“Included in the *meaning* of the words,” he must have meant (for it is obvious that neither Socrates the man nor “Socrates,” his name, forms any part of the words “All men”), but this contradicts Mill’s own insistence that the meaning of general terms like “men” lies wholly in their “connotation” and that “All men are mortal” means that wherever the attributes of humanity are present, mortality is present, too. He rightly chided Brown, who thought that the meaning of “Socrates is mortal” (like that of “Socrates is an animal”) is already contained in the minor premise “Socrates is a man,” for failing to distinguish the actual connotation of “man” (i.e., the attributes by which its application is determined) from other attributes (such as mortality) which we may empirically discover these to be attended with, but his own view in the passage cited is similarly negligent.

Mill’s main point, however, is different and more defensible. When careful and extensive observation warrants the conclusion that, say, all men are mortal, and we

then observe that the duke of Wellington is a man and conclude that he is therefore mortal, we have in effect an induction followed by a syllogism. Mill pointed out that if this procedure is justified at all, the introduction of the syllogistic major is superfluous. For if the original body of evidence really does warrant the inference that all men are mortal, it is certainly sufficient to warrant the inference that the duke of Wellington is mortal, given that he is a man. In other words, if we really are justified in the move from particular observations to the general proposition, and from there to new particulars, we would be equally justified in moving directly “from particulars to particulars.”

What the syllogistic major does, Mill argued, is simply to sum up in a single formula the entire class of inferences to new particulars which the evidence warrants. That is, “All men are mortal” means, in effect, that if we ever find anyone to be a man we are justified in inferring, from the observations we have previously amassed, that he is mortal. “The conclusion is not an inference drawn from the formula”—that is, from “All men are mortal” thus understood—“but an inference drawn according to the formula” (ibid., p. 4). Mill here anticipated Gilbert Ryle’s treatment of “lawlike statements” as “inference licenses” and echoed Sextus’s point that it is inconsistent to require that such licenses be added to the premises of the inferences they permit, since what they license is precisely the drawing of the conclusion from those premises.

Mill in fact here shifted the discussion from Sextus’s first skeptical “topic” to his second—from the charge of circularity to the question of what distinguishes a rule of inference from a premise. On this point more was said later in the nineteenth century by C. S. Peirce. Peirce, like Mill, distinguished sharply between the premise or premises from which, and the “leading principle” according to which, a conclusion is drawn. He also noted, as did Mill, that what is traditionally counted as a premise may function in practice as a “leading principle.” But it need not, and, indeed, what is traditionally counted as a “leading principle” (say the *dictum de omni et nullo*) may sometimes be, conversely, treated in practice as a premise. Certainly, since *all men are mortal* (leading principle 1), we are justified in inferring the mortality of Socrates (or the duke of Wellington, or Elijah) from his humanity. But equally, since *all members of any class are also members of any class that contains the former as a subclass* (leading principle 2), we are justified in inferring the mortality of Socrates from his being a man *and* from men’s being a subclass of mortals. For the very same reason (that all members of any class are also members of any class that

contains the former as a subclass) we are justified in inferring the mortality of Socrates from his being a member of a subclass of the class of mortals *and* from the membership of any member of a class in all classes of which it is a subclass. In this last example we have one and the same proposition functioning as a premise and as a leading principle in the same inference (not merely, like “All men are mortal” in the preceding two examples, as a leading principle in one and a premise in another); to be capable of this, Peirce thought, is the mark of a “logical” leading principle.

It is not certain that Peirce’s method of distinguishing “logical” from other sorts of “leading principles” will bear inspection. However, he seems to have established his basic point, that what it would be fatal to require in all cases—the treatment of a leading principle as a premise—we may safely permit in some. There may be useful and valid reasoning about subjects of all degrees of abstraction, including logic itself.

**HYPOTHETICAL AND DISJUNCTIVE SYLLOGISMS.** Traditional textbooks, aside from developing the theory of categorical propositions and syllogisms, have a brief appendix mentioning “hypothetical” (or “conditional”) and “disjunctive” propositions and certain “syllogisms” to which they give rise.

“Hypothetical” syllogisms are divided into “pure,” in which premises and conclusion are all of the form “If  $p$  then  $q$ ” (notably the syllogism “If  $p$  then  $q$ , and if  $q$  then  $r$ ; therefore, if  $p$  then  $r$ ,” analogous to Barbara), and “mixed,” in which only one premise is hypothetical and the other premise and the conclusion are categorical. The mixed hypothetical syllogism has two valid “moods”:

- (1) *Modus ponendo ponens*: If  $p$  then  $q$ , and  $p$ ; therefore,  $q$ .
- (2) *Modus ponendo tollens*: If  $p$  then  $q$ , but not  $q$ ; therefore, not  $p$ .

In both these moods the hypothetical premise is called the major, the categorical the minor. *Ponere*, in the mood names, means to affirm, *tollere* to deny. In (1), by affirming the antecedent of the hypothetical we are led to affirm its consequent; in (2), by denying its consequent we are led to deny its antecedent. The fallacies of “affirming the consequent” and “denying the antecedent” (i.e., of doing these things *to start with*, in the minor premise) consist in reversing these procedures—that is, in arguing “If  $p$  then  $q$ , and  $q$ ; therefore,  $p$ ” and “If  $p$  then  $q$ , but not  $p$ ; therefore, not  $q$ .”

“Disjunctive” syllogisms—that is, ones involving “Either-or” propositions—have the following two “mixed” moods:

- (3) *Modus tollendo ponens*: Either  $p$  or  $q$ , but not  $p$ ; therefore,  $q$  (or, but not  $q$ ; therefore,  $p$ ).
- (4) *Modus ponendo tollens*: Either  $p$  or  $q$ , and  $p$ ; therefore, not  $q$  (or, and  $q$ ; therefore, not  $p$ ).

Mood (4) is valid only if “Either  $p$  or  $q$ ” is interpreted “exclusively”—that is, as meaning “Either  $p$  or  $q$  but not both”—whereas (3) is valid even if it is interpreted as “Either  $p$  or  $q$  or both.” There is also a *modus tollendo ponens* with the simple “Not both  $p$  and  $q$ ” as major and the rest as in (4).

**DILEMMAS.** Hypothetical and disjunctive premises may combine to yield a categorical conclusion in the *dilemma*, or “horned” syllogism (*sylogismus cornutus*), with its two forms:

- (5) *Constructive*: If  $p$  then  $r$ , and if  $q$  then  $r$ , but either  $p$  or  $q$ ; therefore,  $r$ .
- (6) *Destructive*: If  $p$  then  $q$ , and if  $p$  then  $r$ , but either not  $q$  or not  $r$ ; therefore, not  $p$ .

These basic forms have a number of variations; for instance,  $q$  in (5) may be simply “not  $p$ ,” making the disjunctive premise the logical truism “Either  $p$  or not  $p$ ”; or  $p$  may imply  $r$  and  $q$  imply  $s$ , giving as conclusion “Either  $r$  or  $s$ ” rather than the categorical  $r$ ; or the disjunctive premise may be conditionalized to “If  $s$  then either  $p$  or  $q$ ,” making the conclusion “If  $s$  then  $r$ .”

A typical dilemma is that put by Protagoras to Euathlus, whom he had trained as a lawyer on the understanding that he would be paid a fee as soon as his pupil won a case. When the pupil simply engaged in no litigation at all, Protagoras sued him for the fee. His argument was “If Euathlus wins this case, he must pay my fee by our agreement, and if he loses it he must pay it by the judge’s decision (for that is what losing this case would mean), but he must either win or lose the case; therefore, in either case he must pay.”

“Escaping between the horns” of a dilemma is denying the disjunctive premise; for example, Euathlus might have argued that he would neither win nor lose the case if the judge refused to make any decision. “Taking a dilemma by the horns” is admitting the disjunction but denying one of the implications, as Euathlus might have done by arguing that if he won he would still not be bound by the agreement to pay Protagoras, because this was not the sort of case intended in the agreement.

“Rebutting” a dilemma is constructing another dilemma drawing upon the same body of facts but leading to an opposite conclusion. This is what Euathlus did, arguing that if he won the case he would be dispensed from paying by the judge’s decision, and if he lost it the agreement would dispense him, so either way he was dispensed from paying. Rebuttal, however, is possible only if one of the other moves (though it may not be clear which) is also possible, for a single set of premises can lead by equally valid arguments to contradictory conclusions only if they contain some fault in themselves.

Dilemmatic reasoning obtains a categorical conclusion from hypothetical and disjunctive premises; the Port-Royalists pointed out that we may also obtain hypothetical conclusions from categorical premises. For in any categorical syllogism we may pass directly from one of the premises to the conclusion stated not categorically but conditionally on the truth of the other premise; for instance, from “Every man is mortal” we may infer that if Socrates is a man he is mortal, and from “Socrates is a man” that if every man is mortal Socrates is, and similarly with all other syllogisms. This “rule of conditionalization” is much used in certain modern logical systems.

## TRADITIONAL AND MODERN LOGIC

Not only the “rule of conditionalization” but the whole subject of hypothetical and disjunctive reasoning fits more comfortably into modern than into traditional logic, being an inheritance from the Stoics, the first “modern” logicians, rather than from Aristotle. Traditionalists have often been worried at its finding any place at all in their general *corpus* and have sometimes attempted to justify it by “reducing” hypothetical and disjunctive propositions and syllogisms to “categorical” ones.

Disjunctives, to begin with, may be eliminated as a distinct form by equating “Either  $p$  or  $q$ ” with the conditional “If not  $p$  then  $q$ ,” and the conditional form does sometimes look as if it might be a mere verbal variant of the categorical universal. This last is especially true where the conditional is introduced not by the plain “if” but by “if ever” or “if any”; “If ever a gas is heated it expands” and “If any gas is heated it expands” seem simply variants of “Every heated gas expands.” But here the antecedent and consequent of the conditional are not, as J. N. Keynes put it, complete propositions with an “independent import”—“it expands” is not on its own a comprehensible sentence; the “it” refers back to the heated gas of the antecedent. Keynes suggested that the term *conditional* be used for precisely this type of “If-then” statement and the term *true hypothetical* confined to cases in which the

antecedent and consequent do have “independent import,” such as “If Socrates is damned, then there is no justice in heaven.” And the representation of “true hypotheticals” as categorical universals is not easy.

In modern logic, from the Stoics through some of the medieval *moderni* to the “logicians” of our own century, “the stone which the builders rejected has been made the head of the corner.” “Pure hypotheticals,” together with other forms in which entire propositions are linked by various “connectives,” have been made the subject of the most elementary part of logic, the propositional calculus. Aristotelian universals and particulars are built out of these forms (by means of prefixes called “quantifiers”) rather than vice versa. (Details are given in the entries Logic, Modern and Russell, Bertrand, section on logic and mathematics.) The essential procedure is to read “Every *A* is a *B*” as “For every individual *x*, if *x* is an *A* then *x* is a *B*” and “Some *A* is a *B*” as “For some individual *x*, *x* is an *A* and *x* is a *B*.” Here, instead of a Keynesian “conditional” being explained as a categorical universal in disguise, the explanation is reversed, and the components which, as Keynes said, are “not propositions of independent import” are represented as “propositional functions” in which the place taken in a genuine proposition by an individual name is taken by a variable (“bound” by the initial quantifier “for all *x*”). But the “if” which links these components is the very same “if” which in the “pure hypotheticals” of the propositional calculus links genuine propositions. This “if” is not explained in terms of anything else (except perhaps other connectives) but is taken as fundamental.

In this way the traditional themes are not banished from modern logic but are incorporated into a much larger subject. When the Aristotelian forms are thus interpreted, however, their laws seem to require modification at some points. In particular, the A-form “For any *x*, if *x* is an *A* then *x* is a *B*” does not seem to imply the I-form “For some *x*, *x* is an *A* and *x* is a *B*,” for the former does not imply that any *x* in fact is an *A* (it says only that if any *x* is an *A* it is a *B*), whereas the latter does imply this (if some *x* both is an *A* and is a *B*, then that *x* is at least an *A*). This eliminates inference by subalternation and whatever else in the traditional theory depends on it, such as subaltern conversion and syllogisms, like Darapti, which require this for reduction to Figure 1.

Modern logic, however, is not at all monolithic in character, and the sketch just given is a little stylized, depicting modern logic not as a living discipline but rather as a new “tradition” that has displaced the old and against which there are already dissentient voices that give

the older tradition a measure of justification (rather like that accorded to pre-Copernican astronomy by the more radical forms of relativity theory). We cannot go back to the prison that would confine all logic to the Aristotelian syllogism, but it is possible to defend (a) something like the view that the form “Every *X* is a *Y*” is more fundamental than either “For all *x*, *f*(*x*)” or “If *p* then *q*” and (b) the traditional ignoring (in inference by subalternation, etc.) of terms that have no application.

As to (a), we now know how to define both “for all *x*” and “if” in terms of a single undefined logical operator which amounts to “for all *x*, if”; for we can take as our fundamental logical complex the form “Anything such that *α* is such that *β*” and read “If *p* then *q*” as the special case of this in which *α* and *β* are “propositions with independent import,” and “For all *x*, *β*” as the special case in which *α* is logically true anyway (for instance, in which it has the form “Anything such that *β* is such that *β*”) and so can be ignored as a “condition” of *β*’s truth. C. S. Peirce—at almost every point the most imaginative and flexible of the “moderns,” although he died in 1914—always regarded some such reduction as possible in principle and saw the difference between the “terms” out of which categorical propositions are constructed and the “propositions” out of which we construct hypotheticals as a point of little logical importance.

Peirce, moreover, gave a highly modern justification for the traditional view that within syllogistic logic only the first figure is strictly necessary. Traditional methods of “reducing” other figures to the first do indeed involve another form of inference, namely conversion, and although this can be represented as a kind of enthymematic syllogism, it comes out as syllogism that is already in the second and third figures. For we do it by letting the term *B* be the same as *A* in the two syllogisms

No *C* is a *B* (i.e., an *A*);  
Every *A* is a *B* (i.e., an *A*);  
Therefore, no *A* is a *C*

(Cesare, Figure 2) and

Every *B* (i.e., *A*) is an *A*;  
Some *B* (i.e., *A*) is a *C*;  
Therefore, some *C* is an *A*

(Datisi, Figure 3). The replacement of *B* by *A* turns the universal affirmative premise into the logical truism “Every *A* is an *A*,” which can be dropped, and the conclusion into the converse of the remaining premise.

We can, however, derive second-figure syllogisms from first-figure ones by a variant of the *reductio ad*

absurdum method, employing nothing but Barbara in its terminal and propositional forms, the forms

(a) Every  $A$  is a  $B$ , and every  $B$  is a  $C$ ; therefore, every  $A$  is a  $C$ ; and

(b) If  $p$  then  $q$ , and if  $q$  then  $r$ ; therefore, if  $p$  then  $r$ ,

together with freedom to rearrange our premises and to “conditionalize” and “deconditionalize” conclusions, that is, to make such passages as that from (a) to, and to (a) from,

(c) Every  $A$  is a  $B$ ; therefore, if every  $B$  is a  $C$  then every  $A$  is a  $C$

and from (b) to, and to (b) from,

(d) If  $p$  then  $q$ ; therefore, if (if  $q$  then  $r$ ) then if  $p$  then  $r$ .

As a special case of (d) we have

(e) If every  $B$  is a  $C$  then every  $A$  is a  $C$ ; therefore, if (if every  $A$  is a  $C$  I am much mistaken) then if every  $B$  is a  $C$  I am much mistaken.

Forms (c) and (e) will take us from the premise to the conclusion of

(f) Every  $A$  is a  $B$ ; therefore, if (if every  $A$  is a  $C$  I am much mistaken) then if every  $B$  is a  $C$  I am much mistaken.

But “If  $X$  then I am very much mistaken” just amounts to “Not  $X$ ,” and (f) therefore amounts to

(g) Every  $A$  is a  $B$ ; therefore, if not every  $A$  is a  $C$ , not every  $B$  is a  $C$ ,

that is, a conditionalized form of Bocardo, Figure 3.

The equation of “Not  $X$ ” with “If  $X$  then I am much mistaken” is Peirce’s variant, at this point, of one account of denial. It makes it possible to present the other traditional forms as complexes of “if” and “every” (and “if” and “every,” as was shown, are basically the same form of linkage), as follows:

Not every  $X$  is a  $Y$  (O) = If every  $X$  is a  $Y$  I am much mistaken.

No  $X$  is a  $Y$  (E) = Every  $X$  is not-a- $Y$  = Every  $X$  is such that if it is a  $Y$  I am much mistaken.

Some  $X$  is a  $Y$  (I) = Not (no  $X$  is a  $Y$ ) = If every  $X$  is such that if it is a  $Y$  I am much mistaken, then I am much mistaken.

Syllogisms, in all figures, involving these forms are derivable from Barbara by methods similar to that used to

obtain Bocardo above, although the derivations will often be more complicated than the one given. For some of them we require Barbara in yet another form besides (a) and (b) above, namely the mixed terminal and propositional

Every  $X$  is a  $Y$ ; therefore, anything such that if it is a  $Y$ , then  $p$ , is such that if it is an  $X$ , then  $p$ ,

and a kind of terminal principle of *modus ponens*,

Whatever is an  $X$  is a thing such that if its being an  $X$  implies that  $p$ , then  $p$ .

Modern logic will not admit that Barbara gives us all the logic there is, but its techniques do bring out anew the extreme fecundity of this ancient form.

Turning now to the failure of certain traditional forms of inference when terms without application are employed, there have been two more recent lines of attack on the view that traditional logic is simply “wrong” in accepting such forms as “Every  $X$  is a  $Y$ ; therefore, some  $X$  is a  $Y$ .” One, used by Łukasiewicz, is formalistic in character; it is a mistake, Łukasiewicz says, to interpret the traditional propositional forms in terms of modern quantification theory in the ways above indicated, or in any other ways. If we just take them as they stand, without interpretation, we can find a rigorous symbolism for them and show that the traditional laws form a self-consistent system; worries about their interpretation are extralogical. T. J. Smiley, on the other hand, thinks the interpretation of the traditional forms in quantification theory worth attempting but points out that quantification theory, as now developed, offers us wider choices of interpretation than was once thought. For quantification theory now handles cases of the form “For all  $x$ ,  $f(x)$ ” in which the range of the variable  $x$  is restricted to objects of some particular sort, each sort of object having its own type of variable. We need not, therefore, interpret “Every man is mortal,” say, in the standard modern way as “For any individual object  $x$ , if that object is human it is mortal” but may read it, rather, as “For any *human* individual  $m$ , that human individual is mortal” (with no “ifs” about it). This interpretation, when embedded in a suitable theory of “many-sorted” quantification, will yield all the traditional results.

### **Bibliography**

Peter of Spain’s *Summulae Logicales* (modern reprint, edited by I. M. Bocheński, Turin, 1947), Tractatus I–V and VII, is the best-known medieval compendium of the traditional

material. In the post-Renaissance epoch the most influential work has been the so-called Port-Royal logic, Antoine Arnauld and Pierre Nicole's *Logique, ou l'art de penser* (translated by T. S. Baynes as *The Port-Royal Logic*, Edinburgh: Sutherland and Knox, 1851). Richard Whately's crisp, homely, and pugnacious *Elements of Logic*, which appeared in successive editions in the first half of the nineteenth century, is another classic. But the most comprehensive treatment of logic along traditional lines is J. N. Keynes's *Studies and Exercises in Formal Logic* (London and New York, 1884; 4th ed., London: Macmillan, 1906).

J. S. Mill's views on the denotation and connotation of terms are developed in his *System of Logic* (London, 1843), Book I, Chs. 2, 5, and 6; his views on the uses of the syllogism are in Book II, Ch. 3. The views of C. S. Peirce are in his *Collected Papers*, edited by Charles Hartshorne, Paul Weiss, and Arthur W. Burks (8 vols., Cambridge, MA: Harvard University Press, 1931–1958), 2.455–516 and 3.154–197, and in his article "Syllogism" in the *Century Dictionary* (6 vols., New York: Century, 1889–1891).

For modern systematizations and interpretations, see Jan Lukasiewicz, *Aristotle's Syllogistic* (2nd ed., Oxford: Clarendon Press, 1957); J. C. Shepherdson, "On the Interpretation of Aristotle's Syllogistic," in *Journal of Symbolic Logic* 21 (1956): 137–147; and T. J. Smiley, "Syllogism and Quantification," in *Journal of Symbolic Logic* 27 (1962): 58–72.

## LOGICAL FORM

One can use sentences to present arguments, some of which are valid. Sentences are complex linguistic expressions that exhibit grammatical structure. And the grammatical properties of sentences need not be obvious. As discussed in this entry, certain arguments seem to be valid because the relevant premises and conclusions exhibit nonobvious logical structure. But this raises questions

about what logical structure is and how it is related to grammatical structure.

## PATTERNS OF REASONING

An ancient thought is that premises and conclusions have parts and that valid arguments exhibit valid forms, like the following: **Q** if **P**, and **P**; so **Q**. One can say that the variables (in bold) range over propositions, leaving it open for now what propositions are: sentences of some (perhaps unspoken) language, abstract states of affairs, or whatever. One can also assume that declarative sentences can be used, in contexts, to indicate or express propositions. But each sentence of English is presumably distinct from the potential premise/conclusion indicated with that sentence in a given context. Different speakers can use *I swam today* at different times to indicate various propositions, each of which could be expressed in other languages. Nonetheless, propositions seem to be sentence-like in some respects, especially with regard to being composite.

The conclusion of (1)

(1) Chris swam if Pat swam, and Pat swam; so Chris swam.

is evidently part of the first premise, which has the second premise as another part. But simple propositions, without propositional parts, also seem to have structure. Aristotelian schemata like the following are valid: Every *P* is *D*, and every *S* is a *P*; so every *S* is *D*. The italicized variables are intended to range over predicates—logical analogs of nouns, adjectives, and other classificatory terms (like *politician*, *deceitful*, and *senator*). Simple propositions appear to have subject-predicate structure; where a subject can consist of a predicate and a quantifier (indicated with a word like *every*, *some*, or *no*).

Medieval logicians explored the hypothesis that all propositions are composed of simple propositions and a few special elements, indicated with words like *or* and *only*. While they expected some differences between grammatical and propositional structure, the idea was that sentences reflect the important aspects of logical form. The medieval logicians also made great strides in reducing Aristotelian schemata to more basic inferential principles: one concerning replacement of a predicate with a less restrictive predicate, as in *Rex is a brown dog*, so *Rex is a dog*; and one concerning converse examples, like *Rex is not a dog*, so *Rex is not a brown dog*.

Nonetheless, traditional logic/grammar was inadequate. If Juliet kissed Romeo, then Juliet kissed someone. And predicates containing quantifiers were problematic.

If *respects some doctor* and *respects some senator* indicate nonrelational proposition-parts, like *is tall* and *is ugly*, then the argument indicated with (2)

- (2) Some patient respects some doctor, and every doctor is a senator; so some patient respects some senator.

has the following form, which is not valid: Some  $P$  is  $T$ , and every  $D$  is an  $S$ ; so some  $P$  is  $U$ . One can introduce a variable  $R$  ranging over relations and offer schemata like the following: Some  $P$   $R$  some  $D$ , and every  $D$  is an  $S$ ; so some  $P$   $R$  some  $S$ . But this is not a basic inference pattern; and such schemata do not capture the validity of inferences like the following: Every patient who met every doctor is tall, and some patient who met every doctor respects every senator; so some patient who respects every senator is tall. Relative clauses posed difficulties as well. If sentence (3) is true, so is sentence (4):

- (3) Every patient respects some doctor.  
 (4) Every old patient respects some doctor.

But in (5) and (6) the direction of valid inference is reversed:

- (5) No lawyer who saw every patient respects some doctor.  
 (6) No lawyer who saw every old patient respects some doctor.

## FUNCTIONS AND ARGUMENTS

Gottlob Frege showed how to deal with these examples and more. But on his view, propositions have function-argument structure. Let  $S$  stand for the successor function. Frege interpreted the arithmetic expression  $S(3)$  as having a semantic value: the value of the relevant function given the relevant argument; that is, the number four. The division function can be represented as a mapping from ordered pairs of numbers to quotients:  $Q(x, y) = x/y$ . Functions can also be specified conditionally; consider the function that maps every even integer onto itself, and every odd integer onto its successor. On Frege's view, *Mary sang* indicates a proposition with the following structure:  $\text{Sang}(\text{Mary})$ . And he took the relevant function to be a conditional mapping from individuals in a given domain to truth values:  $\text{Sang}(x) = \mathbf{t}$  if  $x$  sang, and  $\mathbf{f}$  otherwise; where for each individual  $x$ ,  $\text{Sang}(x) = \mathbf{t}$  if and only if (iff)  $x$  sang, and  $\text{Sang}(x) = \mathbf{f}$  iff  $x$  did not sing. The proposition that John admired Mary, like the proposition that Mary was admired by John, was said to have the following structure:  $\text{Admired}(\text{John}, \text{Mary})$ ; where  $\text{Admired}(x, y) = \mathbf{t}$  if  $x$  admired  $y$ , and  $\mathbf{f}$  otherwise.

Frege's treatment of quantification departed more radically from tradition. Let  $F$  be the function indicated by *sang*, so that someone sang iff some individual  $x$  is such that  $F(x) = \mathbf{t}$ . Using modern notation, someone sang iff  $\exists x[\text{Sang}(x)]$ ; where the quantifier binds the variable. Every individual in the domain sang iff  $F$  maps each individual onto  $\mathbf{t}$ ; in modern notation,  $\exists x[\text{Sang}(x)]$ . With regard to the proposition that some politician is deceitful, subject-predicate grammar suggests the division *Some politician / is deceitful*. But for Frege the logically important division is between the existential quantifier and the rest, with the quantifier binding two occurrences of its variable:  $\exists x[\text{P}(x) \ \& \ \text{D}(x)]$ ; some individual is both a politician and deceitful. Likewise with regard to the proposition that every politician is deceitful:  $\forall x[\text{P}(x) \rightarrow \text{D}(x)]$ ; everyone is such that if he or she is a politician then he or she is deceitful. In which case, *every politician* does not indicate a constituent of the proposition. Grammar also masks a logical difference between the existential and universal propositions: predicates are related conjunctively in the former, but conditionally in the latter.

The real power of Frege's logic is most evident in his discussion of how the proposition that every number has a successor is logically related to more basic arithmetic truths. But just consider the following analyses of (3a–6a):

- (3a)  $\forall x\{\text{P}(x) \rightarrow \exists y[\text{D}(y) \ \& \ \text{R}(x,y)]\}$   
 (4a)  $\forall x\{[\text{O}(x) \ \& \ \text{P}(x)] \rightarrow \exists y[\text{D}(y) \ \& \ \text{R}(x,y)]\}$   
 (5a)  $\neg \exists x\{\text{Lx} \ \& \ \forall y[\text{P}(y) \rightarrow \text{S}(x,y)] \ \& \ \exists z[\text{D}(z) \ \& \ \text{R}(x,z)]\}$   
 (6a)  $\neg \exists x\{\text{Lx} \ \& \ \forall y\{[\text{O}(y) \ \& \ \text{P}(y)] \rightarrow \text{S}(x,y)\} \ \& \ \exists z[\text{D}(z) \ \& \ \text{R}(x,z)]\}$

Given Frege's rules of inference, (3a) implies (4a), while (5a) follows from (6a). Frege concluded that natural language is not suited to the task of representing propositions perspicuously. On his view, premises/conclusions have function-argument structure, which is often masked in natural language. But one can try to invent languages whose sentences depict true propositional structure.

Frege originally took propositional constituents to be the relevant functions and (ordered  $n$ -tuples of) entities that such functions map to truth-values. But he later refined this view, taking the sense of an expression to be a mode of presentation of the corresponding semantic value. Frege identified propositions—or what he called thoughts (*Gedanken*)—with senses of sentences in an ideal language, which allowed him to distinguish the

proposition that Hesperus is bright from the proposition that Phosphorus is bright. Thus, Frege could deny that the inference *Hesperus is Hesperus, so Hesperus is Phosphorus* is an instance of the valid form *P, so P*.

## DESCRIPTIONS AND MISMATCH

One might think that the logical form of any proposition indicated with *The boy from Canada sang* is  $Sang(b)$ , where  $b$  stands for the individual in question. But this makes elements of the description logically irrelevant. And if the boy from Canada sang, then a boy sang. Moreover, *the* implies uniqueness (at least within a context). So Bertrand Russell (1919) held that a proposition expressed with *The boy sang* has the following structure:  $\exists x\{Boy(x) \ \& \ \forall y[Boy(y) \rightarrow y = x] \ \& \ Sang(x)\}$ ; where the middle conjunct is one way, among many, of expressing uniqueness. According to Russell, even if a speaker refers to a certain boy when saying *The boy sang*, that boy is not a constituent of the indicated proposition—which has the form of an existential quantification, as opposed to a function saturated by the boy. In this respect, *the boy* is like *some boy*. Though on Russell's view, not even *the* indicates a propositional constituent. This extended Frege's idea that natural language is misleading, while letting Russell account for the meaningfulness of descriptions that describe nothing.

Let **Frank** be the proposition indicated (now) with *The (present) king of France is bald*. If **Frank** consists of some function saturated by an entity indicated with *The king of France*, there must be such an entity. But instead of appealing to nonexistent kings, or ways of presenting them, Russell held that **Frank** is of the form  $\exists x\{K(x) \ \& \ \forall y[K(y) \rightarrow y = x] \ \& \ B(x)\}$ . In which case, the true negation of **Frank** is not of the form  $\exists x\{K(x) \ \& \ \forall y[K(y) \rightarrow y = x] \ \& \ \neg B(x)\}$ . This invited the thought, developed by Ludwig Wittgenstein (1922, 1953) and others, that many philosophical puzzles might dissolve if one properly understood the logical forms of one's claims. Russell also held that one bears a special relation to constituents of propositions one can entertain and that one typically does not bear this relation to the individuals one refers to with names. This led Russell to say that names are disguised descriptions. On this view, *Hesperus* is associated with a complex predicate—say, for illustration, of the form  $E(x) \ \& \ S(x)$ . Then *Hesperus is bright* indicates a proposition of the form  $\exists x\{[E(x) \ \& \ S(x)] \ \& \ \forall y\{[E(y) \ \& \ S(y)] \rightarrow y = x\} \ \& \ B(x)\}$ . It follows that Hesperus exists iff  $\exists x[E(x) \ \& \ S(x)]$ ; and this was challenged by Saul Kripke (1980). But Russell could say that “Phosphorus is bright” indicates a proposition of the form  $\exists x\{[M(x) \ \& \ S(x)] \ \&$

$\forall y\{[M(y) \ \& \ S(y)] \rightarrow y = x\} \ \& \ B(x)$ ; where  $E(x)$  and  $M(x)$  indicate different functions, specified in terms of evenings and mornings, leaving room to discover that  $E(x) \ \& \ S(x)$  and  $M(x) \ \& \ S(x)$  both indicate functions that map Venus alone to the truth-value **t**.

Positing unexpected logical forms thus had payoffs. But if mismatches between sentential and propositional structure are severe, one wonders how one manages to indicate propositions. This worry was exacerbated by increasing suspicion that talk of propositions is (at best) a way of talking about how one should regiment one's verbal behavior for purposes of scientific inquiry and that one should regiment natural language in first-order predicate calculus. From this perspective, associated with Willard Van Orman Quine (1950), mismatches between logical and grammatical form are to be expected. Another strand of thought, inspired by Wittgenstein's later work, also suggested that a single sentence could be used (on different occasions) to express different kinds of propositions. Peter Strawson (1950) argued, contra Russell, that a speaker could use an instance of *The F is G* to express a singular proposition about the F in the context at hand. Keith Donnellan (1966) contended that a speaker could even use an instance of *The F is G* to express a singular proposition about an individual that is not an F. Various considerations suggested that relations between spoken sentences and propositions are at best very complex and mediated by speakers' intentions.

With hindsight, though, one can see that the divergence between logical and grammatical form was exaggerated. Consider again the proposed regimentation of the proposition indicated with *Some boy sang*:  $\exists x[Boy(x) \ \& \ Sang(x)]$ . With restricted quantifiers, one can offer another logical paraphrase that parallels the grammatical division between *some boy* and *sang*. Let  $\exists x:Boy(x)$  be an existential quantifier that binds a variable ranging over boys in the domain. Then  $\exists x:Boy(x)[Sang(x)]$  means that for some individual  $x$  such that  $x$  is a boy,  $x$  sang. Likewise,  $\forall x:[Tall(x) \ \& \ Boy(x)]\{Sang(x)\}$  is logically equivalent to  $\forall x\{[Tall(x) \ \& \ Boy(x)] \rightarrow Sang(x)\}$ . And  $\exists x:[Boy(x) \ \& \ \forall y:Boy(y)[x = y]]\{Sang(x)\}$  means that for some boy  $x$  such that  $x$  is identical with every boy,  $x$  sang. Richard Montague (1974) offered a similar rewrite of Russell's hypothesis about the logical form of *The boy sang*. On this view, *The boy* corresponds to a propositional constituent, even though the boy referred to (if such there be) does not.

Still, the subject-predicate structure of *Mary trusts every doctor* diverges from the function-argument structure of  $\forall y:Doctor(y)[Trusts(Mary, y)]$ . Grammatically,

*trusts* and *every doctor* form a phrase; though logically, *trusts* combines with *Mary* and a variable to form a complex predicate that in turn combines with a restricted quantifier. Given Montague's (1974) techniques, one can provide algorithms that systematically associate quantificational sentences of natural language (described in subject-predicate terms) with Fregean propositional structures. But it seemed that mismatches between grammatical and logical form remained, at least in cases of complex predicates with quantificational constituents.

## TRANSFORMATIONAL GRAMMAR AND LF

One must not, however, assume a naive conception of grammar when thinking about its relation to logic. For example, the grammatical form of a sentence need not be determined by the order of its words. Using brackets to indicate phrasal structure, one can distinguish sentence (7) from the homophonous sentence (8).

(7) {Mary [saw [the [boy [with binoculars]]]]}

(8) {Mary [[saw [the boy]] [with binoculars]]}

The direct object of (7) is *the boy with binoculars*, while in (8), *saw the boy* is modified by an adverbial phrase. And a leading idea of modern linguistics is that many grammatical structures are transformations of others.

Expressions often appear to be displaced from positions canonically associated with certain grammatical relations. In (9), *who* seems to be associated with the direct-object position of *saw*.

(9) Mary wondered who John saw

And (9) can be glossed as *Mary wondered which person is such that John saw him*. This invites the hypothesis that the structure of (9) is as shown in (9-SS), reflecting a transformation of the simpler expression shown in (9-DS):

(9-SS) {Mary [wondered [who<sub>i</sub> {John [saw ( \_ )<sub>i</sub> ]}]]}

(9-DS) {Mary [wondered {John [saw who]}]}

where coindexing indicates a grammatical relation between the coindexed positions. The idea was that each sentence has a surface structure and a deep structure and that the former will differ from the latter when expressions like *who* are displaced as in (9). As an illustration of the kind of data relevant to such hypotheses about grammar, note that (10–12) are perfectly fine sentences, while (13) is not:

(10) The boy who sang was happy

(11) Was the boy who sang happy

(12) The boy who was happy sang

(13) Was the boy who happy sang

The ill-formedness of (13) is striking, since one can ask whether or not the boy who was happy sang. This suggests that (11-SS) is the result of a permissible transformation, but (13-SS) is not:

(11-SS) Was<sub>i</sub> {[the [boy [who sang]]] [ ( \_ )<sub>i</sub> happy]}

(13-DS) Was<sub>i</sub> {[the [boy [who [ ( \_ )<sub>i</sub> happy]]]] sang}

As transformational grammars were elaborated, many linguists posited another level of grammatical structure—LF, intimating logical form—obtained by displacing quantificational expressions. In particular, it was proposed that structures like (14-SS) were transformed, as in (14-LF):

(14-SS) {Pat [trusts [every doctor]]}

(14-LF) {[every doctor]<sub>i</sub> {Pat [ trusts ( \_ )<sub>i</sub> ]}}

Clearly, (15-LF) does not reflect the pronounced word order in English. But there is independent evidence for covert (inaudible) quantifier-raising in natural language. The suggestion was that each sentence has a PF (intimating phonological form) that determines pronunciation, and an LF that determines interpretation. On this view, the scope of a quantifier must be determined at LF, as in (14-LF). And one can say this, while also saying that the pronunciation of *Pat trusts every doctor* reflects the untransformed surface structure (14-SS). Many apparent examples of grammar-logic mismatches were thus rediagnosed as mismatches between different aspects of grammatical structure. This preserves the idea that surface appearances are often misleading with regard to propositional structure. But it also suggests that grammatical form and logical form converge, once one moves beyond traditional subject-predicate conceptions of structure with regard to both logic and grammar. And further simplification may be possible.

Given a conception of grammar according to which each sentence has a PF and an LF, perhaps involving different transformations, it is not obvious that one needs to posit other levels of grammatical analysis. Each expression of a natural language may just be a PF-LF pair that can be generated in accordance with certain constraints on how expressions can be combined and transformed. One can hypothesize that a sentence like (9) is formed in stages, including stages like those depicted in (9-DS) and (9-SS), without saying that any one stage is special in ways that deep structure and surface structure were said

to be. On this view, (10–12) correspond to natural ways of associating a PF with an LF, but the string of words in (13) does not. From this perspective, urged by Noam Chomsky and others, talk of PFs and LFs need not be understood in terms of interlevel transformations (Chomsky 1995, Hornstein 1995). Rather, PFs and LFs can be viewed simply as generable linguistic structures that reflect pronunciation and meaning. In which case questions about grammatical form and linguistic meaning are largely questions about LFs.

Nonetheless, there is still an important conceptual distinction between the linguist's notion of LF and the logician's notion of logical form. The LF of a sentence may, in various ways, underdetermine the structure of the proposition a speaker expresses with that sentence (in a given context). The LF may, however, provide a scaffolding that can be elaborated in particular contexts, with little or no mismatch between basic sentential and propositional structure. These issues remain unsettled. But discoveries of rich grammatical structure reinvigorated the idea that natural languages are semantically compositional.

Prima facie, *Every tall sailor respects some doctor* and *Some short boy likes every politician* exhibit common modes of linguistic combination. So a natural hypothesis is that the meaning of each sentence is somehow fixed by these modes of combination, given the word meanings. Inspired by Alfred Tarski's development of Frege in 1956, Donald Davidson (1967) conjectured that there are recursively specifiable theories of truth for natural languages. And while there are many apparent objections, the conjecture has been fruitful. This raises the possibility that talk of logical forms should be construed in terms of the structure(s) that speakers impose on words to understand natural language systematically. From this tendentious perspective, the phenomenon of valid inference would be largely a reflection of semantic compositionality.

At this point, many issues become germane. Given any sentence of natural language, one can ask interesting questions about its grammatical structure and what it can be used to say. (Modal claims and propositional attitude reports have been studied intensively.) It is not obvious how one should characterize meanings or logical relations. (Are theories of meaning theories of truth? Which valid inferences, if any, cannot be captured in first-order terms?) The role of context is large and ill understood. But it seems clear that the traditional questions—what kinds of structures do propositions and sentences exhibit, and how do thinkers who also speak relate these struc-

tures—must be addressed in terms of increasingly sophisticated conceptions of logic and grammar.

## LOGICAL KNOWLEDGE

“Logical knowledge” can be understood in two ways: as knowledge of the laws of logic and as knowledge derived by means of deductive reasoning. Most of the following is concerned with the first of these interpretations; the second will be treated briefly at the end. Furthermore, only deductive logic will be treated: As yet, there is no set of laws of inductive logic enjoying the kind of consensus acceptance accorded to deductive logic.

To begin with, we must specify what is a law of logic—not an entirely straightforward task. There are three, not all mutually exclusive, conceptions of logic laws. First, one could take them to be valid schemata (of statements), such as the familiar law of excluded middle, “ $p$  or not  $p$ ”. A second conception is that they are valid rules of inference, such as the familiar *modus ponens*—that is, from “ $p \rightarrow q$ ” and  $p$  infer  $q$ . The third conception of logic law, due to Gottlob Frege and Bertrand Russell, takes them to be maximally general, true (not valid) second-order quantified statements (see Goldfarb, 1979). The following discussion is confined, by and large, to the second conception; but the philosophical problems canvassed arise with respect to the other conceptions as well.

In order to appreciate the problems involved in the analysis of knowledge of logical laws, note first that, however these laws are conceived, knowledge of them appears to be propositional. That is, to know a law of logic is to know that a rule of inference (or a schema) is valid (or a statement true). But, given the classical analysis of knowledge as justified true belief, it follows that knowledge of the validity of a rule of inference requires justification. There are two uncontroversially entrenched forms of justification: inductive and deductive justification. By the nature of inductive reasoning an inductive justification of validity shows, at best, that a rule of inference usually leads from true premises to a true conclusion (or that it is sufficiently highly likely to do so). This is too weak; a valid rule of inference, as noted above, necessarily leads from true premises to true conclusions. So it appears that the justification of validity must be deductive.

On the basis of this conclusion it can be shown that the justification of the validity of any rule of inference either is circular or involves an infinite regress. The argument has two parts. To begin with, there certainly are deductive justifications of rules of inference that raise no serious philosophical questions. Take the justification of the rule “existential specification” in Benson Mates’s widely used *Elementary Logic*: “To justify this rule,... we observe that ... we may ... obtain the inference it permits

[using certain basic rules] ... Assuming ... that the basic rules ... are [valid], ... the above description of how any [existential specification] inference can be made using only [those] rules ... shows that [existential specification] is [valid], too” (Mates, 1972, p. 123). The rule is justified by explicitly assuming the validity of other rules, so the justification here is only relative. If all logical laws are justified in this way, then, plausibly, the justification of any given rule will be either circular, by explicitly assuming its own validity, or will involve an infinite regress.

One might conclude from this that there must be some set of rules that are not justified on the basis of the assumed validity of other rules. Let us call these rules fundamental. Unfortunately, there is a simple argument that the justification of fundamental rules will involve a similar circularity or infinite regress.

What counts as a deductive justification of a proposition depends on what forms of inference are taken to be valid. For, if any rule of inference used in an argument is invalid, then the argument could not constitute a deductive justification of anything. Let us formulate this point as: A deductive argument presupposes the validity of the rules of inference it employs. Given this formulation, we can state an intuitive principle: If an argument for the validity of a rule of inference presupposes the validity of that very rule, then the argument is circular. To distinguish this notion of circularity from the one used above, let us call this pragmatic circularity, and the former, direct circularity.

Suppose a fundamental rule of  $\rho$  is justified by an argument  $\pi$ . Now either  $\pi$  employs nonfundamental rules, or it does not. Suppose  $\pi$  employs a nonfundamental rule  $\sigma$ . By the first part of the argument,  $\sigma$  is justified by assuming the validity of fundamental rules. Again, either the justification of  $\sigma$  assumes the validity of  $\rho$  or it does not. Now assume further that if an argument employs a rule whose justification assumes the validity of another, then it presupposes the validity of the second. Thus, in the first case, the justification of  $\rho$  is pragmatically circular. In the second case, the justification of  $\rho$  presupposes the validity of a set of other fundamental rules.

Now suppose that  $\pi$  does not employ nonfundamental rules. Then, either it employs  $\rho$  or it does not. In the first case the justification is pragmatically circular. In the second, again, the justification of  $\rho$  presupposes the validity of a set of other fundamental rules. Hence, the justification of any fundamental rule either is pragmatically circular or involves an infinite regress. (See Goodman 1983, pp. 63–64; see also Bickenbach 1978, Dummett 1973, and Haack 1976.)

One might object to the notion of circularity of argument used in the second part of the argument. Unlike the more familiar variant of circularity, the conclusion in this case is not actually assumed as a premise but is presupposed by the inferential transitions. Thus, it is unclear that this sort of circular argument suffers from the principal difficulty afflicting the more familiar sort of circular argument, namely, that every conclusion is justifiable by its means.

This, however, is not a very strong objection. One might reply, to begin with, that pragmatically circular arguments are just as objectionable as directly circular ones in that both assume that the conclusion is not in question, by assuming its truth in the one case and by acting as if it were true in the other. Moreover, while it is unclear that every rule of inference is justifiable by a pragmatically circular argument, it is clear that such an argument can justify both rules that we take to be valid and rules that we take to be fallacies of reasoning. For example, the following is an argument demonstrating the validity of the fallacy of affirming the consequent (see Haack, 1976):

1. Suppose " $p \rightarrow q$ " is true.
2. Suppose  $q$  is true.
3. By the truth table for " $\rightarrow$ ," if  $p$  is true and " $p \rightarrow q$ " is true, then  $q$  is true.
4. By (2) and (3),  $p$  is true and " $p \rightarrow q$ " is true.
5. Hence,  $p$  is true.

Second, one might accept that deductive justification is not appropriate for fundamental logical laws but conclude that there is another kind of justification, neither deductive nor inductive, for these laws. There have been two proposals about a third kind of justification.

One proposal, due to Herbert Feigl (1963), claims that fundamental logical laws require pragmatic, instrumental justification. An immediate difficulty is, What counts as a pragmatic justification of a logical law? Surely, if there is anything that a rule of inference is supposed to do for us, it is to enable us to derive true conclusions from true premises. So, it looks as if to justify a logical law pragmatically is to show that it is suited for this purpose. And that seems to require showing that it is valid. Feigl is aware of this problem and argues that, in the context of a pragmatic justification, circularity is not a problem, since all that such a justification is required to do is provide a recommendation in favor of doing things in some particular way, not a proof that this way necessarily works. It is not clear, however, that this constitutes a compelling response to the philosophical problem of justifying

deduction, since, far from needing a letter of reference before employing deductive reasoning, its use is inescapable.

Another proposal for a third kind of justification is due to J. E. Bickenbach (1978), who argues that rules of inference are justified because they "fit with" specific instances of arguments that we accept as valid; for this reason he calls this kind of justification "instantial." The problem with this approach is that, in the case of rules of inference having some claim to being fundamental, such as *modus ponens*, it is plausible that we take the validity of the rule to be conceptually prior to the validity of any instance of it. For example, in the case of *modus ponens*, where there appear to be counterinstances to the rule, such as the sorites paradox, we take the problem to lie not in *modus ponens* but in vague concepts. Hence, whatever force "instantial" justification has, it seems incapable of conferring on fundamental rules of inference the kind of conceptual status we take them to have.

One might simply accept the conclusion of the argument, that fundamental logical laws cannot be justified, as indicating the philosophical status of these laws: They are simply constitutive rules of our practice of deductive justification. That is, there is no such thing as deductive justification that fails to conform to these rules, just as there is no such thing as the game of chess in which the queen is allowed to move in the same way as the knight. This third response leads to at least two philosophical questions: (1) How do we identify the fundamental laws of logic? (2) Is there such a thing as criticism or justification, as opposed to mere acceptance of a deductive practice?

A natural way to answer the first question is to take the fundamental rules to be determined by the meanings of the logical constants. This answer has been developed in some detail by Dag Prawitz (1977) and Michael Dummett (1991). Following Gerhard Gentzen (1969), they take the natural deduction introduction and elimination rules for a logical constant to be determined by the meaning of that constant. (More detail on the answer is provided in the final paragraph of this article.) Part of an answer to the second question has been provided by A. N. Prior (1967) and Nuel Belnap (1961), who showed that there exist sets of rules of inference that we can recognize as internally incoherent.

This third response has the consequence that our relation to the fundamental laws of logic is not one of knowledge classically construed and, hence, is different from our relation to other laws, such as the laws of physics, or of a country.

We turn now to the notion of knowledge derived from deductive reasoning. The question this notion raises, first studied by J. S. Mill (1950, bk. 2, chap. 3), is to explain how deductive reasoning could be simultaneously necessary and informative. It is undeniable that we can understand the premises and the conclusion of an argument without knowing that the former implies that latter; this is what makes it possible for us to gain information by means of deductive reasoning. This fact does not by itself conflict with the necessity of deductive implication, since there is no conflict between the existence of something and our lack of knowledge thereof. But, a problem can arise if the explanation of the necessity of deductive implication entails constraints on the notion of understanding. The following are two ways in which the problem of deduction arises.

First, consider Robert Stalnaker's (1987) analysis of the notions of proposition and of understanding. The proposition expressed by a statement is a set of the possible worlds, the set of those worlds in which the proposition is true. To understand a statement is to know the proposition it expresses; hence, to understand a statement is to know which possible worlds are those in which the proposition it expresses is true. These claims have two consequences: First, that all necessary statements, and hence all deductive valid statements, express the same proposition, namely, the set of all possible worlds; second, to understand any necessary statement is to know that the proposition it expresses is the set of all possible worlds. From these consequences it would seem to follow that in virtue of understanding any valid statement, one would know that it is necessarily true. It seems plausible that if one understands the premises and the conclusion of a valid argument, then one must also understand the conditional whose antecedent is the conjunction of the premises and whose consequent is the conclusion. But if the argument is valid, so is this conditional. Hence, if an argument is valid, then anyone who understood its premises and conclusion would know that this conditional expressed a necessary truth. It is now plausible to conclude that one can know whether an argument is valid merely on the basis of understanding its premises and conclusion by knowing whether the corresponding conditional expressed a necessary truth.

Next, consider Dummett's (1973, 1991) analysis of deductive implication. According to this analysis, deductive implication is based on the meanings of the logical constants. Thus, for example, the fact that  $p$  and  $q$  imply " $p$  and  $q$ " is explained by the fact that the meaning of "and" is such that the truth condition of " $p$  and  $q$ " is sat-

isfied just in case those of  $p$  and of  $q$  are. Similarly, the meaning of the existential quantifier is such that if the truth condition of " $a$  is  $F$ " is satisfied, then so must the truth condition of "There is an  $F$ ". Thus, corresponding to each logical constant, there is an account of the truth conditions of logically complex statements in which that constant occurs as the principal connective, in terms of the truth conditions of its substatements. This account explains the validity of rules of inference to those statements from their substatements and hence determines the set of fundamental rules, rules whose validity must be acknowledged by anyone who understands the meanings of the logical constants. But there are, as we have seen, cases in which we can understand the premises and the conclusion of an argument without knowing that the former implies the latter. So, how is deductive implication to be explained in those cases? This question is easy to answer if all the inferential transitions in these arguments are instances of fundamental rules determined by the senses of the constants. But the fact is otherwise; we acknowledge a number of rules of inference that are not reducible to fundamental rules. The problem is thus not an epistemological one; it arises because our conception of deductive implication includes rules whose necessity is not explainable on the basis of our understanding of the logical constants.

## LOGICAL PARADOXES

A paradox is an argument that derives or appears to derive an absurd conclusion by rigorous deduction from obviously true premises. Perhaps the most famous is Zeno's paradox of the runner, who, before she can reach her destination, first has to reach the point halfway there, and who, before reaching the halfway point, has to reach the quarter point, before which she must reach the point one-eighth of the way to the destination, and so on. The conclusion is that no runner ever reaches her goal, or even gets started.

To contemporary ears the argument does not sound so irresistible, since we can attribute its appeal either to an ambiguity in the use of "never" ("at no point in time" *versus* "at no point in the sequence") or to a dubious hidden premise that it is impossible to perform infinitely many tasks in a finite time, perhaps because there is a positive minimum to the length of time each task requires. To the ancients, however, the paradox was deeply disturbing. The most influential response was that of Aristotle, who concluded that it was not possible to partition the runner's path into infinitely many parts. Any segment of the runner's course can be divided in two, so that there is no finite bound on how many pieces the path contains, but the process of partitioning the path never concludes in a path with infinitely many parts. The number of segments that make up the path is said to be *potentially infinite*. The moral Aristotle drew from Zeno is that there is, in nature or in mathematics, no *actual infinite*. "Potentially infinite" is not like "potentially hot." When we say that a poker is potentially hot, we mean that, at some time and circumstance, it could be actually hot, whereas when we say that a line is potentially infinite, we mean that it can

always be made longer but not that there is any time at which it is actually infinite.

Aristotle's doctrine commanded wide adherence among philosophers and mathematicians, but toward the end of the nineteenth century it came widely to be seen as too restrictive. New mathematics embraced not only infinitely long lines, but also an analysis of a line as made up of infinitely many points, as well as infinite sets, infinite numbers, and infinite-dimensional geometry.

The new mathematics brought a spate of new paradoxes, which, in their formal structure, resemble the semantic paradoxes, the first of which appeared in the sixth century BCE when Epimenides, himself a Cretan, declared that Cretans always lie. Provided Epimenides' neighbors are sufficiently mendacious, we are driven to the conclusion that, if his statement is true, it is false, and if false, true. Deep problems, or perhaps a single deep problem in different manifestations, afflict the foundations of both mathematics and linguistics.

## COUNTING BEYOND THE FINITE

Broadly speaking there were two reasons for repudiating of Aristotle's prohibition of the actual infinite. First as mathematics became vastly more general, finitistic techniques came to be seen as confining. The ancient Greeks had a marvelously sophisticated theory of polygons and conic sections, but a fully general theory of shapes requires such techniques as approximating an unruly curve by an infinite sequence of curves that are better behaved.

The second reason was the so-called arithmetization of geometry, brought about by the investigation of alternatives to Euclid's axiom that, given a line and a point not on the line, there is on their plane exactly one line through the point that never intersects the given line, no matter how far the two lines are extended. Once alternatives to Euclidean geometry emerged, one could no longer be fully confident that Euclid's axioms correctly described the world around us (and, indeed, these suspicions are confirmed by the general theory of relativity). The theory of real numbers remained at the center of modern mathematics, but since one could no longer identify the positive real numbers as the ratios of lengths of physical line segments, one was no longer sure what the theory referred to.

A strategy for answering this question can be found in William Hamilton's treatment of the complex numbers. Extending the real number system by introducing a fictitious solution to the equation " $x^2 + 1 = 0$ " proves

enormously useful mathematically, but one cannot help fretting that addressing algebraic problems with make-believe solutions is more an exercise in wishful thinking than legitimate science. Hamilton proposed to soothe this consternation by taking “complex number” to refer not to new and ontologically dubious entities but to familiar mathematical objects thought of in a new way. Namely, we treat a complex number as an ordered pair of ordinary real numbers, with appropriate operations.

Hamilton’s construction presupposed the real numbers, but we can apply the same technique to secure the real numbers on a firmer basis. The starting point is easy enough. We can identify the positive rational numbers as ordered pairs of relatively prime positive integers, but the rationals have gaps— $\sqrt{2}$ , for instance—and the modern theory of continuity and limits requires a number system without gaps. More precisely we want assurance that the *least upper bound principle*, according to which every nonempty set of real numbers that is bounded above has a least upper bound, is satisfied. Richard Dedekind solved this problem by identifying the real number with pairs  $\langle A, B \rangle$  that partition the rationals into nonempty, nonoverlapping sets with every member of  $A$  less than every member of  $B$ .

Dedekind’s construction succeeded in securing the real numbers on a foundation that did not presuppose the truth of Euclidean geometry, but it required the unapologetic acceptance of infinite sets. It permitted real analysis to be seen as built upon a foundation in the theory of sets, and indeed set theory is widely perceived as providing a uniform foundation for all of mathematics.

The elevation of set theory to its central role received its greatest impetus from the work of Georg Cantor (1895, 1897) who extended elementary-school arithmetic so that infinite as well as finite sets could be counted. Doing so required him to confront Galileo’s paradox. Two sets have the same number of elements if there is a one-one correspondence by which each member of one set is paired off with one and only one member of the other. It follows that there are just as many perfect squares as there are nonnegative integers, since we can pair off  $n$  with  $n^2$ . But it seems obvious that there are more nonnegative integers than there are squares. A lot more, in fact, since as  $N$  grows the proportion of perfect squares among the first  $N$  integers becomes vanishingly small. The moral Galileo drew from this is that the notions of more and fewer cannot be applied to the infinite.

Overcoming Galileo’s paradox was largely a matter of raw intellectual courage. Cantor had to resolve to follow the computations where they led, no matter how strongly

the results he obtained contravened the intuitions obtained from grade-school experience with finite numbers. Stipulating that the cardinal number of  $S$  is equal to the cardinal number of  $T$  (in symbols,  $\#(S) = \#(T)$ ) if and only if  $S$  and  $T$  can be put in one-one correspondence and that  $\#(S) \leq \#(T)$  if and only if  $S$  has the same cardinal number as a subset of  $T$ , we find that the familiar laws of order carry over directly, with one glaring exception. As Galileo’s paradox illustrates, you can have  $\#(S) \leq \#(T)$  even though  $T$  is a proper subset of  $S$ . Defining, for  $S$  and  $T$  disjoint,  $\#(S) + \#(T) = \#(S \cup T)$ , we find that the familiar laws of addition are largely upheld, but that particular computations yield wildly unexpected results. If we let  $\aleph_0$  be the number of natural numbers, we find that  $\aleph_0 + \aleph_0 = \aleph_0$ . Similarly if we define  $\#(S) \cdot \#(T)$  to be the cardinal number of the set of ordered pairs  $\langle s, t \rangle$  with  $s \in S$  and  $t \in T$ , we find  $\aleph_0 \cdot \aleph_0 = \aleph_0$ . In fact for any infinite numbers  $\kappa$  and  $\lambda$ , we have  $\kappa + \lambda = \kappa \cdot \lambda = \max(\kappa, \lambda)$ .

It is starting to look as if infinite arithmetic is remarkably easy: Whatever the question, the answer is “ $\aleph_0$ .” This happy impression is dispelled when we turn to infinite exponentiation. Defining  $\#(S)^{\#(T)}$  to be the number of functions from  $T$  to  $S$ , we find that  $2^{\aleph_0}$ , which is the cardinal number of the *power set* of  $T$  (the set  $\wp(T)$  of subsets of  $T$ ), is strictly greater than  $\#(T)$ . That is,  $2^{\aleph_0} \geq \aleph_0$  and  $2^{\aleph_0} \neq \aleph_0$ . That  $\#(\wp(T)) \geq \#(T)$  is easy; use the function that takes an element  $x$  of  $T$  to  $\{x\}$ . To see that  $\#(T) \neq \#(\wp(T))$ , let  $F$  be a function from  $\wp(T)$  to  $T$ . We want to see that  $F$  is not one-one, that is, that there exist distinct subsets  $U$  and  $V$  of  $T$  with  $F(U) = F(V)$ , which we do by assuming  $F$  were one-one and deriving a contradiction. Define a binary relation  $E$  on  $T$  by stipulating that  $xEy$  if and only if  $x$  is an element of some set  $W$  with  $y = F(W)$ . Then for any element  $x$  of  $T$  and any subset  $V$  of  $T$ , we have  $xEF(V)$  if and only if  $\forall x$ . (Why? If  $xEF(V)$ , then there is a  $W$  with  $F(V) = F(W)$  and  $Wx$ ; because  $F$  is one-one, we must have  $V = W$ , hence  $\forall x$ . Conversely if  $\forall x$ , then we can find our set  $W$  with  $F(V) = F(W)$  and  $Wx$  by setting  $W$  equal to  $V$ .) In particular if we let  $R$  be the set of all elements of  $T$  that do not bear the relation  $E$  to themselves, we have, for any  $x$ ,  $xER(R)$  if and only if  $Rx$ , which happens if and only if not  $xEx$ . Taking  $x$  equal to  $F(R)$  reveals a contradiction.

In particular, the number of real numbers is  $2^{\aleph_0}$  so that there are more real numbers than there are natural numbers. To see that the real numbers are equinumerous with the numbers in the interval from 0 to 1, use the function that takes  $x$  to  $\frac{x}{|x|+1}$ . The proof that the real numbers between 0 and 1 are equinumerous with the sets of natural numbers uses the function that takes a real

number to the set of places in its binary decimal expansion where 1s appear, although one has to tinker a bit to make allowance for numbers like  $\frac{1}{2}$ , which has two different binary decimal expansions,  $0.1010000000 \dots$  and  $0.1001111111 \dots$ .

There are two fundamental ways we apply the counting numbers: To measure the size of a set, and to mark positions in a queue. For the first purpose we employ the English nouns, “one,” “two,” “three,” and so on, whereas for the second we use the adjectives “first,” “second,” “third.” ... To generalize the first concept into the infinite Cantor developed his theory of infinite cardinal numbers, and for the second he introduced a theory of infinite so-called *ordinal numbers*. First some definitions. A binary relation  $L$  on a set  $S$  is an *ordering* if it meets the following three conditions, for any  $x, y$ , and  $z$  in  $S$ : If  $xLy$  and  $yLz$ , then  $xLz$ ; not  $xLx$ ; and either  $xLy, yLx$ , or  $x = y$ . The usual way of ordering the real numbers is an ordering, but it doesn't distinguish a first, second, and third real number. In order for the members of an ordered set to be counted by ordinal numbers, a further condition is required: A binary relation  $L$  on a set  $S$  is *well-founded* just in case every nonempty subset  $R$  of  $S$  has an  $L$ -least element, an element  $x$  of  $R$  such that there is no element  $y$  of  $R$  with  $yLx$ ; equivalently there is no infinite sequence  $s_0, s_1, s_2, s_3, \dots$  with  $s_{n+1}Ls_n$ . A well-founded ordering is a *well-ordering*. Cantor's second great innovation was to extend the notion of ordinal number to infinite well-orderings.

If  $L$  well-orders a set  $S$  and  $M$  well-orders  $T$ , an *order isomorphism* from  $L$  to  $M$  is a one-one correspondence that preserves the order relation, so that, for any  $x$  and  $y$  in  $S$ , we have:  $xLy$  if and only if  $f(x)Mf(y)$ . Two well-orderings have the same ordinal number if and only if they are order isomorphic. If  $\alpha$  is the ordinal number of an ordering  $L$  on  $S$  and  $\beta$  is the ordinal number of an ordering  $M$  on  $T$ , we say that  $\alpha \leq \beta$  if and only if  $L$  is order-isomorphic to an initial segment of  $M$ . This provides a well-ordering of the ordinals, which supplies for each ordinal  $\alpha$  a well-ordering of the ordinals less than  $\alpha$ ; its ordinal number is  $\alpha$ . If  $L$  is a well-ordering of a set  $S$  there is a unique ordinal number associated with each element  $x$  of  $S$  that marks its position, namely the ordinal number of the well-ordering we get by restricting  $L$  to  $\{y \in S: yLx \text{ and } y \neq x\}$ .

Ernst Zermelo discovered a deep connection between cardinal and ordinal numbers: The cardinal numbers are well-ordered, so that the infinite cardinals can be placed in a sequence,  $\aleph_0, \aleph_1, \aleph_2, \aleph_3, \dots$ , and every cardinal number has the form  $\aleph_\alpha$ , for some ordinal  $\alpha$ .

## MR. RUSSELL'S BARBER

The program of securing the theory of sets on a unified axiomatic basis was trenchantly pursued by Gottlob Frege. A prerequisite for such a program is a system of logic that is both highly powerful and fully explicit, and before Frege there was no such logic. Frege's program has a philosophical motive. He wanted to show that the laws of arithmetic are analytic, so that, by providing suitable definitions, the laws of arithmetic can be reduced to pure logic. The key idea is that to say Traveler is a horse and to say that Traveler is an element of  $\{x: x \text{ is a horse}\}$  are two ways of saying the same thing, just like “Lee rode Traveler” and “Traveler was ridden by Lee.”

The specific form taken by Frege's reduction of arithmetic to logic depends on his doctrine of concepts and objects. Proper names (such as “Traveler”), definite descriptions (such as “the horse Lee rode into battle”), and sentences (such as “Traveler is a horse”) are *saturated* expressions, and they denote *objects*. Under Frege's rather eccentric usage, sentences are a species of name; they denote either the True or the False, which are objects. Open sentences, like “ $x$  is a horse” and “Lee rode  $x$  into battle,” are *unsaturated*, and they denote *concepts*. When we complete an open sentence by replacing the variable by a name, we get a sentence that denotes either the True or the False. Open sentences are a special case of *function sign*, an unsaturated expression whose completion yields a name. A concept is a special kind of function, one that cannot take any values other than the True and the False. There are, in addition, functions that demand more than one argument, represented by such multiply unsaturated phrases as “ $x$  rode  $y$ ,” and so-called *second-level* functions that take ordinary functions as arguments.

The fundamental principle of Frege's set theory, his Basic Law V (Basic Laws I through IV are unexceptionable principles of logic), associates a set, the object  $\{x: Fx\}$ , with each concept  $F$  in such a way that, for any concepts  $F$  and  $G$ ,  $\{x: Fx\}$  is equal to  $\{x: Gx\}$  if and only if, for every object  $x$ , we have  $Fx$  if and only if  $Gx$ . The left-to-right direction of this axiom is the axiom of extensionality, which has proven harmless. Extensionality is what distinguishes sets from properties. The property of being a human being is different from the property of being a featherless biped, even though  $\{x: x \text{ is a featherless biped}\} = \{x: x \text{ is a human being}\}$ . The right-to-left direction has proven deeply problematic. It asserts that the second-level function taking the concept  $F$  to  $\{x: Fx\}$  is one-one. On the basis of this axiom we can define “ $\in$ ”:  $z \in y$  if and only if, for some  $F$ ,  $y = \{x: Fx\}$  and  $Fz$ , and we can derive the so-called *comprehension principle* that, for any  $F$  and

$z, z \in \{x: Fx\}$  if and only if  $Fz$ , just as in the proof of Cantor's theorem, and just as before, we can derive a contradiction by asking whether  $\{x: x \notin x\}$  is an element of itself.

Bertrand Russell discovered the paradox and communicated it to Frege just as the second volume of Frege's monumental *Grundgesetze der Arithmetik* was going to press. Frege regarded it as devastating. "With the loss of my Basic Law V," he wrote in reply to Russell (1902, pp. 127–128), "not only the foundations of my arithmetic, but also the sole possible foundations of arithmetic, seem to vanish." Later scholarship, led by George Boolos, has seen the devastation as not quite so complete as Frege took it. Roughly speaking there are two principal components to the *Grundgesetze*: First the employment of Basic Law V (together with suitable definitions) to derive what Frege calls Hume's Principle, that, for any concepts  $F$  and  $G$ , the numbers associated with  $F$  and  $G$  are equal if and only if there is a one-one correspondence between the objects that fall under  $F$  and those that fall under  $G$ ; and second the derivation from Hume's Principle of the fundamental laws of arithmetic. The latter component is a substantial mathematical accomplishment that is unharmed by Russell's paradox.

A couple of other set-theoretic paradoxes emerged at about the same time, one, due to Cantor, involving cardinal numbers, and the other, due to Cesare Burali-Forti, about ordinal numbers.

For Cantor's paradox, let  $V$  be the set of all sets. Since every set of sets is a set,  $\wp(V)$  is a subset of  $V$ , and so  $\#(\wp(V)) \leq \#(V)$ . Yet Cantor's theorem tells us that  $\#(\wp(V)) > \#(V)$ . Cantor concluded from the contradiction that there is no set of all sets, invoking a distinction reminiscent of Aristotle's distinction of potentially and actually infinite. The sets measured by the  $\aleph_\alpha$ 's are transfinite, whereas the set of all sets, if there were such a thing, would be absolutely infinite. There is no such thing as  $V$  because the sets do not form a completed whole. There is no absolute infinity in mathematics; absolute infinity is the province of God alone.

For Burali-Forti's paradox, consider that the ordinals are well-ordered, and so they have an ordinal number. Call it  $\alpha$ .  $\alpha$  also the ordinal of the collection of ordinals less than  $\alpha$  and so there is an order-isomorphism  $f$  from the collection of all the ordinals to the collection of ordinals less than  $\alpha$ .  $f(\alpha) < \alpha$ , and so, since the ordering on the ordinals is well-founded, there has to be a least ordinal  $\beta$  with  $f(\beta) \neq \beta$ . We have  $f(\beta) =$  the least ordinal greater than

all the members of  $\{f(\gamma): \gamma < \beta\} =$  the least ordinal greater than all the members of  $\{\gamma: \gamma < \beta\}; = \beta$ .

Mirimanoff's paradox emerged a little later. Let us say that a set is *hereditarily well-founded* if it belongs to a collection  $C$  with the following properties: Every element of an element of  $C$  is an element of  $C$ ; and the elements of  $C$  are well-founded (that is, the restriction to an element of  $C$  of the elementhood relation is well-founded). It is easy to verify that the collection of all hereditarily well-founded sets is hereditarily well-founded. But this gives us the absurd prospect of a well-founded set that is an element of itself.

Russell illustrated the logical structure of his paradox with an amusing example. Imagine a village whose barber (an adult male villager) shaves all and only the adult male villagers who do not shave themselves. A contradiction arises when we inquire whether the barber shaves himself, by reasoning exactly analogous to the thinking that gets Russell's paradox. Unlike the set-theoretic paradox, however, the puzzle about the barber has an easy solution. There can be no such barber, however plausible the story that said there was one sounded on first hearing. One would like to obtain a similar resolution to Russell's paradox, denying that there is such a set as  $\{x: x \notin x\}$  (and, presumably, also that there are such sets as  $V$ , the set of all ordinals, and the set of all hereditarily well-founded sets) by restricting the range of open sentences that can be substituted for " $F$ " in the comprehension principle. The trick is to do this in a principled, credible way that avoids contradictions while maintaining the set existence principles required to do mathematics. Before asking how this might be done, let us examine the semantic analogues of the set-theoretic paradoxes.

## SEMANTIC PARADOXES

*Semantics*, as Alfred Tarski characterized it, is the branch of linguistics that studies the connections between expressions of a language and the things or states of affairs those expressions refer to. Its principal theoretical concepts are *truth*, *reference*, and *satisfaction*. A name, like "Traveler" or "Robert E. Lee's horse," refers to (or *names* or *denotes*) an object, in this case a stallion. An open sentence, like "x is a horse," represents a concept. The sentence got by substituting a name for the variable in an open sentence is true just in case the object referred to by the name falls under the concept represented by the open sentence. Because Traveler falls under the concept *horse*, the sentence "Traveler is a horse" is true. The reason for using the variable "x" to mark the place in the open sentence where a name needs to be supplied is to accommo-

date open sentences like “ $x$  rode  $y$  into battle,” which represent concepts with more than one argument. The account of satisfaction needs to be complicated a bit to allow for such open sentences, but that need not concern us here.

Another, more substantial, complication is that one should not really speak of a sentence being true, but rather of a sentence being true in a language in a context, or perhaps of a sentence expressing, in a language in a context, a proposition that is true. “I am now riding Traveler” is true when Lee says it while riding his horse, but it is false in most other contexts. This complication too can be set aside here.

Here our concern is with the semantic paradoxes. Epimenides is credited with the earliest formulation, although it is doubtful that he recognized that his statement was paradoxical. Someone acutely aware of the paradox was Eubulides of Miletas (a contemporary of Aristotle), who asked, “A man says that he is lying; is what he says true or false?” Eubulides formulated other notorious paradoxes, among them the *Bald Man* (The observation that plucking a single hair from a man who is not bald will not make him bald leads, by multiple application, to the conclusion that not even a man with no hair at all is bald) and the *Hooded Man* (You know who your father is, and you do not know who the hooded man is, even though, unknown to you, the hooded man is your father; this violates the law of identity, which allows the exchange of names that denote the same thing).

To avoid fretting about indexicals and also to avoid consternation that only purposefully false statements count as “lies,” let us consider what we may call the Liar Sentence, the sentence “The Liar Sentence is not true.” We would naively expect the notion of truth to be governed by the (T)-schema, “\_\_\_\_\_’ is true if and only if \_\_\_\_\_;” “Traveler is a horse,” for example, is true if and only if Traveler is a horse. However filling the blank with “The Liar Sentence is not true,” and noting that “The Liar Sentence is not true” = the Liar Sentence, results in contradiction.

The Liar paradox does not have a direct set-theoretic analogue, but there are paradoxes involving satisfaction and reference that have such analogues. The analogue to Russell’s paradox is due to Kurt Grelling. We would intuitively expect satisfaction to be governed by a principle exactly parallel to the comprehension principle in set theory, telling us, for example, that, for any  $y$ ,  $y$  satisfies “ $x$  is a horse” if and only if  $y$  is a horse. The phrase “ $x$  is a horse” is not a horse, and so “ $x$  is a horse” does not satisfy itself, whereas “ $x$  is an open sentence” does satisfy itself.

For any  $y$ ,  $y$  satisfies “ $x$  is an open sentence that does not satisfy itself” if and only if  $y$  is an open sentence that does not satisfy itself. Taking  $y$  to be the open sentence “ $x$  is an open sentence that does not satisfy itself” yields a contradiction.

Cantor’s paradox is obtained by generalizing Cantor’s argument that there are more real numbers between 0 and 1 than there are positive integers, which proceeds by assuming for *reductio ad absurdum* that there were a list that enumerated all the real numbers between 0 and 1, then asking where on the list there appears the number  $r$  given by stipulating that the  $n$ th digit in the binary decimal expansion of  $r$  is equal to one if and only if zero is the  $n$ th digit in the binary decimal expansion of the  $n$ th number on the list. *Richard’s paradox* invites us to consider, in particular, the list gotten by enumerating the English expressions that denote real numbers between 0 and 1 in alphabetical order. Cantor’s argument gives us a real number between 0 and 1 that is not named by any expression of English. But is Cantor’s number not named by the expression “the number  $r$ , between 0 and 1, such that the  $n$ th binary digit of  $r$  is equal to one if and only if zero is the  $n$ th binary digit of the number named by the alphabetically  $n$ th English phrase that names a real number between 0 and 1”?

The number of English expressions that name ordinal numbers is  $\aleph_0$  since the expressions are finite strings of words from a finite vocabulary. There are more than  $\aleph_0$  ordinals, so there are ordinals not named by an expression of English, and hence a least ordinal number not named by an expression of English. But “the least ordinal number not named by an expression of English” names it. This is *König’s paradox*. *Berry’s paradox* is the finitary version, got by noting that “the least natural number that cannot be named by an English expression of fewer than thirty syllables” is an English expression that names a natural number in twenty-eight syllables.

## PRINCIPIA MATHEMATICA

Alfred North Whitehead and Bertrand Russell undertook to solve simultaneously both the set-theoretic paradoxes and the semantic paradoxes. The aim of their highly ambitious *Principia Mathematica* was to secure all of mathematics on a basis in pure logic. In their system the role hitherto played by sets was taken over by *propositional functions*, which are a kind of amalgam of Frege’s concepts and Frege’s propositions. *Propositions* are, for Frege, the objects of belief and judgment, the sort of thing referred to by “that” clauses in English. According to Russell if you prefix the word “that” to an open sentence, you

get an expression that names a propositional function, a function taking objects to propositions. If you supply an object as argument, the output is the proposition you would express if you substituted a name of that object into the open sentence. With *Traveler* as argument, the propositional function designated by “that Lee rode  $x$  into battle” yields the proposition that Lee rode *Traveler* into battle.

This account was considered and rejected by Frege on the basis that it would yield the result that the proposition that *Traveler* is white is identical to the proposition that the horse Lee rode into battle is white, in spite of the fact that someone who did not realize that *Traveler* is the horse Lee rode into battle might believe one but not the other. For Frege, the argument of the propositional function is not the horse *Traveler* but the sense (*Sinn*) of the name “*Traveler*.” Russell thought he could thwart Frege’s objection by a logical analysis according to which “the horse Lee rode into battle” is, despite appearances, not a denoting phrase. The relative merits of Frege’s and Russell’s conceptions of propositional functions have been much debated.

Whitehead and Russell proposed to avert the paradoxes by adopting the *vicious circle principle* (which they attribute to Henri Poincaré), according to which you cannot have a proposition that refers to itself since before you could formulate such a proposition you would have to already possess the proposition you were trying to formulate. You cannot have a propositional function that has itself or any of its values as argument, nor can you have a propositional function in whose formulation you are required to talk about the propositional function or any of its arguments. To formulate an analogue to Russell’s paradox in terms of propositional functions, you would have to suppose that the phrase “that  $x$  is a propositional function not true of itself” denoted a propositional function, and such a propositional function would violate the vicious circle principle. Whitehead and Russell adopted a (maddeningly elaborate) formalism in which such phrases were grammatically ill-formed.

The vicious circle principle evades the paradoxes (as far as anyone knows), but it also rules out ordinary mathematics. If  $r$  is the least upper bound of a given collection of real numbers then it is the least element of a totality that includes  $r$  itself.

In *Principia Mathematica*, the propositional functions are arrayed in layers, where the level of a given function is determined by the levels of its possible arguments and also by the levels of the propositional functions utilized in defining the given function. A propositional func-

tion is said to be *predicative* if it is at the lowest level it could possibly be at, given what its arguments are. Either it is defined without referring to anything beyond its potential arguments (say, by giving a list), or the things referred to are sufficiently low-level that they do not affect the level of the function. Whitehead and Russell obtained the least upper bound principle by adopting the *axiom of reducibility*, according to which for every propositional function there is a predicative propositional function true of the same things. Given a collection  $C$  of real numbers, take a predicative function  $Fx$  that is coextensive with “ $x$  is an upper bound of  $C$ ,” we get the least upper bound of  $C$  as the least number that satisfies  $Fx$ .

The justification of the axiom of reducibility is purely pragmatic—it is needed for mathematics—and its adoption seriously undermines Whitehead and Russell’s claim to have reduced mathematics to logic.

Once we have the axiom of reducibility on board, there is no longer any useful purpose in having the position in the hierarchy of a propositional function depend on the positions of the things we refer to in defining the function as well as on the positions of the potential arguments. We can obtain both the same mathematical results and the same degree of insulation from paradox simply by taking the type of a propositional function to be immediately above the types of its arguments, no matter how the propositional function is defined. Frank Ramsey first recognized this, effecting an enormous simplification in the system. W. V. Quine took the observation a step further, noticing that there was no longer any benefit in supposing coextensive propositional functions to be distinct, so that we could take the things the “Ramseyfied” theory was about to be sets and relations, rather than propositional functions of one or more variables.

The system can be further streamlined by replacing talk about binary relations between individuals with talk about sets of ordered pairs of individuals, replacing talk about ternary relations with talk about sets of ordered triples, and so on. There is no need to take ordered triples as primitive, since we can define  $\langle a, b, c \rangle$  as the ordered pair  $\langle a, \langle b, c \rangle \rangle$ . In fact—this is an ingenious observation of Norbert Wiener—there is no need to take ordered pairs as primitive, since we can define  $\langle a, b \rangle$  as  $\{\{\{a\}, \emptyset\}, \{\{b\}\}\}$ . This stipulation enables us to derive the principle that, for any  $a, b, c$ , and  $d$ ,  $\langle a, b \rangle = \langle c, d \rangle$  if and only if  $a=c$  and  $b=d$ , which is the only thing one ever needs to know about ordered pairs. The resulting system is arrayed in a simple hierarchy. There are individuals, sets of individuals, set of sets of individuals, and so on. It is this hierarchical struc-

ture, rather than the vicious circle principle, that precludes paradox.

### ZERMELO-FRAENKEL SET THEORY

The most prominent of *Principia Mathematica's* rivals originates, not in a philosophical analysis of methods of reasoning that lead to the paradoxes, but in a mathematical examination of ways of reasoning that never cause problems. Zermelo's 1904 proof that every set can be well-ordered, with its corollary that the cardinal numbers are well-ordered, met considerable resistance. It was felt that it skirted too close the edge of the newly discovered paradoxes. Poincaré, for example, complained about vicious circularity. Zermelo replied that the methods of forming sets that figure in the paradoxes are far removed from the methods that are gainfully employed by working mathematicians, and that the principles that figure in the deduction of the well-ordering theorem fall into the latter category. To make this reply more precise Zermelo wrote down axioms of set theory sufficient to derive the well-ordering theorem, in the hope that all could see that the proof required only well-established principles of workaday mathematics that had never been implicated in paradox.

Zermelo's axioms did not come equipped with a diagnosis of the paradoxes, but a couple of widely accepted further principles do have diagnostic import. Although Zermelo's axioms are immensely powerful, they omit some common and apparently harmless mathematical practices, like forming infinite sequences of the form  $\langle s_0, s_1, s_2, s_3, \dots \rangle$ . Abraham Fraenkel proposed to rectify this situation by adopting the *replacement axiom schema*, which says that for any open sentence that defines a function, if the inputs to the function form a set, so do the outputs. In Frege's logic, in which there was one style of variables ranging over sets and other objects and another style ranging over functions, the replacement axiom would be expressed by saying the restriction of a function to a set domain invariably has a set as its range. Fraenkel is only able to produce a schema that applies to definable functions because his logical resources are restricted to the first-order predicate calculus, which only has variables ranging over individuals. The new principle is formulated as a formula that contains a schematic letter, so understood that the formulas of the language of set theory obtained by substituting a formula for the schematic letter are regarded as axiomatic. This retreat to first-order logic results from relinquishing the program of trying to produce a logic so powerful that set theory can be reduced to it. The existence of sets cannot be established

by logic alone, and the first-order formulation makes set theory's existence assumptions fully explicit.

The replacement axioms assure us that an open sentence has a set as its extension unless the things that satisfy it are more numerous than the members of any set. The doctrine of *limitation of size* has it that things form a set unless there are too many of them, and that the paradoxes arise from attempts to form sets that are too large to hang together. The Burali-Forti paradox, for example, tells us that the ordinals are too numerous to form a set.

Mirimanoff's paradox distinguishes the hereditarily well-founded sets—what Mirimanoff calls the *ordinary sets*—from the others. It turns out that extraordinary sets (if there are any) are never needed for mathematics, and if we restrict our attention to ordinary sets, adopting an axiom that the elementhood relation is well-founded, an attractive picture of the universe of set appears. Sets are built up in stages. At the bottom level the so-called *urelements* are whatever non-sets you may want to count or measure. (For pure, as opposed to applied, mathematics, no urelements are needed.) At the second level are sets of urelements. At the third level are sets whose elements are urelements and sets of urelements. And so on. At each stage the available building blocks are the urelements and the sets built at earlier stages, and every set is constructed at some, possibly transfinite, stage. Because new sets and new ordinals are added at every stage, there is no stage at which one constructs a set that contains all the ordinals or a set that contains all the sets that do not contain themselves (which would be a set that contained all sets). The purported sets that threaten paradox never appear.

The two strategies for blocking the paradoxes—limitation of size and construction in stages—are by no means in conflict. Indeed one could argue (although it is certainly not obvious) that the stage construction ensures that no stage ever produces a set large enough to violate the limitation of size. On the other hand Peter Aczel (1988) has devised an alternative to standard set theory, provably consistent if ordinary set theory is, that upholds limitation of size but allows non-well-founded sets in great profusion.

The Whitehead-Russell system and the Zermelo-Fraenkel system are by no means the only extant responses to the set-theoretic paradoxes—Quine, for example, devised a method for restricting the comprehension principle so as to allow a universal set, without apparent contradiction—but they are the most prominent. Their rivalry is not so implacable as first appears. Indeed Kurt Gödel (1944/1983) has noted that we can think of the Zermelo-Fraenkel system as obtained from

*Principia Mathematica*, as simplified by Ramsey, Quine, and Weiner, by generalizing in two directions. First we allow the types to be cumulative, so that the possible elements at a type level are not just the sets of the immediately preceding type but sets of all the preceding types. Second we allow the type levels to extend into the transfinite.

One question the axiomatizations leave unanswered is how comprehensive the theory of sets is intended to be. Not all collections are sets. A stamp collection for example can survive the acquisition of a new stamp, whereas when you add a stamp to a set of stamps, you get a different set. But perhaps set theory accounts for all extensional collections. If not then the set theorist has two tasks: To say what extensional collections there are, and to say which of the extensional collections are sets. John von Neumann gave such an account. His theory has two kinds of *classes*, namely, sets and *proper classes*. Classes are made up of sets and urelements, and a class is a set if and only if it is not equinumerous with the class of all ordinals. The proper classes form the top element of the cumulative hierarchy.

Zermelo has a different perspective, reminiscent of Aristotle's doctrine that a line or the integers never form a completed whole. The universe of set theory does not form a completed whole, according to Zermelo. Candidates for the "universe" of set theory are only provisional, and one can always advance to a higher perspective from which a candidate universe is seen as a set within a larger universe.

## SEMANTIC PARADOXES

In looking at possible solutions to the set-theoretic paradoxes, the semantic paradoxes have been set aside. One cannot happily say about the Liar Sentence the same thing one wants to say about the alleged set of all ordinals, namely, that there is no such sentence. One might want to say that what goes wrong with the Liar Sentence is that it does not express a proposition, but any satisfaction this gives us is short-lived. A propositionalist theory of truth has to account for two things, the truth conditions for propositions and the connection between a sentence and the proposition it expresses, and the latter relation remains troublesome. Consideration of the Propositional Liar Sentence ("The Propositional Liar Sentence does not express a true proposition") seems to force us the self-defeating conclusion that the Propositional Liar Sentence does not express a proposition, and hence that it does not express a true proposition.

The standard response to the semantic paradoxes was given by Alfred Tarski, who insists that, in developing a semantic theory, the language one employs (the *meta-language*) must be richer in expressive power than the language one is talking about (the *object language*), so that one can never formulate the theory of truth, reference, and satisfaction for a language within the language itself.

A number of ingenious extensions of Tarski's basic idea have been developed. Notable among them is Saul Kripke's (1975) demonstration that, thinking of such troubled sentences as the Liar as neither true nor false, one can add the predicate "true" to a language and partition the sentences of the resulting language in such a way that a sentence *S* is counted as true, false, or undecided according as the statement that *S* is true is accounted true, false, or undecided. The enriched language cannot, however, express the equivalence of *S* with the statement that *S* is true, nor can it express the proof that the Kripke construction yields the equivalence. These things can only be said within a richer metalanguage. Indeed, in the best known version (there are a number of variants), the addition of the truth predicate results in a drastic restriction in the range of truth-preserving inferences, so that the object language has an enervated logic in which nothing resembling ordinary mathematical or philosophical reasoning can be carried on (as Solomon Feferman's investigations have made abundantly clear). Hartry Field (2003) has proposed enriching the Kripke construction by adding a new, nonclassical conditional, which behaves enough like the everyday "if... then" to accommodate a substantial range of familiar inferences. With Field's novel interpretation of "if and only if," the (T)-sentences are all counted as true.

Field's construction is too complicated to describe here, but its key idea comes from revision theory, which employs full classical logic but regards the "if and only if" that appears in the (T)-sentences as a special connective that represents definitional equivalence. Developed by Anil Gupta and Nuel Belnap (1993) on a foundation laid down independently by Gupta and Hans Herzberger, revision theory treats the (T)-sentences as defining "true," and it ascribes to the "if and only if" of definition a special logic that allows for circular definitions. If "*F*" is defined by "*F*(*x*) if and only if \_\_\_\_\_," where the defined predicate "*F*" appears in the blank, and if *C* is proposed as a possible candidate for the extension of "*F*," then the map that takes *C* to {*x*: *x* satisfies \_\_\_\_\_ when *C* is taken as the extension of "*F*"} gives us, by iteration, better and better candidates for the extension of

“F.” Throughout the revision process, the Liar sentences keeps flip-flopping between true and false, but sentences that have an intuitively correct truth value eventually settle down to their intuitively expected values, even in the presence of extensive self-reference and cross-reference. Tarski’s restriction is still observed, inasmuch as the entire construction is developed within a richer metalanguage.

Tarski’s doctrine works happily for formal languages, but it leaves us unable to understand how the notion of truth and reference apply to natural languages, since “true in English” is a phrase of English and not some unnatural metalanguage.

Some progress has been made by adapting the *Principia Mathematica* idea of subscripted “true”s. There is a predicate “true<sub>0</sub>” that applies to sentences that contain no semantic notions; a predicate “true<sub>1</sub>” that applies to sentences with no semantic notions other than “true<sub>0</sub>,” “true<sub>2</sub>” that applies to sentences with no semantic notion other than “true<sub>0</sub>” and “true<sub>1</sub>” and so on. Tyler Burge (1979) and Charles Parsons (1974) have proposed applying this notion to English by supposing that the English word “true” is ambiguous, and that disambiguating subscripts are tacitly ascribed by contexts in such a way that a truth attribution is supplied a subscript one greater than the maximum of those that appear in the sentences one is talking about. Eubulides’s derivation of a contradiction is seen as committing a fallacy of equivocation, inasmuch as the tacit subscript changes during the course of his argument.

The *Principia*-inspired approach still has limitations. For one thing there does not appear to be any uniform, non-arbitrary way of coping with situations in which *A* talks about all the things *B* says at the same time *B* talks about all things *A* says. For another the description of the subscripting machinery lies outside the object language, so that we are provided with no good way of dealing with “This sentence is not true<sub>α</sub>, for any α.”

A different approach tries to consolidate the Liar paradox and the Bald Man by developing the idea that, if Harry is a borderline case of “bald,” “Harry is bald” should be neither true nor false. “‘Harry is bald’ is either true or false” follows logically (defining falsity as truth of the negation) from the conditionals we get by substituting “Harry is bald” and “Harry is not bald” into the right-to-left direction of the (T)-schema. Allowing that “Harry is bald” is neither true nor false requires restricting the right-to-left direction of (T) so that it does not apply to such things as border applications of vague terms, which are semantically defective. This restriction yields an attractive response to the Bald Man, but the answer to the

Liar is problematic. The left-to-right direction of (T) (“If ‘The Liar Sentence is not true’ is true then the Liar Sentence is not true”) suffices to yield the conclusion that the Liar Sentence is untrue, and hence, because the right-to-left (T)-schema fails for it, that the statement that Liar Sentence is untrue is semantically defective. This result is unwelcome, because it tells us that a conclusion can be derived by rigorous, careful deduction from secure premises and still be semantically defective.

The argument of the previous paragraph is adapted from Richard Montague’s (1960) argument that a Liar-type paradox can be obtained for necessity in place of truth. Also, as Montague and David Kaplan (1960) showed, for knowledge. It seems safe to say that the semantic paradoxes are currently less well-managed than the set-theoretic paradoxes.

## LOGICAL POSITIVISM

“Logical positivism” is the name given in 1931 by A. E. Blumberg and Herbert Feigl to a set of philosophical ideas put forward by the Vienna circle. Synonymous expressions include “consistent empiricism,” “logical empiricism,” “scientific empiricism,” and “logical neopositivism.” The name logical positivism is often, but misleadingly, used more broadly to include the “analytical” or “ordinary language” philosophies developed at Cambridge and Oxford.

### HISTORICAL BACKGROUND

The logical positivists thought of themselves as continuing a nineteenth-century Viennese empirical tradition, closely linked with British empiricism and culminating in the antimetaphysical, scientifically oriented teachings of Ernst Mach. In 1907 the mathematician Hans Hahn, the economist Otto Neurath, and the physicist Philipp Frank, all of whom were later to be prominent members of the Vienna circle, came together as an informal group to discuss the philosophy of science. They hoped to give an account of science that would do justice—as, they thought, Mach did not—to the central importance of mathematics, logic, and theoretical physics, without abandoning Mach’s general doctrine that science is, fundamentally, the description of experience. As a solution to their problems, they looked to the “new positivism” of Jules Henri Poincaré; in attempting to reconcile Mach and Poincaré they anticipated the main themes of logical positivism.

In 1922, at the instigation of members of the “Vienna group,” Moritz Schlick was invited to Vienna as professor, like Mach before him (1895–1901), in the philosophy of the inductive sciences. Schlick had been trained as a scientist under Max Planck and had won a name for himself as an interpreter of Albert Einstein’s theory of relativity. But he was deeply interested in the classical problems of philosophy, as Mach had not been.

Around Schlick, whose personal and intellectual gifts particularly fitted him to be the leader of a cooperative discussion group, the “Vienna circle” quickly established itself. Its membership included Neurath, Friedrich Waismann, Edgar Zilsel, Béla von Juhos, Felix Kaufmann, Feigl, Victor Kraft, Philipp Frank—although he was by now teaching in Prague—Karl Menger, Kurt Gödel, and Hahn. In 1926 Rudolf Carnap was invited to Vienna as instructor in philosophy, and he quickly became a central figure in the circle’s discussions; he wrote more freely than the other members of the circle and came to be regarded as the leading exponent of their ideas. Carnap had been trained as a physicist and mathematician at Jena, where he had come under Gottlob Frege’s influence. Like other members of the circle, however, he derived his principal philosophical ideas from Mach and Bertrand Russell.

Ludwig Wittgenstein and Karl Popper were not members of the circle but had regular discussions with its members. In particular, Wittgenstein was in close contact with Schlick and Waismann. Wittgenstein’s *Tractatus Logico-Philosophicus* had a profound influence on the deliberations of the circle, where it was interpreted as a development of British empiricism.

The circle ascribed to Wittgenstein the “verifiability principle”—that the meaning of a proposition is identical with the method of verifying it—that is, that a proposition means the set of experiences that are together equivalent to the proposition’s being true. Wittgenstein, they also thought, had shown how an empiricist could give a satisfactory account of mathematics and logic. He had recognized that the propositions of logic and mathematics are tautologies. (The logical positivists paid no attention to Wittgenstein’s distinction between tautologies and identities.) They are “independent of experience” only because they are empty of content, not because, as classical rationalists had argued, they are truths of a higher order than truths based on experience.

In the German-speaking countries, the Vienna circle was a small minority group. For the most part, German-speaking philosophers were still committed to some variety of “German idealism.” Neurath, with his strong sociopolitical interests, was particularly insistent that the circle should act in the manner of a political party, setting out to destroy traditional metaphysics, which he saw as an instrument of social and political reaction.

In 1928 the significantly named Verein Ernst Mach (Ernst Mach Society) was set up by members of the circle with the avowed object of “propagating and furthering a scientific outlook” and “creating the intellectual instru-

ments of modern empiricism.” To welcome Schlick back to Vienna in 1929 from a visiting professorship at Stanford, California, Carnap, Hahn, and Neurath prepared a manifesto under the general title *Wissenschaftliche Weltauffassung, Der Wiener Kreis* (The Scientific World View: The Vienna Circle). This manifesto traced the teachings of the Vienna circle back to such positivists as David Hume and Mach, such scientific methodologists as Hermann Ludwig von Helmholtz, Poincaré, Pierre Maurice Marie Duhem, and Einstein, to logicians from Gottfried Wilhelm Leibniz to Russell, utilitarian moralists from Epicurus to John Stuart Mill, and to such sociologists as Ludwig Feuerbach, Karl Marx, Herbert Spencer, and Menger. Significantly absent were any representatives of the “German tradition”—even, although somewhat unfairly, Immanuel Kant.

In order to make its conclusions familiar to a wider world, the circle organized a series of congresses. The first of these was held in Prague in 1929 as a section of a mathematical and physical, not a philosophical, congress. It was jointly sponsored by the Ernst Mach Society and the Society for Empirical Philosophy, a Berlin group led by Hans Reichenbach and with such members as Walter Dubislav, Kurt Grelling and Carl Hempel, which stood close in its general approach to the Vienna circle.

Meanwhile, the international affiliations of the circle were increasing in importance. American philosophers like C. W. Morris emphasized the link between logical positivism and American pragmatism; Ernest Nagel and W. V. Quine visited Vienna and Prague. In Great Britain, logical positivism attracted the interest of such Cambridge-trained philosophers as L. Susan Stebbing and John Wisdom and the Oxford philosophers Gilbert Ryle and A. J. Ayer, the latter participating for a time in the deliberations of the circle. In France such philosophers of science as Louis Rougier were attracted by logical positivism, as were a group of neo-Thomists led by General Vouillemin, who welcomed the positivist critique of idealism. In Scandinavia, where the way had been prepared by the antimetaphysical philosophy of Axel Hägerström, a number of philosophers sympathized with the aims of the logical positivists; Eino Kaila, Arne Naess, Åke Petzäll, and Jørgen Jørgensen were prominent representatives of the international movement centering on logical positivism. The Polish logicians, especially Alfred Tarski, exerted a considerable influence on members of the circle, particularly on Carnap. German philosophers, except for Heinrich Scholz of Münster and the Berlin group, remained aloof. Undoubtedly, the organizational energies of the circle did much to bring into being in the 1930s an

international community of empiricists; this was largely a consequence of the circle’s isolation within the German countries themselves.

Meanwhile the circle was publishing. In 1930 it took over the journal *Annalen der Philosophie* and renamed it *Erkenntnis*. In the period from 1930 to 1940 it served as a “house organ” for members of the Vienna circle and their associates. In addition, the circle prepared a series of monographs under the general title *Veröffentlichungen des Vereines Ernst Mach* (from 1928 to 1934) and *Einheitswissenschaft* (edited by Neurath from 1934 until 1938).

During the 1930s, however, the Vienna circle disintegrated as a group. In 1931 Carnap left Vienna for Prague; in that year Feigl went to Iowa and later to Minnesota; Hahn died in 1934; in 1936 Carnap went to Chicago and Schlick was shot by a mentally deranged student. The meetings of the circle were discontinued. The Ernst Mach Society was formally dissolved in 1938; the publications of the circle could no longer be sold in German-speaking countries. Waismann and Neurath left for England; Zilsel and Kaufmann followed Feigl, Carnap, Menger, and Gödel to the United States. *Erkenntnis* moved in 1938 to The Hague, where it took the name *Journal of Unified Science*; it was discontinued in 1940. Logical positivism, too, disintegrated as a movement, absorbed into international logical empiricism.

## CRITIQUE OF TRADITIONAL PHILOSOPHY

Mach denied that he was a philosopher. He was trying, he said, to unify science and, in the process, to rid it of all metaphysical elements; he was not constructing a philosophy. The general attitude of the Vienna circle was very similar. Schlick was the exception. With logical positivism, he argued, philosophy had taken a new turn, but logical positivism was nonetheless a philosophy. Carnap, in contrast, wrote that “we give no answer to philosophical questions and instead *reject all philosophical questions*, whether of Metaphysics, Ethics or Epistemology” (*The Unity of Science*, p. 21). Philosophy, on his view, had to be destroyed, not renovated.

Undoubtedly, this intransigent attitude to philosophy can in part be explained by the peculiar character of German idealism and its hostility to science. The logical positivists thought of themselves as extending the range of science over the whole area of systematic truth and as needing for that purpose to destroy the claim of idealist philosophers to have a special kind of suprascientific access to truth.

**METAPHYSICS.** Of the traditional branches of philosophy, the positivists rejected transcendental metaphysics on the ground that its assertions were meaningless, since there was no possible way of verifying them in experience. Nothing that we could possibly experience, they argued, would serve to verify such assertions as “The Absolute is beyond time.” Therefore, the positivists held, it tells us nothing. The rejection of transcendental metaphysics was not a novelty; Hume had described transcendental metaphysics as “sophistry and illusion” and had alleged that it makes use of insignificant expressions; Kant and the neo-Kantians had rejected its claim to be a form of theoretical knowledge; Mach had sought to remove all metaphysical elements from science. But whereas earlier critics of metaphysics had generally been content to describe it as empty or useless or unscientific, the logical positivists took over from Wittgenstein’s *Tractatus* the rejection of metaphysics as meaningless. The propositions of metaphysics, they argued, are neither true nor false; they are wholly devoid of significance. It is as nonsensical to deny as to assert that the Absolute is beyond time.

**EPISTEMOLOGY.** Neo-Kantians had sometimes suggested that philosophy could be reduced to epistemology or “theory of knowledge,” which discussed such topics as “the reality of the external world.” But assertions about the external world, the positivists argued, are quite as meaningless as assertions about the Absolute or about things-in-themselves. For there is no possible way of verifying the assertion that there is, or the assertion that there is not, an external world independent of our experience. Realism and idealism, considered as epistemological theses, are equally meaningless. So far as epistemology has any content, it reduces to psychology, to assertions about the workings of the human mind, and these have nothing to do with philosophy.

**ETHICS.** The logical positivists disagreed about ethics. Of course they all rejected any variety of transcendental ethics, any attempt to set up a “realm of values” over and above the world of experience. Assertions about values, thus conceived, fall within the general province of transcendental metaphysics and had therefore to be rejected as nonsensical. But whereas Schlick sought to free ethics from its metaphysical elements by converting it into a naturalistic theory along quasi-utilitarian lines, Carnap and Ayer argued that what are ordinarily taken to be ethical assertions are not assertions at all. To say that “stealing is wrong,” for example, is neither, they suggested, to make an empirical statement about stealing nor to relate

stealing to some transcendental realm. “Stealing is wrong” either expresses our feelings about stealing, our feelings of disapproval, or, alternatively (positivists’ opinions differ about this), it is an attempt to dissuade others from stealing. In either case, “stealing is wrong” conveys no information.

**PHILOSOPHICAL MEANINGLESSNESS.** In general, the positivists explained, when they said of philosophical assertions that they were meaningless, they meant only that they lacked “cognitive meaning.” Ethical and metaphysical assertions have emotional associations; this distinguishes them from mere jumbles of words. Such statements as “God exists” or “Stealing is wrong” are, on the face of it, very different from a collocation of nonsense syllables. But the fact remains, the positivists argued, that such “assertions” do not convey, as they purport to do, information about the existence or character of a particular kind of entity. Only science can give us that sort of information.

Not all philosophers, however, have devoted their attention to describing pseudo entities such as “the Absolute” or “values” or “the external world.” Many of them have been mainly concerned with empirical-looking concepts such as “fact,” “thing,” “property,” and “relation.” Russell’s lectures on logical atomism and Wittgenstein’s *Tractatus* are cases in point.

Wittgenstein suggested, however, that the sections in the *Tractatus* in which he talked about facts, or attempted to show how propositions can picture facts, must all in the end be rejected as senseless—as attempts to say what can only be shown. For it is impossible in principle to pass beyond our language in order to discuss what our language talks about. Philosophy is the activity of clarifying; it is not a theory.

Schlick carried to its extreme Wittgenstein’s *Tractatus* doctrine that philosophy is an activity. Philosophy, he suggested, consists in the deed of showing in what the meaning of a statement consists; that is, philosophy is a silent act of pointing. The ultimate meaning of a proposition cannot consist in other propositions. To clarify, therefore, we are forced in the end to pass beyond propositions to the experience in which their meaning consists.

This view won few adherents. It was generally agreed that philosophers could not avoid making the sort of ontological assertions Wittgenstein made in the *Tractatus* and that it is altogether too paradoxical to suggest that all propositions about, for example, the relation between facts and language are nonsensical, even if “important” nonsense. Neurath, in particular, insisted that nonsense

cannot be “important,” cannot act as a ladder by which we arrive at understanding, as Wittgenstein had said.

**STATEMENTS ABOUT LANGUAGE.** Carnap suggested that Wittgenstein was mistaken in supposing that his ontological assertions were without any sense. They were, however, meaningful assertions about language, not about a world beyond language. No doubt, Carnap admits, ontological statements have the appearance of being about the world or, at least, about the relation between language and the world. But this is so only because they have been wrongly formulated in what Carnap calls “the material mode.”

Carnap distinguishes three classes of sentences: object sentences, pseudo object sentences, and syntactical sentences. Any ordinary sentence of mathematics or science is an object sentence. Thus, for example, “Five is a prime number” and “Lions are fierce” are both object sentences. Syntactical sentences are sentences about words and the rules governing the use of words. For example, “Five is not a thing-word but a number-word” and “Lion is a thing-word” are syntactical sentences. Pseudo object sentences are peculiar to philosophy; they look like object sentences but if rightly understood turn out to be syntactical sentences. To understand them rightly we have to convert them from the “material mode” into the “formal mode,” that is, from sentences that look as if they are about objects into sentences that are obviously about words. Examples are “Five is not a thing but a number” and “Lions are things.” Once these sentences are converted out of the “material mode” into the corresponding “formal” (or syntactical) mode, they can be discussed; in the material mode they are quite undiscussable.

But how are syntactical disputes to be settled? Suppose one philosopher asserts and another denies that “numerical expressions are class-expressions of the second level”—Carnap’s “translation” of “numbers are classes of classes”—how is it to be determined which is correct? All such statements, Carnap argues, are relative to a language; they are either statements about the characteristics of some existing language or proposals for the formation of a new language. Fully expressed, that is, they have the form “In language *L*, such-and-such an expression is of such-and-such a type.” It can be immediately determined whether such a syntactical statement is true by examining the language in question.

## PROBLEMS OF POSITIVISM

**VERIFIABILITY.** The course taken by the subsequent history of logical positivism was determined by its attempts

to solve a set of problems set for it, for the most part, by its reliance on the verifiability principle. The status of that principle was by no means clear, for “The meaning of a proposition is the method of its verification” is not a scientific proposition. Should it therefore be rejected as meaningless? Faced with this difficulty, the logical positivists argued that it ought to be read not as a statement but as a proposal, a recommendation that propositions should not be accepted as meaningful unless they are verifiable. But this was an uneasy conclusion. For the positivists had set out to destroy metaphysics; now it appeared that the metaphysician could escape their criticisms simply by refusing to accept their recommendations.

Recognition of this difficulty led Carnap to suggest that the verifiability principle is an “explication,” a contribution to the “rational reconstruction” of such concepts as metaphysics, science, and meaning, to be justified on the quasi-pragmatic grounds that if we ascribe meaning only to the verifiable we shall be able to distinguish forms of activity that are otherwise likely to be confused with one another. It is not, however, by any means clear in what way the verifiability principle can be invoked against a metaphysician who takes as his point of departure that his propositions clearly have a meaning. The most that can be said is that the onus is then on the metaphysician to distinguish his propositions from others that he would certainly have to admit to be meaningless.

A second set of problems hinged on the nature of the entities to which the verifiability principle applies. Since “proposition” had ordinarily been defined as “that which can be either true or false,” it seemed odd to suggest that a proposition might be meaningless. Yet it was no less odd to suggest that a sentence—a set of words—could be verified, even if there was no doubt that it could be meaningless. Ayer suggested as an alternative the word *statement*, and he wrote as if the problem were a purely terminological one. But it is a serious question whether “true,” “false,” and “meaningless” are alternative descriptions of the same kind of occurrence or whether to describe a sentence as “meaningless” is not tantamount to denying that any statement has been made, any proposition put forward. This would have the consequence that we can consider whether a statement is verifiable only after we have settled the question of the meaning of the sentence used to make the statement.

The logical positivists themselves were much more concerned about the fact that the verifiability principle threatened to destroy not only metaphysics but also science. Whereas Mach had been happy to purge the sci-

ences, the logical positivists ordinarily took for granted the substantial truth of contemporary science. Thus, it was a matter of vital concern to them when it became apparent that the verifiability principle would rule out as meaningless all scientific laws.

For such laws are, by the nature of the case, not conclusively verifiable; there is no set of experiences such that having these experiences is equivalent to the truth of a scientific law. Following Frank Plumpton Ramsey, Schlick suggested that laws should be regarded not as statements but as rules permitting us to pass from one singular statement to another singular statement. In Ryle's phrase, they are "inference-licenses." Neurath and Carnap objected to this on the ground that scientific laws are used in science as statements, not as rules. For example, attempts are made to falsify them, and it is absurd to speak of "falsifying a rule." Furthermore, Carnap pointed out, ordinary singular statements are in exactly the same position as laws of nature; there is no set of experiences such that if I have these experiences there must be, for example, a table in the room.

For these and comparable reasons "verifiability" was gradually replaced by "confirmability" or by the rather stronger notion of "testability." Whereas at first the meaning of a proposition had been identified with the experiences that we would have to have in order to know that the proposition is true, now this was reduced to the much weaker thesis that a proposition has a meaning *only if it is possible to confirm it*, that is, to derive true propositions from it. Carnap, in accordance with his "principle of tolerance," was prepared to admit that a language might be constructed in which only verifiable propositions would count as meaningful. He was content to point out that such a language would be less useful for science than a language that admits general laws. But most positivists, interested as they were in the actual structure of science, simply replaced the verifiability principle by a confirmability principle.

If, however, the original principle proved to be too strong, the new principle threatened to be too weak. For, on the face of it, the new principle admitted as meaningful such metaphysical propositions as "Either it is raining or the Absolute is not perfect." Whether the confirmability principle can so be restated as to act as a method of distinguishing between metaphysical statements as meaningless and scientific statements as meaningful remains a question of controversy.

UNIFICATION OF SCIENCE. A further set of problems hinges on the question of what sort of things act as "ver-

ifiers" or "confirmers." One of Mach's main concerns, which the logical positivists shared, had been to unify science, especially by rejecting the view that psychology is about an "inner world" that is different from the "outer world" that physical science investigates. The doctrine that both physics and psychology describe "experiences" made such a unification possible. In his earlier writings Carnap tried to show in detail how "the world" could be constructed out of experience, linked together by relations of similarity. But then a new difficulty arose; one about how it is possible to show that one person's experiences are identical with another's. On the face of it, an experience-based science is fundamentally subjective; science is verified only at the cost of losing its objectivity.

To overcome this difficulty, Schlick drew a distinction between "content" and "structure." We can never be sure, he argued, that the content of our experience is identical with the content of any other person's experience, for example, that what he sees when he says that he sees something red is identical with what we see when we say we see something red. For scientific purposes, however, this does not matter in the slightest. Science is interested only in the structure of our experience, so that provided, for example, we all agree about the position of red on a color chart, it is of no importance whether our experience of red differs.

Yet Schlick still thought that such "experiences" are what gives content, meaning, to science, converting it from a conceptual frame into real knowledge. Thus, it appears that the ultimate content of science lies beyond all public observation. There is no way of verifying that another person is even experiencing a content, let alone a content that is like or unlike the content of my experience.

PHYSICALIST THEORIES. Profoundly dissatisfied with the conclusion that the ultimate content of scientific truths is private, Neurath was led to reject the view—which logical positivists had so far taken for granted—that it is "experiences" which verify propositions. Only a proposition, he argued, can verify a proposition. Carnap accepted this conclusion and developed the conception of a "protocol statement," the ultimate resting point of verifications, a statement of such a nature that to understand its meaning and to see that it is true are the same thing. Carnap still suggested, however, that a protocol statement records a private experience, even though every such statement—indeed every statement—can be translated into the public language of physics. Statements of the form "Here now an experience of red" can, he argued, be

translated into statements about the physical state of the body of the person who has the experience of red. (Subsequently this “physicalist” thesis was expressed in the weaker form, that every statement is linked by means of correspondence rules with the statements of physics.)

Neurath was still dissatisfied. Protocol statements, he argued, must form part of science as distinct from merely being translatable into its language. Otherwise, science still rests on essentially private experience. In fact, protocol statements must take some such form as “Otto Neurath reports that at 3:15 p.m. there was a table in the room perceived by Otto.” The effect of this suggestion, as Schlick remarked with horror, is to leave open the possibility that the basic protocol statements may not be true. They, rather than some natural law with which they are incompatible, can be rejected as false. Schlick persisted in arguing that the ultimate confirmations of scientific propositions must be experiences of the form “here, now, blue”—which he described as “the only synthetic statements which are not hypotheses.” Carnap came to agree with Neurath, however, that all synthetic statements are hypotheses.

At first, indeed, Carnap replied to Neurath by invoking his principle of tolerance. One has a free choice, he argued, between a language that incorporates protocol statements and a language into which they can be translated. Subsequently he has moved more and more in Neurath’s direction. Statements of the form “the body Carnap is in a state of green-seeing,” he now suggests, are sufficient to act as confirmations, and it is not necessary at any point to use the “phenomenal language” that Mach had thought to be the basic language of science. But Carnap still writes as if the issue between physicalist and non-physicalist hinges on the choice of a language. Logical positivism, we might say, split into three groups, one asserting physicalism, the second rejecting it, and the third expressing a preference for the physicalist language.

In his *Logical Syntax of Language* Carnap had argued that all statements about the “meaning” or “significance” of statements are of the “pseudo object” type and should be translated into a syntactical form. Thus, for example, “This letter is about the son of Mr. Miller” has to be read as asserting that in this letter a sentence occurs which has the expression “the son of Mr. Miller” as its subject. This was a highly implausible doctrine, since, clearly, a letter can be about the son of Mr. Miller without using the phrase “the son of Mr. Miller.” Under Tarski’s influence Carnap decided that his original thesis had been unduly restrictive; philosophy had to refer to the semantical as well as the syntactical characteristics of language in order

to give a satisfactory explication of, for example, the conception of “truth.” Now Carnap found himself in opposition to Neurath. To try to pass beyond language to what language signifies, Neurath argued, is at once to reintroduce the transcendental entities of metaphysics. The subsequent development of semantics at Carnap’s hands would have done nothing to relieve Neurath’s qualms. Languages can be constructed, Carnap argues, in a variety of ways, and the question whether, for example, one accepts a language that includes names for abstract entities is a matter of practical convenience, not admitting of argument at any other level. The influence of Mach on Carnap’s thinking has now been almost entirely dissipated; he writes, rather, in the spirit of a Poincaré or a Duhem.

### THE INFLUENCE OF POSITIVISM

Logical positivism, considered as the doctrine of a sect, has disintegrated. In various ways it has been absorbed into the international movement of contemporary empiricism, within which the disputes that divided it are still being fought out. Originally, it set up a series of sharp contrasts: between metaphysics and science, logical and factual truths, the verifiable and the nonverifiable, the corrigible and the incorrigible, what can be shown and what can be said, facts and theories. In recent philosophy, all these contrasts have come under attack, not from metaphysicians but from philosophers who would in a general sense be happy enough to describe themselves as “logical empiricists.” Even among those philosophers who would still wish to make the contrasts on which the logical positivists insisted, few would believe that they can be made with the sharpness or the ease that the logical positivists at first suggested.

Logical positivism, then, is dead, or as dead as a philosophical movement ever becomes. But it has left a legacy behind. In the German-speaking countries, indeed, it wholly failed; German philosophy, as exhibited in the works of Martin Heidegger and his disciples, represents everything to which the positivists were most bitterly opposed. In the United States, Great Britain, Australia, the Scandinavian countries, and in other countries where empiricism is widespread, it is often hard to distinguish the direct influence of the positivists from the influence of such allied philosophers as Russell, the Polish logicians, and the British “analysts.” But insofar as it is widely agreed that transcendental metaphysics, if not meaningless, is at least otiose, that philosophers ought to set an example of precision and clarity, that philosophy should make use of technical devices, deriving from logic,

in order to solve problems relating to the philosophy of science, that philosophy is not about “the world” but about the language through which men speak about the world, we can detect in contemporary philosophy, at least, the persistence of the spirit that inspired the Vienna circle.

### Bibliography

The essays by leading logical positivists included along with an introduction by Ayer and an extensive bibliography in Alfred J. Ayer, ed., *Logical Positivism* (Glencoe, IL: Free Press, 1959), are the best introduction to the movement as a whole. Other representative writings by members of the Vienna circle and its associates include the following: Alfred J. Ayer, *Language, Truth and Logic* (London: Gollancz, 1936; 2nd ed., 1946). Rudolf Carnap, *Der Logische Aufbau der Welt* (Berlin: Weltkreis, 1928), translated by R. George as *The Logical Structure of the World* (London: Routledge and Kegan Paul, 1967); “Die physikalische Sprache als Universalsprache der Wissenschaft,” in *Erkenntnis* 2 (5–6) (1932): 423–465, translated by Max Black as *The Unity of Science* (London: Kegan Paul, 1934); *Logische Syntax der Sprache* (Vienna: Springer, 1934), translated by Amethe Smeaton as *The Logical Syntax of Language* (London and New York: Kegan Paul, 1937); *Philosophy and Logical Syntax* (London: Kegan Paul, 1935); “Testability and Meaning,” in *Philosophy and Science* 3 (4) (1936): 419–471, and 4 (1) (1937): 1–40; *Meaning and Necessity* (Chicago: University of Chicago Press, 1947); “Empiricism, Semantics and Ontology,” in *Revue internationale de philosophie* 4 (11) (1950), reprinted in *Semantics and the Philosophy of Language*, edited by Leonard Linsky (Urbana: University of Illinois Press, 1952), pp. 208–228; and “Intellectual Autobiography” and “Reply to My Critics,” in *The Philosophy of Rudolf Carnap*, edited by P. A. Schilpp (La Salle, IL: Open Court, 1963).

## LOGICAL TERMS

The two central problems concerning “logical terms” are demarcation and interpretation. The search for a demarcation of logical terms goes back to the founders of modern logic, and within the classical tradition a partial solution, restricted to logical connectives, was established early on. The characteristic feature of logical connectives, according to this solution, is truth-functionality, and the

totality of truth functions (Boolean functions from  $n$ -tuples of truth values to a truth value) determines the totality of logical connectives. In his seminal 1936 paper, “On the Concept of Logical Consequence,” Alfred Tarski demonstrated the need for a more comprehensive criterion by showing that his semantic definition of logical consequence—the sentence  $\sigma$  is a logical consequence of the set of sentences  $\Sigma$  iff (if and only if) every model of  $\Sigma$  is a model of  $\sigma$ —is dependent on such a demarcation. (Thus suppose the existential quantifier is not a logical term, then its interpretation will vary from model to model, and the intuitively logically valid consequence, “Rembrandt is a painter; therefore there is at least one painter,” will fail to satisfy Tarski’s definition. Suppose “Rembrandt” and “is a painter” are both logical terms, then the intuitively logically invalid consequence, “Frege is a logician; therefore Rembrandt is a painter,” will satisfy Tarski’s definition.) Tarski, however, left the general demarcation of logical terms an open question, and it was not until the late 1950s that the first steps toward developing a systematic criterion for logical predicates and quantifiers were taken.

In his 1957 paper, “On a Generalization of Quantifiers,” A. Mostowski proposed a semantic criterion for first-order logical quantifiers that generalizes Frege’s analysis of the standard quantifiers as second-level cardinality predicates. Technically, Mostowski interpreted a quantifier,  $Q$ , as a function from universes (sets of objects),  $A$ , to  $A$ -quantifiers,  $Q_A$ , where  $Q_A$  is a function assigning a truth-value to each subset  $B$  of  $A$ . Thus, given a set  $A$ , the existential and universal quantifiers are defined by: for any  $B \subseteq A$ ,  $\exists_A(B) = T$  iff  $B \neq \emptyset$  and  $\forall_A(B) = T$  iff  $A - B = \emptyset$ . Intuitively, a quantifier is logical if it does “not allow us to distinguish between different elements” of the underlying universe. Formally,  $Q$  is logical iff it is invariant under isomorphic structures of the type  $\langle A, B \rangle$ , where  $B \subseteq A$ ; that is,  $Q$  is a logical quantifier iff for every structure  $\langle A, B \rangle$  and  $\langle A', B' \rangle$ : if  $\langle A, B \rangle \cong \langle A', B' \rangle$ , then  $Q_A(B) = Q_{A'}(B')$ . Quantifiers satisfying Mostowski’s criterion are commonly called *cardinality quantifiers*, and some examples of these are “ $!\delta x$ ” (“There are exactly  $\delta$  individuals in the universe such that ...”), where  $\delta$  is any cardinal, “Most  $x$ ” (“There are more  $x$ ’s such that ... than  $x$ ’s such that not ...”), “There are finitely many  $x$ ,” “There are uncountably many  $x$ ,” and so forth.

In 1966, P. Lindström extended Mostowski’s criterion to terms in general: A term (of type  $n$ ) is logical iff it is invariant under isomorphic structures (of type  $n$ ). Thus, the well-ordering predicate,  $W$ , is logical since for any  $A, A'$ ,  $R \subseteq A^2$  and  $R' \subseteq A'^2$ : if  $\langle A, R \rangle \cong \langle A', R' \rangle$ , then

$W_A(R) = W_{A'}(R')$ . Intuitively, we can say that a term is logical iff it does not distinguish between isomorphic arguments. The terms satisfying Lindström’s criterion include identity,  $n$ -place cardinality quantifiers (e.g., the 2-place “Most,” as in “Most  $A$ ’s are  $B$ ’s”), relational or polyadic quantifiers like the well-ordering predicate above and “is an equivalence relation,” and so forth. Among the terms not satisfying Lindström’s criterion are individual constants, the first-level predicate “is red,” the first-level membership relation, the second-level predicate “is a property of Napoleon,” and so forth. Tarski (1966) proposed essentially the same division.

The Mostowski-Lindström-Tarski (MLT) approach to logical terms has had a considerable impact on the development of contemporary model theory. Among the central results are Lindström’s characterizations of elementary logic, various completeness and incompleteness theorems for generalized (model-theoretic, abstract) logics, and so forth. (See Barwise and Feferman 1985). But whereas the mathematical yield of MLT has been prodigious, philosophers, by and large, have continued to hold on to the traditional view according to which the collection of (primitive) logical terms is restricted to truth-functional connectives, the existential and/or universal quantifier and, possibly, identity. One of the main strongholds of the traditional approach has been Willard Van Orman Quine, who (in his 1970 book) justified his approach on the grounds that (1) standard first-order logic (without identity) allows a remarkable concurrence of diverse definitions of logical consequence, and (2) standard first-order logic (with or without identity) is complete. Quine did not consider the logicality of non-standard quantifiers such as “there are uncountably many,” which allow a “complete” axiomatization. L. H. Tharp (1975), who did take into account the existence of complete first-order logics with nonstandard generalized quantifiers, nevertheless arrived at the same conclusion as Quine’s.

During the 1960s and 1970s many philosophers were concerned with the interpretation rather than the identity of logical terms. Thus, Ruth Barcan Marcus (1962, 1972) and others developed a substitutional interpretation of the standard quantifiers; Michael Anthony Eardley Dummett (1973) advocated an intuitionistic interpretation of the standard logical terms based on considerations pertaining to the theory of meaning; many philosophers (e.g., van Fraassen) pursued “free” and “many-valued” interpretations of the logical connectives; Jaako Hintikka (1973, 1976) constructed a game theoretic semantics for logical terms. In a later development, G.

Boolos (1984) proposed a primitive (non-set-theoretic) interpretation of “nonfirstorderizable” operators, which has the potential of overcoming ontological objections to higher-order logical operators (e.g., by Quine).

In the mid-1970s philosophers began to search for an explicit, general philosophical criterion for logical terms. The attempts vary considerably, but in all cases the criterion is motivated by an underlying notion of logical consequence. Inspired by Gerhard Gentzen’s proof-theoretic work, Ian Hacking (1979) suggests that a logical constant is introduced by (operational) rules of inference that preserve the basic features of the traditional deducibility relation: the subformula property (compositionality), reflexivity, dilution (stability under additional premises and conclusions), transitivity (cut), cut elimination, and so forth. Hacking’s criterion renders all and only the logical terms of the ramified theory of types genuinely logical. A. Koslow’s (1992) also utilizes a Gentzen-like characterization of the deducibility relation. Abstracting from the syntactic nature of Gentzen’s rules, he arrives at a “structural” characterization of the standard logical and modal constants. Both Koslow and Hacking incorporate lessons from an earlier exchange between A. N. Prior (1960, 1964) and N. Belnap (1962) concerning the possibility of importing an inconsistency into a hitherto consistent system by using arbitrary rules of inference to introduce new logical operators.

C. Peacocke (1976) approaches the task of delineating the logical terms from a semantic perspective. The basic property of logical consequence is, according to Peacocke, a priori.  $\alpha$  is a logical operator iff  $\alpha$  is a non-complex  $n$ -place operator such that given knowledge of which objects (sequences of objects) satisfy an  $n$ -tuple or arguments of  $\alpha$ ,  $\langle \beta_1, \dots, \beta_n \rangle$ , one can know a priori which objects satisfy  $\alpha(\beta_1, \dots, \beta_n)$ . Based on this criterion Peacocke counts the truth-functional connectives, the standard quantifiers, and certain temporal operators (“In the past ...”) as logical, while identity (taken as a primitive term), the first-order membership relation, and “necessarily” are nonlogical. Peacocke’s criterion is designed for classical logic, but it is possible to produce analogous criteria for nonclassical logics (e.g., intuitionistic logic). T. McCarthy (1981) regards the basic property of logical constants as topic neutrality. He considers Peacocke’s condition as necessary but not sufficient, and his own criterion conjoins Peacocke’s condition with Lindström’s invariance condition (MLT). The standard first-order logical vocabulary as well as various nonstandard generalized quantifiers satisfy McCarthy’s criterion, but cardi-

nality quantifiers do not (intuitively, cardinality quantifiers are not topic-neutral).

Sher (1991) considers necessity and formality as the two characteristic features of logical consequence. Treating formality as a semantic notion, Sher suggests that any formal operator incorporated into a Tarskian system according to certain rules yields consequences possessing the desired characteristics. Viewing Lindström’s invariance criterion as capturing the intended notion of formal operator, Sher endorses the full-fledged MLT as delineating the scope of logical terms in classical logic.

The theory of logical terms satisfying Lindström’s criterion has led, with various adjustments, to important developments in linguistic theory: a systematic account of determiners as generalized quantifiers (Barwise and Cooper, Higginbotham and May); numerous applications of “polyadic” quantifiers (van Benthem, Keenan); and an extension of Henkin’s 1961 theory of standard branching quantifiers, applied to English by Hintikka (1973), to branching generalized quantifiers (Barwise and others).

## LOGICAL TERMS, GLOSSARY OF

This glossary is confined, with few exceptions, to terms used in formal logic, set theory, and related areas. No attempt has been made to cover what is often called "inductive logic," although several terms in this field have been included for the convenience of the reader.

It should be noted that many topics dealt with very briefly here are treated in full in various other entries in this encyclopedia. Cross references to these will be enclosed in quotation marks; cross references to other glossary entries will be indicated by boldface italics (e.g., "see *relation*").

**abduction.** (1) A syllogism whose major premise is known to be true but whose minor premise is merely probable. (2) C. S. Peirce's name for the type of reasoning that yields from a given set of facts an explanatory hypothesis for them.

**abstraction.** (1) In traditional logic, the process of deriving a universal from particulars. (2) In set theory, the process of defining a set as the set of all objects that have a particular property.

**abstraction, axiom of (axiom of comprehension).** An axiom in set theory stating that for any predicate *P*, there exists a set of all and only those objects that satisfy *P*. It was the unrestricted use of this axiom that led to the paradoxes of set theory.

**abstract term.** In traditional logic, a term that is a name of the common nature of many individuals, considered apart from them or from what distinguishes them from one another. A common example of an abstract term is "humanity."

**accident.** See *predicables*.

**actual infinite.** The infinite regarded as a completed whole.

**a fortiori.** A nonsyllogistic mediate inference of the form "*B* is greater than *C*; *A* is greater than *B*; hence, *A* is greater than *C*." It is clear that the validity of this argument follows from the transitivity of the relation "greater than," and therefore some authors extend the term to cover all relational syllogisms whose validity depends on the transitivity of the relation involved. See *relation*.

**aggregate.** A collection of objects satisfying a given condition.

**alephs.** The symbols, introduced by Georg Cantor, that designate the cardinality of infinite sets (see entry "Set Theory"). *Aleph-null* ( $\aleph_0$ ) designates the cardinality of the smallest infinite set, aleph-one ( $\aleph_1$ ) the cardinality of the next largest infinite set, etc. See *continuum hypothesis*; entry "Set Theory."

**algebra of logic.** A system in which algebraic formulas are used to express logical relations. In such a system many familiar algebraic laws that hold for numbers are not retained. The work of George Boole contains the first important example of an algebra of logic.

**algorithm.** A mechanical procedure for carrying out, in a finite number of steps, a computation that leads from certain types of data to certain types of results. See *decision problem*; *effectiveness*.

**alternation.** See *disjunction, exclusive*.

**alternative denial.** See *Sheffer stroke function*.

**ambiguity.** Capability of being understood in two or more ways. The term is strictly applied only in cases where the possibility of different interpretation is due not to the expression itself but to some feature of the particular use of the expression; when this possibility is due to the expression itself the expression is called *equivocal*. Many authors, however, do not make this distinction.

**amphiboly.** An equivocation that arises not out of an equivocation in a word or phrase but because the grammatical structure of the sentence or clause leaves the place of the phrase in the whole not entirely determinate. An example is “The shooting of the hunters was finished quickly.”

**ampliation.** In medieval logic, the extension of a common term from a narrow supposition to a wider one.

**analogy.** A comparison between two or more objects that indicates one or more respects in which they are similar. An *argument from analogy* is an inference from some points of resemblance between two or more objects to other such points. The method of *refutation by logical analogy* is a method for showing that an argument is fallacious by giving an example of another argument of the same form whose invalidity is immediately apparent.

**analysis, mathematical.** The theory of real and complex numbers and their functions.

**analytic.** Used of a proposition whose denial is self-contradictory. Such a proposition is true either by virtue of its logical form alone (in which case it is called a *logical truth*, or *logically necessary*) or by virtue of both its logical form and the meaning of its constituent terms. An instance of a logical truth is “It is raining or it is not raining”; an example of an analytic truth that is not a logical truth is “All bachelors are unmarried.” Analytic propositions cannot be false and are therefore said to be *necessary truths*. Whether there are necessary truths that are not also analytic truths is a matter of much dispute. See entry “Analytic and Synthetic Statements.”

**ancestral relation.** For a given relation  $R$ , the relation  $R^*$  that exists between two objects  $x$  and  $y$  if and only if  $y$  has every  $R$ -hereditary property that  $x$  has. A property is said to be *R*-hereditary when, if it is correctly predicated of  $b$  and if  $aRb$ , then it is also correctly predicated of  $a$ . For example, let  $R$  be the property “is the successor of.” Then “is a natural number” (where this property also applies to 0) is *R*-hereditary, since if  $b$  is a natural number and  $a$  is the successor of  $b$ , then  $a$  is also a natural number. Given this fact, we can define the property “is a natural number” as the property of all objects that bear the ancestral relation to 0 for the relation “is the succes-

sor of”—that is, as the property of all objects that have every “is the successor of”-hereditary property that 0 has. One of these properties is “is a natural number,” and therefore only the natural numbers can meet this definition.

It should be noted that the above definition is an example of an *impredicative definition*, since “is a natural number” is defined in terms of the class of “is the successor of”-hereditary properties, a class of which it is a member.

**antecedent.** The part of a hypothetical proposition that precedes the implication sign.

**antilogism.** A triad of propositions such that the joint truth of any two of the propositions implies the falsity of the third. Christine Ladd-Franklin’s principle of the syllogism states that a valid syllogism is one whose premises taken with the contradictory of the conclusion constitute an antilogism. Thus, the syllogism whose premises are “All men are mortal” and “Socrates is a man” and whose conclusion is “Socrates is mortal” is a valid syllogism, for the joint assertion of any two of the three propositions that constitute the premises and the contradictory of the conclusion implies the falsity of the third proposition.

**antinomy.** See *paradox*.

**apodictic (apodeictic) proposition.** See *modality*.

**appellation.** In medieval logic a term is said to have appellation if it is applicable to some existing thing. Thus, “the present queen of England” has appellation, but “the present queen of the United States” does not.

**A-proposition.** In traditional logic, a universal affirmative categorical proposition. An example is “All men are mortal.”

**Archimedean property.** The property of a system of numbers whereby for any two numbers  $a$  and  $b$ , if  $a$  is less than  $b$ , then there is a number  $c$  such that  $a$  multiplied by  $c$  is greater than  $b$ .

**argument of a function.** A member of the domain of a given function.

**arithmetical predicate.** A predicate that can be explicitly expressed in terms of the truth-functional connectives of propositional calculus, the universal and existential quantifiers, constant and variable natural numbers, and the addition and multiplication functions.

**arithmetization of mathematics (arithmetization of analysis).** The definition, which was developed by Karl Weierstrass, Richard Dedekind, and Georg Cantor, of the nonnatural numbers as certain objects construed out of

the natural numbers and set-theoretic objects and the corresponding reduction of the properties of the former to the properties of the latter.

**arithmetization of syntax.** The process of correlating the objects of a formal system with some or all of the natural numbers and then studying the relations and properties of the correlated numbers so as to gain information about the syntax of the formal system. This was done systematically by Kurt Gödel in the researches that led to his incompleteness theorems. See entry “Gödel’s Theorem.”

**ars combinatoria.** A technique of deriving complex concepts by the combination of relatively few simple ones, which are taken as primitive. This technique was proposed by Gottfried Wilhelm Leibniz as a valuable aid for the study of all subjects. He proposed the development of a universal language (*characteristica universalis*) containing a few primitive symbols in terms of which all other symbols would be defined. A universal mathematics (*mathesis universalis*)—that is, a universal system of reasoning—would then be added, and all subjects could be studied in this language. Leibniz program is often viewed as an early forerunner of the formalization of various disciplines.

**assertion sign.** The sign  $\vdash$ , introduced by Gottlob Frege to indicate in the object language that a proposition is being judged as true and is not merely being named. Some authors now use this sign in the metalanguage to express that the formula to which it is prefixed is a theorem in the object language.

**assertoric proposition.** See *modality*.

**associativity.** The property of a relation  $R$  that consists in the identity of “ $aR(bRc)$ ” and “ $(aRb)Rc$ ,” where  $a$ ,  $b$ , and  $c$  are any elements of the field of  $R$ . Addition has this property, since “ $a + (b + c)$ ” is the same as “ $(a + b) + c$ .”

**attribute.** Although it is now often used synonymously with “property,” this term was traditionally confined to the essential characteristics of a being.

**Aussonderungsaxiom.** An axiom in set theory, first introduced by Ernst Zermelo, which states that for any set  $a$  and any predicate  $P$ , there exists a set containing all and only those members of  $a$  that satisfy the predicate  $P$ .

**axiom.** A basic proposition in a formal system that is asserted without proof and from which, together with the other such propositions, all other theorems are derived according to the rules of inference of the system. See *postulate*.

**axiomatic method.** The method of studying a subject by beginning with a list of undefined terms and a list of axioms and then deriving the truths of the subject from these postulates by the methods of formal logic.

**axiom schema.** A representation of an infinite number of axioms by means of an expression containing syntactical variables and having well-formed formulas as values. Every value of the expression is to be taken as an axiom.

**axiom schema of separation.** See *Aussonderungsaxiom*.

**Barbara.** See *mnemonic terms*.

**Baroco.** See *mnemonic terms*.

**biconditional.** A binary propositional connective ( $\leftrightarrow$ ,  $\equiv$ ), usually read “if and only if” (often abbreviated “iff”), whose truth table is such that “ $A$  if and only if  $B$ ” is true when  $A$  and  $B$  are either both true or both false and is false when one is true and the other false. “ $A$  if and only if  $B$ ” is equivalent to “if  $A$  then  $B$ , and if  $B$  then  $A$ .”

**binary connective.** See *connective*.

**Bocardo.** See *mnemonic terms*.

**Boolean algebra.** The first algebra of logic. It was invented by George Boole and given its definitive form by Ernst Schröder.

**Boolean functions.** Functions that occur in Boolean algebra. The more important ones are the class-union function, the class-intersection function, and the class-complement function.

**bound occurrence of a variable.** An occurrence of a variable  $a$  in a well-formed part of a formula  $A$  either of the form “for all  $a$ ,  $B$ ” or of the form “there is an  $a$  such that  $B$ .”

**bound of a set.** For a given relation  $R$ , a *lower bound* (or first element) of a set  $a$  is any member of  $a$  that bears the relation  $R$  to all members of  $a$ ; an *upper bound* of  $a$  is any member of  $a$  to which all members of  $a$  bear the relation  $R$ . A *greatest lower bound* of a set  $a$  (or *infimum* of  $a$ ) is a lower bound of  $a$  to which all lower bounds of  $a$  bear the relation  $R$ ; a *least upper bound* of  $a$  (or *supremum* of  $a$ ) is an upper bound of  $a$  that bears the relation  $R$  to all upper bounds of  $a$ .

**bound variable.** A bound variable of a formula  $A$  is a variable that has a bound occurrence in  $A$ .

**Bramantip.** See *mnemonic terms*.

**Burali-Forti’s paradox.** See *paradox*.

**calculus.** Any logistic system. The two most important types of logical calculi are *propositional* (or senten-

tial) calculi and *functional* (or predicate) calculi. A propositional calculus is a system containing propositional variables and connectives (some also contain propositional constants) but not individual or functional variables or constants. In the *extended* propositional calculus, quantifiers whose operator variables are propositional variables are added. Among the *partial* propositional calculi, in which not all the theorems of the standard propositional calculus are obtainable, the most important are David Hilbert's *positive* propositional calculus (this contains all those parts of the standard propositional calculus that are independent of negation) and the *intuitionistic* propositional calculus (in this system axioms about negation acceptable from the intuitionistic point of view are added to the positive propositional calculus). A functional calculus is a system containing, in addition to the symbols of propositional calculus, individual and functional variables and/or constants, as well as quantifiers that take some of these variables and constants as their operator variables. In a *first-order* functional calculus (or *first-order logic*) the quantifiers have as their operator variables only individual variables, and the functions have as their arguments only individual variables and/or constants. In a *second-order* functional calculus (or second-order logic) the operator variables of the quantifiers can be functional variables. After that, each odd order adds functional variables and/or constants some of whose arguments are of the type introduced two orders below, and each even order allows the use of the variables introduced one order below as operator variables for the quantifiers. When there are no individual or functional constants present the functional calculus is called *pure*; when either is present it is called applied.

*Camenes*. See *mnemonic terms*.

*Camestres*. See *mnemonic terms*.

*Cantor's paradox*. See *paradox*.

*Cantor's theorem*. The theorem stating that for any given set  $a$ , the power set of  $a$  has a greater cardinality than  $a$  has.

*cardinality (power)*. For a given set, the cardinal number associated with it.

*cardinal number*. An object  $a$  that is associated with all and only the members of a set of equipollent sets. Various authors disagree on what this object is. The *Frege-Russell definition* of cardinal number is simply the identification of  $a$  with the set of equipollent sets.

*Cartesian product*. For a given set  $a$ , the set whose members are all and only the sets that contain one member from each member of  $a$ .

*categorematic*. In traditional logic, used of a word that can be a term in a categorical proposition. In contemporary logic, used of any symbol that has independent meaning. An example of a categorematic word is "men." Cf. *syncategorematic*.

*categorical proposition*. See *proposition*.

*category*. A general or fundamental class of objects or concepts about whose members assertions can significantly be made which differ from those that can significantly be made about nonmembers of this class. The two most famous lists of categories are those of Aristotle and Immanuel Kant. Aristotle's list comprises substance, quantity, quality, relation, activity, passivity, place, time, situation, and state. Kant's comprises unity, plurality, and universality (categories of quantity); reality, negation, and limitation (categories of quality); substantiality, causality, and reciprocity (categories of relation); and possibility, actuality, and necessity (categories of modality).

*Celarent*. See *mnemonic terms*.

*Cesare*. See *mnemonic terms*.

*choice, axiom of (multiplicative axiom)*. An axiom in set theory stating that if  $a$  is a disjoint set which does not have the null set as one of its members, then the Cartesian product of  $a$  is different from the null set. It can be proved that this axiom is equivalent to the well-ordering theorem.

*choice function*. A function  $R$  whose domain includes (or, according to some authors, is identified with the set of) all the nonempty subsets of a given set  $a$  and whose value is a member of any such subset.

*Church's theorem*. The theorem, stated and proved by Alonzo Church, that there is no decision procedure for determining whether or not an arbitrary well-formed formula of the first-order functional calculus is a theorem of that system.

*Church's thesis*. The thesis that every effectively calculable function (effectively decidable predicate) is general recursive.

*circular reasoning*. See *fallacy*.

*class*. (1) An aggregate. (2) In Gödel-von Neumann-Bernays set theory, where a distinction is made between sets and classes, a class is an object that can contain members but cannot be a member of any object. See *set*.

**classification.** Two of the issues of concern to traditional logicians were the nature of the process of grouping individuals into classes of individuals (*species*), these classes into further classes, and so on (the process of classification), and the nature of the reverse process (the process of *division*)—breaking a class down into its subclasses, these into their subclasses, and so on, until the simplest classes are broken down into the individuals that are their members.

In the process of classification one begins with a group of individuals and arranges them into classes, called *infimae species*, none of which can be broken down into species but only into individuals. One then groups the *infimae species* into other classes, of which the *infimae species* are subclasses. (For any species the class of which it is a subclass is called the *proximum genus*.) The grouping continues until one reaches the class of which all the original individuals are members. This is the *summum genus*, and when one reaches it the process of classification is finished. (All the classes between the *infimae species* and the *summum genus* are called the *subaltern genera*.)

In the process of division one begins with the *summum genus* and breaks it down into its subclasses, continuing until one reaches the *infimae species*. Finally, these are broken down into the individuals that are their members.

Several rules were set up for classification and division: (1) at each step only one principle may be used for breaking down the classes or grouping them together; (2) no group may be omitted at any step; (3) no intermediate step may be omitted. When applied to division this last rule is known as the rule of *division non faciat saltum*.

A *dichotomy* is a form of division (or of classification) in which at each stage the genus is divided into species according to whether or not the objects possess a certain set of differentiae. The two species formed (*proxima genera*) are therefore mutually exclusive and jointly exhaustive.

**closed sentence (closed schema).** A sentence (or schema) that has no free variables.

**closed with respect to (closed under) a relation.** A set is closed under a relation  $R$  if and only if for all  $a$ , if  $aRb$  and if  $a$  is a member of the set, then  $b$  is a member of the set.

**closure of a formula.** A formula formed by placing before an original formula  $A$  quantifiers binding all variables that occur freely in  $A$ . A *universal* closure is the formula formed when only universal quantifiers are used,

and an *existential* closure is the formula formed when only existential quantifiers are used.

**collective term.** In traditional logic, a term that denotes a collection of objects regarded as a unity. An example is “the Rockies.”

**combinatory logic.** A branch of mathematical logic where variables are entirely eliminated, their place being taken by certain types of functions that are unique to this branch of logic.

**commutativity.** The property of a relation  $R$  that consists in the equivalence of  $aRb$  and  $bRa$ , where  $a$  and  $b$  are any elements of the field of  $R$ .

**comparability, law of (law of trichotomy).** The principle in set theory that the cardinality of two sets is always comparable; that is, for any two sets  $a$  and  $b$ ,  $a$  is greater than  $b$  or equal to  $b$  or less than  $b$ .

**complement of a set (negate of a set).** The set of all and only those objects that are not members of a given set  $a$ .

**completeness.** The word *completeness* is used in varying senses. In the strongest sense (E. L. Post) a logistic system is said to be complete if and only if for any well-formed formula  $A$ , either  $A$  is a theorem of the system or the system would become inconsistent upon the addition of  $A$  as an axiom (without any other changes); in this sense propositional calculus, but not pure first-order functional calculus, is complete. In a second, weaker sense (Kurt Gödel) a logistic system is said to be complete if and only if all valid well-formed formulas are theorems of the system; in this sense both propositional calculus and pure first-order functional calculus are also complete. In a third, and still weaker, sense of completeness (Leon Henkin) a logistic system is said to be complete if and only if all secondarily valid well-formed formulas are theorems of the system; in this sense the pure second-order functional calculus and functional calculi of higher order are complete.

**complete set.** A set all of whose members are subsets of it.

**composition, fallacy of.** See *fallacy*.

**comprehension, axiom of.** See *abstraction, axiom of*.

**computable function.** See *Turing-computable*.

**conclusion.** That which is inferred from the premises of a given argument.

**concrete term.** In traditional logic, a term that is the name of an individual or individuals. An example of such a term is “Socrates.”

**condition.** A *necessary condition* is a circumstance in whose absence a given event could not occur or a given thing could not exist. A *sufficient condition* is a circumstance such that whenever it exists a given event occurs or a given thing exists. A *necessary and sufficient condition* for the occurrence of a given event or the existence of a given thing is therefore a circumstance in whose absence the event could not occur or the thing could not exist and which is also such that whenever it exists the event occurs or the thing exists.

This terminology is sometimes extended to the formal relations that exist between propositions. Thus, the truth of a proposition *A* is said to be a necessary condition for the truth of another proposition *B* if *B* implies *A*, and the truth of *A* is said to be a sufficient condition for the truth of *B* if *A* implies *B*.

**conditional.** See *implication*.

**conditional proof.** A proof that begins by making certain assumptions,  $A_1, A_2, \dots, A_n$ , deducing *B* from them, and then asserting on the basis of this the truth of the hypothetical proposition “if  $A_1$ , then if  $A_2$ , then if  $\dots$ , then if  $A_n$ , then *B*.” The *rule of conditionalization* is the rule that allows one to make this last step on the basis of the preceding ones.

**conjunction.** A binary propositional connective (&, .), usually read “and,” whose truth table is such that “*A* and *B*” is false when *A* or *B* or both are false and is true when both are true.

**connective.** A symbol that is used with one or more constants or forms to produce a new constant or form. When the constants or forms are propositional ones the connective is known as a *propositional connective* (or *sentential connective*). The most common propositional connectives are negation, conjunction, disjunction, implication, and biconditional. They are classified as *singular*, *binary*, etc., according to the number of propositional constants or forms with which they combine.

**connotation.** See *meaning*, *Frege’s theory of*.

**consequence.** Any proposition that can be deduced from a given set of propositions. Thus, given the set of propositions {*A*, if *A* then *B*}, the proposition *B* is a consequence of the set, since it can be deduced from the members of the set by one application of *modus ponens*.

**consequent.** The part of a hypothetical proposition that follows the implication sign or the “then.”

**consequentia.** The name given by medieval logicians to a true hypothetical proposition. *Formal consequentiae* (those which hold for all substitutions of the categore-

matic terms) were distinguished from *material consequentiae* (those holding only for particular categorematic terms).

**consistency.** A set of propositions has consistency (or is consistent) when no contradiction can be derived from the joint assertion of the propositions in the set. A logistic system has consistency when no contradiction can be derived in it. Two syntactical definitions of the consistency of a logistic system are Alfred Tarski’s, that a system is consistent if not every well-formed formula is a theorem, and E. L. Post’s, that a system is consistent if no well-formed formula consisting of only a propositional variable is a theorem. There is, in addition, a semantical definition of consistency, according to which a set of propositions (or a logistic system) is consistent if there is a model for that set of propositions (or for the set of all the theorems of the system). It must not be assumed that any of these definitions are equivalent; in any case where it is claimed that they are, a proof is required.

**constant.** A symbol that, under the principal interpretation, is a name for something definite, be it an individual, a property, a relation, etc.

**constructive existence proof.** A proof of the existence of a mathematical object having a property *P* that gives an example of such an object or at least a method by which one could find such an example.

**contingent.** Logically possible. See *logical possibility*.

**continuity.** An ordered dense class all of whose non-empty subsets which have an upper bound have a least upper bound has continuity (or is continuous). See entry “Continuity.”

**continuum hypothesis.** The hypothesis, proposed by Georg Cantor, that the cardinality of the power set of a set whose cardinality is aleph-null ( $\aleph_0$ ) is aleph-one ( $\aleph_1$ )—that is, that there is no set whose cardinality is greater than aleph-null but less than the cardinality of the power set of a set whose cardinality is aleph-null. The *generalized continuum hypothesis* is the hypothesis that for the cardinality of any infinite set, the next highest cardinality is the cardinality of its power set.

**contradiction.** The joint assertion of a proposition and its denial.

**contradiction, law of.** See *laws of thought*.

**contradictory.** Two propositions are contradictory if and only if their joint assertion would be a contradiction. “All men are mortal” and “Some men are not mortal,” for example, are contradictory propositions. Two terms are contradictory when they jointly exhaust a universe of dis-

course and are mutually exclusive. In the domain of natural numbers other than 0, for example, “odd” and “even” are contradictory terms. See *contrary*.

**contraposition.** In traditional logic, a type of immediate inference in which from a given proposition another proposition is inferred that has as its subject the contradictory of the original predicate. (It should be noted that a change of quality is involved in some cases.) *Partial* contraposition results in a new proposition that is the same as the subject of the original proposition; *full* contraposition results in a predicate of the new proposition that is the contradictory of the subject of the original proposition. The process of contraposition (whether partial or full) yields an equivalent proposition only when the original proposition is an A- or O-proposition; when it is an E-proposition traditional logicians allowed for contraposition *per accidens* (or by limitation)—that is, contraposition plus a change in the quantity of the proposition from universal to particular—claiming that the proposition formed is equivalent to the original proposition. The process of contraposition yields no equivalent proposition when the original proposition is an I-proposition. See entry “Logic, Traditional.”

**contrary.** Applied to two propositions that cannot both be true but can both be false. “All men are mortal” and “No men are mortal,” for example, are contrary propositions. Also applied to two terms that are mutually exclusive, but need not be jointly exhaustive, in a universe of discourse. In the domain of natural numbers, for instance, “less than 7” and “more than 19” are contrary terms. See *contradictory*.

**contrary-to-fact (counterfactual) conditional.** A conditional proposition whose antecedent is known to be false.

**converse domain of a relation (range of a relation).** For any relation  $R$ , the set of all objects  $a$  such that there exists an object  $b$  such that  $bRa$ .

**converse of a relation (inverse of a relation).** For any relation  $R$ , the relation  $R^*$  such that  $aR^*b$  if and only if  $bRa$ .

**conversion.** In traditional logic, a type of immediate inference in which from a given proposition another proposition is inferred that has as its subject the predicate of the original proposition and as its predicate the subject of the original proposition (the quality of the proposition being retained). The process of conversion yields an equivalent proposition only when the original proposition is an E- or I-proposition; when it is an A-proposition traditional logicians allowed for conversion *per accidens*

(or by limitation)—that is, conversion plus a change in the quantity of the proposition from universal to particular. Thus, the E-proposition “No men are immortal” yields “No immortals are men,” but the A-proposition “All men are mortal” can be converted only by limitation, yielding “Some mortals are men.” The process of conversion yields no equivalent proposition if the original proposition is an O-proposition. See entry “Logic, Traditional.”

**copula.** In traditional logic, the term that connects the subject and predicate in a categorical proposition. It is always a form of the verb “to be.”

**corollary.** A proposition that follows so obviously from a theorem that it requires little or no demonstration.

**counterfactual conditional.** See *contrary-to-fact conditional*.

**course-of-values induction.** An argument from mathematical induction such that in the induction step one proves that “if the property  $P$  holds for all numbers before  $a$ , it holds for  $a$  as well,” where  $a$  is any number.

**Darapti.** See *mnemonic terms*.

**Darii.** See *mnemonic terms*.

**Datisi.** See *mnemonic terms*.

**decision problem.** The problem of finding an algorithm (a *decision procedure*) that enables one to arrive, in a finite number of steps, at an answer to any question belonging to a given class of questions. For a logistic system in particular, this is the problem of finding a decision procedure for determining, for any arbitrary well-formed formula of the system, whether or not it is a theorem of the system.

A positive solution to a decision problem consists of a proof that a decision procedure exists. A negative solution to a decision problem consists of a proof that no such procedure is possible. An example of a positive solution is the proof that the truth tables provide a decision procedure for the propositional calculus; an example of a negative proof is Church’s theorem.

**decision procedure.** See *decision problem*.

**Dedekind finite.** See *finite set*.

**Dedekind infinite.** See *finite set*.

**deducible.** A set of propositions is said to be deducible from another set of propositions if and only if there is a valid deductive inference which has the latter set as its premises and the former set as its conclusion.

**deduction.** A form of inference such that in a valid deductive argument the joint assertion of the premises and the denial of the conclusion is a contradiction.

**deduction theorem.** For a given logistic system, the metatheorem that states that if there is a proof in the system of  $A_{n+1}$  from the assumptions  $A_1, A_2, \dots, A_n$ , then there is also a proof in the system of the proposition “if  $A_n$ , then  $A_{n+1}$ ” from the assumptions  $A_1, \dots, A_{n-1}$ .

**definiendum.** That which is defined in a definition.

**definiens.** That which, in a definition, defines the definiendum.

**definite descriptions, theory of.** A definite description is a description which, by virtue of the meanings of the words in it, can apply to only one object. A standard example of a definite description is “the author of *Waverley*.” The theory of definite descriptions, introduced by Bertrand Russell, aims at eliminating definite descriptions. Unlike most other eliminative theories, Russell’s does not attempt to offer a way of explicitly defining definite descriptions. Instead, it shows how in any given context the description together with the context can be eliminated in such a way that the resulting linguistic expression is equivalent to the original one. It is for this reason that Russell’s theory is said to offer a way of contextually defining definite descriptions.

If we symbolize the definite description as “( $x$ ) $P$ ” (“the unique  $x$  such that  $P$ ,” where  $P$  is any well-formed expression), Russell’s theory can be stated as follows (unless otherwise indicated, it will be supposed that the scope of the occurrence of a definite description is the smallest well-formed part of the formula that contains that occurrence of the definite description): Let us symbolize the scope of the definite description as  $M$  and the whole formula as  $A$ .  $M$  is replaced by the expression “ $(\exists y)(z)[(Pz \equiv z = y). M']$ ,” where  $y$  and  $z$  are the first two variables not occurring in  $A$  and  $M'$  is the result of substituting  $y$  for every occurrence of “( $ix$ ) $P$ ” in  $M$ . The resulting formula,  $A'$ , is equivalent to  $A$  but lacks the definite description that we set out to eliminate.

The motivation for this theory is to be found in certain difficulties that arose for Russell’s theory of meaning, the theory that the meaning of a term is its reference. It has been suggested, primarily by W. V. Quine, that since similar difficulties can arise for names in general, this theory should be extended to all names. Russell, however, thought that there was a class of names, *logically proper names*, for which these difficulties could not arise; he therefore favored retaining names of this class. See entry “Proper Names and Descriptions.”

**definition.** The description or explanation of the meaning of a word or phrase. Various types of definitions have been distinguished by logicians. To begin with, there is the distinction between a *lexical* definition (a report of a meaning the word already has) and a *stipulative* definition (a proposal to assign a meaning to a word). One must also distinguish, with traditional logicians, the following techniques for defining: (1) *dictionary* definition, giving a word or phrase that is synonymous with the definiendum; (2) *ostensive* definition, giving examples of objects to which the word or phrase is properly applied; and (3) definition *per genus et differentiam*, giving the genus of the objects to which a word or phrase is properly applied and the differentiae that distinguish these objects from the other members of the genus. See *predicables*.

Some new types of definition that have been discussed by contemporary logicians include (4) definition *by abstraction*, defining a class term by specifying the properties that an object must have in order to be a member of the class, and (5) *recursive (inductive)* definition, defining a number-theoretic function or predicate term by giving the value or values of the function or predicate when 0 is the argument and then giving the value or values when the successor of any number  $a$  is the argument in terms of  $a$  and the value when  $a$  is the argument (cf. *recursive function*). Finally, one must distinguish (6) *contextual* definitions, which give meaning to the definiendum only in particular contexts, not in isolation.

**definition, Aristotelian theory of.** See *predicables*.

**demonstration (derivation).** A deductive proof offered for a given set of propositions.

**De Morgan’s laws.** The theorems of propositional calculus that assert the material equivalence of “not ( $A$  or  $B$ )” with “not- $A$  and not- $B$ ” and “not ( $A$  and  $B$ )” with “not- $A$  or not- $B$ .” De Morgan, in his book *Formal Logic*, did not actually state these laws; he gave, instead, the corresponding laws for the logic of classes. It should be noted that some of the medieval logicians stated these theorems for the logic of propositions.

**denotation.** See *meaning, Frege’s theory of*.

**dense.** Used of an ordered set such that between any two elements of the set there is another element of the set.

**denumerable set.** A set whose cardinality is aleph-null ( $\aleph_0$ ). Some authors extend “denumerable” so as to make it synonymous with “enumerable.”

**derivable.** See *deducible*.

**derivation.** See *demonstration*.

*derived rule of inference.* A metalinguistic theorem asserting that under certain conditions there is a proof in the object language for a certain type of well-formed formula. The point of such theorems is that they enable us to state that certain well-formed formulas are theorems of the object language without having to find a proof in the object language for these formulas.

*descending induction.* An argument that shows that a certain property holds for no number by demonstrating that if it held for any number, it must hold for a lesser number.

*diagonal proof.* The proof, given by Georg Cantor, that there are infinite sets that cannot be enumerated.

*dichotomy.* See *classification*.

*dictum de omni et nullo.* The principle of syllogistic reasoning that asserts that whatever is distributively predicated (whether affirmatively or negatively) of any class must be predicated of anything belonging to that class.

*difference of sets.* For any two sets  $a$  and  $b$ , the set of all and only those objects that are members of  $a$  but not of  $b$ .

*differentia.* See *predicables*.

*dilemma.* An argument whose major premise is the conjunctive assertion of two hypothetical propositions and whose minor premise is a disjunctive proposition. If the minor premise alternatively affirms the antecedents of the major premise, the dilemma is said to be *constructive*; if the minor premise alternatively denies the consequents of the major premise, the dilemma is said to be *destructive*. Constructive dilemmas are divided into *simple constructive* dilemmas (the antecedents of the major premise are different and the consequents are the same) and *complex constructive* dilemmas (both the antecedents and the consequents of the major premise are different). Destructive dilemmas are divided into *simple destructive* dilemmas (the consequents of the major premise are different and the antecedents are the same) and *complex destructive* dilemmas (both the consequents and the antecedents of the major premise are different).

*Dimaris.* See *mnemonic terms*.

*Disamis.* See *mnemonic terms*.

*discreteness.* The property possessed by all ordered sets that lack the property of continuity.

*disjoint sets.* Sets that have no members in common.

*disjunction, exclusive (alternation).* A binary propositional connective, one possible interpretation of “or,” whose truth table is such that “ $A$  or  $B$ ” is true if and only if one of the two propositions is true and the other false.

*disjunction, inclusive.* A binary propositional connective ( $\vee$ ), one possible interpretation of “or,” whose truth table is such that “ $A$  or  $B$ ” is true in all cases except where both  $A$  and  $B$  are false.

*distributed term.* In a categorical proposition the occurrence of a term is distributed if and only if the term as used in that occurrence covers all the members of the class that it denotes. In a universal categorical proposition the subject is distributed; in a negative categorical proposition the predicate is distributed.

*distributivity.* The relation that exists between two relations  $R$  and  $R^*$  when “ $aR(bR^*c)$ ” is identical with “ $(aRb)R^*(aRc)$ .”

*division.* See *classification*.

*division non faciat saltum.* See *classification*.

*domain of a relation.* For any relation  $R$ , the set of all objects  $a$  such that there exists an object  $b$  such that  $aRb$ .

*domain of individuals.* For a given interpretation of a given logistic system, the set of objects that is the range of the individual variables.

*duality.* The relation that exists between two formulas that are the same except for the interchanging of the universal with the existential quantifier, the symbol for the null class with that for the universal class, sum of sets with product of sets, and conjunction with disjunction (where conjunction, disjunction, and negation are taken as primitive, all other propositional connectives being defined in terms of them). The two formulas are said to be the duals of each other. “ $A$  and  $B$ ” and “ $A$  or  $B$ ,” for example, are duals.

*dyadic relation.* A two-place relation.

*effectiveness.* A notion is said to be effective if there exists an algorithm for determining, in a finite number of steps, whether or not the notion applies to any given object. For example, in a logistic system the notion of a proof is effective, since there is a mechanical procedure for determining, in a finite number of steps, whether or not in that system a given sequence of well-formed formulas constitutes a proof of another given well-formed formula.

*element.* A member of a given set.

*elementary number theory.* The theory of numbers insofar as it does not involve analysis.

*empty set.* See *null set*.

*entailment.* The relation that exists between two propositions one of which is deducible from the other.

**enthymeme.** A syllogism in which one of the premises or the conclusion is not explicitly stated. An example of an enthymeme is the inference of “Socrates is mortal” from “All men are mortal,” the missing premise being “Socrates is a man.”

**enumerable set.** A set that either is finite or has a cardinality of aleph-null ( $\aleph_0$ ). Cf. *denumerable set*.

**epagoge.** In traditional logic, the process of establishing a general proposition by induction.

**epicheirema.** A syllogism in which one or more of the premises is stated as the conclusion of an enthymematic prosyllogism. See *polysyllogism*.

**episyllogism.** See *polysyllogism*.

**E-proposition.** In traditional logic, a universal negative categorical proposition. An example is “No men are mortal.”

**epsilon.** In set theory, the name of the symbol ( $\epsilon$ ) for set-membership.

**equality.** A relation that exists between two or more sets, equated by some authors with *identity* and by others with *equivalence relation*.

**equipollent.** Used of sets between which there exists a one-to-one correspondence.

**equivalence relation.** A relation that is reflexive, symmetric, and transitive (see *relation*). Identity is a standard example of an equivalence relation.

**equivalent.** Used of two propositions that are so related that one is true if and only if the other is true. Some authors also use this term, as applied to sets, synonymously with “equipollent.”

**equivocation.** See *fallacy*.

**eristic.** The art of fallacious but persuasive reasoning.

**essence.** See *predicables*.

**Euler's diagrams.** The representations, generally attributed to Leonhard Euler, of relations among classes by relations among circles. See entry “Logic Diagrams.”

**excluded middle, law of.** See *laws of thought*.

**existential generalization, rule of.** The rule of inference that permits one to infer from a statement of the form “Property *P* holds for an object *a*” a statement of the form “There exists an object such that property *P* holds for it.”

**existential import.** The commitment to the existence of certain objects that is entailed by a given proposition.

**existential instantiation, rule of.** The rule of inference that permits one to infer from a statement of the

form “There exists an object such that property *P* holds for it” a statement of the form “Property *P* holds for an object *a*.” Because this inference is not generally valid, restrictions have to be placed on its use.

**existential quantifier.** The symbol (*E*) or ( $\exists$ ), read “there exists.” It is used in combination with a variable and placed before a well-formed formula, as in “( $\exists a$ ) \_\_\_\_\_” (“There exists an object *a* such that \_\_\_\_\_”).

**extension.** Although often used synonymously with “denotation,” this term is sometimes used to refer to the set of species that are contained within the genus denoted by a given term. In the first sense the extension of “men” is the set of all men; in the second sense it is the set of sets into which humankind can be divided.

**extensional.** Used of an approach to a problem which in some respect confines attention to truth-values of sentences rather than to their meanings. Thus, a logic in which, for purposes of deductive relations, truth-values may be substituted for sentences is an extensional logic. Cf. *intensional*.

**extensionality, axiom of.** An axiom in set theory stating that for any two sets *a* and *b*, if for all *c*, *c* is a member of *a* if and only if *c* is a member of *b*, then *a* is identical with *b*.

**fallacy.** An argument that seems to be valid but really is not. There are many possible types of fallacy; traditional logicians have discussed the following ones: (1) *accentus*, a fallacy of ambiguity, where the ambiguity arises from the emphasis (accent) placed on a word or phrase; (2) *affirmation of the consequent*, an argument from the truth of a hypothetical statement and the truth of the consequent to the truth of the antecedent; (3) *ambiguity*, an argument in the course of which at least one term is used in different senses; (4) *amphiboly*, a fallacy of ambiguity where the ambiguity involved is of an amphibolous nature; (5) *argumentum ad baculum*, an argument that resorts to the threat of force to cause the acceptance of the conclusion; (6) *argumentum ad hominem*, an argument that attempts to disprove the truth of what is asserted by attacking the asserter or attempts to prove the truth of what is asserted by appealing to the opponent's special circumstances; (7) *argumentum ad ignorantiam*, an argument that a proposition is true because it has not been shown to be false, or vice versa; (8) *argumentum ad misericordiam*, an argument that appeals to pity for the sake of getting a conclusion accepted; (9) *argumentum ad populum*, an argument that appeals to the beliefs of the multitude; (10) *argumentum ad verecundiam*, an argument in which an authority is

appealed to on matters outside his field of authority; (11) *begging the question* (*circular reasoning*), an argument that assumes as part of the premises the conclusion that is supposed to be proved; (12) *composition*, an argument in which one assumes that a whole has a property solely because its various parts have that property; (13) *denial of the antecedent*, an argument in which one infers the falsity of the consequent from the truth of a hypothetical proposition and the falsity of its antecedent; (14) *division*, an argument in which one assumes that various parts have a property solely because the whole has that property; (15) *equivocation*, an argument in which an equivocal expression is used in one sense in one premise and in a different sense in another premise or in the conclusion; (16) *ignoratio elenchi*, an argument that is supposed to prove one proposition but succeeds only in proving a different one; (17) *illicit process*, a syllogistic argument in which a term is distributed in the conclusion but not in the premises; (18) *many questions*, a demand for a simple answer to a complex question; (19) *non causa pro causa*, an argument to reject a proposition because of the falsity of some other proposition that seems to be a consequence of the first but really is not; (20) *non sequitur*, an argument in which the conclusion is not a necessary consequence of the premises; (21) *petitio principii*, see (11) *begging the question*; (22) *post hoc, ergo propter hoc*, argument from a premise of the form “A preceded B” to a conclusion of the form “A caused B”; (23) *quaternio terminorum*, an argument of the syllogistic form in which there occur four or more terms; (24) *secundum quid*, an argument in which a proposition is used as a premise without attention given to some obvious condition that would affect the proposition’s application; (25) *undistributed middle*, a syllogistic argument in which the middle term is not distributed in at least one of the premises. See entry “Fallacies.”

*Felapton*. See *mnemonic terms*.

*Ferio*. See *mnemonic terms*.

*Ferison*. See *mnemonic terms*.

*Fesapo*. See *mnemonic terms*.

*Festino*. See *mnemonic terms*.

*field of a relation*. The union of the domain and the converse domain of a given relation.

*figure*. A way of classifying categorical propositions. According to most traditional logicians, since figure depends on the position of the middle term in the premises, there are four possible figures. In the first figure the middle term is the subject of the major premise and the predicate of the minor premise. In the second figure the middle term is the predicate of both premises and in the

third figure the subject of both premises. In the fourth figure the middle term is the predicate of the major premise and the subject of the minor premise. Aristotle allowed only three figures and treated as being indirectly in the first figure those syllogisms that later logicians placed in the fourth. See entry “Logic, Traditional.”

*finitary method*. The type of method to which David Hilbert and some of his followers restricted themselves in their metamathematical research. The clearest statement of the restrictions was made by Jacques Herbrand, who insisted that the following conditions be met: (1) One must deal only with a finite and determined number of objects and functions. (2) These are to be so defined that there is a univocal calculation of their values. (3) One should never affirm the existence of an object without indicating how to construct it. (4) One must never deal with the set of all the objects of an infinite totality. (5) That a theorem holds for all of a set of objects means that for every particular object it is possible to repeat the general argument in question, which should then be treated as only a prototype of the resulting particular arguments.

*finite set* (*inductive set*). A set that either is empty or is such that there exists a one-to-one correspondence between its members and the members of the set of all natural numbers less than a specified natural number. A set which is not finite is said to be *infinite*.

Richard Dedekind introduced a different characterization of finite and infinite sets. A *Dedekind finite* set is one that has no proper subset such that there exists a one-to-one correspondence between the elements of the set and the elements of that proper subset. A *Dedekind infinite* set (or *reflexive* set) is one that is not Dedekind finite. It can be shown that Dedekind’s characterization is equivalent to the previous one; the proof, however, involves the axiom of choice.

*first element of a set*. See *bound of a set*.

*first-order logic*. First-order functional calculus. See *calculus*.

*formalism*. The doctrine, advanced as a program by David Hilbert and his followers, that the only foundations necessary for mathematics are its formalization and a proof by finitary methods that the system thus produced is consistent. See entry “Mathematics, Foundations of.”

*formalization*. The construction of a logistic system whose intended interpretation is such that under it the truths of a given body of knowledge are the interpreted theorems of the system.

*formalized language.* A logistic system with an interpretation.

*formally imply.* A proposition  $A$  is said to formally imply a proposition  $B$  in a given logistic system if there is, in that system, a valid proof of  $B$  from  $A$  taken as a hypothesis.

*formal system.* See *logistic system*.

*formation rules.* For a given logistic system, the rules that determine which combinations of symbols are well-formed formulas and which are not.

*formula.* For a given logistic system, any sequence of primitive symbols.

*foundation, axiom of (Axiom der Fundierung, axiom of regularity).* An axiom in set theory stating that every nonempty set  $a$  contains a member  $b$  which has no member in common with  $a$ .

*free occurrence of a variable.* For a given variable  $a$  that occurs in a given well-formed formula  $A$ , an occurrence of  $a$  in no well-formed part of  $A$  which is of the form “For all  $a, B$ ” or of the form “There exists an  $a, B$ .”

*free variable.* A free variable of a formula  $A$  is a variable in  $A$  that has no bound occurrence in  $A$ .

*Fresison.* See *mnemonic terms*.

*function.* A many-one correspondence.

*functional calculus.* See *calculus*.

*future contingents, problem of.* The problem, first discussed by Aristotle, of whether any contingent statement about the future has a truth-value prior to the time it refers to.

*Galenian figure.* The fourth syllogistic figure, supposedly introduced by Galen.

*generalization, rule of.* The rule of inference that allows one to infer from every proposition another proposition that is the same as the original one except that it is preceded by a universal quantifier binding any variable.

*general term.* A term that is predicable, in the same sense, of more than one individual.

*Gentzen’s consistency proof.* The proof, first given by Gerhard Gentzen in 1936, of the consistency of classical pure number theory with the unrestricted-induction postulate. The proof employs transfinite induction up to the ordinal  $\epsilon_0$ .

*Gentzen system.* A system of logic characterized by the introduction into the object language of a new connective (symbolized by  $\rightarrow$ ) that has properties analogous

to the ordinary metalinguistic idea of “provable in the system.” The rules of inference of such a system apply to *Sequenzen*—that is, to formulas of the form “ $A_1, A_2, \dots, A_n \rightarrow B_1, B_2, \dots, B_m$ ” where  $m$  and  $n$  are equal to or greater than 0, and  $A_1, A_2, \dots, A_n, B_1, B_2, \dots, B_m$  are formulas of ordinary logical systems.

*genus.* See *predicables*.

*Gödel-numbering.* The assignment of a natural number to each entity of a formal system. See *arithmetization of syntax*.

*Gödel’s completeness theorem.* The theorem, first introduced by Kurt Gödel in 1930, that every valid well-formed formula of pure first-order functional calculus is a theorem of that system.

*Gödel’s incompleteness theorems.* Two theorems that were first proved by Kurt Gödel in 1931. One states that any  $\omega$ -consistent system adequate for elementary number theory is such that there is a valid well-formed formula of the system not provable in the system. J. B. Rosser, in 1936, extended this result to any consistent system. The second theorem states that any consistent system adequate for elementary number theory is such that there can be no proof of the consistency of the system within the system. See entry “Gödel’s Theorem.”

*Gödel-von Neumann–Bernays set theory.* The form of axiomatic set theory that avoids the paradoxes of set theory by distinguishing between sets (collections that can also be elements of other collections) and classes (collections that cannot be elements of other collections) and ensuring that all the objects leading to paradoxes (for example, the universal class) are classes and not sets.

*Henkin’s completeness theorem.* The theorem, proved by Leon Henkin in 1947, that every secondarily valid well-formed formula of pure second-order functional calculus is a theorem of that system.

*hereditary property.* See *ancestral relation*.

*Hilbert program.* See *formalism*.

*ideal mathematics.* For David Hilbert, the nonfinitary part of mathematics, which, although necessary, was suspect and therefore required a consistency proof. See *real mathematics*.

*idempotency.* A binary operation is idempotent if and only if that operation, when performed on any element with itself, results in just that element.

*identically false.* Used of a well-formed formula of propositional calculus whose truth-value is falsehood for all possible values of its constituent well-formed formulas.

*identically true.* Used of a well-formed formula of propositional calculus whose truth-value is truth for all possible values of its constituent well-formed formulas.

*identity.* A relation that holds only between an object and itself.

*identity, law of.* See *laws of thought*.

*identity of indiscernibles.* Gottfried Wilhelm Leibniz's principle that two objects are identical if for every class, one object belongs to the class if and only if the other does. This is not to be confused with what W. V. Quine has called the *indiscernibility of identicals*, the principle that if two objects are identical, they belong to the same classes.

*iff.* A common abbreviation for "if and only if." See *biconditional*.

*ignoratio elenchi.* See *fallacy*.

*image.* The members of the converse domain of a relation that are values of the relation when its argument is a member of a set that is part of its domain.

*immediate inference.* An inference of a conclusion from a single premise. Traditional logicians discussed two types: (1) *opposition of propositions*, the inference, from the truth or falsity of one proposition, of the truth or falsity of another proposition having the same subject and predicate (such inferences involve contradictory, contrary, subalternate, and subcontrary propositions), and (2) *eductions*, the inference, from one proposition, of another differing from it in subject or predicate or in both (these involve obversion, conversion, contraposition, and inversion).

*imperfect figures.* The second and third syllogistic figures, the valid arguments of which, according to Aristotle, are such that their validity can be known only by their reduction to valid syllogisms in the perfect first figure.

*implication (conditional).* A binary propositional connective ( $\rightarrow$ ,  $\supset$ ), usually read "if-then," of which there are two major interpretations: (1) *Material implication.* Under this interpretation, "If  $A$  then  $B$ " is true in all cases except when  $A$  is true and  $B$  false. (2) *Strict implication.* Under this interpretation, "If  $A$  then  $B$ " is true only when  $B$  is deducible from  $A$ . *Philonian* implication is the Stoic version of material implication, and *Diodorean* implication is the Stoic interpretation of "if-then" according to which "If  $A$  then  $B$ " is true if whenever (in the past, present, or future)  $A$  is true,  $B$  is also true.

*implicit definition.* A set of axioms implicitly define the undefined terms in them by, in effect, confining the

references of these terms to the intended ones. The axioms do this by stating conditions satisfiable by only one set of objects.

The idea that a set of axioms can implicitly define the undefined terms in them is usually credited to J. D. Gergonne (1819). It was once thought that the basic terms of arithmetic could be implicitly defined by the axioms (namely, Peano's postulates) containing them; however, it is now known that this cannot be done, since Peano's postulates admit of more than one interpretation.

*impredicative definition.* Definition of an object in terms of a totality of which it is a member. For an example of impredicative definition, see *ancestral relation*.

*inclusion.* A relation that holds between two sets when all the members of one are members of the other. The relation of set-inclusion must be distinguished from that of set-membership.

*inconsistent.* Used of a set of propositions from which, or a logistic system in which, a contradiction can be derived.

*indemonstrables.* The Stoics' name for the axioms of their propositional logic.

*independence.* An axiom  $A$  of a given logistic system is independent (or has independence) if and only if in the system obtained by omitting  $A$  from the axioms of the given system,  $A$  is not a theorem. A rule of inference  $R$  of a given logistic system is independent if and only if in the system obtained by omitting  $R$  from the rules of inference of the given system,  $R$  is not a derived rule of inference.

*indirect proof (reductio ad absurdum).* An argument that proves a proposition  $A$  by showing that the denial of  $A$ , together with accepted propositions  $B_1, B_2, \dots, B_n$ , leads to a contradiction. Strictly speaking, this fails to prove the truth of  $A$ , since one of the previously accepted premises may be false; the force of the argument therefore rests on using premises that are far better established than the denial of  $A$ , so that the denial of  $A$  will be rejected and  $A$  accepted.

*individual (particular).* (1) Anything considered as a unit. (2) In the theory of types, any member of the lowest type.

*induction.* Among acceptable inferences, logicians distinguish those in which the joint assertion of the premises and the denial of the conclusion is a contradiction from those in which that joint assertion is not a contradiction. The former are deductive inferences; inductive inferences are to be found among the latter.

Much has been written about the precise nature of inductive inferences, but few definite results have been obtained. It is likely that there is a wide variety of types of inductive inferences. Two quite different types are the inference from observational data to theoretical conclusions and the inference from the composition of a sample to the composition of a whole population.

**induction, mathematical.** An inference of the form “0 has the property *P*; if any natural number *a* has the property *P*, then its successor has the property *P*; therefore, every natural number has the property *P*.” The first step is called the *basis*, or the *zero step*, of the induction, and the second is called the *induction step*.

**inductive set.** See *finite set*.

**inference.** Derivation of a proposition (the conclusion) from a set of other propositions (the premises). When the inference is acceptable the premises afford good reasons to assert, or render certain, the conclusion.

**infima species.** See *classification*.

**infinite set.** See *finite set*.

**infinity, axiom of.** An axiom in set theory that guarantees the existence of an infinite number of individuals. This axiom takes various forms, all having in common the property of being valid in at least one infinite domain of individuals while not being valid in any finite domain of individuals.

**initial ordinal.** An ordinal that is not equipollent with any smaller ordinal.

**insolubilia.** The medieval name for antinomies. The antinomies that are usually referred to by this name are variants of the Liar paradox.

**intension.** A term sometimes used by traditional authors as synonymous with “connotation.” In contemporary logical works “intension” has come to be synonymous with “sense.” See *meaning, Frege’s theory of*.

**intensional.** (1) Used of an approach which in some respect considers the meaning as well as the truth-value of a formula. A characteristic of such systems is that some propositions in them are referentially opaque. Systems of modal logic are usually intensional systems.

(2) Used of a proposition that contains a referentially opaque part. Cf. *extensional*.

**intention, first (primary).** In medieval logic, signs that signify things and not other signs are said to have first intention. See entry “Logic, Traditional.”

**intention, second (secondary).** In medieval logic, signs that signify other signs and not things are said to have second intention. See entry “Logic, Traditional.”

**interpretation.** An interpretation of a set *A* of well-formed formulas consists of a nonempty set (the *domain of the interpretation*) and a function which assigns to each individual constant appearing in any of the members of *A* some fixed element in the domain, to each *n*-place predicate letter appearing in any of the members of *A* some *n*-place relation in the domain, and to each *n*-place function letter appearing in any member of *A* some function whose arguments are *n*-tuples of elements of the domain and whose values are also elements of the domain. The individual variables are thought of as ranging over the elements of the domain, and the connectives are given some meaning. Such an interpretation provides meaning for the members of *A*.

The *principal* interpretation is the intended interpretation. The *secondary* interpretations of a set of well-formed formulas are all the interpretations, other than the principal one, such that under them all the members of the set are true.

**intersection of sets (product of sets).** The set of all the objects that are elements of all the sets  $a_1, a_2, \dots, a_n$  (symbolized “ $a_1 \cap a_2 \cap \dots \cap a_n$ ”).

**intuitionism.** The doctrine, advanced by L. E. J. Brouwer and his followers, whose key thesis is that a mathematical entity with a particular property exists only if a constructive existence proof can be given for it. As a result the actual infinite is ruled out of mathematics, and only denumerably infinite sets, viewed as potentially infinite, are allowed. Furthermore, the law of excluded middle is rejected in the sense that when infinite classes are being dealt with, a disproof of a universal statement is not automatically a proof of its denial—that is, an existential statement. See entry “Mathematics, Foundations of.”

**intuitive set theory.** The form of set theory that is based on an unrestricted use of the axiom of abstraction. The paradoxes of set theory were generated within a system of intuitive set theory.

**inverse of a relation.** See *converse of a relation*.

**inversion.** In traditional logic, a type of immediate inference in which from a given proposition another proposition is inferred whose subject is the contradictory of the subject of the original proposition. See entry “Logic, Traditional.”

**iota operator.** The definite description operator,  $\iota$ . It is read: “The unique \_\_\_\_\_ such that \_\_\_\_\_.”

**I-proposition.** In traditional logic, a particular affirmative categorical proposition. An example is “Some men are mortal.”

**joint denial.** A binary propositional connective ( $\downarrow$ ) whose truth table is such that “A joint-denial B” is true if and only if both A and B are false. Joint denial and the Sheffer stroke function are the only binary propositional connectives that are adequate for the construction of all truth-functional connectives.

**judgment.** (1) The affirming or denying of a proposition. (2) The proposition affirmed or denied.

**Lambert’s diagrams.** The representation, introduced by J. H. Lambert, of relations among classes by relations among straight lines.

**law of logic.** Any general truth of logic.

**laws of thought.** Three laws of logic that were traditionally treated as basic and fundamental to all thought. They were (1) *the law of contradiction*, that nothing can be both *P* and not-*P*; (2) *the law of excluded middle*, that anything must be either *P* or not-*P*; and (3) *the law of identity*, that if anything is *P*, then it is *P*.

**lekton.** The Stoic name for the sense of a formula.

**lemma.** A theorem proved in the course of, and for the sake of, the proof of a different theorem.

**level (order).** In the ramified theory of types, a class of objects that is composed of all and only those objects such that the definition of one of them requires no reference to a totality containing other members of the class. A hierarchy of levels is built up by beginning with the class of those objects that can be defined without reference to any totality and continuing with succeeding levels, members of each of which are defined in terms of totalities of objects of the previous level.

**Liar paradox.** See *paradox, Epimenides’ paradox*.

**limit.** For a given sequence of numbers, the number *a* such that for any arbitrarily small number *b* greater than 0 there exists a number *c* such that for any number *d* larger than *c* the absolute value of the difference between the *d*th member of the sequence and *a* is less than *b*.

**limit number.** An ordinal number that is not 0 and is such that if *a* is a member of it, then the successor of *a* is also a member of it.

**limit ordinal.** See *limit number*.

**logic.** The study of the validity of different kinds of inference. This term is often used synonymously with *deductive logic*, the branch of logic concerned with infer-

ences whose premises cannot be true without the conclusion’s also being true. The other major branch of logic, *inductive logic*, is concerned with inferences whose premises can be true even if the conclusion is false.

**logical fiction.** The apparent denotation of a symbol that really has no denotation. Formulas containing such symbols are translatable into formulas containing no symbol or symbols that even appear to have this denotation.

**logical form.** It is commonly said that logic is concerned with the form, not the matter, of a proposition or argument. The distinction between form and matter is, however, seldom made precise; it can therefore best be seen by consideration of an example:

If it is raining, people will carry umbrellas.

It is raining.

People will carry umbrellas.

Analysis of this inference shows that it is valid because it is of the form “If A, then B; A; therefore, B.” The values of the variables make no difference in the validity of the argument. Formal logic is concerned with inferences, like this one, whose validity depends on their form.

As the example shows, the form of a proposition is nothing more than the result of substituting, in the proposition, free variables for the constants, whereas the *matter of a proposition* is that for which the variables are substituted. The form of an argument is the result of substituting, in all the premises and in the conclusion of the argument, free variables for constants.

In some contemporary works any formula that contains one or more free variables is called a form.

**logical implication.** The relation that holds between two propositions when one is deducible from the other.

**logically necessary.** See *analytic*.

**logical possibility (possible truth).** A proposition that is not self-contradictory. Some authors restrict this term to propositions that are also not logically necessary.

**logical truth.** See *analytic*.

**logic diagram.** A diagram used to represent logical relations. See entry “Logic Diagrams.”

**logicism.** The doctrine, advanced by Gottlob Frege and Bertrand Russell, that all the concepts of mathematics can be derived from logical concepts through explicit definitions and all the theorems of mathematics can be derived from logical axioms through purely logical deduction. See entry “Mathematics, Foundations of.”

**logistic method.** The method of studying a subject by formalizing it.

**logistic system (formal system).** A system whose primitive basis is explicitly stated in the metalanguage.

**Löwenheim's theorem.** See *Skolem-Löwenheim theorem*.

**major premise.** In a categorical syllogism, the premise that contains the major term.

**major term.** In a categorical syllogism, the term that is the predicate of the conclusion.

**many-one correspondence.** A relation  $R$  such that for every element  $a$  of its domain there is only one member  $b$  of its converse domain such that  $aRb$ . "Son of" is a many-one correspondence since for every member of its domain (for every son) there is only one member of the converse domain (his father) of which it is true that the member of the domain is the son of the member of the converse domain.

**many-valued logic.** A system of logic in which each formula has more than two possible truth-values.

**map of one set into another.** A one-to-one correspondence between two sets whose domain is the first set and whose converse domain is a proper subset of the second set.

**map of one set onto another.** A one-to-one correspondence between two sets whose domain is the first set and whose converse domain is the second set.

**material implication.** See *implication*.

**mathematical induction.** See *induction, mathematical*.

**matter of a proposition.** See *logical form*.

**meaning, Frege's theory of.** According to this theory, propounded by Gottlob Frege in 1892, the meaning of a proper name has two aspects, the *sense* and the *reference*. The reference of a proper name is that which it is a name of. Thus, the reference of "Sir Walter Scott" is Sir Walter Scott. Frege claimed that there must be, besides the reference, another aspect of the meaning of such a name. "Sir Walter Scott" and "the author of Waverley" have the same reference, but it would be most implausible to say that they have the same meaning. The aspect of meaning that distinguishes "Sir Walter Scott" from "the author of Waverley" is called the sense of the proper name.

It should be noted that this is a theory of the meaning of proper names, not common names. It is for common names that John Stuart Mill first introduced his distinction between *denotation* (the objects to which the

common name is properly applied) and *connotation* (the characteristic or set of characteristics that determines to which objects the common name properly applies). Unlike Frege, Mill thought that the meaning of a proper name is simply that which it denotes.

**mediate inference.** An inference in which the conclusion follows from two or more premises.

**membership.** The relation that exists between a set and its elements. The relation of set-membership must be distinguished from the relation of set-inclusion.

**mention of a term.** An occurrence of a linguistic expression in quotation marks for the purpose of talking about that linguistic expression. For example, in "Cicero has six letters" it is not the orator himself but the word referring to him that is being discussed.

This is to be contrasted with *use of a term*, the occurrence of a linguistic expression for the purpose of talking about something other than the expression.

**metalanguage.** A language used to talk about an object language; a *meta-metalanguage* is a language used to talk about a metalanguage, and so forth. Derivatively, a proposition is said to be in the metalanguage if and only if it is about an expression in the object language.

**metamathematics (proof theory).** The study of logistic systems. Some authors restrict this term to investigations employing finitary methods.

**metatheorem.** A theorem in a metalanguage.

**metatheory.** The metamathematical investigations relating to a given logistic system.

**method of construction.** Bertrand Russell's name for the method of introducing new types of numbers by defining them in terms of previously introduced numbers and the usual logical and set-theoretic notation. Opposed to the method of construction is the *method of postulation*, whereby one introduces new types of numbers as primitive terms with appropriate axioms.

**middle term.** In a categorical syllogism, the term that occurs in both premises but not in the conclusion.

**minor premise.** In a categorical syllogism, the premise that contains the minor term.

**minor term.** In a categorical syllogism, the term that is the subject of the conclusion.

**mnemonic terms.** The names that the medieval logicians introduced for the valid syllogisms. One such term is "Barbara." The key for these mnemonics is as follows: The three vowels respectively indicate the three constituent propositions of the syllogism as A, E, I, or O. For

first-figure syllogisms the initial consonants are arbitrarily the first four consonants; for the other figures the initial consonants indicate to which of the first-figure syllogisms the syllogism in question may be reduced. Other consonants occurring in second-, third-, and fourth-figure mnemonics indicate the operation that must be performed on the proposition indicated by the preceding vowel in order to reduce the syllogism to a first-figure syllogism. The key for this is as follows: “s” indicates simple conversion, “p” indicates conversion *per accidens*, “m” indicates metathesis (interchanging of the premises), “k” indicates obversion, and “c” indicates *convertio syllogism* (that is, the syllogism is to be reduced indirectly). In mnemonic terms the only meaningless letters are “r,” “t,” “l,” “n,” and noninitial “b” and “d.” More elaborate mnemonics have been devised for syllogisms in which two or more of the premises exhibit modality. See entry “Logic, Traditional.”

**Mnemonic Terms**

Name	Figure	Major premise	Major premise	Conclusion
Barbara	first	A	A	A
Baroco	second	A	O	O
Bocardo	third	O	A	O
Bramantip	fourth	A	A	I
Camenes	fourth	A	E	E
Camestres	second	A	E	E
Celarent	first	E	A	E
Cesare	second	E	A	E
Darapti	third	A	A	I
Darii	first	A	I	I
Datisi	third	A	I	I
Dimaris	fourth	I	A	I
Disamis	third	I	A	I
Felapton	third	E	A	O
Ferio	first	E	I	O
Ferison	third	E	I	O
Fesapo	fourth	E	A	O
Festino	second	E	I	O
Fresison	fourth	E	I	O

**modality.** (1) The characteristic of propositions according to which they can be described as “apodictic,” “assertoric,” or “problematic.” An *assertoric* proposition asserts that something is the case; an *apodictic* proposition asserts that something must be the case; a *problematic* proposition asserts that something may be the case. This type of modality was called by the medieval logicians *modality sine dicto (de re)*.

(2) The characteristic of propositions according to which they can be described as “necessary,” “impossible,” “possible,” or “not-necessary.” Medieval logicians called this type *modality cum dicto (de dicto)*.

**modal logic.** The study of inferential relations among propositions which are due to their modality. Most logi-

cians treat systems of modal logic as intensional, basing them upon strict implication. An alternative approach is to treat these systems as extensional, basing them upon a many-valued logic. See entry “Modal Logic.”

**model.** An interpretation of a given set of well-formed formulas according to which all the members of the set are true. The *standard* model corresponds to the principal interpretation, and a *nonstandard* model corresponds to a secondary interpretation. See *interpretation*.

**modus ponendo tollens.** An inference of the form “Either A or B; A; therefore, not-B.” This type of inference is valid only if “or” is interpreted as exclusive disjunction.

**modus ponens.** An argument of the form “If A then B; A; therefore, B.” Some authors use the term to designate the rule of inference that allows arguments of this form.

**modus tollendo ponens.** An argument of the form “Either A or B; not-A; therefore, B.”

**modus tollens.** An argument of the form “If A then B; not-B; therefore, not-A.” Some authors use the term to designate the rule of inference that allows arguments of this form.

**mood.** A way of classifying categorical syllogisms according to the quantity and quality of their constituent propositions.

**multiplicative axiom.** See *choice, axiom of*.

**name.** In traditional logic, a word or group of words that can serve as a term in a proposition. A *general* name is one that can be significantly applied to each member of a set of objects, a *singular* name is one that can be significantly applied to only one object, and a *collective* name is one that can be significantly applied to a group of similar things regarded as constituting a single whole.

**natural number.** A member of a certain subset of the cardinal numbers. There are various ways of defining this subset so that it contains all and only the desired objects (namely 0, 1, 2, 3, . . .); the most common way is to define it as the set of all objects that belong to all sets containing 0 and closed under the successor relation.

**necessary condition.** See *condition*.

**necessary truth.** See *analytic*.

**negate of a set.** See *complement of a set*.

**negation.** A singular propositional connective ( $\neg$ ,  $\bar{\quad}$ ,  $\sim$ ,  $\neg$ ), usually read “not,” whose truth table is such that “not-A” is true if and only if A is false.

**negative name.** In traditional logic, a name that implies the absence of one or more properties or that

denotes everything with the exception of some particular thing or set of things. An example of such a name is “non-Briton.”

*non sequitur.* See *fallacy*.

*normal system of domains.* A system of domains such that the axioms of second-order functional calculus are valid in them and the rules of inference of second-order functional calculus preserve validity in them.

*null set (empty set).* A set with no members.

*number.* See *cardinal number*; *natural number*; *rational number*; *real number*; entry “Number.”

*object language.* A language used to talk about things, rather than about other languages. Derivatively, a proposition is said to be in the object language if and only if it is not about any linguistic expression. “Socrates was a philosopher” is therefore in the object language, whereas “Socrates’ has eight letters” is not.

*obversion.* In traditional logic, a type of immediate inference in which from a given proposition another proposition is inferred whose subject is the same as the original subject, whose predicate is the contradictory of the original predicate, and whose quality is affirmative if the original proposition’s quality was negative and vice versa. Obversion of a proposition yields an equivalent proposition when applied to all four types (A, E, I, and O) of propositions that traditional logicians considered. See entry “Logic, Traditional.”

*omega.* The smallest infinite ordinal (denoted by  $\omega$ ), the order type associated with the set of all natural numbers as ordered in their natural order.

*omega-complete.* Used of a system which, if it contains the theorems that property  $P$  holds of 0, of 1, of 2, and so on, contains the theorem that  $P$  holds of all numbers.

*omega-consistent.* Used of a system which, if it contains the theorems that property  $P$  holds of 0, of 1, of 2, and so on, does not contain the theorem that  $P$  holds of all numbers.

*one-many correspondence.* A relation  $R$  such that for every member  $a$  of its converse domain, there is more than one object  $b$  that is a member of its domain such that  $bRa$ . “Father of” is an example of a one-many correspondence, since for every member of its converse domain (everyone who has a father) there is only one member of its domain (that person’s father) such that the member of the domain is the father of the member of the converse domain.

*one-to-one correspondence.* A relation  $R$  such that for every member  $a$  of its converse domain, there is only one object  $b$  that is a member of its domain such that  $bRa$ . A one-to-one correspondence is said to be *order-preserving* if both its domain and its converse domain are simply ordered and if, for all  $c$  and  $d$  that are members of its domain and are such that  $c$  precedes  $d$  in the ordering of the domain, it is the case that their respective images  $e$  and  $f$  in the converse domain are such that  $e$  precedes  $f$  in the ordering of the converse domain.

*open schema.* A formula containing free individual and functional variables.

*open sentence.* A formula containing free individual variables.

*operator.* A symbol or combination of symbols that is syncategorematic under the principal interpretation of the logistic system it occurs in and that may be used with one or more variables and one or more constants or forms or both to produce a new constant or form. Universal and existential quantifiers are the most common examples of operators.

*O-proposition.* In traditional logic, a particular negative categorical proposition. An example is “Some men are not mortal.”

*order.* See *Level*.

*ordered, partially.* A set  $a$  is partially ordered if and only if there is a relation  $R$  such that for all  $b, c$ , and  $d$  that are members of  $a$ , (1) if  $bRc$  and  $cRd$ , then  $bRd$ , and (2) it is not the case that  $bRb$ .

*ordered, simply.* A set  $a$  is simply ordered if and only if there is a relation  $R$  such that  $a$  is partially ordered by  $R$  and for all  $b$  and  $c$  that are members of  $a$  and are not identical, either  $bRc$  or  $cRb$ .

*ordered, well.* A set  $a$  is well ordered if and only if there is a relation  $R$  such that  $a$  is simply ordered by  $R$  and for every nonempty subset of  $a$ , there is a first element of that nonempty subset.

*ordered pair.* For given objects  $a$  and  $b$ , the ordered pair  $(a,b)$  is the pair set of which one member is the unit set whose only member is  $a$  and the other member is the pair set whose members are  $a$  and  $b$ .

*order-preserving.* See *one-to-one correspondence*.

*order type.* The set of all sets that are ordinally similar to a given set.

*ordinally similar.* Two or more sets are ordinally similar if and only if there exists between them a one-to-one order-preserving correspondence.

**ordinal number.** An order type of a well-ordered set.

**pairing axiom.** An axiom in set theory stating that for any two objects *a* and *b*, there is a set *c* whose members are *a* and *b* only.

**pair set.** A set that contains exactly two members.

**paradox (antinomy).** A statement whose truth leads to a contradiction and the truth of whose denial leads to a contradiction. Since F. P. Ramsey it has been customary to distinguish between *logical paradoxes* (often called *paradoxes of set theory*), which can arise in the object language because they involve only the usual logical and set-theoretic symbols, and *semantic paradoxes*, which can arise only in the metalanguage because they involve semantic concepts.

The most prominent logical paradoxes are the following: (1) *Russell's paradox*. Consider the set of all objects that are not members of themselves. Is that set a member of itself? If it is, then it is not. If it is not, then it is. (2) *Cantor's paradox*. Consider the set of all sets. Is it equal to or greater than its power set? If it is equal, then there is a contradiction, since there is a proof that the power set of any set is greater than the set itself. If it is not, then there is a contradiction, since the power set of any set is a set of sets and must therefore be a subset of the set of all sets, and there is a proof that the subset of a set cannot be greater than the set itself. (3) *Burali-Forti's paradox*. Consider the set of all ordinals. Does it have an ordinal number? If it does not, there is a contradiction, since by the "less than" relation it is well ordered, and there is a proof that all well-ordered sets have ordinal numbers. If it does, there is a contradiction, since it can be proved that the set's ordinal number must be both equal to and less than its image in the mapping of the set of all ordinals onto the set of all ordinals less than its own ordinal.

The most prominent of the semantic paradoxes are the following: (1) *Berry's paradox*. Consider the expression "the least natural number not namable in fewer than 22 syllables." Is the number it denotes namable in fewer than 22 syllables? If it is, there is a contradiction, since by definition it cannot be. If it is not, there is a contradiction, since we can produce a way of naming it in 21 syllables—the way we named it in stating this paradox. (2) *Epimenides' paradox*. Consider the sentence "This sentence is not true." Is it true? If it is, then it is not; if it is not, then it is. (3) *Grelling-Nelson paradox of heterologicality*. A predicate is heterological if the sentence ascribing the predicate to itself is false. Is the predicate "heterological" itself heterological? If it is, then it is not; if it is not, then

it is. (4) *Paradox of the Liar*. See *Epimenides' paradox* (although the name is often used to refer to the nearly identical paradox beginning with the sentence "This statement expresses a lie"). (5) *Richard's paradox*. Consider the set of all real numbers between 0 and 1 that can be characterized in a finite number of English words. This set has only denumerably many members. It can be shown, in a manner very similar to Cantor's diagonal proof, that we can specify in a finite number of English words a number that cannot belong to the set. Does it belong to the set? If it does, there is a contradiction, since it cannot. If it does not, there is a contradiction, since it can be characterized in a finite number of English words, and all such numbers belong to the set. See entry "Logical Paradoxes."

**paradoxes of material implication.** These so-called paradoxes consist in the fact that if "if \_\_\_\_\_ then \_\_\_\_\_" is taken in the sense of material implication, then any proposition of that form is true if the antecedent is false no matter what the consequent is or if the consequent is true no matter what the antecedent is. Thus, "If Eisenhower were premier of France, then the moon would be made of cheese" and "If  $2 + 2 = 17$ , then Johnson is the president of the United States" are both true propositions if "if-then" is interpreted in the sense of material implication.

**paralogism.** Any fallacious reasoning.

**particular.** See *individual*.

**Peano's postulates.** A system of five postulates from which one can derive the rest of arithmetic. The five postulates are (1) 0 is a number; (2) the successor of any number is a number; (3) there are no two numbers with the same successor; (4) 0 is not the successor of any number; (5) every property of 0 also belonging to the successor of any number that has that property belongs to all numbers.

**per accidens.** Used of a predication to the subject of one of its accidents.

**perfect figure.** The first figure of the syllogism. According to Aristotle, this is the only figure to which the *dictum de omni et nullo* is directly applicable.

**per se.** Used of a predication to the subject of one of its essential attributes.

**petitio principii.** See *fallacy*, (11) *begging the question*.

**polysyllogism.** A series of syllogisms so linked that the conclusion of one is a premise of another. In such a series a syllogism is said to be a *prosyllogism* if its conclu-

sion is a premise of the syllogism with which it is connected and an *episylogism* if one of its premises is the conclusion of the syllogism with which it is connected. See *sorites*.

*possible truth*. See *logical possibility*.

*post hoc, ergo propter hoc*. See *fallacy*.

*postulate*. Although often used synonymously with “axiom,” this term is sometimes confined to the basic propositions of a particular discipline, with the axioms being the basic propositions common to all disciplines (for example, the laws of logic). The distinction arises only when one is concerned not merely with a formal system but also with its interpretation.

*postulation, method of*. See *method of construction*.

*potential infinite*. The infinite regarded as a limiting concept, as something becoming rather than as something completed.

*power*. See *cardinality*.

*power set*. The set of all subsets of a given set.

*power-set axiom*. An axiom in set theory stating that for any given set, its power set exists.

*pragmatics*. See *semantics, formal*.

*predicables*. A classification of things and concepts as predicated of subjects, first made by Aristotle. His four predicables were definition, genus (in which he included differentia), proprium, and accident. Medieval logicians, following Porphyry, offered a list of five predicables—species, differentia, genus, proprium, and accident—which was adopted by most traditional logicians.

For Aristotle one defined a term by stating the *essence* of the object that it names (this statement is called the *definition*). The essence of a thing is that property which makes it the type of thing it is and not some other type of thing. The essence has two aspects: the *genus* is that which is predicable essentially of other kinds of things as well, and the *differentia* is that which is possessed essentially only by things of one type (members of one species) and not by things of any other type. Thus, in “Man is a rational animal” the genus is “animal,” and the differentia is “rational.”

Aristotle distinguished between the essence of a thing and other properties which belong only to that type of thing but are not part of its essence; such a property is called a *proprium*. The precise manner in which he hoped to make this distinction is not very clear. He also recognized that a thing might have a property that it need not have. He called such a property an *accident*.

*predicate*. Traditionally, the word or group of words in a categorical proposition that connote the property being attributed to the subject or denote the class which the subject is being included in or excluded from. The term is often extended, in contemporary works, to cover all words or groups of words that connote properties or relations in any type of proposition. Thus, in “All men are mortal” the predicate is “mortal.”

*predicate calculus*. See *calculus*.

*predication*. The attributing of a property to a subject.

*premise*. A member of the set of propositions, assumed for the course of an argument, from which a conclusion is inferred.

*primitive basis*. The list of primitive symbols, formation rules, axioms, and rules of inference of a given logistic system.

*primitive symbols*. Those symbols of a given logistic system that are undefined and are not divided into parts in the course of operating within the system. One can, following John von Neumann, divide these symbols into constants, variables, connectives, operators, and bracket-like symbols.

*privative name*. A name that implies the absence of a property where it has been or where one might expect it to be.

*problematic proposition*. See *modality*.

*product of sets*. See *intersection of sets*.

*proof*. For a given well-formed formula  $A$  in a given logistic system, a proof of  $A$  is a finite sequence of well-formed formulas the last of which is  $A$  and each of which is either an axiom of the system or can be inferred from previous members of the sequence according to the rules of inference of the system.

*proof from hypothesis*. A proof from a given set of hypotheses  $A_1, A_2, \dots, A_n$  in a given logistic system is a sequence of well-formed formulas the last of which is the conclusion of the proof and each of which is either an axiom of the system or one of  $A_1, A_2, \dots, A_n$  or a formula that can be inferred from previous formulas in the sequence by the rules of inference of the system.

*proof theory*. See *metamathematics*.

*proper class*. An object which contains members but which cannot itself be a member of any object.

*proper subset*. A subset of a given set that is not identical with the given set.

**proposition.** There is no uniform use of the word *proposition* among logicians and philosophers. Many writers distinguish a proposition from a sentence; thus, “Socrates was a philosopher” and “Socrates war ein Philosoph” would be two different sentences that express the same proposition. Other writers use *sentence* and *proposition* interchangeably. To avoid some of the associations of the word *proposition* some contemporary philosophers abandon the term altogether in favor of *statement*. For a discussion of some of the philosophical controversies arising in this connection, see entry “Propositions.” For present purposes it is assumed that the reader has a rough idea of what the term *proposition* means. This discussion will accordingly confine itself to an account of the different kinds of propositions distinguished by logicians.

Propositions may be classified in many ways. To begin with, one must distinguish *simple* (or *atomic* or *elementary*) propositions, propositions that do not have other propositions as constituent parts, from *compound* (or *molecular*) propositions, propositions that do have other propositions as constituent parts.

Among simple propositions the more important types are *categorical* (or *subject-predicate*) propositions, which affirm or deny that something has a property or is a member of a class, and *relational* propositions, which affirm or deny that a relation holds between two or more objects. A categorical proposition is *singular* when its subject is the name of an individual and *general* when its subject is the name of a property or class, affirmative when its predicate is affirmed of the subject and *negative* when its predicate is denied of the subject. A general categorical proposition is *universal* when it is talking about all the members of the subject class or all the objects that have the subject property and *particular* when it is talking about only some of the members of the subject class or some of the objects that have the subject property.

Among compound propositions the most important types are *alternative* (or *disjunctive*) propositions, which are of the form “A or B,” *conditional* (or *hypothetical*) propositions, of the form “If A then B,” *conjunctive* propositions, of the form “A and B,” and *negative* propositions, of the form “Not-A.” Many propositions that seem to be simple turn out under proper analysis to be compound. Such propositions are known as *exponible* propositions.

Kant, and many logicians following him, distinguished a class of *infinite* (or *limitative*) propositions, affirmative propositions with a negative term as predicate. This distinction has been challenged by many

authors. A more widely accepted addition to our classification is the *indefinite* proposition, a proposition that is equivocal because no indication is given of whether it is universal or particular. Finally, modality provides still another means of classifying propositions.

**propositional calculus.** See *calculus*.

**propositional connective.** See *connective*.

**propositional function.** A function whose range of values consists exclusively of truth-values. Thus, “*a* is the father of George Washington” is a propositional function, since for any argument for *a*, the value of the whole unit is truth or falsehood, depending on whether or not the argument is the name of George Washington’s father.

**proprium.** See *predicables*.

**prosyllogism.** See *polysyllogism*.

**protothetic.** A form of the extended propositional calculus, first introduced by Stanisław Leśniewski, to which have been added variables whose values are truth-functions and a notation for the application of a function to its argument or arguments, and in which the quantifiers are allowed to have variables of any kind as operator variables. In the *higher* protothetic, variables whose values are propositional functions of truth-functions are added.

**proximum genus.** See *classification*.

**quality of a proposition.** The characteristic that makes a proposition affirmative or negative. Kant, and logicians following him, added a third type, infinite propositions. See *proposition*.

**quantification of the predicate.** The prefixing of a sign of quantity, “some” or “all,” to the predicate of a proposition in the same way as to the subject, a device introduced by Sir William Hamilton. The claim was that this would make explicit what was implicit in the proposition.

**quantifier.** An operator of which it is true that both the constant or form it is used with and the constant or form produced are propositions or propositional forms. Thus, an existential quantifier, when joined to a proposition or propositional form *A*, produces a new proposition or propositional form “ $(\exists a)M$ .”

**quantity of a proposition.** The characteristic that makes a proposition universal or particular. Kant and others considered singular propositions as being a third, distinct type of quantity.

**Quine’s set theories.** A group of set theories proposed by W. V. Quine, combining some of the features of type theory with some of the features of the Zermelo-Fraenkel

and Gödel–von Neumann–Bernays set theories. As in the set theories, the axiom of abstraction is not retained in its full power, and the formation rules of intuitive set theory are not modified; as in type theory, the notion of stratification is used, since in certain key axioms only stratified formulas generate sets.

**range of a relation.** See *converse domain of a relation*.

**range of values.** The class of those things that are ambiguously named by a given variable.

**rational number.** A number that can be put into the form  $a/b$ , where  $a$  is any integer and  $b$  any natural number.

**real mathematics.** For David Hilbert, that part of mathematics that is finitary in character, has therefore a clear and intuitive meaning, and poses no problem about its foundation except for the fact that when ideal mathematics is adjoined to it the possibility of inconsistency arises. See *ideal mathematics*.

**real number.** Any number which can be represented by an unending decimal.

**recursive function.** There are various types of recursive functions. In order to explain them we must first introduce some terminology: a *constant function* is a function that has the same value for all of its arguments; a *successor function* has as its value for any given argument the successor of that argument; an *identity function* is a function of  $n$  arguments whose value is always the  $i$ th argument. All such functions are known as *fundamental functions*.

A function of  $n$  arguments is defined by *composition* when, given any set of previously introduced functions of  $n$  arguments, the value of the new function is equal to the value of a previously introduced function whose arguments in any particular case are the values of each of the members of the set of functions when their arguments are the arguments of the newly introduced function in that particular case. In symbols, where  $P$  is the new function being defined by composition,  $P(a_1, a_2, \dots, a_n) = R(S_1(a_1, a_2, \dots, a_n), S_2(a_1, a_2, \dots, a_n), \dots, S_m(a_1, a_2, \dots, a_n))$ , where  $R$  and  $S_1, S_2, \dots, S_m$  are previously introduced functions.

A function is defined by *recursion* in the following circumstances: (1) A value is assigned to the function for the case where one of its arguments is 0 in terms of a previously introduced function whose arguments, except for 0, are in any particular case all and only the arguments of the new function in that particular case. In symbols, where  $P$  is the new function and  $R$  the previously introduced function,  $P(a_1, a_2, \dots, a_n, 0) = R(a_1, a_2, \dots, a_n)$ . (2)

A value is given to the new function when 0 is not one of its arguments and when one of its arguments is the successor of any number  $b$ , in terms of a previously introduced function  $S$ , whose arguments, except for the successor of  $b$ , are in any particular case all the arguments of the newly introduced function,  $b$  itself, and the value of the new function when its arguments are all and only the arguments already given for  $S$ . In symbols,  $P(a_1, a_2, \dots, a_n, b + 1) = S(a_1, a_2, \dots, a_n, b, P(a_1, a_2, \dots, a_n, b))$ .

Any numerical function that is a fundamental function or can be obtained, by composition or recursion or both, from the fundamental functions by a finite sequence of definitions is a *primitive recursive numerical function*. A function  $P$  is introduced by the *least-number operator* if its value for a given set of arguments is the least number  $b$  such that the value of a previously introduced function  $R$ , whose arguments in any particular case are the arguments of  $P$  in that case and  $b$ , is equal to 0 provided that there is such a  $b$ ; if there is no such  $b$ , the function is undefined for those arguments. In symbols,  $P(a_1, a_2, \dots, a_n) =$  the least  $b$  such that  $R(a_1, a_2, \dots, a_n, b) = 0$ , provided that there is a  $b$  such that  $R(a_1, a_2, \dots, a_n, b) = 0$ . Any numerical function that either is a fundamental function or can be obtained from the fundamental functions by a finite sequence of definitions by composition, recursion, and the least-number operator (when this operator is used in defining a general recursive function, it must be the case that for all  $a_1, a_2, \dots, a_n$  there is a  $b$  such that  $R(a_1, a_2, \dots, a_n, b) = 0$ ) is a *general recursive numerical function*.

**recursively enumerable.** Used of a set or class that is enumerated (allowing for repetitions) by a general recursive function. That is, there is a general recursive function whose converse domain has the same members as the set when its domain is the set of natural numbers.

**recursive number theory.** The development of number theory, instituted by Thoralf Skolem, in which no quantifiers are introduced as primitive symbols, in which universality is expressed by the use of free variables, and in which functions are introduced through definitions by recursion.

**recursive set.** A set that is enumerated (allowing for repetitions) by a general recursive function and whose complement is also enumerated (allowing for repetitions) by a general recursive function.

**reducibility, axiom of.** An axiom, introduced by Bertrand Russell and A. N. Whitehead in *Principia Mathematica*, which says that for any propositional function of

arbitrary level there exists a formally equivalent propositional function of the first level.

*reductio ad absurdum.* (1) See *indirect proof*. (2) The method of proving a proposition by showing that its denial leads to a contradiction. In this sense it is often known as a *reductio ad impossibile*.

*reduction of syllogisms.* The process whereby syllogisms in imperfect figures are expressed in the first figure. Reduction is *direct* when the original conclusion follows from premises in the first figure derived by conversion, obversion, etc., from premises in an imperfect figure. Reduction is *indirect* when a new syllogism is formed which establishes the validity of the original conclusion by showing the illegitimacy of its contradictory. See entry "Logic, Traditional."

*reference.* See *meaning, Frege's theory of*.

*referential opacity.* An occurrence of a word or sequence of words such that one cannot in general supplant the word or sequence of words with another word or sequence of words that refers to the same thing while preserving the truth-value of the containing sentence. For example, although "9 is necessarily greater than 7" is true, the result of substituting for "9" a sequence of words that refers to the same thing, "the number of planets," is the false proposition "The number of planets is necessarily greater than 7." Therefore, in this occurrence "9" is referentially opaque.

*reflexive relation.* See *relation*.

*reflexive set.* See *finite set*.

*regularity, axiom of.* See *foundation, axiom of*.

*relation.* This term is not adequately defined in traditional logic. The failure to offer an adequate definition is symptomatic of the lack of serious consideration, on the part of traditional logicians, of the significant differences between categorical and relational propositions. Augustus De Morgan and C. S. Peirce were the first logicians in the contemporary period to study the logic of relational propositions. Since their time this subject has become an important part of logic. In contemporary works, particularly in works on set theory, a relation is defined as a set of ordered pairs.

A relation  $R$  is *reflexive* if " $aRa$ " holds for all  $a$  that are members of the field of  $R$ , *irreflexive* if " $aRa$ " holds for no members of the field of  $R$ , and *nonreflexive* if " $aRa$ " holds for some but not all members of the field of  $R$ . For example, "is a member of the same family as" is a reflexive relation, "is not a member of the same family as" is an irreflexive relation, and "loves" is a nonreflexive relation.

A relation  $R$  is *symmetric* if for all  $a$  and  $b$  that are members of the field of  $R$ ,  $aRb$  if and only if  $bRa$ , *asymmetric* if for all  $a$  and  $b$  that are members of the field of  $R$ ,  $aRb$  if and only if not- $bRa$ , and *nonsymmetric* when " $aRb$ " and " $bRa$ " hold for some but not all  $a$  and  $b$  that are members of the field of  $R$ . For example, "is a member of the same family as" is a symmetric relation, "is a child of" is an asymmetric relation, and "is a brother of" is a nonsymmetric relation.

A relation  $R$  is *transitive* when for all  $a$ ,  $b$ , and  $c$  that are members of the field of  $R$ , if  $aRb$  and  $bRc$ , then  $aRc$ , *intransitive* when for all  $a$ ,  $b$ , and  $c$  that are members of the field of  $R$ , if  $aRb$  and  $bRc$ , then not- $aRc$ , and *nontransitive* when if  $aRb$  and  $bRc$ , then " $aRc$ " holds for some but not all of the  $a$ ,  $b$ , and  $c$  that are members of the field of  $R$ . For example, "is a descendant of" is a transitive relation, "is a child of" is an intransitive relation, and "is not a brother of" is a nontransitive relation.

The foregoing classifications are said to apply to a relation in a set if the corresponding properties hold for all members of the field of a relation that are members of the set. A relation is *connective* in a set if for all distinct  $a$  and  $b$  that are members of the set, either  $aRb$  or  $bRa$ .

The study of relational propositions has raised many philosophical issues—and has greatly influenced discussions of older issues—about the nature of relations. On these matters, see entry "Relations, Internal and External."

*replacement, axiom of (axiom of substitution).* An axiom in set theory stating that for any set  $a$  and any single-valued function  $R$  with a free variable  $b$ , there exists a set that contains just the members  $R(b)$ , with  $b$  being a member of  $a$ .

*representative of a cardinal number.* A set that has a given cardinal number as its cardinality.

*Richard's paradox.* See *paradox*.

*rule of inference (transformation rule).* For a given logistic system, any rule in its metalanguage of the form "From well-formed formulas of the form  $A_1, A_2, \dots, A_n$ , it is permissible to infer a well-formed formula of the form  $B$ ."

*Russell's paradox.* See *paradox*.

*Russell's theory of definite descriptions.* See *definite descriptions, theory of*.

*Russell's vicious-circle principle.* The principle according to which impredicative definitions are not allowed.

*satisfiable*. A well-formed formula that is satisfiable in some nonempty domain of individuals.

*satisfiable in a domain*. A well-formed formula is satisfiable in a given domain of individuals if and only if it has the value truth for at least one system of possible values of its free variables.

*Schröder-Bernstein theorem*. The theorem, first conjectured by Georg Cantor and proved by Felix Bernstein and Ernst Schröder, which states that if  $a$  and  $b$  are sets such that  $a$  is equipollent with a subset of  $b$  and  $b$  is equipollent with a subset of  $a$ , then  $a$  and  $b$  are equipollent.

*scope of a quantifier*. For a given occurrence of a quantifier as part of a well-formed part of a well-formed formula, the rest of that well-formed part.

*secondarily satisfiable*. Used of a well-formed formula that is satisfiable in some normal system of domains.

*secondarily valid*. Used of a well-formed formula that is valid in every normal system of domains.

*second-order logic*. Second-order functional calculus. See *calculus*.

*section of a set*. See *segment of a set*.

*segment of a set (section of a set)*. The subset of a given set ordered by a given relation whose members are those members of the set that precede a given member in the given ordering.

*selection set*. A set that contains one member from each subset of a given set.

*self-contradiction*. A proposition that in effect both asserts and denies some other proposition.

*semantical rule*. Any rule in the metalanguage that concerns the meaning of expressions in the object language.

*semantics, formal (semiotics)*. The study of linguistic symbols. Following C. W. Morris, it is customary to divide formal semantics into three areas: (1) *Syntax*, the study of the relations between symbols. The study of the ways in which the symbols of a given language can be combined to form well-formed formulas is one part of syntax. (2) *Semantics*, the study of the interpretation of symbols. Following W. V. Quine, it is customary to distinguish between the theory of reference, which studies the reference or denotation of symbols, and the theory of meaning, which studies the sense or connotation of symbols. (3) *Pragmatics*, the study of the relations between symbols, the users of symbols, and the environment of the users. Thus, the study of the conditions in which a

speaker uses a given word is part of pragmatics. See entry "Semantics."

*sense*. See *meaning, Frege's theory of*.

*sentential calculus*. See *calculus*.

*sentential connective*. See *connective*.

*sequence*. A function whose domain is a subset, not necessarily a proper one, of the set of natural numbers. Some authors extend the term to any function whose domain is ordered.

*set*. (1) An aggregate. (2) In Gödel–von Neumann–Bernays set theory, where a distinction is made between sets and classes, sets are those objects that can both contain members and be members of some other object.

*Sheffer stroke function (alternative denial)*. A binary propositional connective ( $\downarrow$ ), whose truth table is such that "A stroke-function B" is false if and only if A and B are both true. The Sheffer stroke function and joint denial are the only binary propositional connectives adequate for the construction of all truth-functional connectives.

*simultaneously satisfiable*. A class of well-formed formulas is said to be simultaneously satisfiable if there is some nonempty domain of individuals such that for all the free variables in all the formulas that are members of the class, there exists at least one system of values in that domain for which every formula in the class has the value truth.

*singular term*. A term that, in the sense in which it is being used, is predicable of only one individual. For example, any definite description is a singular term.

*singular connective*. See *connective*.

*Skolem–Löwenheim theorem*. In 1915, Leopold Löwenheim proved that if a well-formed formula is valid in an enumerably infinite domain, it is valid in every nonempty domain. A corollary is that if a well-formed formula is satisfiable in any nonempty domain, it is satisfiable in an enumerably infinite domain. In 1920, Thoralf Skolem generalized this corollary—and thus completed the theorem—by proving that if a class of well-formed formulas is simultaneously satisfiable in any nonempty domain, then it is simultaneously satisfiable in an enumerably infinite domain.

*Skolem's paradox*. The seemingly paradoxical fact that systems in which Cantor's theorem is provable, and which therefore have nondenumerable sets, must, by virtue of the Skolem–Löwenheim theorem, be satisfiable in an enumerably infinite domain.

*sorites*. A chain of syllogisms in which the conclusion of each of the prosyllogisms is omitted. If each of the conclusions forms the minor premise of the following episyl-

logism, the sorites is an *Aristotelian* sorites; if each of the conclusions forms the major premise of the following episyllogism, it is a *Goalenian* sorites.

**sound.** Used of an interpretation of a logistic system such that under the interpretation all the axioms either denote truth or always have the value truth, and all the rules of inference are truth-preserving.

**species.** See *classification*.

**square of opposition.** A diagrammatic representation of that part of the traditional doctrine of immediate inferences between categorical propositions that went under the name of the opposition of propositions. See entry "Logic, Traditional."

**stratification.** The substitution of numerals for variables in a formula (the same numeral for each occurrence of a single variable) in such a way that the symbol for class-membership is flanked always by variables with consecutive ascending numerals.

**subalternation.** The relation between a universal and a particular proposition of the same quality. Traditionally this relation has been viewed in such a way that the universal proposition implies the particular proposition. The universal proposition is called the *subalternant*; the particular proposition is called the *subalternate*.

**subaltern genera.** See *classification*.

**subcontrary propositions.** Two propositions that cannot both be false but may both be true. Any I- and O-propositions with the same subject and the same predicate form a pair of subcontrary propositions.

**subject.** The word or words in a categorical proposition that denote the object to which a property is being attributed or the class which is either included in or excluded from some other class.

**subset.** Any set *b* such that all the members of *b* are members of a given set *a*.

**substitution, axiom of.** See *replacement, axiom of*.

**substitution, rule of.** A rule of inference that allows one to infer from a given formula *A* another formula *B* that is the same as *A* except for certain specified changes of symbols. The various rules of substitution differ in the types of changes they allow.

**successor.** For a given number, the number that follows it in the ordinary ordering of the numbers. In Peano's axiomatic treatment of arithmetic "successor" is treated as a primitive term. In the various set-theoretic treatments of arithmetic it is defined differently. For example, "the successor of *a*" is sometimes defined as the unit set whose only member is *a*.

**sufficient condition.** See *condition*.

**sumum genus.** See *classification*.

**sum of sets.** See *union of sets*.

**sum set.** For a given set *a*, the set whose members are all and only those objects which are members of members of *a*.

**sum-set axiom.** An axiom in set theory stating that for any set *a*, its sum set exists.

**supposition.** Roughly, the property of a term whereby it stands for something; the doctrine of supposition was extensively developed by the medieval logicians. *Material* supposition is possessed by those terms that stand for an expression, and *formal* supposition is possessed by those terms that stand for what they signify. Among terms having formal supposition, those that are common terms have *common* supposition, and those that are properly applicable to only one individual have *discrete* supposition. When in a given occurrence a common term stands for the universal, it has *simple* supposition; opposed to this is *personal* supposition, a property possessed by a common term in those occurrences where it stands for particular instances.

**syllogism.** A valid deductive argument having two premises and a conclusion. The term is often restricted to the case where both premises and the conclusion are categorical propositions that have between them three, and only three, terms. More careful authors distinguish this case by referring to it as a *categorical* syllogism. A *hypothetical* syllogism is one whose premises and conclusions are hypothetical propositions, and a *disjunctive* syllogism is one whose premises and conclusion are disjunctive propositions. All of these cases, where the three propositions are of the same type, are *pure* syllogisms. A *mixed* syllogism is one in which there occur at least two types of propositions.

A *strengthened* syllogism is one in which the same conclusion could be obtained even if we substitute for one of the premises that is a universal proposition its subalternate. Thus, the syllogism whose premises are "All men are mortal" and "All baseball players are men" and whose conclusion is "Some baseball players are mortal" is a strengthened syllogism, since it would have been sufficient to have as a premise "Some baseball players are men." A *weakened* syllogism is one whose premises imply a universal proposition but whose conclusion is the subalternate of that universal proposition. The above example is also an example of a weakened syllogism, since the premises, as they stand, imply "All baseball players are mortal."

*symbol, improper.* A symbol that is syncategorematic under the principal interpretation of the logistic system it occurs in. An example of such a symbol is “and.”

*symbol, proper.* A symbol that is categorematic under the principal interpretation of the logistic system it occurs in. Any individual constant is a proper symbol.

*symmetrical relation.* See *relation*.

*syncategorematic.* In traditional logic, used of a word which cannot be a term in a categorical proposition and which must be used along with a term in order to enter into a categorical proposition. An example of this is “all.” In contemporary logic the term refers to any symbol that has no independent meaning and acquires its meaning only when joined to other symbols. Cf. *categorematic*.

*syntactical variable.* A variable ranging over the names of symbols and formulas.

*syntax.* See *semantics, formal*.

*synthetic.* Used of a proposition that is neither analytic nor self-contradictory.

*systematic ambiguity (typical ambiguity).* A convention, introduced by Bertrand Russell and A. N. Whitehead, whereby one does not specify the type or order to which the variables in a formula belong, thus allowing one formula to represent an infinite number of formulas, namely all those formulas that are exactly like it except for the fact that their variables are assigned orders and types in such a manner that the formula formed is well-formed according to the formation rules of the ramified theory of types.

*tautology.* A compound proposition that is true no matter what truth-values are assigned to its constituent propositions. Thus, “A or not-A” is a tautology, since if “A” is true, then the whole proposition is true, and if “A” is false, then “not-A” is true, and therefore the whole proposition is still true.

*term.* Traditionally, the subject or predicate in a categorical proposition. Some authors extend the word *term* to cover all occurrences of categorematic words or expressions which, although not propositions by themselves, are parts of a proposition.

*tertium non datur.* The law of excluded middle. See *laws of thought*.

*theorem.* Any well-formed formula of a given logistic system for which there is a proof in the system.

*theorem schema.* A representation of an infinite number of theorems by means of an expression that contains syntactical variables and has well-formed formulas as values. Every value of the expression is to be taken as a theorem.

*theory of types.* The theory, introduced by Bertrand Russell and A. N. Whitehead in *Principia Mathematica*, which avoids the paradoxes of set theory by modifying the formation rules of intuitive set theory. In the *simple theory of types* the only modification is that every variable is assigned a number that signifies its type, and formulas of the form “a is a member of b” are well-formed if and only if a’s type-number is one less than b’s. In *ramified type theory* each variable is also assigned to a particular level, and certain rules are introduced about the levels of variables; these rules are such as to exclude classes defined by impredicative definitions. See entry “Types, Theory of.”

*tilde.* The name of the symbol for negation ( $\sim$ ).

*token.* A specified utterance of a given linguistic expression or a written occurrence of it. An expression-type, on the other hand, is an entity abstracted from all actual and potential occurrences of a linguistic expression. In “John loves John,” for example, there are three word-tokens but only two word-types.

*transfinite cardinals.* All cardinal numbers equal to or greater than aleph-null ( $\aleph_0$ ).

*transfinite induction.* A proof by course-of-values induction where the numbers involved are the ordinal numbers. This type of proof is important because it can be used to show that a property holds not only for the finite ordinals but for the transfinite ordinals as well.

*transfinite ordinal.* The order-type of an infinite well-ordered set.

*transfinite recursion.* A definition of a function by recursion in such a way that a value is assigned not only when the argument is a finite ordinal but also when it is a transfinite ordinal.

*transformation rule.* See *rule of inference*.

*transitive relation.* See *relation*.

*transposition.* A rule of inference that permits one to infer from the truth of “A implies B” the truth of “Not-B implies not-A,” and conversely.

*trichotomy, law of.* See *comparability, law of*.

*truth-function.* A function whose arguments and values are truth-values. A compound proposition is said to be a truth-functional proposition if the connective that is adjoined to the constituent propositions to form the compound proposition has a truth-function associated with it. In such a case, since the only arguments of the function are truth-values, the truth-value of the compound proposition depends only on the truth-values of its constituent propositions.

**truth table.** A table that shows the truth-value of a compound proposition for every possible combination of the truth-values of its constituent propositions.

**truth-value.** One of two abstract entities, truth and falsehood, postulated in Fregean semantics to serve as the reference of true and false sentences. In many-valued logics other truth-values are introduced.

**Turing-computable.** Used of a function whose value for any given argument a Turing machine can compute. The notion of Turing computability, due to A. M. Turing, is often introduced as a way of making precise the notion of an effectively computable function.

**Turing machine.** A machine that is capable of being in any one of a finite number of internal *states* at any particular time. The machine is supplied with a linear tape divided into squares on which symbols (from a fixed finite alphabet) may or may not be printed. It scans one, and only one, square at any given time and can erase a symbol from the scanned square and print some other symbol on it. The machine's behavior (in terms of changing what is on the scanned square, changing its internal state, and moving the tape so as to scan a different square) is governed by a *table* of instructions that determines what the machine is to do, given any *configuration* (a combination of the state the machine is in and the symbol on the scanned square) of the machine.

**type.** (1) See *token*. (2) In the theory of types, a class of objects all of whose members are such that they can be members of the same object. The lowest type is composed of all individuals, the next type of all sets of individuals, and each succeeding type of sets whose members are objects of the immediately preceding type.

**typical ambiguity.** See *systematic ambiguity*.

**union of sets (sum of sets).** The set whose members are all and only those objects that are members of at least one of two or more sets.

**unit set.** A set with only one member.

**universal generalization, rule of.** The rule of inference that permits one to infer from a formula of the form "Property *P* holds for an object *a*" a formula of the form "Property *P* holds for all objects." Because this inference is not generally valid, restrictions have to be placed on its use.

**universal instantiation, rule of.** The rule of inference that permits one to infer from a statement of the form "Property *P* holds for all objects" a statement of the form "Property *P* holds for an object *a*."

**universal quantifier.** The symbol  $(\forall)$  or  $(\forall)$ , read "for all." It is used in combination with a variable and placed before a well-formed formula, as in " $(a)$  \_\_\_\_\_" ("For all *a*, \_\_\_\_\_").

**universal set.** A set such that there is no object *a* that is not a member of the set.

**universe of discourse.** Those objects with which a discussion is concerned.

**univocal.** A linguistic expression is univocal if and only if it is neither ambiguous nor equivocal.

**use of a term.** See *mention of a term*.

**valid formula.** A well-formed formula that is valid in every nonempty domain. A well-formed formula is said to be valid for a given domain of individuals if it is true for all possible values of its free variables.

**valid inference.** An inference the joint assertion of whose premises and the denial of whose conclusion is a contradiction.

**value.** A member of the range of values of a given variable.

**value of a function.** That member of the converse domain of a function with which a given argument is paired under the function.

**variable.** A symbol that under the principal interpretation is not the name of any particular thing but is rather the ambiguous name of any one of a class of things.

**Venn diagram.** A modification, first introduced by John Venn, of Euler's diagrams. The key differences between Euler's diagrams and Venn's diagrams stem from the fact that Venn, and many other logicians, wanted to deny the traditional assumption that propositions of the form "All *P* are *Q*" or "No *P* are *Q*" imply the existence of any *P*'s. For details, see entry "Logic Diagrams."

**vicious-circle principle.** See *Russell's vicious-circle principle*.

**well-formed formulas.** Those formulas of a given logistic system of which it can sensibly be asked whether or not they are theorems of the system. In any particular system, rules are given that define the class of well-formed formulas and enable one to determine mechanically whether or not a given string of symbols is a well-formed formula of the system.

**well-ordering theorem.** The theorem stating that for any set there is a relation that well-orders it. See *choice, axiom of*.

**wff.** A common abbreviation for "well-formed formula."

*Zermelo-Fraenkel set theory.* That form of axiomatic set theory that avoids the paradoxes of set theory by dropping the axiom of abstraction and substituting for it a set of axioms about set-existence.

*Boruch A. Brody (1967)*

## LOGIC AND THE FOUNDATIONS OF MATHEMATICS

A very detailed account of main developments of logic will be found in *Logic, History of*. Brief explanations of many of the terms commonly used by logicians will be found in *Logical Terms, Glossary of*. The Encyclopedia also features the following articles dealing with questions in logic and the foundations of mathematics: *Artificial and Natural Languages; Combinatory Logic; Computability Theory; Computing Machines; Decision Theory; Definition; Existence; Fallacies; Geometry; Gödel's Theorem; Identity; Infinity in Mathematics and Logic; Laws of Thought; Logical Paradoxes; Logic Diagrams; Logic Machines; Many-Valued Logics; Mathematics, Foundations of; Modal Logic; Negation; Number; Questions; Semantics; Set Theory; Subject and Predicate; Synonymity; Syntactical and Semantical Categories; Types, Theory of; and Vagueness*. See "Logic" and "Mathematics, Foundations of," in the index for entries on thinkers who have made contributions in this area.

## LOGIC DIAGRAMS

"Logic diagrams" are geometrical figures that are in some respect isomorphic with the structure of statements in a formal logic and therefore can be manipulated to solve problems in that logic. They are useful teaching devices for strengthening a student's intuitive grasp of logical structure, they can be used for checking results obtained by algebraic methods, and they provide elegant demonstrations of the close relation of logic to topology and set theory.

Leonhard Euler, the Swiss mathematician, was the first to make systematic use of a logic diagram. Circles had earlier been employed, by Gottfried Wilhelm Leibniz and others, to diagram syllogisms, but it was Euler who, in 1761, first explained in detail how circles could be manipulated for such purposes. Euler's contemporary Johann Heinrich Lambert, the German mathematician, in his *Neues*

**FIGURE 1**

*Organon* (1764) used straight lines, in a manner similar to Euler's use of circles, for diagramming syllogisms.

### VENN DIAGRAMS

The Euler and Lambert methods, as well as later variants using squares and other types of closed curves, are no longer in use because of the great improvement on their basic conception which was introduced by the English logician John Venn. The Venn diagram is best explained by showing how it is used to validate a syllogism. The syllogism's three terms, *S*, *M*, and *P*, are represented by simple closed curves—most conveniently drawn as circles—that mutually intersect, as in Figure 1. The set of points inside circle *S* represents all members of class *S*, and points outside are members of class not-*S*—and similarly for the other two circles. Shading a compartment indicates that it has no members. An *X* inside a compartment shows that it contains at least one member. An *X* on the border of two compartments means that at least one of the two compartments has members.

Consider the following syllogism:

Some *S* is *M*.

All *M* is *P*.

Therefore, some *S* is *P*.

The first premise states that the intersection of sets *S* and *M* is not empty. This is indicated by an *X* on the bor-

FIGURE 2

der dividing the two compartments within the overlap of circles *S* and *M* (Figure 2). The second premise states that the set indicated by that portion of circle *M* that lies outside of *P* is empty. When this area is shaded (Figure 3) the *X* must be shifted to the only remaining compartment into which it can go. Because the *X* is now inside both *S* and *P*, it is evident that some *S* is *P*; therefore, the syllogism is valid.

Venn did not restrict this method to syllogisms. He generalized it to take care of any problem in the calculus of classes, then the most popular interpretation of what is now called Boolean algebra. For statements with four terms he used four intersecting ellipses, as shown in Figure 4. Since it is not possible for five ellipses to intersect in the desired manner, statements with five or more terms must be diagrammed on more complicated patterns. Various methods of forming nonconvex closed curves for Venn diagrams of statements with more than four terms have been devised.

### RECTANGULAR CHARTS

Statements involving a large number of terms are best diagrammed on a rectangle divided into smaller rectangles that are labeled in such a way that the chart can be manipulated efficiently as a Venn diagram. Many different methods of constructing such charts were worked out in the late nineteenth and early twentieth centuries, each

FIGURE 3

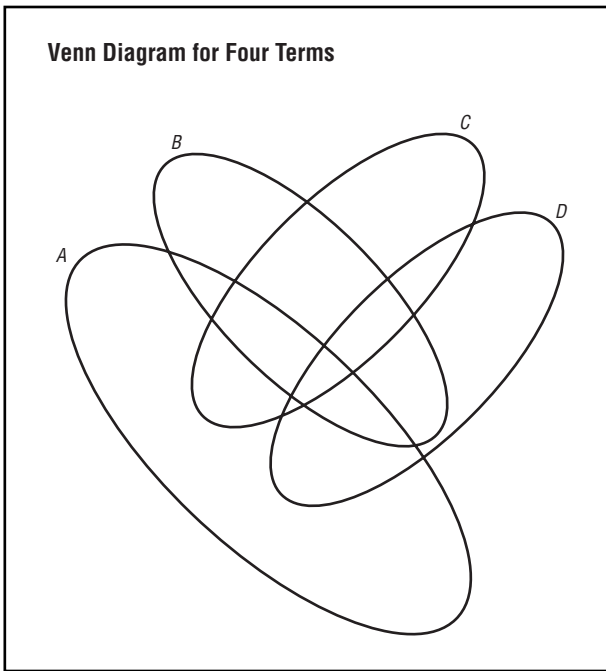

with merits and defects. The first to be published was that of Allan Marquand in 1881. Figure 5 shows a Marquand chart for four terms. Alexander Macfarlane preferred a narrow strip, which he called a “logical spectrum,” subdivided and labeled as in Figure 6. Later, in “Adaptation of the Method of the Logical Spectrum to Boole’s Problem” (in *Proceedings of the American Association for the Advancement of Science* 39 [1890]: 57f.), Macfarlane used his chart for solving a complicated problem in George Boole’s *Laws of Thought* (1854).

Other types of rectangular charts were devised by William J. Newlin, William E. Hocking, and Lewis Carroll. Carroll introduced his chart in a book for children, *The Game of Logic* (London and New York, 1886). Instead of shading compartments, he proposed marking them with counters of two colors, one for classes known to have members, the other for null classes.

An elaborate diagrammatic method designed to cover all types of logic, including modal logics, was devised in 1897 by the American philosopher Charles Sanders Peirce and later discussed in several brief, obscurely written papers. Although Peirce considered these “existential graphs,” as he called them, his greatest contribution to logic, they aroused little interest among later logicians and have yet to be fully explicated and evaluated.

**FIGURE 4**

**DIAGRAMS FOR THE PROPOSITIONAL CALCULUS**

In the early twentieth century the class interpretation of Boolean algebra was supplemented by a more useful interpretation in which classes are replaced by propositions that are either true or false and related to one another by logical connectives. The Venn diagrams, as well as their chart extensions, work just as efficiently for the propositional calculus as for the class calculus, but cultural lag has prevented this fact from entering most logic textbooks. For example, the class statement "All apples are red" is equivalent to the propositional statement "If  $x$  is an apple, then  $x$  is red." The same Venn diagram is therefore used for both statements (Figure 7). Similarly, the class statement "No  $A$  is  $B$ " is equivalent to the propositional statement "Not both  $A$  and  $B$ ," symbolized in modern logic by the Sheffer stroke. Both statements are diagrammed as in Figure 8.

A major defect of the Venn system is that it is difficult to distinguish the shading of one statement from the shading of another, so that one loses track of individual premises. This is best remedied by diagramming each statement on a separate sheet of transparent paper and superposing all sheets on the same basic diagram. Such a method using cellophane sheets shaded with different colors and superposed on a rectangular diagram was devised by Karl Döhmann, of Berlin.

**FIGURE 5**

A network method for solving problems in the propositional calculus, designed to keep statements separate and to bring out visually the nature of the logical connectives, is given in Martin Gardner's *Logic Machines and Diagrams* (1958), Chapter 3. Each term is represented by two vertical lines, one for "true," the other for "false." A connective is symbolized by "shuttles" that connect truth-value lines in the manner indicated by the "true" lines of a truth table for that connective. Figure 9 shows the diagram for implication.

A "Boole table," devised by Walter E. Stuerman, also keeps individual statements separate and can be used for graphing any type of Boolean algebra. It combines features of Macfarlane's chart with Lambert's linear method. John F. Randolph has developed a simple method of handling a Marquand diagram by sketching nested cross marks and using dots to indicate nonempty compartments.

Although the Venn circles and their various chart extensions can obviously be given three-dimensional forms, no three-dimensional techniques for diagramming Boolean algebra have been found useful because of the extreme difficulty of manipulating solid diagrams. In this connection, however, mention should be made of a curious cubical chart, devised by C. Howard Hinton in 1904, that is constructed with 64 smaller cubes and used for identifying valid syllogisms.

**FIGURE 6**

Boolean algebra is now known to be a special type of lattice, which in turn is a certain type of partially ordered set. A lattice diagram for a Boolean algebra of two terms is easily drawn, and although of little use in problem solving, it displays graphically many features of the propositional calculus.

In the logic of relations a large variety of useful diagrams have been widely used. The tree graph, for example, which goes back to ancient Greece, is an efficient way to indicate a familiar type of relation. Examples include the tree of Porphyry, found in medieval and Renaissance logics, the later tree diagrams of Peter Ramus, diagrams showing the evolution of organisms, family tree graphs, and graphs of stochastic processes in probability theory. The topological diagrams in Kurt Lewin's *Principles of Topological Psychology* (1936), as well as modern "sociograms," transport networks, and so on, may be called logic diagrams if "logic" is taken in a broad sense. However, such diagrams are now studied in the branch of mathematics called graph theory and are not generally considered logic diagrams. In a wide sense any geometrical figure is a logic diagram since it expresses logical relations between its parts.

**AREAS FOR EXPLORATION**

All diagrams for Boolean algebras work most efficiently when the statements to be diagramed are simple binary relations. Compound statements with parenthetical expressions are awkward to handle unless the statements are first translated into simpler expressions. Attempts

**FIGURE 7**

have been made to extend the Venn diagrams and other types of Boolean graphs to take care of parenthetical statements directly, but in all cases the diagrams become too complex to be useful. Perhaps simpler methods will be found by which traditional diagrams can be made to accommodate parenthetical expressions.

Little progress has been made in developing good diagrammatic methods for minimizing a complex logical statement—that is, for reducing it to a simpler but equivalent form. Several chart methods for minimizing have been worked out. The closest to a diagrammatic technique is the Karnaugh map, first explained by Maurice Karnaugh in 1953. The map is based on an earlier diagram called the Veitch chart, in turn based on a Marquand chart.

Work on better methods of minimizing is still in progress. The work has important practical consequences because electrical networks can be translated into Boolean algebra and the expression minimized and then translated back into network design to effect a simplification of circuitry. It is possible that a by-product of new minimizing methods may be a diagrammatic method superior to any yet found.

Another field open to exploration is the devising of efficient ways to diagram logics not of the Boolean type, notably modal logics and the various many-valued logics.

**FIGURE 8**

**Bibliography**

Venn’s *Symbolic Logic*, rev. 2nd ed. (London: Macmillan, 1894), remains the best single source for the early history of logic diagrams. It also contains the fullest exposition of his own method, which he first presented in “On the Diagrammatic and Mechanical Representation of Propositions and Reasonings,” *Philosophical Magazine* 10 (July 1880): 1–18. For more recent history and references, consult Martin Gardner, *Logic Machines and Diagrams* (New York: McGraw-Hill, 1958).

Euler’s explanation of his circles can be found in his *Lettres à une princesse d’Allemagne*, Vol. II, letters 102–108 (St. Petersburg: Academie Impériale des Sciences, 1768). Lambert’s method, in an improved form, is explained in J. N. Keynes, *Studies and Exercises in Formal Logic*. 4th ed. (London: Macmillan, 1906), p. 243.

For Venn diagrams of statements with more than four terms, see W. E. Hocking, “Two Extensions of the Use of Graphs in Elementary Logic,” in *University of California Publications in Philosophy* 2 (2) (1909): 31–44; Edmund C. Berkeley, “Boolean Algebra and Applications to Insurance,” in *Record*, American Institute of Actuaries 26 (1937): 373–414, and 27 (1938): 167–176 (reprinted, New York, 1952); Trenchard More Jr., “On the Construction of Venn Diagrams,” in *Journal of Symbolic Logic* 24 (1959): 303–304; and Stephen Barr, *Experiments in Topology* (New York: Crowell, 1964), p. 206. A method of drawing five irregular but congruent convex pentagons intersecting in the required manner is explained by David W. Henderson in “Venn Diagrams for More Than Four Classes,” *American Mathematical Monthly* 70 (1963): 424–426.

On rectangular Venn charts, see Allan Marquand, “A Logical Diagram for *n* Terms,” in *Philosophical Magazine* 12 (1881): 266–270; Alexander Macfarlane, “The Logical Spectrum,” in *Philosophical Magazine* 19 (1885): 286–289; William J. Newlin, “A New Logical Diagram,” in *Journal of Philosophy, Psychology, and Scientific Methods* 3 (1906): 539–545; and the Hocking paper mentioned above. Carroll’s method is further developed in his *Symbolic Logic* (London and New

**FIGURE 9**

York, 1896; paperback ed., New York, 1958). Peirce’s papers are reprinted in the *Collected Papers of Charles Sanders Peirce*, edited by Charles Hartshorne and Paul Weiss, Vol. IV (Cambridge, MA: Harvard University Press, 1933).

An explanation of how Venn circles can be used to handle problems in the propositional calculus appears in Gardner’s *Logic Machines and Diagrams* (op. cit.), pp. 48–54.

Döhmann explained his method in a privately printed booklet, *Eine logistische Farbenquadrat-Methode* (Berlin, 1962). Stuerman described his “Boole table” in “Plotting Boolean Functions,” *American Mathematical Monthly* 67 (1960): 170–172, and in “The Boole Table Generalized,” *American Mathematical Monthly* 68 (1961): 53–56.

Randolph’s method is given in “Cross-Examining Propositional Calculus and Set Operations,” *American Mathematical Monthly* 72 (1965): 117–127. Hinton explained his cubical chart in his eccentric book *The Fourth Dimension* (London: Sonnenschein, 1904), pp. 100–106. John Evenden presented a two-term lattice diagram for Boolean algebra in “A Lattice-Diagram for the Propositional Calculus,” *Mathematical Gazette* 46 (1962): 119–122.

Karnaugh first explained his map in “The Map Method for Synthesis of Combinational Logic Circuits,” *Transactions of the American Institute of Electrical Engineers*, Part 1, 72 (1953): 593–599. E. W. Veitch explained his earlier diagram in “A Chart Method for Simplifying Truth Functions,” *Proceedings of the Association for Computing Machinery* (May 2 and 3, 1952), 127–133.

**Martin Gardner (1967)**

**LOGICISM**

See *Mathematics, Foundations of*

## LOGIC MACHINES

Because logic underlies all deductive reasoning, one might say that all computers are logic machines. In a wider sense, any mechanical device is a logic machine (for example, an eggbeater spins clockwise “if and only if” its crank turns clockwise). Generally, however, the term is restricted to machines designed primarily or exclusively for solving problems in formal logic. Although a digital computer, or even a punch-card data-processing machine, can be programmed to handle many types of logic, it is not considered a logic machine in the strict sense.

The rotating circles of Ramón Lull, thirteenth-century Spanish mystic, cannot be called logic machines even though they were used as reasoning aids. The first true logic machine was a small device called a “demonstrator,” invented by Charles Stanhope, third Earl Stanhope, an eighteenth-century English statesman. By sliding two panels (one of gray wood, the other of transparent red glass) behind a rectangular opening, he could test the validity of traditional syllogisms, as well as syllogisms with such quantified terms as “Most of *a*” and “8 of 10 of *a*.” Stanhope also used his device for solving elementary problems in what he called the logic of probability.

### JEVONS'S MACHINE

The first logic machine capable of solving a complicated problem faster than a human could solve it without the aid of a machine was the “logical piano” invented by the nineteenth-century economist and logician William Stanley Jevons. The machine was built for him by a clockmaker at Salford in 1869 and first demonstrated by Jevons in 1870 at a meeting of the Royal Society of London. The device (now owned by the Oxford Museum of the History of Science) resembles a miniature upright piano, about three feet high, with a keyboard of 21 keys. On the face of the piano are openings through which one can see the 16 possible combinations of 4 terms and their negatives. A statement in logic is fed to the machine by pressing keys according to certain rules. Internal levers and pulleys eliminate from the machine's face all combinations of terms inconsistent with the statement. When all desired statements have thus been fed to the machine the face is inspected to determine what term combinations, if any, are consistent with the statements.

Jevons believed that this machine, designed to handle Boolean algebra, provided a convincing demonstration of the superiority of George Boole's logic over the tradi-

tional logic of Aristotle and the Schoolmen. John Venn's system of diagramming follows essentially the same procedure as Jevons's machine. In both cases the procedure gives what are today called the valid lines of a truth table for the combined statements under consideration. Neither the Venn diagrams nor Jevons's machine is capable of reducing these lines to a more compact form. This criticism of the machine was stressed by the English philosopher F. H. Bradley in his *Principles of Logic* (1883).

### OTHER MECHANICAL DEVICES

Jevons's logical piano was greatly simplified by Allan Marquand, who built his first model in 1881, when he was teaching logic at Princeton University. Like Jevons's, Marquand's machine is limited to 4 terms, but the 16 possible combinations are exhibited on its face by 16 pointers, each with a valid and an invalid position, arranged in a pattern that corresponds to Marquand's chart for 4 terms (see the entry “Logic Diagrams,” Figure 5). The number of keys is reduced to 10, and the device is about a third the height of Jevons's machine. Both Marquand and Jevons interpreted Boolean algebra primarily in class terms, but their machines operate just as efficiently with the propositional calculus.

A third machine of the Jevons type was invented in 1910 by Charles P. R. Macaulay, an Englishman living in Chicago. It is a compact, ingenious boxlike device with interior rods operated by tilting the box a certain way while pins on the side are pressed to put statements into the machine. Consistent combinations of four terms and their negatives appear in windows on top of the box.

A curious contrivance for evaluating the 256 combinations of syllogistic premises and conclusions was constructed in 1903 by Annibale Pastore, a philosopher at the University of Genoa. It consists of three wheels, representing a syllogism's three terms, joined to one another by an arrangement of endless belts appropriate to the syllogism being tested. If the syllogism is valid, all three wheels turn when one is cranked.

### GRID CARDS

Logic grid cards are cards that can be superposed so that valid deductions from logical premises are seen through openings on the cards. A set of syllogism grid cards invented by the Englishman Henry Cunyngame, a contemporary of Jevons, was depicted by Jevons in Chapter 11 of *Studies in Deductive Logic* (London, 1884). A differently designed set is shown in Martin Gardner's “Logic Machines” (in *Scientific American* 186 [March 1952]: 68–73). A more elaborate set, indicating the nature of the

fallacy when a syllogism is invalid, can be found in Gardner's *Logic Machines and Diagrams* (New York, 1958) and Richard Lampkin's *Testing for Truth* (Buffalo, NY, 1962). Triangular-shaped grid cards, for binary relations in the propositional calculus, are described in Gardner's book and in H. M. Cundy and A. P. Rollett's *Mathematical Models* (2nd ed., Oxford, 1961; see pp. 256–258). Gardner described a simple way to make punch cards that can be sorted in such a manner as to solve logic problems in "Mathematical Games" (in *Scientific American* 203 [December 1960]: 160–168).

### ELECTRICAL MACHINES

Marquand sketched an electrical circuit by which his machine could be operated, but the electrical version was probably never built. Benjamin Burack, a psychologist at Roosevelt College, Chicago, was the first actually to construct an electrical logic machine, in 1936. His device tested all syllogisms, including hypothetical and disjunctive forms. Since then many different kinds of electrical syllogism machines have been constructed.

In 1910, in a review in a Russian journal, Paul Ehrenfest pointed out that because a wire either carries a current or does not, it would be possible to translate certain types of switching circuits into Boolean algebra. Work along such lines was done by the Russian physicist V. I. Šestakov in 1934–1935, but his results were not published until 1941. Similar views were set forth independently in 1936, in a Japanese journal, by Akira Nakasima and Masao Hanzawa. It was the mathematician Claude E. Shannon, however, who impressed the engineering world with the importance of this isomorphism by his independent work, first published in 1938.

Shannon's paper inspired William Burkhart and Theodore A. Kalin, then undergraduates at Harvard University, to design the world's first electrical machine for evaluating statements in the propositional calculus. The Kalin-Burkhart machine was built in 1947. Statements with as many as twelve terms are fed into it by setting switches. The machine scans a truth table for the combined statements, and a set of twelve small bulbs indicates the combination of true and false terms for each truth-table row as it is scanned. If the combination is consistent with the statements, this is indicated by another bulb. The machine is thus an electrical version of Jevons's device but handles more complex statements and presents valid truth-table rows in serial time sequence rather than simultaneously.

A three-term electrical machine was built in England in 1949 without knowledge of the Kalin-Burkhart

machine. Advances in switching components made possible more sophisticated logic machines in the United States and elsewhere during the early 1950s. Of special interest is a ten-term machine built at the Burroughs Research Center in Paoli, Pennsylvania, using the parenthesis-free notation of Jan Łukasiewicz.

### DIGITAL COMPUTERS

While the special machines were being developed it became apparent that statements in Boolean algebra could easily be translated into a binary notation and analyzed on any general-purpose digital computer. As digital computers became more available, as well as faster and more flexible, interest in the design of special-purpose logic machines waned. Since 1955 almost all machine-aided investigations in logic have been conducted with digital computers. In 1960, Hao Wang described how he used an IBM 704 computer to test the first 220 theorems of the propositional calculus in *Principia Mathematica*. The machine's total running time was under three minutes.

The similarity between switching circuits and the nets of nerve cells in the brain suggests that the brain may think by a process that could be duplicated by computers. Much work is being done in programming computers to search for proofs of logic theorems in a manner similar to the heuristic reasoning of a logician—that is, by an uncertain strategy compounded of trial and error, logical reasoning, analogies with remembered experience, and sheer luck. The work is closely related to all types of learning machines. Such work may prove useful in exploring logics for which there is no decision procedure—or no known decision procedure—but no special machines have yet been built for such a purpose. Work is also under way on the more difficult problem of designing a machine, or programming a digital computer, to find new, nontrivial, and interesting theorems in a given logic.

Attempts have been made to design machines capable of reducing a statement in Boolean algebra to simpler form. A primitive minimizing machine was constructed by Daniel Bobrow, a New York City high school student, in 1952. At about the same time, Shannon and Edward F. Moore built a relay circuit analyzer that makes a systematic attempt to simplify circuits, a problem closely related to the logic minimizing problem.

No special machines are known to have been constructed for handling many-valued logics, but many papers have been published explaining how such machines could be built, as well as how digital computers

could be programmed to handle such logics. Kurt Gödel's undecidability proof has ruled out the possibility of an ultimate logic machine capable of following a systematic procedure for testing any theorem in any possible logic, but whether the human brain is capable of doing any kind of creative work that a machine cannot successfully imitate is still an open, much debated question.

### Bibliography

For a history of logic machines, see Martin Gardner, *Logic Machines and Diagrams* (New York: McGraw-Hill, 1958), and Rudolf Tarján, "Logische Maschinen," in *Digital Information Processors*, edited by Walter Hoffmann (New York: Interscience, 1962), which includes a bibliography of 119 references. Stanhope's machine is discussed in Robert Harley, "The Stanhope Demonstrator," *Mind* 4 (1879): 192–210.

Jevons described his logical piano in "On the Mechanical Performance of Logical Inference" (1870), reprinted in his *Pure Logic and Other Minor Works* (London: Macmillan, 1890); a briefer discussion appears in his *Principles of Science* (London: Macmillan, 1874; reprinted, New York, 1958). Marquand discussed his machine in "A New Logical Machine," *Proceedings of the American Academy of Arts and Sciences* 21 (1885): 303–307. Marquand's machine was praised by C. S. Peirce in "Logical Machines," *American Journal of Psychology* 1 (November 1887): 165–170. Pastore wrote an entire book about his device, *Logica formale, dedotta della considerazione di modelli meccanici* (Turin, 1906). The book was reviewed at length by André Lalande in *Revue philosophique de la France et de l'étranger* 63 (1907): 268–275.

Wolfe Mays, "The First Circuit for an Electrical Logic-Machine," in *Science* 118 (1953): 281–282, and George W. Patterson, "The First Electric Computer, a Magnetological Analysis," in *Journal of the Franklin Institute* 270 (1960): 130–137, describe Marquand's sketches. A description of Macaulay's device is in his U.S. patent, No. 1,079,504, issued in 1913.

Burack first described his 1936 machine in "An Electrical Logic Machine," *Science* 109 (1949): 610–611. Shannon's historic paper on the isomorphism of Boolean algebra and certain types of switching circuits is "A Symbolic Analysis of Relay and Switching Circuits," in *Transactions of the American Institute of Electrical Engineers* 57 (1938): 713–723. The Kalin-Burkhart machine is described in Edmund C. Berkeley, *Giant Brains* (New York: Wiley, 1949). The English three-term machine is discussed in Wolfe Mays and D. G. Prinz, "A Relay Machine for the Demonstration of Symbolic Logic," *Nature* 165 (1950): 197. The Burroughs machine is discussed in A. W. Burks, D. W. Warren, and J. B. Wright, "An Analysis of a Logical Machine Using Parenthesis-Free

Notation," *Mathematical Tables and Other Aids to Computation* 8 (1954): 53–57, and in William Miehle, "Burroughs Truth Function Evaluator," *Journal of the Association for Computing Machinery* 4 (1957): 189–192.

Hao Wang's description of his use of the IBM 704 is in "Toward Mechanical Mathematics," *IBM Journal of Research and Development* 4 (1960): 2–22, reprinted in *The Modeling of Mind*, edited by Kenneth Sayre and Frederick J. Crosson (Notre Dame, IN: University of Notre Dame Press, 1963). On computer simulation, see Allen Newell and H. A. Simon, "Computer Simulation of Human Thinking," in *Science* 134 (1961): 2011–2017, and references cited there. On the Shannon-Moore relay circuit analyzer, see Shannon and Moore's "Machine Aid for Switching Circuit Design," in *Proceedings of the Institute of Radio Engineers* 41 (1953): 1348–1351.

**Martin Gardner (1967)**

## LOGOS

The Greek term *logos* is multiply ambiguous. The unabridged Greek dictionary gives five and a half long columns of definitions and examples. *Logos* is a noun corresponding to the verb *legein* (say), signifying, among other things, speech, statement, sentence, account, definition, formula, calculation, ratio, explanation, reasoning, and faculty of reason. Early studies of the term tended to talk about a concept of *logos*, as if there were some single concept or theory associated with it. In fact, the term was employed in different ways by different thinkers. Yet, there is a kind of interplay in concepts associated with the term that makes a single study worthwhile.

Scholars sometimes speak of a change from *mythos* to *logos*; roughly, a transition in expression from storytelling in myths, usually expressed in poetry, to scientific, philosophical, or historical accounts, usually expressed in prose. Philosophers of the sixth century BCE were among the first Western writers to compose treatises in prose. The new medium of expression permitted a more analytic and detached view of things, and it embodied a revolution in thinking about the world. Although *logos* (plural: *logoi*) could signify a story, increasingly *logoi* were taken to be scientific accounts in contrast to *mythoi* "stories" and *epea* "verses" (see Plato *Timaeus* 26e). But for the sophists, a *mythos* can be used to express a *logos* (Plato *Protagoras* 320c)—but only insofar as *logos* is seen as a more basic kind of explanation.

### THE PRESOCRATICS

*Logos* soon came to signify something of the content of rational discourse as well as the medium, and it is this sense, or set of senses, that this entry will focus on. Hera-

clitus (c. 500 BCE) was the first philosopher to raise *logos* to the level of a principle. He opens his book by saying, “Of this *Logos*’s being forever do men prove to be uncomprehending, both before they hear and once they have heard it. For although all things happen according to this *Logos* they are like the unexperienced experiencing words and deeds such as I explain when I distinguish each thing according to its nature and show how it is” (fr. 1). Heraclitus’s *logos* can be shared with people, and indeed he explicates it in his own treatise; but he anticipates that most people will fail to understand the message. “Although this *Logos* is common,” Heraclitus writes, “the many live as if they had a private understanding” (fr. 2). Somehow the *logos* is publicly available but ignored by the many, who lack philosophical insight. The *logos* has a particular message, or implication: “Listening not to me but to the *Logos* it is wise to agree that all things are one” (fr. 50). Heraclitus regards the *logos* as transcending his own personal communication, and teaching the unity of things.

Heraclitus’s *logos* is a kind of structural principle as well as a message, a reciprocal law of exchange. It has a kind of syntax like language that orders the changes of the world. Heraclitus plays with statements that are syntactically ambiguous, as if to show that the same words can make different statements, which at another level complement each other. So the world is based on a single structure that manifests itself in contraries. Language provides a model for the world.

In the early fifth century BCE, Parmenides presented an argument against change, in the form of a revelation from a goddess. Yet the goddess tells the narrator, “Judge by *logos* the contentious refutation spoken by me” (fr. 7). Here *logos* seems to mean something like *reasoning*, which clearly becomes the key to philosophical truth. For, despite the religious imagery and associations of his poem, Parmenides’s message is above all an argument addressed to the reason.

In the latter half of the fifth century BCE the sophists traveled about Greece teaching practical skills to help young men succeed in politics and, above all, the art of public speaking. They saw a knowledge of *logos*—and especially, for them, the spoken word—as the key to controlling emotions and hence the reactions of audiences to a message. As Gorgias observed, “*Logos* is a great potentate, who by means of the tiniest and most invisible body is able to achieve the most godlike results” (fr. 11, section 8). Sophists composed contradictory arguments (*antilogikoi logoi*) on a single topic to teach skill in argumentation, and sometimes studied elements of language and argumentation.

## PLATO AND ARISTOTLE

By the fourth century BCE *logos* is established not only as speech and the like, but as the faculty of reason. Speech becomes the manifestation of reason, and reason the source of speech. According to Plato an understanding of rhetoric presupposes a knowledge of souls—what would later be called psychology—and the use of dialectic to implant truth in souls (*Phaedrus*). In fact, thinking (*dianoia*) is just internal speech (*Sophist* 263e, *Theaetetus* 189e). Thus speech becomes a model for thought, and ultimately a representation for the world; for a sentence (*logos*), such as “Theaetetus is sitting,” is true just in case it correctly describes an action or condition of Theaetetus (*Sophist* 263a–b). In another context, Plato suggests that one can more safely study the world in *logoi* than by means of sensations, and he consequently adopts a method of hypothesis (*Phaedo* 99d–100a).

The sign that one has knowledge is one’s ability to give an account (*logos*) or explanation (*Phaedo* 76b), and one who can give an adequate account is a dialectician (*Republic* 534b). At one point Plato considers as a definition of *knowledge* “true judgment accompanied by an account [*logos*],” but rejects this in part because a satisfactory explanation of *logos* cannot be given independently of knowledge (*Theaetetus* 201c ff.). While the ability to give a rational account provides evidence of knowledge, the account is no mere component of knowledge.

Aristotle accepts Plato’s view of the relation between language and the world along with some of Plato’s terminology (*Categories* 2–4; *On Interpretation* 1–7). He recognizes, if somewhat obscurely, the two relationships that allow language to connect to reality: reference (*semainein*) and predication (*katêgoria*)—the latter primarily a link between a substance and its attributes, but mirrored in the link between grammatical subject and predicate. The basic unit of communication is the sentence (*logos*), which when it makes an assertion (*apophantikos*) is the bearer of truth or falsity. Whereas reference connects words with things, (grammatical) predication asserts that the things are connected in a certain way; if the assertion corresponds to the way things are, it is true; otherwise it is false. Building on this basic theory of language, Aristotle developed the first system of logic, showing how certain propositions follow logically from certain other propositions (*Prior Analytics*). Moreover, he conceived of a science as a set of propositions arranged in a logical order with axioms and definitions as starting points, and theorems as conclusions (*Posterior Analytics* I)—laying out this ideal structure that would be realized by the axiomatization of geometry a generation

or two after his death. Thus in a certain sense Aristotle saw the world as possessing a thoroughgoing logical structure that could be captured in language. Indeed, whereas contemporary logicians often think of logical systems as arbitrary human constructs, some of which are useful for capturing certain linguistic relationships, Aristotle thinks of his logic as having its basis in the nature of things (*Prior Analytics* I 27).

## HELLENISTIC PHILOSOPHY

According to the Stoics, the world is ultimately composed of fire, which is identical with God. Fire pervades the world and functions as a world-soul. Reason (*logos*) is found in the world-soul, which orders and controls the world; it is the active principle and is identical with God (Diogenes Laertius 7.134). Soul is found in all animals, and in humans there is also a ruling principle that possesses reason. Thus *logos* in the human mind is like *logos* in the cosmos. Through the activity of fire, reason controls the creation and the history of the world. The world periodically perishes in a conflagration that turns all the elements back into fire, from which a new world arises, seeded by seminal *logos*, a structural principle that directs the cosmogony (Diogenes Laertius 136). The events of the world are ultimately under the control of reason, so that the world is governed by providence (Diogenes Laertius 138–9). The Stoics distinguish between uttered discourse (*prophorikos logos*) and internal discourse (*endiathetos logos*); the former humans have in common with parrots, but the latter is peculiar to humans (Sextus Empiricus *Against the Professors* 8.275).

Philo of Alexandria (early to mid-first century CE), combining Judaism and Platonism by using Plato's theory to explicate the Bible, recognizes *logos* as an image of the invisible God, and human beings as created in the image of the *logos* (*On Dreams* 239, *The Confusion of Tongues* 147). God also acts by his word, for "His word is his deed" (*The Sacrifices of Able and Cain* 65). The world is itself the product of a plan in the mind of God, consisting of the Platonic Forms (*On the Creation* 17–19), which are thus conceived of as present in the mind of God. From this model of the world the creator makes first an invisible world, then a visible one (29–36).

## CHRISTIANITY AND NEOPLATONISM

The Gospel according to John begins by affirming the central role of the *Logos*, or Word: "In the beginning was the Word, and the Word was with God, and the Word was God. ... All things were made by him; and without him was not any thing made that was made. ... And the Word

was made flesh, and dwelt among us" (John 1.1, 3, 14). It may be that the *Logos* of John derives from Jewish rather than Greek conceptions, yet the notion was close enough to Greek philosophical conceptions to allow early Christian thinkers to see in it a point of contact between their scriptures and pagan philosophy. They saw Philo as an inspired writer who shared their vision of the Word of God as an intermediary between God and humans. Jesus of Nazareth was the Word of God, who manifested the power of God on earth and prepared the way for his disciples to become sons of God (1.12).

In the mid-second century Justin Martyr identifies Jesus as the *Logos* that wise men, including philosophers, partake of. He finds references to the *Logos* in Plato's *Timaeus*, and more general instances of divine reason in Heraclitus and the Stoics (*First Apology* 5, 40; *Second Apology* 8, 10, 13). He explains that Christians "call Him [Jesus] the Word, because He carries tidings from the Father to men: but maintain that this power is indivisible and inseparable from the Father" (*Dialogue with Trypho* 128). In the most systematic statement of the early church fathers, Origen (third century), commenting on the opening lines of Hebrews, says that Jesus as Word is the invisible image of the invisible God—apparently apprehensible only by reason—who "interpret[s] the secrets of wisdom, and the mysteries of knowledge, making them known to the rational creation" (*On Principles* 1.2.6–7).

Plotinus borrowed from the Stoics at least the general conception of *logos* in a seed to account for the influence Soul has on the visible world. The world "was ordered according to a rational principle [*kata logon*] of soul potentially having throughout itself power to impose order according to rational principles [*kata logous*], just as the principles in seeds shape and form living creatures like little worlds" (*Enneads* 4.3.10). This also helps one understand how Mind orders things by comparing its operation to that of a seed with a rational principle; in such a way reason (*logos*) flows out from Mind to the world (3.2.2). And one can understand how timeless realities have foresight over the world of change by supposing that events unfold according to an archetype, which is effortlessly realized by the imposition on matter of rational principles (4.4.12). Indeed, Plotinus proclaims in a theodicy, "The origin [of events in the world] is *logos* and all things are *logos*," even if they seem to be irrational or evil to our limited view (3.2.15).

In the early fifth century Augustine argued that a word in the heart precedes the articulate word of speech. This inner word is a likeness of the Word of God, by whom God carried out the creation of the world, and

which came to be embodied in flesh in a way analogous to that in which the inner word becomes articulated in language. Thus the preverbal cognition that humans have in themselves an image of the Word of God (*On the Trinity* 15.11.20).

Although in Greek philosophy many different versions of how language, reason, and rational principles connect with the world can be found, what is remarkable is the widespread commitment to some view whereby reason is imbedded in the cosmos. Human reason does not simply impose some extraneous order on the world, but it discovers in nature a structure that mind has in common with the world.

## LOISY, ALFRED

(1857–1940)

Alfred Loisy, the French biblical exegetist, was the best-known and most controversial representative of the Modernist movement in France at the end of the nineteenth and beginning of the twentieth centuries. His scholarly investigation led him to the kind of destructive criticism

of the Gospel narratives and Christian dogmas carried on earlier by such scholars as D. F. Strauss and Ernest Renan, whose lectures at the Institut Catholique Loisy attended from 1882 to 1885. Loisy’s long career, from his entry into the priesthood in 1879 to shortly before his death, was one of much controversy and progressive estrangement from personal religion.

Loisy was born at Ambrière, Marne, and died at Cefonds, Haute Marne. He became professor of Hebrew in 1881, and of Holy Scripture in 1889, at the Institut Catholique. Loisy’s views on the date of the book of Proverbs soon aroused misgivings, and he was warned that continuation of such unorthodoxy would place him in danger of official censure.

Loisy’s superior, Monsignor d’Hulst, was an enlightened man and not intolerant of the work of the modern critical school, but as head of the Institut Catholique he was in a responsible and difficult position. The head of the College of St. Sulpice had forbidden his students to attend the heterodox Loisy’s lectures, and when in 1892 Loisy started his own periodical, *L’enseignement biblique*, for the instruction of young priests, d’Hulst felt obliged to urge caution. In 1892, soon after Renan’s death, d’Hulst himself wrote an article on Renan in *Le correspondant*. Without condoning Renan’s break with Catholicism, d’Hulst upheld his complaint, in *Souvenirs d’enfance et de jeunesse*, that the instruction given at such seminaries as St. Sulpice was out of touch with modern scholarship and the modern world. A further article by d’Hulst, aimed at promoting tolerance of the more searching kind of biblical criticism, gave offense in orthodox quarters, and d’Hulst felt obliged to clear his institute of any suspicion of unorthodoxy. Therefore, when Loisy continued to declare his critical independence of dogma and revelation, and to present a historical Jesus apart from the Christ of faith, he was forced to resign his chair in 1893.

As a reply to modernist exegesis, the pope issued the encyclical *Providentissimus Deus* (November 18, 1893), denying that error is compatible with divine authorship. Loisy wrote to Leo XIII, professing submission to the encyclical’s demand that the truth of the Bible should not be questioned. His insincerity can be inferred, however, for his activities remained unchanged. In fact, on receiving a reply in a mollified tone that invited him to devote himself to less contentious studies, Loisy openly expressed his impatience.

Loisy criticized the Protestant scholar Carl Gustav Adolf von Harnack’s *Wesen des Christentums* (Leipzig, 1900) in his *L’évangile et l’église* (Paris, 1902), which was condemned by the archbishop of Paris as undermining

faith in the authority of Scripture and the divinity of Jesus Christ. Loisy wrote an apology, *Autour d'un petit livre* (Paris, 1903), which, with four other works of his, was condemned by the Holy Office and placed on the Index in 1903. The papal secretary of state required the archbishop of Paris to demand that Loisy withdraw the five offending volumes, but Loisy refused.

He wrote in conciliatory terms to Pope Plus X, but the development of his religious ideas—or, in Catholic eyes, the disintegration of his faith—could ultimately lead only to his exclusion from the Roman communion. He regarded such mysteries as the incarnation of God as mere metaphors and symbols, and described his own religious belief as pantheistic, positivistic, or humanitarian rather than Christian. He conceived the basic problem facing the man torn between belief and doubt to be whether the world contains or embodies any spiritual principle apart from man's own consciousness.

In 1907 the papal secretary of state called upon Loisy to repudiate certain propositions, attributed to him and condemned in the decree *Lamentabili* (July 2, 1907), and to disown Modernism, condemned in Plus X's encyclical *Pascendi Dominici Gregis* (September 6, 1907). Loisy replied that where his views were not misrepresented in the decree, he felt obliged to stand by them, since he regarded them as true. The demands were repeated, and Loisy was required to submit within ten days. He still refused and was thereupon excommunicated.

Loisy's break with the church in 1908 put an end to what had become a false and increasingly impossible position. In 1909 he was appointed professor of the history of religion at the Collège de France, a chair that he held until 1927 and that allowed him to continue publishing in freedom. He published memoirs of his most controversial years in *Choses passées* (Paris, 1913).

His *Naissance du christianisme* (Paris, 1933) drew together and presented more intransigently views that he had held and expressed earlier, but his disbelief in the truth of the Gospel narratives and the Acts of the Apostles was now more pronounced. The supernatural elements were discredited, and the view of the historical Jesus was not very different from those of Strauss and Renan. A prophet appeared in Galilee and was crucified while Pontius Pilate governed Judaea. The rest—the alleged events of Jesus' life and his subsequent deification by his followers—belonged, for Loisy as for Renan, to the realm of myth and Messianic aspiration in search of its symbolic figure.

## LONGINUS (PSEUDO)

From its first publication in 1554 until the early nineteenth century, the fragmentary text *Peri hupsous* was all but unquestioningly attributed to Cassius Longinus, a Greek of the third century CE. Prevalent scholarly opinion now places the origin of the text in the first half of the first century; but, nothing beyond the text itself being known of its actual author, and nothing of comparable interest being known to have been written by the historical Longinus, the use of the latter name for the author of the text has stuck.

Problems of interpretation of the text begin with its title. Although the word *hupsēlos* is commonly translated as “sublime,” Longinus, in contrast with modern writers, uses it neither as a quasi-technical term nor as the expression of an aesthetic concept coordinate with “the beautiful” but as an ordinary term of praise (even if special praise) for compositions of words. A case has even been made for taking the term, as he uses it, to signify nothing

more specific than greatness or excellence in discourse (Grube 1957).

However, there are also grounds for supposing that Longinus has in mind a specific literary virtue. The sublime, he says, is the echo of a great mind; its effect is to transport us; it fills us with joy and pride as if we ourselves had produced what we hear. Some of these passages may give the modern reader a faint tingle of Kant, but Longinus, however often he compares sublime writing to thunderbolts, volcanoes, and the like, never applies the word *hupsēlos* to natural phenomena—only to verbal productions. Even where he compares writing to painting and to music, he never attributes sublimity to products of those media, but only to works of words. In short, the Longinian *hupsos*, unlike the modern “sublime,” is a quality of discourses only.

At the same time, Longinus holds that the power to produce sublime discourse is more a product of nature than of art (*technē*), the latter being understood as a teachable, specialized form of know-how. For Longinus, whatever contribution is made by the calculated use of figures, diction, and word arrangement—devices whose exposition in fact takes up the major part of *Peri hupsous*—the chief source of sublimity is the inborn power to form great conceptions. (Longinus’s term for this power, *megalophuia*, usually translated “genius,” literally means “great-naturedness.”) Sublime discourse thus turns out to be discourse in which the natural greatness of the mind of the writer or speaker is seemingly imparted to the reader or hearer.

*Peri hupsous* enjoyed a great vogue following the publication of Nicholas Boileau’s French translation in 1674, then passed out of fashion over the next century as the application of the term *sublime* shifted from discourse to nature, and the underlying conception from rhetoric to psychology. One can argue, however, that by explaining sublimity of discourse in terms of the nature of the author and the mind of the audience, Longinus himself provided the basis for that shift.

## LOPATIN, LEO MIKHAILOVICH

See *Lopatin, Lev Mikhailovich*

## LOPATIN, LEV MIKHAILOVICH

(1855–1920)

Lev Mikhailovich Lopatin, the Russian philosopher and psychologist, was one of a number of Russian thinkers—such as A. A. Kozlov—to advance a pluralistic idealism or personalism inspired by the monadology of Gottfried Wilhelm Leibniz. Lopatin was for many years professor of philosophy at Moscow University, president of the Moscow Psychological Society, and editor of the leading Russian journal, *Voprosy Filosofii i Psikhologii* (Problems of Philosophy and Psychology). He wrote extensively and is famous for the clarity and beauty of his style. His thought owed much not only to Leibniz (and to Rudolf Hermann Lotze) but also to his longtime friend, the Russian philosopher Vladimir Solov’ev.

Lopatin held that every activity or process presupposes an agent. In his metaphysics there is a plurality of agents, which are spiritual entities (monads), supratemporal, and thus indestructible (since destruction involves cessation of existence in time). He held that God is related to this plurality as its unifying ground, but he did not develop fully the character of this relationship. Lopatin’s chief contributions to the general doctrine of monads are his view of the substantiality of the individual spirit and his doctrine of “creative causality.” According to the former, the individual spirit is neither a substance that is

separate from its phenomena nor a pure succession of absolute states; each of these conceptions is fundamentally self-contradictory. Rather, the spirit is a substance that is immanent in its phenomena; its phenomena are the direct realization of its nature. Each individual spirit, moreover, is a “creative” or productive cause; temporal, mechanical causality, and necessity, as well as all material properties—such as extension—are derivatives of the primary causality of supratemporal spirit.

Lopatin was the first of the Russian Leibnizians to give thorough attention to the moral sphere. The doctrine of creative causality gave him a basis for asserting the freedom of the will and for developing an ethical personalism in which moral phenomena represent the highest manifestation of the creative activity of individual spirit. Thus moral phenomena have metaphysical significance, and despite the evil and the inefficacy of good that we observe in the world, reality contains a moral order and is not “indifferent to the realization of the moral ideal.”

Just as in ethics Lopatin maintained that unaided experience is not an adequate guide, so in epistemology generally, he discounted pure empiricism in favor of “speculative” principles, defining speculative philosophy as “the knowledge of real things in their principles and in their ultimate signification.” Man’s immediate inner experience is the source of his knowledge of real things, but philosophy works on this experience and goes beyond it through rational speculation.

## LOSEV, ALEKSEI FĚDOROVICH

(1893–1988)

Aleksei Fēdorovich Losev was a Russian philosopher and classicist and the author of numerous works on ancient and early modern aesthetics, language, symbolism, myth, and music aesthetics. A native of Novocherkassk, he graduated from Moscow University in 1917 with degrees in philosophy and classical philology and later taught at the University of Nizhnii Novgorod and Moscow Conservatory. Before they ceased to exist in 1922 he attended the meetings of the Vladimir Sergeevich Solov’ev (Solovyov) Religious-Philosophical Society and Nikolai Aleksandrovich Berdyaev’s Free Academy of Spiritual Culture, where he met the leading figures of the so-called religious-philosophical renaissance.

During the 1920s Losev forged his own version of Christian neoplatonism for which he drew on ancient Platonists, Greek church fathers, German idealism (especially Friedrich Wilhelm Joseph von Schelling and Georg Wilhelm Friedrich Hegel), Russian religious-philosophical thought, and Edmund Husserl. The later, largely forced, assimilation of Marxism was neither purely cosmetic nor did it cause any fundamental shift in his outlook. Losev accepted the valuable aspects of Marxism but eschewed its limitations. In 1929 he secretly took monastic vows. Between 1927 and 1930 he published eight volumes on ancient philosophy, philosophy of language, mathematics, music aesthetics, and philosophy of myth. The last book in this series, *Dialektika mifa* (The dialectics of myth; 1930), became the cause of Losev’s arrest and sentence of ten years in labor camps. He was freed, almost totally blind, in 1933 and for the next twenty years he was not allowed to publish his own work or teach philosophy. After teaching part time at provincial universities he became a professor at Moscow University in 1942 and was even awarded a doctorate in classical philology. The appointment was soon withdrawn, however, on charges of idealism and Losev was transferred to Moscow State Pedagogical Institute, where he remained until retirement. He resumed publishing in 1953 and eventually established himself, against considerable official resistance, as one of the most respected authors on ancient philosophy and culture in the Soviet Union. By the end of his life Losev’s oeuvre included more than 30 monographs and 400 scholarly publications. Posthumous editions have increased this number almost twofold. The crowning achievement of his life’s labor was an eight-volume study on ancient aesthetics—an original interpreta-

tion of antiquity without precedent, in scope and size, in world classical scholarship.

Losev's output over his lifetime is marked by a remarkable continuity. The themes of antiquity, language, symbol, myth, mathematics, and music remained constant from his earliest to his last publications. His vast oeuvre, however, still requires much study and any judgment of it must remain provisional at this stage.

## METHOD

Losev elaborated his phenomenological-dialectical method in the 1920s and later only supplemented it by new influences, among which Marxism and structuralism were perhaps most notable. In Marxism Losev found support for his conviction about a meaningful link between socioeconomic and intellectual processes but, in contrast to Marxism, he did not reduce the latter to the former. He considered the eidos of classical phenomenology, which he described as "the integral semantic face (*smyslovoi lik*) of a thing" (1927a, p. 53), too static and supplemented it by establishing dynamic dialectical relations among its constituent parts. Like Hegel, Losev understood dialectics as the rhythm of both thinking and objective reality, but his own version of dialectics was derived largely from ancient and Christian neoplatonist sources.

Losev had a penchant for developing multilayered analytic structures of the phenomena that he studied. Often, the key element in these conceptual constructions is what he calls the dialectical tetraktis: the development of meaning via the four steps of unity, multiplicity, the ideal synthesis of the two, and, finally, the fact in which this synthesis is realized.

Throughout his life Losev argued strenuously against the dogmatic one-sidedness of both materialism and idealism and strove to position himself above these abstract divisions.

## LANGUAGE

Central to Losev's entire outlook was the philosophy of language articulated in *Filosofia imeni* (Philosophy of the name; 1927b). Losev's view was informed by onomatodoxy (*imiaslavie*), a trend in Orthodox theology centered on the veneration of God's name. He understood language in terms of ontological symbolism, that is, as access to the reality of being. "The name," he argued, "is life. ... The mystery of the word consists precisely in that it is the tool of our intimate and conscious encounter with the inner life of things. ... The world is created and is held together by the name and the word" (1993, pp. 617, 642,

746). The name, according to Losev, embraces being in its entirety, from the meonic formlessness of pure matter, to the rational, eidetic formation of all natural and social phenomena, to the suprarational regions of thinking where it passes into "noetic ecstasy" (pp. 676–677). Losev's meticulous gradations of this phenomenological-neoplatonist terrain are held together by a dialectical hierarchy of various "moments" in the structure of words. Later in life Losev attentively studied structuralism with which the eidetic aspect of his analysis of language had much in common. He consistently objected, however, to all nondialectical treatments of language, be they positivist, neo-Kantian, or structuralist.

## SYMBOL

Losev's theory of the symbol was inspired by the thought of Pavel Aleksandrovich Florenskii and Viacheslav Ivanovich Ivanov, but it also absorbed other influences as it evolved from his early work, such as *Antichnyi kosmos i sovremennaia nauka*, to later writings, such as *Problema simvola i realisticheskoe iskusstvo* (The problem of symbol and realistic art, 1976). In the latter Losev analyses in detail the structure of symbol and argues that symbols are means of practical, creative "re-making of reality" (pp. 15–17). In Losev's view a symbol is the perfect fusion of inner meaning and its external expression. It is this balance that distinguishes it from allegory, where the image outweighs the abstract idea, or from a scheme, where the idea is rich but its representation arid.

## MYTH

Losev regards myth as a necessary category of consciousness and defines it as "unfolded magical name" (2003, pp. 186–187)—a formula that highlights myth's verbal (narrative) form, personalistic nature, and the presence of the miraculous in it. As a story about reality it is distinct from poetry and art in general; as a prereflexive story about a miraculous reality, myth is distinct from science and metaphysics. Myths form the foundations of people's outlooks, Losev argues, and thus determine cultural and historical processes on the most fundamental level. He views the history of culture as a constant struggle among various mythologies, and one of his tasks is to uncover the inner logic of this process. "Whatever one's view of myth, any critique of mythology is always merely a profession of another, new mythology" (1927b, p. 771). According to Losev no historical epoch is free of mythology and, despite its hostility toward myth, modernity is emphatically mythological. Modern cosmology advances, he impugns, a vision of the world as an infinite dark void,

ruled by a “blind, deaf, and dead” monster, that is, matter. Losev’s other targets among modern myths include titanic Prometheanism that he critiqued at length in *The Problem of Symbol and Realistic Art*. The key notion in Losev’s critique of modernity was what he called in *Estetika Vozrozhdeniia* (Renaissance aesthetics; 1978) “the absolutization of the human subject.”

The reconciliation of myth and philosophy is Losev’s goal in his essay “Absoluitnaia mifologiia = absoluitnaia dialektika” (Absolute mythology = absolute dialectics; 1929–1930, published in 2000). Taken by themselves, both myth and dialectics are limited and an adequate outlook can be based, Losev insists, only on their synthesis. Dialectics inevitably comes up against the ultimate limit of rational cognition, and in the suprarational realm beyond this boundary it should be fused with mythology (p. 275). In his early period Losev found the optimal candidates for such a synthesis in the mythology of Eastern (Orthodox) Christianity and Russian religious-philosophical thought.

Losev applied his theoretical ideas to numerous analyses of specific myths ranging from ancient Greco-Roman to modern mythology (*Ocherki antichnogo simvolizma i mifologii* [Essays on ancient symbolism and mythology; 1930]; *Mifologiia grekov i rimlian* [The mythology of the Greeks and Romans; 1930s, published in 1996]; and *The Problem of Symbol and Realistic Art*).

## ANTIQUITY

In *Istoriia antichnoi estetiki* (History of ancient aesthetics; 1963–1994) Losev’s point of departure is that all ancient philosophizing, from pre-Socratics to Proclus, is based “on the intuitions of a thing, rather than of personhood” (*Istoriia antichnoi filosofii v konspektivnom izlozhenii* [History of ancient philosophy: a conspectus], p. 155). He emphasizes the link between the “material-thingly” (*material’no-veshchestvennaia*) basis of thinking and ancient slave-owner economy but rather than a particular economic order the ultimate intuitive ground of ancient philosophy was “the sensible, material cosmos” (p. 15). From this impersonal absolute stems ancient fatalism that gradually evolves, via Stoics and other schools, toward providentialism. Ancient philosophy ends, Losev claims, when this original, astronomical intuition is replaced by the personalistic and historical vision of reality in Christianity. Losev argues for a dialectical view of this process, in which ancient philosophy grows out of specific mythological intuitions in the late archaic and early classical period, and in the end returns to embrace and justify this original mythology on rational grounds—

only to yield to a new mythology and a philosophy that evolves on its basis.

## MUSIC

Losev’s philosophy of music combines Pythagoreanism and Romanticism, both refracted through his dialectical phenomenology. Eventually, he also explored Marxist themes, such as music and ideology—especially in his philosophical prose of the early 1930s (published posthumously). The culmination of Losev’s early philosophy of music was *Muzyka kak predmet logiki* (Music as the subject of logic; 1927), where music is defined as the expression of “the life of numbers.” In its depth this life is a total “coincidence of opposites” and “extreme formlessness” that defies all categories of the understanding (1990, p. 209). At the same time a musical work possesses an “eidetic completeness” (p. 269). Fused with the chaos of “pure musical being,” this mathematically determined fullness of form makes music “the eidos of the alogical” (p. 279). Losev further evokes Plotinus to define time as “the alogical becoming of the number” (p. 328) and links this idea with the temporal nature of music. The closing passages of the book are devoted to deriving from these insights such elements of musical form as melody, rhythm, harmony, and even timbre. Losev both used and further elaborated his philosophy of music in a number of essays, written in the course of his lifetime, on specific composers, such as Nikolai Rimsky-Korsakov (1844–1908), Aleksandr Scriabin (1872–1915), and Richard Wagner (1813–1888).

Losev is one the key philosophers—perhaps *the* key philosopher—who preserved the continuity of Russian religious-philosophical tradition in Russia against a concerted effort by the Soviet regime to destroy it. In the post-Soviet period Losev emerged as one of the central figures of twentieth-century Russian thought—a position confirmed by numerous editions of his works and his broad influence on the current philosophical discourse. The significance of his work, however, reaches far beyond the Russian context. While the strikingly broad reach of his thought makes the recognition of his contribution difficult, it also comprises highly valuable insights into the nature of thinking, history, personhood, and expression.

## LOSSKII, NIKOLAI ONUFRIEVICH (1870–1965)

Nikolai Losskii (Lossky), a Russian religious philosopher, was born in the province of Vitebsk in western Russia. He studied history, philology, and natural sciences at St. Petersburg University (1891–1898), as well as philosophy under the neo-Kantian Aleksandr Vvedenskii (1856–1925). Losskii continued his philosophical education in Germany (1901–1903) with Wilhelm Windel-

band, Wilhelm Wundt, and Georg Müller. He received his master's degree in 1903, and his doctorate in philosophy four years later. From 1900 Losskii taught at St. Petersburg University, where he was appointed to a chair of philosophy in 1916. In 1921 Losskii was dismissed from the university for his religious beliefs, and in 1922 he was exiled by the Soviet government from the homeland. From 1922 to 1945 he settled in Czechoslovakia, where he taught in universities in Prague, Brno, and Bratislava. From 1946 Losskii lived in the United States and taught at St. Vladimir's Orthodox Theological Seminary in New York (1947–1950).

Losskii was a systematic philosopher and prolific writer whose works have been translated into many foreign languages. His writings cover most of the traditional philosophical disciplines, though he gave special emphasis to epistemology, metaphysics, and ethics. His philosophy is variously labeled as intuitivism, hierarchical personalism, or ideal-realism, depending on what part of his comprehensive system the commentator focuses on. The central idea of Losskii's philosophy is, in his own words, the insight that "everything is immanent in everything" (Zenkovsky 1953, p. 668). In his religious views Losskii adhered to Christian doctrine, though some of his views, such as his teachings about reincarnation and creation, seem incompatible with the Orthodox tradition.

In his epistemology, Losskii rejected the possibility of transcendent knowledge and affirmed that in the process of cognition, subject and object must be connected. In acts of knowing, the object of knowledge is not a representation of an entity but the actual entity itself. The subject or self becomes cognizant of the world of nonself by a special act that Losskii called "epistemological coordination." Although the object of knowledge is part of the process of knowing, the content of knowledge contains more than its own object; rather, it is the result of the subject's efforts at comparing and distinguishing. Hence, the truth that one can achieve in the cognitive process is never complete, because the process of differentiating, however strong it may be, always leaves unexplored some part of reality.

In Losskii's theory of knowledge, named "intuitivism," intuition is not merely one aspect of cognition, but permeates all cognitive processes. Though all knowledge is intuitive by nature, knowledge can be differentiated by the type of intuition. Losskii distinguished three types of intuition: sensuous, intellectual, and mystical, corresponding respectively to the real, ideal, and meta-logical levels of existence.

In his ontology, Losskii defended an “organic,” or holistic, worldview. In his view, any object constitutes a system by virtue of a principle that lies beyond that system. As a systemic unity, the world requires a principle that stands beyond it and represents its foundation. This principle is called “the Absolute” in philosophy and “God” in religion. No positive definition grasps the Absolute as such, but philosophers can study its manifestations in the created world.

In the created realm, Losskii distinguished three levels of reality: the real, the abstract, and the concretely ideal, the last of which consists of living agents, whom he sometimes referred to as concrete ideal entities, substances, or, more precisely, substantival agents. As compared with the abstract ideal, which includes, for instance, abstract relations, ideal entities are active agents who independently determine their own manifestations in time. The human self is one such substantival agent. As an entity that transcends space and time, it is responsible for creating psychic processes in time and realizing material events in a spatiotemporal framework.

In Losskii’s view, God’s creation stops with substantival agents, who are free to choose their own evolution. The original sin of self-centeredness, symbolically described in the Biblical story of the fall of Adam and Eve, does not signify that humanity once attained perfection and then freely lost it. The life of the spirit has to result from efforts exercised by the creature itself; otherwise the creature’s freedom is falsified. Those substantival agents who choose selfishness and prefer their own interests to God’s will must continue their evolution on the lower levels of reality and are subjected to a long and difficult process of redemption.

Since the universe is an integral holistic system, an organism, all substantival agents are interconnected with each other. Their consubstantiality is crowned with and headed by the cosmic substance, which Losskii, following the Solov’evian tradition, called “Sophia.” Though not identified with the Absolute, this supreme substance, like all other creatures belonging to the created realm, is perfect and unites the multiplicity of creation into one cosmic whole. The kingdom of God, led by Sophia, represents the ontological basis of absolute values and the ultimate goal for every substantival agent. The existence of the spiritual kingdom makes it possible for fallen beings to restore their original divine identities and to partake of the heavenly life. In the kingdom of God, everyone is in harmony with all, and everyone is all. In the life of the kingdom of God, headed by Sophia, every member experiences constant growth in all possible

dimensions that ideally complement and enrich one another.

Though Losskii wrote comparatively little on political philosophy, in his few articles on the subject he consistently stood for democratic values. According to him, in the course of an increasingly complex social life, the state is unified more securely by the dispersion of power and by constitutional limits on the absolute power of the monarch. The ultimate choice between monarchy and republic depends on which can best balance the united will of the nation with the rights and development of its members.

LOTMAN, IURII  
MIKAILOVICH  
(1922–1993)

Iurii Mikailovich Lotman was a specialist in the theory of literature and aesthetics, the history of Russian literature, semiotics, and study of culture. He was born in Petrograd (now St. Petersburg). In 1939 he commenced his studies in the philology department of Leningrad University. In the fall of 1940 he joined the army and fought in World War II from 1941 to 1945. In 1946 he continued his studies at the university, finishing them in 1950. Because of the anti-Semitic campaign in the Soviet Union, Lotman was not able to work in Leningrad and moved to Estonia. From 1950 to 1954 he taught at the Tartu Pedagogical Institute. In 1952 he defended his dissertation in philology on the ideas of A. N. Radishchev and N. M. Karamzin. In 1954 he was named docent of Tartu University, and from 1960 to 1977 he was the head of the Department of Russian Literature there. In 1961 he received a doctorate in philology by defending the dissertation titled *Puti razvitiia russkoi literatury preddekabrist-skogo perioda* (Paths of the development of Russian literature in the pre-Decemberist period).

FROM THE HISTORY OF LITERATURE  
TO SEMIOTICS

Lotman's chief historical works are devoted to the history of Russian literature from the eighteenth century to the mid-nineteenth century. He examines this literature in conjunction with other cultural phenomena, particularly philosophical thought, history, and sociopolitical life. From the beginning of the 1960s Lotman develops a structural-semiotic approach to the study of works of art, organized the publication of the series *Trudy po znakovym sistemam, Semiotika* (*Sign Systems Studies*,

*Semiotics*), and directed regularly held "summer schools," conferences, and seminars on the semiotic study of various domains of culture. The combination of these activities, which included the participation not only of Tartu scholars but also of scholars from Moscow and other cities, became the internationally known Tartu-Moscow School of Semiotics (Grzybek 1989). The first issue of *Sign Systems Studies* included his *Lektsii po struktural'noi poetike* (Lectures on structural poetics) (Lotman 1964).

The works of Lotman and those of his colleagues and followers on the semiotic analysis of various cultural texts, including artistic texts in particular, are united by the idea of "secondary modeling systems," where the text is interpreted as a unity of models of objective and subjective reality, as well as in the capacity of a sign system secondary in relation to the signs of natural languages, which represent the "primary modeling system." Headed by Lotman, the "Tartu school" of semiotics continues the traditions of the Russian "formal school," especially Iurii Tynianov, and structural linguistics (Ferdinand de Saussure and Roman Jakobson), taking into account the efforts to develop semiotic structuralism in various countries. However, the Tartu school does not limit itself to the study of the formal structure of works of art; it focuses primarily on the semantics of sign structures (Lotman 1970, Shukman 1977). Together with his semiotic studies, Lotman also continues his historico-literary investigations, in which he employs a structural-semiotic methodology. The novelty of his work is that he attempts to combine structuralism with historicism, the premise being that a semiotician must also be a historian. Lotman's work in the history of literature is characteristically theory-laden.

FROM SEMIOTICS TO THE STUDY OF  
CULTURE

At the beginning of the 1970s Lotman arrived at the view that the semiotic object must be adequately understood not simply as a separate sign but as a text existing in culture—as a text constituting "a complex device storing multiple and diverse codes, capable of transforming received messages and of generating new ones, like an information generator possessing traits of intellectual personality" (Lotman 1981, p. 132). Taking this as his point of departure, Lotman considers culture itself in its semiotic aspect, in the multiplicity of its communicative connections (Lotman 1970–1973). By analogy with V. I. Vernadskii's concepts of "biosphere" and "noosphere," Lotman introduced the concept of "semiosphere," which is characterized by the limits of semiotic space, its struc-

tural heterogeneity and internal diversity, forming a structural hierarchy whose components are in a dialogic interrelationship (Lotman 1984). Lotman thus realized the transformation of the initial semiotics and overcomes its total schematism. But he did this not through post-structuralism and “deconstruction” (in the spirit of Jacques Derrida) but through a semiotic interpretation of cultural texts, taking into account their uniqueness, creative character, and intertextual dialogues. Not only is culture as a whole understood as a text, but any text is viewed as a product of culture.

Lotman’s theoretical views take into account the development of contemporary scientific knowledge, especially information theory, cybernetics, the theory of systems and structures, the theory of the functional asymmetry of the brain, and the ideas of synergetics (Lotman 1990, 1992). At the same time these views also rely on the abundant material of world culture, primarily Russian culture, which is considered in its typological significance. Lotman’s works on the history of Russian culture are of great value. Highly popular was his series of television broadcasts on Russian culture, aired posthumously in 1994 (Lotman 1994).

### PHILOSOPHICAL POSITION

Lotman did not explicitly declare his philosophical views. In the presemiotic period of his activity, philosophy interested him only as an object of historical study. But semiotic and culturological studies presupposed a theoretico-philosophical self-definition. Lotman had a broad knowledge of philosophy and closely studied the ideas of Gabriel de Mably, Jean-Jacques Rousseau, and Alexander Radischev (Lotman 1958, 1960). He also identified in a masterful way the philosophical content of the work of literary artists (Lotman 1987, 1988). His own philosophical-methodological ideas underwent a specific evolution (Kim Soo Hwan 2003). In the 1960s the adherents of the “Tartu school” held positivist views, maintaining that semiotics was in fact their philosophy (Stolovich 1994). But later Lotman began to search for a philosophy that would correspond to his semiotic culturology. He turned to Leibniz’s monadology, proposing that the semiosphere consists of a multiplicity of “semiotic monads” as intellectual units—that is, bearers of Reason. In his own words, “man not only thinks but also finds himself within a thinking space, just as a bearer of speech is always immersed in a certain language space.” The existence of the external world is accepted, but it too is “an active participant in the semiotic exchange” (Lotman 1989, pp. 372, 375). God for Lotman is a universally significant phe-

nomenon of culture. Although his attitude toward religion was respectful, he himself was a theological agnostic (Egorov 1999, pp. 236–237).

Lotman keenly absorbed the ideas of various thinkers, including Leibniz, Rousseau, Kant, Hegel, and Freud. In 1967 and 1971 he published in the journal *Semiotics* certain works of the Russian religious philosopher and scientist Pavel Florenskii, who had been repressed by the Soviet authorities. Lotman also reacted positively to Bakhtin’s conception of dialogue (Egorov 1999, pp. 243–258). However, Lotman’s own philosophical views cannot be reduced to any one system, be it Platonism (Vetik 1994), Kantianism (M. Lotman 1995), Hegelianism, or Marxism. His philosophical views can be defined as a type of “systemic pluralism,” which presupposes the combination of heterogeneous ideological components in a specific system.

Living and being educated in the Soviet Union, Lotman could not fail to feel the influence of Marxism. He assimilated that aspect of Marxism that was related to Hegel’s dialectic, the principle of historicism, and the social factor in the development of culture. But the ideological content of Marxism was alien to Lotman (Gasparov 1996, pp. 415–426). His structural-historical studies provoked the suspicion and displeasure of official circles (at the beginning of the 1970s, he was even interrogated by the KGB and his belongings were searched). At the same time his popularity grew immensely and he was considered a scholar of the first rank and a brilliant personality in intellectual circles both in the Soviet Union and abroad. He was elected as a corresponding member of the British Academy, as an academician of the Norwegian, Swedish, and Estonian academies of science, and as vice president of the International Semiotics Association. The institute for Russian and Soviet culture in Germany was named after him: Lotman-Institut für russische und sowjetische Kultur, Ruhr-Universität Bochum.

## LOTZE, RUDOLF HERMANN (1817–1881)

Rudolf Hermann Lotze, the German idealist metaphysician, was born in Bautzen He studied medicine and philosophy at the University of Leipzig, taking his doctorates in both fields. He studied mathematics and physics with E. H. Weber, W. Volckmann, and G. T. Fechner and philosophy with C. H. Weisse, who influenced him greatly. In 1841 he became instructor in medicine at Leipzig, where he subsequently taught philosophy. While at Leipzig he published two short works, the *Metaphysik* (Leipzig, 1841) and *Logik* (Leipzig, 1843), which adumbrated the essentials of his later philosophy. In 1844 Lotze succeeded Johann Friedrich Herbart as professor of philosophy at the University of Göttingen. He remained there until 1881, when he was called to the University of Berlin. Shortly after joining the faculty at Berlin, he contracted pneumonia and died.

Lotze pursued his interests in the medical sciences, psychology, philosophy, the arts, and literature throughout his life. As a result of his medical training, he developed a strong love for exact investigation and precise knowledge, but art and literature made him particularly

sensitive to the central role of feeling and value in the total life of a culture. He wanted nothing to interfere with the growth of the exact sciences in all areas of human experience, yet he insisted that both intellect and scientific knowledge were essentially the means and tools of feeling, emotion, and intuition.

### NEW CONCEPTION OF METAPHYSICS

Like many thinkers born in the first two decades of the nineteenth century, Lotze faced three great schisms: the schism between science and Christianity, which was known at that time as the conflict between science and religion; the schism between reason and feeling; and the schism between knowledge and value. To Lotze, these schisms had to be rationally harmonized in some manner. It seemed impossible to him for any rational man to reject any one of the trinity that composes the total culture of man: science, art, and value. Each has its place in the life of man and the universe, and none can be eliminated without distorting and destroying that life. However, Lotze felt that their proper relationship cannot be established by the older metaphysical methods. There is no possibility of rationally deducing the basic categories and values of existence by any sort of logical dialectic, either Platonic or Hegelian. Knowledge of existence depends upon knowledge of fact acquired through observation and experimentation. Consequently, the empirical sciences are the proper investigators of existence. All that metaphysics can do is to analyze, clarify, and order those concepts and theories that the sciences create into as adequate a system as the facts permit. Metaphysics cannot go beyond this in any scientific sense. Nevertheless, Lotze admitted that metaphysics has another, broader purpose. The urge to be metaphysical is not to be found in metaphysics itself but in ethics, in the desire to know and attain some ultimate good. Thus, metaphysics involves speculating beyond what is scientifically warrantable in order to include that which drives men to write metaphysics: the experience of ultimate goodness.

Because metaphysics must be founded upon science, Lotze objected to any philosophical system that claimed completeness. All philosophical systems, like his own, must remain open and undogmatic. They must not even provide provisional answers to profound questions for which not even provisional answers exist. He thought it was far better for a philosopher to raise questions and to stimulate inquiry than to offer sterile answers lacking any reasonable foundation in fact.

### IDEALISTIC MONADISM, MECHANISM, AND GOD

Lotze was essentially an idealist, but his idealism was tempered by his respect for science and his emphasis upon feeling as the dominant element guaranteeing meaning to the life of man.

From the beginning, Lotze considered thought as one aspect of the soul. Thought is aware only of ideas about reality; it does not know reality, for knowledge and reality can never be identical. Neither are experience and thought to be identified. Identity with reality or object can be achieved as experience, never as thought, for thought is purely representative. Truth is attained in ways different from thought. Thought must fuse with the total feeling experience, since it is in feeling that we have direct awareness of good and evil, beauty and ugliness, worth and unworth, contradiction and harmony; these rest in the soul's original capacity to experience pain and pleasure. Consequently, Lotze thought that feeling is the ultimate arbiter of consistency and intellectual harmony, the ultimate judge of the worth of anything, and the ultimate creator of imagination and its works. Moreover, feeling is the *nisus* that drives man to seek whatever total unity of comprehension and action is possible for him. His love of knowledge, goodness, and beauty arises from, and finds its fulfillment in, feeling. Thus, the essential nature of feeling is love, which constantly drives man toward a greater overall comprehension, of his life and the cosmos. "If ... love did not lie at the foundation of the world ... this world ... would be left without truth and without law."

Feeling convinced Lotze that the world is psychical and thus consists of souls as well as a personal deity. A soul is not simply a stream of impressions united by memory; it is a substantial entity, causally related to the body and interacting with it. Nevertheless, the soul is the greater influence and governs the body in ways closed to it. Both soul and body act according to law, but the laws of bodies as such are purely physical. The laws of the soul are on a higher level; they are teleological and unite the physical and the mental. They do not contradict the laws of the physical world, but they do control and reorder them.

A personal deity, God, follows from the existence of souls and ends. How else can they be explained? The world and everything in it is the personal creation of God and the means by which he attains his ends and the ends of his creatures. However, Lotze tempered this conviction by insisting that God attains his ends through the mechanisms or causal nexuses that science discovers, and he

further insisted that these mechanisms are characteristic of both the living and the nonliving.

Lotze rejected the notion that telic and nontelic explanations are incompatible with each other. He opposed the older forms of vitalism popular in his day. He argued that mechanisms are simply the instruments, or tools, by which God accomplishes his ends in the world. Although it is true that God might have used other means, he preferred mechanism as a way of establishing universal law in both the physical and psychic realms.

Lotze argued further that the thesis of mechanism should not be identified with materialism. Mechanism does not imply the nonexistence of ends or of psychic beings; it implies only the existence of uniform modes by which things come into being. The world can just as easily be psychic as material, but the psychic interpretation is rationally to be preferred because it does not make a mystery or a paradox of the presence of feeling and values in the world.

In the *Mikrokosmos*, Lotze continued to elaborate this position. Mechanism is simply a method of research; it is not a fundamental explanation of life and mind. Only the most exhaustive survey of the life of man can provide such an explanation and relate his life to the cosmos and God. Furthermore, mechanism does not repudiate free will; it is simply the necessary condition for the will to express its autonomy.

For Lotze, there are three realms of observations: the realm of fact, the realm of universal law, and the realm of values, which serve as standards of meaning for the world. These realms are only logically separable; they cannot be separated in reality. Fact and law are the means, the mechanisms, by which values are attained in this world; they are also the means by which men discover that certain values are foolish, contradictory, unrealizable, or in other words, false. Since fact and universal law are not existentially separable from value, God must also be the creator of everything and the quintessence of whatever deserves to exist for its own sake. Moreover, since feeling is fundamental, a sort of pluralistic idealism in which the only realities are living spirits and God in interaction is justified. All other realities are so only secondarily, as manifestations of these spiritual activities.

Lotze ultimately accepted a variant of Leibnizian monadism as a correct interpretation of experience. There is no single unity or oneness to existence. Direct experience reveals an irreducible multiplicity of things. Reality is always in flux, always involving constant doing and suffering. Nevertheless, the flux, the doing, and the

suffering occur within a fixed order, a preestablished harmony between God and the multitude of spirits.

Lotze recognized that this metaphysical theory is neither a logical deduction from experience nor completely intelligible, but he believed it to be a reasonable inference from the manner in which the valid experiential concepts of our thought, the flux of facts, and the order of values interconnect in our experience. To limit ourselves to what science understands is to exclude unjustifiably the realms of feeling and values, and to exclude the latter is to render our experience unintelligible.

## PIETY

To Lotze, nature and the social life are the two fundamental sources for religious ideas. From nature we derive the concept of God; from our social life, the concepts of ethical living. Paganism has tended to emphasize the cosmological; Christianity, the ethical. Christianity has sought to fuse both into one complete theological scheme. In this it is mistaken. To Lotze, the ethical element in religion is far more significant than the cosmological (which can properly be left to science), even though the emphasis upon cosmology leads to recognition of God. The true mark of the religious man is not his cosmology but his feeling for, and search after, what ought to be, his passion for, and loyalty to, the highest possible ideals. This passion and loyalty, however, are not so much activist as contemplative.

Piety, for Lotze, is found in the inner life, in a feeling for the holy that attains so high a state of intuitive comprehension that logic, reason, becomes futile and inessential. Piety lies beyond any sectarian interest, Christian or not, for it drives men to seek a totality of feeling in which truth is completely fused with goodness and beauty. In consequence, the holy is not merely what men think it is; it is rather the unattained, the beyond in our lives that is without contradiction, defect, or dissonance. It is manifested in the endless striving for that immortal sea that is the infinite parent of all things. In this contemplative striving, in this endless search for total harmony and for the ought-to-be lies the possibility of progressively uniting science, religion, and art. However, the overwhelming realization of this unity occurs only at particular moments when one is moved by the experience of total beauty. In such moments, one knows absolutely that the fusion has, as far as possible, been accomplished.

## INFLUENCE

Lotze's influence in Germany, France, and England was considerable during his lifetime. Philosophers became

more empirical-minded, less dogmatic. More consideration was given to the feeling, experiential aspects of human life. Nevertheless, Lotze left few, if any, disciples, and no Lotzean school of philosophers arose.

In America, Lotze's influence during the 1870s and 1880s was felt both in church and philosophical circles. The Reverend Joseph Cook of Boston made him widely popular, hailing him as the seer who had made the microscope the instrument of immortality and science the humble servant of the Bible. Leading American philosophers such as B. P. Bowne, G. T. Ladd, and Josiah Royce were particularly influenced, for he offered them an experiential mode of reconciling their strong Christian commitments with the methods and conclusions of science.

### Bibliography

The principal writings of Lotze include *Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften* (Leipzig, 1842); *Medicinische Psychologie oder Physiologie der Seele* (Leipzig: Weidmann, 1852); *Mikrokosmos*, 3 vols. (Leipzig, 1856–1864), translated by E. Hamilton and E. E. C. Jones as *Microcosmos*, 2 vols. (Edinburgh, 1885–1886); and *Die Geschichte der Aesthetik in Deutschland* (Munich, 1868). Lotze planned a comprehensive account of his philosophy in three volumes titled *System der Philosophie*. The first part was *Logik* (Leipzig: Hirzel, 1874), and the second, *Metaphysik* (Leipzig: Hirzel, 1879). These were translated into English and edited by Bernard Bosanquet as *Lotze's System of Philosophy* (Oxford: Clarendon Press, 1884). The third volume, which was to have covered religion, art, and practical philosophy, was incomplete at the time of his death. See also *Kleine Schriften*, edited by D. Peipers, 3 vols. (Leipzig, 1885–1891).

For literature on Lotze, see Karl Robert Eduard von Hartmann, *Lotzes Philosophie* (Leipzig: Friedrich, 1888); Henry Jones, *A Critical Account of the Philosophy of Lotze* (Glasgow, 1895); J. W. Schmidt-Japing, *Lotzes Religionsphilosophie in ihrer Entwicklung ...* (Göttingen, 1925); E. E. Thomas, *Lotze's Theory of Reality* (London: Longmans, Green, 1921); and Max Wentscher, *H. Lotze. Lotzes Leben und Werke*, Vol. I (Heidelberg: Winter, 1913).

## LOVE

“Love” as a concept enters philosophy at one point through religion, particularly when the origin of the world is expressed as an act of procreation or the Creator is conceived of as loving his creation either as a whole or

in part (i.e., the human race). But the concept of love is also a subject for philosophic meditation in regard to ethical problems. Love, as one of the most powerful of human impulses, was early seen to be much in need of control, especially if man as rational animal was to be able to use his rational capacities. Much of the ethical writing on love is designed to suggest some means whereby the pleasures and other values of loving may be preserved without entailing the supposed evils of intemperate sexuality. This type of speculation ran from Plato through the Neoplatonists—those of both the early Christian period and the Italian Renaissance. In the Platonic tradition love had a unique metaphysical status, for it existed in both the material and the ideal worlds. Love can take on many forms, from gross sexual passion to a devotion to learning, but, it was argued, the ultimate object of love is the beautiful. The goodness that God sees in his creation is its beauty and to feel the beauty of the world is to love it and its Creator.

### CLASSICAL MYTHOLOGY

The word *eros* as it is found in Homer is not the name of a god but simply a common noun meaning “love” or “desire.” In Hesiod's *Theogony* Eros becomes one of the three primordial gods, the other two being Chaos and Earth. Although Eros has no offspring and seems to play no role in the genealogy of the gods, he has the greatest power over his fellow immortals. He unnerves the limbs and overcomes the reason of both gods and men. When Aphrodite is born from the sperm of Uranus (Heaven), Eros and Himeros (desire, longing, lust) accompany her into the council of the gods. Whether Hesiod was talking in terms of personalized abstractions or was actually thinking of anthropomorphic beings is not clear, for the *Theogony* is a curious mixture of both kinds of expression. For the history of philosophy, the importance of Hesiod's brief mention of Eros lies in the attribution to him of a power that is the enemy of reason. Something similar is to be found in Sophocles' *Antigone* in the chorus that is sung just after Creon has announced that Antigone must die for having buried her brother's body. Eros is addressed as the god who has brought about Antigone's tragedy. He is described as unconquerable, destructive, roaming over the sea and among the dwellers of the wilderness. Neither the gods nor ephemeral humankind can escape him; he drives his victims to madness and turns the just to evil. An even stronger denunciation of the god may be found in Euripides' *Hippolytus*, along with the additional warning that whether one surrenders to love or refuses to capitulate to it, one is

doomed. And indeed, Phaedra, whose successors are obviously Vergil's Dido and Racine's Phèdre, became the prototype of a woman ruined by Eros.

Such poetic passages reflect certain observations about human nature and human behavior. They point to a struggle within man's psyche between a rational, controllable, prudent, and wise agent and an irrational, uncontrollable, mad, and foolish agent. When the former is in control, man will behave in praiseworthy fashion, but when the latter gains the upper hand, he will act like a beast. He will abandon reason that, according to most of the ancients, alone distinguishes him from the beasts. Although man also has an animal nature, to yield to its demands is to betray his essential nature. The notion that Eros might reinforce the human element in man does not appear in the pre-Platonic writers.

### EARLY PHILOSOPHIC REFLECTIONS

The Greeks admitted several forms of love, including heterosexual and homosexual passion; parental, filial, and conjugal affection; fraternal feeling; friendship; love of country; and the love of wisdom. All were associated with either Eros or *Philia* (fondness or friendship). Love was believed to be a power capable of uniting people in a common bond. And since not only people but also animals and the elements were thus united, it was appropriate to conceive of this power as lodged in a single agent that governed the whole cosmos. According to Parmenides, Love was created by the goddess Necessity, and in the writing of Empedocles, love emerges as one of the two universal forces (the other being strife) that explain the course of cosmic history. These two agents—the one of union, the other of decomposition—are not simply names for the fact that composition and decomposition occur; on the contrary, love and strife are not resident in things but are external to them and act upon them. According to Empedocles, the cosmos, so to speak, is held in tension between the forces of harmony and disunion. Were the two forces to be synchronously present, the world would clearly be in a state of disorder. Hence, Empedocles introduced the idea of cycles into his philosophy, as well as the concept of world history as an alternation of the reigns of Love and Strife. When Love is in control, the elements form compounds out of which arise more complex units and, eventually, animate beings. In the primitive period of the cycle, men worship Aphrodite, are innocent of slaughter and, presumably, of war, and are, moreover, vegetarians. “The altar did not reek of the unmixed blood of bulls, but this was the greatest abomination among men, to snatch out the life and eat the

goodly limbs” (Fragment 128). But when Strife is dominant, disorganization, the ultimate disaggregation of the elements, and war and all its attendant evils, take the place of the blessings of love. As far as we can tell from the surviving fragments, Empedocles believed that the cyclical process was everlasting.

The attribution of peace and harmony to the goddess Aphrodite (Empedocles' name for love) is clearly a renunciation of the early poets' idea of love. Empedocles' conception of her resembles the *alma* Venus of Lucretius. Yet she remains the goddess of sexual love, for sexual love has become one example of the universal power of union: It provides the philosopher with empirical evidence of a metaphysical principle.

PLATO. For a complete expression of a philosophic concept of love, one must turn to Plato's *Symposium*. Probably no other document in European literature has had as much influence on the philosophy of love. The various speeches that are reported in this dialogue represent points of view with which Plato does not always agree but which he apparently thought important enough to be presented as typical. These speeches range from an encomium of love's effect on morality to a description of its effect on knowledge. Phaedrus likened the passionate attachment between Achilles and Patroclus to the conjugal affection between Alcestis and Admetus. In both cases it is the lover, not the beloved, who has gained virtue through his or her love. In the following speech, by Pausanias, two kinds of love are distinguished, that of the heavenly Aphrodite and that of the earthly Aphrodite, or the love of the soul and the love of the body. The former is more likely to be the love of a young man (not a boy) at the time when his reason begins to develop and his beard begins to grow. In this speech honorable love is clearly the attraction that a man has for a virtuous soul and is fused in the mind of the speaker with philosophy itself, which is the love of wisdom. It is this honorable love that Eryximachus then describes as the source of harmony and the preserver of the good.

The conclusion drawn from these encomiums is that love is in essence the love of beauty and that beauty is nothing material; it is an ideal. But no man desires the ideal until he has been educated through philosophic training. In the final speech, which supposedly reports the philosophy of the seeress Diotima, we find that there is a scale of beauty, progressing from that of bodies through that of forms, thoughts, minds, institutions and laws, the sciences, to absolute or ideal beauty.

Beauty, for Plato, was the one bridge between the two realms of the material and the ideal, particulars and universals. (This appears clearly enough in the *Phaedrus*; what the *Symposium* adds is a discussion of the power that draws men to beauty in its many modes.) The two realms present not simply a duality of kind but also of value, for the ideal and the universal, which are perfect and eternal, are always to be preferred to the material and the particular. Sexual love itself, although lowest on the scale of love, is nevertheless the seed of ideal love, since what attracts a man to the beloved is beauty.

ARISTOTLE. Plato's account of love, insofar as it concerns friendship, was amplified by Aristotle in the eighth and ninth books of the *Nicomachean Ethics*. But Aristotle treated chiefly the ethical and psychological aspects of the matter. He also utilized the metaphor of the attractive power of love in explaining the motion of the planetary spheres, the Unmoved Mover being the beloved and the planetary system the lover. With important differences that will be mentioned below, the Unmoved Mover became a part of the Christian concept of God.

#### TRANSITION TO CHRISTIANITY

In the *Magna Moralia*, which was probably composed at least in part by Aristotle, it is written that "It would be strange if one were to say that he loved Zeus.... It is not love towards God of which we are in search ... but love towards things with life, that is, where there can be a return of affection." God then is thought to be incapable of returning our love for him, assuming that we can have love for him. In fact, although there are myths in which gods and mortals have been in love with each other, the gods always first disguise themselves as mortals, as Aphrodite did when she fell in love with Anchises, or take on various other forms, which was the habit of Zeus. These myths all deal with sexual intercourse, not with friendship or paternal affection. Omitting the culture heroes, there was no god or goddess in ancient mythology who had any love for humankind. Prometheus is an exception, but he was punished for his help to mortals, and in all probability the historic Greeks thought of him as simply a personification of forethought.

There is no god in classical religion who could be called "our father in heaven." The attitude that Lucretius tried to foster in the minds of his fellow Romans was supposed to be an antidote to their fear of the gods. According to the legends, however, there was good reason to fear them. Ceres and Bacchus may have given men bread and wine, but most of the divinities did little more than take

revenge on the human race for the injuries they had received from their fellow gods. In Judaism and Christianity, however, a new relationship to the divinity was established. As early as Deuteronomy 6:5 the commandment was laid down to love God "with all thine heart, and with all thy soul, and with all thy might," a commandment repeated by Jesus (Matthew 22:37) as the first and great commandment, followed by the second, "Thou shalt love thy neighbor as thyself." It will be observed that now love is not seen as a power that destroys man's reason, but rather, as an emotional attitude that can be voluntarily produced. It is praised in the Psalms (for example, 91:14) and also in the First Epistle to the Corinthians and the First Epistle of John (I John 4:16–20). Both epistles cite the power of love to heal discord and fear, and love is represented as a bond between God and man. According to the Gospel of John (3:16), it is because of God's love for the world that redemption is brought to man.

That man could love God, even if he could not love Zeus, had been seen by Philo Judaeus in his *Questions on Genesis* (XVIII, 16) in which he says that once a man has received a clear impression of God and God's powers, his soul is filled with longing for union with God. Thus, in the First Epistle of John, God is identified with love, "and he that dwelleth in love dwelleth in God, and God in him" (I John 4:16). This idea was also found in non-Christian theologians of Hellenistic times, for example, in the *Hermetica* (*Asclepius* II, Sec. 21), in which all things, including God, are said to be bisexual, a unity that is approximated by men and women in sexual love. This unity is admittedly incomprehensible and what "you might correctly call either Cupid or Venus." But in both Philo and the *Hermetica*, as in Plotinus and Cleanthes' "Hymn to Zeus," the original stimulus to the love of God is knowledge, not sexual love. In *Asclepius* (XIII, 9) the love of God is reduced to worship, sacrifice, prayer, and reverence, and these follow upon a knowledge of the divine nature. In Plotinus the union with God, although aided by ascetic practices, is nevertheless the climax of cognition. Since knowledge occurs only between similar beings, to know God is to be like him; since God is unique, one must become absorbed into his being in order to know him. This may seem to be suggested in the verses from the First Epistle of John cited above, but actually in John the love of God, although it unites man and God, is an act of will similar to the love for one's fellow man. It would presumably be made manifest by one's acts and one's faith; it is not the conclusion or fulfillment of a metaphysical system.

Although the Church Fathers came closest to an identification of God with Aristotle's Unmoved Mover and later Christian philosophers gave God the attributes of that ontological principle, there were differences that have too often been obscured. The Unmoved Mover was neither a person nor a creator; he was uniquely able to produce change without being altered himself, and he could thus suffer no emotions whatsoever. The biblical God was the very antithesis of this. But in order to give an analogy of the way in which the Unmoved Mover moves the world, Aristotle took recourse to the metaphor of the beloved who attracts the lover. This, of course, became in time Dante Alighieri's "love which moves that sun and the other stars." For Aristotle, however, the Unmoved Mover could not return the love of the beings who are below him. In Christianity, as in Judaism, it was essential that God love his creatures as they love him, and, as previously mentioned, love seems to have been thought of as subject to volition. According to Plato (to limit the discussion to him), love arose involuntarily at the sight of a beautiful body. A man's erotic education consisted in a denial, after an analysis of the nature of beauty, of the acts that usually follow such a sight. Once that denial became a part of a man's character, he could rise to allegedly nobler beauties until the final goal—the contemplation of absolute beauty completely detached from anything corporeal—was reached.

The early Christians had more confidence in man's will than had their pagan contemporaries. Both love of God and religious faith were thought to be subject to volition. The concept of believing in order to understand, as St. Augustine put it, was based on the assumption that belief was not the effect but the source of understanding. To what extent the early Christian writers were aware of the psychological effect of practicing certain rites, as Pascal later was, is difficult to say. But since great emphasis was put upon ceremonious expressions of devotion and upon the refusal to carry out pagan rites, we can assume that the practices were believed to induce the appropriate emotions. The most famous of such ceremonies was the Christian agape, in which the devout met to share a supper and to rejoice in their common beliefs. The word *agape* means both love and the object of love, although the pagan satires treated it as if it meant a sexual orgy. The participants in the agape probably thought of it as a ceremony of brotherly love commemorating the Last Supper, although according to the testimony of the Epistle of Jude (12), it was abused at a fairly early date. Whatever its origin and its primitive significance, it is clear that it was supposed to be a ceremony of affection, and it reinforced the friendliness that members of the same religion might

be expected to have toward one another. Two emotional factors that seem to have been absent from paganism thus came into prominence in early Christianity—fraternal love as an essential of piety and filial love to a divine father, both of which were reciprocated. These forms of love were strengthened by the persecutions to which the early Christians were subjected—persecutions that bound them together in a special community and led to self-sacrifice in the various forms of martyrdom.

AUGUSTINE. Of the Church Fathers, it is St. Augustine who gives us the most detailed analysis of love, ranging from his youthful sexual escapades to his final love of God. The famous opening of Book II of the *Confessions* described his condition as one of utter subservience to the flesh. Just as he was capable of enjoying sin (in his case, petty theft), not for the loot it brought him but for the joy of sinning, so he enjoyed love not for the sake of his beloved, but for the sake of his own self-centered pleasure. He described in vivid terms the loathing that invaded him while satisfying his passion. The death of a dear friend aroused in him a realization of the egocentricity of his passion, and in planning to organize a small group of fellow Christians who would live in charity and share their belongings (a plan that came to nothing), he first approached unselfish love. Through self-knowledge he learned to look upon the eternal light and ultimately came to the complete love of God, which he described in the tenth book of the *Confessions*. The fruit of this love was knowledge of the divine. Whereas for Plato and Philo cognition led to love, for Augustine it was love that led to cognition. This theme was developed in the twelfth century by such writers as William of Saint Thierry and St. Bernard of Clairvaux.

#### MIDDLE AGES

The ecstatic loss of self that accompanies sexual love was also assumed to be one of the features of the beatific vision. It is apparent in mystical literature that erotic language is especially effective in communicating mystical experience, and the similarities between religious and sexual ecstasy are manifest in, for example, the Song of Solomon. One should not conclude, however, that the medieval mystics were actually aware of the similarity between the beatific vision and sexual union, for those who are supposed to have made "mystic marriages," like the two St. Catherines, had presumably never had a corporeal marriage. Nonetheless, in mysticism the climax of the love of God was self-annihilation, much as in the Indian *mithuna*, and although the church never encour-

aged mystic practices, it had to admit their importance when they led to the immediate knowledge of God.

Thus, love in itself became an object of study, and the casuistry of love was elaborated in textbooks and poems as early as the twelfth century. Most of these writings seem to have taken as their source the *De Amore* of André le Chapelain which, whether intended to be serious or not, was taken seriously by most of its readers. It would appear to be a manual on seduction and to have only the most remote relevance to love. The time of its publication, however, coincided with the appearance of many commentaries on the Song of Solomon, and its influence on the rituals of the courts of love has been admitted by most medievalists. As the etiquette of the courts of love developed, love became an end in itself and was not necessarily to be gratified by sexual experience. The lover was supposed to serve his lady with no recompense other than the consciousness of his having served her.

One can only guess at how faithfully the precepts of courtly love were carried out, but as a set of ideas they form an important part of European moral philosophy. By elevating women to a position of irrefragable sovereignty over men, the ideals of courtly love became interwoven with the religious ideal of unquestioned loyalty to church and to God. The sovereign woman became identified with the Blessed Virgin to whom were applied many of the epithets of the bride in the Song of Solomon—rose of Sharon, the closed garden, the tower of ivory—phrases whose symbolical meaning had already been elaborated by St. Bernard. In the thirteenth century the question of the relative primacy of God's reason and will was disputed. For those who believed in the primacy of God's will, it followed that obedience rather than understanding was to be given the higher value. This was also true of courtly love and of chivalry as a doctrine.

**DANTE.** The culmination of the medieval writing on love is, for modern readers, Dante's *Vita nuova*. However else this book may be interpreted, it is the story of how love that begins with the sight of a girl's beauty ends with a vision which Dante intimated was to be that of the *Divine Comedy*. For Dante the Johannine phrase "God is love" was of essential importance in religion. In ending the *Divine Comedy* with the love that moves the sun and the other stars, he identified his own love and all love with the love that the cosmos has for its Creator. His "new life" was not to be fulfilled in a union with the woman whom he loved but in her guiding him through paradise. Few words occur more frequently in the poems of Dante than "amore." Sometimes he seems to be writing in the vein of

courtly love, sometimes in the mystical vein of St. Bernard, but in both cases love is represented as a force that attracts man to a nobler life. Dante does not overlook the sufferings of a man in love; indeed, he emphasizes them. But to suffer because of love appears to be analogous to the sufferings of the martyrs—an abnegation of the self for a value that transcends egoism.

## RENAISSANCE NEOPLATONISM

In Plotinus a distinction was made between three forms of love—love as a god, as a daemon, and as a passion. The first of these was again divided into the celestial and terrestrial Aphrodite. The celestial Aphrodite inspires the love of ideas and is the soul of the intelligible world. The terrestrial Aphrodite presides over marriage and is the soul of the sensible world. Love as a demon is identified with the souls of individual human beings. As a passion it is the love of beauty in temperate men and the love of sexual pleasure in those who dwell exclusively in the material world of ugliness. All love, however, is the love of some degree of beauty. Plotinus adopted the scale of beauties that had been outlined in the *Symposium* and read into it a hierarchy of being. At the apex stood the One; the "way up" to the One led from the beauty of material objects to that of ideas. In this instance one sees again the fusion of the erotic passion with the ecstasy of the mystic vision. Paradoxically, an experience that is intimately associated with our bodily life was thought of as the one escape from it.

This complex of confused ideas permeated Renaissance Neoplatonism. Philosophers such as Marsilio Ficino and Count Giovanni Pico della Mirandola constantly emphasized the power of love to free the soul from its bodily prison. They took over the theme of the two Venuses, and they assigned separate human faculties to each. They gave different names to the kinds of love—namely, divine, human, and animal.

**LEONE EBREO.** The philosophy of love expounded by Ficino and Mirandola was most fully developed by Leone Ebreo (Judah Abrabanel) in his *Dialoghi d'amore* (1501–1502), a work that circulated extensively not only in Italy but (in translation) through all Europe. Leone tied together the religious, philosophic, and literary traditions into a single network of ideas.

In the *Dialogues* the two interlocutors are Philo and Sophia, obviously elements of the word *philosophia*. Philo is the lover, and Sophia is the beloved. The first dialogue distinguishes between love and desire and describes the various forms of love; the second discusses the presence

of love in all natural operations, from the synthesis of the four elements to the movements of the planetary spheres; and the third deals with the love of God as the force that holds the universe together. Thus, it is asserted that love is a single principle permeating all things, from the material through the spiritual, and that this principle is the dynamic factor in cosmic change. There is no difference in essence between the attraction the elements have for one another and the forms of love that exist in human beings. The appraisal of the kinds of love is based on the objects of love, and Leone, like most of his contemporaries, thought that wisdom was inherently more valuable than pleasure.

It should be noted that the concept of a single dynamic power, whether it was called love or force or attraction, became more and more widely used as time went on. Its most extreme form was the *Sehnsucht* (“longing”) of some German romantic philosophers, the *Streben* (“striving”) of Johann Gottlieb Fichte, and Novalis’s endless and unfulfilled search for the blue flower. One of the characteristics of love, at least in the mind of Leone, is its inability ever to be satisfied. Though Philo in the *Dialogues* pleads with Sophia to tell him that she responds to his love, she will not do so.

## MODERN PERIOD

During the seventeenth and eighteenth centuries the interest in love was largely psychological and was expressed mainly in novels, poems, and maxims. While love of neighbor and God was approved, sexual love was morally more problematic. The ideal of female chastity was still upheld; in English novels, such as those of Samuel Richardson, a man was allowed to love a woman as long as he did not infringe upon her virginity. Whereas André le Chapelain graded sexual relations according to the social ranks of the maiden and her seducer, Richardson put all men and women on the same level in this respect. Thus, love was democratized. Sexual love was not to be condoned unless sanctified by the sacrament of marriage.

In such French novels as *Le grand Cyrus* by Madeleine de Scudéry, *Les liaisons dangereuses* by Choderlos de Laclos, and *La nouvelle Héloïse* by Jean-Jacques Rousseau, one finds more subtle distinctions and analyses. These authors continue the Renaissance casuistry about the different kinds of love and their respective values, but it must be remembered that their psychology of love was developed against the background of Christian moral principles. There is a constant conflict between the fervent religious and moral desire not to satisfy one’s longings (described in

*La nouvelle Héloïse*) and an awareness of the almost unlimited force of the individual’s erotic desires (treated in *Les liaisons dangereuses*).

SPINOZA. The *Ethics* of Benedict de Spinoza was published in Holland in 1677. In this posthumous work, as in earlier publications, Spinoza emphasized man’s need of perfection—that is, the fulfillment of both his intellectual and his emotional powers, which indeed were not existentially separate. He maintained that the more adequate an idea, the more it is pleasing, liberating, and intrinsically human. The culmination of the ethical life—that is, the life devoted to freedom of the intellect—is found in the “intellectual love of God.” This phrase may have come from Leone Ebreo, but the idea goes back to St. Augustine. Both the *Confessions* and the *Ethics* are built on premises that are discovered by the intuitive process. The God of Spinoza is far from being the God of St. Augustine, but the method of finding him in the inner life and becoming aware of his presence is curiously similar. Both philosophers present a similar paradox: One must lose oneself in order to find oneself, but in so doing, one finds that what one has really discovered is God.

OTHER WRITERS. The analysis of love now passes into the hands of psychologists. Comte Destutt de Tracy and the novelist Stendhal both wrote books on love in which they attempted to probe its motivation and its effects upon conduct, but neither attempted to do more than to discuss love as a sexual experience. Destutt de Tracy’s *De l’amour* was not published until 1926, although it may have been known in manuscript form; Stendhal’s *On Love*, however, was published in 1822, and although it had no popular success at the time, it was later widely read. In Germany, on the other hand, such books as Johann Wolfgang von Goethe’s *Sorrows of Young Werther*, *Elective Affinities*, and, of course, *Faust* gave a quasi-religious tone to the sexual experience. The impossibility of attaining complete satisfaction led men of this tendency to idealize Don Juan as a perfectionist who seeks a goal that he can never reach, for the ideal is precisely that which ought to be and never is. K. W. F. Schlegel’s *Lucinde* is a perfect example of this interpretation of love as the ever-sought and unrealizable ideal.

SCHOPENHAUER. Arthur Schopenhauer was unique in condemning all forms of love on the grounds that they tie one to the will-to-live. But he found this will even in the subanimate world of nature; thus, he was reverting to the ancient tradition of an omnipresent principle and was more interested in the metaphysical status of this princi-

ple than in the details of human psychology. Although Schopenhauer's condemnation of love follows from his general metaphysical position, he supplemented this condemnation with an essay, "Metaphysics of the Love of the Sexes," in which he tried to show that poets and novelists had recognized the evil of loving, although they had not formulated the abstract principles that would justify this point of view. Love drives men and women to suicide, madness, and extremes of sacrifice. Pointing out that he has no philosophic precedents to guide him, Schopenhauer flatly declares that all forms of love are rooted in sexuality and that, obviously, the existence of future generations depends upon its gratification. But the sexual instinct can disguise itself in various ways, especially as "objective admiration," although in reality the will-to-live is aiming at the production of a new individual. Because sexual union exists for the benefit of the species, not for the individuals involved in it, marriages should not be made for love but for convenience. Thus, he says, there is guilt in loving, for its culmination is simply the perpetuation of the will-to-live, with all its attendant miseries.

**FREUD.** Historically, Schopenhauer's influence on Sigmund Freud is more important than his theory of the will-to-live in itself. Freud renamed the will-to-live the libido and at one time even saw its goal as death. The concept of the death wish paralleled Schopenhauer's emphasis on art and pity as the two ways of escape from life, and it had no great success in psychological circles. The libido as a term for generalized desire, on the other hand, has become part and parcel of the terminology of psychodynamics. Like most philosophic concepts, it has been distorted by both its supporters and its adversaries, but by reintegrating humanity and its strivings into the natural world, it has revived in a new form the kernel of Diotima's speech in the *Symposium*. Freud, along with most Platonists, would deny this. However, since love in the *Symposium* is found not only in sexual attraction but also in scientific research and philosophic meditation, there is only a verbal difference between the two philosophies. Freud, to be sure, does not preach the denial of bodily love, but at the same time he never denied the need for self-restraint and self-discipline. Although he may have said that the scientist is dominated by an anal-erotic urge, he did not deprecate science in these terms; rather, he explained what he thought was its general etiology. He also opened the door to a franker discussion of human motivations, and his contribution to ethics can hardly be overestimated. He attempted to show men how to realize the ideal of self-knowledge that philosophers had advocated for centuries without indicating how one might

attain it. By pointing out the universality of love in its various forms and suggesting how it becomes deformed and alienated from its natural goals, Freud laid the foundation for an ethics that would be freed from ecclesiastical dogmatism. Although his followers have modified some of his ideas, as was inevitable, they have not denied either the preeminence of the libido as a driving power in human affairs or its ability to mask itself. One cannot overlook Freud's contribution toward giving men the ability to understand both one another and themselves—a type of understanding that had been preached over the centuries but always on the assumption that human nature could be observed in conscious behavior.

As is always the case in intellectual history, ancient beliefs survive and take on new forms. This is as true of the history of the idea of love as it is of other ideas. It is obvious that although no one believes any longer in the myth of the two Aphrodites as anthropomorphic deities each of whom is accompanied by a special Eros, the distinction between the two still persists as the contrast between carnal and spiritual love. The First Epistle of John and the Gospel of John have been by no means discarded in the Occident, nor has the commandment to love God and one's neighbor been forgotten. *Caritas* as both brotherly love and charity is still preached, if not practiced, and the Neoplatonic notion that through love we shall have harmony and through harmony, peace, is as potent a force in social education as it has ever been. Philosophy sometimes takes as its goal the rationalization of common sense, or at least of widely held beliefs, and according to the available evidence, no one has ever maintained that the whole duty of man consists in hating, provoking disorder, and disobeying what are at various times called the laws of God or of nature. Philosophers writing on love have attempted in numerous ways, first, to describe the unique part it plays in human life; second, to seek its similarity to other impulses; third, to appraise the ends that it wishes to achieve; and finally, to work out a systematic account of all these distinctions and put them into a logical network of ideas.

## LOVE [ADDENDUM]

Since the middle of the twentieth century, analytic philosophers have taken diverse interests in love. Philosophers of mind have asked what kind of psychological state love is. A natural answer is that love is an emotion like any other. Some philosophers, however, find love to be an anomalous emotion, or even not to be an emotion at all. Most types of emotions seem to be triggered by, or partially to consist in, a belief that the emotion is warranted by some fact about its object. Fear of something, for example, typically involves the thought that the thing feared is dangerous or threatening. Love seems to be an exception, since it is unclear what fact about one's beloved might warrant one's love for this person. Some are willing to accept love as an emotion despite this anomaly, while others insist that love must be a psychological state of a different kind. The most commonly proposed alternative is that love is a desire, or set of desires, regarding one's beloved.

The view that love is an anomalous emotion stems from a perception that nothing warrants or justifies it. This raises a second issue that has occupied philosophers: whether there are reasons for love, and if so, what these reasons might be. The most natural candidates for reasons for love would seem to be properties or qualities of the beloved, such as wit, beauty, or kindness. Among many problems with this proposal, three have attracted especially close attention. First, some find the proposal fetishistic, or at least misdirected. It appears to represent love as focused on the beloved's accidental properties, rather than on that person's essence. Second, if one's reasons for loving the beloved are properties, then one's love ought to wane as the beloved loses those properties. This seems at odds with the thought, famously expressed by William Shakespeare, that “Love is not love/Which alters when it alteration finds.” Finally, if one's reasons for loving the beloved are properties, then insofar as one's love is responsive to those reasons, it will soon migrate to another person with those properties in sufficient proportion. This too seems antithetical to love.

Impressed by some of these problems, Harry Frankfurt concludes that while love creates reasons, there are no reasons for love. Love is a structure of desires for which there is no antecedent justification. Love is focused on the particular person whom one loves; it is not a response to some generalizable, justifying property that the person has. Since Jane, say, is the particular person she is and she can neither lose this trait nor share it with anyone else, one's love for her does not alter as it alteration finds, nor does it transfer to her twin. David Velleman (1999), resisting Frankfurt's conclusion, suggests that love is a response to a justifying feature that is also identical with the beloved's essence: Jane's rational nature or capacity for valuation, for instance. However, this suggestion seems to leave one's beloved vulnerable to being replaced—indeed, replaced by any other person with a rational nature. A different strategy for avoiding Frankfurt's conclusion is to suggest that love is a response to the reasons provided by one's shared history with the person one loves. This would explain why one's love does not alter as the beloved's wit or beauty fades, and why one's love does not accept a substitute with whom no such history is shared. However, the appeal to shared history again threatens to make love focused on the beloved's accidental properties, rather than on that person's essence. It also seems to put the cart before the horse. Love seems to precede many relationships, rather than develop with them.

Moral philosophers have been particularly concerned that love, and similar attitudes such as friendship, are in tension with morality, at least as understood in certain theories. The tension is thought to arise because these moral theories—most notably, utilitarianism and Kantianism—require one to be impartial, that is, to give equal weight to everyone's interests. Love, in contrast, seems to impel one to be partial: to give greater weight to the interests of one's beloved. The tension has been thought to be more acute at the level of deliberation than at the level of action. While there may be utilitarian and Kantian justifications for permissions, or even requirements, to act as love directs, deliberating in terms of such justifications seems incompatible with love. This incompatibility has generally been seen as a problem for such moral theories, rather than as a problem for love. The incompatibility makes these moral theories seem self-defeating or overly demanding, or it reveals that they fail to take into account something of genuine value.

In defense of these moral theories, some philosophers have insisted that the incompatibility is only apparent. Indirect utilitarians have pointed out that while

utilitarianism requires one to do what is best from an impartial standpoint, utilitarianism need not require one to deliberate in impartial terms. Indeed, there may be strong utilitarian reasons for not so deliberating. Kantians have similarly observed that the moral agent need not always be guided by specific reflection on what it is morally permissible to do. A less concessive Kantian response appears in Velleman's work. Love, he argues, is a "moral emotion," by which he seems to mean, at least in part, that love is animated by the same value that underlies morality itself.

Other philosophers, however, have insisted that the incompatibility is real. Some of these philosophers urge rejecting impartial moral theories, perhaps in favor of a virtue-based approach. Others see the incompatibility as casting doubt not on the impartiality of morality, but instead on its authority over our lives.

LOVEJOY, ARTHUR  
ONCKEN  
(1873–1962)

Arthur Oncken Lovejoy, the American philosopher and historian of ideas, was born in Berlin, Germany, the son of the Reverend W. W. Lovejoy of Boston and Sara

Oncken of Hamburg. Educated at the University of California (Berkeley) and at Harvard, where he received his MA, Lovejoy began his teaching career at Stanford University (1899–1901) and then taught for seven years at Washington University in St. Louis. After short periods at Columbia University and the University of Missouri, he went to Johns Hopkins in 1910 as professor of philosophy, remaining there until his retirement in 1938. In 1927 he gave the Carus Lectures, published as *The Revolt against Dualism* in 1930, and the William James Lectures, published as *The Great Chain of Being* in 1933. Lovejoy was widely known as an epistemologist, a philosophic critic, a historian of ideas, and a man of action. He helped to organize the Association of American University Professors, in which he served for many years as chairman of the group that investigated all charges of violation of academic freedom. In this connection he wrote the article “Academic Freedom” for the *Encyclopaedia of the Social Sciences*.

Lovejoy’s works fall into two main groups—those on epistemology and those on intellectual history—although he also wrote essays on ethics, religion, and social problems.

### PHILOSOPHICAL WORKS

For many years Lovejoy confined his writings to articles, a great number of them critical. These were often directed against various forms of anti-intellectualism: “The Thirteen Pragmatisms” (1908), “Some Antecedents of the Philosophy of Bergson” (1913), and “The Paradox of the Thinking Behaviorist” (1922). These articles, however, were frequently examinations of certain contemporary movements in philosophy, such as the New Realism: “Reflections of a Temporalist on the New Realism” (1911) and “On Some Novelty of the New Realism” (1913). Some were even on the supposed philosophical implication of the theory of relativity: “The Travels of Peter, Paul and Zebedee” (1932) and “The Paradox of the Time-Retarding Journey” (1931).

It was not until 1930 that Lovejoy published his major work, *The Revolt against Dualism*, in which he attempted to defend epistemological dualism against the reigning modes of monism. He began by sketching what he called naive dualism, which assumes that (1) many possible objects of knowledge (*cognoscenda*) are at places external to the body of the percipient; (2) man must have real traffic with things that existed in the past and may exist in the future; (3) man can have knowledge of things as they would be if they were not directly known; (4) other minds and experiences exist; and (5) *cognoscenda* in

other places and at other times are apprehensible by other knowers. The book analyzed this naive dualism and defended a corrected form of it. On the whole, although not in detail, Lovejoy was more interested in the duality of two existents (of two five-cent stamps, for instance) than qualitative duality such as of red and green. The duality of two things is demonstrated, he wrote, by the fact that one of the supposed pair has a spatial, a temporal, or a spatiotemporal position that is inconsistent with that empirically exhibited by the other. If, then, it can be shown that our ideas of objects have positions that can be shown not to be those of the objects, then the two cannot rightly be believed to be one. Qualitative duality would be demonstrated in analogous fashion, but the inconsistency would lie between two sets of qualities.

In his autobiographical essay, “A Temporalistic Realism,” in Volume II of *Contemporary American Philosophy*, edited by G. P. Adams and W. P. Montague (London and New York, 1930), Lovejoy pointed out that one of his earliest philosophical theses was that experience itself is temporal. Any philosophical position that overlooks or denies this, or conflicts with it, would, in his opinion, be condemned as contradicting a manifest truth. (This does not, of course, assert that any philosophy—such as that of Henri Bergson—that admits the empirical reality of time is thereby proved.) The various forms of monism fail to evade, and cannot evade, the consequences of this fact. For instance, the date at which a visual datum occurs is not the date of the object that one is seeing. There is a time lag between the emission of light rays from a star and their arrival at the retina of a human eye, to say nothing of the arrival of the nerve current stimulated by them at the cerebral cortex, where it apparently causes a visual image to appear. Indeed, some stars that we perceive now may have become extinct many light-years ago. Analogous statements can be made about sound, odor, and taste.

Although Lovejoy also used other criteria, this criterion of duality suffices to establish existential duality between object and sensum. To deny the duality, Lovejoy asserted, would be equivalent to asserting that two particulars can each be in two places at the same time, that one particular has or consists of many shapes and other inconsistent qualities at the same time, that it has two dates in the same temporal order, that it can be at the same time both the beginning and the end of a causal series, and, finally, that error is impossible. Lovejoy discussed each of these theses in connection with epistemological positions widely held at the time the book was written: the New Realism, objective relativism, Alfred

North Whitehead's denial of simple location, and Bertrand Russell's epistemology as given in *The Analysis of Mind* (London and New York, 1921) and *The Analysis of Matter* (London and New York, 1927).

Lovejoy's dualism differed from that of the naive dualist in that the latter is likely to believe that his objects are qualitatively, if not existentially, identical with the objects of others. Our ideas, Lovejoy held, do not necessarily have properties identical with the properties of anything in the physical world, but we are not therefore condemned to know nothing whatsoever of that world. We cannot prove beyond doubt that some of the properties of our ideas are also properties of the physical world, but such is "a natural assumption which no one can prove to be false" (*Revolt against Dualism*, p. 273). Qualities that vary with percipients must be held to be subjective, but there are certain residual properties—extension, shape, relative position, temporal succession, and motion—that may reasonably be said to characterize both our ideas and their objects. The reasonableness of the hypothesis rests on its ability to give us grounds for framing a "coherent, simple, unifying, scientifically serviceable" set of hypotheses for explaining both the rise of our sensory data and their peculiar characteristics. It will, in short, account for a world that is causally efficacious, that exists between our perceptual moments, and that has a past and future independent of any percipients.

## INTELLECTUAL HISTORY

To separate Lovejoy's philosophical views from his historical studies is artificial, for his philosophy is based on a wide knowledge of history, and his historiography is based on his belief in the existence and efficacy of ideas. However, such a distinction may be made for purposes of classification.

Lovejoy was the chief promoter in the United States of the historiography of ideas. His continuing interest in this area dated back at least to his monograph *The Dialectic of Bruno and Spinoza* (Berkeley, CA, 1904). He was the originator and first editor of the *Journal of the History of Ideas*. He studied such general ideas as romanticism, evolutionism, naturalism, and primitivism, showing the ambiguities resident in them and their ingression into fields that have no ostensible logical connection with them.

In the preface to *Essays in the History of Ideas*, Lovejoy defined his conception of the historiography of ideas: (1) It studies the presence and influence of the same ideas in very diverse provinces of thought and in different periods; thus, an idea that may have originated in logic may

turn up in biology, or vice versa. (2) There are certain catchwords, such as *nature*, that have taken on new meanings over time, although the people using them are seldom aware of their ambiguities. The historian of ideas will analyze these various meanings as they occur. An example from fairly recent history (not one of Lovejoy's own) would be the eulogistic usage of the word *organic*. (3) It has also been noticed that a given author will prove susceptible to the emotional aura of certain terms and, probably because of this, will waver between a valid meaning of an idea and an incongruous meaning. It is usually assumed that the thought of a given writer must be consistent and unified; but by accepting this assumption, a historian may overlook precisely those thoughts expressed by a writer that were in fact influential. A fuller explanation of the program is given in Lovejoy's essay "The Historiography of Ideas," first published in 1938 and republished as the opening chapter in *Essays in the History of Ideas*.

**THE GREAT CHAIN OF BEING.** Lovejoy's most influential single contribution to the history of ideas is *The Great Chain of Being*. The idea whose fortunes he traced in this book was first expressed by Plato in the *Timaeus*. There Plato maintained that the Demiurge, being good, was not jealous and, not being jealous, wanted the world to lack nothing; therefore, if the world were to lack nothing, all possibilities must be realized. The realization of all possibilities is the great chain of being, and the principle it rests upon was called by Lovejoy the principle of plenitude.

This apparently simple idea, contained in a creation myth, was introduced into Christian theology through Neoplatonism and into cosmography by Hasdai Crescas with his supposition of many worlds, by Johannes Kepler, by Nicholas of Cusa with his theory of a boundless universe, and, above all, by Giordano Bruno with his open acceptance of the principle as it applies to stellar bodies. In Benedict de Spinoza it appeared as the doctrine that all ideas of God must be realized, and in Gottfried Wilhelm Leibniz as the principle of sufficient reason. Lovejoy showed how the principle entered into biological speculations in the eighteenth century and how it was "temporalized." In the idea of the great chain of being, which he presented with a richness of erudition, Lovejoy found one of the most fertile yet neglected ideas in Western philosophy and masterfully traced its ramifications and subsequent history.

**PRIMITIVISM.** A second dominant idea, the study of whose history Lovejoy initiated, is that cluster of notions known as primitivism. Primitivism has two forms—a

chronological form, exemplified in the myth of the Golden Age, and a cultural form, best exemplified in cynicism and in all attempts to rediscover the so-called natural life. Each of these forms has two subspecies, “hard” primitivism and “soft” primitivism. Hard primitivism maintains that the state of nature (man’s primordial condition) was rugged and unencumbered with superfluities, a state very close to that of the legendary noble savage. Soft primitivism, on the contrary, maintains that the state of nature was agreeably gentle, that earth gave man her fruits spontaneously without any labor on his part, and that there was no private property and hence no covetousness, no war, no foreign trade, none of the complications that the arts and sciences introduce.

Lovejoy urged as early as 1917 that there would be more progress in philosophical studies if there were more cooperation among philosophers (“On Some Conditions of Progress in Philosophical Inquiry”). A documentary history of primitivism provided, it seemed, an ideal opportunity for such cooperation. Lovejoy and three other scholars formed a team and agreed to publish a four-volume work, to be titled *A Documentary History of Primitivism and Related Ideas*, covering the ground from early Greek times to the recent past. Of this projected work only one volume, *Primitivism and Related Ideas in Antiquity*, written by Lovejoy with George Boas, was completed, although a number of smaller works by various scholars came out as contributions to the subject. The published volume contained, along with documents and commentaries, two supplementary essays—“Primitivism in Ancient Western Asia,” by W. F. Albright, and “Primitivism in Indian Literature,” by P.-E. Dumont—and an appendix by Lovejoy—“Some Meanings of ‘Nature.’” Although the original four-volume plan was never carried out, what did appear may have shown historians of philosophy that primitivism was a philosophic theme neglected by the historical tradition that had nevertheless permeated Occidental thought.

## LOYALTY

“Loyalty,” as a moral rather than a political concept, has received scant attention in philosophical literature. In fact, at the present time [1967] it seems banished from respectable ethical discussions, owing, no doubt, to its historical association with an obsolete metaphysics (idealism) and with such odious political movements as the extreme nationalism of Nazism. However, the supposed implications suggested by these disreputable associations are ill-founded. On the contrary, loyalty is an essential ingredient in any civilized and humane system of morals.

Philosophical issues regarding loyalty may be separated into the question of the object of loyalty, and the question of the moral value of loyalty.

### THE OBJECT OF LOYALTY

Granted that loyalty is the wholehearted devotion to an object of some kind, what kind of thing is this object? Is it an abstract entity, such as an idea or a collective being? Or is it a person or group of persons?

The idealist contends that loyalty is “the willing and practical and thoroughgoing devotion of a person to a cause” (Josiah Royce, *The Philosophy of Loyalty*, p. 17). Its object is “a cause beyond your private self, greater than you are ... impersonal and superpersonal” (ibid., pp. 19–20). As a cause it is something that transcends the individual, “an eternal reality.” Apart from familiar metaphysical and logical objections to this concept of a superpersonal reality, this view has the ethical defect of postulating duties over and above our duties to individual men and groups of men. The individual is submerged and lost in this superperson not only ontologically but also morally, for it tends to dissolve our specific duties and obligations to others into a “superhuman” good.

Opposing the idealistic position is the view, characteristic of social atomism (empiricism or utilitarianism, for example), that denies any distinctive status to loyalty on the grounds that metaphysically there can be no such superpersonal entity to serve as its object. Insofar as the concept of loyalty has any validity at all, it reduces to other kinds of relations and dispositions, such as obedience or honesty. Most empiricists are inclined to agree with David Hume, however, that loyalty is a virtue that holds “less of reason, than of bigotry and superstition.”

Thus, it is generally assumed that we must either accept the notion of a superperson or some other abstract entity as the object of loyalty or reject the notion of loyalty altogether as founded on an illusion. This assumption is open to question.

In answer to the idealists, it should be pointed out that in our common moral language, as well as historically, “loyalty” is taken to refer to a relationship between persons—for instance, between a lord and his vassal, between a parent and his children, or between friends. Thus, the object of loyalty is ordinarily taken to be a person or group of persons.

Loyalty is conceived as interpersonal, and it is also always specific; a man is loyal to *his* lord, *his* father, or *his* comrades. It is conceptually impossible to be loyal to people in general (to humanity) or to a general principle, such as justice or democracy.

The social atomist fails to recognize the special character and significance of the ties that bind individuals together and provide the basis for loyalties. Loyalty is not founded on just any casual relationship between persons, but on a specific kind of relationship or tie. The special ties involved arise from the twofold circumstance that the persons so bound are comembers of a specific group (community) distinguished by a specific common background and sharing specific interests, and are related in terms of some sort of role differentiation within that group. A friendship, a family, or such a highly organized group as a political, priestly, or military community illustrates the presence of these conditions. Special ties of this sort provide both the necessary and the sufficient conditions for a person to be a proper object of loyalty.

The impersonal or objective element mentioned by Royce and other idealists is explained by the fact that it is the ties, the mutually related roles, rather than any particular personal characteristics of the individuals involved that provide the grounds for loyalty. Why should I be loyal to *X*? Because he is *my R* (friend, father, leader, comrade). More purely personal characteristics of *X*, such as his kindness, courage, amiability, honesty, or spirituality cannot serve as *grounds* for loyalty. That the conditions of loyalty abstract from the personal characteristics of the individuals concerned does not, of course, entail that loyalty must relate to a superpersonal entity (cause, whole) any more than the fact that an algebraic formula contains a variable within it (such as *Fx*) entails that there must be some kind of supernumber to satisfy the function.

### THE MORAL VALUE OF LOYALTY

Is loyalty something good in itself? Is it always good? Can there be bad loyalties?

On these questions the idealist takes an extreme position, for he holds that loyalty is the highest moral good. According to Royce, a man’s wholehearted devotion

to a cause is *eo ipso* good and becomes evil only when it conflicts with other loyalties. The supreme good is loyalty to loyalty: “so choose and so serve your individual cause as to secure thereby the greatest increase of loyalty amongst men” (ibid., p. 121).

The view that loyalty has an inner value, “whatever be the cause to which this man is loyal,” can be used to redeem the most evil acts of men. Such a belief outrages our moral feelings, for we want to say that a cause which demands injustice or cruelty as the price of devotion renders that devotion an evil in itself. It is impossible to separate logically the moral quality of devotion from the moral quality of its object, if that object is a cause. (Incidentally, a distinction must be made between devotion to a thoroughly evil purpose and devotion that is simply misdirected, in the sense that it is well-intentioned but wrong for some other reason.)

Even assuming that the problem of bad loyalties can be resolved by invoking “loyalty to loyalty,” the idealist may still be accused of turning morality, which properly concerns man’s relations to his fellows, into service of an abstract principle or a cause, thus treating man as a mere means rather than as an end-in-itself.

The social atomist, on the other hand, regards the moral value of loyalty, construed as devotion or obedience to persons or institutions, entirely as a function of its benign or mischievous consequences. This view, however, robs loyalty of any special moral significance. It fails to account, for example, for the admirable side of a mother’s loyalty to her son even when, considering the total picture, it is not entirely justified morally.

We must ask what loyalty demands of a person. The etymology of the word *loyalty* gives a clue, for it comes from the French word *loi* and thus means something akin to *legality*. Loyalty, strictly speaking, demands what is morally due the object of loyalty. A loyal subject is one who wholeheartedly devotes himself to his duties to his lord. What is due or owed is defined by the roles of the persons concerned. The fact that loyalty gives what is due also explains why we can demand the loyalty of others.

It follows that mere blind obedience to every wish of the person who is the object of loyalty is not loyalty; it is a perversion of loyalty. There is no moral value to it at all, since it is not something that is morally due. A loyal Nazi is a contradiction in terms, although a loyal German is not.

There are, to be sure, conflicts of loyalties, but this fact does not entail that any of the loyalties involved are improper or invalid. It is simply a logical consequence of

the fact that there are conflicts of duties; my duty to my parents may conflict with my duty to my wife or to my fellow countrymen. Sometimes there are clear ways of resolving these conflicts and sometimes there are not, but we cannot eliminate the problem of conflicting loyalties either by a metaphysical trick or by the mechanical application of a value calculus.

One final observation must be made concerning the distinction between loyalty and fidelity. Loyalty includes fidelity in carrying out one’s duties to the person or group of persons who are the object of loyalty; but it embraces more than that, for it implies an attitude, perhaps an affection or sentiment, toward such persons. Furthermore, at the very least, loyalty requires the complete subordination of one’s own private interest in favor of giving what is due, and perhaps also the exclusion of other legitimate interests. In this sense, loyalty may often be one-sided, although it need not be. If we could not count on the loyalty of others or give them our loyalty, social life would be not only bleak but also impossible.

## LUCIAN OF SAMOSATA

(c. 115–c. 200)

Lucian of Samosata, the philosophical satirist and satirist of philosophy, was born at Samosata (Samsat) on the Euphrates and was educated there. He then studied rhet-

oric in Asia Minor, after which he was a lawyer for a while, toured Greece and Italy as a lecturer, and held a chair of literature in France. In middle age he settled in Athens, where he wrote and gave public readings of his most successful dialogues, many of which were on philosophical themes. Late in life he joined the staff of the Roman governor of Egypt. Nothing is known of his death except that it occurred after 180.

Lucian's philosophical position is not easy to define because he expresses contradictory attitudes, and his persistent irony and his obvious wish to entertain make it hard to know how seriously to take his statements. The contradictions have been used as a basis for several different theories of his intellectual development, but the chronological order of his works is too uncertain for any such interpretation to be wholly convincing.

In *The Fisher*, Lucian claimed to be a champion of philosophy, which he described elsewhere as a civilizing and morally improving study; however, he constantly criticized pseudo philosophers for their greed, bad temper, sexual immorality, and the general inconsistency between their preaching and their practice. The historical occasion for such attacks was the encouragement of philosophy by Marcus Aurelius, which had made philosophers almost as numerous as monks and friars were in the Middle Ages.

Lucian's favorite target was the Stoic, but he also savagely attacked such Cynics as Peregrinus, and in *The Sale of Lives* he made fun of every school. However, he sometimes wrote approvingly of individual philosophies. The *Nigrinus* appears to be a eulogy of Platonism, although this may be ironical or simply an excuse for satirizing Roman society. The *Cynicus* is a less ambiguous defense of Cynicism, and in several dialogues Lucian speaks through a character called Cyniscus or through that of the Cynic Menippus. Diogenes is once mentioned favorably, and in the *Alexander* there is enthusiastic praise for Epicurus, "a really great man who perceived, as no one else has done, the beauty of truth."

The *Hermotimus* rejects all philosophical systems on the grounds that they are mutually contradictory and thus cannot all be right, and life is too short to discover which of them is nearest to the truth. The wisest course is to get on with the business of living, guided by common sense. Tiresias in the *Menippus* gives the same advice.

In general, Lucian disliked philosophies that encourage superstition, such as Platonism and Stoicism, and preferred materialists like Democritus and Epicurus. Although he made fun of the Skeptics, he was tempera-

mentally inclined to skepticism, or to an eclecticism of the kind described in the *Life of Demonax*.

His own positive ideas included a conception of society free from racial, social, and economic distinctions. He valued such human qualities as sincerity, courage, cheerfulness, and kindness; and he continually stressed the importance of facing facts, especially the fact of death.

Lucian's influence on later thought was exerted largely, but not entirely, through the medium of literary technique. He facilitated the spread of humanism in the sixteenth century by suggesting one of the basic themes (the absurdity of plutocracy) and some of the incidental jokes in Thomas More's *Utopia*, but his main contributions were the lighthearted manner, the form (a fantastic journey described in a familiar dialogue), and the trick of using proper names that etymologically imply nonexistence or nonseriousness. He also aided in the Reformation by providing literary precedents and humorous devices for the satire on ecclesiastics, theologians, monks, and superstitions in Desiderius Erasmus's *Encomium Moriae* and in the work of François Rabelais. Voltaire's *Candide* is Lucianic in both manner and theme (the refutation of philosophical theory by reality), and its final moral is identical with that of the *Menippus*. The *Conversation between Lucian, Erasmus and Rabelais in the Elysian Fields* shows that Voltaire regarded Lucian as one of his masters in the strategy of intellectual revolution.

Bacon called Lucian a contemplative atheist, and as such Lucian evidently interested David Hume, who described him as a very moral writer, quoted him with respect when discussing ethics and religion, and read him on his deathbed. Since then, professional philosophers have tended to ignore him, but perhaps his spirit is still alive in those who (as Bertrand Russell did), are prepared to flavor philosophy with wit.

## LUCRETIUS

(?–c. 55 BCE)

Little is known of Lucretius (d. ca. 55 BCE [Donatus, *Life of Virgil*] or perhaps a few years later; cf. Hutchinson 2001) apart from his poem in six books, *On the Nature of Things* (*De rerum natura*), an exposition in Latin hexameters of the doctrines of the Greek philosopher Epicurus, who lived two centuries earlier. Saint Jerome, in his *Chronicle* (Olympiad 171.3), claims that he committed suicide as a result of taking a love potion, and that he wrote his poem "in intervals of insanity," presumably meaning between, rather than during, such episodes.

Jerome also asserts that Cicero "emended" Lucretius' text, that is, corrected it for publication, after his death (as Jerome gives it) in 51/50. It is possible that this is an inference from a letter of Cicero's to his brother (2.9, February 54 BCE), in which he praises Lucretius' poem, though Cicero himself had translated the Greek poet Aratus into Latin hexameters, and might well have taken an interest in a fellow poet's work.

Internal evidence reveals some repetitions and inconsistencies (e.g., the doublet at 4.45–53 and 4.26–44), which Lucretius would doubtless have eliminated in a final version; Lucretius also states that he will treat in greater detail the nature and habitation of the gods (5.155), but no such passage survives. Some scholars have supposed that he planned to include it in a seventh or even later book, and that accordingly the poem as we have it is radically incomplete; in particular, Lucretius did not intend to conclude with the depressing spectacle of the Athenian plague (summary of views in Boyancé 1963: 79–83). But there are good justifications for this ending, and Lucretius could have changed his mind about the theological section, or treated it briefly within the compass of the poem as we have it. In the proem to Book 6 (91–94) he indicates plainly that he is approaching the end of the poem.

The Pre-Socratic philosophers Parmenides and Empedocles had written treatises in verse, and Empedocles' poem, which Lucretius regarded highly enough to deem its author "godlike" (1.716–741), may have borne the same title (*Peri phuseôs*, or perhaps the even closer *Peri phuseôs tôn ontôn*: Sedley 1998: 21–22; the title may not have been Empedocles' own: Schmalzriedt 1970), and may have extended to several thousand lines (Diogenes Laertius 8.77). Empedocles' proem was likely a model for Lucretius' own (Gale 1994: 59–74; Sedley 1998: 1–34). Later, the medium for philosophy was decidedly prose, and Epicurus himself was suspicious of poetry (fr. 229 Usener; cf. Gale 1994: 14–18). In the Hellenistic period (third–first centuries BCE), didactic poetry was composed on a variety of topics, from astronomy and farming to poisonous snakes, but these genre pieces were not usually intended to provide serious instruction; Lucretius' poem was. He succeeds remarkably in conveying rigorous arguments concerning such matters as the constitution of the universe, which for the Epicureans was composed solely of atomic matter and empty space (Books 1–2), the materialist basis of perception and cognition (Books 3–4), and the evolution of the earth and of human civilization (Book 5), along with such special topics as the nature of magnetism (Book 6), even as he strug-

gles with the relative poverty of the Latin philosophical vocabulary, as opposed to Greek (1.136–39, 832, 3.260; cf. Cicero *De finibus* 3.51).

Given the mainly fragmentary or hostile character of our sources concerning Epicurus' doctrines (three short essays by Epicurus in the form of letters are reproduced by Diogenes Laertius, Book 10), Lucretius provides the single extended exposition of Epicurean physics that survives by a follower of the school. Doubtless, the medium of verse imposed some limitations, and Lucretius' understanding of certain points was perhaps faulty, but the poem is immensely valuable for the history of philosophy. It is also a magnificent work of literature, shot through with a moral passion that brightens even the most painstaking arguments about atoms and void.

### SOURCES AND ORIGINALITY

This said, it is obviously important to determine what sources Lucretius himself employed, and over this question there is considerable controversy. It is in principle possible that Lucretius relied on no particular text but composed an independent poetical treatise based on his immersion in Epicureanism (Clay 1983: 31). David Sedley (1998), in turn, has argued forcefully that Lucretius adhered principally to a single treatise by Epicurus—*On Nature*—and was almost completely indifferent to or unaware of more recent currents in Epicureanism, or of ongoing debates with other schools, above all the Stoics (he dubs Lucretius a “fundamentalist” in this respect; cf. Furley 1967). Other scholars have seen clear indications of later influences in Lucretius' poem, for example in his attack on skepticism (Vander Waerdt 1989, Lévy 1997), his account of socio-political evolution (Schrijvers 1996 detects the influence of Polybius' theory of constitutions), and his arguments against teleology (Schmidt 1990: 152–160). Some have found it implausible that Lucretius should have been wholly isolated from the contemporary revival of Epicureanism in Italy, and have sought to demonstrate parallels between Lucretius' poem and the treatises of Philodemus (Kleve 1997), burned and buried in the eruption of Vesuvius in 79 CE, but still partly legible. Evidence that Lucretius' poem was among the scrolls in Philodemus' library remains inconclusive.

No one denies that Lucretius composed more freely in the proems with which he prefaced each of the six books, where, for example, he speaks of Venus as the ancestress of the Romans (1.1), and often too in the conclusions, or that he sometimes resorted to other sources than Epicurus (e.g., the description of the plague, based closely on Thucydides 2.47–54; cf. the analysis of pas-

sionate love at the end of Book 4, esp. vv. 1121–1191, and the personification of Nature scolding the man who fears death at 3.931–977, both indebted to Greek styles of diatribe [Wallach 1976, Reinhardt 2002]). So too, his choice of imagery in technical passages is frequently his own, for instance his illustration of the flow of thin membranes or simulacra from the surface of objects by reference to the colors cast on the audience by the awnings stretched above a Roman amphitheater (4.75–83). Some passages are more difficult to decide. When Lucretius explains the drive to accumulate wealth as a function of the fear of death, he says that poverty is imagined the “antechamber to hell” (3.65–69). Is this a Lucretian metaphor, or a piece of Epicurean doctrine? So too, Lucretius affirms that the legendary torments in the underworld, like Tantalus' perpetual hunger and the Danaids' task of carrying water in leaky pails, are really images of the forever frustrated pursuit of wealth and power in this world (3.978–1023). This may be a poetical flourish, but conceivably it reflects a genuine Epicurean explanation of the fear of punishment in the afterlife (Konstan 1973: 13–27).

Apart from such passages, in its broad outline Lucretius' poem conforms to the subjects that we know Epicurus treated in his principal statement of his views, above all his *On Nature* (*Peri phuseôs*), of which some substantial, though lacunose, fragments have been recovered on papyrus (see Sedley 1998: 133 for a possible reconstruction). To all appearances, Lucretius set about to versify a treatise on the atomic theory, and its implications for human psychology and society. He did not incorporate into his poem substantial arguments from Epicurus' ethical writings (for example, *On Lives* or *On the End*; cf. Diogenes Laertius 10.30). What is more, he shows no interest in many of the issues with which Philodemus was concerned, such as rhetoric, literary theory, virtues and vices, governance, semiotics, or the right methods for training disciples, which became central concerns of the school after the founder's death. Nor does he engage systematically and polemically with later opponents of Epicureanism, or with dissident views within the school, as Philodemus does (cf. the debates that Cicero stages between Epicureans, Stoics, and Academics); if indeed there are traces of such controversies in his poem, it is nonetheless remarkable that the philosophers whom he refutes explicitly and at length are Empedocles, Heraclitus, Anaxagoras, and Democritus: no mention of later thinkers. His poem purports to present classical Epicureanism in a palatable but accurate form to a Roman public—sweetening the spoon of medicine, in Lucretius' image (1.936–950, 4.11–25). He describes himself as

planting his feet in Epicurus' footprints (3.3–4, 5.55–56), and this seems a fair statement of his intentions.

This fidelity to Epicurus' major exposition of his doctrine need not be taken as a sign of intellectual narrowness or a quasi-religious commitment to the word of the Master (Sedley 1998: 93). It was the custom of Hellenistic didactic poets to take as their source a scientific treatise, as Aratus, for example, did in his *Phaenomena* or *Constellations*, where he followed Eudoxus' work of the same name (fr. 3a Lasserre), even as he modelled his style on that of the archaic poet Hesiod. The Roman poet Ennius, whom Lucretius praises extravagantly despite his mistaken belief in the underworld (1.117–126), did something similar when he rendered into prose the pseudo-scientific narrative of Euhemerus. Lucretius was writing as much in the sophisticated Alexandrian tradition as in that of the pre-Socratic poet-philosophers.

It is a separate question whether Lucretius sometimes altered Epicurus' order of presentation, and with this his chain of reasoning, and whether he added to or modified the arguments of the Master here and there, either independently or by mining other works of Epicurus or early Epicureans. He seems to claim some responsibility for the sequence in which he presents a series of proofs (1.52, 3.419–420; cf. Clay 1983: 38). Sedley (1998: 148–152) speculates that Lucretius planned a more extensive rearrangement of topics, but did not live to finish revising the entire poem. Lucretius may have been influenced also by the order of subjects in standard collections of doctrines, whether doxographies or rhetorical disquisitions (Runia 1997; on rhetoric, Classen 1986: 371).

## LUCRETIUS AND EPICUREAN DOCTRINE

No doubt, Lucretius' vivid analogies and images are not without philosophical interest, though some will have had antecedents in Epicurus' works or elsewhere; for example, the proof of atomic motion from the visible vibration of dust motes in a sunbeam (2.114–141), comparable to Brownian motion, was evidently already proposed by Democritus (cf. Aristotle *De anima* 404a3–4). The image of a flock of sheep on a distant hillside (2.317–322), by which Lucretius illustrates how a compound may be seen as proceeding slowly although its constituent particles are moving rapidly, was likely Lucretius' own. Epicureanism tended, more than other ancient schools, to admit proof by analogy—a principal means of inferring the properties of the invisible atomic world from perceptible events—and this favored the probative value of similes (cf. 2.112–113). Isolating philo-

sophically significant innovations in Lucretius, however, is a delicate task, given the scrappy condition of his principal source or sources (even where he composed freely rather than drawing on specific texts), and a novel comparison does not necessarily constitute a new argument.

In the circumstances, there are several ways to proceed. First, one may identify arguments in Lucretius that have no known parallel in Epicurus' own writings or those of later Epicureans; these at least are possible candidates for Lucretian innovation. Second, one may demonstrate Lucretius' dependence on some other, non-Epicurean source, e.g., Polybius or Thucydides, bearing in mind that Lucretius' references to early writers may have been filtered through Epicurus. Third, one may note specifically Roman or personal nuances of the sort that alter or affect in some measure orthodox Epicurean doctrine. Finally, one may discover places where Lucretius seems to disagree with what we know to have been Epicurus' view. The last is certainly the most dramatic, and indeed there is one apparent case of such a discrepancy: Lucretius speaks of four components of the soul (3.231–245)—air, ether, fire, and an unnamed, superfine element—whereas Epicurus, in the *Letter to Herodotus* (63), mentions just three, and in somewhat different terms. It is hardly likely that Lucretius is silently introducing here a modification of Epicurean doctrine. Conceivably, he was simply mistaken; alternatively, and more probable, Epicurus' account in the *Letter* is compressed, and he elaborated the fuller view in the relevant, now lost, passage in *On Nature* (Sedley 1998: 71n47).

Given the state of Epicurean texts, Lucretius is often our best guide to Epicurean doctrine, especially since there is not sufficient reason to suppose that his treatment is original. For example, Lucretius appeals to the so-called swerve of atoms, by which they shift by a minimal amount in their downward course at no determinate time or place (2.216–293), to account for free will and also for the initial interaction of atoms, which could not have collided had they maintained their natural downward motion at uniform speed. The latter argument seems particularly weak, since there is no beginning to the Epicurean universe, but it may nevertheless have been broached by Epicurus himself (cf. Fowler 2002: 301–309). Lucretius' account of the development of human civilization departs from parallel treatments known from other writers (Cole 1967), among other ways by inserting passages on the origin of religion and of language; again, this sequence may very well go back to Epicurus himself (Konstan 1973: 44–55; Campbell 2003: 15–18, 283–293). But Lucretius inclines to multiplying arguments—for

example, he offers 28 or 29 different proofs for the mortality of the soul (3.417–614)—and it is plausible that he may have added several to the common Epicurean stock, especially since only one or two are attested in Epicurus (Boyancé 1986: 141–142).

Epicurus discouraged active participation in politics because it produced the kinds of psychological tensions that his teachings were designed to eliminate. Lucretius, however, expresses a desire for peace (1.21–49) so that Memmius, the Roman aristocrat to whom he addresses his poem, will not have to engage in public service (perhaps an allusion to his praetorship in 58 BCE; Hutchinson (2001) sees a reference to the civil war that began in 49 BCE, and dates the poem to this period); in this way, Memmius will be free to dedicate himself to philosophy and achieve the tranquillity that Epicureanism held to be the goal of life. Epicureanism had a certain vogue among Roman nobles who had no intention of giving up their political status and activities—Julius Caesar himself is said to have been an adherent—and Lucretius was no doubt adapting his advice here to the outlook and social realities of his time (as did Philodemus). Whether this represents a change of principle or simply a tactical shift of rhetoric is difficult to say (cf. Fowler 1989).

Epicurus affirmed that sex should be avoided, since it has never done any good and is often harmful (Diogenes Laertius 10.118, fr. 62 Usener; VS 51); he also discouraged marriage (Diogenes Laertius 10.119 [textually corrupt], Epictetus *Discourses* 3.7.19–20, etc.). Lucretius' attitude toward love and sex is not inconsistent with Epicurus' own, though Epicurus' surviving writings are not so fervent on the subject, but he appears, at the end of Book IV (1278–1287), to introduce a newly positive view of matrimony and parenthood (Nussbaum 1994: 185–187; Brown 1987: 87–91, 118–122 sees no discrepancy here between Epicurus and Lucretius). Again, the fear of death, and of punishment in the afterlife, was the central cause of mental perturbation, according to Epicurus, and here too Lucretius is wholly in agreement; but his approach seems “more personal and emotional” than Epicurus' (Segal: 1990: 6; cf. 27–33, 51–54, 113; for the arguments, see Warren 2004); indeed, the Roman poet Statius spoke of the “burning passion of learned Lucretius” (*Silvae* 2.7.76). Further, Lucretius' anguished distress at the needless suffering of his fellow men (2.14–19) lends his poetry a proselytizing fervor, and this, like the shuddering pleasure (3.25–30) he experiences at the vision of a world without a hell, may seem to admit into Epicureanism a passion at odds with its goal of quietude.

Why did Lucretius end his poem with the grisly description of the plague that struck Athens in 429 BCE? Some scholars have supposed that it serves as a “final exam” in Lucretius' course on Epicureanism, testing whether readers have learned the lesson that death holds no terrors. This seems an adequate explanation (cf. Commauer 1957, Bright 1971), even without an explicit moral to point the message. The plague is an accelerated image of life itself, which invariably terminates in death. Since Epicurus taught that pleasure does not increase with length of time (*Principal Doctrines* 18–20; Lucretius 3.944–945, 1080–1081), a life cut short by illness is not cause for apprehension.

Lucretius' poem immediately became famous: Virgil (*Georgics* 2.490–492) wrote, “Blessed is he who is able to know the causes of things,” with obvious reference to Lucretius (*Ovid Amores* 1.15.23–24). Its rediscovery in the Renaissance inspired philosophical didactic poetry down through the eighteenth century, when the genre came to an end.

## LUKÁCS, GEORG

(1885–1971)

Georg (György) Lukács, the Hungarian Marxist philosopher and literary critic, was professor of aesthetics and the philosophy of culture at the University of Budapest from 1945 to 1956. Lukács was born in Budapest into a rich and eminent family (before he became a communist he wrote under the family name "von Lukács"). He took a doctorate in philosophy in Budapest (1906) and then studied under Georg Simmel at Berlin and under Max Weber at Heidelberg. Since Lukács was recognized as one of Europe's leading literary critics when he joined the Communist Party of Hungary in December 1918, he was offered the post of people's commissar for culture and education in the communist regime of Béla Kun (March–August 1919). After the fall of Kun, Lukács took refuge in Vienna, where he edited the review *Kommunismus* and carried on a struggle with Kun (exiled in Moscow) for control of the Hungarian underground movement. Publication in Berlin in 1923 of Lukács's collection of essays, *Geschichte und Klassenbewusstsein*, decided the issue in favor of Kun—for the book was denounced as "deviationist." Lukács was ousted from the central committee of the Communist Party and from the editorship of *Kommunismus* after publishing his "self-criticism." He took refuge in Russia when Adolf Hitler came to power and, after a further and more thorough act

of self-criticism, worked in the Institute of Philosophy of the Soviet Academy of Science from 1933 to 1944. Returning to Hungary, he became a member of parliament and professor of aesthetics. In 1956 Lukács was a leader of the Petofi circle, which played a role in the anti-Russian insurrection, and then minister for culture in the short-lived Imre Nagy government. After the defeat of the revolution, Lukács was deported to Romania, but he was allowed to return to Budapest in April 1957 to live in retirement and to devote himself to a monumental work on aesthetics, of which one volume was published, in Hungarian.

### AESTHETICS AND CRITICISM

Lukács's fame as one of the few philosophers produced by the Marxist movement rests on a book that he repudiated soon after its publication, *Geschichte und Klassenbewusstsein* (History and class consciousness). His later work—some thirty books and hundreds of articles—constitutes an attempt to found a Marxist aesthetic that could be used to criticize modernist, formalist, and experimental art in the name of socialist realism. This critical work entailed some confusion of literary criticism with political polemic, of which the following judgment on Kafka is typical: “no work of art based on *Angst* (anxiety) can avoid—objectively speaking—guilt by association with Hitlerism and the preparations for atomic war” (*The Meaning of Contemporary Realism*, p. 81). Lukács's influence as a critic has been intensely conservative, for he held that “realism is not one style among others; it is the basis of literature” (p. 48).

In his first aesthetic studies, *Die Seele und die Formen* (The soul and the forms) and *Die Theorie des Romans* (The theory of the novel), Lukács was still a neo-Kantian. He held that literature was the striving for expression of the irrational soul in and through an alien and hostile reality. He stressed the value of “inwardness” and the uselessness of society to the individual. These works have been claimed as among the sources of existentialism, but Lukács himself denounced them as “false and reactionary” upon his conversion to communism. Thereafter he contrasted Marxism, as a philosophy that integrated the individual in society, with all modern “philosophies of crisis and evasion,” and in particular with existentialism, which isolated men outside social and economic relations.

Lukács's stress on social relationships became the basis of his aesthetics. Form, he argued, should be determined by content (therefore abstract art and formalism are degenerate), and “there is no content of which Man

himself is not the focal point” (*The Meaning of Contemporary Realism*, p. 19). Since man exists only in a social and historical context, aesthetics inevitably is concerned with politics. If the subject of a work of art is man seen statically, then that work declines into subjectivism and allegory. Literature must be dynamic, setting characters in historical perspective in order that they might be shown as having direction, development, and motivation. For literature to be dynamic, the major historical movement of the day must be taken into account. In the twentieth century that movement was socialism. The only valid contemporary literary styles are socialist realism, which is practiced inside the socialist movement, and critical realism, which is practiced by authors sympathetic to socialism. Lukács's theories naturally entailed condemnation of most twentieth-century art, literature, and music, but they were fruitfully applied to the historical novel.

### SOCIAL AND HISTORICAL ANALYSIS

*Geschichte und Klassenbewusstsein*, the censored masterpiece of communist thought, became the classic text of Western Marxism as contrasted with Soviet orthodoxy. It led to a reevaluation of Marxism by setting it in a Hegelian context. Lukács was the first to see that Karl Marx's theory of history and even his economics could be read as an application of the Hegelian dialectic. He did this a decade before the discovery and publication of Marx's *Economic and Philosophic Manuscripts of 1844*, which amply confirmed his theory, at least with regard to the young Marx. Having meanwhile disowned his book, Lukács could not claim credit for that brilliant piece of philosophical reconstruction, but he later could show the profound similarity between the philosophies of G. W. F. Hegel and Marx (*Der junge Hegel*). His idealist reading of Marx clashed with the accepted Leninist version, and, since Lukács worsened his case in 1923 by revealing the influence of Georges Sorel and Rosa Luxemburg on his thought, his book was condemned with a ferocity unusual even in communist polemics.

Lukács had rejected Friedrich Engels's and V. I. Lenin's conception of the Marxist dialectic as a set of laws applying to nature, and he rejected too the notion that historical materialism deduces all social and moral life from the economic base. Historical materialism and the dialectic, he said, both mean the same thing, namely that in society subject and object are one. When men know (or enter into any other relation with) social entities—whether these are institutions or economic goods or another age's culture—the relation established is not the sort of relation they have with the natural objects studied by physical science. Social

entities are reified personality or alienated spirit, while men themselves are the product of historical forces. The knower and the known, subject and object, are moments of one entity, society, and their relations are necessarily ambiguous, two-way, or dialectical.

Marx had said, “As personal interests become autonomous in the shape of class interests, the personal conduct of the individual becomes reified and alienated and thereby becomes a thing apart from him, an independent force.” It is just such alienated forms of conduct that make up society. In the nineteenth century in particular, because of the development of industry, “material forces were saturated with spiritual life, while human existence was made animal, became a material force.” Marx meant, said Lukács, that spirit had become thing and things were steeped in spirit, so that history was a fabric of meanings-become-forces. This dialectical relation of subject and object was most marked in the case of the proletariat because the proletariat had been reduced by capitalism to labor, a mere economic commodity, and yet it could still take cognizance of itself as a commodity by acquiring class consciousness. Thereupon, it saw through the supposed natural laws of economics and revolutionized capitalism. “For this class, self-knowledge means at the same time correct knowledge of the whole of society ... so this class is at once subject and object of knowledge” (*Geschichte und Klassenbewusstsein*). Its self-knowledge is history knowing itself, and in that total clarity lies the promise of a return from alienation.

The difficulties raised by historical relativism—difficulties that had been seen by all who asked how Marxism alone among social opinions could escape being vitiated by its relation to a given class and age—can be resolved only by going right to the extreme of relativism. That is to say, historical materialism must be applied to itself until it is seen as relative and provisional. This means abandoning the notion of absolute truth and denying the complete opposition of true and false. History is a dialectical totality of knowers and things known, and every piece of culture, no matter how deformed by class position and historical situation, reflects that totality. Truth exists, but it exists only in the future tense; it is the presumptive totality to be attained by permanent self-criticism. “The criterion of truth is grasp of reality. But reality is not at all to be confounded with empirical being, what actually exists. Reality *is* not; it becomes—and not without the collaboration of thought” (*Geschichte und Klassenbewusstsein*). Rejecting the representative theory of knowledge made orthodox for Marxists by the examples of Engels and Lenin (the “concepts in our heads” are

“true images of reality”), Lukács held that truth is not something to be reflected but something to be made by us by collaborating with what is new and progressive in historical forces. The vague notion of a moving totality of things, of the whole of history, is essential to this “relativization of relativism.” Lukács did not clearly delineate this notion, but it evidently bears a resemblance to the Hegelian Absolute.

Lukács’s three main doctrines—the dialectical unity of subject and object in society; the promise of a return from alienation when society, through the proletariat, attains self-knowledge; and the notion of truth as a totality yet to be achieved—were attractive to some Western existentialists. Lukács complained that their “treacherous” use of his work was a “falsification of a book forgotten for good reason.” Another line of influence was through his former associate Karl Mannheim, who developed the relativization of all ideologies into the sociology of knowledge. Within the communist world, the only doctrine of Lukács’s censored book to enjoy some surreptitious authority was his “proof” of the communist intellectual’s duty to accept the Communist Party as the supreme expression of proletarian class consciousness and thus as endowed with the correct view of history. This doctrine Lukács himself practiced rigorously, even to the extent of repudiating his own major contribution to modern thought.

## ŁUKASIEWICZ, JAN (1878–1956)

Jan Łukasiewicz, the Polish philosopher and logician, was born in Lvov. After studying mathematics and philosophy at the University of Lvov he was graduated in 1902 with a PhD in philosophy. Łukasiewicz taught philosophy and logic first at Lvov and from 1915 at the University of Warsaw. In 1918 he interrupted academic work to accept a senior appointment in the Polish ministry of education in Ignacy Paderewski's cabinet. At the end of that year, however, he returned to the university and continued as professor of philosophy until September 1939. During that period he served twice as rector of the university (1922/1923 and 1931/1932). Toward the end of World War II Łukasiewicz left Warsaw. After some time in Münster and then in Brussels, in 1946 he accepted an invitation from the Irish government to go to Dublin as professor of mathematical logic at the Royal Irish Academy, an appointment that he held until his death.

Łukasiewicz held honorary degrees from the University of Münster and from Trinity College, Dublin. He was a member of the Polish Academy of Sciences in Kraków, the Society of Arts and Sciences in Lvov, and the Society of Arts and Sciences in Warsaw.

### EARLY WRITINGS

Łukasiewicz studied under Kazimierz Twardowski, who was occupied with conceptual analysis. The rigorous, clear thinking Twardowski advocated is easily recognizable in the first major essays published by Łukasiewicz. Of these works, *O zasadzie sprzeczności u Arystotelesa* (On the principle of contradiction in Aristotle; Kraków, 1910) was one of the most influential books in the early period of the twentieth-century logical and philosophical revival in Poland. It must have stood high in the author's own estimation, for in 1955 he began translating it into English. The main point of the book is that in Aristotle's work one can distinguish three forms of the principle of contradiction: ontological, logical, and psychological. The ontological principle of contradiction is that the same property cannot both belong and not belong to the same object in the same respect. The logical principle says that two contradictory propositions cannot both be true, and the psychological principle of contradiction holds that no one can, at the same time, entertain two beliefs to which there correspond two contradictory propositions. Łukasiewicz supported his findings with quotations from the writings of Aristotle and then examined the validity of Aristotle's argumentation. One chapter brought to the notice of Polish readers Bertrand Russell's antinomy concerning the class of all classes that are not members of themselves. The appendix contains an elementary exposition of the algebra of logic, as well as an original and interesting methodological classification of the ways of reasoning, a problem with which at least two of Łukasiewicz's early papers were concerned.

Łukasiewicz's writings published before 1918 suggest that until that time he was in quest of topics to which he could devote all his intellectual resources. He found such topics in the logic of propositions and in the logic of the ancient Greeks. From 1918 onward, deviations from this double line of research are few and of little significance.

### LOGIC OF PROPOSITIONS

**MANY-VALUED LOGICS.** The first and perhaps most important result obtained by Łukasiewicz in the logic of propositions was his discovery of three-valued logic in 1917. Our ordinary logic of propositions is two-valued, presupposing only two logical values, truth and falsity,

and it tacitly adheres to the principle of bivalence, that a propositional function holds of any propositional argument if it holds of the constant true proposition (usually symbolized by 1) and if it holds of the constant false proposition (represented by 2). If we use  $\delta$  as a functorial variable that, when followed by a propositional argument, forms a propositional expression, then we can express the principle of bivalence by saying “if  $\delta 1$  then if  $\delta 2$  then  $\delta p$ ,” where  $p$  is a propositional variable. The meaning of the logical constants forming such expressions as, for instance,  $Cpq$  (“if  $p$  then  $q$ ”),  $Kpq$  (“ $p$  and  $q$ ”),  $Apq$  (“ $p$  or  $q$ ”), and  $Np$  (“it is not the case that  $p$ ”) are, in two-valued logic, conveniently and adequately determined by means of the familiar two-valued truth tables:

$$\begin{aligned} C11 = C21 = C22 = 1 \\ C12 = 2 \\ K11 = 1 \\ K12 = K21 = K22 = 2 \\ A11 = A12 = A21 = 1 \\ A22 = 2 \\ N1 = 2 \\ N2 = 1 \end{aligned}$$

In three-valued logic the principle of bivalence does not hold. It is replaced by the principle of trivalence, which presupposes three logical values: the constant true proposition represented by 1, the constant false proposition by 3, and the constant “possible” proposition by 2. The principle then says “if  $\delta 1$  then if  $\delta 2$  then if  $\delta 3$  then  $\delta p$ .” As a consequence the meanings of implication, conjunction, alternation, and negation have to be readjusted, and the following three-valued truth tables suggest themselves for the purpose:

$$\begin{aligned} C11 = C21 = C22 = C31 = C32 = C33 = 1 \\ C12 = C23 = 2 \\ C13 = 3 \\ K11 = 1 \\ K12 = K21 = K22 = 2 \\ K13 = K23 = K31 = K32 = K33 = 3 \\ A11 = A12 = A13 = A21 = A31 = 1 \\ A22 = A23 = A32 = 2 \\ A33 = 3 \\ N1 = 3 \\ N2 = 2 \\ N3 = 1 \end{aligned}$$

In this logic alternation and conjunction can be defined as follows:  $Apq = CCpqq$ , and  $Kpq = NANpNq$ . All expressions involving only  $C$  and  $N$  and verified by the new truth tables can be constructed into a deductive system based on the axioms  $CpCqp$ ,  $CCpqCCqrCpr$ ,  $CCCpNppp$ ,

and  $CCNpNqCqp$ . This was shown by Mordchaj Wajsberg, who had studied logic under Łukasiewicz in Warsaw. Wajsberg’s system, however, does not enable us to define all the functors available in three-valued logic. In particular the functor  $T$ , whose truth table says that  $T1 = T2 = T3 = 2$ , cannot be defined in terms of  $C$  and  $N$ . Jerzy Słupecki, who had also been a pupil of Łukasiewicz, subsequently proved that by adding  $CTpNTp$  and  $CNTpTp$  to Wajsberg’s axioms we get a functionally complete system of three-valued logic, in which any functor can be defined.

The conception of three-valued logic was suggested to Łukasiewicz by certain passages in Aristotle. Purely formal considerations, such as those that led E. L. Post to comparable results, played a subordinate role in Łukasiewicz’s thinking. By setting up a system of three-valued logic Łukasiewicz hoped to accommodate the traditional laws of modal logic. He also hoped to overcome philosophical determinism, which he believed was entailed by the acceptance of the bivalence principle and which he had always found repulsive. Interestingly enough, he modified his views in the course of time and saw no incompatibility between indeterminism and two-valued logic.

Once a system of three-valued logic had been constructed, the possibility of four-valued, five-valued, ...,  $n$ -valued, and, finally, infinitely many-valued logics was obvious. At one time Łukasiewicz believed that the three-valued and the infinitely many-valued logics were of greater philosophical interest than any other many-valued logic, for they appeared to be the least arbitrary. In the end, however, he interpreted Aristotelian modal logic within the framework of a four-valued system.

The philosophical significance of the discovery of many-valued logic can be viewed in the following way: The laws of logic had long enjoyed a privileged status in comparison with the laws propounded by natural sciences. They had been variously described as a priori or analytic, the purpose of such descriptions being to point out that the laws of logic were not related to reality in the same way as were the laws of natural sciences, which had often been corrected or discarded in the light of new observations and experiments. The laws of logic appeared unchallengeable. By discovering many-valued logics Łukasiewicz showed that even at the highest level of generality—within the field of propositional logic—alternatives were possible. By adhering to the principle of bivalence or any other  $n$ -valence principle we run the same risk of misrepresenting reality that the scientist does when he offers any of his generalizations.

**THE CLASSICAL PROPOSITIONAL LOGIC.** Although Łukasiewicz contemplated the possibility that a nonclassical logic of propositions applied to reality, he made the classical propositional logic the principal subject of his research. He showed that the axiom systems of the calculus of propositions proposed by Frege, Russell, and Hilbert each contained a different redundant axiom. He proved that all the theses of the *CN*-calculus could be derived from the three mutually independent axioms *CCNppp*, *CpCNpq*, and *CCpqCCqrCpr*. He solved the problem of the shortest single axiom for the *E*-calculus and the *C*-calculus by showing that the *E*-calculus, whose only functor means “if and only if,” with  $E11 = E22 = 1$  and  $E12 = E21 = 2$  as its truth table, could be based on any of *EEpqEErqEpr*, *EEpqEEprErq*, and *EEpqEErpEqr* and on no shorter thesis and by proving that *CCCpqrCCrpCsp* is the shortest thesis strong enough to yield the *C*-calculus. The first single axiom for *CN*-calculus, consisting of 53 letters, was discovered by Alfred Tarski in 1925. It was soon followed by a series of successive simplifications devised by Łukasiewicz and by Bolesław Sobociński. The latest in this series is a 21-letter axiom, *CCCCCpqCNrNsrtCCtpCsp*, discovered by C. A. Meredith, Łukasiewicz’s Irish colleague. It is likely to prove to be the shortest possible axiom for the *CN*-calculus.

**CONSISTENCY, COMPLETENESS, AND INDEPENDENCE.** The metalogical study of deductive systems of the logic of propositions includes the study of consistency and completeness, and, in the case of systems based on several axioms, the mutual independence of the axioms has also to be considered. Independently of Post, Łukasiewicz developed both a method of proving consistency and one of proving the completeness of systems of the calculus of propositions. The completeness proof was based on the idea that if the system under consideration is not complete, there must be independent propositions, that is, propositions not derivable from the axioms of the system which on being adjoined to the axioms lead to no contradiction. If there are independent propositions, then there must be a shortest one among them. Following Łukasiewicz’s method, one tries to show that any proposition that is meaningful within the system either is derivable from the axioms or is longer than another proposition inferentially equivalent to it. This method dispenses with the concept of “normal expressions” and is very useful for proving weak completeness of partial systems. Mutual independence of theses is usually established by an appropriate reinterpretation of the constant terms occurring in them. Many such reinterpretations have been provided by Łukasiewicz’s many-valued logics.

The wealth of metalogical concepts and theorems worked out in Łukasiewicz’s logical seminar in Warsaw by Łukasiewicz himself, Tarski, Adolf Lindenbaum, Sobociński, and Wajsberg can best be seen in “Untersuchungen über den Aussagenkalkül,” which summarizes the results obtained there between 1920 and 1930.

**FUNCTORIAL CALCULUS.** In Dublin, Łukasiewicz became interested in a two-valued calculus of propositions involving functorial variables. Since he used only functorial variables requiring one propositional argument to form a propositional expression, his new calculus was only a part of what Stanisław Leśniewski had called protothetic. A very strong rule of substitution invented by Łukasiewicz, together with the usual substitution rules for propositional variables, allows us, for instance, to use a thesis of the form  $\delta\alpha$  to infer not only  $N\alpha$  but also such theses as *Cpα*, *Cαp*, *CαCNαp*, *Cαα*, and  $\alpha$ . By means of the new rule Łukasiewicz was able to base the calculus on the single axiom *CδC22Cδ2δp*. This axiom is identical with the principle of bivalence, because  $C22 = 1$ . Meredith succeeded in showing that Łukasiewicz’s axiom could be replaced by *Cδδ2δp* or by *CδpCδNpδq*. He was also able to prove completeness of the system.

#### ANCIENT LOGIC

Concurrently with his investigations of the logic of propositions Łukasiewicz was engaged in a thorough reappraisal of ancient logic. For centuries the logic of the Stoics had been regarded as a sort of appendage to the Aristotelian syllogistic. Łukasiewicz was the first to recognize in it a rudimentary logic of propositions. He found evidence that the main logical functions, such as implication, conjunction, exclusive disjunction, and negation, were known to the Stoics, who, following Philo of Megara, interpreted them as truth-functions, just as we do now. He pointed out that the Stoics, unlike Aristotle, had given their logic the form of schemata of valid inferences. Some of these schemata had been accepted axiomatically and others were rigorously derived from them. He subjected to severe but justified criticism the treatments of Stoic logic by such authorities as Carl Prantl, Eduard Zeller, and Victor Brochard. His preliminary investigations of medieval logic showed beyond doubt that in this field too there was room for fruitful research.

Equally successful was Łukasiewicz’s inquiry into Aristotle’s syllogistic. No sooner had he mastered the elements of symbolic logic for himself than he realized that the centuries-old traditional treatment of the Aristotelian

sylogistic called for revision. A new presentation of the logic of Aristotle was before long included in his regular lectures at the university and then published in *Elementy logiki matematycznej* (Elements of mathematical logic; Warsaw, 1929). Łukasiewicz completed a detailed monograph on the subject in Polish in the summer of 1939, but the manuscript and all printed copies were lost during the war. *Aristotle's Syllogistic* (1951) is a painstaking reconstruction undertaken by Łukasiewicz on his arrival in Dublin. The monograph can rightly be called revolutionary. In it Łukasiewicz argued that Aristotelian syllogisms are logical laws rather than schemata of valid inferences, as is taught in traditional textbooks. He put in historical perspective Aristotle's introduction of variables and, referring to a forgotten Greek scholium, gave a plausible explanation of the problem of the so-called Galenian figure. Among more formal results, we owe to Łukasiewicz the first modern axiomatization of syllogistic. The system he set up, based on the axioms *Aaa* ("every *a* is *a*"), *Iaa* ("some *a* is *a*"), *CKAbcAabAac*, and *CKAbcIbalac*, seems to be in perfect harmony with Aristotle's own treatment of the subject in the *Analytica Priora*. The axioms are jointly consistent and mutually independent. Moreover, Śłupecki has ingeniously solved the decision problem for the system.

## MODAL LOGIC

During the last few years of his life Łukasiewicz devoted much attention to modal logic. The results are presented in "A System of Modal Logic," and in the second edition of *Aristotle's Syllogistic* (1957) they serve as the basis for a critical examination of Aristotle's theory of modalities. Łukasiewicz's principal idea is that of "basic modal logic," obtained by adding to the classical calculus of propositions the axioms *CpMp* and *EMpMNNp* and by axiomatically rejecting *CMpp* and *Mp*. In these formulas *Mp* stands for "it is possible that *p*." According to Łukasiewicz any modal system must contain basic modal logic as a part. This condition is fulfilled by the four-valued modal system based on *CδpCδNpδq* and *CpMp* as the only axioms, with *CMpp* and *Mp* axiomatically rejected.

The logical symbolism used in this entry was worked out by Łukasiewicz in the early 1920s. It requires no punctuation signs, such as brackets or dots, which from the point of view of metalogical investigations is its greatest merit. At the same time Łukasiewicz worked out a simple and perspicuous method of setting out proofs in the logic of propositions and in syllogistic. Both his symbolism and his proof technique have been adopted by many logicians outside Poland.

Łukasiewicz was not only a resourceful and imaginative scholar but also a gifted and inspiring teacher. He was one of the founders, and the life and soul, of the Warsaw school of logic. Tarski, Lindenbaum, Stanisław Jaśkowski, Wajsberg, Father Jan Salamucha, Sobociński, Śłupecki, and Meredith have been his most outstanding pupils or collaborators.

## LULL, RAMÓN

(c. 1232–1316)

Ramón Lull (or Llull), the Franciscan philosopher, was born in Palma de Mallorca in the Balearic Islands. Lull received the education of a rich knight of the period, but was converted from dissipation to a devout life in about 1263. At that time Majorca was largely populated by Muslims, and Islam was still the great rival of Christianity. Lull resolved to dedicate himself to the conversion of Muslims and to seek martyrdom for their sake. After selling almost all his possessions and undertaking various pilgrimages, Lull spent nine years (c. 1265–1274) in Majorca, acquiring a profound knowledge of Arabic. In 1274 he had a vision that revealed to him the Principles on which his combinatory Art should be based. In 1275 James II of Majorca had Lull’s early writings examined for orthodoxy, and in 1276 James founded at Miramar in Majorca a monastery where

Franciscans could study Arabic and Lull’s Art to prepare for missions to Islam.

Lull appears to have divided his time in the years 1276–1287 between Miramar and Montpellier. In 1287 he began a series of journeys to the courts of kings and popes with the hope of persuading them to support his missionary, his reforming, and (later) his crusading projects. Lull placed his hopes principally in the papacy and in the kings of France and Aragon. His only apparent success was when the Council of Vienne (1311–1312) ordained the creation of chairs for Hebrew, Arabic, and “Chaldean” in five centers. Lull also undertook missions to Tunis (1293), to Bougie, in Algeria (1307), and again to Tunis (1314–1315). The traditional account of his martyrdom at Bougie cannot be sustained. He seems to have died in Majorca before March 25, 1316. He has been beatified by the Roman Catholic Church.

In the years 1288–1289, 1297–1299, 1309–1311, and probably 1306, Lull taught at the University of Paris; he also lectured publicly at Naples and Montpellier. Starting about 1272, he began to write incessantly. Some 240 of his approximately 290 works have survived. About 190 are only preserved in Latin (over 100 of these Latin works remaining unpublished until recently), although most of them were originally written in Catalan. Some of his works were originally written in Arabic; all these Arabic versions, however, are lost.

The desire to bring about the conversion of Muslims and Jews, as well as pagan Tartars, which inspired Lull’s ceaseless activity, also inspired his writings. The desire for the reunification of the church (divided into hostile East and West), and for the complete reunification of humankind, through Christianity, dominated Lull’s life. Lull’s Art and his whole philosophy are apologetic and Franciscan, aimed at conversion by peaceful persuasion. Lull’s advocacy of an armed crusade came late in his life; it was intended as subsidiary to missions. Lull’s life was a continual battle with Islam, not only in Spain and North Africa, but also, from 1298, in Paris, with the “Averroists.” In opposition to the “double-truth” theory imputed to such rationalist philosophers as Boethius of Dacia and Siger of Brabant, whose master was Aristotle as interpreted by Averroes, Lull sought to reestablish the unity of truth in philosophy and theology.

#### THE ARS COMBINATORIA

According to Lull, God, insofar as he can be known to men, consists of a series of divine attributes, or “Dignities,” which are also the absolute Principles of Lull’s Art. These Dignities (in the later works goodness, greatness,

eternity, power, wisdom, will, virtue, truth, glory) are the instruments of God's creative activity, the causes and archetypes of all created perfection. The essence of the Art does not (as is often thought) consist in demonstration, but in the metaphysical reduction of all created things to the Dignities, which are Principles of knowing as well as of Being, and in the comparison of particular things between themselves in the light of the Dignities, by means of such relative predicates as difference, agreement, contrariety, beginning, middle, end, majority, equality, minority. The absolute and relative predicates together form the self-evident principles common to all the sciences. These principles are combined in circular figures, where letters are substituted for their names (*B* = goodness, and so on).

Lull's treatises on different sciences (cosmology, physics, law, medicine, astronomy, geometry, logic, psychology) are applications of his general Art. Lull made continual efforts to simplify and popularize his Art, from the primitive version in the *Ars Magna* of about 1274 to the final *Ars Generalis Ultima* of 1308. The latter work and also the *Arbre de ciència* (*Arbor Scientiae*) of 1296 are more philosophical and less polemical in purpose than the original Art. A vast encyclopedia that found favor in the Renaissance, the *Arbre* is an attempt to classify all knowledge under a unified plan. Lull's influence was acknowledged by Gottfried Wilhelm Leibniz in the later philosopher's search for the *characteristica universalis* and *ars combinatoria*, which he hoped would make possible the deduction of all truths from basic concepts. Despite the clear analogies between the two systems, Leibniz only took over part of Lull's ideas, omitting Lull's original purpose of the Art as a means of converting infidels.

Lull was the first Christian philosopher of the Middle Ages to use a language other than Latin for his major works. Although he did not receive a university training, he enjoyed advantages denied to the great Scholastics. Of the three Mediterranean cultures of his time he knew Latin Christianity and Islam well and was aware of Greek Christianity. The basis of Lull's philosophy was Neoplatonic realism as transmitted through the Augustinian tradition: his exact use of John Scotus Erigena, Anselm, the Victorines, Bonaventure, and Roger Bacon is still debated. Lull was also familiar with the writings and beliefs of his Jewish and Muslim contemporaries.

All Lull's contemporaries shared a vision of the world based on Neoplatonism. The common belief in a hierarchy, or ladder, of creation, the theories of the four elements and of the spheres, the organization of reality by numerical-geometrical symbolism, the idea of man as a

microcosm, were all incorporated by Lull into his system. That excellent scholars have seen the inspiration of Lull's theory of the Dignities in the Muslim *hadras* or in the Jewish kabbalist *sefirot* (both terms for the divine attributes) shows that Lull's doctrine (although of Christian derivation) provided a reasonable basis for a dialogue with the Muslim and Jewish elites. Much the same is true of the doctrine of correlative principles, developed in Lull's later works, by which each attribute unfolds into a triad of interconnected principles, agent, patient, and the action itself, expressing the relations between God, a creature, and God's action. Lull probably took this doctrine from the Arabic writer al-Ghazālī, whose *Logic* he translated. It is more probable that Lull derived the idea for the figures that illustrate his Arts from contemporary Spanish kabbalists or from the circular figures of Isidore of Seville's well-known cosmological treatise *De Natura Rerum* than from Ibn al-'Arabī of Murcia, who has been suggested as his source.

Two of the most striking characteristics of Lull's philosophy and theology—his "rationalism" and his emphasis on the importance of action, shown in his constant appeals to Christian rules—owe their prominence in his system to its polemical inspiration. Lull's "necessary reasons," by which he proposed to "prove" the articles of faith, are reasons of congruence and analogy, not purely deductive principles. In opposition to Islamic scholastic theology (the *kalam*), which tried to demonstrate the Faith, Lull sought to show that the Muslim, who began with a belief in monotheism and the divine attributes, must proceed to Christianity. Despite the nondeductive character of his works, Lull's thought is deeply rational. Only seldom in his mystical writings does love eclipse the intellect or obscure its powers. For him, contemplation issues in action. *Blanquerna* and *Felix* are the first philosophical-social novels of Europe. In *Blanquerna* Lull sketched his plan for a *Pax Christiana*, a society of nations presided over by the papacy.

### **Bibliography**

Lull's Latin works may be found in a new critical edition, *Raimundi Lulli Opera latina* (vols. 1–5, Palma, 1959–1967; vols. 6–, Turnhout, Belgium, 1978–; at present 28 vols. have

appeared). Reprint editions have made two important earlier collections of Lull's Latin works available, one by the printer Zetzner, *Raimundus Lullus, Opera* (2 vols., Strasbourg, 1651; reprinted, Stuttgart, 1996), another by Ivo Salzinger, *Raymundi Lulli Opera omnia* (8 vols., Mainz, 1721–1742; reprinted, Frankfurt am Mainz, 1965). Dr. Viola Tenge-Wolf has undertaken the digitalization of the over 2,000 microfilms of Lullian manuscripts in the Raimundus-Lullus-Institut of the University of Freiburg im Breisgau.

Editions of Lull's Catalan works include *Obres de Ramon Lull* (21 vols., Palma and Barcelona, 1906–1950) and the supplementary *Nova edició de les obres de Ramon Lull* (Palma, 1990–, in progress). A handy edition is *Ramon Lull, Obres essencials* (2 vols., Barcelona, 1957–1960). *Selected Works of Ramon Lull* have been translated into English by Anthony Bonner (2 vols., Princeton, NJ, 1985; who has also published the Catalan texts in 2 vols., Palma, 1989; these volumes include an important chronological catalog of Lull's Works, pp. 1257–1304 in the English edition). A complete catalog of the printed editions of Lull's works has been published by Elies Rogent and Estanislau Duran, *Bibliografia de les impressions lul·lianes* (Barcelona, 1927).

For studies of Lull's life and work see Tomás y Joaquín Carreras y Artau, *Historia de la filosofía española*, vol. 1 (Madrid: Real Academia de Ciencias Exactas, Físicas y Naturales, 1939) pp. 231–640; vol. 2 (Madrid, 1943) contains a valuable history of Lullism. For an English biography of Lull see E. Allison Peers, *Ramon Lull: A Biography* (London, 1929), which should now be supplemented by Jocelyn N. Hillgarth, *Ramon Lull and Lullism in 14th-Century France* (Oxford, 1971). A general introduction to Lull's worldview is provided by Robert Pring-Mill, *El microcosmos lul·lià* (Palma: Editorial Moll, 1962; in German, Stuttgart, 2001). For the intellectual and religious context in which Lull's Art developed see Harvey J. Hames, *The Art of Conversion: Christianity and Kabbalah in the 13th Century* (Leiden, 2000). For Lull's influence in the sixteenth century see Frances A. Yates, *Lull & Bruno: Collected Essays* (2 vols., London, 1982).

Rudolf Brummer has published a *Bibliographia lulliana: Ramon-Llull-Schriftum, 1870–1973* (Hildesheim, 1976); which has been supplemented for the years 1974–1984 by Marcel Salleras i Carolà in *Randa* (Barcelona) 19 (1986): 153–198. Current bibliography may also be found in the review *Estudios lulianos* (now *Studia lulliana*), published in Palma since 1957.

## LUNACHARSKII, ANATOLII VASIL'EVICH

(1875–1933)

Anatolii Vasil'evich Lunacharskii (also Lunacharsky), the Marxist philosopher and literary critic and Soviet administrator, joined the Russian Social Democratic Party in Kiev in 1892. Because of his political activities as a secondary school student, he was denied admission to Russian universities. He attended lectures at Kiev University and at the University of Zürich, where in 1894–1895 he studied under Richard Avenarius, who converted him to empiriocriticism. Lunacharskii returned to Moscow in 1897, was exiled to Vologda (1899–1902), and spent several years in western Europe between 1904 and 1917. He was the first Soviet people's commissar for education (1917–1929).

Lunacharskii's contributions to philosophy are concentrated in value theory (which he rather misleadingly called biological aesthetics), ethics, and philosophy of religion. Like the positivists, he denied the adjudicability of value disputes. "In order to show," he wrote, "that a given type of valuation is in its very root worse than another type, the scientist must oppose one criterion to another, but the choice between criteria is a matter of taste, not knowledge" ("K voprosu ob otsenke" [On the question of valuation], 1904, reprinted in *Etiudy*, Moscow, 1922, p. 55).

In ethics and social philosophy Lunacharskii was a "Nietzschean Marxist." He called himself an aesthetic amoralist and rejected the categories of duty and obligation, stressing instead free creative activity, the "artistic" shaping of ends and ideals. "Nietzsche," he declared, "and all the other critics of the morality of duty, have defended the autonomy of the individual person, the individual's right to be guided in his life solely by his own desires" ("Problemy idealizma'..." [Problems of idealism...] in *Obrazovanie* 12 [2] [1903]: 133).

Lunacharskii called his individualism macropsychic, or "broad-souled," to distinguish it from "narrow-souled" (micropsychic) individualism. It approached collectivism in its stress on the historical community of the creators of culture.

Traditional religious attitudes and institutions, according to Lunacharskii, could and should be given a new, socialist content. The old religions—supernatural, authoritarian, "antiscientific"—must be replaced by a new religion that will be humanistic, libertarian, and "scientific." The building of socialism and the shap-

ing of the high human culture of the future will be a building of God (*bogostroitel'stvo*). "Scientific socialism," Lunacharskii declared, "is the most religious of all religions, and the true Social Democrat is the most deeply religious of men" ("Budushchee religii" [The future of religion], p. 23). The religion of God-building will soften the sting of mortality by intensifying man's awareness of the "universal connectedness of life, of the *all-life* which triumphs even in death" ("Eshche o teatre i sotsializme [Once more on the theater and socialism], in *Vershiny*, Vol. I, 1909, p. 213). The new religion, imparting a sense of "joyous union with the triumphant future of our species," will be full of drama and passion, having its own "saints and martyrs." It will be worthy to stand beside medieval Christianity in the "universal arsenal of art and inspiration" (*R. Avenarius: Kritika chistogo opyta v populiarnom izlozhenii A. Lunacharskovo* [R. Avenarius: *Critique of Pure Experience*, Expounded for the layman by A. Lunacharskii], Moscow, 1905, p. 154).

## LUTHER, MARTIN

(1483–1546)

Martin Luther, the German theologian and leader of the Protestant Reformation, was born at Eisleben, Saxony. His father came of peasant stock, but established himself during Luther's boyhood as a successful copper miner in Mansfeld. From 1501 to 1505 Luther attended the Uni-

versity of Erfurt, and then, at his father's wish, he began the study of law; but a spiritual crisis, occasioned by a violent thunderstorm, induced him to enter the Erfurt monastery of the Augustinian Friars. Despite conscientious and even overscrupulous attention to his monastic duties, Luther was obsessed by dread of God's anger, and his superior tried to direct the young man's energies and undoubted ability into a scholar's calling. From 1512 he was biblical professor at the new University of Wittenberg, a position he held, despite interruptions, until his death.

### THEOLOGICAL DEVELOPMENT

Three stages may be distinguished in Luther's theological development. Between 1512 and 1517, and probably (in the judgment of most scholars) not later than 1515, his biblical studies led to a theological reorientation, at the center of which was an interpretation of the justice of God in Romans 1:17, not as a divine attribute expressed in punishment and reward, but as the activity by which God makes men just ("justifies" them). This justice of God is identical with His grace: It is not conditional upon human merit, but is received by faith alone (faith itself being a work of God in man). The working out of this basic insight made Luther increasingly critical of late scholastic theology and of ecclesiastical abuses. The appearance of the Ninety-five Theses on indulgences (1517), although they were not intended as "un-Catholic," was interpreted by Luther's opponents as ecclesiastically disloyal and subversive. Luther had, indeed, touched on the heart of medieval piety, the sacramental system, since indulgences belonged to the sacrament of penance.

The second period of Luther's development, from 1517 to 1521, was marked by his struggle with the Roman authorities, during which he abandoned the theory of papal, and even ecclesiastical, infallibility. In his *Babylonian Captivity* (1520), he made a systematic attack on the sacramental system, reinterpreting a sacrament as, like preaching, a form of the divine Word, by which God offers man His justice and creates the response of faith. The "church" is defined, not in terms of hierarchical authority, but as the communion of those whom Christ rules with His Word, all of whom are priests. Luther's basic insight into the character of Christian justice (or righteousness) was sharpened during this same period by greater precision in the distinction (already made before 1517) between Law and Gospel. The Law of God can only demand and condemn; it cannot be used by man as a means of self-salvation through strict obedience. The

security of man before God lies solely in the Gospel, with its word of free forgiveness.

During the third period, after 1521, Luther's attention was turned to rival reformers who departed from him on particular points, or who demanded a more radical transformation of the church than he was prepared to countenance. Many of the radicals sought to establish communities in which the ethic of the Sermon on the Mount should be the sole rule of social conduct. Against them, Luther again argued for the distinction between Law and Gospel. Just as it is wrong to place Law between God and the conscience, so it is wrong to regulate society by the Gospel. The conscience needs the gospel of forgiveness, but society can only be founded upon the law of retributive justice (though Law should always be the agency of love). The two "realms," or "kingdoms," of Heaven and Earth—that is, the two ways in which God rules over the world of men—are not to be confused.

In his controversy with the humanist leader Desiderius Erasmus, which also belongs within the third stage of his development, Luther again believed himself to be fighting for the gospel of forgiveness. He acknowledged that Erasmus's selection of the theme to be debated—namely, the freedom of the will—came closer to the decisive issue than did the questions of the papacy, purgatory, and indulgences. Luther was not, of course, interested in the psychology of human action as such but in preserving his original insight into the agency of divine grace. He acknowledged a measure of human freedom in matters that do not concern salvation, but refused to make salvation depend at any point on the inherent possibilities of human nature. He therefore located the power of man's decision for God in the Gospel itself, and in the secret influence of the Holy Spirit. For Luther, this did not mean that God acts coercively, thereby doing violence to man's will, but that God is sovereign over the will and can direct it to His ends. Man acts voluntarily (that is, as he wills) even in those matters that concern his salvation. But the will itself is controlled by God. It cannot change itself from an evil to a good will: It must *be* changed under the influence of the Spirit.

Luther was not, of course, a philosopher. He was primarily a theologian, obliged by circumstances to become a rebel and a reformer. Indeed, it is often supposed that he was an implacable enemy of philosophy, and to this problem the remainder of this article will be devoted. It will appear how closely Luther's views on reason and philosophy are related to the central theological concerns (Christian justice and the two realms of Heaven and Earth) that have been sketched above.

## ATTITUDE TOWARD PHILOSOPHY

It is not hard to document from Luther's own writings the common accusation that he was an anti-intellectualist. His description of reason as "the Devil's Whore" is well known, and he recommended that the faithful sacrifice reason, or slay it, as the enemy of God. Many have seen in this apparent antirationalism evidence of Luther's Ockhamist heritage, but this is an oversimplification of an intricate historical problem. Luther did not invariably decry reason. In his celebrated appearance before the Diet of Worms (1521) he seemed to appeal to a double norm—Scripture and reason. (He refused to recant unless convinced by "the testimonies of Scripture or by evident reason.") And sometimes he showered extravagant praise upon reason as the greatest of God's gifts, as the "inventress and mistress of all the arts, of medicine and law, of whatever wisdom, power, virtue and glory men possess in this life."

Luther accepted the traditional view that reason set man apart from the brute beasts and gave him dominion over the world. Clearly, the problem is to explain, not an extreme one-sidedness, but a strange ambivalence. And the appeal to Luther's alleged Ockhamist heritage cannot help to explain his attitude until the Ockhamist understanding of reason is itself clarified and the extent of Luther's overall dependence upon nominalism is carefully assessed. The persistent image of nominalist theology as antirational and un-Catholic requires reconsideration in the light of recent studies, and verbal echoes of nominalism in Luther's writing may prove of no great significance. In any case, the primary historical task is to examine Luther's actual utterances on reason and philosophy and to view them in relation to the inner structure of his thought.

**THE CONCEPT OF REASON.** The apparent ambiguities in Luther's utterances on reason can be explained, in part, by his fundamental distinction between the two realms of human existence. At one and the same time, man lives toward God in the Heavenly Kingdom and toward his natural and social environments in the Earthly Kingdom. Luther judges human reason to be an adequate instrument for dealing with earthly affairs, that is, the maintaining of physical subsistence (*oeconomia*) and the regulation of life in society (*politia*). In this realm, reason is legitimately exercised and affords the only light man needs. But in spiritual affairs the situation is quite different. Reason has no understanding of what it is that commends a man to God. Therefore God has given His Word (in the Scriptures), and reliance upon reason could, in

this realm, only be perverse and presumptuous. The way of salvation could never have been thought out by rational enquiry, for all God's works and words transcend reason. The Word of God is apprehended, not by reason, but by faith.

This does not mean that, for Luther, reason must be totally excluded from theology. He allowed for the possibility of taming reason's presumptuousness. It then becomes the handmaid of faith. Luther spoke of reason as illumined by faith, regenerated, or born anew. Sometimes the notion of regenerate reason tended to coalesce with the notion of faith itself. But generally, Luther seemed to think of regenerate reason as the human capacity for orderly thought being exercised upon material provided by the Word. Perhaps this is what he meant by the correlation of Scripture and reason in his answer before the Diet of Worms: He was willing to be persuaded either by direct biblical citations or by plain inferences from them. He certainly did not mean to set reason beside Scripture as an independent and supplementary source of theological knowledge.

The doctrine of the two realms provides, then, the framework for a threefold distinction by means of which Luther's various utterances on reason may, for the most part, be harmonized. We have to distinguish between natural reason, ruling within its own domain (the Earthly Kingdom); presumptuous reason, encroaching on the domain of faith (the Heavenly Kingdom); and regenerate reason, serving faith in subjection to the Word of God. Luther does not represent an anti-intellectualist dismissal of disciplined thought; he tries to formulate a theological critique of reason, in which the boundary lines of reason's competence are sharply drawn. Only in the second of these three contexts does reason appear as "the Devil's Whore." In the first it is the greatest of God's gifts; in the third, an excellent instrument of godliness.

It is necessary, however, to carry the analysis further and to show that Luther's invective against reason is focused upon a quite specific blunder that reason makes when it trespasses, unregenerate, upon the domain of faith. It then appears that the *sacrificium intellectus* for which he calls cannot be understood simply as an epistemological doctrine, but rests upon a more strictly theological (or soteriological) concern. For in many passages from his writings, what Luther meant to express by his colorful invective against reason, was his constant astonishment at the heart of his own gospel: the unconditioned character of God's grace. Reason must be "put to death" because it cannot comprehend the miracle of divine forgiveness, and therefore stands in the way of man's receiv-

ing the justice of God. Reason became identified in Luther's mind with the religious attitude of the natural (that is, unregenerate) man, who can conceive only of a strictly legalistic relationship to God. *Ratio* became virtually synonymous with a definite *opinio*, and it is by no means accidental that the two words can be found side by side in several passages. Nor, of course, was this usage wholly eccentric, since Lewis and Short's Latin-English dictionary gives as one of the meanings of *ratio* a "view or opinion resting upon reasonable grounds." And Luther fully acknowledged a certain reasonableness about the assumption that a just God must require "good works" as the precondition of communion with Him.

Consequently, the proclamation of an unconditioned grace—which demands nothing, save the acceptance of faith—can be greeted by reason only with incredulity. What needs to be "sacrificed," therefore, is not human rationality, without qualification, but rather the legalistic mentality of the natural man. As Luther put it, grace must "take us out of ourselves," and we must learn to "rise above reason." In short, Luther's concept of reason (at least, when his remarks about it are pejorative) is not formal, but material. *Ratio* is a concrete attitude rather than the faculty or structure of reasoning. When the natural man turns his thoughts to religion, he carries over into the Heavenly Kingdom presuppositions that, however appropriate in dealing with his social existence in the Earthly Kingdom, no longer apply. For the Kingdom of Christ is a realm, not of law, but of grace (*das Reich der Gnaden*).

THE CONCEPT OF PHILOSOPHY. Because Luther's views on reason are set in a theological context, they are not always directly relevant to the problem of faith and reason as the philosopher normally understands it. But Luther's standpoint certainly had consequences for the philosophy of religion, and more particularly for the problem of a natural theology. For Luther there could be no question of treating the truths of reason as a kind of foundation for the truths of revelation. The continuity between nature and grace, as presented in the classical scholastic scheme, is broken. There is no rational preamble to faith, because reason is not a neutral instrument for the discovery of objective truths; it is misled by its own bias and even corrupted by sin—that is, by the egocentricity of the unredeemed man. For man in sin actually prefers a God of law, upon whom he can establish a claim. Revelation does not confirm or supplement reason: It stands in contradiction to reason, until the natural man is "born anew." The religion of reason is not merely insufficient or imperfect, but perverted and erroneous. Luther

does not deny that a limited knowledge of God is available to reason; but the egocentricity of man in sin is a fatal defect, productive of idolatry and superstition. Reason makes God as it wills Him to be, and turns this natural knowledge into idolatry. The god of reason is a false God.

In general, Luther's direct statements about philosophy closely parallel his judgment on reason. As early as the Lectures on Romans (1515–1516) he had come to see his mission as a protest against philosophy, and his writings are interspersed with abusive descriptions of Aristotle ("the stinking philosopher," "the clown of the High Schools," "the blind pagan," etc.). Thomas Aquinas, who symbolized the attempt to synthesize Aristotle and the Christian faith, is treated with similar disrespect. Nevertheless, Luther could on occasion speak deferentially of philosophy and even of Aristotle. He approved of much that the Greek philosopher had written on social ethics and ranked Cicero's ethics even higher. He freely acknowledged that the Christian had much to learn from philosophy in this area.

The key to Luther's ambivalence lies, as with his concept of reason, in the distinction between the two realms. The boundaries are carefully drawn. Philosophy is an excellent thing in its own place, but if philosophical categories are transferred into theology, the result can only be confusion. Luther saw philosophy as tied to the empirical world (the Earthly Kingdom), whereas theology is concerned with things unseen (the Heavenly Kingdom). He was not, strictly speaking, hostile to Aristotle, but to the theological application of Aristotelianism by the Schoolmen. Of course, some of the Greek philosopher's doctrines already had a theological bearing (for example, on the immortality of the soul and on divine Providence). These Luther dismissed. But he approved Aristotle's treatises on the sermonic arts (logic and rhetoric) and, with qualifications, those on moral philosophy.

Perhaps the most important illustration of Luther's attitude toward Aristotle is afforded by his discussions of moral "habit" (Latin, *habitus*; Greek, *hexis*). In the *Nicomachean Ethics*, Aristotle taught that "we become just by performing just acts." Luther's opponents apparently gave this doctrine a theological application: That is, it was used to support the claim that good works must precede justification. In assailing the concept of habit, Luther is not offering a philosophical critique of Aristotle, but rejecting the theological application of Aristotelian doctrines. A philosophical theory belongs within the Earthly Kingdom. The Schoolmen mix the kingdoms.

COMPARISON WITH NOMINALISM. Luther's distinction between two spheres of knowledge (philosophy and theology) and between two organs of knowing (reason and faith) certainly invites comparison with late medieval Scholasticism. There is perhaps a *prima facie* probability that Luther's views on reason and philosophy were under the influence of the nominalists. His main instructors at Erfurt were nominalists, and it is noteworthy that Luther could speak of William of Ockham with apparent respect, even calling him "my dear master." He adopted the nominalist view of universals, and he explicitly owned a debt to the nominalist Pierre d'Ailly in the doctrine of the Real Presence. Other possible debts have been argued with more or less plausibility, although it can hardly be denied that Luther left nothing unchanged that he borrowed from others. At least the possibility is open that at the outset the sharp distinction between faith and reason may have been suggested to him by his familiarity with the Ockhamist school.

It may be that the separation of theology and philosophy in Luther is to be explained partly by his acceptance, along with the nominalists, of a strict Aristotelian concept of science. Against Thomas, Luther agreed with the nominalists that since theology rests upon assertions of faith, it cannot be classed as a science. Philosophy (which is the sum total of rational knowledge and embraces the various sciences) deals with the visible world, which is accessible to reason. Theology deals with an invisible world, accessible only to faith. Such points of agreement between Luther and the Ockhamists cannot, however, conceal the sharp differences between them. Quite apart from the fact that Luther developed a divergent concept of faith, his standpoint represents a different basic concern. The interest of the Ockhamists in the problem of faith and reason was primarily epistemological. Hence they devoted considerable thought to relating the cognition of reason to the cognition of faith, and sought in various ways to bridge the gap that they had apparently cut between the two. Nominalist theologians tried to comprehend both faith and reason within a single epistemological scheme. They regarded theological propositions (once established) as subject to rational scrutiny, believed that merely probable arguments could lead to faith when the will cooperates, and argued that revelation was given precisely to those who made maximum use of their rational capacities. Luther, on the other hand, was not interested in narrowing the epistemological gap. On the contrary, the problem for him was graver, because he allowed for the corruption of reason by human sinfulness. Hence his restrictions on reason, even if they were built on a nominalist view of science, go beyond it in

what is primarily a theological, rather than philosophical, concern.

**THE THEORY OF "DOUBLE TRUTH."** The nominalist distinction between the spheres of faith and of reason has commonly been interpreted as though there were a disharmony, or even a contradiction, between them. Indeed, the doctrine of a "double truth"—that is, that a proposition may be true in theology, but false in philosophy—has been attributed to the nominalist theologian Robert Holkot. Properly speaking, double truth seems never to have been a consciously adopted "doctrine" in the Middle Ages, but rather an accusation leveled against theological opponents. There does not seem to be adequate reason to attribute it to any of the nominalists. True, they admitted some apparent conflicts, for instance, that the Christian belief in the Trinity, when formulated according to the rules of Aristotelian logic, contained real contradictions. But this simply prompted the quest for a higher logic, which could embrace both the traditional Aristotelian rules and also the rules appropriate to the peculiarities of theological truth.

A doctrine of double truth could, however, be attributed to Luther with some plausibility, since he explicitly said that "the same thing is not true in different disciplines" (*Disputation on the Proposition, "The Word became flesh,"* 1539). But Luther himself did not use the expression "double truth," and a close inspection of his argument suggests that, despite appearances, he really had a rather different thesis in mind. What he was trying to defend might better be called a "theory of multiple meaning." Neither "twofold" nor "truth" quite pinpoints Luther's thesis, and perhaps even "manifold truth" (Bengt Hägglund's phrase) is still misleading. If we may paraphrase the drift of Luther's argument, he seems to be saying that *homo loquens* reflects and communicates, not by means of a single, universally valid language, but by means of several languages, which are relative to particular disciplines or areas of experience. Hence the meaning of a term or proposition is determined by the area of discourse: If transferred from one area of discourse to another, a term may acquire a different meaning, or have no meaning at all. To use Luther's own examples, it makes no sense to ask the weight of a line or the length of a pound.

Whether correct or not, this argument bears a close resemblance to ideas that played an important role in twentieth-century linguistic philosophy, and is therefore not likely to be dismissed as obscurantism or anti-intellectualism. Unfortunately, Luther's argument is not

developed with adequate precision, either in this *Disputation* or elsewhere. But it is not an isolated argument. The basic thesis—that the same form of words may have different meanings in different disciplines—underlies many of his remarks about the relation of ethics and theology. For example, the proposition that fallen man can do no good is fundamental to Luther's teaching on justification. But Luther admits that this is true only in a theological, not in an ethical, context, for in each context the word *good* means something different. This is, perhaps, a statement of double truth, but only because it rests on a theory of multiple meaning. Thus interpreted, "double truth" does not imply contradiction, but excludes it, since real contradiction is possible only within a single realm of discourse. As Luther put it in the first thesis of the *Disputation*: "Although we must hold to the saying, 'One truth agrees with another,' nevertheless the same thing is not true in different disciplines."

## Bibliography

### WORKS BY LUTHER

The definitive German edition of Luther's writings in Latin and German is *D. Martin Luthers Werke. Kritische Gesamtausgabe* (Weimar, 1883–). The most comprehensive English version is *Luther's Works: American Edition*, edited by Jaroslav Pelikan and Helmut T. Lehmann (St. Louis: Concordia, 1955–1986, 55 vols.).

### WORKS ON LUTHER

#### Recent Studies

Three twentieth-century books dealing with Luther's views on reason and philosophy are Bengt Hägglund, *Theologie und Philosophie bei Luther und in der occamistischen Tradition. Luthers Stellung zur Theorie von der doppelten Wahrheit* (Lund: Gleerup, 1955); Bernhard Lohse, *Ratio und Fides. Eine Untersuchung über die Ratio in der Theologie Luthers* (Göttingen: Vandenhoeck and Ruprecht, 1958); and B. A. Gerrish, *Grace and Reason: A Study in the Theology of Luther* (Oxford: Clarendon Press, 1962). One of the most adequate treatments of Luther's intellectual background is still Otto Scheel, *Martin Luther, Vom Katholizismus zur Reformation*, Vol. I, 1st ed. (Tübingen: n.p., 1916); Vol. II, 3rd and 4th eds. (Tübingen, 1930).

#### Luther and Nominalism

The literature dealing with the general question of Luther's relation to nominalism is sketched in Leif Grane, *Contra Gabrielem. Luthers Auseinandersetzung mit Gabriel Biel in der Disputatio contra scholasticam theologiam 1517* (Copenhagen: Gyldendal, 1962). Grane's own discussion is focused on the theological rather than on the philosophical

points, as is the work of Reinhard Schwarz, *Fides, Spes und Caritas beim jungen Luther unter besonderer Berücksichtigung der mittelalterlichen Tradition* (Berlin: De Gruyter, 1962). The work of Heiko Augustus Oberman in *The Harvest of Medieval Theology: Gabriel Biel and Late Medieval Nominalism* (Cambridge, MA: Harvard University Press, 1963) is intended to lay the foundations for a study of nominalism in relation to the beginnings of Reformation theology.

#### **Additional Background**

For the wider aspects of Luther's thought, see the articles and bibliographies under "Luther" in *Die Religion in Geschichte und Gegenwart*, 3rd ed. (Tübingen, 1960), Vol. IV, pp. 480–523, which may be brought up to date by the annual listings of the *Luther-Jahrbuch*.

**B. A. Gerrish (1967)**

## LUTHER, MARTIN [ADDENDUM]

The renaissance of Luther studies enjoyed by the twentieth century continues apace. The massive critical, or Weimar (WA), edition of his work has recently been finished in 127 volumes. Important interpretive works have been published and discussed, including a major three-volume theological biography by Martin Brecht (1985–1993). Despite, or perhaps because of, this wide variety of scholarship, even such a seemingly simple theme as faith and philosophy in Luther has no consensus among interpreters.

There has been a welcome re-reception of Luther by Catholic scholars, starting with Joseph Lortz in 1939. A significant ecumenical consensus was reached by evangelical and Catholic scholars on the occasion of Luther's 500th birthday, noting that Vatican II reflects many of the concerns Luther addressed in his own witness to the gospel. This larger ecumenical interpretation has led to studies that appreciate the more Catholic side of Luther as a reformer and teacher of the whole church, not excluding his doctrine of justification by faith.

The importance of understanding each of Luther's distinct writings within its own historical, institutional, and rhetorical context is a major virtue of modern Luther studies. Equally important is an understanding of Luther against his late-medieval background. This has led to a new appreciation for Luther's dependence upon nominalism, especially the school of Ockham (*via moderna*). Recent scholarship has documented Luther's use of philosophy and logic in his theological arguments, including elements of nominalist logic from Gabriel Biel and Pierre d'Ailly. Luther's strong language against reason, philoso-

phy, and Aristotle were aimed at a particular target, namely, the scholastic theology of an earlier age (*via antiqua*). Unlike the Neo-Kantian and existentialist interpretations of Luther, recent scholars have argued that Luther nowhere has a complete condemnation of metaphysics or ontology in theological understanding. Indeed, some scholars now find a kind of ontology in Luther's conception of salvation.

At the heart of contemporary controversy surrounding the interpretation of Luther is the so-called Finnish school, including the work of Tuomo Mannermaa (2005). On this view, Luther taught that Christ is really and personally present in faith for the Christian. Justification is not simply alien, external, and forensic but also relational and ontological. The relationship between human being and the divine Trinity is understood not only as an external declaration of a righteousness that is not our own but also as the growth of Christ-like love through faith. The similarities of Luther's view thus understood, and the Eastern Orthodox notion of *theosis* (divinization), has been a key point in the Finnish school. Even given this new understanding, Luther consistently rejected philosophical ontology and scholastic metaphysics. When discussing the presence of Christ, he refused to go beyond what was promised in the Word. "But how He is present—this is beyond our thought; for there is darkness." (*Lectures on Galatians* [1535], WA 40/1:229). Thus, Luther appears to have used philosophical tools and concepts but refused to build theology on philosophical systems. For Luther, theology is grounded on the Word of God, not philosophical speculation.

## LU XIANGSHAN

(1139–1193)

Lu Xiangshan, also called Lu Jiuyuan, started the idealistic trend in Chinese philosophy. He emphasized the supremacy and self-sufficiency of the mind, contrary to his contemporary Zhu Xi, who stressed the need to discover reason and to acquire knowledge of the external world. He lived in the province of Jiangsi. His father was a respected member of the gentry, and from his early youth Lu was able to devote himself to the study of Confucius and Mencius. He disagreed with the views of the scholar Cheng Yi of the Northern Sung Dynasty.

Lu Xiangshan is known for the following:

When a sage arises in the East,  
The mind is the same,  
And so is reason.

The same is true of sages born in the West, the North, and the South and of those born thousands of generations earlier and later. What he meant is that mind is the same the world over and at all times. From this fundamental thesis he drew the conclusions that mind has priority over all things and that reason has a universal validity.

Yang Jian, a disciple of Lu and a submagistrate, asked him, “What is the Original Mind?” Lu quoted the words of Mencius concerning the four kinds of virtues—*ren* (benevolence), *yi* (righteousness), *li* (decency), and *zhi* (knowledge)—and said, “This is the Original Mind.” But Yang failed to understand what Lu meant. Some time after, a lawsuit was brought by a salesman of fans for Yang’s verdict, and Yang again came to Lu with the same question. Lu answered, “In trying the case of the fan salesman, you were able to judge right that which is right and wrong that which is wrong. This is the Original Mind.” Yang was then convinced that the mind is self-conscious and self-evident.

Lu was firmly convinced that there is a universal mind and a universal rationality: “What fills the universe is rationality; what the scholars should search for is to render the idea of rationality clear to all. The scope of rationality is boundless.” He also quoted Cheng Hao’s

words, “The universe is great; yet it has its limitation,” and then inferred from them that what is more perfect than the universe is rationality.

Again he said: “Rationality in the universe is so evident that it is never concealed. The greatness of the universe lies in the existence of rationality which is an order publicly followed and without partiality. Man with Heaven and Earth constitutes the triad. Why should one be egocentric and not in conformity with rationality?” Lu’s main idea is that since each one has a mind and reason is inherent in mind, mind is reason. Furthermore, he says: “What is the happening of the universe is the ought-to-do-duty of man; what is the ought-to-do-duty is the happening of the universe.”

## LYING

Lying may be defined as the making of a declarative statement to another person that one believes to be false, with the intention that the other person believe that statement to be true, and the intention that the person believe that one believes that statement to be true. Lying may be distinguished from other forms of intentional deception insofar as it involves the use of conventional signs arranged to make a statement. Intentional deception using natural signs, such as fake smiling, shamming a limp, or wearing a disguise, does not count as lying. Intentional deception using conventional signs that are neither spoken nor written, such as deceptively nodding

one's head, sending deceptive smoke signals, or deceptive signaling by semaphore, does count as lying, at least insofar as one is making a statement.

Lying requires that a statement be made; hence that form of deception that consists in withholding a statement from another person with the intention that the other person infer a believed falsehood—sometimes called a lie of omission or a concealment lie—does not count as lying. Exaggerating, being misleading, hedging, or being evasive, with the intention that the other person infer a believed falsehood, also does not count as lying. Lying does not require that the statement that is made is false, but it does require that the statement made is believed to be false rather than merely not believed to be true, or believed to be possibly false or probably false. Lying does not require that the other person is real, only that the other person is believed to be a person and is believed to be real. This does not resolve the questions of whether one can lie to no other person in particular (for example, by publishing a believed false account of an event), or whether there can be intrapersonal lying (for example, an earlier self lying to a later self).

The most important philosophical discussions of lying are to be found in St. Augustine, St. Thomas Aquinas, and Immanuel Kant. Aquinas differed from Augustine and Kant in holding that making a declarative statement to another person that one believes to be false is sufficient for lying; no further deceptive intention is needed. All three held that lying is wrong and that one should never lie; however they distinguished between not lying or being truthful, which is required, and being candid or volunteering believed truths, which is not. Augustine and Aquinas held that some lies, such as lies told to save the lives of innocents or lies told to avoid being defiled, that do not harm the particular person(s) lied to, are less egregious than other lies, such as malicious lies and lies told in the teaching of religion. All three argued that lying is a perversion of the faculty of speech, the natural end of which is the communication of thoughts. Augustine and Kant argued that in telling a lie one harms oneself, and undermines trust in society; hence there can never be a harmless lie. Kant also argued that a person cannot consent to being told a particular lie; hence in lying to another person one is necessarily treating that person as a mere means to one's end.

## LYOTARD, JEAN-FRANÇOIS (1924–1998)

Born in Versailles, France, on August 10, 1924, Jean-François Lyotard was educated in Paris. As a child, Lyotard wanted to be a monk, painter, historian, or novelist, but settled a career in philosophy. He began teaching philosophy at the secondary school level in Constantine, Algeria, and later at La Flèche, France. From 1954 to 1966, Lyotard was a member of a leftist revolutionary group called Socialism ou Barbarie (either socialism or barbarism), eventually joining a splinter group called Pouvoir Ouvrier (Worker's Power) in 1964. He broke with the group in 1966 after becoming critical of Marxism's tendency toward universalism. He began work as a philosophy professor, and was employed at University of Paris X, Nanterre, during the student protests of May 1968. He gained a full position at the University of Paris VIII, Vincennes, where he spent many years and became an emeritus faculty member in 1987. He was also a founding member of the Collège International de Philosophie in Paris. With *The Postmodern Condition: A Report on Knowledge* (1979) he achieved international renown, and was guest lecturer at many universities throughout the world. On April 21, 1998, Lyotard died of leukemia in Paris. Lyotard's philosophical influences are diverse,

including research on topics in Marxism, psychoanalysis, aesthetics, continental and analytical philosophy. An overall theme throughout his works is the inability for a single theory to capture the whole of reality, typically stressing what has been left out or forgotten in a particular theory.

Lyotard's initial writings of the 1950s and early 1960s were political and focused on the Marxist concerns of *Socialism ou Barbarie*, with particular attention to the ending the French occupation of Algeria. Additionally, he published *La phénoménologie* (*Phenomenology*) that supports many aspects of phenomenology, but is critical of its tendency to prioritize the transcendental ego in isolation from the material concerns addressed in Marxism. After attending Jacques Lacan's lectures in the 1960s, Lyotard wrote his first major work, *Discours, figure* to complete his *doctorat d'état*. Published in 1971, *Discours, figure* compares the approaches of structuralism and phenomenology by examining the relationship between textual words of reading, and the figural or visual image of seeing that resists signification and rational concepts. Lyotard argues that text and figure cannot be neatly separated from one another, and neither word nor image should be privileged. His next important work, *Libidinal Economy*, published in 1974, is strongly influenced by Freud, Marx, and Nietzsche, though Lyotard later recants his self-professed "evil book" (*Perigrinations*, 13). *Libidinal Economy* is a break from the rest of Lyotard's work because it retreats entirely from the intellectualism of rational concepts in favor of an examination of drives, affects, intensities, and energy flows that can be ordered in a variety of ways by society.

Lyotard attained fame with the publication of *The Postmodern Condition* in 1979, which was commissioned by the Quebec government to examine the status of knowledge in highly developed societies. The publication of this book catapulted Lyotard into the international spotlight. Often, Lyotard's use of the term "postmodernism" is misunderstood as a historical era following the modern period, though in *The Postmodern Condition* Lyotard insists that the postmodern occurs within the modern period as an "incredulity toward meta-narratives" (p. xxiv). For Lyotard, modernism relies upon meta-narratives that are overarching discourses that try to explain all phenomena according to their own terms.

Lyotard utilizes Ludwig Wittgenstein's terminology of "language games" during this period to suggest that different language games follow their own rules and cannot be adequately translated to one another. While scientific discourse is denotative, ethical discourse is

prescriptive, and to translate the descriptive into the prescriptive would be analogous to translating the rules of chess into those of checkers. Universal grand narratives in modernity suppose that language games are indeed commensurable and result in a kind of "terror" that cannot accept other kinds of games. Lyotard questions the hierarchical priority of scientific and technological forms of knowledge in developed societies that exclude other types of knowledge. According to Lyotard, grand narratives cannot legitimate their authority, and the postmodern breaks through the modern when grand narratives lose their credibility. The epistemological questions raised in *The Postmodern Condition* turn toward political themes in *The Differend*.

Published in 1983, *The Differend: Phrases in Dispute* is thought to be Lyotard's most important work because of its elaboration of the central concept of the book, the "differend." Lyotard defines the *différend* as a "case of conflict, between (at least) two parties, that cannot be equitably resolved for lack of a rule of judgment applicable to both arguments" (p. xi). Lyotard uses the instance of proving the horror of the gas chambers at Auschwitz as his paradigmatic model of a *différend*. Revisionist historian Robert Faurisson denies that the Holocaust occurred because there are no victims who were eyewitnesses to the atrocity. In order for there to be an eyewitness, one would have to be a victim that survived the gas chambers, making it impossible to establish the crime according to Faurisson's criterion. This situation is used as a touchstone to examine various political scenarios in which the victim cannot establish the existence of an injustice, because his or her experience does not conform to present criterion for establishing a legitimate "injustice," and for that reason, the plaintiff becomes a victim of a further wrong. A *différend* follows the structure of a double bind, where it is impossible for the plaintiff to prove damage by the rules of current authority, and differs from litigation that can be established within the present rules. For Lyotard, the *différend* is signaled by a sublime feeling because it involves an overwhelming feeling of pleasure and a feeling of pain. The pain in the sublime comes from the inability to express the wrong of the *différend*, but the feeling of pleasure arises from the potential for the creation of new idioms of discourse that can express the wrong. Lyotard uses Kant's theory of aesthetical judgments of the sublime to describe a theory of political judgment where judgments are made without recourse to a universal rule. Because of the incommensurability of language genres, the *différend* cannot be eliminated for good, but one can bear witness to *différends* and even strain to hear their call.

Much of Lyotard's later work explores Kant's theory of the sublime in greater detail. Lyotard also published many important books of essays focusing on art, literature, history, technology, politics, and postmodernism, in addition to books on several other topics. According to Geoffrey Bennington (1988), Lyotard personally believed that his major works were *Discourse, figure, Libidinal Economy*, and *The Differend*.

## MACH, ERNST (1838–1916)

Mach, Ernst, Austrian physicist and philosopher, was born at Turas near Brno, Moravia (now in the Czech Republic). As with many great figures, a profound psychological experience in youth had lasting effect. Mach describes it in *The Analysis of Sensations*:

I have always felt it as a stroke of special good fortune that early in life, at about the age of fifteen, I lighted, in the library of my father, on a copy of Kant's *Prolegomena to Any Future Metaphysics*. The book made at the time a powerful and ineffaceable impression upon me, the like of which I never afterwards experienced in any of my philosophical reading. Some two or three years later the superfluity of the role played by "the thing in itself" abruptly dawned on me. On a bright summer day in the open air, the world with my ego suddenly appeared to me as *one* coherent mass of sensations, only more strongly coherent in the ego. Although the actual working out of this thought did not occur until a later period, yet this moment was decisive for my whole view.

Examination of Mach's life and work confirms this statement. Fired by the stimulus, he studied in Vienna and became professor of mathematics at Graz in 1864. In 1867 he took a chair of physics at Prague and in 1895 became professor of the history and theory of inductive science at Vienna. In 1901, he was appointed to the upper house of the Austrian parliament. His interests were extraordinarily wide: In physics he made contributions to acoustics, electricity, hydrodynamics, mechanics, optics, and thermodynamics, and in psychology to perception and aesthetics. William James, who met Mach in 1882, reported that he appeared to have read and thought about everything. At the start of the twentieth century, he and Henri Poincaré were the two outstanding popularizers of science in the world. Lenin's main philosophical work is an onslaught on Machian thought, which was highly regarded by Russian socialists who opposed Lenin. Albert Einstein's 1916 obituary of Mach includes this comment: "His direct joy in seeing and comprehending, Spinoza's *amor dei intellectualis*, was so overwhelming that in high old age he still stared at the world with the inquisitive eyes of a child in order to take simple delight in understanding the connection of things." On another occasion, Einstein (1949) praised Mach's "incorruptible skepticism."

## MACH'S INFLUENCE

Mach gave his name to three things in science. A crude but revealing measure of his enduring significance is given by the number of Internet entries listed by Google, at the time of writing, for each of them: the Mach number (41,400), Mach's principle (2,820), and Mach bands (1,580). For comparison, the uncertainty principle of Heisenberg has 56,500 entries. Under Ernst Mach, one finds 92,100 entries. David Hume has 249,000, and Einstein 1,070,000.

Mach has been described as a superb experimentalist but unusual theorist. The Mach number is named after him because he was the discoverer of shock waves, which he observed directly in a brilliant early use of flash photography. He explained the sonic bang first heard in the Franco-Prussian war of 1870. For this outstanding work he was twice nominated for the Noble Prize near the end of his life. However, this was at a time when discoveries were flooding in, and he never received the prize he undoubtedly deserved. For his many other experimental researches—including the discovery of Mach bands in psychology—the reader is referred to Blackmore's biography cited at the end of this entry. This article is about his influence on philosophy of science and, more significantly, natural philosophy in the great tradition of the seventeenth century.

Mach's vivid holistic experience in youth became the unifying core of his *The Science of Mechanics: A Critical and Historical Account of Its Development*. Published in 1883 and widely read ever since, it argues fiercely for the primacy of empirical facts and the need to understand the contingent historical nature of progress in science. Mach was strongly antimetaphysical and questioned the foundations of all knowledge. Physical concepts are not immutable and should always be based on universally observed connections within phenomena. Newton had given a circular definition of mass; Mach replaced it with an operational definition based on the observed accelerations that interacting bodies impart to each other. Einstein recognized the key importance of Mach's approach in his own celebrated operational definition of simultaneity in the special theory of relativity in 1905.

Perhaps even more important than this influence was Mach's intense distrust of the invisible rigid structure of absolute space and time that Newton had introduced in his *Principia* in 1687 in order to formulate his first law motion. Now known as the law of inertia, it states that every body continues in a state of rest or uniform motion in a straight line unless acted upon by external forces. Absolute space was widely attacked as a dubious concept

in Newton's time, above all by Gottfried Wilhelm Leibniz and George Berkeley. However, Mach was the first person to offer a plausible alternative to the framework that Newton had introduced on the basis of rather strong empirical evidence. Mach argued that the locally observable inertial motion of force-free bodies could in reality be "guided" by the integrated physical effect of the totality of matter in the universe rather than by absolute space. Einstein dubbed this idea *Mach's principle*. It was undoubtedly the greatest single stimulus that led to the creation of his general theory of relativity in 1915. Ironically, the actual status of Mach's principle within general relativity is still controversial, although the present writer believes that the theory is almost perfectly Machian when correctly understood.

Mach also had an influence, though far less decisive, on the discovery of quantum mechanics. By the early 1920s, many physicists had come to despair of ever finding a description of atomic phenomena within the traditional framework of space and time. Strongly influenced by Mach's contention that science should solely concern itself with connections between directly observable phenomena, and impressed by Einstein's "Machian" successes, the youthful Werner Heisenberg embarked on a radical approach. The single-sentence abstract of his 1925 paper in which he created quantum mechanics in a matrix representation reveals the depth of Mach's influence: "This paper," Heisenberg wrote, "attempts to create foundations for a quantum-theoretical mechanics that is based exclusively on connections between quantities that are in principle observable." (Heisenberg 1925, p. 879) Mach also had an influence on the formulation of the so-called Copenhagen interpretation of quantum mechanics by Heisenberg and Niels Bohr in 1926 and 1927. In a decidedly Machian manner, they argued that it was the job of science to establish correlations between phenomena and not to attempt a direct description of "reality."

## MACH IN THE TWENTIETH CENTURY

Although Mach's ideas manifestly played a strongly positive role in the great discoveries of twentieth-century physics, his actual philosophy of science has had a mixed and generally negative reception. There is no doubt that he underestimated the value of pure theoretical speculation in scientific discoveries, especially in physics. There are many important discoveries that clearly could never have been made had theoreticians stuck rigidly to Mach's precept that the role of science is solely to establish directly the immediate connection of phenomena. They include general relativity, Erwin Schrödinger's wave-

mechanical formulation of quantum mechanics, and the modern theory of gauge interactions. Many working scientists now accept Karl Raimund Popper's contention that in physics at least significant progress is often made through a bold conjecture that can in no way be justified by direct experience. Instead, the theoretician relies on intuition and accumulated experience to create a conceptual framework from which conclusions are drawn deductively and then tested against observation. In this approach, which is alien to Mach's philosophy, theories are always tentative and liable to empirical refutation.

The weakness of Mach's approach can probably be attributed to two main factors. First, his youthful epiphany made him an idealist rather like Berkeley. The extent to which Mach claimed ontological primacy for direct sense perceptions comes out startlingly in the opening chapter of *The Analysis of Sensations*. The difficulty with such an approach, which does have intellectual coherence, is that it has hitherto proved impossible to go beyond purely qualitative statements. The interconnection of directly experienced phenomena is notoriously difficult to grasp, as is the nature of the phenomena themselves. The second factor is the age in which Mach lived and worked. Theories based on invisible mechanically operating microscopic constituents of matter and substances such as phlogiston and caloric had indeed had a dismal track record more or less up to Mach's time. However, Newton had already given striking examples of rigorous, mathematically based use of hypotheses and deduction, and in Mach's time theoreticians had considerably refined in their art. The twentieth century saw their skill increase still further with spectacular effect. In contrast, it is characteristic that Mach's desire to "see connections" led him to make the famous flash photographs of shock waves for which he so nearly won the Nobel Prize. This was the greatest direct triumph of his approach to science.

The article by Peter Alexander in the previous edition of this encyclopedia, with twice the length of this entry, goes into much more detail about the various aspects of Mach's philosophy of science. The present writer therefore felt it would be useful to concentrate on Mach's great influence in natural philosophy. Within the narrower confines of philosophy of science, Mach was described by Philipp Frank in his *Modern Science and Its Philosophy* as one of the "spiritual ancestors ... and real master of the Vienna Circle." The Vienna Circle was influential. Mach was also an important inspiration for the operationalism of Percy W. Bridgman.

## Bibliography

### WORKS BY MACH

Mach wrote numerous books, and it is a mark of his impact that several are still in print in English translations. Lack of space precludes a detailed bibliography, which can be found at the end of the article by Peter Alexander. Mach's best known work is *Die Mechanik in ihrer Entwicklung historisch-kritisch dargestellt* (1883), translated as *The Science of Mechanics* by T. J. McCormack (LaSalle, IL: Open Court, 1960). Among his more physical writings, one can certainly recommend his *Die Geschichte und die Wurzel des Satzes von der Erhaltung der Energie* (1872), translated by P. E. B. Jourdain as *History and Root of the Principle of the Conservation of Energy* (Chicago: Open Court, 1911) and the *Populärwissenschaftliche Vorlesungen*, translated by T. J. McCormack as *Popular Scientific Lectures* (Chicago: Open Court, 1894), which includes a beautiful account of his work on shock waves. Also interesting but of uneven standards are his *Space and Geometry* (Chicago: Open Court, 1894) and *Die Prinzipien der Wärmelehre*, the last of Mach's major books to be translated (*Principles of the Theory of Heat*. Dordrecht, Netherlands: D. Reidel, 1986). His most important book laying out his philosophy is undoubtedly *Die Analyse der Empfindungen* (1906) (*The Analysis of Sensations*, available from Dover Publications, 1959) and there is also *Erkenntnis und Irrtum* (1905) (*Knowledge and Error*. Dordrecht, Netherlands: D. Reidel, 1976). There is a valuable exhaustive list of Mach's scientific papers and books (and much secondary literature in German) in Joachim Thiele's "Ernst Mach-Bibliographie" published in *Centaurus* 8 (1963): 189–237.

### WORKS ON MACH

Einstein's obituary of Mach appeared in the *Physikalische Zeitschrift*, Volume 17, No. 7, pp. 101–104, 1919. His comment about Mach's incorruptible skepticism appears in his "Autobiographical Notes" in *Albert Einstein: Philosopher-Scientist*, edited by P. Schilpp, New York: Harper and Row (1949), p. 1. Heisenberg's article that created the matrix formulation of quantum mechanics is: "Über quantentheoretische Umdeutung kinematischer und mechanischer Beziehungen," *Zeitschrift für Physik*, Vol. 33, No. 12, 879 (1925). Philipp Frank made his comment about Mach and the Vienna Circle in his book *Modern Science and Its Philosophy*, Harvard: Harvard University Press, 1950. The English-language secondary literature is extensive. Blackmore's biography *Ernst Mach: His Life, Work, and Influence* (Berkeley and Los Angeles: University of California Press, 1972) is a mine of information but uneven in the

discussion of his philosophy. Alexander's article is another useful guide to earlier literature, but in this modern age the scholar who really wishes to make an in-depth study of the literature is probably best advised to trawl the Internet. In 1988, the Charles University in Prague organized an excellent conference to mark the 150th anniversary of Mach's birth. The conference papers *Ernst Mach and the Development of Physics* (Prague: Karolinum, 1991) are a useful compendium but probably difficult to obtain. A special conference *Mach's Principle: From Newton's Bucket to Quantum Gravity* was held at Tübingen, Germany in 1993. The proceedings, edited by Julian Barbour and Herbert Pfister, were published in 1995 by Birkhäuser (Boston) and include the present writer's article arguing that general relativity is Machian and includes much other material by physicists, historians, and philosophers.

*Julian Barbour (2005)*

## MACHIAVELLI, NICCOLÒ

(1469–1527)

Niccolò Machiavelli, the Italian politician and political thinker, is famous for his treatise on princship titled *The Prince* (*Il principe*) and for a discussion of how to establish a good republican government, *The Discourses* (*Discorsi sopra la prima deca di Tito Livio*). Machiavelli also wrote poems and comedies (including the *Mandragola*), a *History of Florence*, and a book titled *Art of War*. They contain many original ideas and were widely read, but today these writings arouse interest mainly because their author was the man who, with *The Prince* and *The Discourses*, inaugurated a new stage in the development of political thought.

When Machiavelli wrote *The Prince* and *The Discourses*, he was aware that he was saying things about politics that had not been expressed before; in the introduction to *The Discourses* he stated that he was resolved “to open a new route which has not yet been followed by anyone.” Nevertheless, Machiavelli would not have claimed to be a systematic political philosopher. *The Prince* was written in 1512–1513; the date of *The Discourses* is less certain, but it was certainly completed by 1517. Machiavelli was then in his forties and, in the preceding years of his life, he had been a practical politician who had never shown interest in becoming a political writer or in embarking on a literary career.

In 1498, after the expulsion of the Medici from Florence and the fall of Girolamo Savonarola, Machiavelli had entered the Florentine chancellery, where his special function was to serve as the secretary of The Ten, a group of magistrates charged with the conduct of diplomatic

negotiations and the supervision of military operations in wartime. In this position Machiavelli carried out a number of diplomatic missions in Italy, France, and Germany. His ability attracted the attention of Gonfalonier Piero Soderini, the official head of the Florentine government, and Machiavelli became Soderini's confidant—his “lackey,” according to Soderini's enemies. Machiavelli's close relationship with Soderini became a serious handicap when, in 1512, the republican regime was overthrown and the Medici returned to Florence. Other members of the chancellery were permitted to continue in office, but Machiavelli was dismissed and forced to withdraw to a small estate near Florence, where he lived in straitened economic circumstances.

It was at this time that Machiavelli turned to literary work in the hope that through his writings he would gain the favor of influential men who might help him to regain a position in the Florentine government. *The Prince* was dedicated to Lorenzo de' Medici, a nephew of Pope Leo X and the actual ruler of Florence. *The Discourses* was dedicated to members of the Florentine ruling group, and his *History of Florence* was written at the suggestion of Cardinal Giulio de' Medici, who in 1523 became Pope Clement VII. In the 1520s Machiavelli's efforts began to bear fruit. Clement VII entrusted him with a number of minor political commissions, and Machiavelli devoted himself to this kind of work, relegating the completion of his literary projects to the background. However, in 1527, before Machiavelli had been firmly reestablished in a political position—actually, at a moment when his future had again become uncertain because the Medici had once more been driven from Florence—he died.

Thus, Machiavelli's attitude in composing *The Prince* and *The Discourses* was not that of a disinterested scholar; his aims were practical and personal. He wanted to give advice that would prove his political usefulness, and he wanted to impress those who read his treatises. Therefore, Machiavelli was inclined to make numerous startling statements and extreme formulations. A characteristic example is his saying that the prince “must abstain from taking the property of others, for men forget more easily the death of their father than the loss of their patrimony” (*The Prince*, Ch. 17).

### ARTS OF WAR

Machiavelli's statements were startling not only because of their form of presentation but also because of their content. One aspect of political affairs with which Machiavelli had been particularly concerned and in which he was especially interested was the conduct of military

affairs. He thought deeply about the reasons why the French had so easily triumphed over the Italians in 1494 and had marched from the north to the south of Italy without meeting serious resistance. Machiavelli's explanation was that the governments of the various Italian states, whether they were republican regimes or principalities, had used mercenary soldiers led by hired *condottieri*. He therefore recommended that in case of war the prince should lead his troops himself and that his army should be composed of his own men; that is, the Italian governments should introduce conscription. Moreover, Machiavelli polemicized against other favorite notions of his time on military affairs; for instance, he denied that artillery was decisive in battle or that fortresses could offer a strong defense against an invading army.

### MORALS AND POLITICS

Machiavelli's rejection of traditional political ideas emerged most clearly in his discussions of the relation between morals and politics. The most revolutionary statements on these issues are found in chapters 15–19 of *The Prince*, which deal with the qualities a prince ought to possess. In the Mirror of Princes literature of the ancient world and of the Middle Ages, a prince was supposed to be the embodiment of human virtues; he was expected to be just, magnanimous, merciful, and faithful to his obligations, and to do everything that might make him loved by his subjects. Machiavelli objected to such demands. According to him, a prince “must not mind incurring the scandal of those vices without which it would be difficult to save the state, and if one considers well, it will be found that some things which seem virtues would, if followed, lead to one's ruin and that some others which appear vices result in one's greater security and well-being.” This sentence and chapters 15–19 have frequently been understood as meaning that instead of being mild a prince ought to be cruel; instead of being loyal, treacherous; instead of aiming to be loved, he should aim to be feared. But this is a misunderstanding. A closer reading shows that Machiavelli admonishes a prince to disregard the question whether his actions would be called virtuous or vicious. A ruler ought to do whatever is appropriate to the situation in which he finds himself and may lead most quickly and efficiently to success. Sometimes cruelty, sometimes leniency, sometimes loyalty, sometimes villainy might be the right course. The choice depends on circumstances. To illustrate his point of view Machiavelli used as an example the career of Cesare Borgia, which he outlined in chapter 7 of *The Prince*.

Machiavelli's views have frequently been interpreted as meaning that wickedness is more effective than goodness. This distortion of his views has been regarded as the essence of Machiavelli's teaching, as identical with what later centuries called Machiavellism. It should be stated that Machiavelli was not concerned with good or evil; he was concerned only with political efficiency. His rejection of the *communis opinio*—whether in the special area of military affairs or in the general field of ethics—was a reflection of a new and comprehensive vision of politics. Before Machiavelli, the prevailing view had been that the task of government was distribution and maintenance of justice. Machiavelli believed that the law of life under which every political organization existed was growth and expansion. Thus, force was an integral, and a most essential, element in politics.

Machiavelli's interest in military affairs had its basis in his conviction that possession of a powerful and disciplined military force was a requisite for the preservation of political independence. Moreover, because political life was a struggle, the conduct of life according to Christian virtues could endanger political effectiveness; Christianity, by preaching meekness and selflessness, might soften men and weaken a political society. Machiavelli directed some very strong passages against the effeminacy to which Christianity had led. Political man needed not virtues but *virtù*, “vitality.” The possession of *virtù* was the quality most necessary for a political leader, but according to Machiavelli both individuals and entire social bodies could and should possess *virtù*. That is why, in *The Prince*, Machiavelli could write a “handbook for tyrants,” while in *The Discourses* he could advocate a free republican regime. Every well-organized, effective political organization must be permeated by one and the same spirit and must form an organic unit. There are few if any passages in Machiavelli in which he uses the word *stato* (*stato*) in the modern sense of an organic unit embracing individuals and institutions. However, there can be no doubt that his concept of an organized society producing *virtù* among its members comes very close to the modern concept of state.

### METHOD OF ARGUMENT

The new vision of the character of politics required a new method of political argumentation. Rules for the conduct of politics could not be formulated on the basis of theoretical or philosophical assumptions about the nature of a good society; successful political behavior could be learned only through experience. Machiavelli stated in his dedication of *The Prince* that he wanted to tell others

what he had “acquired through a long experience of modern events and a constant study of the past.” Thus, experience was not limited to those events in which a person participated but embraced the entire field of history. To Machiavelli the most instructive period of the past was that of republican Rome. Machiavelli thought that, because the Romans succeeded in extending their power over the entire world, no better guide for the conduct of policy could be imagined than that of Roman history. It is indeed true that previous writers on politics, particularly the humanists, had used historical examples, but to rely exclusively on historical experience in establishing political laws was an innovation; Machiavelli’s writings implied that every true political science ought to be based on history.

It has been said that, in rejecting the validity of the doctrines of theology and moral philosophy for the conduct of politics, Machiavelli established politics as an autonomous field. He could do so because he regarded political bodies not as creations of human reason but as natural phenomena. In Machiavelli’s opinion all political organizations, like animals, plants, and human beings, are subject to the laws of nature. They are born, they grow to maturity, they become old, and they die. Well-organized political bodies might live longer than others, but even the best-constructed political society, even Rome, could not escape decline and death. This view of the instability and impermanence of all things gives Machiavelli’s recommendations their particular tenor. Men or political bodies are entitled to use all possible means and weapons because the moments when they can flourish and triumph are brief and fleeting. Despite Machiavelli’s claim that political success depended on acting according to the political laws he established in his writings, he was always conscious of the role of accident and fortune in human affairs.

## INFLUENCE

It is of some importance to distinguish between the shocking novelty of Machiavelli’s particular recommendations and his general concepts of politics, from which his practical counsels arose. Such a distinction helps to explain the contradictory reception his ideas found in the following centuries. Machiavelli’s writings soon became known in Italy and then in other European countries, particularly France and England, although in 1559 his works were placed on the Index. Generally he was considered an adviser of cruel tyrants, an advocate of evil; Cardinal Reginald Pole said that Machiavelli wrote “with the finger of the Devil.” Although nobody in the sixteenth

century dared publicly to express anything but abhorrence, a school of political writers arose in Italy who explained that the criteria of a statesman’s or ruler’s actions were the interests of the state. These advocates of the doctrine of “reason of state”—even if they did not acknowledge their obligations to Machiavelli—followed the course Machiavelli had charted. The Enlightenment, with its belief in the harmony of morality and progress, could only condemn Machiavelli’s view that political necessity permitted the neglect of ethical norms. An example is the *Anti-Machiavel* that Frederick II of Prussia composed as a young man. Some eighteenth-century thinkers, however, recognized truth in Machiavelli’s approach to politics. For instance, Gabriel Bonnot de Mably and Jean-Jacques Rousseau admired Machiavelli because he had realized that the strength of a political organization depends on the existence of a collective spirit that is more than a summation of individual wills.

In the nineteenth century, students of Machiavelli, following the interpretation that the German historian Leopold von Ranke had given, did not believe that Machiavelli had wanted to separate ethics and politics. Because the last chapter of *The Prince* contains an appeal for the liberation of Italy from the barbarians, they assumed that Machiavelli had permitted the violation of moral rules only for the purpose of a higher ethical goal; that his purpose had been to point the way toward the foundation of a unified Italy. Thus, in the nineteenth century Machiavelli became respectable as the prophet of the idea of the national state. In the later part of the century Machiavelli was also referred to by those who wanted to free man from the oppressive shackles of traditional morality and believed that man’s faculties could be fully developed only if he placed himself “beyond good and evil.” Friedrich Nietzsche’s superman was supposed to have “virtue in the style of the Renaissance, *virtù*, virtue free from morality.”

## Bibliography

The literature on Machiavelli is very extensive. A more recent critical edition of his works is that edited by Sergio Bertelli and Franco Gaeta and published by Feltrinelli in its Biblioteca di classici italiani. So far four volumes containing Machiavelli’s literary works and three volumes containing his *Legazioni e commissarie* have appeared (1960–1964). This edition provides a critical discussion of the Machiavelli literature. The best recent translation is Allan Gilbert, *Chief*

*Works, and Others*, 3 vols. (Durham, NC: Duke University Press, 1965).

Older biographies have become obsolete since the appearance of Roberto Ridolfi's *Vita di Niccolò Machiavelli* (Rome, 1954), translated by Cecil Grayson as *The Life of Niccolò Machiavelli* (Chicago: University of Chicago Press, 1963). Machiavelli's intellectual development is well analyzed by Gennaro Sasso in his *Niccolò Machiavelli: Storia del suo pensiero politico* (Naples: Nella sede dell'Istituto, 1958). For the relation of Machiavelli's thought to that of his contemporaries, see Felix Gilbert, *Machiavelli and Guicciardini* (Princeton, NJ: Princeton University Press, 1965). The main lines of the influence of Machiavelli's ideas on the political thought of later centuries are traced in Friedrich Meinecke, *Die Idee der Staatsräson in der neueren Geschichte* (Berlin: R. Oldenbourg, 1924), translated by Douglas Scott as *Machiavellism* (New Haven, CT: Yale University Press, 1957). For Machiavelli's impact on English political thought, see Felix Raab, *The English Face of Machiavelli: A Changing Interpretation 1500–1700* (London: Routledge and Paul, 1964).

## MACHIAVELLI, NICCOLÒ [ADDENDUM]

Many readers come to Machiavelli with their minds made up about who he was and what he espoused. A more balanced assessment must take into account many approaches to his work and possible influences from the classical world.

### EVALUATING MACHIAVELLI

In order to evaluate Machiavelli one must first decide what he was doing and second decide how to balance the assessment of the texts. The traditional assessment of Machiavelli is “expedient egoist.” Under this reading one would cite passages from *The Prince* in which rulers are advised to employ deceit and cruelty for the sake of political advantage. However, it is unclear whether these passages should be taken at face value or rather as an invective set in its European historical perspective: (a) a striving to connect to the past—particularly to the Roman Empire and its eloquent Republican spokesman, Cicero; and (b) a chafing with the Papal authority over the legacy of the Roman Empire—especially the bogus “Donation of Constantine.” In this forged document the Roman Emperor Constantine supposedly granted the whole of the Roman Empire to the pope who, in turn, allowed the daily duties of running the secular to fall upon the emperor. This document sought to establish a legal claim for the pope's universal secular power. It could

be that Machiavelli, in the first case, was interested in espousing the republican message of Cicero. It could also be, in the second case that Machiavelli was consciously breaking away from established forms of exposition in order to create another mode of political discourse.

In recent scholarship (over the second half of the twentieth century) Ernst Cassirer (1946) believed that Machiavelli espoused a clear and coherent argument based upon a vision that moved the modern world forward in a realistic fashion. Isaiah Berlin (1972 [1953]) followed in asserting that Machiavelli put forth a cogent secular vision that was consistent. Leo Strauss (1958) agreed that the vision was consistent, but said that both from the points of view in *The Prince* and of *The Discourses on Livy* that Machiavelli was a teacher of evil (namely, an expedient egoist).

Certainly, the worldviews presented in *The Prince* and *The Discourses on Livy* appear both different and the same. They are *different* in that in the former case there seem to be many aphorisms that violate ethical laws whereas in the latter it seems that Machiavelli is concerned to uphold public morality—such as eliminating public corruption for the sake of the republic. One might reasonably ask whether the same person wrote both works.

However, they are *similar* in that they are both pragmatically oriented toward solving problems. Thus, we are faced with one interpretative option of which work should be seen as representing the author's “true vision”? Because of the caveats mentioned above, (a) and (b), some of the so-called “Cambridge School” (Pocock, Skinner, and Viroli) have accentuated the emphasis upon the rule of law, common good, and general republicanism as seen from the *Discourses* as evidence that Machiavelli was really a forward-thinking republican thinker.

If [this] reading of Machiavelli is correct, then he is a thinker who is not an advocate of expedient egoism, but rather is a thinker who saw various dead ends in the way political philosophy was being explored. To start anew he tries to jettison the views of the reigning paradigm and start afresh. This is an interesting interpretation, but it has one possible flaw: Machiavelli does not spend time on theoretical foundations. Any theory asserted to be present there must be read into the text. And so what theory might support his pragmatic observations?

Two candidates are Aristotle and Cicero. At this period of history, Aristotle's *Politics* and *Ethics* had recently been translated into Latin. Cicero had been the established authority (because of his association with

Rome and because of the rhetorical structure of the *Discourses*) and so most commentators seem to think that he is the dominant influence. Another argument along this line is that Aristotle thought that civic virtue derived from man fulfilling his nature in the context of society (so that politics flows from ethics). Machiavelli does not employ such an explanatory framework. Can his texts be read from this perspective? Perhaps, but it may be a stretch because the practicality of Machiavelli works against Aristotle's essentialism.

The candidate left standing is Cicero. If this is the case, then Cicero's presence best describes the Muse of Machiavelli. The structure of the *Discourses* seems to suggest this as it follows the classical rhetorical form: (for example, observe the titles of the first three chapters: (1) What Have been Universally the Beginnings of Any City Whatever, and What was That of Rome; (2) Of How Many Species Are Republics, and Which Was the Roman Republic; (3) What Accidents Made the Tribunes of the Plebs Be Created in Rome, Which Made the Republic More Perfect).

However, once this is accepted, then other results may follow. The postmodernists assert that literary constructions can substitute for a traditional exposition of the pursuit of a universal Truth (as per Aristotle). Instead, the use of Ciceronian rhetoric might resonate with the etymology of "rhetoric" à la speaking in public or engaging in discourse with others. If this understanding is correct, then the philosophy of discourse and *construction from discourse* as per Foucault, Ricoeur, Derrida, or Habermas might be more apropos than the use of rhetoric as a means of transmitting already settled truths.

Such an interpretation may have many advantages. First, it might resolve the contradictions between the various texts of Machiavelli. This is because contradictions are only a problem if one is creating a systematic work of philosophy, such as was aspired to by Aristotle or Thomas. Second, it might blunt the traditional "bad boy" image of Machiavelli by bringing him into the realm of merely revealing various approaches to the questions of what policies might be necessary for running a state. By bringing out various options and interacting with them, Machiavelli might be eschewing the conventional method of discourse (even though he employs traditional forms) in favor of creating a new realpolitik.

This reinvigorated conception would find its sources in the way politics are actually practiced. So, for example, *The Prince* might be seen not as a way things *ought to be*, but a description of the way things *are*. If we are to go anywhere, here is the starting point. Let us all accept this.

And in the *Discourses* if Rome is a model of a civilization that worked well for a long time, then the focus should be upon what can be done to correct the flaws that brought it down. Under this sort of reading, the exploration of politics is not about creating treatises on political theory, but instead of initiating a dialogue among readers about the "deal points" in running a state. The completion of the text lies in the audience.

## MACHINE INTELLIGENCE

Computers beat the best human chess players. Computers guide spacecraft over vast distances and direct robotic devices to explore faraway astronomical bodies. Computers outpace humans in many respects, but are they actually intelligent? Can they think? Even if one is skeptical about the mentality of today's computers, the interesting philosophical issue remains: Might computers possess significant intelligence someday? Indeed, might computers feel or even have consciousness? And, how would we know?

### THE HISTORICAL DEBATE

These issues of machine intelligence are not new to philosophy. The debate about whether a machine might think has its philosophical roots in the seventeenth and eighteenth century with the development of modern science. If the universe is fundamentally materialistic and mechanistic, as the emerging scientific paradigm suggested, it would follow that humans are nothing more than machines. Possibly, other machines might be constructed that would be capable of thought as well. Thomas Hobbes (1588–1679), who advocated a materialistic, mechanistic view, argued that reasoning is reckoning and nothing more. Humans reason by calculation with signs involving addition, subtraction, and other mathematical operations. Hobbes took these signs to be material objects that have significance as linguistic symbols. Julien La Mettrie (1709–1751), another materialist and mechanist, speculated that it might be possible to teach a language to apes and to build a mechanical man that could talk.

Not every philosopher of that era agreed with such radical predictions. René Descartes (1596–1650) held that animals are, indeed, complex machines but as such, necessarily lack thought and feeling. People have bodies that are in themselves nothing but complex machines, but people also have minds, nonmaterial entities that are in time but not space, that interact with their bodies. On this dualistic conception, intelligence and consciousness of people exist only as part of their minds, not as part of their bodies. Constructing a nonhuman machine that by itself had intelligence or consciousness was an impossibility for Descartes. Descartes admitted that a machine could be built that might give an impression of possessing intelligence, but it would be only a simulation of real intelligence and could be unmasked as a thoughtless machine. In fact, Descartes offered two certain tests by which a machine can be distinguished from a rational

human being even if the machine resembled a human in appearance. First, although a machine may utter words, a machine will never reply appropriately to everything said in its presence in the way that a human can. Second, although a machine may perform certain actions as well as or even better than a human, a machine will not have the diversity of actions that a human has.

## THE CONCEPTION OF COMPUTING MACHINES

The contemporary debate about the possibility of machine intelligence ignited with the advent of modern electronic computers that are accurate, reliable, fast, programmable, and complex. Nobody did more in the twentieth century to construct a coherent concept of computing and to generate the contemporary debate about the intellectual possibilities of computers than Alan Turing (1912–1954). Turing explained computability in terms of abstract mathematical machines, now called *Turing Machines*. A Turing machine consists of a potentially infinite tape, divided into individual cells, on which a read–write head travels either left or right one cell at a time. The read–write head follows instructions that are found in a table of transition rules. The table of transition rules is the program that directs the Turing machine. Each instruction in the table specifies for a given a state of the Turing machine and a particular symbol being read on the tape, what the read–write head should do (print a symbol, erase the symbol, move right, or move left), and which state the machine should go to next.

Turing showed how such simple, elegant machines could compute ordinary arithmetic functions, and he conjectured that anything that is effectively computable could be computed by such a machine. In addition, Turing developed the concept of a universal Turing machine that can compute what any Turing machine can compute. Turing also showed the limitations of his machines by demonstrating that some functions are not computable, even by a universal Turing machine. Turing’s seminal work on computable numbers and computing machines provided much of the conceptual foundation for the development of the modern computer. During World War II Turing applied some of his theoretical insights in designing special computing equipment to decipher the German Enigma codes. After World War II Turing led efforts to design some of the earliest computers, including the Automatic Computing Engine (ACE) in 1945.

The concept of computing developed by Turing provided not only a theoretical foundation for computer sci-

ence but also a theoretical framework for much of artificial intelligence and cognitive science. A central paradigm of these fields is that mental processes and, in particular, cognitive processes are fundamentally computational. Processes that constitute and demonstrate human intelligence and general mentality, such as perception, understanding, learning, reasoning, decision making, and action, are to be explained in terms of computations. On the computational view, a mind is an information processing device. In its strongest form the computational theory of the mind holds that an entity has a mind *if and only if* that entity has computational processes that generate mentality.

Three important aspects of the theory of computation support the possibility of machines possessing intelligence and various aspects of minds. First, computation is understood in terms of the manipulation of symbols. Symbolic manipulation can represent information inputted, information processed, information stored, and information outputted. If human intelligence depends on the ability to represent the world and to process information, then the symbolic nature of computation offers a promising environment in which to conceive and develop intelligent machines. Much, though not all, of machine intelligence work has been conducted within this framework.

Second, if intelligence and mentality are computational in nature, then it does not matter what material conducts the computations. The computational structures and processes are multiply realizable. They might be instantiated in human brains, in computers, or even in aliens comprised of a different assortment of chemicals. All may have mentality as long as they have the appropriate computational processes. Indeed, it is possible to have mixed systems comprised of different materials. Cochlear implants and bionic eyes send information to human brains from external stimuli. Humans with these implants hear and see although part of their processing channels are inorganic.

Third, the computational model suggests an account of the connection between mind and body that other theories of the mind leave mysterious. The computational model explains intelligence and overall mental activity on the basis of decreasingly complex components. A hierarchy of computational systems is hypothesized, each of which is made up of simpler computational systems, until at bottom—as in a computer—there is nothing but elementary logical components, the operations of which can be explained and easily understood in terms of physical processes.

## THE TURING TEST

For many people the phrase *machine intelligence* is an oxymoron. Machines by their nature are typically regarded as unintelligent and unthinking. How could a mere machine demonstrate actual intelligence? Turing believed that computing machines could be intelligent but was concerned that our judgments of the intelligence of such machines would be influenced by our biases and previous experiences with the limitations of machines. In his seminal article, "Computing Machinery and Intelligence" (1950), Turing considered the question "Can machines think?" but did so by replacing that question with another. The replacement question is explained in terms of a game that he calls "the imitation game." The imitation game is played by a man (A), a woman (B), and a human interrogator (C). The interrogator is in a room apart from the other two and tries to determine through conversation which of the other two is the man and which is the woman. Turing suggested that a teleprinter be used to communicate to avoid giving the interrogator clues through tones of voice. In the game the man may engage in deception in order to encourage the interrogator to misidentify him as the woman. The man may lie about his appearance and preferences. Turing believed that the woman's best strategy in the game is to tell the truth.

After he explained how the imitation game is played in terms of a man, a woman, and a human interrogator, Turing introduced his replacement question(s). Turing said, "We now ask the question, 'What will happen when a machine takes the part of A in this game?' Will the interrogator decide wrongly as often when the game is played like this as he does when the game is played between a man and a woman? These questions replace our original, 'Can machines think?'" (Turing, 1950, p. 434). Although his proposed version of the imitation game, now called the *Turing test*, may seem straightforward, many questions have been raised about how to interpret it. For example, to what extent does gender play a role in the test? Some maintain that Turing intended, or should have intended, that the computer imitate a woman just as the man did in the original imitation game. The more standard interpretation of the test is that the computer takes the part of A but that the part of B is played by a human—a man or a woman. On the standard interpretation the point of the test is to determine how well a computer can match the verbal behavior of a human, not necessarily a woman. The examples of questions for the test that Turing suggested are not gender specific but

rather more general inquiries about writing sonnets, doing arithmetic, and solving chess problems.

Turing neglected to elaborate on many details of his test. How many questions can be asked? How many judges or rounds of judging are there? Who is the average interrogator asking questions? What counts precisely as passing the test? And, importantly, what conclusion should be drawn from a Turing test if it were passed? Turing moved quickly to replace the initial question "Can machines think?" with questions about playing the imitation game. He suggested that the original question "Can machines think?" is "too meaningless to deserve discussion" (Turing, 1950, p. 442). He could not have been claiming that the question is literally meaningless, or his own replacement project would not make sense. What he was suggesting is that terms like *machine* and *think* are vague terms in ordinary speech, and what people typically associate with a machine is not something that has or perhaps could have intelligence. What he was proposing with his test is a way to make the overall question of machine thinking more precise so that at least in principle, an empirical test could be conducted. Still, the issue is left open as to exactly what passing the Turing test would establish. Could it ever show that a machine is intelligent or that a machine thinks or possibly even that a machine is conscious?

A widely held misconception is that Turing proposed the test as an operational definition of thinking or considered the test to give logically necessary and sufficient conditions for machine intelligence. Critics of the test frequently point out that exhibiting intelligent behavior in this test is neither a logically necessary nor logically sufficient condition for thinking. But this common objection against the test misses the mark, for Turing never said he was giving an operational definition and never argued that the test provided a logically necessary or sufficient condition for establishing machine intelligence. Indeed, Turing argued for the opposite position. He did not take his test to be a necessary condition for intelligence, for he readily admitted that a machine might have intelligence but not imitate well. He never maintained that passing the test is logically sufficient for intelligence or thinking by a machine. On the contrary, he argued that demanding certainty in knowledge of other minds would push one into solipsism, which he rejected.

A more plausible interpretation of the Turing test is to regard it as an *inductive* test. If a machine passed a rigorous Turing test with probing questioning on many topics, perhaps by different judges over a reasonably extended period of time, then good inductive evidence

for attributing intelligence or thinking to the machine might exist. Behavioral evidence is used routinely to make inductive judgments about the intelligence of other humans and animals. It would seem appropriate to use behavioral evidence to evaluate machines as well. In judging human-like intelligence linguistic behavior seems particularly salient. There would be no logical certainty in such a judgment any more than there is logical certainty in scientific testing in general, and revision of judgments in light of new evidence might be required. Regrettably, other evidence like relevant to a judgment of machine intelligence, such as evidence from non-linguistic behavior and evidence about the internal operation of the machine, cannot be directly gathered within the Turing test. Turing realized this, but thought it more important to eliminate bias so that a machine would not be excluded as intelligent simply because the person making the judgment knew it was a machine.

### CRITICISMS OF THE TURING TEST

Turing himself considered and replied to a variety of criticisms of his test ranging from a theological objection to an extrasensory perception objection. At least two of the objections he discussed remain popular. One is the Lady Lovelace objection based on a remark by Ada Lovelace that Charles Babbage's Analytical Engine, a nineteenth-century mechanical computer, had no pretension to originate anything. A similar point is often made by claiming that computers only do what they are programmed to do. The objection is difficult to defend in detail because computers can surprise even their programmers, are affected by their input as well as their programming, and can learn. Of course, one might argue that, at bottom, computers are merely following rules and therefore are not creative. But to firmly establish this objection, one would need to show that, at bottom, humans are not merely following rules and that anything merely following rules cannot be creative.

Another objection that Turing considered is the mathematical objection that utilizes results in mathematical logic, such as Kurt Gödel's incompleteness theorem. This argument, later developed by J. R. Lucas (1961) and by Roger Penrose (1989), maintains that fundamental limits of logical systems are limits of computers but not of human minds. But, as Turing himself pointed out, it has not been established that these logical limits do not apply equally well to humans.

In addition to these classical criticisms, a number of contemporary objections to the Turing test have been advanced. Robert French (1990) has maintained that the

test is virtually useless because there will always be subtle subcognitive behavior that will allow an interrogator to identify humans from machines. If true, the Turing test would be more difficult to pass and possibly not very useful, but this outcome would also enhance the potential inductive sufficiency of the Turing test if it were passed.

In another criticism of the Turing test, Ned Block (1981) has suggested that a computer program that worked as a conversation jukebox so that it gave a stored but appropriate response to every possible remark by an interrogator throughout a conversation would pass the test. Because the test occurs during a finite period and in that period only a finite, though very large, number of responses can be made, such a program seems logically possible. Whether such a program could exist in practice given the complexity of semantic relations in a conversation and the changing facts of the world is unclear, but even taken as a thought experiment, the success of the jukebox program would at most show that the Turing test does not provide a logically sufficient condition for the possession of intelligence, a position to which Turing agreed.

John Searle (1980) developed one of the most popular contemporary objections against machine intelligence: the Chinese Room Argument. Simply put, a computer program running on a digital machine is only manipulating symbols syntactically and necessarily lacks semantics. Thus, even if a machine passed a Turing test, it would not understand anything. A digital computer might simulate intelligence, but on Searle's view it would not have a mind. Some critics of this argument have suggested that humans acquire semantics through interaction with the environment, and possibly, machines equipped with sensory inputs and motor outputs could acquire semantics in this way as well. More telling, the Chinese Room Argument does not validly establish what it claims. Searle has maintained that a human brain has the causal powers to produce a mind; the Chinese Room Argument does not demonstrate that computer programs, once loaded and running on a physical machine, could not have similar causal powers.

The Turing test is a possible test for machine intelligence and one that has received enormous philosophical discussion, but it is not the only test. Normally, the intelligence of animals and other humans is tested and inferred by examining an entity's relevant behavior in various situations. Similarly, machine intelligence can be tested based on its ability to demonstrate such processes as understanding, reasoning, and learning regardless of how well it can imitate a human. Human intelligence is

not the only kind of intelligence. Along these lines Patrick Hayes and Kenneth Ford (1995) have argued that too much emphasis on passing the Turing test has actually been detrimental to progress in artificial intelligence.

## THE FUTURE OF MACHINE INTELLIGENCE

Turing believed that human language and understanding of machines and mentality would shift by the year 2000, and indeed, the notion of a machine being intelligent is not as outlandish as it once was. In his 1950 article (p. 442) Turing also made a very famous specific prediction that has not fared as well. He said: "I believe that in about fifty years' time it will be possible to programme computers, with a storage capacity of about  $10^9$ , to make them play the imitation game so well that an average interrogator will not have more than 70 per cent chance of making the right identification after five minutes of questioning." No computer has come close to meeting this standard in a rigorously conducted Turing test. But it should be noted that behind Turing's prophecy was a plan that has not come to pass. He imagined that one day a computer would learn just as a child does. And like a human the computer gradually would obtain a larger and larger understanding of the world. Machine learning in specific contexts has been a reality for decades, but general learning by a machine remains an elusive goal, and without it, the intelligence of machines will be limited.

The long-term future of machine intelligence is a matter of considerable philosophical debate. Here are four visions of the future that have been suggested. On the *android vision* some intelligent machines of the future will look like humans or at least resemble humans in their intellectual capacities. Because humans are the most intelligent creatures known, human intelligence is taken as the obvious standard. Turing's own proposals employed much of this vision. From this viewpoint it is sensible to ask whether robots someday will be the intellectual peers of humans and might deserve rights as rational beings. But some critics argue that computers will never be much like humans without similar emotional needs and desires. On the *slave vision* intelligent machines of the future will give humans increasingly sophisticated assistance but, like their not-so-intelligent predecessors, they will be slaves, possibly held in check by Isaac Asimov's well-known three laws of robotics (1991). On the *successor vision* machine intelligence will become increasingly sophisticated and machines will evolve beyond humans. Hans Moravec (1999) has argued that humans will be surpassed by machines in terms of intel-

ligence within a relatively short time. Such machines might evolve and progress rapidly through a Lamarckian transmission of culture to the next generation. Finally, on the *cyborg vision*, advanced by Rodney Brooks (2002) and others, machine intelligence will increasingly be embedded in us. Machine intelligence will be used to augment our abilities and will blend into our nature. Machine intelligence will become part of our intelligence, and we will become, at least in part, intelligent machines.

## MACINTYRE, ALASDAIR (1929–)

Alasdair Chalmers MacIntyre was born in Glasgow, Scotland. He was philosophically trained at Manchester University and subsequently taught at Manchester, Leeds University, Oxford University, and the University of Essex before emigrating to the United States in 1970. Since then he has held teaching posts at Brandeis University, Boston University, Vanderbilt University, Duke University, and the University of Notre Dame.

By his late teens MacIntyre became sympathetic to Marxism as a theoretical articulation of the failures of contemporary social, economic, and political institutions, resulting in the publication of his first book, *Marxism: An Interpretation*, at the age of twenty-three. While never giving up his view that modernity merits wide-ranging criticism and that such criticism must come from a rationally defensible theoretical standpoint, he came to believe that Marxism lacked the necessary resources. What is needed, MacIntyre held, is a moral and political philosophy built on an adequate theory of human nature and the human good—though this theory would have to recognize that human nature and the human good are deeply historically conditioned. What is also needed is an adequate account of how such a theory can be shown to be rationally superior to its rivals—though, again, this account would have to recognize that standards of rationality in inquiry are themselves deeply historically conditioned. MacIntyre's mature philosophy, expressed in the series of books *After Virtue* (1981), *Whose Justice? Which Rationality?* (1988), *Three Rival Versions of Moral Enquiry* (1990), and *Dependent Rational Animals* (1999), respond to these perceived needs and exhibit the most noteworthy features of his work: his account of tradition-constituted rationality, his Aristotelian ethics of virtue, and his Aristotelian politics of local community.

### TRADITION-CONSTITUTED RATIONALITY

MacIntyre's view is that the most salient feature of contemporary moral and political discourse is interminable disagreement. Defenders of rival views become ever more

sophisticated in the development and advocacy of their theories, but there is no progress toward resolution of these disagreements. It seems to be the aspiration of participants in these debates to offer a defense of their respective theories that is acceptable to any rational agent. MacIntyre calls this aim of providing a defense of morality acceptable to rational agents as such The Enlightenment Project, and holds that, for all the substantive differences between figures such as David Hume and Immanuel Kant, it is their common objective to provide a basis for morality that commands rational acceptance by all. After all, one might think that the alternative is an unacceptable relativism whereby different theories are justified in terms of different standards, with no way to bring rival theories truly into competition.

MacIntyre's contribution is to argue for the existence of rival and incompatible standards of rational assessment while denying that this affirmation brings with it a commitment to relativistic conclusions. We are confronted with different traditions of rational inquiry, each with its own theories and standards for assessment of theories, and each with a history within which various positions have been forwarded, defended, and to whatever extent affirmed or rejected. There is no neutral rationality-as-such by which we can decide between these various competing traditions. But relativistic conclusions do not follow, MacIntyre argues, because it is always possible that one tradition can show itself superior to a rival tradition by showing that one's tradition fares better than the rival even in that rival's own terms.

MacIntyre's positive views in ethics and politics are versions of Aristotelianism. In keeping with his conception of rationality in inquiry, his basis for affirming these views is that Aristotelianism is more defensible than rival traditions, even on those rival traditions' own terms.

### THE ETHICS OF VIRTUE

MacIntyre argues in *After Virtue* that of the classical moral theories presented by Hume, Kant, Jeremy Bentham, and John Stuart Mill, neither they nor their contemporary defenders offer anything like compelling reasons to affirm these theories, nor do we have any reason to think that such reasons are forthcoming. Should we then, MacIntyre asks, follow Friedrich Nietzsche in thinking that the institution of morality is a fraud, to be jettisoned as the institution of taboo was jettisoned?

MacIntyre holds that there is an alternative to the moral theories defended in the Enlightenment and in the wake of the Enlightenment: Aristotelianism. On Aristotle's view ethics deals with the transformation of human

beings from their immature condition into a condition that constitutes their true end, the realization of their specifically human potentialities, which realization occurs through the acquisition and exercise of various moral and intellectual virtues. Aristotelianism fell by the wayside during the Enlightenment—in part because of its close identification with Roman Catholic scholasticism and in part because of the discrediting of Aristotelian science in the Scientific Revolution—but MacIntyre argues that this rejection was unwarranted, for an ethics coming out of the Aristotelian tradition is the best hope for moral philosophy.

MacIntyre's original formulation of this virtue ethics in *After Virtue* defines the virtues in terms of those qualities of character and intellect that are necessary for one's achievement of goods specific to practices (for example, games, crafts, arts, sciences, and other complex activities), for the sustenance of one's quest for the good life, and for the maintenance of one's community and one's traditions. He does not there formulate his view as part of a teleological conception of human nature and, indeed, in that work, he treats it as a desideratum for a restated Aristotelian ethics that it not rest on such a *metaphysical biology*. But in later works, most clearly *Dependent Rational Animals*, MacIntyre argues that ultimately we have to understand the virtues in terms of just such a teleological conception—a version of Aristotelianism grounded in the work of Thomas Aquinas—and that this conception is not at odds with the well-founded claims of contemporary science.

### THE POLITICS OF LOCAL COMMUNITY

MacIntyre's views in political philosophy are frequently labeled *communitarian*, but this is a mistake if by communitarian we mean the position that states should be in some way guided by the ideals of the value of community. MacIntyre's position is more radical, for he holds that every conception of politics that is built on the attempt to justify the state is doomed to failure. For the state—a hierarchically structured apparatus of political control—is not justifiable; all attempts to explain why the state is authoritative have failed. This does not mean that politics is an empty enterprise or that authority is inevitably illegitimate. It means, rather, that the goods of politics are realized not through the state but through much more local communities in which people can engage in genuine argument and have effective control over how their common life is structured. Only in local communities can the politics of the common good rather than that of individ-

ual advantage or class dominance be practiced. This emphasis on the necessarily local character of good politics also marks MacIntyre's views as Aristotelian.

### MACKIE, JOHN LESLIE (1917–1981)

John Leslie Mackie was born in Sydney, Australia, and educated under John Anderson at the University of Sydney, and at Oxford, where he graduated with a First in Literae Humaniores in 1940. After the war, he returned to an academic position in the University of Sydney, and in 1955 he took up the Chair in Philosophy at the University of Otago, in Dunedin, New Zealand. In 1959 he returned to the University of Sydney to replace Anderson in the Challis Chair. After five years he left for Great Britain, going first to fill the foundation Chair of Philosophy at the new University in York. In 1967 he became Fellow of University College, Oxford, and University Reader in 1978. He remained at Oxford until his death in 1981.

Mackie's work is characterized by an acute, unwearyed, and always dispassionate analysis of alternative solutions to specific philosophical problems. Striving first for full clarity in the statement of the problem, he proceeds by careful exploration and appraisal of the arguments available in support of alternative proposed solutions. Mackie applied this analytic style of reasoning across a broad range of issues. He made contributions to, among other topics, logic—and particularly the understanding of logical paradoxes; to the nature of conditionals and the theory of causality; to the interpretation of counterfactual conditionals; to the theory of space and time; to the theological problem of evil; to the theory of ethics; to the relations between reason, morality, and law; to the philosophy of mind; to the philosophy of biology; and to the interpretation of Locke's epistemology and metaphysics, and of Hume's ethics.

For many years, Mackie published a succession of important articles, but no books. This pattern of publication was transformed in 1973 with the appearance of *Truth, Probability, and Paradox*, a collection of essays on logical themes. This was followed in rapid succession by *The Cement of the Universe* (1974), which presents his views on causation, and *Problems from Locke* (1976). In this work Mackie takes up a group of characteristically Lockean themes, including primary and secondary qualities, perception, substance, universals, identity, and innate ideas, and relates them to contemporary discussion of the same issues. In *Ethics, Inventing Right and Wrong* (1977) he presents a sustained argument for a distinctive error-projection account of human moral thinking, which was provided with some additional support in his extended discussion of Hume's moral theory, which appeared in a book of that name in 1980. Lastly, posthumously, *The Miracle of Theism* was published in 1982. Its subtitle—*For and Against the Existence of God*—sufficiently indicates its contents. Though scrupulously fair, Mackie himself was firmly convinced by the case for atheism. This burst of productivity propelled Mackie to the forefront among British philosophers of his generation, and his relatively early death, while still at the height of his powers, was keenly felt.

### MACKIE'S THESES

Although contributing to many debates in the course of his career, Mackie is principally celebrated for four distinctive theses. The first, in philosophical theology, is his insistence, patiently argued over many years, that all the attempts to reconcile the existence of evil with the classical Christian conception of God as omnipotent, omni-

cient, and benevolent are failures, and that any plausible variations on them will fail also.

The second is in philosophical logic, in which Mackie argues that despite appearances, counterfactual conditionals are not actually propositions at all, but rather condensed and elliptically expressed arguments. The conditional's antecedent is the argument's premise, and its consequent is the conclusion. The counterfactual conditional is to be accepted if the argument is good as it stands, or can be made good by the supply of plausible understood additional premises.

The third thesis pertains to metaphysics, specifically causation. Recognizing that in almost every case the whole cause of an event involves multiple factors, Mackie proposed an account of causal factors. These, he held, are INUS conditions—that is: insufficient but necessary parts of unnecessary but sufficient conditions for the occurrence of the effect.

In ethics, the area of Mackie's fourth distinctive thesis, he argues that although the semantics of ordinary indicative moral discourse apparently require that there be moral facts in virtue of which human moral claims are true or false, there are no such moral facts. Moral discourse must therefore be explicated as arising from widespread error. The denial of objective moral facts is the aspect of his thought that most clearly shows the influence of his Andersonian education. Mackie argued that people's attitudes and feelings when considering their behavior and its effects lead them to assume, falsely, the existence of objective features of right or wrong, good or bad, in human situations, which correspond to, and validate, those attitudes and feelings. As there are no such validating properties, people must take on themselves the responsibility for the judgments they make.

In the years since his death, Mackie's philosophy has continued to be influential. In particular, his controversial views in ethics and philosophical theology continue to attract critical but respectful discussion.

## MACROCOSM AND MICROCOSM

“Macrocosm” and “microcosm” are philosophical terms referring, respectively, to the world as a whole and to some part, usually man, as a model or epitome of it. According to one version of this ancient analogy, man and the universe are constructed according to the same harmonic proportions, each sympathetically attuned to the other, each a cosmos ordered according to reason. By an imaginative leap, the universe itself was thought to be, like man, living and conscious, a divine creature whose nature is reflected in human existence. Animism and panpsychism also regard the world as alive throughout, but the microcosm idea is distinct in emphasizing the unity or kinship of all life and thought in the world. If man is the microcosm of the universe, then not only is everything animated by *some* soul or other, but there is *one* world soul by which everything is animated. Thus, the followers of Pythagoras and Empedocles held, according to Sextus Empiricus, that “there is a certain community uniting us not only with each other and with the gods but even with the brute creation. There is in fact one breath pervading the whole cosmos like soul, and uniting us with them” (W. K. C. Guthrie, *A History of Greek Philosophy*, Vol. I, p. 278).

Because the word *kosmos* can mean order as well as world or world order, “microcosm” can signify not only man in relation to the universe (or in relation to the state, as in Plato’s *Republic*) but also any part of a thing, espe-

cially a living thing, that reflects or represents the whole it belongs to, whenever there is a mirroring relation between the whole and each of its parts. Nicholas of Cusa’s doctrine of individuals as “contractions” of the form of the universe is a microcosm theory, as is Gottfried Wilhelm Leibniz’s theory of monads as “perpetual living mirrors of the universe”; similarly, to cite an example from nonphilosophical discourse, the composer Béla Bartók’s collection of piano pieces *Mikrokosmos* is a little world of modern musical style and technique.

The idea of the microcosm appears in pre-Socratic philosophy in connection with the problem of relating the One and the Many. Taking all of nature to derive ultimately from a single common substance, they supposed it to have inherent in it a principle of motion and change (which they identified with life, soul). Since some of the resulting entities possess consciousness, so too must their source. And if the universal soul is eternal and divine, then the human soul, which is a “fragment” of the One, as the Pythagoreans held, must also be eternal and divine. The return of the individual soul to its divine origin could be realized by philosophical understanding of the cosmos; since like is known by like, as the cosmos becomes known the knower is assimilated to it. Thus, man is, and discovers himself to be, the part that most perfectly reveals the nature of the whole.

Man the microcosm is a commonplace of Greek thought from Anaximenes, the Pythagoreans, Heraclitus, and Empedocles to the Stoics and Neoplatonists. It is a staple theme for variation in the Orphic, Gnostic, and Hermetic texts and in the literature of mysticism, pantheism, and the occult. That man is the microcosm was, in the Renaissance, widely taken to mean that cosmic knowledge and influence might be achieved through contemplation of the powers and tendencies men find in their own imaginations. Such knowledge would be based not on mere inference from resemblance but rather on the kinship or identity of human life and consciousness with the forces governing nature as a whole.

The notion that man is the microcosm has always played both rational and mystical roles in Western thought. Well into the period of the scientific revolution, the microcosm was an image of the order and harmony pervading the world. Saying that the universe is controlled by a single principle (in the way that rational thought is the controlling principle in man) expressed the unified and self-regulating character of the world as understandable in its own terms, fit for scientific investigation. Similarly, human thought itself was conceived to be self-regulating and self-correcting—thus entered the

idea of the autonomy of reason that has played an important part in the history of rationalism and of Western philosophy generally. According to Plato's recollection doctrine, "All nature is akin, and the soul has learned everything, so that when a man has recalled a single piece of knowledge—*learned* it, in ordinary language—there is no reason why he should not find out all the rest" (*Meno* 81D, E). By recollection Plato meant the recovery of systematic knowledge of necessary truths from within oneself, but it is easy to see how it could also be thought of as an intuitive, nontheoretical process—a stream of consciousness leading to memory of past reincarnations or of the soul's celestial origin.

The thought that the universe is ordered not by chance but by one spiritual principle stimulated the wish for direct mystical union with this soul, and even for influence over things through it, as easily as it encouraged the pursuit of systematic understanding of the world. The first impulse produced such exalted sentiments as those lavished upon the universe in the Hermetic religious writings; the second pushed open the door to that underground world of magic, astrology, alchemy, and spiritualism that claimed to utilize the same unifying principles assumed in science and in the astral theology of the philosophers. Perhaps something may be said for a generous interpretation of this magical view of nature, which even in antiquity was distinguishable from its rationalistic and humanistic counterpart. For the practitioners of the occult and for their opponents, the view of the world as a "be-souled" creature was neither an isolated hypothesis nor an idle conceit; the microcosm was an almost omnipresent presupposition, the basis of the very language in which the phenomena whose explanation was sought were represented. Yet there were always philosophical skeptics, and often the same writers who affirmed the world soul or the microcosm—for example, Plotinus, Giovanni Pico della Mirandola, Johannes Kepler—also tried to restrict it in ways that precluded the possibility of undesirable magical application.

## ANCIENT THOUGHT

In the *Timaeus* Plato presents a mythical account of the creation of the world according to which the world's soul and body are made by the Demiurge, who copies the Form of the ideal living creature (not itself any species of animate being but embracing the types of them all). The world soul is constructed according to a complex musical pattern, and, in order to be capable of thought, the elements of discourse—sameness, difference, and existence—are blended to form its mind. The body joined to

the world soul is said to be unlike the human body or that of any animal in the world, being perfectly spherical, devoid of organs of sense, respiration, and ingestion; however, the processes of the universe are said to be reproduced even in the details of microcosmic processes, such as the moment of blood in humans. And because of the affinity between the divine part in humans and the thoughts and revolutions of the universe, the study of the rhythms of the macrocosm are recommended as a means of "correcting those circuits in the head that were deranged at birth."

A methodological discussion forms the context of a playful passage in the *Philebus* (27A–31B) in which the microcosm image also appears. All philosophers hold mind to be the king of heaven and earth, Socrates observes: "in reality they are magnifying themselves. And perhaps they are right." Socrates and Protarchus agree that the order of the world proves that the cosmos is governed by "Mind [*nous*] and a wondrous regulating Intelligence." Socrates argues further that the elements composing our bodies are but fragments produced and sustained by the elements in the universe. Because the unity of the elements in us makes up our bodies, the collective unity of elements in the universe must make up the world's body; because our bodies have souls, the body of the universe must have one, too; for where could our bodies have gotten their souls "if the body of the universe, which has elements the same as our own though still fairer in every respect, were not in fact possessed of a soul?" Strictly, this much of the argument concludes merely in the existence of a world soul that is the cause of the mixture of the body's elements—there is as yet barely a hint of the world soul's having a structure of its own apart from the body, of its being rationally ordered and the cause not just of all mixture but of all movement in the cosmos. Ultimately, the universal soul itself is said to be produced by Cause (later identified with Mind), yet this Mind cannot come into existence without soul (30C). To the extent that we can distinguish the Demiurge from the world soul (in the *Timaeus*), we can say that the Cause of the *Philebus* is probably more like the first of these.

Aristotle's physical system seems to have been designed to avoid the view of the cosmos as "besouled" or as alive in all its parts. Thus, in *De Caelo* the motion of the stars is explained not by any life in them but mainly in terms of the circular motion natural to the *aether* of which they are composed. In Book II (Ch. 2) Aristotle rejects the view that "it is by the constraint of a soul that it [the heaven] endures forever." The Demiurge as designer of the world is wholly excluded; no conscious-

ness is needed of the rational (but unpremeditated) pattern to which nature adheres. Although there is a reference (to the views of others) in the *Physics* (Book VIII, Ch. 2), which may be the first occurrence of the Greek expression for “microcosm,” Aristotle seems not to have organized his conception of nature around the view of it as an organism in any significant way. (For a contrasting account, see W. K. C. Guthrie, “Man as Microcosm.”)

What is missing in Aristotle reappears (partly under Heraclitus’s influence) in the thought of the Stoics—the sense of the world as an animate and conscious continuum each part of which affects all others by its *sympathy*, its “sharing of experience” with the others. The doctrine of sympathies and antipathies among the parts of the world animal guided the physical research of the Stoics and predisposed them to accept and to attempt to rationalize the particulars of astrology and divination. And man as microcosm was the source of their efforts to locate the basis of human conduct in natural law; by playing one’s assigned role in the cosmos, one’s *logos*, his “inner self,” would be linked to that of the whole (Hans Jonas, *The Gnostic Religion*, p. 248).

Plotinus, like the Stoics, treated the world as a single creature, “living differently in each of its parts.” If the world soul of Plato’s system is thought of as operating purposefully and consciously, and if the Nature of Aristotle’s system is taken to work purposefully but unconsciously, we should say that for Plotinus the world as a whole is governed consciously yet produces individual things “as in a dream,” spontaneously, without reasoning, choice, or calculation. According to Plotinus only a unity of soul among us could explain our sympathetic relations to one another, “suffering, overcome, at the sight of pain, naturally drawn to forming attachments” (*Ennead* IV, ix, 3). Plotinus denied that the unity he spoke of entailed the transference of a person’s emotions to places outside his body; the souls of the sufferer and of the sympathizer do not feel as one. Rather, his model of unity is that of a science, where individual truths cannot be considered apart from the whole; “the whole is in every part: ... The one detail, when it is matter of science, potentially includes all” (IV, ix, 5). In geometry, for example, “the single proposition includes all the items that go to constitute it and all the propositions which can be developed from it” (IV, ix, 5). Perhaps this very strict sense of unity, which asserts that each thing is internally connected with every other thing (or that there is one thing with which each is connected) has always been latent in the microcosm doctrine; if so, it is an aspect of the doctrine that seems to offer small encouragement to the search for the actual

relations in nature. The question “Which things are causally connected, which are not?” has little point if all can affect all alike.

The general ancient view of the world as a perfect organism may have been responsible, as Samuel Sambursky suggests, for the insistence of ancient thinkers on the attempt to understand the world as a whole, in its entirety, and for their almost total avoidance of experimentation—the isolation of phenomena, or “dissection of nature,” characteristic of modern science.

## MEDIEVAL AND MODERN THOUGHT

Man as microcosm of the universe is not integral to Jewish and Christian doctrine in the way that it is to the Gnostic religious system, for example; thus, Philo Judaeus and Moses Maimonides employed the idea of the world soul only dialectically. In *The Guide of the Perplexed* (Pt. I, Ch. 72) Maimonides at first argues that the world is like a human being, but he then presents so many points of difference between the two that in the end it is clear that he considers the possession of a rational order to be their only common factor. As a cosmological view, the microcosm has little or no place in Augustine or in Thomas Aquinas, who treats it as a mere figure of speech. By contrast, Joseph ibn Zaddik states one of the microcosm’s main attractions when he proposes to show how self-knowledge will lead to knowledge of the whole—a “short cut” through the study of man, bypassing the sciences. Bernard of Tours and other members of the school of Chartres assimilated the world soul of Plato’s *Timaeus* to the Third Person of the Trinity. Drawing upon Bernard, Hildegard of Bingen, in her visionary writings, represented detailed correspondences between heavenly motions, winds, elements, humors, and bodily and spiritual states in the individual.

Plato had typically employed the microcosm image to portray the transformation of consciousness through theoretical knowledge of whatever cosmic order science reveals; Ibn Zaddik reverses the process, seeking to discover in man what the cosmic order must be. Where Plato stressed the dissimilarity between the living cosmos and the structure and functioning of any particular animal, including man, Hildegard dwells on their supposed similarity in picturesque detail. The idea that inner experience of human nature supplies a direct route to reality is prone to magical extension in a way that Plato’s view is not, but it was this conception that took hold in medieval and Renaissance microcosm literature.

Renaissance speculation on the microcosm centered on the idea that human nature partakes of bodily, intel-

lectual, and divine existence, uniting in itself the whole of the sublunary, celestial, and supercelestial realms. Human consciousness, by which man can know all things, connects him with all things; consciousness is itself a link between thought and its objects. Through consciousness man can know and become all that he wills. A similar doctrine of connections drawn from the Kabbalah underlies the various magical theories of language which asserted that quasi-physical influences join names and things, beyond the conventions of the various natural languages. Partly controllable influences also form the structure of the elaborate identities and correspondences that Agrippa von Nettesheim and Paracelsus described between minerals, animals, heavenly bodies, psychic powers, and parts of the human body. Such influences are also involved in the interaction between thought and its objects that Giordano Bruno assumed in his search for direct awareness of the sympathies controlling nature through memory and the ideas of them in his imagination.

The occult “applications” of the microcosm idea did not survive the advance of the mechanistic worldview. By the eighteenth century, occult qualities, or anything that seemed like them—for example, action at a distance—were in such wide disrepute that even Isaac Newton, to avoid the appearance of being committed to an occult doctrine, refrained from expressing fully his theory of the mode of action of atomic “Central Forces.” But in the second edition of the *Principia* (1713), he described the ether as “a certain most subtle spirit which pervades and lies hid in all gross bodies ... by the force and action of which spirit the particles of bodies attract one another at near distances and cohere ... and all sensation is excited, and the members of animal bodies move at the command of the will, namely by vibrations of this spirit”—a view not far from that of the Stoics, as Stephen Toulmin and June Goodfield remark (*The Architecture of Matter*, p. 195).

Even later, belief in psychic planetary action had not lost all ground; thus, Franz Anton Mesmer’s explanation of “animal magnetism,” or hypnosis, assumed a “responsive influence ... between the heavenly bodies, the earth, and animated bodies,” which the hypnotist drew upon. And the idea of a psychic force in the world beyond our immediate awareness, of which our conscious lives are parts or manifestations, endured, for example, in Johann Wolfgang von Goethe’s Nature philosophy and in Arthur Schopenhauer’s world will—ancestors of the concept of the unconscious. Perhaps some aspects of the microcosm idea can be found in Sigmund Freud’s attempts to explain

the instincts in man as repetitions of the reactions of living matter to drastic changes in the prehistoric environment. (Thus, we might say that man’s instincts are a microcosm of his evolution.) Among the known “enforced alterations in the course of life ... stored for repetition,” Freud, along with Sándor Ferenczi, noted the drying up of the oceans which left life to adapt on land and the cultural development necessitated by the glacial epoch. These are reexperienced at birth, in the diphasic onset of man’s sexual life, and in the latency period. Freud invokes the contending forces, Love and Strife, of Empedocles’s “Cosmic phantasy,” pointing out their similarity to Eros and Destructiveness, the two primal instincts of his biopsychical theory. These instincts, which “present the delusive appearance of forces striving after change and progress” actually impel the organism toward the reinstatement of earlier, more stable states, ultimately to inorganic existence. The originally biological principle that ontogeny recapitulates phylogeny has received very wide psychological extension in psychoanalysis; most recently, Carl Jung has (somewhat cryptically) identified his doctrine of the collective unconscious with that of “the microcosm containing the archetypes of all ideas.”

Perhaps the microcosm image is not entirely the scientific dead end it has understandably been taken for; as early attempts to construct models of the embodied soul’s structure, development, and dynamics, some versions of the image may stand to scientific psychological research as alchemy stands to chemistry.

Three useful histories of the microcosm theme are G. P. Conger, *Theories of Macrocosms and Microcosms in the History of Philosophy* (New York: Russell and Russell, 1922), which includes a survey of critical discussions up to 1922; Rudolph Allers, “Microcosmus, From Anaximandros to Paracelsus,” in *Traditio* 2 (1944): 319–407; and W. K. C. Guthrie’s “Man as Microcosm,” in *Proceedings of the European Cultural Foundation* (Athens, 1966); all contain

- many references. W. K. C. Guthrie's discussion of the microcosm, to which this article is indebted, in *A History of Greek Philosophy* (Cambridge, U.K.: Cambridge University Press, 1962–), Vol. I, is the most important one for the period covered; this volume, *The Earlier Presocratics and the Pythagoreans*, also contains valuable remarks on Plato and Aristotle. The microcosm in Plato is discussed by F. M. Cornford throughout his commentary on the *Timaeus* in *Plato's Cosmology* (London: K. Paul, Trench, Trubner, 1937); G. M. A. Grube discusses the microcosm as part of Plato's theory of the soul in *Plato's Thought* (London: Methuen, 1935), Ch. 4; see also F. M. Cornford, "Psychology and Social Structure in the Republic of Plato," in *Classical Quarterly* (1912): 247–265; R. Hackforth's translation of the *Philebus*, with commentary, in *Plato's Examination of Pleasure* (Cambridge, U.K., 1945); and Gregory Vlastos, "Anamnesis in the *Meno*," in *Dialogue* 4 (2) (September 1965): 143–167, which interprets the recollection theory with comments on its connection with the doctrine of reincarnation. Possible oriental influences on Plato are discussed in A. Olerud, *L'idée de microcosmos et de macrocosmos dans la Timée de Platon* (Uppsala, 1951). Two valuable relevant studies of Aristotle are W. K. C. Guthrie's introduction to the text and translation of *Aristotle on the Heavens* (London, 1939) and Friedrich Solmsen's *Aristotle's System of the Physical World* (Ithaca, NY: Cornell University Press, 1960).
- On the Stoics, see Samuel Sambursky, *The Physics of the Stoics* (Princeton, NJ: Princeton University Press, 1987.)
- On Plotinus, see the introductions and translations in E. R. Dodds, *Select Passages Illustrating Neoplatonism* (London, 1923), and A. H. Armstrong, *Plotinus* (London: Allen and Unwin, 1953). Remarks bearing on the microcosm in ancient thought generally are contained throughout E. R. Dodds, *The Greeks and the Irrational* (Boston: Beacon, 1957); Hans Jonas, *The Gnostic Religion* (Boston: Beacon, 1963), especially Ch. 10, "The Cosmos in Greek and Gnostic Evaluation"; A.-J. Festugière, *Personal Religion among the Greeks* (Berkeley: University of California Press, 1954); E. A. Lippman, *Musical Thought in Ancient Greece* (New York: Columbia University Press, 1964); and Samuel Sambursky, *The Physical World of the Greeks* (London: Routledge and Paul, 1956). See also E. W. Beth, *The Foundations of Mathematics: A Study in the Philosophy of Science*, rev. ed. (New York, 1964), Chs. 1 and 2, "The Pre-history of Research into Foundations" and "Aristotle's Theory of Science."
- Hildegard of Bingen's life and writings are examined in Charles Singer, *From Magic to Science* (New York: Dover, 1958), Ch. 6, "The Visions of Hildegard of Bingen," a rewritten chapter from *Studies on the History and Method of Science*, Vol. I (Oxford, 1917). Ernst Cassirer, *Individuum und Kosmos in der Philosophie der Renaissance* (Leipzig: Teubner, 1927), translated by Mario Domandi as *The Individual and the Cosmos in Renaissance Philosophy* (New York: Harper, 1963), is the standard discussion of the microcosm in Renaissance thought. On the difficult subject of Renaissance occult literature, see D. P. Walker, *Spiritual and Demonic Magic from Ficino to Campanella* (London: Warburg Institute, University of London, 1958). Three chapters in Frederick Copleston's *A History of Philosophy*, Vol. III, *Late Medieval and Renaissance Philosophy*, Part 2 (Westminster, MD: Newman Bookshop, 1953), are useful surveys; Ch. 15 discusses the microcosm in Nicholas of Cusa, Chs. 16 and 17 are on the philosophy of nature. An important interpretation of Bruno is Frances Yates, *Giordano Bruno and the Hermetic Tradition* (Chicago: University of Chicago Press, 1964). There are also interesting discussions in Alexandre Koyré, *Mystiques, spirituels, alchimistes du XVI<sup>e</sup> siècle allemand* (Paris, 1955), and in Werner Pauli, "The Influence of Archetypal Ideas on the Scientific Theories of Kepler," in *The Interpretation of Nature and the Psyche* (New York: Pantheon, 1955). Microcosm and macrocosm are discussed in the context of the idea of the chain of being in E. M. W. Tillyard, *The Elizabethan World Picture* (New York, 1941); see also W. C. Curry, *Shakespeare's Philosophical Patterns* (Baton Rouge: Louisiana State University Press, 1937). On the transition from animism to mechanism in science, see E. J. Dijksterhuis, *Mechanization of the World-Picture*, translated by C. Dikshoorn (Oxford: Clarendon Press, 1961); M. B. Hesse, *Forces and Fields* (London: T. Nelson, 1961); and Stephen Toulmin and June Goodfield, *The Architecture of Matter* (New York: Harper and Row, 1962).
- A brief account of Mesmer's ideas can be found in Clark L. Hull, *Hypnosis and Suggestibility* (New York: Appleton-Century, 1933), pp. 6–11. Schopenhauer's doctrine of the microcosm and its influence on Ludwig Wittgenstein are discussed in Patrick Gardiner, *Schopenhauer* (Baltimore: Penguin, 1963). Wittgenstein's remark "I am my world. (The microcosm.)" appears in the *Tractatus*, but without the connection with the world-spirit doctrine it has in his *Notebooks* (pp. 84–85). Wittgenstein's idea of an internal connection between language, thought, and reality is discussed in Erik Stenius, *Wittgenstein's Tractatus* (Oxford, 1960), and Max Black, *A Companion to Wittgenstein's Tractatus* (Ithaca, NY: Cornell University Press, 1964).
- A short discussion of the microcosm image as employed by Freud and other analysts is contained in Philip Rieff's introduction to *General Psychological Theory* (New York, 1963), which is a volume in the paperback edition of Freud's *Collected Papers*; see pp. 9–17. Freud discusses Empedocles in "Analysis Terminable and Interminable," in the volume *Therapy and Technique*, edited by Philip Rieff (New York, 1963), the paperback edition of Freud's *Collected Papers*. Jung's ideas are expressed in his *Naturklärung und Psyche* (Zürich: Rasche, 1952), translated by R. F. C. Hull as *The Interpretation of Nature and the Psyche* (New York: Harcourt Brace, 1955). Ch. 3 of his essay "Synchronicity: An Acausal Connecting Principle" contains numerous quotations from earlier microcosm literature.
- Problems that arise in trying to characterize the universe as a unified whole (or as a "whole" at all) on the basis of information concerning only a part and in trying to treat scientifically the nature of a necessarily unique object are presented in D. W. Sciama, *The Unity of the Universe* (Garden City, NY: Doubleday, 1959), pp. 69–205. For further discussion and bibliography, see the Cosmology and Rationalism entries.

Donald Levy (1967)

## MAILLET, BENOÎT DE

(c. 1656–1738)

Benoît de Maillet was a French diplomat, traveler, and natural scientist. Information concerning the place and date of his birth, details of his life, and the significance of his works is, at best, sketchy and contradictory. A member of the impoverished nobility, Maillet presumably received the customary classical education of the day. He seems to have led an apathetic existence until his appointment to the French consulate in Cairo at the age of thirty-six. As consul, he handled the king's business well and, for services rendered, was named ambassador to Ethiopia in 1702. He declined the honor, ostensibly for reasons of health but actually because his duties would be less concerned with Franco-Ethiopian relations than with the formidable task of converting the natives to Christianity. In 1707, at his own request, he left his post in Cairo to assume charge of the French consulate in Livorno, Italy. He was so successful as consul and later as inspector of French settlements in other parts of the Mediterranean that, upon his retirement in 1724, he received a handsome pension and spent the remaining fourteen years of his life in Marseille. There, besides attending to a large correspondence, most of which is now lost, he wrote several works, including *Description de l'Égypte* (1735) and the vastly more important *Telliamed, ou entretiens d'un philosophe indien avec un missionnaire françois* (1748), which appeared posthumously.

## TELLIAMED

The years of Maillet's consulships, his travels in the Mediterranean basin, and his wide readings and careful observations formed much of the background for *Telliamed* (the author's name spelled backward). First published in Amsterdam, it was closely followed by other editions in both French and English, the most important being that of the Abbé Le Mascrier (1755). The work consists of a series of conversations in which Maillet, speaking through his Indian philosopher, Telliamed, puts forth various geological and biological speculations about Earth's cosmogony and its evolution—together with the organic beings it supported—into its present state. According to Maillet's system, Earth, product of a whirlpool of cosmic dust, was for countless ages entirely covered with swirling waters. As the waters gradually receded, the primordial mountains formed by the currents of these waters slowly emerged from the depths. The crashing of the waves against these mountains formed new mountains, and with the appearance of life in the seas, fossil strata were formed.

Primitive forms of aquatic life, produced in ever-increasing abundance through the aeons, underwent gradual modifications of structure and function in keeping with changing habits and new environments. Thus, creatures along the shallow coastal waters moved into the marshes and, after much trial and error, finally emerged with wings for flying or legs for walking. Beneath this speculation lay the work's basic theme that everything in the universe, through the processes of time, was undergoing constant change. Occasionally the author's boldly imaginative thought resulted in whimsy, which was interpreted by many of his critics as folly or childish fantasy.

*Telliamed* immediately became a center of controversy that extended well into the nineteenth century. Maillet's heretical views, which ran counter to the tenets of Genesis, aroused the theologians of the day, while many eighteenth-century rationalists and scientists, led by Voltaire, were violently opposed to his ideas on other grounds. Disparaging criticisms continued in the writings of such eminent men of science as Étienne Geoffroy Saint-Hilaire and Georges Cuvier. Nonetheless, Comte de Buffon, Denis Diderot, Chevalier de Lamarck, and Erasmus Darwin, among others, availed themselves of Maillet's theories as a starting point for even more daring concepts of their own.

## MAIMON, SALOMON

(1753–1800)

Born in 1753 in a small village in Lithuania, Shlomo ben-Yehoshua later named himself "Maimon" after the great medieval Jewish philosopher Moses Maimonides. After being married at the age of eleven and fathering a child at fourteen, Maimon left his native country around 1778 in search of "Enlightenment." Following extraordinary adventures as a wandering beggar and scholar, Maimon

arrived in Berlin in March 1780. There he became acquainted with Moses Mendelssohn and his circle. Maimon formulated many of his views (on Judaism and religion in general, and on Spinoza) in overt or covert criticism of Mendelssohn. Until 1791 Maimon contributed to projects of Jewish Enlightenment (*Haskala*), which he wished to promote in the first place through scientific knowledge. Later he became estranged from Jewish affairs.

Maimon's rather coarse way of life, which offended both Jewish ceremonial law and bourgeois decorum, forced him to leave Berlin in 1783. From June 1783 until March 1785 he studied in a German high school in Altona (Hamburg), and improved his knowledge of German and mathematics as he also learned Latin, English, and French. Back in Berlin, Maimon was supported almost entirely by benefactors. By the end of 1789, following praise from Immanuel Kant, Maimon published his first German book, *Versuch über die Transzendentalphilosophie* (*An Essay on Transcendental Philosophy*), which is a critical commentary on Kant's *Critique of Pure Reason*. A prolific writer, Maimon produced a number of publications, including both books and journal articles. Almost all of Maimon's works are commentaries of a sort on different writers, a method of philosophizing that is certainly a legacy of his Jewish education. In 1795 Maimon met Graf Adolf Kalkreuth, later himself a philosophical writer, and moved into his house near Berlin, and later to his estate in Silesia. There Maimon died on November 11, 1800.

In his autobiography (1792–1793) Maimon interprets his life as a process of progressive formation (*Bildung*) leading from traditional orthodox Judaism in Lithuania to the center of Enlightenment in Berlin. This change is conceived as “spiritual rebirth” (*Gesammelte Werke* 1:301), a classical term of contemporary Pietism. This work inspired many later autobiographies of European Jews seeking Enlightenment ideals, and it sets the stage for Maimon's own brand of philosophy.

#### RATIONAL DOGMATISM AND EMPIRICAL SKEPTICISM

In the *Versuch*, Maimon describes his position as “rational dogmatism and empirical skepticism,” and despite the oddity of the combination, this is an apt description of his views (*Gesammelte Werke* 2, 432). Maimon follows the rationalists (particularly B. Spinoza and G. W. Leibniz) in granting the principle of sufficient reason unlimited scope: There is nothing inexplicable in the world, and reason's demands are unconstrained. But at the same

time, while we can be sure that the principle of sufficient reason in general holds universally, our finitude prevents us from knowing with any certainty whether any *particular* judgment we make about the world accords with this rational condition. As such, whereas rationalism is right about the nature of knowledge, skepticism infects particular knowledge claims.

The exception to this, Maimon claims, is mathematics, in which we can achieve certain knowledge, for here our situation is compared to the “divine”: In our mathematical claims we create the contents of mathematical judgments, by constructing *a priori* the objects of geometry and arithmetic. Here we can be assured (although in geometry this is not always the case) that our concepts apply to objects, because the objects themselves are created according to the concepts. But whereas certainty is guaranteed in the field of mathematics, our empirical judgments do not rise to this level, because they can never be shown to possess the “determinable” relation between subject and predicate demanded of “real thought.”

#### DETERMINABILITY AND REAL THOUGHT

According to Leibniz, analytic thought is governed by the law of identity or contradiction: The complete concept of the subject contains all predicates that can be truthfully predicated of it. All true propositions are hence either overtly or “virtually” analytic. Maimon maintains that if there are synthetic judgments *a priori* (as Kant holds), there must also be a principle of such judgments. Since Maimon rejects the thesis that synthesis is the result of the application of the understanding to intuition, he maintains that synthetic thought must have a principle in reason itself. This is his Law of Determinability. The principle distinguishes between the subject that can be thought by itself and the predicate that can be thought only in relation to a subject: It thus permits the synthesis “square table” and excludes “tablish square,” because “table” can be thought by itself and the property “square” cannot.

A further, seemingly paradoxical component of the law of determinability is that in a “real synthesis” there is exactly *one* predicate for each subject term. It thus demands for “line” either “straight” or “curved” and excludes “sweet line.” Finally, it positively determines that a “real synthesis” is only a synthesis that produces a new object. The hallmark of an object determined through real thought is that new consequences follow from it that flow neither from the subject nor from the predicate terms alone, but only from their synthesis. Thus a trian-

gle has certain “consequences” (e.g., that the sum of its internal angles equals two right angles), whereas the Pythagorean theorem is a further consequence of the synthesis of “triangle” and “right angle.”

Real thought then depends on a determinable relation between subject and predicate, and this in turn can be guaranteed only in cases where an object is constructed according to a concept. While this occurs in geometry, the determinable relation cannot be shown to hold in cases in which we are passively given empirical objects through sensibility. Here it is also conspicuous that “real synthesis” is equivalent to the construction of the object itself, and that it proceeds from general to particular concepts. This and the unique relation between subject and predicate imply that if we could generate predications according to the law of determinability, we would be able to (re)construct the *entire* conceptual structure of the world. Because rationalism assumes that complete knowledge exhausts its object, the generation of this conceptual structure would be tantamount to the construction of the world. In mathematics we are hence similar to God (*Gesammelte Werke* 4:42). But this divinity is sharply limited: because proper knowledge consists in such determinable relations that in empirical cases we cannot produce but are merely given, most of what we think of as empirical human knowledge does not in fact deserve the name. Our beliefs about the merely encountered world of objects fail to meet the criteria of real knowledge. This is one source of Maimon’s skepticism, which plays a key role in his critique of Kant.

### QUID FACTI/QUID JURIS

The difficulty Maimon finds in Kant’s views on synthetic judgments a priori centers on two crucial questions that drive the Transcendental Deduction of the Categories in the *Critique of Pure Reason*. There, Kant distinguishes between the *quid facti* (or, the question of fact) and the *quid juris* (or the question of right or warrant) of the use of the pure concepts of the understanding. The first question concerns whether we indeed have certain synthetic judgments due to the application of categories to intuitions, whereas the second asks about our right or justification in doing so. Kant is largely concerned with the second question, because he assumes, according to Maimon, that our experience reveals that we in fact have certain knowledge. But Maimon calls this assumption into question, by challenging the Kantian idea that our experience really involves supposedly objective and necessary claims such as “The sun warms the stone.” Kant can assume this to be the case, but this will not convince

the skeptic—yet the central argument of the Deduction needs just this supposition, Maimon argues, to establish that the categories are legitimately employed in experience. As a result, only by begging the question “*quid facti*” against a Humean skeptic can Kant’s argument succeed.

Maimon also remains suspicious of Kant’s answer to the question *quid juris*. Kant aims to show that the legitimate employment of the categories rests on the way in which they can be applied to the intuitive contents of experience delivered by the faculty of sensibility; this depends on his fundamental commitment to a model of experience that distinguishes between intuitions (which are singular and immediate) and concepts (which are general and mediate). Kant’s system endorses a kind of cognitive dualism, in which the separate faculties of the understanding and sensibility each contribute distinct and ineliminable elements of cognition. Yet Maimon finds this dualism problematic, for it faces all the challenges and problems that traditionally confront other dualisms such as that between mind and body. For how can wholly separate faculties nonetheless interact in the way that cognition requires? Maimon claims that for this reason Kant’s cognitive dualism cannot answer the *quid juris* in a satisfactory manner.

In Maimon’s critique of Kant, his allegiances to both skepticism and rationalism come to the fore. The challenge to the *quid facti* draws upon a kind of Humean skepticism about the structure of experience, and calls into question the notion of experience with which Kant’s project begins. The critique of the *quid juris* rests upon Maimon’s rationalist commitments, for it demands that some sufficient reason or explanation be provided for what Maimon takes to be a wholly mysterious relation between concepts and intuitions. Maimon’s challenge to Kant is so interesting and powerful precisely because of his odd brand of skepticism, for it allows him to mount simultaneous attacks on the critical system from both an empiricist and a rationalist position.

### MAIMON AND THE TRADITION

Kant famously described Maimon as his most acute critic, and this admiration—even if tinged with occasional acrimony—was shared by a number of other figures in German philosophy. The renown provided by Kant’s comments allowed Maimon to engage in conversations and disputes with a number of the leading lights of the day. Maimon corresponded with K. L. Reinhold (and later had a bitter falling out when Maimon published their letters without Reinhold’s permission), and penned a series

of pseudonymous responses to the then-anonymous author of *Aenesidemus* (G. E. Schulze). In all of these works Maimon pressed his version of empirical skepticism and rational dogmatism.

Maimon's most lasting influence, however, was on J. G. Fichte, who shared Kant's respect for Maimon's intellect, and who saw more clearly than others the threat that Maimon's position posed for Kant's philosophy. Fichte's formulations of his *Wissenschaftslehre* in large part stand as attempts to meet the challenge Maimon posed to Kant, in particular to answer the charge that a dualistic model of cognition cannot explain how its disparate elements interact. Fichte's solution—which turns on rejecting Kant's model of cognition in favor of the positing activity of the Absolute-I—marked the beginning of Absolute Idealism, which reached its fruition in Schelling and Hegel. Maimon himself was certainly no Absolute Idealist—in fact, in his correspondence with Fichte he distances himself from Fichte's project—but his challenge to Kant provided an important goad in the development of Fichte's *Wissenschaftslehre*, and through him the systems of Schelling and Hegel. Thus Maimon's "dogmatic rationalism" found successors but neither his "empirical skepticism" nor his unique combination of both attracted adherents.

But Maimon's combination of skepticism and rationalism is of interest not simply as a historical step on the road from Kant to Hegel, but as a fascinating and often compelling position in its own right. Maimon's skepticism is unique in being based not upon a suspicion of the claims of rational inquiry, but, perhaps paradoxically, on an uncompromising commitment to the demands of reason. The challenge Maimon poses to all accounts of cognition is to explain how the understanding can apply to the contents of sensibility (whether *a priori* or *a posteriori*). Maimon ultimately resorts to a skeptical answer to this question, yet a nonskeptical response to the challenge he presents is something contemporary theories of cognition continue to struggle to meet.

## MAIMONIDES

(1135–1204)

Maimonides was the most celebrated Jewish philosopher of the Middle Ages. "Maimonides" is the Latinized cognomen of Moses son of Maimon. Also called RaMBaM, the acronym for Rabbi Moses ben Maimon, he was born in Córdoba, which belonged at that time to Muslim Spain. His father, Maimon son of Joseph, was a distinguished scholar versed in traditional Jewish lore. At the age of thirteen, Maimonides left his native town after it was conquered by the army of the Almohads, an intolerant Muslim sect. After various journeys he and his family settled in northern Africa, under the oppressive rule of the Almohads. In 1165 they went to Egypt, where Maimonides became a court physician and leader of the Jewish community. He died in Cairo.

Maimonides was and is regarded as an outstanding authority on Jewish religious law, the Halachah. His writings in this field include a commentary in Arabic on the Mishnah that contains a treatise on ethics known as "Eight Chapters" and a list of the thirteen fundamental dogmas of the Jewish faith as established by Maimonides; another of these works, known under the two titles *Mishnah Torah* and *Yad Hazakah*, is a voluminous codification of the Law written in Hebrew, whose first portion, the "Book of Knowledge," expounds a system of religious beliefs and is markedly influenced by philosophy.

The fact that a considerable portion of Maimonides' activity was devoted to legal doctrine is by no means irrelevant in a consideration of his philosophical attitude. In a sense this was a practical activity that can be assimilated to that of a statesman; it was accordingly consonant with Maimonides' Platonizing contention that certain superior individuals are able to combine a mode of existence given over to contemplation and intellection with a life of action.

Maimonides also wrote several medical treatises in Arabic. One of them, known as *Moses' Chapters* (*Fuṣūl Mūsā*), contains a critique of Galen, part of which deals with the Greek physician's animadversions on the Law of Moses. He also composed two popular tracts, "Treatise on Resurrection" and "Epistle to Yemen," the latter treatise rebutting the claims of a pseudo Messiah who had appeared in Yemen. Maimonides is also the author of one philosophical treatise on logic, composed in his early youth.

#### GUIDE OF THE PERPLEXED

Maimonides' reputation as a philosopher rests squarely upon his *Guide of the Perplexed* (*Dalālat al-Hāirīn* in Arabic), a work that its author did not regard as being of a philosophical nature. The "perplexed" to whom the *Guide* is supposed to have been addressed are men who are well grounded in the Jewish religious tradition and have some knowledge of certain philosophical sciences; the disciple to whom Maimonides addresses the "Introductory Epistle" at the beginning of the *Guide* is said to be conversant with logic and mathematics but not with physics or metaphysics. These semi-intellectuals are regarded by Maimonides as being in a state of mental confusion because they consider that the theses of the Greek sciences contradict religious faith. The word *hayra*, "perplexity," which is connected with the participle *hā'irīn* figuring in the title of the work under discussion, appears to have served as a technical term denoting the state of mind induced by a tug of war between two opposed beliefs. Both al-Farabi and, in the generation before Maimonides, the Jewish philosopher Abraham ibn Da'ud also used the term *perplexed* to describe people who hesitate between the conflicting claims of philosophy and religion. In one passage of the *Guide* Maimonides seems to indicate that his purpose in writing the work was to help such of the perplexed as were endowed with the requisite intellectual capacities to achieve a full knowledge of philosophical truths without giving up the observance of the religious commandments.

Maimonides, however, like his contemporary Averroes, was convinced that philosophy could constitute a terrible threat to the social fabric if a vulgarized version of its doctrines were to spread among ordinary people and destroy simple faith in authority. Systematic treatises, giving a step-by-step account of the Aristotelian doctrines, avoided this danger through recourse to technical terms and logical argumentation, which were incomprehensible to noninitiates. Maimonides employed another method, set forth in his introduction to the *Guide*. In the case of this work his very considerable gift for literary composition, which had enabled him to succeed in the extremely difficult task of producing a well-ordered code comprising the whole of Talmudic law, was called upon to disarrange and make a jumble of the systematic expositions of Aristotle and the Aristotelians. Maimonides makes it quite clear that in order to make understanding more difficult, he carefully tore apart conceptions that belong together. The reader is thus faced with the challenge of reconstructing the original whole out of pieces dispersed in various portions of the *Guide*. Maimonides even states that on certain points he deliberately makes two contradictory assertions. These and other precautions, which were intended to confuse readers of insufficient intellectual caliber or preparation, have turned the *Guide* into an enigma; any solution of the enigma can be impugned by an appeal to some statement of Maimonides' that may or may not have been meant to be taken at its face value.

#### INFLUENCES ON MAIMONIDES

There is a question whether the *Guide* was meant to be an apologetic attempt to render religion intellectually respectable by exposing the limitations of human reason, beyond which lies the domain of faith in things that may be true although they are unknown to philosophers; or, alternatively, whether it was meant to demonstrate that religion has a purely practical use. If the latter, then Maimonides meant to say that theoretical truth is essentially, although perhaps not completely, revealed by philosophy and to deny that religion has anything to offer except, in the most favorable cases, myths and parables to be interpreted with the help of scientific knowledge. A knowledge of the philosophical authors whose influence was avowed by Maimonides or may be discerned in his work may help to determine what actually was the main object of the *Guide*.

In a letter to Samuel ibn Tibbon, who translated the *Guide* into Hebrew, Maimonides wrote that he considered Plato's writings to be superseded by those of Aristotle, which are the root and foundation of all philosophy.

Nevertheless, he thought that Aristotle should be studied only with the help of the commentators Alexander of Aphrodisias, Themistius, and Averroes (a contemporary of Maimonides, who was not acquainted with the Muslim philosopher's commentaries at the time the *Guide* was written). Maimonides esteemed al-Farabi above all the other Islamic philosophers (a typical attitude of the philosophers of Spain), and also praised Ibn Bājja, the Muslim Spanish Aristotelian. His reaction to Avicenna, who was the dominant philosophical influence in the Islamic East, was ambivalent.

Maimonides does adopt certain conceptions of Avicenna's. Thus, his view that existence is an accident derives from Avicenna's fundamental doctrine that essences *per se* are neutral with respect to existence, which supervenes on them as an accident. However, in points that have an obvious bearing on religious beliefs, Maimonides sometimes does not hesitate to prefer Aristotelian notions, although they appear to be incompatible with the Jewish tradition prevalent in his time, to views that are more easily reconcilable with this tradition and that, through Avicenna's adhesion, were given the hallmark of philosophical respectability. To cite an outstanding example, Maimonides holds no brief for Avicenna's opinion that the individual human soul survives the death of the body and is immortal. Like Alexander of Aphrodisias and other Aristotelians, he considers that in man only the actual intellect—which lacks all individual particularity—is capable of survival. In adopting this view, Maimonides clearly shows that, at least on this point, he prefers the philosophical truth as he sees it, however opposed it may seem to be to the current religious conceptions, to the sort of halfway house between theology and philosophy which, in the severe judgment of certain Spanish Aristotelians—notably Averroes—Avicenna had sought to set up.

To cite another instance, Maimonides does not give the slightest indication of recognizing, as Avicenna did, the mystical ecstatic way to God as being on the same level as the way of the intellect (the Muslim philosopher may have claimed even more for it than simple equality). According to the *Guide*, the religious commandment enjoining the love of God entails the duty of knowing whatever may be known of him, for love is proportionate to the knowledge man has of the beloved.

### THEORY OF DIVINE ATTRIBUTES

What kind of cognition of God is possible to man? The *Guide* sets forth at considerable length and with stronger emphasis than in Avicenna the doctrine of negative the-

ology. According to this doctrine, nothing positive can be known about God, who has nothing in common with any other being. No predicate or descriptive term can legitimately be applied to him unless it is given a meaning that is wholly different from the one the term has in common usage and is purely negative. All statements concerning God considered in himself should, if they are to be regarded as true, be interpreted as providing an indication of what God is *not*. This applies even to the statement that God exists. Maimonides maintains that progress in this kind of negative knowledge is of considerable value, for it does away with false ideas concerning God.

On the other hand, the positive knowledge that man is capable of is concerned with quite a different domain; it deals not with God in himself but with his governance of nature, or, in other words, with the order obtaining in the cosmos and determining the events that occur in it. According to Maimonides' interpretation of Exodus 33, only this knowledge is granted to Moses, and such are the limitations of human science. As far as this conception is concerned, the acts of God may be identified with the operations of nature (or with historical happenings brought about by natural causes). Maimonides' view of the world being by and large Aristotelian, these operations are subject to the rule that they do not destroy but, rather, safeguard the perpetuity of the immutable order of nature, including the preservation of humankind and of the various other species of living beings.

Some of the operations of God (or of nature) seem, from the human point of view, to be beneficent, for instance, the operation that instills into progenitors the impulse to care for their young; others, such as earthquakes or large floods, seem destructive. Because of the anthropomorphic tendency, men witnessing happenings of the first kind speak of God as being merciful and may impute havoc and death to God's being vengeful. These are two of the so-called divine attributes of action. Quite evidently they are not concerned with the essence of God but reflect a purely human evaluation of God's, or nature's, actions. In contrast with other medieval Aristotelian philosophers, Maimonides does not recognize the divine attributes of relation.

### DIVINE INTELECTION

As the Aristotelian system of physics requires, and as Maimonides demonstrates by means of a number of proofs taken over from earlier philosophers, this world is dependent upon God (who is the Prime Mover); but, contrary to Aristotle's conception (already modified by

some of the late Greek Neoplatonists, whose views reached Maimonides through the Islamic philosophers), God is regarded as the efficient and formal as well as the final cause of the cosmos. This God is pure intellectual activity, to which (in Maimonides' view as well as in Aristotle's) man's intellection bears a certain resemblance. Indeed, Maimonides seems to go out of his way to point out this similarity. In this connection a comparison between a statement of his and one of al-Farabi's is instructive. In accordance with the doctrine of Book A of Aristotle's *Metaphysics*, the Muslim philosopher states quite unequivocally that it is because God intellects only himself that the subject, object, and act of divine intellection are identical. Maimonides, too, maintains this threefold identity with regard to God (*Guide*, Part I, Ch. 68); but he points out that it exists equally in the case of man's intellection of any object, for instance, a piece of wood, because according to an opinion of Aristotle, the actual intellect is identical with the object cognized by it. (This opinion was apparently quite unconnected with Aristotle's conception of God.) This comparison of man's cognition to God's, which argues similarity between the two, appears to be incompatible with Maimonides' negative theology. This point had already been made in the Middle Ages and must be taken into account in any interpretation of the *Guide*.

Furthermore, the fact that Maimonides uses as an example the intellection of a piece of wood seems to suggest that, unlike Aristotle and al-Farabi but in accordance with many of the medieval Aristotelians, he tends to believe that God cognizes not only himself but all the intelligibles. Since cognition involves identity, this conception would appear to entail the identification of God with the intelligible structure of the universe, regarded both as the subject and as the object of cognition. The argument does not entail the identification of matter with God or with an attribute of the Deity. To call Maimonides' position or its logical corollaries "pantheism" would therefore be to go beyond the evidence.

## ORIGIN OF THE WORLD

A main theme of the *Guide* concerns the contradiction between the idea of God upon which Judaism is founded and the philosophical view of God. The philosophical view for Maimonides is the conception of God as an intellect rather than as described by the speculations of negative theology. Maimonides is fully aware of the crucial character of the issue and of the impossibility of achieving a true reconciliation between the philosophical and the religious points of view. He remarks in the *Guide*

(Part II, Ch. 20): "For to me the combination between [the world] existing in virtue of necessity and being produced in time in virtue of a purpose in the world ... comes near to being a combination of two contraries." Maimonides points out the "very disgraceful conclusions" that follow from the first opinion:

Namely it would follow that the Deity, whom everyone who is intelligent recognises to be perfect in every kind of perfection, could as far as all beings are concerned, produce nothing new in any of them; if He wished to lengthen a fly's wing or shorten a worm's foot, He would not be able to do so. But Aristotle would say that He would not wish it and that it is impossible to will something different from what is; that it would not add to His perfection, but would perhaps from a certain point of view be a deficiency. (*Guide*, Part II, Ch. 22)

In Maimonides' interpretation of the Aristotelian position, God's will is assimilated to the divine Intellect, which is identical with God himself, and the world may be regarded as something like an intellection necessarily produced by this Intellect. A consequence of Aristotle's theory as understood by Maimonides is that every characteristic of things existing in the world must be supposed to have a cause grounded in the natural structure of the universe (as opposed to a supernatural cause not determined by this structure). It may be added that as far as bodies are concerned, Maimonides seems to believe that in cases in which a mechanistic explanation can be found, it might provide such a cause. If this were accepted, it would mean that no part of the natural order could be, or could ever have been, different from what it actually is, for its existence is guaranteed by the immutability of divine reason. In other words, the world could not have been created in time.

From this point of view Maimonides is quite consistent in describing temporal creation as the greatest of miracles and in stating that if this is admitted, the intellectual acceptance of other direct interventions of God in the natural course of events does not present any difficulties. Since it serves Maimonides' purpose to make out the best case possible for what he designates as the religious conception of God, he attempts to show that a structure of the universe that is necessary, because it is rationally determined in every respect, does not exist—or at least he seems to do so. In fact, he does not go beyond the demonstration, made at some length, that as far as the heavenly spheres are concerned, Aristotelian physics (although it gives satisfactory explanation of the phenomena of the

sublunar world) is incapable of propounding a comprehensive scientific theory that can be regarded as certain and that provides cogent proof for the assumption that the cosmic order could not be different from what it actually is. In this critique of Aristotle's celestial physics he is helped by the much-debated discrepancy that exists between Aristotle's natural science and the Ptolemaic system.

Maimonides also puts forward an argument of somewhat different character. He points out that man's knowledge of the order of nature is based on the empirical data of which he is cognizant. It is, however, conceivable that the existence of the data that are known to man had a beginning in time. No man who studies this problem should ignore this possibility, for if he does so, his case would be analogous to that of a person who disbelieves on empirical grounds—because he has met only adults—that human beings are brought into the world through birth after having been embryos.

Maimonides' critique of the inconsistencies and the insufficiency of the Aristotelian physics is pertinent within its scheme of reference. However, the doctrine of the eternity of the world does not rest exclusively upon physical theory. It is also corollary to the conception of God as Intellect, and Maimonides is aware of this. It is certainly significant, and it may be a deliberate omission, that when Maimonides is dealing with the problem of the eternity of the world in the *Guide*, he does not mention this conception although other portions of the work prove he had adopted it. Thus he does not allude to God as Intellect when he proclaims in the *Guide* (Part II, Ch. 25) that he does not accept the doctrine of the eternity of the world for two reasons: (1) because it has not been demonstrated; (2) because its adoption would be tantamount to destroying the foundations of the Law, for it would mean denying the claims of the prophets and rejecting the belief in miracles.

## SOURCES OF KNOWLEDGE

That Maimonides rejected the doctrine of the eternity of the world partly because (as his second reason) it would have destroyed the foundations of religious law may appear to affirm the claim of religious belief to have a decisive voice in theoretical questions that are of paramount concern to it. That is, it may appear to affirm this claim, provided that the intellect is unable to reach a fully demonstrable conclusion with regard to the moot points. Clearly such a claim can have far-reaching implications. It could be argued that this position leads to the recognition of suprarational theoretical truths or, alternatively, to the

assertion of validity of conclusions in the sphere of theory adopted only on the basis of practical reason. Maimonides himself, however, does not at all countenance such a demotion of theoretical reason. In the *Guide* (Part I, Ch. 2) he explains the superiority of theoretical reason, which is concerned with the difference between truth and falsehood, over practical reason, which deals with the distinction between good and evil. His allegorical interpretation of Adam's fall entails the conclusion that practical reason has the comparatively lowly function of curbing the appetite to which man is prone when he is not given over to theoretical contemplation.

As for prophecy and divine revelation, they cannot be regarded as sources of suprainTELLECTUAL knowledge conceived as being independent of, and superior to, the system of sciences produced by theoretical reason. This comes out clearly in Maimonides' description of the characteristics peculiar to prophets. According to him, prophets must have both an outstanding intellectual capacity and an outstanding imaginative capacity. Given these two preconditions, and suitable conduct, prophecy is a natural phenomenon; the gift of prophecy can be withheld from a person having the required qualifications only by means of a miracle. The intellectual capacity of prophets is similar at least in kind to that of the philosophers; it enables them to receive what Maimonides terms a "divine overflow," an influx coming from the Active Intellect, which, according to the interpretation of the Aristotelian doctrine adopted by Maimonides, brings about the actualization of man's potential intellect. The Active Intellect is the last of the ten incorporeal Intellects; its special sphere of action is the sublunar world.

There is no suggestion that the conclusions reached by the prophets through the use of the intellect are in any way different from those of the philosophers, though the prophets may reach them more rapidly; all prophets are philosophers. This clearly applies also to Moses, in spite of a statement in the *Guide* that none of the author's assertions about the prophets pertain to Moses. In other writings Maimonides describes Moses as having attained union with the Active Intellect; according to the conception of certain Islamic Aristotelians, union with the Active Intellect represents the highest goal and is reached by the great philosophers.

Imagination is inferior to intellect for Maimonides, who was on this point an orthodox Aristotelian. Imagination enables the prophet to see veridical dreams and visions, for the divine overflow spills over from the intellectual to the imaginative sphere. But it certainly does not

give access to a supraintellectual truth. In fact the superiority of Moses over all other prophets is, according to Maimonides' interpretation, partly the result of the circumstance that in his prophecy he did not have recourse to imagination.

### POLITICAL PHILOSOPHY

Religious revelation thus does not procure any knowledge of the highest truth that cannot be achieved by the human intellect; it does, however, have an educative role—as well as a political one. In Maimonides' words, "The law as a whole aims at two things: the welfare of the soul and the welfare of the body" (*Guide*, Part III, Ch. 27).

Because of the great diversity of human character, a common framework for the individuals belonging to one society can be provided only by a special category of men endowed with the capacity for government and for legislation. Those who have only a strong imagination, unaccompanied by proportionate intellectual powers, are not interested in the intellectual education of the members of the state which they found or govern. On the other hand, the foremost example of an ideal lawgiver is Moses.

The law instituted by Moses had to take into account the historical circumstances—the influence of ancient Oriental paganism—and had to avoid too great a break with universal religious usage. To cite one example, sacrifices could not be abolished, because this would have been an excessively violent shock for the people. In spite of these difficulties, however, Moses succeeded in establishing a polity to which Maimonides, in the "Epistle to Yemen," applies the term *al-madīna al-fādila* ("the virtuous city") used by the Muslim philosophers to designate the ideal state of Plato's *Republic*—a work that, perhaps mainly through the mediation of al-Farabi, had a considerable impact on Maimonides' political thought.

### MORAL PHILOSOPHY

The polity is not alone in regulating men's actions in the best possible way. The Scriptures by which the polity is ruled also contain hints that may guide such human individuals as are capable of understanding its hints to philosophical truths. Some of these truths are to be discovered in the beliefs taught to all those who profess Judaism; these dogmas are for evident reasons formulated in a language adapted to the understanding of ordinary unphilosophical people. There are, however, other religious beliefs that, although they are not true, are necessary for the majority of the people, to safeguard a tolerable public order and to further morality. Such are the belief that God is angry with those who act in an unjust manner and

the belief that he responds instantaneously to the prayer of someone wronged or deceived (*Guide*, Part III, Ch. 28). The morality suited to men of the common run aims at their exercising a proper restraint over the passions of the appetite; it is an Aristotelian middle-of-the-road morality, not an ascetic one. The ascetic overtones that are occasionally encountered in the *Guide* concern the philosopher rather than the ordinary man.

There is a separate morality for the elite, which is or should be called upon to rule, to which Maimonides alludes in the *Guide* (Part I, Ch. 54; Part III, Chs. 51 and 54). This ethical doctrine is connected with Maimonides' interpretation of what ought to be man's superior goal, which is to love God, and, as far as possible, to resemble him.

From the point of view of negative theology, love of God can be achieved only through knowledge of divine activity in the world, the only knowledge of God possible. This supreme goal can be reached through a study of natural science and of metaphysics, which appears to signify that the highest perfection can be attained only by a man who leads the theoretical life—the man whose superiority was proclaimed by Aristotle. However, Maimonides is at pains to show—and this seems to be a Platonic element in his doctrine—that the theoretical life can be combined with a life of action, as proved by the examples of the patriarchs and of Moses.

What is more, a life of action can constitute an imitation of God. For the prophetic legislators and statesmen endeavor to imitate the operations of nature, or God (the two are equivalent; the expression "divine or natural actions," which occurs in the *Guide*, may have been in Benedict de Spinoza's mind when he first spoke of *Deus sive natura*). Maimonides emphasizes two characteristics that belong both to the actions of God-nature and to the actions of superior statesmen. First, however beneficent or destructive—or, in ordinary human parlance, however merciful or vengeful—the actions in question appear to be, neither God nor the prophetic statesman is actuated by passions. Second, the activity of nature (or God) tends to preserve the cosmic order, which includes the perpetuity of the species of living beings, but it has no consideration for the individual. In the same way the prophetic lawgivers and statesmen, who in founding or governing a polity should imitate this activity, must have in mind first and foremost the commonweal, the welfare of the majority, and must not be deterred from following a politically correct course of action by the fact that it hurts individuals.

The imitation of the works of God (or of nature) by the prophets means (*Guide*, Part III, Ch. 32) that the prophets imitate in leadership the indirect and complicated way through which nature obtains its desired results, as seen, for instance, in the extremely intricate mechanism of living organisms. Maimonides calls this indirect method a “gracious ruse” of God and his wisdom; he may have taken the expression over from Alexander of Aphrodisias’s work “Principle of the All” (extant only in Arabic translation). It is reminiscent, not only on the verbal plane, of G. W. F. Hegel’s “Cunning of Reason.” According to the *Guide*, Moses used the indirect method in making the sons of Israel wander for forty years in the desert instead of leading them straight to the land of Canaan, for he wanted the people to shed slavish habits and acquire in the hard school of the desert the warlike virtues necessary for conquest. He also used it in adapting the commandments to the historical and geographical circumstances.

### INFLUENCE OF THE *GUIDE*

The *Guide* was first translated into Hebrew in Maimonides’ lifetime, by Samuel ibn Tibbon and a little later by al-Harizi. Its first translation into Latin was also produced in the thirteenth century. Maimonides’ injunction to follow his example in writing the Arabic text of the work only in Hebrew characters (and thus to prevent its being read by non-Jews) was not always observed. The work is mentioned by some later Muslim writers but does not appear to have had more than a very slight impact on Muslim thought.

In the period after Maimonides the *Guide* was the fundamental text of medieval Jewish thought and was much debated. In the thirteenth and fourteenth centuries it was violently denounced for being antireligious and as vehemently defended against this charge; commentaries upon it were written by Shem-Tov Falaquera, Joseph ibn Kaspi, Moses of Narbonne, Isaac Abravanel, and others, and its theses are discussed at length in such capital philosophical works as Gersonides’ *Milhamot Adonai* (The wars of the Lord) and Hasdai Crescas’s *Or Adonai* (Light of the Lord). At first blush it is therefore rather surprising that among Jewish philosophers, relatively few of Maimonides’ disciples have been content to adopt his apparently agnostic attitude toward fundamental metaphysical problems and thus to leave what he believed to be a necessary loophole for religious belief. In fact, no doubt partly because of the unsystematic mode of exposition of the *Guide*, some philosophically minded commentators (notably Moses of Narbonne) expounded Averroes’s con-

ceptions rather than Maimonides’ in their commentaries on the *Guide*. Other commentators—for example, Abravanel—often criticized him from a traditionalistic religious point of view.

The *Guide* had a strong influence on later Jewish philosophers, many of whom owe their introduction to philosophy to the *Guide*. This can be seen in Spinoza (a considerable portion of the *Tractatus Theologico-politicus* is devoted to a critique of Maimonides, although the explicit references to him are few) and in Salomon Maimon, who wrote a commentary on the *Guide*.

The influence of Maimonides on the medieval Christian Schoolmen seems to have been considerable; the matter has not yet been sufficiently investigated, though several studies dealing with the subject do exist. It may be noted that by elaborating the doctrine of suprarational truths the systems of Thomas Aquinas and of other Scholastics found a way of legitimating from a theoretical point of view Maimonides’ decision to opt for the belief in temporal creation, because the existence of religion hinged on this belief’s being generally accepted.

## MAIMONIDES [ADDENDUM]

Since Shlomo Pines's entry, scholars have come to accept 1138, not 1135, as the year of Maimonides' birth. Some scholars also believe that the youthful treatise on logic (*Millot ha-Higayon*) is not by Maimonides. The major development in Maimonidean studies, however, is an interpretive one. Pines worked closely with Leo Strauss on the 1963 English translation of Maimonides' *Guide of the Perplexed*, which remains the best complete English version of his philosophical magnum opus. Strauss, who wrote the introductory essay to the translation, had an idiosyncratic way of reading many premodern thinkers, including Maimonides. In brief, Strauss understood Maimonides to be engaged in a vast project of deception, of concealing his real beliefs, in order that those incapable of understanding and accepting them not become perplexed and dislodged from their simple pieties.

Strauss's way of reading Maimonides finds its way into this article when Pines suggests that Maimonides was a closet Aristotelian who (really) believed in the eternity of the world. Never mind that Maimonides says the opposite to this; for the Straussian, this is just the point: to conceal one's real beliefs, and to suggest the opposite from what one explicitly argues for. There are still Straussian interpreters and interpretations, but they are in retreat. Philosophical scholars tend to rest content with mulling over the actual arguments that Maimonides presents. Further, in response to the Straussian position that there exists a deep divide between philosophy and the law (religion), between Athens and Jerusalem, recent scholars such as Isadore Twersky (1967) and David Hartman (1976) argue that, on the contrary, Maimonides grounds philosophy in the law and understands the law as subserving in large part suprapolitical ends.

Scholars seem less taken with the Maimonidean reaction to Avicenna (Ibn Sīnā) than Pines appears to be. The Islamic thinkers who have more recently emerged as significant for Maimonides are al-Fārābī and Ibn Bājja (Avepace). They tend to be important for their influence on Maimonides' moral and political theorizing. Pines is still good on Maimonides' practical philosophy. Especially to be noted is his insistence on a Platonic element in his view of the summum bonum. Often Maimonides is presented as endorsing Aristotle's view that human happiness is a function of contemplative activity alone. Pines rightly resists this, noting that Moses, the political prophet, is paradigmatic for Maimonides. Indeed, the end of the *Guide* makes clear that imitation of God mirrors God's providential care for the created world.

## MAINE DE BIRAN

(1766–1824)

Maine de Biran, the French statesman and philosopher, was born Marie François Pierre Gonthier de Biran, receiving the name "Maine" from the name of his family's property (le Maine). He attended the *collège* at Périgueux, dominated by the secular, moderate constitutional Royalists called *Doctrinaires*, and excelled there in mathematics. In 1784 he joined the king's guard and in 1789 was wounded defending Louis XVI in a mob uprising. To escape the Reign of Terror, he retired to his estate in 1793 and began intensive psychological and philosophical investigations. In 1797 he was elected to the Council of Five Hundred, and this election of a moderate royalist was a symptom of the beginning of the end of the Reign of Terror. This post and other public duties did not keep him from reaping the fruits of his earlier meditations. He became acquainted with the *Idéologues* Pierre-Jean Georges Cabanis and Comte Destutt de Tracy by winning first prize in an essay contest sponsored by the Institute of France with the essay *L'influence de l'habitude sur la faculté de penser* (*The Influence of Habit on the Faculty of Thinking*). He won membership in the institute in 1805 by gaining another first prize, for *Mémoire sur la décomposition de la penser* (*The Analysis of Thought*). While continuing to write outstanding philosophic and psychological essays, he intensified his political activities, became a member of the Chamber of Deputies, and was made commander in the Legion of Honor. Under the first restoration he returned to the National Assembly and was put in charge of liaison between the assembly and the king on financial matters. Despite these public activities, he was at the time of his death acknowledged by most of his distinguished contemporaries as their master (*maître à tous*) in philosophy.

His famous *Journal intime* reveals a melancholy, emotionally changeable person, of poor health, who was highly sensitive to climatic and personal surroundings. He spent much of his personal and philosophic life trying to understand and mitigate this sensitivity.

## PHILOSOPHICAL DEVELOPMENT

Maine de Biran's philosophic development can be summarized briefly as a movement toward a more and more detailed conviction that man's inward experience is (1) different from his outwardly experienced "impressions," and (2) an important source and basis of knowledge. His most mature essays speak of an "inward sense" (*sens intime*) that reveals our experience of willed bodily move-

ment (*effort voulu*); in the course of his philosophic development he gave to this experience a more and more important role, progressively more subtly analyzed. The names of John Locke, Étienne Bonnot de Condillac, and Charles Bonnet, all of whom emphasized outward impressions as the ultimate source of knowledge, occurred as frequently in his early notes as did the name of Jean-Jacques Rousseau, whose “Profession of Faith of a Savoyard Vicar” in *Émile* had aroused Maine de Biran’s interest in the “inner light” (*lumière intérieure*).

But the outwardly oriented epistemologies of Condillac and Locke and their disciples, the *Idéologues*, soon grew less adequate for Maine de Biran, as did Bonnet’s explanations of perception in terms of physiological mechanisms (explanations based upon outward “impressions”). After 1802 and his first great prize essay, *The Influence of Habit on the Faculty of Thinking*, which was similar in many ways to the writings of the *Idéologues*, Maine de Biran moved into his longest and most original period of philosophizing, during which he became quite critical of his former masters and developed and defended the key doctrine of his philosophy, that the *effort voulu* is a unique source of basic knowledge. In this stage he wrote *Mémoire sur la décomposition de la penser* (which won him membership in the Institute of France) and his most mature completed philosophic work, *Essai sur les fondements de la psychologie* (Essay on the Foundations of Psychology; 1812).

From 1814 to the end of his life he developed—but never with great precision—a doctrine derived from Immanuel Kant (by way of Maine de Biran’s friend André Marie Ampère), a doctrine that identified “belief” (*croissance*) as one of the inner sources of knowledge. At first Maine de Biran spoke of belief as revealing the transphenomenal substance of things, and from 1815 on he applied this notion of a “faculty of belief” to problems of theology. According to Maine de Biran, *croissance*, like the *effort voulu*, originates inwardly, but—unlike voluntary bodily movement—is always passive; its function is to receive God’s grace. Still, he continued to speak of the importance of the *effort voulu*; the doctrine of the significance of the faculty of belief in relation to religious matters was not a repudiation of the significance of the activist, individualistic capacity of the *effort voulu* in matters of natural knowledge. In fact, during this last period, from 1814 to 1824, he wrote some of his finest essays developing his doctrine that the *sens intime* is a unique and important source of knowledge. Two of his outstanding works on this subject were *Examen des leçons de philosophie de M. Laromiquière* (An Examination of

Laromiquière’s Lessons in Philosophy; 1817) and his unfinished masterpiece, *Nouveaux Essais d’anthropologie* (New Essays in Anthropology; 1824), both of which cast much light on the doctrine of *effort voulu*. In fact this doctrine was far more thoroughly developed than the doctrine of *croissance*. Nevertheless, the emphasis given to belief in the last stage of his thought confirms the generalization that the whole tendency of his philosophic development was toward a more profound conviction that inward experience—whether of willed effort or of belief itself—is the richest basis of knowledge.

## LEARNING AND EXPERIENCE

Condillac, the forerunner of the *Idéologues*, had insisted on clarifying terms and validating claims to knowledge by reference to simple, directly experienced outward “sensations” stripped of the increments of learning. The leader of the *Idéologues* in Maine de Biran’s day, Destutt de Tracy, had continued Condillac’s line of thought but had noticed that (1) some experiences get duller and vaguer by repetition, while others become more distinct; and that (2) there is a capacity to move our bodies voluntarily (Destutt de Tracy called it “*motilité*”) that has a vital function in our learning to perceive objects. In addition, Destutt de Tracy’s colleagues Cabanis and Bonnet had seen the importance of physiological conditions for an analysis of the human mind.

In his first prize-winning essay Maine de Biran developed all of these suggestions. He not only distinguished between outer impressions and felt effort, but he distinguished what he called “sensations” (such as tastes and smells), wherein the impression is vivacious and our voluntary bodily movement is minimal, from what he called “perceptions” (such as talking aloud and hearing ourselves), wherein the outward impression is less important than the inward experience of moving our organs.

But these distinctions might have no importance for an analysis of knowledge, he thought, if they do not help us to understand learning more fully. And so in his first essay he set about trying to discover whether habituation or repetition has a different effect on passive sensations than on active perceptions; if different effects were found to exist it could be assumed that the distinction between sensations and perceptions is important. He found that passively experienced sensations got vaguer with habituation, and perceptions that are involved with our willed bodily movement became more and more precise. Our sense of smell loses its refinement in a hothouse, but we walk, talk, play games better by practicing. Therefore, he concluded, in perceptions alone do we find the possibility

of learning, of moving from the passive sensational confusion of the infant to the subtle distinctions of the adult mind. If Condillac's passively received outward impressions were all that was available to consciousness, the repetition of these impressions would have resulted in a vague blur. The development of mind is linked with willed bodily movement, with perceptions.

One of our most important perceptions is our experience of speaking and hearing our own words; this is the most active perception, and the least dependent upon adventitious external impressions. Sounds uttered by us are among the first signs we know; they are outwardly experienced signs of our own inward actions, and it is the inward action that constitutes the meaning of the sign. There are other signs too: We learn to associate two or more external impressions as natural, or physical, signs of each other. But for Maine de Biran the sign-relationship most directly involved in human reasoning is the relationship between spoken words or conventional signs and our inwardly experienced effort to move our organs of speech. In the course of acquiring by habituation a more subtle and distinct way of talking we acquire a more subtle and distinct mentality. Maine de Biran never lost sight of natural sign-relationships between impressions or between images of impressions as part of our learning process, but he insisted that oral, conventional sign-relationships were basic to human mentality. To describe human thinking only in terms of associated images of outward impressions is to ignore speech, the faculty that makes human thought peculiarly human.

In 1812, in his "Essay on the Foundations of Psychology," Maine de Biran set out to find a primary experience, a *fait primitif* antecedent to all learning or habituation (Condillac had sought such a fact and had claimed to find it in outward sensations). Maine de Biran held that such a basic experience must satisfy three criteria: First, it must be within the limits of awareness (although he sometimes talked of unconscious perceptions); second, it must, of course, not be learned or deduced, but must be directly experienced; finally, it must be persistent, for knowledge must have a firmer basis than the passing moment. He rejected outward impressions and inward emotions and affections because they were fleeting, and he rejected the physiological findings he had once been attracted to because they were the results of inferences or deductions, not immediately experienced. In the end he adopted as his primary experience the *effort voulu* he had found to be so crucial to the learning process: We are aware of it, although sometimes not vivaciously; it is not itself learned, although we learn how to move various mem-

bers skillfully; and this experience persists in various degrees of tension (ranging from sensations up to perceptions) throughout our waking life. The most lucidly developed part of Maine de Biran's philosophy is his explanation and defense of this triple claim involved in calling the *effort voulu* a primary experience.

## SELFHOOD, CAUSALITY, AND LIBERTY

Philosophers such as Locke, Condillac, and the *Idéologues* had great difficulty accounting for our idea of a persistent, inwardly experienced self, because they assumed that experience was made up of nothing but fleeting, outward impressions. But the origin of this idea loses its mystery if we give our attention to our persistent, inward experience of our own willing against our varying bodily resistance to that willing. Throughout our lives we feel this relationship at the center of our experience in varying degrees of tension. The center is the self (*le moi*), the periphery, or the surrounding impressions, is the nonself. In fact, the unity of our own more or less resisting body as felt in the *sens intime* is the origin of our whole notion of unity or identity, whether it occurs in mathematics or elsewhere.

The felt relationship between the body and our more or less active willing to move that body is for Maine de Biran our basic experience of causation. In defending this claim he argued that the term *cause* cannot be explained by hazy references to "innate" ideas, or by question-begging, tautological assertions about effects presupposing causes; in this he agreed with David Hume. He also agreed with Hume that our disparate impressions do not reveal any instance of necessary connection. But he flatly disagreed with Hume's double assumption that outward impressions are basically similar to and are the origin of any inward experience we may have. Maine de Biran insisted that in our *sens intime* we find a unique, primary experience of necessary connection.

Hume's main objections to this claim occur in his *Enquiries concerning the Human Understanding and concerning the Principles of Morals*; he points out that in cases such as palsy or amputation we cannot be sure our own bodily movement will follow our willing. Moreover, the means by which the will and our body are united is, in Hume's word, "mysterious." How then can we be said to experience an instance of necessary connection when neither connection nor necessity is experienced here? Maine de Biran responded to these objections by using his basic distinction between impressions and the *effort voulu*, or between images, or copies of outward impressions, and our idea of inward felt effort. To the first objection he replied that bodily movement is simultaneous with the

willing that is its cause, and that if there is any failure or disappointment, it is the failure or disappointment of a plan involving memory and anticipatory images concerning a succession of experiences. Willed effort itself, involving the simultaneity of cause and effect, never fails; only plans involving successive outward impressions may fail. According to Maine de Biran, Hume mistakes our *pensées* for our *effort voulu*, confuses disparate outward impressions and their images with intimately related, inwardly simultaneous willing and movement.

Hume's second objection is that no connection or "means" connecting the will to the body is present in willed effort. By "means" Hume chiefly meant physiological means that can be demonstrated through outward impressions and derived hypotheses concerning the connection between the willed effort and bodily movement. Maine de Biran answered, however, that in the face of the plainly felt experience of inward causation, one need not ask for "connecting" entities deviously derived from a different sort of experience; Hume, in doing so, simply reasserted his old prejudice in favor of outward impressions and their images. No assertion concerning our physiological structures can diminish or put in question our inwardly experienced relationship between willing and our body. To say that it does is like claiming that remarks about a Caruso's anatomy diminish or put in question the greatness of his artistry. The greatness lies in the singing itself, just as our certainty in experiencing the *effort voulu* lies in this experience itself, not in any hypothetical structures based on quite different experiences. Finally, Maine de Biran pointed out that we apply the term *cause* or *necessary connection* to outward impressions by projecting our inward experience of simultaneity into the outward world of successive impressions; our original experience of causation or necessary connection is inward; all other uses of the term *causation* are derivative from it.

The certainty of the experienced relationship between will and bodily movement is the basis of man's liberty. Deterministic arguments that have been invoked to contest man's liberty depend on causal laws that are less certain than, and indeed irrelevant to, the experience of moving our bodies ourselves. Maine de Biran was willing to assert that in varying degrees strong motives or desires incline us to will certain movements. He was even willing to agree that our passions are sometimes overwhelming, for example, under the influence of hunger or fear, but he went on to say that there are times when the crucial causal factor in any action is our will, which is capable of rejecting any given desire or inclining motive.

At those times we are free, and no dubious hypotheses concerning determining causes can hold up against the plain fact that we can and do withstand particular external or internal pressures. Our freedom does exist, although it is occasional and is tempered by the degree of inclination or pressure.

## Bibliography

### WORKS BY MAINE DE BIRAN

The first published edition of Maine de Biran's works was *Oeuvres philosophiques de Maine de Biran*, edited by Victor Cousin, 4 vols. (Paris: Ladrangé, 1841). This edition is incomplete and should be avoided, except by those who wish to account for the gross misunderstandings of Maine de Biran's thought that were current in the nineteenth century. The definitive edition of Maine de Biran's notes, essays, and letters is the one edited by Pierre Tisserand and Henri Gouhier: *Oeuvres de Maine de Biran*, 14 vols. (Paris: Alcan, 1920–1942). Gouhier has also edited the definitive edition of Maine de Biran's philosophically revealing *Journal intime* (Neuchâtel, 1954–1957). Only one of Maine de Biran's works has been translated into English—his first prize-winning essay, translated by Margaret Boehm as *The Influence of Habit on the Faculty of Thinking* (Baltimore: Williams and Wilkins, 1929).

### WORKS ON MAINE DE BIRAN

No definitive biography has been written; the most detailed life now in print is that by Amable de La Vallett-Monbrun, *Maine de Biran: Essai de biographie historique et psychologique* (Paris, 1914). Sainte-Beuve's brief biography of him in *Causeries du Lundi*, Vol. VIII (Paris, undated), is famous for its eloquence.

On the development of Maine de Biran's philosophy three excellent books have been written. Henri Gouhier's *Les conversions de Maine de Biran* (Paris: Vrin, 1947) is the best account we have of the influences upon him. *Maine de Biran et son oeuvre philosophique*, by Victor Delbos (Paris: Vrin, 1931), is a lucid, impartial summary of the key works. *L'expérience de l'effort et de la grâce chez Maine de Biran*, by George Le Roy (Paris, 1934), uses a Bergsonian approach but even so is faithful and perceptive; it is the best consecutive account of his development. A perceptive, memorable account of his thought occurs in *French Philosophies of the Romantic Period*, by George Boas (Baltimore: Johns Hopkins Press, 1925).

A few useful works on specific topics include Henri Gouhier, "Maine de Biran et Bergson," in *Les études bergsoniennes*, Vol. I (Paris, 1948); Philip Paul Hallie, *Maine de Biran, Reformer of Empiricism* (Cambridge, MA: Harvard University Press, 1959); Jacques Paliard, *Le raisonnement*

*selon Maine de Biran* (Paris, 1925); Euthyme Robef, *Leibniz et Maine de Biran* (Paris, 1927); Ian W. Alexander, Ian W. “Maine De Biran and Phenomenology,” *Journal of the British Society for Phenomenology* 1 [1970]: 24–37; Francis C. Moore, Francis C., *The Psychology of Maine De Biran* (Oxford: Clarendon Press, 1970); Serge J. Morin, “Maine De Biran: A New Dualism,” *Philosophical Forum* (5[1974]: 441–459); Jean Pucelle, “The Meaning of Experience in Maine De Brian’s Philosophy,” *International Philosophical Quarterly* (13[1973]: 25–32); Christopher C. Rodie, “Delacroix, Maine De Biran, and the Aesthetics of Romanticism.” *Dialogue* (17[1974]: 13–24).

## MAISTRE, COMTE JOSEPH DE

(1754–1821)

Comte Joseph de Maistre, the Savoyard philosopher and diplomat, was born in Chambéry. After the conquest of Savoy by the French revolutionary forces, he retired to Lausanne, where he lived for three years, devoting himself mainly to writing his *Considérations sur la France* (1796), an attack on the political philosophy of republicanism. He was then summoned to Turin by the king of Sardinia and later moved to Cagliari, the capital of the very diminished kingdom of Sardinia. In 1802 he was appointed Sardinian minister plenipotentiary to St. Petersburg and remained there for fourteen years, composing his famous *Soirées de Saint-Petersbourg*, which was not published until the year of his death.

### ULTRAMONTANISM

De Maistre is best known for his ultramontanist and traditionalist views, which are most forcibly stated in *Du pape*, written in 1817, although anticipated in certain details in his *Considérations sur la France*. His presuppositions were those of any medieval Roman Catholic—the church is a divine institution; its foundation was given to St. Peter; St. Peter was the first pope; his successors have inherited the powers conferred on him by Jesus Christ himself. The book opens with a demonstration of papal infallibility. Identifying the sovereignty of the pope with that of any secular ruler, de Maistre argued that sovereignty implies infallibility, since no ruler is sovereign whose decisions can be set aside or be subject to appeal. He thus made no distinction between executive competence and validity. As parliaments exist simply to inform the sovereign of matters of which he might not be aware or to make requests and express occasional desires, so the church

councils have no power to do more than this. They are convoked and presided over by the pope, who is not bound by their decisions, for they have no real power of decision. The notion that matters of faith and doctrine can be decided by a council is as absurd as the notion that a parliament can actually rule. De Maistre maintained that when the pontiff speaks *ex cathedra* and without restraint to the church, he has never erred nor can he ever err in questions of faith. He might be constrained to make a false pronouncement, or he might be speaking merely as a man and not as a pope, but in his function as a sovereign monarch, it is impossible that he should ever be in error.

The reason we require any kind of government is that we are born corrupt, yet with a sense of morality. Our souls are thus in a state of conflict. Sovereigns exist in order to prevent the disasters that arise from this conflict and to keep order within the state. No man is capable of governing himself, for no man can spontaneously quell the evil that is in him; therefore, the power to do so must reside in the hands of one ruler who will be above criticism and have absolute power. This ruler, whether he is a king or a pope, does not rule by the consent of his people but because of their needs. Kings, although infallible in regard to their own provinces, are nevertheless subject to the laws of God, and the pope is the only possible judge of whether they have been faithful to them. The pope is the deputy of God, and when a secular ruler has erred, he can be deposed and his subjects can be freed from their oaths of allegiance to him by papal decree. This power, de Maistre maintained, has been used only rarely where hereditary sovereigns were involved; it was used more freely against elected sovereigns, such as the Holy Roman emperors, for they were chosen by man, not by God. The pope, it should be noted, does not interfere in purely secular problems of administration; his intervention is invoked only in morals and religion.

Nevertheless, the pope is not a universal sovereign, for his power is checked by the canons, the laws, the customs of nations, duty, fear, prudence, and opinion, “which governs the world.” Is it not better, de Maistre asked, to settle disputes by the decision of a wise and prudent ruler, inspired by God himself, than by rebellions, civil wars, and all the evils that follow from them? Such an arbitrator will inevitably submit to the commands of duty and prudence, will be sensitive to custom and opinion, and will intuitively know which road to take when conflict arises.

## TRADITIONALISM

A reader of *Du pape* will be impressed by de Maistre's use of tradition to justify his conclusions. The supremacy of the pope, he argued, has always been acknowledged, even by his critics. That is, they all admitted that he has done what de Maistre said he has the power to do, and, de Maistre added, no one except those who had suffered at his hands objected to his power. That something has always been done is to de Maistre proof that it has been done correctly. He even denied the right to liberty on the ground that slavery was the fate of most men until the rise of Christianity.

To de Maistre the human race is a single being, the soul of which is expressed in its language. Language develops, but so does tradition. The tradition of Catholicism is simply the fulfillment of the covenant God gave to Abraham; passed to Moses and then to Aaron, the high priest; and so on down to the promise made to Peter. But in every tradition, in spite of its development, there is a unity of idea, and the maintenance of that unity is entrusted to the pontiff.

## ROYALISM

Concurrent with de Maistre's traditionalism was his royalism. He was so convinced of the need for absolute monarchs that he even maintained that since kings had a longer life expectancy than other men, royal families differ in nature from nonroyal families, as a tree differs from a shrub. A king is not a private individual and must not be judged as such. He is the nation in the same way that the pope is the church. Consequently, his power is also absolute, for when he speaks, it is the nation speaking through him. Kings alone preserve national unity. The word *unity* was a eulogistic term for de Maistre. To be unified is better than to be manifold; to remain the same is better than to change. And although de Maistre had to admit those changes that have obviously occurred and are not evil, he insisted on the unity that underlay them.

De Maistre usually carried his ideas to their logical conclusions. His famous apostrophe to the hangman in the *Soirées* is based on de Maistre's presupposition of the twofold nature of man. If the hangman is removed from society, order will give way to chaos, thrones will totter, and society will disappear. "God who is the author of sovereignty is also the author of punishment." He is the author of punishment so that corrupt man may still be redeemed. But if man is to be punished, there must be an absolute and unquestioned power to execute the punishment, and that power is the king's.

De Maistre was the first philosopher of the counter-revolution in France. With the vicomte de Bonald, he gave a set of arguments to legitimists and Catholics. But although de Maistre was admired by many for his consistency in both principle and inference, his variety of political philosophy was never popular, even during the restoration. The anti-intellectualism of François René de Chateaubriand and Mme. de Staël, as fully opposed to the extremes of revolution as was de Maistre's traditionalism, gained more adherents. Moreover, ultramontanism was disclaimed by the Vatican. This disclaimer, perhaps, was the main reason for the failure of de Maistre's thought to become popular in France.

## MAJOR, JOHN

(1469–1550)

John Major, or Mair, was a Scottish theologian, active at the University of Paris for some years before and after he secured a license in theology in 1506. Major helped to revive, if only briefly, the spirit of fourteenth-century nominalism. He was entirely sympathetic with the approach of William of Ockham and Jean Buridan, even though he adopted some doctrines of John Duns Scotus and other realists.

Major came to Paris in 1493 after studying at Cambridge. He taught at the University of Paris for most of his lengthy career, with the exception of seven years at the Scottish universities of Glasgow and St. Andrews. When he arrived at Paris, scholasticism, pietism, and humanism were rivals within the university itself. Late medieval pietism was reflected in the ascetic discipline instituted at the Collège de Montaigu, the school that so repelled Desiderius Erasmus by its austerity and its logic-chopping. Major, with his frugal Scottish background, found the atmosphere of Montaigu less forbidding, and he responded with initial enthusiasm to its manner of disputing. He seems to have been little influenced by the sort of humanism being advocated at the time by Jacques Lefèvre d'Étaples, who stressed the value of knowing Aristotle and the Church Fathers in the original Greek. Major belonged to the scholastic tradition completely. His theological and philosophical works proceed entirely from a formal analysis of separate arguments. He made no use of Greek, although he clearly was conversant with Latin literature.

Major's earliest published work consisted of short treatises on terminist logic, published separately from 1500 to 1503, and then together at Lyons in 1505 as a commentary on Peter of Spain. Later he published commentaries on Aristotle's *Ethics* and *Physics*. In theology, he wrote commentaries on the *Sentences* of Peter Lombard and on the Gospels. All of these writings reflect his teaching duties, even in their style. Toward the close of his long life, Major complained mildly at having been forced to accommodate himself to the "manner of our ancestors" and admitted that students had not always found the disputatious style agreeable. In addition to the works already mentioned, Major wrote *A History of Greater Britain*, a landmark in the writing of Scottish history and a most unusual work for a nominalist theologian. Many passages in this work—such as those in defense of the "oaten bread" of Scotland or of ale as opposed to wine—suggest a personality by no means dry and pedantic. Neverthe-

less, Major's philosophical style has put off scholars, and his work still awaits total and mature evaluation. Almost all present-day accounts of Major continue to be colored by humanist criticisms of theology made in the spirit of Erasmus, with little sympathy for medieval logic.

### Bibliography

A reliable, although sketchy, account of Major's philosophical opinions is given by Ricardo Garcia Villoslada in *La universidad de Paris durante los estudios de Francisco de Vitoria* (Rome: Universitatis Gregoriana, 1938), pp. 127–164. Carl Prantl, in *Geschichte der Logik im Abendlande* (Leipzig, 1927), Vol. IV, pp. 247–250, gives a few excerpts from Major's logical writings. Major's views on church matters (he was a conciliarist and champion of Gallicanism) are sometimes dealt with briefly in histories of political theory. The details of his life are presented in Aeneas J. G. Mackay's biography, prefixed to an English translation of *A History of Greater Britain* (Edinburgh: Edinburgh University Press, Scottish History Society, 1892), which also contains a bibliography of Major's writings. This bibliography needs to be supplemented, however, by the additions given by Hubert Élie, *Le traité "De l'infini" de Jean Mair* (Paris: Vrin, 1938); James F. Keenan, "The Casuistry of John Major: Nominalist Professor of Paris (1506–1531)," *Annual of the Society of Christian Ethics* (1993, pp. 205–221).

## MALCOLM, NORMAN

(1911–1990)

Norman Malcolm, one of America's best-known philosophers, was born in Selden, Kansas, in 1911. After studying philosophy with O. K. Bouwsma at the University of Nebraska, he enrolled as a graduate student at Harvard in 1933. The decisive period for Malcolm's career, however, was probably the time he spent at Cambridge University in 1938–1939, when he met G. E. Moore and Ludwig Wittgenstein. Although Moore exerted a strong influence on him, it is perhaps not unfair to say that most of Malcolm's published work was an attempt to understand Wittgenstein, to explain his thought to others, and to apply Wittgenstein's characteristic manner of approaching philosophical questions to areas the latter did not directly treat.

Malcolm's published work deals especially with the nature of necessary truth; empirical certainty; the connections between common sense, ordinary language, and philosophy; knowledge and perception; and such topics in the philosophy of mind as memory, dreaming, and the problem of other minds. He also wrote on topics in the philosophy of religion. What follows will be confined to the first three topics.

### NECESSARY TRUTH

"Are Necessary Propositions Really Verbal?" and its companion piece, "The Nature of Entailment" (in *Knowledge and Certainty*), together form an interesting statement of the linguistic theory of the a priori. In the former, Malcolm points out that some philosophers (for example, C. D. Broad, Moore, and A. C. Ewing) hold that necessary propositions state very general truths about reality—for instance, that nothing is both red and green all over. Others (for example, A. J. Ayer and the early Wittgenstein) apparently believe that if necessary propositions state anything at all, they state truths about language; they are "merely verbal." Malcolm tries to show that, although it is false, literally speaking, that necessary propositions are merely verbal, there is nonetheless considerable merit in saying that they are. He argues this point by claiming that we learn necessary truths by observing how people use certain expressions. Finding out that a pair of propositions are equivalent, for example, is the same thing as finding out that some pairs of expressions are used interchangeably. What makes a given statement necessary is some empirical fact about linguistic usage. (Although Malcolm considers the objection that on this account any necessary statement turns out to be identical with or equivalent to some contingent statement about linguistic expressions, he does not, it seems, have a clear answer to it.) Accordingly, he says, it is false that necessary statements are merely verbal or are rules of grammar or are not really propositions; it is nonetheless worthwhile to say these things in that they prevent one from supposing, for example, that there are two kinds of facts or truths, necessary and contingent, a supposition that is, literally speaking, true but nonetheless misleading. Why? Perhaps Malcolm believed that in saying this one minimizes the vast and important difference between necessary and contingent truths, the difference being that the necessary truths depend upon or reflect facts of linguistic usage in a way that the contingent truths do not.

### EMPIRICAL CERTAINTY

In "The Verification Argument" and "Certainty and Empirical Statements" (in *Knowledge and Certainty*), Malcolm objects to the view that no empirical statements are ever really certain. "The Verification Argument" is a careful, clear, and very impressive examination of the arguments philosophers (in particular, C. I. Lewis, who was a teacher of Malcolm's at Harvard) have offered for this skeptical view. Where *S* is any empirical statement, Malcolm points out that these arguments always invoke as a premise the claim that the consequences of *S* may not occur and deduce from this that it is not certain that the consequences of *S* will occur. What Malcolm shows is that there is no interpretation of the former statement according to which it both is true and entails the latter.

### ORDINARY LANGUAGE

In several essays, Malcolm dealt with certain questions about the relationships between ordinary language, common sense, and philosophy. Essentially, what he says is that if a philosopher is investigating a concept of ordinary language (for example, *seeing*) and comes to conclusions at variance with ordinary language, then we may be sure that he has made a mistake. What is it to come to a conclusion that goes against ordinary language? One way of doing this is to hold that a sentence with an ordinary use expresses a logical impossibility: some philosophers, for example, appear to insist that it is logically impossible to see physical objects. We may recognize their error by noting that such sentences as "I see the table in the corner" have a perfectly good ordinary use and therefore cannot be self-contradictory. But it is impossible to convey the full power of Malcolm's arguments without a very detailed consideration of particular cases.

## MALEBRANCHE, NICOLAS (1638–1715)

### EARLY LIFE AND RECHERCHE

One of the major figures in post–René Descartes Cartesianism, Nicolas Malebranche was one of many children born to his mother, Catherine de Lauzon, the sister of a viceroy of Canada, and his father, also Nicolas Malebranche, a secretary to Louis XIII. As in the case of Descartes and Blaise Pascal, Malebranche was born in frail health. His particular afflictions were a severe malformation of the spine and weak lungs, and because of these conditions he needed to be tutored at home until the age of sixteen. Subsequently, he was a student at the Collège de la Marche, and after graduating he went to study theology at the Sorbonne. His education left him with a dislike of a scholasticism that focused on the work of Aristotle. Thus, in 1660 he decided to leave the universities and enter the Oratory, a religious congregation founded in Paris in 1611 by the Augustinian theologian Pierre Bérulle. At the Oratory Malebranche studied ecclesiastical history, linguistics, and the Bible, and with his fellow students he also immersed himself in the work of St. Augustine. Though judged to be merely a mediocre student, he was ordained a priest on September 14, 1664.

The same year he was ordained, Malebranche happened in a Paris bookstall upon a posthumous edition of Descartes’s *Traité de l’homme* (*Treatise on Man*), which provides a sketch of a mechanistic account of the physiology of the human body. Malebranche’s early biographer, Father Yves M. André, reports that he was so “ecstatic” on reading this account that he experienced “such violent palpitations of the heart that he was obliged to leave his book at frequent intervals, and to interrupt his reading of it in order to breathe more easily” (André 1970, pp. 11–12). Though André does not indicate why Malebranche was so moved, one can speculate that he

had discovered in this text a way to investigate the natural world without relying on Aristotelian scholasticism. In any case, after his encounter with *L’homme* Malebranche devoted himself to a decade-long study of the Cartesian method and its results in mathematics and natural philosophy.

The principal fruit of this study was a two-volume work bearing the title *De la recherche de la vérité. Où l’on traite de la nature de l’esprit de l’homme, et de l’usage qu’il en doit faire pour éviter l’erreur dans les sciences* (*The Search after Truth*, first published 1674–1675), in which is treated the nature of the human mind and the use that must be made of it to avoid error in the sciences. It is primarily this text that provides the basis for Malebranche’s reputation in the early modern period. As its full title indicates, the *Recherche* focuses on the principal sources of human error and on the method for avoiding those errors and for finding the truth. The first five books enumerate the various errors deriving from the senses, — imagination, pure understanding, inclinations, and passions, respectively—and a sixth book is devoted to the Cartesian method of avoiding such errors through attention to clear and distinct ideas. The centerpiece of the third book, on pure understanding, is a defense of the claim that the ideas through which one perceives bodies exist in God. Tucked away in the final book, on method, is a critique of “the most dangerous error of the ancients,” namely, the Aristotelian position that there are secondary causes in nature distinct from God.

The first volume of the *Recherche*, containing the first three books, was published in 1674 and drew an immediate response in 1675 from Simon Foucher, the canon of Sainte Chapelle of Dijon. Foucher was an “academic skeptic” who attacked the assumption that ideas in one can represent objects distinct from oneself (see Foucher 1969). The Cartesian Benedictine Robert Desgabets replied to Foucher by insisting that the Cartesian rule that clear and distinct ideas are true presupposes that one’s thoughts correspond to real external objects. In brief prefaces added to various editions of the second volume of the *Recherche*, Malebranche chastised both thinkers for failing to read the work they were discussing, noting in particular that he had explicitly argued in the *Recherche* that the ideas one perceives exist in God rather than in oneself.

Malebranche solicited written responses to the *Recherche* modeled on the sets of objections published with Descartes’s *Meditations*. Perhaps put off by Malebranche’s harsh treatment of Foucher and Desgabets, his critics offered instead only informal objections channeled

through mutual friends. In 1678 Malebranche appended to the *Recherche* a set of sixteen *Eclaircissements*, or clarifications, that respond to these objections. Among the more important objections addressed are those that concern Malebranche's assertion that one has a freedom to "consent" to certain motives for action (*Eclaircissement* I), his claim that reason does not yield a demonstrative argument for the existence of the material world (*Eclaircissement* VI), his doctrine of the vision of ideas in God (*Eclaircissement* X), his conclusion that one knows one's own soul through a confused consciousness rather than through a clear idea of its nature (*Eclaircissement* XI), and his occasionalist thesis that God is the only true cause (*Eclaircissement* XV). In the 1678 edition there is a final *Eclaircissement* that defends the importance "not only for knowledge of nature but also for knowledge of religion and morals" of the view, only hinted at in the text of the *Recherche* itself, that God acts for the most part through "general volitions" (*volontez générales*), and that He acts though "particular volitions" (*volontez particulières*) only in the exceptional case of miracles.

#### NATURE ET GRÂCE AND THE DEBATE WITH ARNAULD

Malebranche developed his theory of divin action in his 1680 *Traité de la nature et de la grâce* (*Treatise on Nature and Grace*). He published this work over the objections of the Jansenist theologian and Cartesian philosopher Antoine Arnauld, who was disturbed by what he saw as Malebranche's denial of the claim in the Scriptures and Catholic tradition that God attends to particular details in matters of grace. Arnauld responded to the publication of *Nature et de la grâce* by publishing a response to Malebranche, and the ensuing battle between these two individuals became one of the major intellectual events of the day. Arnauld's opening salvo was the 1683 *Des vraies et des fausses idées* (*On True and False Ideas*), which attacks not *Nature et de la grâce* but the *Recherche* (see Arnauld 1990). His strategy here is to undermine Malebranche's influence in theological matters by revealing the inadequacy of his philosophical views. In particular, Arnauld attacks Malebranche's assumption that ideas are "representative beings" distinct from one's perceptions, offering instead the position, which he plausibly ascribes to Descartes, that ideas are simply aspects of the perceptual modifications of one's soul. This argument reflects a sympathy for Descartes's views that dates back to Arnauld's set of comments on the *Meditations*.

The same year that Arnauld presented his initial critique, Malebranche published the *Méditations chrétiennes*

*et métaphysiques* (*Christian and Metaphysical Meditations*), where "the Word" (i.e., the Second Person of the Trinity) offers a summary of Malebranche's system that highlights the central role that God plays in both metaphysics and morality. This work was in some ways a follow up to his 1677 *Conversations chrétiennes* (*Christian Conversations*). In this earlier text Malebranche presents a defense of the Christian religion that emphasizes the Augustinian theme of one's dependence on God for knowledge and happiness. In 1684 Malebranche further develop his views in moral philosophy in the *Traité de morale* (*Treatise on Ethics*), in which he argues that moral virtue requires a love of the "immutable order" that God reveals to those who seek to know it.

Also in 1684 Malebranche responded to Arnauld's *Idées*, and after a further exchange on the topic of the nature of ideas the debate turned to the religious issues of divine providence, grace, and miracles. The battle became increasingly bitter, and as a result of a campaign on the part of Arnauld and his supporters, Malebranche's *Nature et de la grâce* was put on the Catholic *Index librorum prohibitorum* (*Index of Prohibited Books*) in 1690 (the *Recherche* was added in 1709). The Malebranche-Arnauld polemic continued even after Arnauld's death in 1694, with the posthumous publication of two letters from Arnauld in 1699 and of Malebranche's responses to those letters in 1704.

#### ENTRETIENS AND DEBATES WITH LEIBNIZ AND RÉGIS

In 1688 Malebranche published his *Entretiens sur la métaphysique et la religion* (*Dialogues on Metaphysics and on Religion*), a concise summary of his main metaphysical doctrines of the vision in God and occasionalism that also addresses the problem of evil. In 1696 he appended to this text the *Entretiens sur la mort* (*Dialogues on Death*), which he composed after a life-threatening illness.

In 1692 Malebranche published a short study, the *Lois de la communication des mouvements* (*Laws of the Communication of Motions*), in which he endorses Descartes's law of the conservation of the quantity of motion but offers rules governing collision that, unlike Descartes's own rules, involve no appeal to a force in bodies to remain at rest. In correspondence with Malebranche, Gottfried Wilhelm Leibniz emphasized difficulties with Descartes's conservation law and that correspondence led Malebranche to insert into a 1700 edition of the *Lois* the claim that experience reveals the falsity of this law.

In 1693 Malebranche responded to the criticisms of the *Recherche* in the 1690 *Système de philosophie* (*System of Philosophy*) by the French Cartesian Pierre-Sylvain Régis. Régis defended an account of ideas similar to the one that Arnauld had defended against Malebranche during the 1680s, and Arnauld used the Régis-Malebranche exchange as an occasion to return to the issue of ideas during the last year of his life (on this exchange, see Schmaltz 2002, chapter 5). Despite their dispute, Malebranche and Régis were both appointed as honorary members of the French Académie des sciences when it was reorganized in 1699. Malebranche presented an inaugural lecture to the Académie that defends against Descartes an account of color in terms of the frequency of vibrations of light. In later published versions of the lecture Malebranche revised his discussion to take into account the theory of the nature of color in the work of the great English natural philosopher Sir Isaac Newton.

#### FINAL WORKS

In 1699 Malebranche published *Traité de l'amour de Dieu* (*Treatise on the Love of God*), along with *Trois lettres à Lamy* (*Three Letters to Lamy*), in which he rejects the claim of the Benedictine François Lamy (not to be confused with his Cartesian contemporary, the Oratorian Bernard Lamy) that passages from the *Traité de morale* and other texts support the quietist position, that moral action derives from a disinterested “pure love of God.” This rejection of Lamy’s quietism provided the basis for Malebranche’s reconciliation with the French cleric and establishment figure Jacques-Bénigne Bossuet. Bossuet had earlier enlisted the aid of François de Salignac de la Mothe Fénelon in writing against Malebranche’s occasionalism and his appeals to God’s “general will,” but later became a bitter enemy of Fénelon’s quietism.

With the support of the apostolic vicar in China, Malebranche published in 1708 *Entretien d'un philosophe chrétien et d'un philosophe chinois, sur l'existence et la nature de Dieu* (*Dialogue between a Christian Philosopher and a Chinese Philosopher on the Existence and Nature of God*). In this text, Chinese philosophy is closely allied with the monism found in the early modern Dutch thinker, Benedict (Baruch) de Spinoza.

A sixth and last edition of the *Recherche* appeared in 1712, and in 1715 Malebranche published his final work, *Réflexions sur la prémotion physique* (*Reflections on Physical Premotion*), in which he responded to the claim of the abbé Laurent-François Boursier that occasionalism leads naturally to the Thomistic position that God determines one’s actions by means of a “physical premotion.” In his

response, Malebranche defended the claim, present from the first edition of the *Recherche*, that one’s free actions involve a “consent” that God does not determine.

#### NATURE OF IDEAS AND THE VISION IN GOD

In a section of the third book of the *Recherche* devoted to “the nature of ideas,” Malebranche argues for his famous doctrine of the vision in God. More precisely, the thesis in this section is that one sees external objects by means of ideas in God. The argument for this thesis begins with the claim at the beginning of this section that “everyone agrees that we do not perceive objects external to us by themselves” since it can hardly be the case that “the soul should leave the body to stroll about the heavens to see the objects present there” (Malebranche 1997b, III-2.i.§1). Arnauld later took exception to this starting point, countering that “ideas, taken in the sense of representative beings, distinct from perceptions, are not needed by our soul in order to see bodies” (Arnauld 1990, p. 18). His main objection is that Malebranche stacks the deck in favor of his doctrine that one sees ideas of bodies in God by assuming from the start that these ideas are distinct from one’s own perceptions.

In developing his own position, Arnauld appeals to Descartes’s distinction in the Third Meditation between the formal reality of an idea as a perceptual modification of mind and its objective reality as a representation of an object. Arnauld insists that a representative idea is simply the objective reality of a perception, and thus not something distinct from that perception. However, it is important to note that Malebranche’s definition of an idea does not rule out such a position from the start. As he himself insists to Arnauld, the claim that one must perceive external objects through ideas leaves open the question of whether an idea is “*a modality of the soul*, according to the opinion of M. Arnauld; an *express species*, according to certain philosophers, or an *entity created with the soul*, according to others; or finally *intelligible extension rendered sensible by color or light*, according to my opinion” (Malebranche 1958–1984, p. 6:95).

Malebranche’s description of his own opinion goes beyond what can be found in the original edition of the *Recherche*. However, his description of the other alternatives is drawn directly from this text. In particular, Malebranche argues that there are only four alternatives to the conclusion that one sees bodies through ideas in God: (1) bodies transmit resembling species to the soul; (2) one’s soul has the power to produce ideas when triggered by nonresembling bodily impression; (3) ideas are created

with the soul or produced in it successively by God; and (4) one's soul sees both the essence and the existence of bodies by considering its own perfections. Malebranche tells Arnauld that because this list constitutes "an exact division ... of all the ways in which we can see objects" and because each of the alternative accounts yields "manifest contradictions," his argument from elimination serves to demonstrate the doctrine of the vision in God (Malebranche 1958–1984, p. 6:198f).

It is difficult to determine from the *Recherche* the precise source of the enumeration. However, Desmond Connell (1967) establishes that Malebranche's argument was drawn from the account of angelic knowledge in the work of the sixteenth-century Spanish scholastic Francisco Suárez. Particularly crucial for Malebranche's enumeration is Suárez's claim that angels must know material objects through species that God adds to their mind given that God alone can know them through His own substance. In light of this claim, one can take Malebranche's first three hypotheses to cover the various ways in which one can perceive bodies through immaterial species "superadded" to one's soul, and his fourth hypothesis to cover the possibility that one perceives bodies in the perfections of one's soul. In arguing against the last hypothesis Malebranche notes that because a finite being can see in itself neither the infinite nor an infinite number of beings (as Suárez argues in the case of angels), and because one in fact perceives both the infinite and infinity in external objects, it must be that one sees these objects by means of perfections contained in the only being that can possess an infinity of ideas, namely, God Himself.

Malebranche takes the conclusion here to confirm the view in "an infinity of passages" in Augustine that "we see God" in knowing eternal truths. This appeal to the Augustinian theory of divine illumination provides the basis for an argument for the vision in God that bypasses the unusual enumeration in the *Recherche*. This more direct argument is introduced in *Eclaircissement X*, where Malebranche urges that the ideas one perceives must exist in an "immutable and necessary Reason" because they are themselves immutable and necessary (Malebranche 1958–1984, p. 3:129f). Malebranche emphasizes that the Augustinian view that eternal truths derive from uncreated features of the divine intellect conflicts directly with the voluntarist conclusion in Descartes that these truths derive rather from God's free and indifferent will. Particularly in his exchanges with Arnauld, Malebranche attempts to present his doctrine of the vision in God as a natural consequence of Descartes's

account of ideas. However, Malebranche's own Augustinian argument serves to show that Descartes could not have accepted this doctrine. Moreover, such an argument reveals the most fundamental reason for Malebranche's rejection of Arnauld's Cartesian identification of ideas with one's own perceptions. Because Malebranche identified these ideas with necessary and immutable essences, and because he held that these ideas derive their necessity and immutability from the divine intellect, he concludes that Arnauld's position can lead only to a radical subjectivism that renders impossible any sort of *a priori* knowledge of the material world.

### INTELLIGIBLE EXTENSION AND EFFICACIOUS IDEAS

*Eclaircissement X* also introduces the notion of "intelligible extension" mentioned in Malebranche's claim to Arnauld quoted earlier concerning his own opinion. According to this text, God has a single ideal extension that serves to represent particular bodies to Him. Arnauld objects that this position involves a retraction of the claim in the *Recherche* that one perceives bodies by means of distinct ideas in God. In response, Malebranche insists that his view all along is that God represents particular bodies by means of His own simple "absolute being." For Arnauld, however, the view that God contains extension in this way is objectionable because it is connected to the heretical view in the work of Spinoza that God is extended substance. The charge of Spinozism reappears in Malebranche's 1713–1714 correspondence with one of his former students, J. J. Dortous de Mairan, who later became the secretary of the Paris Académie des sciences (for this correspondence, see Malebranche 1995). As in the case of Arnauld, so in this correspondence Malebranche vigorously denies this charge. In both cases he responds by emphasizing that the infinite and indivisible ideal extension that exists in God differs from the finite and divisible extension in the material world.

A final feature of Malebranche's doctrine of the vision in God is connected to the notion in his writings of the "efficacious idea" (*idée efficace*). This notion became entrenched in Malebranche's system around 1695, after his encounter with his Cartesian critic Régis (see Robinet 1965). In his *Système de philosophie* Régis challenges the claim in the preface to the *Recherche* that one's mind is united to God in a manner that "raises the mind above all things" and is the source of "its life, its light, and its entire felicity." While he grants the commonplace claim that God must create and conserve one's soul, Régis denies that one is enlightened by means of a union with ideas of

bodies in God. Rather, he insists that God conserves in one ideas that derive directly from the bodies they represent. In his 1693 *Réponse à Régis* (*Response to Régis*) Malebranche emphasizes his Augustinian position that one can be instructed as to the nature of bodies only through a union with God. However, he puts a new spin on this position when he notes that the union with God involves an “affecting” or “touching” of one’s mind by God’s idea of extension.

Already in the 1688 *Entretiens sur la métaphysique* Malebranche suggests that the union with God can be explicated in terms of a causal relation between God’s ideas and one’s mind. After 1695 he develops this suggestion by introducing the notion of “pure” or nonsensory intellectual perceptions that are produced by God’s efficacious idea of extension. Still, he also stresses in this later period that such an idea is the causal source of one’s sensations. One advantage of this extension of the doctrine of efficacious ideas to sensations is that it yields a fairly clear explanation of Malebranche’s claim to Arnauld that an idea is “intelligible extension rendered sensible by color or light.” Before 1695 Malebranche explained how intelligible extension is so rendered by appealing somewhat obscurely to the view that the soul “attaches” colors to a nonsensory idea. However, the theory of efficacious ideas allows him to say that this idea is rendered sensible by causing in one the appropriate sensations of light and color. The claim that one sees ideas in God is thus transformed into the claim that one’s soul has intellectual and sensory perceptions that yield an understanding of the truth concerning bodies in virtue of their causal relation to God’s idea of extension. One scholar concludes that while Malebranche starts with the vision *in* God, he ends with a vision *by* God (Alquié 1974, 209).

## CARTESIAN DUALISM AND SENSATION

Malebranche tells Arnauld that it was Augustine’s authority “which has given me the desire to put forth *the new philosophy of ideas*” (Malebranche 1958–1984, p. 6:80). By contrast, he emphasizes in the preface of the *Recherche* that Augustine failed to see that sensible qualities “are not clearly contained in the idea we have of matter,” adding that “the difference between mind and body has been known with sufficient clarity for only a few years.” The allusion here is to Descartes’s discovery of an idea of matter that reveals that its nature consists in extension alone. This idea dictates that sensible qualities such as colors, tastes, and odors that are not reducible to modes of extension cannot exist external to mind. But since these

qualities exist in the mind, and in particular in the mind’s perception of the qualities, the mind itself must be distinguished from body. In this way the Cartesian idea of matter reveals “the difference between mind and body.”

In the initial book of the *Recherche*, on the errors of the senses, Malebranche proposes that the erroneous belief of the Aristotelians as well as of Augustine that sensible qualities exist in bodies has its source in a misuse of “natural judgments” that help in the conservation of the human body. Here, he is following Descartes’s account in the Sixth Meditation of the “teachings of nature,” and in particular the claim there that the purpose of sensations is not to teach one about the nature of bodies but simply to inform one of what is beneficial or harmful to the human composite. Just as Descartes urged that erroneous beliefs about the nature of body can be avoided by attending to the clear and distinct perceptions of the intellect, so Malebranche counsels that one avoid error by attending to what the clear idea of matter reveals to one about the nature of body. As noted earlier, Malebranche has Augustinian reasons for saying that the idea that so instructs one exists in God. By his own admission, however, the conclusion that the idea that instructs one is an idea of extension derives from Descartes’s discoveries.

Malebranche emphasizes that the clear idea of extension must be distinguished from one’s confused sensations. One point he wants to make is that the idea exists in God while the sensations are only modifications of one’s mind. However, his emphasis that this idea is “pure” or nonsensory indicates that one’s experience of the material world has an intellectual component. His late doctrine of the efficacious idea involved the position that one has pure intellectual perceptions produced by God’s intellectual idea of extension. But his mature position that this idea is also the cause of one’s sensations allows for the claim that one’s most basic sensory contact with the material world has an intellectual component.

Malebranche’s doctrine of the vision in God also conflicts with Descartes’s doctrine of the creation of the eternal truths. However, there are further departures from orthodox Cartesianism that are linked to two qualifications of this doctrine. The first qualification is that God’s idea of extension can reveal only the nature of bodies and not their existence. This qualification is not explicit in the initial edition of the *Recherche*, which says only that the existence of properties of bodies external to one is “very difficult to prove” (Malebranche, 1997b, I.x.§1). Foucher objected that Malebranche has no good reason to affirm the external existence of these properties. In *Eclaircissement VI*, Malebranche urges that the idea of

extension does reveal the possible existence of the material world and that Descartes has shown that one has a probable argument for its actual existence deriving from one's natural propensity to believe that there are bodies. However, he concedes in this text—without crediting Foucher—that neither he nor Descartes can provide an argument from reason that demonstrates “with evidence” or “with geometric rigor” that this belief is true. His claim is that any conclusive argument must appeal to faith in the veracity of the report in the Scriptures that God has created the heavens and the earth.

According to the second qualification of the vision in God—which is found in the original edition of the *Recherche*—one perceives the nature of one's soul not through a clear idea in God, but only through a confused “consciousness or inner sensation” (*conscience ou sentiment intérieur*). Malebranche accepts the Cartesian commonplace that consciousness reveals immediately the existence of the soul. He allows that one knows the nature of one's soul to consist in thought; moreover, he embraces the Cartesian conclusion that the soul as a thinking substance is distinct from the body as an extended substance. Still, he insists that one knows that the soul is distinct from the body not by means of any direct insight into the nature of thought, but by seeing that thought is not contained in the idea of matter. More generally, Malebranche claims that one's lack of access to a clear idea of the soul is evident because one does not have knowledge of thought that matches one's knowledge of the mathematical features of bodies. This last point turns on its head Descartes's own conclusion in the Second Meditation that the nature of the human mind is “better known” than the nature of body; for Malebranche, it is the nature of body that is better known than the nature of mind.

In *Eclaircissement XI* Malebranche attempts to counter “the authority of Descartes” by arguing that the Cartesians themselves must admit that they have only a confused awareness of the nature of the sensory modifications of the soul. He notes that whereas the intellectual idea allows the various modes of extension to be related in a precise manner, there is no clear scale on which one can order one's sensations of different shades of the same color, not to mention one's sensations of sensible qualities of different kinds. Malebranche takes the confusion in the sensations to reveal a confusion in one's perception of the nature of the soul. He adds that Cartesians can discern that sensible qualities are modifications of an immaterial soul only by seeing that they are “not clearly contained in the idea we have of matter” (Malebranche 1958–1984, pp. 3:168, 170f).

## OCCASIONALISM AND GENERAL VOLITIONS

Malebranche is known for his occasionalism, that is, his doctrine that God is the only causal agent and that creatures are merely “occasional causes” that prompt divine action. On the old textbook account, occasionalism was an ad hoc response to the purported problem in Descartes of how substances as distinct in nature as mind and body can causally interact. According to this account, Malebranche was driven by this problem with Cartesian dualism to propose that it is God who brings it about that one's sensations and volitions are correlated with motions in one's body.

However, occasionalism was already an old doctrine at the time that St. Thomas Aquinas wrote against it in the thirteenth century. Thomas indicated that the primary concern of the occasionalists was to strengthen the assertion of God's omnipotence. Though he allowed that God must “concur” with creatures in producing effects, he also claimed that there is reason to conclude that creatures are true secondary causes. For instance, he urged that it is more in accord with divine greatness to say that God communicates His power to creatures. Moreover, he claimed that it is simply evident to the senses that creatures have the power to bring about effects. Thomas also argued that if there were no natures in creatures that explain effects, then there could be no true scientific explanation of effects through their natural causes.

Malebranche was concerned to respond to all these arguments against occasionalism, particularly as they were developed in the work of scholastics such as Suárez. Against the first point that God's greatness requires the communication of His power, Malebranche counters that it is in fact idolatrous to attribute divine power to creatures. His argument that God alone can produce effects relies on the assumption that “a true cause ... is one such that the mind perceives a necessary connection [*liaison nécessaire*] between it and its effects” (Malebranche 1997b, VI-2.iii). Malebranche claims that there is such a connection neither among bodily states, nor between bodily and mental states, nor among mental states. In all these cases one can deny the connections without contradiction. There can be a necessary causal connection in only one case, namely, the connection between the volitions of an omnipotent agent and its upshots. Thus, only such an agent, namely, God, can be a true cause.

In the *Entretiens sur la métaphysique* Malebranche offers a different argument based on Descartes's suggestion in the Third Meditation that God conserves the world by continuously creating it. The argument begins

with the claim that God must create bodies in some particular place and in determinate relations of distance to other bodies. If God conserves a body by creating it in the same place from moment to moment, that body remains at rest, and if He conserves it by creating it in different places from moment to moment, it is in motion. One cannot even create motion in one's own body. Rather, it is God who must produce it on the occasion of volitional states. Moreover, it is not motions in one's brain that cause one's sensory states, but God who produces them on the occasion of the presence of such motions.

Unlike the argument from necessary connection, this argument from continuous creation is for the most part restricted to the case of body. There is a good reason for this restriction since the argument depends on the premise—dictated by a Cartesian understanding of the nature of body in terms of extension alone—that particular bodies cannot exist without bearing determinate relations of distance among themselves. As noted, Malebranche denies that one has a clear knowledge of the nature of the soul. No consideration of the soul could therefore reveal that it can exist only with a determinate set of modes. Indeed, Malebranche allows for the view that God creates souls with an indeterminate inclination toward “the good in general.” Even so, he insists that God must be the cause of “everything real” in one's soul on the grounds that such real effects can be produced only by the power of creation. In this way the argument from continuous creation converges on the conclusion, which Malebranche claims to find in Augustine, that all creatures depend entirely on God.

The second scholastic argument against occasionalism appealed to the purported fact that it is evident to the senses that creatures have causal power. For Malebranche, however, this argument is no more persuasive than the argument that bodies must have qualities such as colors and tastes since one's senses tell one that they do. As indicated earlier, Malebranche offers Cartesian grounds for thinking that the purpose of one's sensations is not to reveal the true nature of the material world, but to indicate what is helpful or harmful to one's body. Malebranche holds that one's attribution of causal powers to bodies manifests in particular an attachment to the body that is an effect of original sin. Because of this attachment, one takes objects in the material world to be a cause of one's happiness rather than God.

In *Eclaircissement XV* Malebranche responds to the scholastic point that occasionalism renders scientific explanation impossible by appealing to the fact that God is not an arbitrary agent, but acts in accord with His wis-

dom. This wisdom dictates that He act “almost always” by means of a “general and efficacious will.” Such a will produces effects that are perfectly lawlike. For instance, God acts by a general will in producing changes in bodies in accord with the law of the communication of motion. Malebranche does allow that God can produce miracles by “particular volitions” that are not lawlike. However, he emphasizes that there are relatively few such volitions in God. Thus, one can offer scientific explanations that appeal to the laws of motion that reflect the nature of God's general will.

Malebranche was not the first Cartesian to endorse occasionalism. There were followers of Descartes, such as Louis de la Forge and Claude Clerselier, who stressed that God must be the cause of the communication of motion in bodily collisions given the passivity of Cartesian matter. These Cartesians attempted to preserve some room for the action of finite minds on the body, but the Cartesian Géraud de Cordemoy went further in claiming that only God can cause changes in the material world. However, none of these thinkers went as far as Malebranche in asserting that God must produce all real changes in nature. Moreover, Malebranche is distinctive in providing an explanation of God's action that distinguishes His general will from His particular volitions.

## THEODICY AND FREEDOM

The presence of various evils in the world is problematic for any theist who claims that this world was created by a God who has infinite power, knowledge, and goodness. However, the problem is particularly acute for an occasionalist, such as Malebranche, who holds that God is the only true cause of effects in nature. Malebranche offers a theodicy that addresses the problem of evil by stressing that in the “order of nature” God acts for the most part through His general will. In *Nature et de la grâce* he starts by admitting that God could have acted by particular volitions to prevent natural evils such as malformed offspring (a fitting example given his own malformed spine), and thus could have produced a more perfect world than He actually did create. However, he urges that God could have done so only by departing from simple laws, thereby sacrificing the simplicity and uniformity of action that is a supreme mark of His wisdom. God produces the natural evils that follow from simple laws not because He wills those particular effects, but because He wills a world that best reflects His wisdom by possessing the most effects governed by the fewest laws.

In his *Réflexions* on Malebranche's *Nature et de la grâce* Arnauld objects to what he takes to be the sugges-

tion in his target text that God has concern only for general features of the world and does not will the details of His effects. For Arnauld, divine providence requires that God intend all the particularities of the world He creates. There is some controversy over whether Arnauld's critique is based on a proper interpretation of Malebranche. Certain commentators follow Arnauld in thinking that Malebranche's claim in *Nature et de la grâce* that God acts by relatively few general volitions involves a rejection of the position that He has volitions for each particular effect. Others insist that this claim says only that God has volitions in accord with general laws and that the doctrine of God's continual creation in the *Entretiens* in fact requires distinct volitions for distinct effects. Some evidence for the former view is provided by the fact that Malebranche emphasizes that the laws themselves are "efficacious" and that God employs relatively few volitions in producing effects in the order of nature.

Malebranche insists that God's general will is operative not only in the order of nature but also in the "order of grace." However, he notes that the production of effects in the latter order also involves human action that is free in the strong sense of not being determined by anything external to the agent. His appeal to this sort of freedom is in fact central to his solution to the problem of moral evil, that is, the compatibility of sin with God's goodness. According to Malebranche God is not responsible for sinful action since such action derives not from Him but from sinful agents. Arnauld objects that this solution is "more pelagian than anything in Pelagius" and that one must side with Augustine, who declares Pelagianism a heresy. Malebranche responds that he does not follow Pelagius in denying the importance of grace and that Augustine himself emphasizes one's freedom in action.

Malebranche also insists that it is obvious by "inner sensation" that one is genuinely free. However, there is some question whether this introspective report is compatible with Malebranche's occasionalist claim that God is the only real cause. As indicated earlier, Malebranche does hold that God alone is the cause of one's indeterminate inclination to love the good in general. However, he insists that one is free to "consent" to the stopping of that inclination at a particular object other than God. Such consent results in an "absolute and intrinsic" love of that object that is sinful given that this love is worthy only of God. The consent is free because one is always able to suspend consent and to search for objects more worthy of one's love. Malebranche claims that one's freedom to consent or suspend consent does not conflict with occasionalism since these acts produce no "real" or "physical"

change in one's mind. Sometimes he suggests that consent is nothing real because it involves merely resting with a particular good. One problem with this suggestion is that it makes it difficult to understand how taking the opposite course of suspending consent could also involve the production of nothing real. However, Malebranche sometimes indicates that both consent and suspense produce nothing real merely in the sense that they create neither new thoughts nor an increase in inclination. He also indicates that though God determines one's "natural love" for particular objects, he leaves undetermined our "free love" for such objects.

Although Malebranche himself is less than explicit on the point, he seems at times to have left at least some room for the position that one's consent involves the determination of one's free love, whereas one's suspense involves leaving that love in its indeterminate state. In neither case is there the production of a physical change because there is no creation of new thoughts or of an increase in inclination. Whether this reflects Malebranche's own considered view is, however, a matter of scholarly dispute.

#### MORAL THEORY AND SELF-LOVE

The theocentrism that is evident in Malebranche's doctrines of the vision in God and occasionalism would lead one to expect that God plays a central role in his moral theory. This expectation is borne out by his remarks in the *Traité de morale*. Indeed, Malebranche's two doctrines are prominent in this work. The vision in God is reflected in the insistence that moral duties are dictated by "relations of perfection" revealed in God's wisdom. As in the case of necessary truths concerning body, so in the case of moral truths Malebranche unequivocally rejects Cartesian voluntarism. The doctrine of occasionalism is reflected in Malebranche's insistence that God is one's greatest good because He alone can cause one's happiness. This point indicates that Malebranche takes moral action to require a consideration not only of abstract relations of perfection but also of the happiness of the self.

Malebranche starts from the Augustinian position that morality concerns the proper ordering of one's love. Given the importance of human freedom for his theodicy, it is not surprising that Malebranche insists that the love required for moral action involve the free exercise of the will. In his view, the "good will" is one that freely strives to be guided in action by objective relations of perfection that hold among the various objects of love. God is the most perfect being and hence the most worthy of

one's love, whereas human beings are more perfect than mere material beings and thus more worthy of one's love. When the intensity of one's love matches the order among perfections, one has a right love that provides the basis for virtue, that is, a habitual inclination to love objects according to their perfections.

Malebranche holds that because of original sin, one is inclined not to right love directed by one's perception of relations of perfection in God's wisdom, but to a disordered love directed by bodily pleasures deriving from the soul-body union. This is the counterpart to the disordered inclination of one's will to make judgments about the nature of the material world that are based on sensations deriving from the union. For Malebranche, a corrective to both of these disorders of the will is to attend to clear ideas that exist in God.

Malebranche sometimes suggested that disordered love of bodily pleasure derives from self-love. Encouraged by this suggestion, one of his followers, François Lamy, claimed that his position leads to the quietist view in Fénelon that moral conduct requires a "pure love of God" that involves no concern for the self or its pleasure. This position, which Lamy himself endorsed, was later condemned by the Catholic Church, due in large part to a campaign against Fénelon directed by his critic, Bossuet. But Malebranche insisted that such a position directly conflicts with his own view that pleasure itself is a good that is required as a motive for action. When critics such as Arnauld and Régis charged that this view results in hedonism, Malebranche responded that it is only ordered pleasures that bring the greatest good. This response is reflected in Malebranche's claim to Lamy that a disordered love of self is to be contrasted not with pure love of God, but with an ordered love that seeks happiness in the contemplation of the greatest good, God. In emphasizing the need for this sort of love of God, Malebranche was returning to his view in the preface to the *Recherche* that it is through a union with God that the mind "receives its life, its light, and its entire felicity."

## HISTORICAL INFLUENCE

Malebranche's influence on seventeenth- and eighteenth-century philosophy was significant. This is clear in the case of Leibniz, who wrote to Malebranche in 1679 that "I enthusiastically approve of the two propositions that you put forward: namely, that we see all things in God and that bodies strictly speaking do not act on us." Moreover, Leibniz's discussion in his 1684 *Discours de la métaphysique* (*Discourse on Metaphysics*) bears an evident relation to Malebranche's *Nature et de la grâce*. Here, Leibniz

follows Malebranche in insisting that God acts in accord with wisdom and that He selects from among an infinity of possible worlds that world that best reflects His perfection by balancing simple laws and variety of effects. Leibniz stresses, in line with Malebranche's views, that the simplicity constraint governs both laws of nature and laws of grace.

The *Discours* also includes a section in which Leibniz comments on the Arnauld-Malebranche debate on the nature of ideas and offers some complimentary remarks concerning the Malebranchean doctrine of the vision in God. In his 1710 *Théodicée*, Leibniz highlights his agreement with the claim in *Nature et de la grâce* that natural evil exists because God's wisdom dictates that He restrict himself to a "general will." However, he also charges in this text that Malebranche's occasionalism leads to a kind of Spinozism insofar as it denies the activity and thus the substantiality of creatures. Leibniz offers his "preestablished harmony," on which creatures have the power to cause alterations in their own states. This theory, which is anticipated in the *Discours*, distinguishes Leibniz's view from Malebranche's. However, Leibniz himself sometimes presents the preestablished harmony as an internal correction to the Malebranchean system that is in accord with Malebranche's own emphasis on the perfection of divine action in creation.

Malebranche's influence extended across the Channel, where he gained admirers such as John Norris, Thomas Taylor, and Arthur Collier. His views drew a more critical reception from John Locke, who wrote *Examination of Père Malebranche's Opinion of Seeing All Things in God*, which was published posthumously in 1706. Though Malebranche himself did not respond to this work, it later received a full reply from the Savoyard cardinal, Giacinto Sigismondo Gerdil, who would have been elected pope in 1800 were it not for the veto exercised by the Austrians on political grounds. In his *Défense du sentiment du P. Malebranche*, published in 1748, Gerdil urged that Malebranche's hypothesis that God causes one's perceptions is more intelligible than Locke's own hypothesis that passive matter is the cause of these states. Because of Gerdil's influence, Malebranche's views gained a following in Italy.

During the eighteenth century Malebranche also won the grudging respect of George Berkeley and David Hume. Berkeley indeed appeared to his critics to be a "Malbranchiste de bonne foi," a view that Berkeley himself counters when he writes in the third (1734) edition of his *Three Dialogues between Hylas and Philonous* that "there are no principles more fundamentally opposed

than [Malebranche's] and mine." Berkeley does differ from Malebranche in rejecting the existence of an external material world, in insisting that ideas exist in one's mind rather than in God's and in claiming that the senses reveal immediately the true nature of sensible objects. However, Berkeley follows Malebranche in rejecting the Aristotelian conception of nature and in attributing causal efficacy in natural interactions to God (though Berkeley does attempt, with questionable success, to leave room for the power of finite spirits to move their own bodies). Also, Berkeley holds with Malebranche that one's perceptions are related to certain "archetypes" in the divine mind that serve as the pattern for God's creation (Luce [1934] is the classic study of the relation between Berkeley and Malebranche).

In 1737 Hume wrote to his friend Michael Ramsey that he should prepare himself for "the metaphysical Parts" of the reasoning in the forthcoming *Treatise of Human Nature* (1739–1740) by reading "once over la Recherche de la Vérité of Pere Malebranche," along with selected works from Descartes, Berkeley, and Pierre Bayle. Malebranche is important primarily for the account of causation and causal belief in the *Treatise*. Hume relies there explicitly on Malebranche's argument for the negative conclusion that neither external nor internal experience affords one any idea of power. With Malebranche, Hume emphasizes the importance of necessary connection to the understanding of causation. Hume does reject Malebranche's own claim that God is the only real cause, noting in a famous passage from the *Enquiry concerning Human Understanding* (1748) that with such a claim "we are got into fairy land, long ere we have reached the last steps of our theory." Hume's preference is for a psychological account of causal belief that sticks closely to "common life and experience" and that emphasizes the central role of the imagination. Nonetheless, Hume's own discussion belies his remark in the *Enquiry* that "the glory of Malebranche is confined to his own nation, and to his own age."

## MALRAUX, GEORGES-ANDRÉ (1901–1976)

Georges-André Malraux, the French author, critic, revolutionist, and statesman, was born in Paris to a well-to-do family. He studied at the Lycée Condorcet and the Institut des Langues Orientales and early in life developed an enduring interest in archaeology, art, and Oriental languages and thought. His life and writing were characterized by a restless, questioning, quasi-apocalyptic intensity that is fully understandable only in terms of the crisis with which Western thought was confronted in the first half of the twentieth century: At grips with a fast-accumulating mass of new knowledge, Western civilization was seeking to adjust to the violent changes that had disrupted its former social, intellectual, and spiritual framework of values.

In 1923 Malraux went on an archaeological expedition into the Cambodian jungle, and soon afterward he returned to the Orient to participate in the revolutionary struggle that was transforming the Asiatic world. He seems at the time to have been in sympathy with the Marxist ideology. *La tentation de l'occident* (Paris, 1926), his first serious work, is a fictional dialogue between a Chinese and a European intellectual and shows how decisive was his first encounter with the Orient. It intensified Malraux's self-styled obsession with the notions of civilization and culture. He was always vitally concerned with the problems of the life and death of civilizations; the specificity, irreducibility, and relativity of all cultures;

their determining action in shaping the mental structures of individuals; and the bearing on his own cultural world of the observations and conclusions of historians and anthropologists such as Oswald Spengler and Leo Frobenius. This initial obsession was nourished and substantiated by Malraux's legendary familiarity with all realms of art (painting and sculpture in particular); his avid and exceptionally broad grasp of literature; and his addiction to passionate debate with leading personalities in Europe and the Orient. Although his thought was always concentrated on a present unremittingly interrogated, it developed within vast perspectives both in time and space.

In the late 1920s Malraux, as art editor for the Gallimard publishing firm in Paris, traveled widely in search of art treasures, while actively participating in the unavailing struggle of the European intellectuals against fascism, Nazism, and anti-Semitism. He later commanded a group of aviators for the Republican forces in the Spanish Civil War, was active in the French resistance after 1940, and became, first, minister of information, then minister of cultural affairs, in the cabinet of General Charles de Gaulle.

He was deliberately “committed” as a writer for intellectual reasons. Western science, he claimed, offers a set of relationships that define the cosmos but, by omitting the observer, it presents a cosmos in which man has no place. According to Malraux, psychoanalysis has revealed the blind, destructive forces at work within the self and has put into question the very notion of a fundamental human personality. To recover some concept of man, Malraux maintained that one must once again examine what man does, thereby redefining his powers. The image of the rational, detached observer—scientist or philosopher—placed outside the world he observes must therefore give way to the participant who is, as it were, a knot of relations with the world. Malraux often reiterated that man “is what he does.” Participation therefore was the first and necessary stage in his search for definition.

The elucidation of an action is the theme of his novels. All revolve around the question, “What can a man best do with his life?”; all are animated by the same answer that is given in *Man's Hope*: “Transform into consciousness an experience as broad as possible.” Writing is the medium through which this transformation takes place; hence the intensity of the process, the inner questioning, and the many-faceted debate that it embodies. His six widely read novels all are wrenched from stages of his own experience: *Les conquérants* (Paris, 1928); *La voie royale* (Paris, 1930); *La condition humaine* (Paris, 1933); *Le temps du mépris* (Paris, 1935); *L'espoir* (Paris, 1937);

and *Les noyers de l'Altenburg* (Lausanne, 1943), the first volume of a two-part novel whose second part was destroyed by the Nazis. These were followed by an impressive series of works on art: *Goya* (Geneva, 1947); *La psychologie de l'art* (3 vols., Geneva, 1947, 1949, 1950); *Le musée imaginaire de la sculpture mondiale* (3 vols., Paris, 1952, 1953, 1954); *Les voix du silence* (Paris, 1953); and *La métamorphose des dieux* (Paris, 1960). A number of reviews, prefaces, and speeches add to this abundant corpus of work.

Despite both the variety of his media and the obscurities inherent in his manner of writing, there is a remarkable degree of consistency and lucidity in Malraux's thought, questionable though many of his assumptions and examples may be. He posits as premise the definitive disappearance from Western civilization of the structure of values established by the Christian *Weltanschauung*. Western man is thus left face to face with a cosmos to which he cannot relate. However, he is still in possession of the inner drive that, since the Greeks, has structured his world—the need to create a coherent, intelligible image of man's fate that gives significance to each individual life. Hence the double burden of lucidity and anguish characteristic of our time, hence its “temptations.” The most prevalent is the nihilism whereby Western man, living in a state of “metaphysical distraction,” renounces his drive toward lucidity and submits to blind necessity and to natural and social conditioning. This, according to Malraux, is an intolerable reversion to the “demons,” that is, to the blind animal instinct within us. Malraux also examined and partially rejected the Asian resorption of the individual into the cosmos (considered as divine). In preference to the Asian view, he sought to define man's power in his capacity to “leave a scar on the planet,” to transform his environment. For a while he understood the process in terms of the Marxist theory of history.

Malraux's final view emerged from his meditations on art. It is a complex outlook related to the study of art styles and their migrations and metamorphoses, an approach that is characteristic of such art historians as Élie Faure and Henri Focillon. In brief, for Malraux a new planetary civilization that has destroyed all significant cultures is now in the making. The structures of values whereby each individual within a human society relates to the cosmos, to the community, and to his own actions now exist only as “relativized absolutes.” This is the first agnostic civilization, the first that does not relate to some form of the divine. It also presents a new phenomenon, the “imaginary museum,” in which all works of art—

whatever their origin—are available, to be perceived as significant in themselves and not for what they once signified. For Malraux this universal presence and significance testifies to a fundamental power of humankind: the power to dominate and transcend fate and to create a universe in some way accessible to all men, who are thereby freed from time, death, and blind necessity. The privileged potential image of humankind, therefore, that Malraux detects as indicative of our present orientation is that of man as creator and as forger of his own freedom. Malraux thus formulated in new terms the age-old problem of freedom and destiny, to serve as the foundation for a new ethic. His work is fundamentally relevant in an age that is deeply preoccupied with the working of the mind, considered on one hand as a form of conditioned mechanism and on the other as a principle of free activity, order, and meaning.

#### WORKS BY MALRAUX

The works listed below are English editions of Malraux's works in the order in which they appear in the text.

*The Temptation of the West*. Translated with an introduction by Robert Hollander. New York: Vintage, 1961.

*The Conquerors*. Translated by W. S. Whale. New York: Harcourt Brace, 1929.

*The Royal Way*. Translated by Stuart Gilbert. New York: Smith and Haas, 1935.

*Man's Fate*. Translated by Haakon Chevalier. New York: Smith and Haas, 1934.

*Days of Wrath*. Translated by Haakon Chevalier. New York: Random House, 1936.

*Man's Hope*. Translated by Stuart Gilbert and Alistair MacDonald. New York: Random House, 1938.

*The Walnut Trees of Altenburg*. Translated by A. W. Fielding. London: Lehmann, 1952.

*Saturn: An Essay on Goya*. Translated by C. W. Chilton. London: Phaidon, 1957.

*The Psychology of Art*. Translated by Stuart Gilbert. Vol. I: *Museum without Walls*; Vol. II: *The Creative Act*. New York: Pantheon, 1949–1951.

*The Voices of Silence*. Translated by Stuart Gilbert. New York: Doubleday, 1953.

*The Metamorphosis of the Gods*. Translated by Stuart Gilbert. New York: Doubleday, 1960.

#### WORKS ON MALRAUX

Blend, Charles. *André Malraux: Tragic Humanist*. Columbus: Ohio State University Press, 1963. A biography and general critical study, with a bibliography of Malraux's work and a brief critical bibliography.

- Frohock, Wilbur. *André Malraux and the Tragic Imagination*. Stanford, CA: Stanford University Press, 1952. A basic work.
- Lewis, R. W. B., ed. *Malraux*. Englewood Cliffs, NJ: Prentice-Hall, 1964. A collection of critical essays.
- Lyotard, Jean Francois. *Soundproof Room: Malraux's Anti-Aesthetics*. Translated by Robert Harvey. Stanford: Stanford University Press, 2001.
- Raymond, Gino. *Andre Malraux: Politics and the Temptation of Myth*. Aldershot: Avebury; Brookfield: Ashgate, 1995.
- Righter, William. *The Rhetorical Hero: An Essay on the Aesthetics of Andre Malraux*. New York: Chilmark Press, 1964.
- Vandergars, André. *La jeunesse littéraire d'André Malraux*. Paris: Pauvert, 1964. Contains a wealth of information on Malraux's Indochinese activities.

## MALTHUS, THOMAS ROBERT (1776–1834)

Thomas Robert Malthus, the English economist and moral philosopher, is most famous for his contributions to population studies. In his *Principles of Political Economy* (1820) and in his controversies with David Ricardo, Malthus seems partly to have anticipated J. M. Keynes; and Keynes himself, in his *Essays in Biography*, generously remarked that “if only Malthus, instead of Ricardo, had been the parent stem from which nineteenth century economics proceeded, what a much wiser and richer place the world would be today!”

Malthus's work on population is contained in two books, misleadingly presented as if they were merely different editions of one. The first, best referred to as the *First Essay*, is actually titled *An Essay on the Principle of Population as It Affects the Future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers*. The second, best thought of as the *Second Essay*, was, with some reserve, offered by Malthus as a much extended second edition. But it was retitled *An Essay on the Principle of Population, or a View of Its Past and Present Effects on Human Happiness with an Inquiry into Our Prospects Respecting the Future Removal or Mitigation of the Evils Which It Occasions*. The *First Essay* is an occasional polemic against utopianism; the *Second*, a labored treatise full of detailed factual material. What they have in common is the same guiding and coordinating theoretical schema, although even this is in one respect importantly amended in the later book.

The fundamental principle is that unfreakish human populations possess a power of multiplying in a geometrical progression. The next step is to urge that this power always is and must be checked by countervailing forces; for, on the most optimistic supposition, means of subsistence could in the long run at best be increased only in an arithmetical progression. (The subsistence of checks could, of course, be inferred without recourse to this misleadingly arithmetized supposition, by referring directly to the fact that no human population ever does achieve its full multiplicative potential.) The questions then arise. What are these checks? what ought they to be?

Checks are classified in two different ways. First, they can be positive or preventive: the former by the time of the *Second Essay* being all causes of (premature) death; and the latter, correspondingly, all checks on the birth rate. The second classification is strongly normative: In the *First Essay* all checks must count as either misery or vice; but in the *Second Essay* a third option, moral restraint, is added. This is defined as “the restraint from marriage which is not followed by irregular gratifications.” Malthus seems never to have entertained the possibility of restraint within marriage; and he categorically rejected any form of contraception, even within wedlock, as vice.

This scheme of ideas constituted an intellectual engine that was immensely powerful both for its primary purpose of confounding utopian optimism and for its secondary function of guiding social inquiry. We also have clear statements from both Charles Darwin and Alfred Russel Wallace that it was reading Malthus on population which independently led each to see the clue to the problem of the origin of species in natural selection through “a struggle for existence,” a phrase used by Malthus himself. Against the utopians the argument was that our inordinate animal power of multiplication is bound—sooner or later, and usually sooner—to run up against the inexorably constricting walls of scarcity. All measures of intended amelioration which directly or indirectly encourage an increase of population that outstrips resources—and most do—will, in the not very distant end, merely multiply the number of bearers of misery and agents of vice. These harsh and gloomy conclusions were only modified, not upset, by the belated recognition of the option of moral restraint. For it was, and remains, hard to cherish high hopes from the preaching of such prudence; and in any society which did generally accept such preaching all but the richest would have to marry women nearing the evening of their reproductive powers.

It is, therefore, not surprising that generations of idealists hoping to reshape the present sorry scheme of things nearer to their heart's desire have released torrents of argument and abuse at "Parson Malthus" and his ideas. Yet, despite the apparent implication of his system—that God has placed humankind in a situation offering little promise of secure improvement—it would be wrong to assume that Malthus as a man or as a thinker was either insensitive or harsh. Compared with the optimistic utopians of his father's reading and acquaintance he could not but appear a jarring pessimist. But this was a matter of facing what he took to be the sober facts of the human condition, not of callous indifference to the relief of man's estate. To quote Keynes again, his work is really in "the tradition which is suggested by the names of Locke, Hume, Adam Smith, Paley, Bentham, Darwin and Mill, a tradition marked ... by a prosaic sanity ... and by an immense disinterestedness and public spirit." As against, say, Condorcet, who wrote of inevitable progress while under the shadow of the guillotine, Malthus was concerned first with finding what the facts are and then with discovering how, in the light of those perhaps recalcitrant facts, we are to do the best we can. It is no accident that in the first chapter of the *First Essay* he acknowledges a debt to David Hume and Adam Smith but not to the impossible and visionary Jean-Jacques Rousseau, whom his father had known and admired.

### THEODICY

The same intellectual associations are seen in his theodicy. William Paley was one of the early converts to Malthus on population, and appropriately, Paley was one of Malthus's favorite theologians. So Malthus insists in the *First Essay* that "Evil exists in the world not to create despair but activity." (It was from this part of the work that Darwin and Wallace most directly derived the idea of a necessary struggle for existence.) What Malthus may have acquired from the dissenting Christians and Unitarians of his father's circle is a note of theological radicalism, a note not caught either by the hostile conventional left, represented then by William Cobbett and William Hazlitt, or by such sentimental conservative opponents as Samuel Taylor Coleridge and Robert Southey.

In the theodicy of the last chapter of the *First Essay* Malthus boldly steps away from Paley and from the whole tradition of Christian orthodoxy by insisting that "it is perfectly impossible to conceive that any ... creatures of God's hand can be condemned to eternal suffering. Could we once admit such an idea, all our natural conceptions of goodness and justice would be completely overthrown,

and we could no longer look on God as a merciful and righteous Being." (Malthus settles his own account with Christianity by accepting the Hobbist interpretation; that eternal death means eternal death and not eternal life in torment. The "doctrine of life and immortality which was brought to light by the gospel" is "the doctrine that the end of righteousness is everlasting life, but that the wages of sin are death." This plausible reading had been unanimously rejected by the orthodox Saints and Fathers, doubtless as being unacceptably merciful.)

### CRITIQUE OF POPULATION THEORY

As a heuristic and explanatory scheme, the population theory resembles bits of classical physics, although it might also be usefully compared with that of Darwinism. The fundamental principle is like the first law of motion in that both describe not what does go on but what would go on if there were no counteracting forces; and in both cases the main theoretical function of the basic law is to generate questions about such forces and checks. Again, Malthus in classifying checks always aims at complete, exhaustive lists; and his arguments often depend on his appreciation that the values of the various checks considered as variables will be, for a given population, inversely connected: the bigger the sum of the preventive checks, the smaller the sum of the positive checks; and so on. These are similarities of which Malthus himself—thanks to his mathematical training at Cambridge—seems to have been aware. (It is doubtless to the same training that we owe his introduction of the supposition of the arithmetical progression to which, and to the consequent comparison of the two progressions, is due much of the appearance of "mathematical certainty" in his demonstrations.)

Malthus never tied up all the various minor logical loose ends in his original conceptual scheme, although he added important appendices to the third and fifth editions of his work in 1806 and 1817 and wrote the article "Population" for the 1824 supplement to the *Encyclopaedia Britannica* (revised and published separately as his last word in 1830). But the main objections to Malthus that emerged from the enormous controversy are two, one moral and one logical. The moral objection repudiates Malthus's total rejection of contraception. It is this repudiation, combined with acceptance of Malthus's warnings on the dangers of overpopulation, which makes a Neo-Malthusian. The suggestion sometimes heard that the spread of contraception has made Malthusian ideas obsolete should be seen as manifestly absurd. Contraception is one kind of preventive check; none at all would be

required if the multiplicative power was not still there to be checked.

The second objection insists on a distinction, which Malthus was forever inclined to overlook, between two senses of *tendency*. A tendency to produce something may be a cause which, operating unimpeded, would produce it. But to speak of a tendency to produce something may also be to say that the result is one that may reasonably be expected to occur in fact. This point seems to have been put against Malthus for the first time by Nassau Senior in his *Two Lectures on Population* (1831) and was grudgingly accepted. It was developed in the following year by Archbishop Whateley in *Lectures on Political Economy* (ninth lecture).

If both these objections are accepted, it becomes possible to recognize the Malthusian menace but to insist that the tendency to catastrophe does not have to be a tendency in the second sense—not if people can be persuaded to employ the means which science has and will put into our hands. Yet Malthus must have the last word. For it was he who most dramatically and powerfully drew attention to an absolutely vital fact, a fact that is still persistently and often disastrously ignored. It is, in the words of Senior, that “no plan for social improvement can be complete, unless it embraces the means both of increasing production, and of preventing population making a proportionate advance.”

## MAMARDASHVILI, MERAB KONSTANTINOVICH (1930–1990)

Merab Mamardashvili was born September 15, 1930, in Gori, Georgia and died November 25, 1990, in Moscow. He was a philosopher most of whose creative life passed in Moscow and Tbilisi, Georgia, in the period from the 1950s through the 1980s. He was an original thinker who received world recognition. His main spheres of inquiry were the philosophy of consciousness, the theory of transformed forms of consciousness; classical and non-classical forms of rationality; the phenomenology of life, love, and death; proof of the necessity of Cartesian, Kantian, and Husserlian themes as “elements” or dimensions of all philosophizing; problems of the existence, consciousness, and action of man under the conditions of

socialism and of the Soviet regime; contemporary civilization and the “anthropological catastrophe.”

Mamardashvili graduated from the philosophy department of Moscow University in 1954 and completed his graduate studies there in 1957. He was on the editorial staff of the journals *Voprosy filosofii* [Questions of philosophy] (1957–1961) and *Problemy mira isotsializma* [Problems of the world and of socialism] (1961–1966). He then worked in a number of institutes of the Academy of Sciences (the Institute of the International Workers Movement and the Institute of the History of Natural Science and of Technology); from 1968 to 1974, he was associate editor-in-chief of *Voprosy filosofii*. From 1980 to 1990, he lived in Tbilisi, where he worked in the Institute of Philosophy of the Georgian Academy of Sciences. From 1972, he was a professor of philosophy.

Having been formed in the period of the “thaw” in the 1950s and having by the 1960s become an original thinker, an opponent of socialism and of the political regime existing then in the USSR (although without being an open dissident), Mamardashvili was compelled to expound his ideas not so much in published works that were subject to censorship, as in lecture courses, which attracted hundreds of listeners. In view of his ability to expound the most complex and recondite philosophical ideas in oral form, he was called “the Georgian Socrates.”

Some of Mamardashvili’s lecture courses were given in France, Italy, and other countries: He was fluent in a number of foreign languages. His popularity and his recognition as a talented philosopher grew. But the opposition of the authorities, who persecuted him, also grew. That is why during his life he was able to publish only three books: *Formy i sodержanie myshleniia. K kritike gegelevskogo ucheniia o formakh poznaniia* (*Forms and Content of Thought. Toward a Critique of Hegel’s Doctrine of the Forms of Knowledge*), Moscow, 1968; *Klassicheskii i neklassicheskii idealy ratsional’nosti* (*Classical and Non-classical Ideals of Rationality*), Tbilisi, 1984; *Kaki ia ponimaiu filosofiiu* (*How I Understand Philosophy*), Moscow, 1990; as well as articles in journals and collected works. There is a principal difficulty in assimilating and evaluating Mamardashvili’s philosophical ideas: The tape recordings of his lectures that served as the basis of the works published under his name after his death were edited and modified by the editors and publishers. Because of this, these books are secondary sources whose status is ambiguous: They are integral parts of Mamardashvili’s philosophical heritage, but at the same time a number of specialists view them as inauthentic.

## MAMARDASHVILI’S MAIN SPHERES OF INQUIRY AND HIS PRINCIPAL IDEAS

Mamardashvili dealt in four major spheres in his lifetime. His principal ideas and concepts are outlined below and a general explanation is given for his contribution to philosophy.

I. ANALYSIS OF CONSCIOUSNESS AND OF THE TRANSFORMED FORMS OF CONSCIOUSNESS IN THE WORKS OF KARL MARX. For Mamardashvili, as well as for a number of other influential philosophers of Russia of the Soviet period, reference to Marx became a means of struggle with the dogmas of dialectical and historical materialism, as well as a means of grounding his own ideas. In Mamardashvili’s exposition, the chief of these are: “The Marxian schemata give rise to the elements of a series of theories: to the elements of (1) a theoretical model of the social conditionedness of consciousness; (2) a theory of fetishism and of the symbolics of the social in consciousness; (3) a theory of ideology (the socio-philosophical critique of ideology developed by Marx was subsequently transformed into that which is now called the sociology of knowledge as an academic discipline); (4) a theory of science and of free spiritual production as particular forms of active consciousness; (5) a theory of consciousness as an instrument of man’s personal development and of his responsibility in the sphere of culture and historical activity” (*How I Understand Philosophy*, Moscow, 1990, pp. 299–300). Later Mamardashvili will say that he found his way to phenomenology not through Husserl but through Marx, who revealed “the phenomenological nature of consciousness, its quasi-objective character,” but—in contradiction to the phenomenology of the twentieth century—always disclosed “behind phenomena” their causal origin and “the social system of communion, which the phenomena of consciousness serve” (p. 303).

To this is appended an interpretation of the concept of “the transformed forms of consciousness,” which we already encounter in Marx, but to which Mamardashvili attributes a broader and more profound theoretical significance. According to Mamardashvili, the transformed forms are characterized by the fact that “the form of manifestation acquires an ‘essential’ significance, is particularized, and content is replaced in the phenomenon by another relation, which merges with the property of the material bearer (substrate) of the form itself (for example, in cases of symbolism) and takes the place of the real relations” (“*Forma prevrashchennaia*” [*Transformed Form*] in *Filosofskaia entsiklopediia* [*Philosophical Ency-*

*lopedia*], vol. 5, Moscow, 1970, p. 387). Examples of this are capitalized cost in the system of bourgeois economics (the case of an irrational transformed form); objective appearance: the movement of the sun and planets around the earth; the operation of sign forms of culture; memory and coding units in computers; and the symbolic processing of links of consciousness (according to Freud).

II. EXISTENTIALISM AND FRENCH MARXISM. It was early on that Mamardashvili began his polemic with existentialism and with French Marxism. He personally debated Sartre and Althusser. During the 1950s and 1960s, like these French authors whom he critically analyzed, Mamardashvili based his thought on Marx's conception, but he was also developing an original conception of society and man. At the center of Mamardashvili's positive analysis was a theory of personality and alienation which rejected Sartre's conception of nature, matter, and the material in socio-historical life: "Taking as his point of departure a phenomenological analysis, Sartre can see in the manifestations of social 'matter' (i.e., the fact of the existence in society of forces and relationships which are independent of individuals and their consciousness) only an extra-human and mysterious power, which bewitches people and their relationships and weaves together with them the thread of factual history" (*"Kategoriia sotsial'nogo bytiia i metod ego analiza v ekzistentsializme Sartra"* [*The Category of Social Being and Its Method of Analysis in Sartre's Existentialism*] in *Sovremenyi ekzistentsializm* [*Contemporary Existentialism*], Moscow, 1966, p. 187).

III. COMPARATIVE ANALYSIS OF RATIONALITY. Mamardashvili devoted a number of his works to a comparative analysis of the classical and non-classical types or ideals of rationality. He discerned the specific character of the classical type of rationality in the following features: (1) the concept of the "objective" in the "classical" type was identified with the external (the spatial), while the spatial was identified with the material, which had important philosophical and methodological consequences; (2) "from within the physical theory, which investigates natural phenomena and comes to a certain objective and intelligible picture of the world, we cannot (from within this theory itself) understand those means which we use to construct this picture" (*The Classical and Non-classical Ideals of Rationality*, p. 5). The understanding of the physical world is bought at the cost of a "lack of scientific understanding" of conscious phenomena (although, as living beings, we freely live and orient ourselves in this sphere). Other features include the princi-

ples of classical rationality: "the principle of the continuity of reproducible experience," "the self-identity of the subject" (p. 9); and reliance on the concept of "phenomenon"; de-anthropomorphization. Non-classical rationality arises under the influence of the theory of relativity and quantum mechanics; and in the social and humanitarian disciplines, it arises under the influence of the theory of Marx's ideology, Husserl's phenomenology, and Freud's psychoanalysis. The main principles and procedures of non-classical rationality are: (1) phenomenon instead of appearance, for "I return to the phenomenological level, which prohibits us from discussing something without first bringing to a stop the premises of our objectifying thought ..." (p. 50); (2) the refusal to accept the existence of some "preestablished world with ready-made laws and essences" (p. 64); (3) a complete and comprehensive understanding that consciousness is "one of the inalienable elements of the very object of investigation" (p. 79).

IV. INTERPRETATIONS OF DOCTRINES OF PROMINENT PHILOSOPHERS. The central place in Mamardashvili's philosophy is occupied by a particular interpretation of the doctrines of a number of prominent thinkers and cultural figures of the past (see the posthumous *Kartezianskie razmyshleniia* [Cartesian Meditations]; *Kantianskie variatsii* [Kantian Variations], Moscow, 1997; and *Lektsii o Pruste* [Lectures on Proust], Moscow, 1995). The originality of this interpretation consists in a free transition from an abstractly philosophical analysis of the doctrines of Descartes or Kant to an illumination of the socio-historical content as well as the trans-historical cultural, moral, aesthetic, and personal content contained in these doctrines. As a result, the philosophical consciousness is closely interwoven with the radical problems, contradictions, and crises of civilization, with orientations of the human personality that have meaning for life. This is realized, for example, in the historico-philosophical as well as socio-philosophical figure of the three "K's": "Kartesian" (Descartes), Kant, and Kafka.

In the interpretation of Descartes the central plane is occupied by the theme of *cogito*, which Mamardashvili calls "the phenomenon of all phenomena," as well as by the paths leading to *cogito*. The consciousness of *ego cogito* is interpreted, on the one hand, as a limit abstraction from all that is historically concrete, even from man, a limit abstraction which implies the "permissibility" and even the inevitability of transcendentalism (in the traditions of Descartes, Kant, and Husserl). On the other hand, this "improbable abstraction" is realized, after which it "becomes in a concealed manner the founda-

tion” of our physical knowledge and of the formulation of physical laws, although it is scarcely the case that we are always conscious of the “accomplishment” of the abstraction. Here, the abstraction of the transcendental *ego* acquires social, personal, and moral foundations and consequences. What this means is that thought is free and thus “paths of *coherent* space must be laid for thought, i.e., paths of open discussion (*glasnost*), mutual tolerance, formal legality...” (*Lektsii o Pruste*, p. 115).

The second “K” (Kant) in Mamardashvili’s interpretation indicates the conditions under which man—a finite, mortal being, whose life could have become meaningless in the face of infinity—creates around himself a special world, a world which presupposes choice, evaluations, decisions; in other words, freedom. This is because everyone who is born not only enters the world of nature with its rigid causal connections, but also encounters and in part creates the world of “intelligible” objects. These latter, according to Mamardashvili, are “*images of integralities*,” as if designs and projects of development.

The third “K” is a figurative reference to the “world of Kafka,” i.e., to the penetration into the human world of certain “zombie-situations,” attesting to the “degeneration” or “regressive variant” of the general K-principle: In opposition to *Homo sapiens*, in other words, to “man who knows good and evil,” a “strange man,” an indescribable man, enters the world of civilization. “Ridiculous, absurd, bizarre, dreamlike confusion and something other-worldly”—that is how Mamardashvili describes the actions of Joseph K. in Kafka’s *Trial*, and this also goes for the situation of the absurd in human society. With the accumulation of the potential of the absurd in human history, including contemporary history, the result can be the most dangerous chaos of civilization, a kind of anthropological catastrophe. “Terrifying idols of passion, soil, and blood cover the world, concealing the hidden paths of order; and it is very difficult to tear oneself away from these idols, and to enter onto the radiant paths of thought, order, and harmony” (p. 210).

## MANDEVILLE, BERNARD

(c. 1670–1733)

Bernard Mandeville, a physician and moralist, was probably born in Rotterdam, Holland, where he was baptized on November 20, 1670. His family was a distinguished one, his father, grandfather, and great-grandfather having been noted physicians. The family name was originally de Mandeville, but Mandeville dropped the “de” in later life. He was educated at the Erasmian School in Rotterdam and then attended the University of Leiden, where he studied philosophy and medicine. He was granted the degree of doctor of medicine in 1691. His medical specialty was the treatment of nerve and stomach disorders, or, as he called them, the “hypochondriack and hysterick passions.” Dr. Johnson is said to have had a high regard for a treatise Mandeville wrote on these diseases.

A short time after taking his degree Mandeville visited London to learn English, and liking the country and the people, he chose to settle in England. Little is known about his English life beyond the bare facts that he married, that he had a son and a daughter, that he practiced medicine, and that he apparently had plenty of time for writing. His success as a writer is all the more remarkable when one remembers that English was his adopted language. His best-known work is *The Fable of the Bees*, with its slogan “private vices, public benefits.” It called forth a number of replies from the outraged defenders of virtue, including George Berkeley in the *Alciphron* and Francis Hutcheson. The book was a regular source of public and private controversy in the eighteenth century. The notoriety that this work gained Mandeville doubtless explains why no very consistent account of his situation and character has come down to us from his contemporaries. But Benjamin Franklin, who once met Mandeville, reported

that he was “a most facetious and entertaining companion.” Mandeville died at Hackney in England.

*The Fable of the Bees* was twenty-four years in the making. It began as a poem of 433 lines called “The Grumbling Hive: Or, Knaves Turn’d Honest” (London, 1705). The many bitter attacks on the poem caused Mandeville to produce several expositions, elaborations, and defenses of it, all of which grew, over the years, into the book *The Fable of the Bees; Or Private Vices, Public Benefits*. In its final form, the sixth edition (1729), the *Fable* consists of two parts. Part I is the original poem followed by several essays: (1) “An Enquiry into the Origin of Moral Virtue,” consisting of twenty-two remarks on various lines or words in the poem, such as luxury, pride, and so on; (2) “An Essay on Charity and Charity Schools”; (3) “A Search into the Nature of Society”; and (4) “A Vindication of the Book” against a presentment of the grand jury of Middlesex and other abuse. Part II, which is as long as the first part, consists of six dialogues in which Cleomenes instructs Horatio in the true meaning of the *Fable*.

As might be expected in a book that was put together over a long period and whose later parts are a defense of the earlier, Mandeville’s targets are several, and assessing the relative importance of his ideas is not easy. His economic doctrines are certainly more thoroughly worked out than his moral theories, and he wanted politicians to take his economic views seriously. Given that a politician desires the nation he governs to be great and wealthy and given that there is a large population to be kept in employment, then a certain kind of economic life must be permitted and even fostered. The production of necessities will neither employ very many people nor by itself make a nation great. Therefore, the production of luxuries must be permitted, and their consumption on the most lavish scale possible encouraged, thus simultaneously achieving splendor and full employment. Mandeville analyzes the making of hooped and quilted petticoats in order to show not only the opportunities for labor the manufacture of this luxury provides in itself, but also the subsidiary employments (shipwright, sailor, dye-finder, and so on) that fashion calls into being.

In “An Essay on Charity and Charity Schools” Mandeville gives some hint of the structure of the society that is required to produce a great and wealthy nation. In this essay, he opposes educating the poor on the grounds that knowledge enlarges and multiplies our desires and that the fewer things a person wishes for, the more easily may his necessities be supplied. As Mandeville understood the English economic system of the eighteenth century, it

required a large number of laboring poor, and he feared that education would make them dissatisfied with their lot and would consequently disrupt the system.

But Mandeville goes on to show the mixed feelings that have always troubled the analytical observer of society who is also a decent human being. He tells us that he does not wish to be thought personally cruel, but he believes that proposing to educate the poor is “to be Compassionate to excess, where Reason forbids it, and the general Interest of the Society requires steadiness of Thought and Resolution.” It is, he argues, no harder on the poor to withhold education from them, even though they may have “natural parts and genius” equaling the rich, than it is to withhold money from them as long as they have the same inclinations to spend as the rich have.

Mandeville strongly favored free trade, seeing clearly that in order for one nation to buy another’s goods, it must be able to sell its own. Any restriction in international trade must cause the loss of markets, with a consequent fall in the level of employment at home. In the eighteenth century Mandeville’s writings became the chief source of arguments in favor of the manufacture of luxuries and against restrictions on trade, either within a given nation or between nations. Adam Smith owed much to his knowledge of *The Fable of the Bees*.

Mandeville did not choose, however, to publish these economic doctrines in a straightforward way. Instead, he offered them in his moralizing poem, “The Grumbling Hive.” The bees in the poem have many vices, but their society thrives. Mandeville’s notion of vice is a threefold one. First, he has in mind such character traits as envy, vanity, love of luxury, and fickleness in diet, furniture, and dress. These traits make buyers eager to spend lavishly and consume prodigiously, so that they will soon be ready to spend again. Second, Mandeville calls vice that behavior necessary to profitable trade. The seller must conceal from the prospective buyer both the original cost of his goods and the lowest price at which he is willing to sell, while the buyer must conceal the highest price at which he will buy. Mandeville believes that success will certainly require deceit on the part of both buyer and seller, not to mention sharper practices that may descend to downright fraud. Third, Mandeville counts crime as a vice that provides public benefits. Thieves are valuable on two counts. The threat of them keeps locksmiths in business, and when they do succeed, they soon squander their gains, thus contributing to the circulation of wealth. Mandeville may therefore conclude, “The worst of all the Multitude/Did something for the Common Good.” In this vein he regards even wars and natural disasters as

valuable to the economic system, for by destroying goods, they provide an opportunity for labor to replace them.

Against his claims for the social utility of vice Mandeville sets the following picture of virtue:

It is certain that the fewer Desires a Man has and the less he covets, the more easy he is to himself ... the more he loves Peace and Concord, the more Charity he has for his Neighbor, and the more he shines in real virtue, there is no doubt but that in proportion he is acceptable to God and Man. But let us be Just, what Benefit can these things be of, or what earthly good can they do, to promote the Wealth, the Glory and Worldly Greatness of Nations?

By a divine fiat the bees of the grumbling hive are all made honest, and their society declines into simplicity and insignificance.

Why did Mandeville present his economic doctrines in a poem praising vice, a poem that could only outrage his contemporaries? The most likely supposition is that in the first writing the motives of the moralist are uppermost. If English economic life is seen as it is and as it will be, then encouraging men to be honest and frugal is a disservice to both them and the continuation of the economic system. By praising those sorts of behavior that are ordinarily called vicious, Mandeville hoped to shock the moralist into seeing the world as it is. He gives the moralist the choice either of accepting the world as it is and changing his tune or of rejecting the world and admitting that the virtues the moralist praises require a context quite different from what is ordinarily supposed. What Mandeville takes to be economic truths thus become the basis for a program that is no less than the reform of moralizing.

As *The Fable of the Bees* grew, Mandeville came to offer bits of moral theory, largely because of his discovery of the writings of the Earl of Shaftesbury. He attacked Shaftesbury bitterly. He calls the claim that men may be virtuous without self-denial “a vast Inlet to Hypocrisy.” He says that Shaftesbury’s search for “a real worth and excellence” in things “is not much better than a Wild-Goose-Chace that is but little to be depended on.” Mandeville’s own view is that “our Liking or Disliking of things chiefly depends on Mode and Custom, and the Precept and Example of our Betters and such whom one way or other we think to be Superior to us. In Morals there is no greater certainty.”

The organization of men into a society arises from the multiplicity of each man’s desires and the need to

overcome the great man’s desires and the need to overcome the great natural obstacles that stand in the way of satisfying these desires. In society each man achieves his own ends by laboring for others. Under a government each member of society is rendered subservient to the whole, and all men, by cunning management, are made to act as one. The key to social organization is man’s pride and his consequent delight in flattery. Thus, governors may flatter men into putting public interest before private interest, and men are led to be pleased with themselves for being virtuous. Indeed, this satisfaction is the reward for virtuous actions, and it is ultimately this feeling that makes virtue possible.

These doctrines place Mandeville in the moral-sense school, but his presentation of them is desultory and unsystematic. A successor, such as David Hume, would have been interested to find these views in the *Fable*. But there is something else in Mandeville’s writings that is even more impressive—the large number of vignettes, anecdotes, and sketches that make the reader feel he is learning what people are really like and that must in the end make him a shrewder observer of human nature.

### Bibliography

The premier modern edition of *The Fable of the Bees* is that prepared by F. B. Kaye, 2 vols. (London, 1924). Kaye’s researches have provided us with a balanced account of Mandeville’s life, and his introductory essay on Mandeville’s thought and influence should be consulted.

Mandeville’s other works include *The Virgin Unmask’d: Or, Female Dialogues betwixt an Elderly Maiden Lady, and Her Niece* (London: J. Morphew, 1709); *Free Thoughts on Religion, the Church, and National Happiness* (London: T. Jauncy and J. Roberts, 1720); *A Modest Defence of Publick Stews* (1724); *An Enquiry into the Causes of the Frequent Executions at Tyburn* (London: J. Roberts, 1725); *An Enquiry into the Origin of Honour, and the Usefulness of Christianity in War* (London: J. Brotherton, 1732); and *A Letter to Dion [Berkeley], Occasion’d by His Book Call’d Alciphron* (1732).

*Elmer Sprague (1967)*

## MANI AND MANICHAËISM

Mani, “the apostle of God,” founder of one of the most widely influential religions of the ancient world, was born in southern Babylonia about 216 CE. Little is definitely

known of his birthplace and parentage, since some statements should probably be discounted as malicious reports from his adversaries. He seems to have been of Persian descent and related, at least on his mother's side, to the royal house of Parthia, which was overthrown in 226 by the Sassanid Ardashir I. He is said to have received his first revelation at the age of twelve, but he did not receive his formal call to apostleship until he was twenty-four. His public activity began with a journey to India, where he founded his first community.

Upon the death of Ardashir in 241, Mani returned to Parthia, where he was welcomed by Ardashir's successor Shapur, for whom he wrote a book, the *Shapurakan*. When Shapur died thirty years later, Mani also enjoyed the favor of his successor, but when Bahram came to the throne in 272 the situation changed. Throughout Mani's career the Magian priests had been his most deadly enemies, and they now secured his impeachment and condemnation. He was executed about 276 CE, and his death apparently was followed by persecution of his adherents.

At least seven works have been ascribed to him, including the *Shapurakan*, another work titled "The Living Gospel," and the *Epistula Fundamenti*, which, on the evidence of Augustine, was used by north African Manichaeans as a handbook of doctrine. To these some Western authorities add the *Kephalaia*, which is extant in Coptic. Resources for the study of Manichaeism—once limited to the information supplied by such opponents as Augustine and Titus of Bostra and to excerpts in the works of Theodore bar Konai, in Hegemonius's *Acta Archelai*, and in such Arabic sources as the *Fihrist* of En-Nadim—had in the twentieth century been enriched by discoveries of original Manichaean documents in Turkestan and Egypt. The fragments discovered at Turfan include texts in several Iranian dialects, Turkish, and Chinese, while the Egyptian discovery includes Coptic versions of the *Kephalaia*, a psalmbook, and a collection of homilies.

## THE SYSTEM OF MANI

The chief characteristic of Mani's system is a consistent dualism that rejects any possibility of tracing the origins of good and evil to one and the same source. Evil stands as a completely independent principle against Good, and redemption from the power of Evil is to be achieved by recognizing this dualism and following the appropriate rules of life. The opposition of God and Matter is seen in the realm of nature as the conflict of Light and Darkness, Truth and Error. The present world, and man in particular, presents a mixture of Good and Evil, the result of a

breach of the original limits by the powers of evil. The whole purpose of the founding of the universe was to separate the two principles and restore the original state of affairs, rendering Evil forever harmless and preventing any future repetition of the intermingling.

It is the special task of the Manichaean, the man who has been brought to the light, to collaborate in this separation. Through the God-sent mind that is in him and that sets him apart from the other creatures, he must become aware of the mixture present in all things. He must thus discover the true meaning and significance of the world and conduct himself accordingly, in such a way as to avoid any further contamination of the light and promote its release from its mixture with the darkness. The death of the body is thus redemption; and true life is the release of the soul, which is light, from its imprisonment in the body and its return to its true abode.

The Manichaean myth begins with the two primal principles of Light and Darkness, each dwelling in its own realm, coeternal but independent. Perception of the Light excites envy, greed, and hate in Darkness, and provokes it to attack the Light. In response the Father of Greatness calls forth the Primal Man, who arms himself with five powers and descends to battle with the Darkness. He is defeated, however, and the five powers of Darkness devour a part of his light and thus bring the mixture into being. In some versions this is explained as part of a deliberate plan to satisfy the powers of Darkness temporarily by the cession of a portion of the light and thus to prevent further attack. The captive portion of light, the armor of the Primal Man, is identified with the soul, which thus becomes subject to the affections of Matter.

The Primal Man appeals to the Father of Greatness, who sends the Living Spirit to deliver him. The archons, or powers of Darkness, are now overcome (although they do not lose their power of action), and heaven and earth are made from their carcasses. From the purest part of the Light in the archons the sun and moon are formed, but even so only a small part of the Light has been delivered. A fresh appeal from the powers of Light leads the Father of Greatness to send a Third Messenger, whose appearance inspires the Darkness to produce Adam and Eve in the image of his glorious form and to enclose in them the Light still at its disposal. The creation of Eve has a special purpose, in that she is more subservient to the demons and serves as their instrument for the seduction of Adam. Procreation serves the ends of Darkness, since each birth means a further dispersal of the Light, another subject for the realm of Darkness, and a prolonging of the captivity of the Light. The powers of Light accordingly send Jesus

on a mission of revelation to Adam, who is still innocent but subsequently disobeys, is seduced by Eve, and so sets the chain of reproduction in motion. This protracts the drama of salvation, and with it the mission of Jesus, into the history of humankind. In one age the revelation comes to India through the Buddha, in another to Persia through Zoroaster, in a third to the West through the historical Jesus, and in the last age it comes through Mani himself, the apostle of the true God.

### MANICHAEAN ETHICS

The cosmogonic myth provides the basis and substructure for the Manichaean ethics and hope of redemption. The ethics are rigorously ascetic: Since procreation only prolongs the reign of the powers of darkness, marriage must be rejected. The Manichaean must abstain from all "ensouled" things and eat only vegetables, so as to avoid, as far as possible, any injury to the Light. The full rigor of Manichaean ethics is reserved for the Elect, and the mass of adherents, the Hearers or Soldiers, are allowed to live under less rigorous rules. Correspondingly there is a difference in their destiny after death: The Elect pass at once to the Paradise of Light, but the Soldiers must return to the world and its terrors until their light is freed and they attain to the assembly of the Elect. The third class of men, the sinners who are outside the Manichaean religion, are doomed to remain in the power of Evil.

### MANICHAEAN GNOSTICISM

It is clear that Manichaeism may be regarded as a form of Gnosticism. Indeed, it has been called "the most monumental single embodiment of the gnostic religious principle, for whose doctrinal and mythological representation the elements of older religions were consciously employed" (Hans Jonas, *The Gnostic Religion*, pp. 207f.). It differs, however, from such older forms of Gnosticism as Valentinianism in that here the dualism is from the beginning an integral part of the myth, and not the result of a development in the myth. In Jonas's words, "the tragedy of the deity is forced upon it from outside, with Darkness having the first initiative," whereas in the other type of Gnosticism, Darkness is the product of the divine passion, not its cause. Any attempt to identify the sources upon which Mani drew for the construction of his system is, however, fraught with difficulty, and it would be dangerous to try to establish any genetic relationship. For example, attempts have been made, on the basis of the statement that his father belonged to a Baptist sect, the *Mugtasila*, to forge a link with Mandaism; but although Mandaean elements have been found in the Manichaean

psalmbook, the identity of the *Mugtasila* with the Mandaeans, or of either with some still older Jewish or Jewish-Christian Baptist movement, is still a matter of debate.

Another possible link is with the Zervanite heresy in Zoroastrianism, but here again caution is necessary. (On this whole subject, see Carsten Colpe, *Die Religion in Geschichte und Gegenwart*, Sec. 5.) In a general way, it may be said that Mani incorporated Christian, Buddhist, and Zoroastrian elements into his religion, but Manichaeism seems to have adapted itself to the dominant religion of a particular area. Moreover, it has been held that he had little more than a hearsay knowledge of Christianity, although he had some acquaintance with the heresies of Bardesanes and of Marcion. It appears that he intended to found not merely a sect but a new religion that could embody the best of the older faiths, fusing elements from Buddhism, Christianity, and Zoroastrianism with his own teaching.

His success is evident from the fact that Manichaeism survived so long and for a time was a serious rival to Christianity. After Mani's death it spread through Syria into the West and spread eastward deep into central Asia. Centuries later Manichaean ideas were current among the Bogomiles in the Balkans (see Dmitri Obolensky, *The Bogomils*) and among the Albigenses and Cathari in Provence (see Steven Runciman, *The Mediaeval Manichee*). There may be debate as to the historical connection of these later movements with the original Manichaeism, but some influence appears beyond dispute. Nor should it be forgotten that Augustine himself was for a time an adherent of Manichaeism. A religion that could arouse the interest of such later thinkers as Pierre Bayle, David Hume, and Voltaire must be regarded as one of profound significance for the history of thought.

## MANNHEIM, KARL (1893–1947)

Karl Mannheim, the German sociologist, was born in Budapest and died in London. He studied at Berlin and Paris, and at Heidelberg under Max Weber, and later taught at Heidelberg, Frankfurt am Main, and, after 1933, in London.

Mannheim's thought resembles that of such philosophers as Auguste Comte and G. W. F. Hegel, who believed that in the past man had been dominated by the historical process whereas in the future he would gain ascen-

dancy over it. Mannheim was deeply influenced by Karl Marx, but he deviated from Marxism in asserting that a better society might be achieved by nonrevolutionary means and also in de-emphasizing the interpretation of the development of society as being semiautomatic and stressing the importance of conscious political effort. He was, in addition, decisively influenced by German historicism and Anglo-Saxon pragmatism. From the former he took the belief that history is the *ens realissimum*, while from the latter he derived his criterion of truth. Both positions pointed toward a radical relativism, which, however, he strove to overcome.

In his first and most important book, *Ideologie und Utopie*, Mannheim asserted that the act of cognition must not be regarded as the effort of a purely theoretical consciousness, because the human consciousness is permeated by nontheoretical elements arising both from man's participation in social life and in the streams and tendencies of willing which work themselves out contemporaneously in that life. The influence of these active factors is all-important; even the categorial structure of the intellect does not escape it. Mannheim therefore maintained that epistemology (as practiced, for instance, by Immanuel Kant) was outdated, and must be superseded by a new discipline, the sociology of knowledge.

According to Mannheim, this new discipline revealed that all knowledge (at any rate, knowledge of things human) was situation-bound (*situationsgebunden*)—that is, tied to a given constellation of sociohistorical circumstances. Each age develops its own style of thought, and comparisons between these styles are impossible, since each posits a different basic (or, so to speak, relatively absolute) sphere. Even within each age there are conflicting tendencies toward conservation, on the one hand, and toward change on the other. Commitment to conservation tends to produce “ideologies”—to falsify thought by excessive idealization of the past and overemphasis on the factors making for stability. Intentness on change is apt to produce “utopias,” which overvalue both the future and factors leading to change.

Between ideology and utopia there is at least the possibility of completely realistic (*situationsgerecht*) thought that functions without friction within the given framework of life, and is set neither on pushing forward nor on holding back the development of society. But Mannheim places little emphasis on this possibility. He sees a very strong tendency toward the polarization of society into hostile camps. Only the comparatively uncommitted intelligentsia is likely to approach nearer the truth. From its special and particularly favorable vantage point, it

could, and should, elaborate a “total perspective” that would synthesize the conflicting contemporary world views and thereby neutralize, and to some extent overcome, their one-sidedness. Such a “dynamic synthesis” is the nearest possible approximation to a truly realistic attitude, within the limitations imposed upon a given epoch.

This estimate of human thought might seem to justify accusing Mannheim of skepticism, but Mannheim held himself innocent of the charge. To rebut it, he developed his doctrine of “relationism,” which he opposed to skeptical relativism. Relationism, he argued, does not impugn the validity of an insight: It merely draws attention to the fact that the insight is dependent upon, and confined within, a specific sociohistorical situation. But this argument merely shifts the relativity, and does not remove it. Mannheim held that every sociohistorical situation is located at a specific point along a unilinear, ever-progressing and never-returning temporal continuum—history. Each situation is therefore unique, and the knowledge to which it gives birth, and which is true within it, is equally unique, bound to its time and place, and relative.

But Mannheim was not primarily concerned with the truth of propositions. Rather, he operated with a radically different conception of “truth.” To him, truth is an attribute, not so much of discourse, as of reality. The individual who is in contact with the living forces of his age has the truth, or better, is in the truth—a conception that shows at once Mannheim’s Marxism, his historicism, and his pragmatism. He was moving close to the belief that the traditional *adaequatio rei et intellectus* (correspondence of thought and reality) should be replaced by a new test, the *adaequatio intellectus et situs* (correspondence of thought and situation). He was interested in the genuineness, rather than in the truth (properly so called), of a given world view.

Mannheim was a confirmed progressivist, and he tended to prefer whatever was, at any time, emergent. After his immigration to England in 1933, he adopted a more practical and political orientation. He argued dialectically, especially in *Mensch und Gesellschaft im Zeitalter des Umbaus* (1935), that a completely unregulated society, such as he thought liberalism had created, was apt to produce its own opposite, totalitarian dictatorship. To secure the values of democracy, it was necessary to avoid the weaknesses of both liberalism and totalitarianism. As a viable synthesis, Mannheim advocated “planning for freedom,” a social system that would ensure economic stability by regulating the more objective aspects of life, such as production, but at the same time

grant freedom to men’s subjective strivings (for example, in matters of taste), thereby releasing cultural creativity. In this context, Mannheim became interested in education as the prime means of radical democratization. Toward the end of his career, he began to feel that a modernized Christianity held out some hope for a new integration of society’s value system, which had become splintered and self-contradictory.

## MANSEL, HENRY LONGUEVILLE (1820–1871)

Henry Longueville Mansel, an English philosopher and divine, was educated at Merchant Taylors' School, London, and St. John's College, Oxford. He became tutor in his college, the first Waynefleete professor of moral and metaphysical philosophy at Oxford University in 1859, Regius professor of ecclesiastical history there in 1866, and dean of St. Paul's in 1868.

Mansel was at Oxford during the period when, after more than a century of slumbers, it was again beginning to take philosophy seriously. But whereas his Oxford contemporaries, such as Benjamin Jowett and T. H. Green, looked to Germany for their philosophy, Mansel looked to France and Scotland.

Indebted to various thinkers, especially to William Hamilton and Victor Cousin, Mansel was remarkably successful in assimilating their influences. When—as on

the question of the perception of an external world—he occupied common ground with Hamilton, Mansel's version was marked by a superior clarity and relevance. Likewise, he more than did justice to what was genuinely original and valuable in Cousin's critique of John Locke's doctrine of judgment, making it the foundation of a subtle and thorough discussion of the relation of thinking to experience begun in the *Prolegomena Logica* and completed in the article "Metaphysics, or the Philosophy of Consciousness."

The point at issue was the relation of meaning to verification. Can we know a proposition to be true or false without first understanding the meaning of the terms involved, in the sense of being able to define each of them separately? Mansel dealt with this difficulty by making a sharp distinction between a *logical judgment*, in which the understanding of the terms precedes the judgment as to the truth or falsity of the proposition, and a *psychological judgment*, in regard to which this sharp distinction cannot be drawn, and in regard to which the understanding of the terms coincides with the judgment as to the truth of the proposition.

Mansel's main point was that the former sort of judgment must always, in the last analysis, rest upon the latter, of which the Cartesian *cogito* is the prime example. In this way the kind of clear-cut empirical knowledge with which science deals rests on the foundation of an essentially vague metaphysical knowledge embodied in the *cogito*. This doctrine, which descended through Cousin from Thomas Reid, was worked out by Mansel in the course of an excellent discussion of the problem of universals and particulars, contained in the article "Metaphysics." What nominalistic atomists had forgotten was that the individual thing is initially given in an essentially vague experience (for example, three objects seen in the far distance and just recognizably human) that withholds the details and reveals only general characteristics.

While this topic of the relation of thinking to experience was central in Mansel's work, he was equally stimulating on other questions. Somewhat in the French style, he held that the will, in the form of attention, forms an integral part of cognition. Following a suggestion of Dugald Stewart's, he tried to illuminate the difference between the presence and the absence of efforts of will by an interesting phenomenology of daydreaming and semi-consciousness. Again influenced by Reid, Mansel was aware—as few were in his time—of the complexities and difficulties of the problem of our knowledge of the existence of other minds, discussing it, appropriately enough, in connection with the moral judgment. Finally, Mansel

dealt interestingly with the distinction between philosophy and science. Philosophy deals with what he called facts of consciousness, whose distinctive feature is that their *esse* is *percipi*, in the sense in which René Descartes had said that, so far as philosophy is concerned, there is no difference between seeing something and thinking one sees it.

The result of this careful phenomenological analysis (the word *phenomenology* had been introduced by Mansel's masters, Hamilton and Cousin) was that Mansel saw human experience as inherently complex and mysterious. In the background of Mansel's philosophy there was always an explicit contrast with a rival kind of reductive analysis that regarded man as being as unmysterious in his inner workings as a pocket watch. This contrast was the key to the controversies aroused by Mansel's Bampton lectures, "The Limits of Religious Thought," delivered in 1858. Mansel held that reason tells us that if evil exists, then God cannot be both perfectly good and all-powerful. However, God's omnipotence and perfect goodness must be accepted as a matter of faith. Although God is perfectly good, we cannot know the nature of his goodness. Man's finite goodness cannot explain God's infinite goodness; they are the same by analogy, not identity.

Mansel's lectures were attacked by F. D. Maurice and Goldwin Smith, and by John Stuart Mill, who devoted Chapter 7 of his *Examination of Sir William Hamilton's Philosophy* to Mansel's views. Mill wrote, "I will call no being good, who is not what I mean when I apply that epithet to my fellow creatures, and if such a being can sentence me to hell for not so calling him, to hell I will go." Mansel replied in *The Philosophy of the Conditioned*, and Mill in turn replied in numerous footnotes in later editions of the *Examination*, listing Mansel first among his critics. For Mansel man's goodness was not clear and God's goodness was inscrutable; both were equally a mystery.

Mansel's *Letters, Lectures, and Reviews*, published posthumously, contains, among other things, interesting articles on the philosophy of language and on mathematical logic.

## MANY-VALUED LOGICS

An orthodox assumption in logic is that (declarative) sentences have exactly one of two values, true (1) and false (0). Many-valued logics are logics where sentences may have more than two values. Aristotle (*De Interpretatione*, chapter 9) was perhaps the first logician to countenance the thought that some sentences (future contingents) may be neither true nor false; Aristotle's ideas were discussed by many logicians in the Middle Ages. However, contemporary work on many-valued logics commenced with the work of the Polish logician Jan Łukasiewicz early in the twentieth century. One hundred years later there are many well-known many-valued logics, and the properties of such logics are well established. The logics have important philosophical applications (e.g., in articulating the views that some sentences are neither true nor false, or both true and false, or that truth comes by degrees). They also have important technical applications (e.g., in establishing various independence results).

In what follows,  $p, q, \dots$  will be used for propositional parameters (variables);  $A, B, \dots$  for arbitrary sentences; and  $\Sigma, \Delta, \dots$  for sets of sentences. For references, see the last section of this entry.

### ŁUKASIEWICZ LOGICS

To illustrate the notion of a formal many-valued logic, consider classical propositional logic with the following

connectives:  $\wedge$  (conjunction),  $\vee$  (disjunction),  $\neg$  (negation), and  $\rightarrow$  (conditional). This may be formulated as follows. The set of semantic values,  $Val$ , is  $\{0, 1\}$ . The set of designated values,  $Des$ , is  $\{1\}$ . An evaluation,  $v$ , assigns every propositional parameter (pp), a member of  $Val$ . All formulas are then assigned such values recursively by the clauses:

$$\begin{aligned} v(\neg A) &= 1 - v(A) \\ v(A \wedge B) &= \text{Min}(v(A), v(B)) \\ v(A \vee B) &= \text{Max}(v(A), v(B)) \\ v(A \rightarrow B) &= 1 \quad \text{if } v(A) \leq v(B) \\ &= 1 - (v(A) - v(B)) \text{ otherwise} \end{aligned}$$

( $\text{Max}(x, y)$  is the maximum of  $x$  and  $y$ ;  $\text{Min}(x, y)$  is the minimum of  $x$  and  $y$ .  $v(A \rightarrow B)$  takes the maximum value minus any amount one has to drop to get from  $A$  to  $B$ .) The inference from  $\Sigma$  to  $A$  is valid ( $\Sigma \models A$ ) just if there is no evaluation that makes all the premises designated but not the conclusion (i.e., there is no  $v$  such that for all  $B \in \Sigma, v(B) \in Des$ , but  $v(A) \notin Des$ ).

If everything is exactly the same, except that  $Val = \{0, \frac{1}{2}, 1\}$ , one has the three-valued Łukasiewicz logic  $\mathbb{L}_3$ . The semantic conditions for the connectives can be depicted in the form of tables, thus:

$\rightarrow$	1	1/2	0
1	1	1/2	0
1/2	1	1	1/2
0	1	1	1

	$\neg$
1	0
1/2	1/2
0	1

$\vee$	1	1/2	0
1	1	1	1
1/2	1	1/2	1/2
0	1	1/2	0

$\wedge$	1	1/2	0
1	1	1/2	0
1/2	1/2	1/2	0
0	0	0	0

More generally, if  $n > 1$  and everything is the same, except that  $Val = \{i/(n-1) : 0 \leq i \leq n-1\}$ , one has the Łukasiewicz  $n$ -valued logic  $\mathbb{L}_n$ . Finally, if everything is the same, except that  $Val = [0, 1]$  (the set of all real numbers between 0 and 1, inclusive), one has the Łukasiewicz continuum-valued logic  $\mathbb{L}_\mathbb{R}$ . (The relationship between these logics is that  $\mathbb{L}_n$  is a [proper] sublogic of  $\mathbb{L}_m$  if and only if

[iff]  $m$  divides  $n$ ; and  $\mathbb{L}_\mathbb{R}$  is a [proper] sublogic of all the  $\mathbb{L}_n$ . The logic in which  $Val$  is the set of rationals between 0 and 1 turns out to be equivalent to  $\mathbb{L}_\mathbb{R}$ .)

**BOTH/NEITHER LOGICS**

The values of a many-valued logic need not be numbers (and the designated values do not need to be a singleton). In another well-known family of logics,  $Val = \{1, b, n, 0\}$ . (1 can be thought of as *true and only true*; 0 as *false and only false*;  $b$  as *both true and false*; and  $n$  as *neither true nor false*.)  $Des = \{1, b\}$ . One can order these values as follows:

If  $v$  is an evaluation of the pps into  $Val$ , it is extended to all formulas by the following conditions:

$$\begin{aligned} v(A \vee B) &= \text{Lub} \{v(A), v(B)\} \\ v(A \wedge B) &= \text{Glb} \{v(A), v(B)\} \end{aligned}$$

( $\text{Lub } X$  is the least element of the lattice greater than or equal to every member of  $X$ .  $\text{Glb } X$  is the greatest element of the lattice less than or equal to every member of  $X$ .) The conditions for negation can be represented as follows:

	$\neg$
1	0
$b$	$b$
$n$	$n$
0	1

$A \rightarrow B$  can be defined as  $\neg A \vee B$ . Note that all these conditions agree with classical logic when the values are just 0 and 1.

These semantics give the logic often called First Degree Entailment (FDE). If one ignores the value  $n$ , one gets the three-valued logic LP. If one ignores the value  $b$ , one gets the strong Kleene three-valued logic,  $K_3$ . FDE and  $K_3$  have no logical truths; LP (and  $\mathbb{L}_3$ ) does. LP and FDE are paraconsistent (i.e., the inference  $A, \neg A \vdash B$  is not valid);  $K_3$  is not. FDE is a sublogic of both logics, but neither is a sublogic of the other (and all three are sublogics

of classical logic). The weak Kleene three-valued logic,  $B_3$ , is the same as  $K_3$ , except that any truth function with an  $n$  as an input gives  $n$  as an output.

For the first-order versions of all the logics in this section and the last, the quantifiers  $\forall$  and  $\exists$  can be thought of as the infinitary generalizations of  $\wedge$  and  $\vee$ , in the usual way. Thus, if  $Dom$ , is the domain of quantification, and every  $d \in Dom$ , has a name,  $c_d$ , (and if not just add them):

$$v(\forall xA(x)) = Glb\{v(A(c_d)) : d \in Dom\}$$

$$v(\exists xA(x)) = Lub\{v(A(c_d)) : d \in Dom\}$$

where the bounds are with respect to the appropriate orderings.

### GENERAL DEFINITION

In general terms, in a semantics for a formal many-valued propositional logic, there is an arbitrary set of semantic values,  $Val$ . (If the cardinality of  $Val$  is  $n$ , the logic is called  $n$ -valued; if it is finite, the logic is called finitely many-valued; if it is infinite, the logic is called infinitely many-valued.)  $Des$ , the set of designated values, is an arbitrary subset of  $Val$ . Each  $n$ -ary connective in the language,  $\#$ , is assigned an  $n$ -place (total) function,  $f_\#$ , with inputs and outputs in  $Val$ . An evaluation of the language,  $v$ , assigns each pp a member of  $Val$ . Semantic values are assigned to all sentences recursively by the equations  $v(\#(A_1, \dots, A_n)) = f_\#(v(A_1), \dots, v(A_n))$ . An inference is valid if there is no evaluation that makes all the premises designated and the conclusion undesignated. (Slightly more general definitions are also possible here.)

For quantifiers, a domain of quantification,  $Dom$ , and denotation function,  $\delta$ , are added. For every constant  $c$ ,  $\delta(c) \in Dom$ ; if  $P$  is an  $n$ -place predicate,  $\delta(P)$  is a (total)  $n$ -place function with inputs and outputs in  $Dom$ .  $v(Pc_1, \dots, c_n) = \delta(P)(\delta(c_1), \dots, \delta(c_n))$ . Each quantifier,  $Q$ , is assigned a (total) function,  $f_Q$ , with inputs that are subsets of  $Val$  and outputs in  $Val$ . Assuming that each object in the domain has a name:  $v(QxA(x)) = f_Q(\{v(A(c_d)) : d \in Dom\})$ .

It is not difficult to check that any many-valued logic is a Tarski consequence relation. That is, it satisfies the following properties. (Here,  $\Sigma, \Delta$  means  $\Sigma \cup \Delta$ ; and set braces for singletons are omitted.)

If  $A \in \Sigma$ ,  $\Sigma = A$

If  $\Sigma = A$  and  $\Sigma \subseteq \Delta$ , then  $\Delta = A$

If  $\Sigma = A$  and  $\Delta, A = B$ , then  $\Sigma, \Delta = B$ .

If  $\Sigma = A$ , then any uniform substitution is valid.

(A uniform substitution is obtained by replacing each occurrence of any pp with the same formula.)

In many cases, the set of values ( $Val$ ), together with the operations on it (the  $f_\#$ s), is a special case of an algebra of a certain kind. In classical logic, these are Boolean algebras; in the case of FDE, these are De Morgan algebras; and in the case of  $\mathbb{L}_\kappa$ , these are MV algebras. Another notion of validity can be obtained by appealing to all the algebras of a kind. At this point, many-valued logic slides into algebraic logic.

### PROOF PROCEDURES

All finitely many-valued logics are decidable (and *a fortiori* axiomatizable, though not necessarily finitely axiomatizable). A uniform algorithm is a generalization of truth tables (often there are more efficient ones). Consider all the possible assignments of values to the relevant pps. In each case, compute the values of the premises and the conclusion, and see if there is any assignment in which all the premises are designated and the conclusion is not.

A simple axiom system for  $\mathbb{L}_3$  is as follows:

$$A \rightarrow (B \rightarrow A)$$

$$(A \rightarrow B) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C))$$

$$(\neg A \rightarrow \neg B) \rightarrow (B \rightarrow A)$$

$$((A \rightarrow \neg A) \rightarrow A) \rightarrow A$$

The only rule of inference is *modus ponens* ( $A, A \rightarrow B \vdash B$ );  $A \vee B$  is defined as  $(A \rightarrow B) \rightarrow B$ ; and  $A \wedge B$  is defined as  $\neg(\neg A \vee \neg B)$ . In each  $\mathbb{L}_n$  a family of  $J$ -functions can be defined, where  $v(J_i A) = 1$  if  $v(A) = i$ , and  $v(J_i A) = 0$  otherwise ( $i$ , here, being any value of the logic). These can be exploited to give a uniform procedure for producing an axiom system for each  $\mathbb{L}_n$ . Similar techniques work for other finitely many-valued logics in which analogues of the  $J$ -functions can be defined. (Much technical effort has gone into investigating which functions can be defined in various many-valued systems.) An axiom system for  $\mathbb{L}_\kappa$  is obtained by replacing the last axiom cited earlier with:

$$((A \rightarrow B) \rightarrow B) \rightarrow ((B \rightarrow A) \rightarrow A)$$

If the designated values are changed to  $[r, 1]$  (closed at the left end) or  $(r, 1]$  (open at the left end), for some rational number,  $r$ , the systems are also axiomatizable. If  $r$  is an irrational number, they may not be.

Appropriate tableau and natural deduction systems for many-valued logics can often be found. For example, here is a tableau system for FDE. Lines of the tableau are of the form  $A: +$  or  $A: -$ . (Intuitively,  $+$  means “is designated” and  $-$  means “is not designated”.) To test the inference  $A_1, \dots, A_n \vdash B$ , start with lines of the form  $A_1: +, \dots, A_n: +, B: -$ . The rules are as follows ( $\pm$  can be disambiguated uniformly either way):

$$\begin{array}{ccc}
 \alpha \wedge \beta: + & \alpha \wedge \beta: - & \neg(\alpha \wedge \beta): \pm \\
 \downarrow & \swarrow \searrow & \downarrow \\
 \alpha: + & \alpha: - \quad \beta: - & \neg\alpha \vee \neg\beta: \pm \\
 \beta: + & & \\
 \\
 \alpha \vee \beta: - & \alpha \vee \beta: + & \neg(\alpha \vee \beta): \pm \\
 \downarrow & \swarrow \searrow & \downarrow \\
 \alpha: - & \alpha: + \quad \beta: + & \neg\alpha \wedge \neg\beta: \pm \\
 \beta: - & & \\
 \\
 & \neg\neg\alpha: \pm & \\
 & \downarrow & \\
 & \alpha: \pm & 
 \end{array}$$

A branch closes if it contains lines of the form  $A: +$  and  $A: -$ . Adding closure whenever there are lines of the form  $A: +$  and  $\neg A: +$ , gives  $K_3$ . Adding closure whenever there are lines of the form  $A: -$  and  $\neg A: -$ , gives LP. (Adding both gives classical logic.) The first-order versions of all the finitely many-valued logics already mentioned also have sound and complete proof procedures. However, first-order  $\mathbb{L}_\kappa$  is not axiomatizable. By contrast, the logics that are the same as  $\mathbb{L}_\kappa$ , except that for some rational number,  $r < 1$ ,  $Des = (r, 1]$  (open at the left end) or  $[r, 1]$  (closed at the left end) are axiomatizable.

## MANY-VALUED AND OTHER LOGICS

A number of important logics, notably intuitionist logic, standard modal, and relevant logics, are demonstrably not finitely many-valued. Specifically, suppose that a logic validates the inferences  $\vdash A \rightarrow A$  and  $A \vdash A \vee B$ . Then for any  $a, b \in Val$ ,  $f_\rightarrow(a, a) \in Des$ , and if  $a \in Des$ ,  $f_\vee(a, b) \in Des$ . Now suppose that the logic is  $n$ -valued, and that  $p_0, \dots, p_n$  are distinct pps. Let  $A$  be the disjunction of all formulas of the form  $p_i \rightarrow p_j$  (for  $0 \leq i \neq j \leq n$ ). Consider any evaluation. For some  $i$  and  $j$ ,  $p_i$  and  $p_j$  must have the same value; hence,  $p_i \rightarrow p_j$ , and so  $A$ , are designated. Hence,  $A$  is a logical truth. The logics just cited can be shown to have no logical truths of this form (where  $\rightarrow$  is the intuitionist, strict, and relevant conditional, respectively).

However, nearly all logics have an infinitely many-valued semantics of a rather unilluminating kind. Consider the set of logical truths of any logic closed under uniform substitution. Let  $Val$  be the set of formulas of the language;  $Des = \{A : \vdash A\}$ ;  $f_\#(A_1, \dots, A_n) = \#(A_1, \dots, A_n)$ . Then  $\vdash A$  iff  $\# = A$ .

[Proof: Suppose that  $A$  is a logical truth. Consider any interpretation,  $v$ . It is easy to check that  $v(A)$  is  $A$  with every pp,  $p$ , replaced by  $v(p)$ . Since the logic is closed under uniform substitution  $v(A)$  is a logical truth; that is, it is designated. Conversely, suppose that  $A$  is not a logical truth. Consider the interpretation,  $v$ , which maps every pp to itself. It is easy to check that  $v(A) = A$ , which is not designated.]

The construction can be extended to show that any Tarski consequence relation with finite sets of premises has a many-valued semantics iff it satisfies one condition. This is called uniformity, and is, loosely speaking, to the effect that pps not involved in an inference are irrelevant to it. Specifically, if  $\Gamma, \Delta = A$ , then  $\Gamma = A$ , provided that:

- 1.)  $\Delta$  is nontrivial (that is, for some  $B$ ,  $\Delta \neq B$ )
- 2.) No formula in  $\Delta$  contains a pp that occurs in a formula in  $\Gamma \cup \{A\}$

It should be noted that not all logics are uniform. In Ingebrigt Johansson’s minimal logic,  $\emptyset \cup \{p, \neg p\} = \neg q$ , but  $\{p, \neg p\}$  is nontrivial, and  $\emptyset \neq \neg q$ .

The finiteness constraint can be dropped if the notion of uniformity is strengthened in an appropriate fashion. (Some interesting differences between single-conclusion inference and multiple-conclusion inference emerge in this case.)

## PHILOSOPHICAL APPLICATIONS

Many-valued logics have been claimed to have numerous philosophical applications. Like all interesting philosophical matters, these applications are debatable.

Łukasiewicz interpreted Aristotle’s argument in *De Interpretatione* (chapter 9) as showing that, though true statements about the past and present are now necessarily true, contingent statements about the future (such as “There will be a sea battle tomorrow”) currently have an indeterminate truth status. He suggested deploying  $\mathbb{L}_3$  in an analysis of this situation, reading the truth values  $\{1, \frac{1}{2}, 0\}$  as necessarily true, indeterminate, and necessarily false, respectively. As one would expect  $A \vee \neg A$  is not logically valid in  $\mathbb{L}_3$ .

Łukasiewicz suggested adding an operator to the language,  $\Box$ , representing necessity, whose truth conditions may be represented as follows:

	$\Box$
1	1
1/2	0
0	0

Its dual, possibility,  $\Diamond$ , that is,  $\neg\Box\neg$ , is as follows:

	$\Diamond$
1	1
1/2	1
0	0

This makes the inference  $A \vdash \Box A$  valid—which is reasonable enough on the Aristotelian picture. However, it also makes the inference  $\Diamond A, \Diamond B \vdash \Diamond(A \wedge B)$  valid—which it is not, even for Aristotle. (Just let  $B$  be  $\neg A$ .) As has already been seen, normal modal logics are not finitely many-valued.

Future contingents are just one example of sentences that have been suggested as being neither true nor false (truth value gaps). Others include: sentences with reference failure (“The king of France is bald,” “3 = 1/0”), category mistakes and other “nonsense” (“This stone is thinking of Vienna”), paradoxical sentences of self-reference (“This sentence is false”), sentences attributing a vague property in a borderline case (“This is a child”—said of someone around puberty), and sentences unverifiable by the appropriate mathematical or scientific procedure (“There are ten consecutive ‘7’s in the decimal expansion of  $\pi$ ,” “This electron has a velocity of exactly 100 m/sec”).

It is often claimed that  $K_3$  (or, sometimes,  $B_3$ ) is the appropriate logic for such cases: Gappy sentences take the value  $n$ . (In the last case, quantum logic and intuitionist logic have also been suggested to handle the matter.) In these logics  $A \vee \neg A$  is not a logical truth, but neither is anything else. In particular, then,  $A \wedge \neg A$  is not a logical falsity. Even if “The king of France is bald” is neither true nor false, “The king of France is bald and not bald” would seem to be logically false.

One way around this problem is to deploy the method of supervaluations. If  $v$  is any  $K_3$  evaluation, let  $\mu$  be a supervaluation of  $v$  ( $v \preceq \mu$ ) iff:

$$\mu(p) \text{ is never } n, \text{ and if } v(p) \neq n, v(p) = \mu(p)$$

An important feature of this logic, not shared by  $L_3$ , is that if  $v(A)$  is 1 or 0, and  $v \preceq \mu$ , then  $\mu(A)$  has the same value.

Now define the supertruth-value,  $v_s$  of a sentence under  $v$  as follows:

$$\begin{aligned} v_s(A) &= 1 \text{ if for all } \mu \text{ such that } v \preceq \mu, \mu(A) = 1 \\ &= 0 \text{ if for all } \mu \text{ such that } v \preceq \mu, \mu(A) = 0 \\ &= n \text{ otherwise} \end{aligned}$$

Define an inference as supervaluation valid if it preserves supertruth-value 1. The inferences that are supervaluation-valid now turn out to be exactly those that are classically valid.

[Proof: If an inference is not classically valid, let  $v$  be an evaluation that makes the premises true and the conclusion false. But  $v$  is a  $K_3$  evaluation and  $v \preceq v$ . Hence the inference is not supervaluation-valid. Conversely, suppose that an inference is not supervaluation valid. Then there is a  $K_3$  valuation,  $v$ , such that every supervaluation of  $v$  gives all the premises the value 1, but not the conclusion. Hence, there is some supervaluation that gives all the premises value 1, but the conclusion value 0. This is a classical evaluation. Hence, the argument is classically invalid.]

On the other side of the street, it has been suggested that some sentences are both true and false (truth-value gluts). These include: paradoxical sentences of self-reference (“This sentence is false”), statements describing instantaneous transition states (“He is in the room”—said at the instant he is symmetrically poised between being in and out), statements of rights and obligations (“She is legally required to do such and such”—when the requirements are based on inconsistent legislation), and sentences attributing a vague property in a borderline case (“This is a child”—said of someone around puberty).

It is sometimes suggested that LP—or FDE if one wants to also take in the possibility of truth value gaps—is the appropriate logic for such cases. The glutty sentences take the value  $b$ . (Other paraconsistent logics have also been suggested for the job.) In these logics  $A \wedge \neg A$  may take a designated value. In LP the negation of this is also a logical truth.

A way to regain classical logic with LP is by the use of subvaluations. Subvaluations and subvaluation validity are defined in the way dual to supervaluation (*b* replacing *n*, and *some* replacing *all*). In the case of subvaluations, one has the equivalence between classical validity and subvaluation validity only in the one-premise case. (But the duality between the two cases is exact. In a classical multiple-conclusion logic  $A \vee B \vdash \neg A, B$  is valid. It is not supervaluation-valid. The equivalence between classical and supervaluational validity holds only because in a single-conclusion inference, one is, in effect, disjoining all the conclusions. In the subvaluation case, this corresponds to conjoining all the premises, which reduces matters to the single premise case.) The technique of super/subvaluations can be generalized to FDE, where there are both gaps and gluts.

A weakness of both LP and FDE is that they do not have a detachable conditional, since  $A, A \rightarrow B \neq B$ . They can be augmented with such a conditional, though. Thus, the many-valued logic  $RM_3$  augments LP with a detachable conditional,  $\Rightarrow$ , whose truth conditions can be represented as follows:

$\Rightarrow$	1	<i>b</i>	0
1	1	0	0
<i>b</i>	1	<i>b</i>	0
0	1	1	1

In the context of information processing, truth value gaps are often interpreted as incomplete information, and truth-value gluts as inconsistent information. While in the context of gaps and gluts, a word should be said about set theory. It is well known that the naive comprehension schema

$$x \in \{y: A(y)\} \leftrightarrow A(x)$$

leads to contradiction (and so triviality)—in the shape of paradoxes such as Russell’s—when the underlying logic is classical. It has often been suggested that the principle might be consistent (or at least inconsistent but nontrivial) when the underlying logic is many-valued. Problems for such suggestions arise because the principle generates triviality if the logic contains contraction  $((A \rightarrow (A \rightarrow B)) \rightarrow (A \rightarrow B))$  and *modus ponens*. Let  $A(y)$  be  $y \in y \rightarrow B$ . Call the set that this defines *c*. Comprehension quickly gives:  $c \in c \leftrightarrow (c \in c \rightarrow B)$ . Contraction and *modus ponens* then give *B*. (This is Curry’s paradox.)  $RM_3, K_3, B_3,$

and  $L_n$  (for finite *n*) all contain *modus ponens* and, if not contraction, something closely related to it that will do the same job. However, the schema based on  $L_\infty$  is consistent. If the extensionality principle  $(\forall x(x \in y \leftrightarrow x \in z)) \rightarrow y = z$  is added, though, then even  $L_\infty$  gives triviality. (Virtually the same comments can be made about the naive *T*-schema (“*A*” is true  $\leftrightarrow A$ ) when self-reference is present. Though here extensionality is, of course, not an issue.)

For a final example of the philosophical application of many-valued logics: It is often claimed that the appropriate semantics for a language with vague predicates is one with degrees of truth. Such logics now usually go under the rubric of fuzzy logics.  $L_\infty$  is a paradigm one such. (It is not the only one:  $L_\infty$  is one of a family of logics in which  $Val = [0, 1]$ . Each is based on a so-called *t*-norm—essentially a function stating the truth conditions for an appropriate conjunction connective.) The only logical inference that the simplest form of the Sorites paradox uses is *modus ponens*. This is valid in  $L_\infty$ ; but if one changes *Des* to, say,  $[0.8, 1]$ , it is not. (Let  $v(p) = 0.9 \in Des$ ,  $v(q) = 0.7 \notin Des$ . Then  $v(p \rightarrow q) = 0.8 \in Des$ .) Note that probability theory is not a many-valued logic. The probability of a compound sentence is not determined by the probabilities of its components. (Let *a* and *b* be independent fair coins. Let  $A_H$  be “Coin *a* will come down heads”;  $A_T$  be “Coin *a* will come down tails”; and  $B_H$  be “Coin *b* will come down heads.”  $Prob(A_H) = Prob(A_T) = Prob(B_H) = 0.5$ . But  $Prob(A_H \wedge A_T) = 0$  and  $Prob(A_H \wedge B_H) = 0.25$ .)

### TECHNICAL APPLICATIONS

Many-valued logics have various technical applications. Perhaps the most important of these, in a philosophical context, is their use in proving independence results. Thus, suppose that one has some axiom system, *T*, and wishes to know whether some formula, *A*, is deducible in it. One way to show that it is not is to construct a many-valued logic such that all the axioms of *T* always take a designated value, and all the rules of *T* preserved designated values. It follows that all theorems always take designated values. If one can find an interpretation of the logic in which *A* does not take a designated value, it follows that it cannot be proved.

For example, the following is a set of axioms for the  $\rightarrow/\neg$  fragment of the relevant logic often called RW (R minus contraction). The only rule of inference is *modus ponens*:

$$\begin{aligned}
 & A \rightarrow A \\
 & (A \rightarrow B) \rightarrow ((B \rightarrow C) \rightarrow (A \rightarrow C)) \\
 & A \rightarrow ((A \rightarrow B) \rightarrow B)
 \end{aligned}$$

$$\neg\neg A \rightarrow A$$

$$(A \rightarrow \neg B) \rightarrow (B \rightarrow \neg A)$$

Now consider the three-valued Łukasiewicz logic,  $\mathbb{L}_3$ . One can check (e.g., by truth tables) that all the axioms always take the designated value and that *modus ponens* preserves that property. Now let  $C$  be the formula:  $(p \rightarrow (p \rightarrow q)) \rightarrow (p \rightarrow q)$ . Take an evaluation,  $v$ , in which  $v(p) = \frac{1}{2}$  and  $v(q) = 0$ . Computation verifies that  $v(C) = \frac{1}{2}$ . Hence  $C$  is not provable. Since  $v(\neg C) = \frac{1}{2}$  as well,  $\neg C$  cannot be proved either. Hence,  $C$  is independent of RW.

A much more technically demanding example of the use of many-valued logics to prove independence is in set theory. If one takes the values of the logic to be those of any Boolean algebra, taking the top value as the only designated value, and interprets the connectives and quantifiers in appropriate ways, the logic delivered is classical logic. Choosing the Boolean algebra in an appropriately set-theoretic way, one can also show that the axioms (and so theorems) of Zermelo Fraenkel set theory, ZF, take the designated value. Choosing the algebra in more cunning fashions, one can show that various important set-theoretic principles, such as the continuum hypothesis, do not receive designated values. Hence, ZF does not entail the continuum hypothesis.

## HISTORY, PERSONS, AND REFERENCES

This entry concludes by putting the investigations discussed earlier in their historical context. Relevant references that may be consulted for further details are also given at the end of each paragraph. For a gentle introduction to many-valued logics, see Graham Priest (2001, chapters 7, 8, 11); for a more detailed introduction, see Alasdair Urquhart (2001); and for further detailed technical discussions, see Richard Hähnle (2001). J. Michael Dunn and George Epstein (1977) provide a bibliography of work on many-valued logics up to 1974.

The first modern many-valued logic was  $\mathbb{L}_3$ . This, and its generalization to  $n$ -valued logics,  $\mathbb{L}_n$ , were published by Łukasiewicz around 1920. At about the same time, the U.S. mathematician Emil Post was also constructing finitely many-valued logics. (The most significant feature of Post's systems is its treatment of negation. If the values of the  $n$ -valued logic are  $0, 1, \dots, n-1$ , then  $v(\neg A) = |1 + v(A)| \pmod{n}$ . Philosophical applications of this many-valued logic are difficult to find.) The logic  $\mathbb{L}_\aleph$  was published by Łukasiewicz and Alfred Tarski in 1930. Much of the early investigation of many-valued logics and their axiomatizations were carried out by Polish logicians including Mordechai Wajsberg and Jerzy

Słupecki. Finding a demonstrably complete axiom system for  $\mathbb{L}_\aleph$  turned out to be a hard problem. Reputedly, it was solved by Wajsberg, but the first proofs to be published were by Alan Rose and Berkeley Rosser and by Chen Chung Chang in the late 1950s. The unaxiomatizability of first-order  $\mathbb{L}_\aleph$  was proved by Bruno Scarpellini in 1962. (Łukasiewicz 1970, Rosser and Turquette 1952, Wójcicki 1988, Malinowski 1993.)

Canonical statements of the other many-valued logics mentioned in this entry were given by the following:  $B_3$ , Dmitriy Anatol'evich Bochvar, 1939;  $K_3$ , Stephen Kleene, 1952; FDE and  $RM_3$ , Alan Ross Anderson and Nuel Belnap, 1975; LP, Graham Priest, 1979. (Rescher 1969, Priest 2001.)

The proof that intuitionist logic is not many-valued was first given by Kurt Gödel in 1933. The idea was applied to modal logic by James Dugunji in 1940. The earliest versions of the idea that every logic has a many-valued semantics are usually attributed to Adolf Lindenbaum in the 1920s. Generalizations are due to Jerzy Łos and Roman Suszko in 1958. (Hughes and Cresswell 1968, Shoesmith and Smiley 1978, Wójcicki 1988.)

The applicability of many-valued logics to the view that some sentences are neither true nor false was pursued by many people in the second half of the twentieth century. These include Richard Routley, Leonard Goddard, Saul Kripke, Kit Fine, and Scott Soames. Supervaluations were invented by van Fraassen in 1969. Toward the end of the twentieth century, their application to vagueness became a very standard idea. The application of many-valued logics to the view that some sentences are both true and false, though less popular, has been pursued by various paraconsistent logicians. These include Newton da Costa, Priest, Routley, and Dominic Hyde. The generalization of supervaluation to logics with gluts as well as gaps was developed by Achille Varzi in the 1990s. (Rescher 1969, Scott 1974, Haack 1978, Dunn and Epstein 1977, Humberstone 1998, Varzi 2000, Priest 2001.)

The possibility of basing the naive comprehension schema for sets on  $\mathbb{L}_\aleph$  was investigated by Thoralf Skolem and Chang in the 1950s. The consistency of the schema (and the inconsistency of extensionality) was proved by Richard White in 1979. (White 1979.)

Fuzzy logics and their applicability to vagueness have been investigated fairly intensely since about the 1970s, by many people, including Kenton Machina and Patrick Grim, and, on the technical side, Lotfi Zadeh, Petr Hájek,

and Daniele Mundici. (Keefe 2000, Hájek 1998, Cignoli, D'Ottaviano, and Mundici 2000.)

The use of many-valued logics in independence investigations goes back to the early years of the subject, though this has flourished with the proliferation of non-classical logics in the second half of the twentieth century. One of the earliest techniques for proving independence results in set theory is that of forcing, developed by Paul Cohen in the early 1960s. That similar things could be done with Boolean-valued models was realized by Robert Solovay, Dana Scott, and others a few years later. (Anderson and Belnap 1975, Bell 1985.)

## MANY WORLDS/MANY MINDS INTERPRETATION OF QUANTUM MECHANICS

The many worlds/many minds formulations of quantum mechanics are reconstructions of Hugh Everett III's (1957a, 1957b, 1973) relative-state formulation of quantum mechanics. Each is presented as a proposal for solving the quantum measurement problem. Much of the philosophical interest in these theories derives from the metaphysical commitments they suggest. They illustrate the roles played by traditional metaphysical distinctions both in formulating and in evaluating physical theories. They also illustrate the range of metaphysical options one must consider if one wants a metaphysics that is consistent with the structure of the physical world suggested by the best physical theories.

The quantum measurement problem is a consequence of the orthodox quantum-mechanical representation of physical properties. In order to account for interference effects, the orthodox view requires that one allows for a physical system to be in a *superposition* of having mutually incompatible classical physical properties. An electron  $e$  might, for example, be in a superposition of being in New York City and being in Los Angeles. If the unit-length vector  $(NYC)_e$  represents the electron

being in New York City and if the orthogonal unit-length vector  $(LA)_e$  represents the electron being in Los Angeles, then the state of the electron in a superposition of being in each city is represented by

$$(S)_e = a(NYC)_e + b(LA)_e,$$

where  $a$  and  $b$  are complex numbers, such that  $a$ -squared plus  $b$ -squared equals one. On the orthodox view, the state represented by the unit-length vector  $(S)_e$  is not a state where the electron is determinately in NYC, it is not a state where the electron is determinately in LA, it is not a state where the electron is determinately in both cities, and it is not a state where the electron is determinately in neither city. Rather, on the standard interpretation of states, an electron in state  $(S)_e$  simply fails to have a determinate position.

While allowing for superpositions of classical properties explains the counterintuitive empirical results of interference experiments, it leaves a puzzle: If electrons are sometimes in such superpositions of position, then why do electrons have determinate positions whenever one looks for them? In its most general form the quantum measurement problem is to explain why physical systems exhibit quantum interference effects, which typically involves talk of superpositions, and to explain why people—when they look for them—always observe physical systems to have determinate physical properties.

## LINEAR DYNAMICS AND COLLAPSE DYNAMICS

The standard von Neumann-Dirac collapse formulation of quantum mechanics (1955 [1932]) explains interference effects and definite measurement results by stipulating two dynamical laws. The *linear dynamics* describes the deterministic continuous evolution of the state of a physical system when no measurement of the system is made. It is this law that describes the evolution of physical systems in superpositions of classical properties and thus explains quantum interference effects. The *collapse dynamics* describes the random discontinuous evolution of the state when a measurement is made of the physical system. It is this law that explains how one gets determinate measurement records at the end of an observation and makes the standard statistical predictions. More specifically, in the case of the electron in state  $(S)_e$ , if an observer  $M$  looks for the electron in NYC, the collapse dynamics predicts that the state will instantaneously and randomly evolve from

$$(\text{Ready})_m (a(NYC)_e + b(LA)_e),$$

a state where  $M$  is ready to look for  $e$  and  $e$  is in state  $(S)_e$ , to either (“In NYC”) $_m$   $(NYC)_e$  (with probability  $(a^2)$ , in which case  $e$  is now determinately in NYC and  $M$  determinately records this fact, or to (“Not in NYC”) $_m$   $(LA)_e$  (with probability  $(b^2)$ , in which case  $e$  is now determinately in LA and  $M$  determinately records that it is not found in NYC.

In order to understand the work done by the collapse dynamics in the standard theory, consider what would happen without the collapse of the quantum-mechanical state. In the measurement above, the linear dynamics predicts that the postmeasurement state of the observer who correlate their records perfectly with the position of the electron, written in the determinate record basis, is

$$(E) = a(\text{“In NYC”})_m (NYC)_e + b(\text{“Not in NYC”})_m (LA)_e.$$

On the standard interpretation of states,  $M$  here has no determinate measurement record. Rather, without the collapse dynamics,  $M$  ends up in an entangled superposition of finding and not finding the electron. This is presumably not what happens.

So, in the standard theory, the collapse dynamics is both responsible for the theory making the standard quantum statistical predictions and for the explanation of determinate measurement results. But because the physical state that results from applying the collapse dynamics to a system is typically different from the state that results from applying only the linear dynamics, the standard formulation of quantum mechanics is at best incomplete and arguably logically inconsistent on a strict reading—unless one can stipulate strictly disjoint conditions for when each dynamical law obtains. In the context of the standard collapse theory, solving the measurement problem would require one to stipulate exactly what interactions count as measurements and hence cause collapses.

Rather than stipulating when collapses occur, Everett’s proposal for solving the quantum measurement problem involved denying that there are collapses. More specifically, Everett proposed simply dropping the collapse dynamics from the standard von Neumann-Dirac theory of quantum mechanics and taking the resulting pure wave mechanics as a complete and accurate description of all physical systems. Everett then intended to deduce the standard statistical predictions of quantum mechanics—the predictions that are explained by the collapse dynamics in the standard formulation of quantum mechanics—as subjective experiences of observers who are themselves treated as ordinary physical systems within the new theory. Dropping the collapse dynamics clearly eliminates potential conflict between the two

dynamical laws; but if one drops the collapse dynamics, one must then explain how we obtain determinate measurement results that exhibit the standard quantum statistics when the linear dynamics alone typically predict entangled postmeasurement superpositions such as  $(E)_e$ .

## RECONSTRUCTING EVERETT'S THEORY

While it is clear that Everett intended for his relative-state formulation of quantum mechanics to explain why one gets determinate measurement results, it is unclear how this was supposed to work. There are several alternative reconstructions of Everett's theory in the literature, all designed to provide quantum mechanics without the collapse dynamics with determinate measurement records while somehow recovering the standard quantum statistics. The many worlds and the many minds formulations of quantum mechanics represent two general approaches to reconstructing Everett's relative-state formulation of quantum mechanics.

The splitting worlds formulation is perhaps the most popular version of the many worlds formulation. The splitting world formulation of quantum mechanics

asserts that it makes sense to talk about a state vector for the whole universe. This state vector never collapses and hence reality as a whole is rigorously deterministic. This reality, which is described *jointly* by the dynamical variables and the state vector, is not the reality we customarily think of, but is a reality composed of many worlds. By virtue of the temporal development of the dynamical variables the state vector decomposes naturally into orthogonal vectors, reflecting a continual splitting of the universe into a multitude of mutually unobservable but equally real worlds, in each of which every good measurement has yielded a definite result and in most of which the familiar statistical quantum laws hold. (DeWitt and Graham 1973, p. v)

Proponents of this view admit that the metaphysical commitments it suggests are counterintuitive: "I still recall vividly the shock I experienced on first encountering this multiworld concept. The idea of  $10^{100}$  slightly imperfect copies of oneself all constantly spitting into further copies, which ultimately become unrecognizable, is not easy to reconcile with common sense. Here is schizophrenia with a vengeance" (DeWitt and Graham 1973, p. 161).

But it is precisely these counterintuitive commitments that explain why observers end up recording determinate measurement results. On the splitting worlds formulation the universe splits whenever one makes a measurement in such a way that every physical possible result in fact determinately occurs in some future world. More specially, there is one world corresponding to each term in the expression of the quantum mechanical state when written in the theory's preferred basis. In choosing the preferred basis, one chooses a single preferred way from among the many different, mathematically equivalent, ways of representing quantum-mechanical states as the sum of mutually orthogonal unit-length vectors. On the splitting worlds formulation, the preferred basis is chosen so that each term in the expansion of the state describes a world where there is a determinate measurement record. The state  $(E)$  above describes two worlds: One where the observer  $M$  determinately records the measurement result "In NYC" and  $e$  is in fact in NYC and another where  $M$  determinately records "Not in NYC" and  $e$  is in fact in LA.

**PROBLEMS WITH THE SPLITTING WORLDS FORMULATION.** While the splitting worlds formulation of quantum mechanics does explain why there are determinate measurement records, it encounters other problems. A standard complaint is that the theory is ontologically extravagant. We presumably only ever need one physical world, our world, to explain our experiences. The reason for postulating the actual existence of a different physical world corresponding to each term in the quantum-mechanical state is that it allows one to explain our determinate experiences while taking the deterministically evolving quantum-mechanical state to be in some sense a complete and accurate description of the physical facts. But again one might wonder whether the sort of completeness one gets warrants the many-world ontology.

Another problem with the splitting worlds formulation concerns the statistical predictions of future events. The standard collapse formulation of quantum mechanics predicts that  $M$  will get the result "In NYC" with probability  $a$ -squared and the result "Not in NYC" with probability  $b$ -squared in the above experiment, and this is what is observed as relative frequencies for such experiments. Insofar as there will be two copies of  $M$  in the future,  $M$  is guaranteed to get each of the two possible measurement results. So, in this sense at least, the probability of  $M$  getting the result "In NYC" is one, which is simply not what is observed if both  $a$  and  $b$  are nonzero. A principle of indifference might lead one to assign a probability of one-half to each of the two possible meas-

urement outcomes. But not only would such a principle be difficult to justify here, probability one-half for each possible outcome is typically not what would be observed for such experiments as relative frequencies. So while the splitting worlds formulation explains why observers get determinate measurement records, as it stands, it makes no empirical predictions for the likelihood of future events.

In order to understand what one would have to add to the theory to get the standard quantum statistical predictions for future events, one might note that the question “What is the probability that *M* will record the result ‘In NYC?’” is, strictly speaking, nonsense—unless one has an account of the transtemporal identity of the observer *M*. Because there is no rule that states which worlds are which at different times, the splitting worlds theory is prevented from making statistical predictions concerning an observer’s future experiences. And not being able to account for the standard quantum probabilities is a serious problem because it was the successful statistical predictions of quantum mechanics that made quantum mechanics worth taking seriously in the first place.

Another problem for the splitting worlds formulation of quantum mechanics concerns the way worlds are supposed to split. In order to explain the determinate measurement records, one must choose a preferred basis so that observers have determinate measurement records in each term of the quantum-mechanical state when written in the preferred basis. The problem is that not just any basis will make records determinate in every world (consider, for example, a basis that includes the vector (E) above). Selecting the preferred basis to use determines when worlds split, and determining when worlds split is as difficult as trying to determine when the collapse occurs in the standard formulation of quantum mechanics. This is the preferred basis problem. This problem is closely analogous to the original measurement problem in the context of the standard collapse formulation of quantum mechanics.

A popular strategy for resolving the preferred basis problem is to try to find a criterion involving the interaction between a quantum-mechanical system and its environment that would dynamically select a preferred basis for a system. As a simple example of an environmental decoherence criterion, one might take the preferred basis of a system to be the one that represents the classical property of the system to which its environment becomes most strongly correlated, whatever this may be. Insofar as a measurement record is easily read, one might argue, the environment becomes strongly with the value of the

record, so such a criterion would be expected select the determinate-record basis as preferred. One problem with having the environment of a system select the preferred basis, however, is that, in the case of the splitting worlds formulation at least, one presumably needs a preferred basis for the entire universe, which does have an environment.

**THE MANY MINDS FORMULATION.** David Albert and Barry Loewer’s many minds formulation of quantum mechanics (1988) provides another approach for interpreting Everett’s relative-state formulation of quantum mechanics. Everett said that his theory “is objectively continuous and causal, while subjectively discontinuous and probabilistic” (1973, p. 9). The many minds formulation of quantum mechanics captures this feature by distinguishing between an observer’s *physical state* and its evolution, which is continuous and causal, and an observer’s *mental state* and its evolution, which is discontinuous and probabilistic. This is a sort of hidden-variable theory, where the variable being added to the standard quantum-mechanical state is the mental states of observers. Stipulating determinate mental states solves the quantum measurement problem by directly providing observers with determinate, accessible measurement records.

In order to get the observer’s complete mental state to supervene on her or his physical state, Albert and Loewer associate with each observer a continuous infinity of minds. The standard quantum-mechanical state always evolves in the usual deterministic linear way, but each mind evolves randomly, with probabilities determined by the particular mind’s current mental state and the evolution of the quantum-mechanical state. In the experiment above, Albert and Loewer’s mental dynamics predicts that the probability of each of the observer’s minds becoming randomly associated with the result “In NYC” (the first term of (E)) is *a*-squared and that the probability of each becoming randomly associated with the result “Not in NYC” (the second term of (E)) is *b*-squared.

An advantage of the many minds formulation over the splitting worlds formulation is that here there is no physically preferred basis. One must choose a preferred basis in order to specify the mental dynamics completely, but this choice has nothing to do with any physical facts. Rather, it can be thought of as part of the description of the relationship between physical and mental states. Another advantage of the many minds formulation is that, unlike the splitting worlds formulation, it makes the standard probabilistic predictions for the future measurement results of each mind. Because the states of particu-

lar minds do not supervene on the physical state here, in order to talk about their states and how they evolve, one must suppose that individual minds have transtemporal identities, which in turn requires a commitment to a strong form of mind-body dualism. But it is also this strong dualism that makes the many minds theory one of the few formulations of quantum mechanics that resolves the quantum measurement problem and is manifestly compatible with special relativity.

One might wonder whether the sort of mental supervenience one gets in the many minds formulation (it is not the states of an observer's individual minds, but only the complete distribution of the states of all of these minds that can be taken to supervene on her or his physical state) is worth the trouble of postulating a continuous infinity of minds associated with each observer. Another option is to suppose that each observer has a single mind that evolves in the Albert and Loewer random way. But here one sacrifices all but the weakest sort of supervenience of mental states on physical states. Here the physical state would only tell one the probabilities of various mental states obtaining.

If one wants to avoid the mind-body dualism involved in the many minds formulation, one can use the evolution of minds to construct an alternative many worlds formulation. On one such theory, the many threads formulation of quantum mechanics, worlds do not split. Rather, one stipulates that there is one world corresponding to each possible trajectory of a single Albert-Loewer mind and that the history of that world is described by the history of the world that would be observed by the mind. Each observer then inhabits exactly one of these worlds, and the global quantum-mechanical state is used to assign prior epistemic probabilities to each physically possible world in fact being a given observer's world. These prior probabilities, concerning which possible world is an observer's actual world, might then be updated as she learns more about the history of her world. In the simplest case, she eliminates from contention all possible worlds that are incompatible with a particular observed event. Unlike the splitting worlds formulation, there is no special problem in understanding probabilities of future events on this account. A particular event is either going to happen or not in our world. The standard quantum probabilities here simply represent our posterior uncertainty concerning which world we in fact inhabit (Barrett 1999).

## MARCEL, GABRIEL

(1889–1973)

Gabriel Marcel, the French philosopher, dramatist, and critic, was born in Paris. His father, a highly cultured man, held important administrative posts in the Bibliothèque Nationale and the Musées Nationaux. Marcel's mother died when he was four. Raised in a home dominated by the cultured agnosticism of his father and the liberal, moralistic Protestantism of his aunt, and nurtured in a scholastic system concerned only with intellectual achievement, he later sought refuge in a modified type of idealism. The shaking experiences of World War I, during which he was an official of the Red Cross concerned with locating missing soldiers, brought home to him the failure of abstract philosophy to cope with the

tragic character of human existence. His conversion to Catholicism in 1929 did not substantially alter the direction of his thought, although it intensified his conviction that the philosopher must take into consideration the logic interior to faith and hope.

### RELATIONSHIP TO EXISTENTIALISM

Marcel's name has most often been linked with "theistic existentialism." Because of the ambiguities of this term and the association of existentialism in the popular mind with Jean-Paul Sartre's philosophy, to which his is almost diametrically opposed, Marcel has preferred the designation "Neo-Socratic" for his thought. This should not obscure Marcel's contributions to existential philosophy or his similarity to other thinkers who are ordinarily associated with it.

Before publication of the major philosophical works of Karl Jaspers and Martin Heidegger, Marcel introduced into French philosophy, in his essay "Existence and Objectivity" (1925) and in his *Metaphysical Journal*, many of the themes that later became central to existentialism. Often making use of an independently developed phenomenological method, he dealt with such themes as participation, incarnation, man as being in the world, and the priority of existence over abstraction (the *cogito*) as a starting point for philosophy.

Marcel's critique of idealism and his defense of faith resemble Søren Kierkegaard's critique of G. W. F. Hegel; Marcel, however, refuses to allow that faith is an irrational leap or that the individual stands alone in his faith. Heidegger and Marcel explore much of the same terrain in seeking to restore the "ontological weight to human experience" (*Being and Having*, p. 103). They share a common view of the nature of truth and language. Marcel, however, unlike Heidegger, includes within his ontology the assurance of fulfillment that is part of faith's apprehension of God as Absolute Presence. In many ways Martin Buber has been Marcel's closest contemporary philosophical relative. Each has independently developed a philosophy of dialogue and communion in which the distinction between the relation of an I to a thou and an I to an it or a him plays a central part.

### PHILOSOPHICAL METHOD

A great injustice is necessarily done in any summary account of Marcel's thought, for the charm and the convincing power of his conclusions are inseparable from his itinerant, tentative, and exploratory philosophical method. One of the most characteristic features of his thinking is the vigor with which he combated the spirit of

abstraction and the conceptual sclerosis that he believes is an occupational hazard of systematic and academic philosophers. But despite his rejection of systematic philosophy, Marcel's work is based on an underlying principle of unity, or more accurately an underlying vision, which, seen dimly from the beginning, has been progressively more clearly apprehended. This vision, which is essentially both Platonic and Christian, expresses itself in the conviction that within the temporal and transient order *homo viator* is given a foretaste of eternal realities.

Marcel's philosophical explorations cannot be divorced from his dramatic writings or from his experimentation in music. His plays are not philosophical in the sense of being popular forums for the presentation of worked-out ideas. Rather, they present complicated situations in which persons find themselves trapped, challenged, and confused; and thus indirectly they explore the nature of the exile into which the soul enters as it becomes alienated from itself, from those it loves, and from God. Marcel believes that in music one finds a foretaste or presentiment of the perfect harmony and communion toward which all authentic human existence strives. Philosophy shares both in the tension that is the essence of drama and in the harmony which is the essence of music. Its starting point is a metaphysical "dis-ease" like that of a person in a fever who shifts around searching for a comfortable position. This search for a home in the wilderness, a harmony in disharmony, a transcendent source of assurance in a transient life takes place through a reflective process that Marcel calls secondary reflection.

### THE NATURE OF THINKING

Marcel distinguishes two degrees or types of thinking, primary and secondary reflection. Primary reflection is characterized as abstract, analytical, objective, universal, and verifiable. The thinking subject in primary reflection is not the individual human person but the thinker qua mind (the *Bewusstsein überhaupt*). Primary reflection deals with the realm of the problematic. As the etymology of "problem" (*pro-ballo*) suggests, the distinguishing feature of the problematic approach to reality is the separation of the questioner from the data about which he questions. The data of primary reflection lie in the public domain and are equally available to any qualified observer. Once a problem is posed, primary reflection proceeds to abstract from the concrete data any elements that are not relevant to the solution of the particular problem under consideration. When a solution or an explanation has been found, the original curiosity and tension that motivated the thinker are alleviated.

Primary reflection, as exemplified in scientific and technical thought, has allowed us to possess and manipulate our world more completely and is therefore indispensable to human culture. However, intellectual and moral confusion results when primary reflection becomes imperialistic and claims the right to judge all knowledge and truth by criteria appropriate only to the realm of the objective and the problematic. When this happens, abstraction gives way to “the spirit of abstraction,” the use of techniques gives way to technocracy, and the inexhaustible riches of a kaleidoscopic world are forced to conform to a black-and-white logic.

Secondary reflection is concrete, individual, heuristic, and open. Strictly speaking, it is concerned not with objects but with presences. Its contemplation begins not with curiosity or doubt but with wonder and astonishment. Hence, it is humble in its willingness to be conformed to categories created by that on which it is focused. It remains open to its object as a lover does to his beloved—not as a specimen of a class but as a unique being. This openness is not a methodological principle as in scientific thought but arises from the possibility of something new being created in the relationship. Secondary reflection is dialogical, not dialectical. Rather than searching for information about the other and dealing with it abstractly, secondary reflection seeks the revelation of total presence, whether the presence be that of my body, the world, the other person, or God. Thus, secondary reflection is brought to bear on data or questions from which the thinker as existing person cannot legitimately abstract himself: “Am I free?” “Is there meaning and value in life?” “Can I commit myself to this person?” In other words, secondary reflection is concerned not with problems but with mystery.

## MYSTERY

According to Marcel, a mystery initially appears to be merely a problem that is difficult to solve. Reflection shows, however, that in dealing with a genuine mystery the distinction between subject and object, between what is in me and what is before me, breaks down. Faced with questions about freedom, the meaning of life, the existence of God, and so forth, no objective standpoint can be found from which a universally valid answer may be discovered. This does not mean that mystery is unknown or unknowable and lies in a realm of vague feelings over which thought has no grasp. Rather, knowledge of mystery presupposes an immediate participation, or what Marcel also calls a “blinded intuition,” but this participation is understood only with the aid of a conceptual

process. Unaided intuition is not an adequate philosophical instrument. However, secondary reflection penetrates into the mystery of existence and being only when it works in conjunction with love, fidelity, faith, and the other “concrete approaches.” It yields a kind of knowledge and truth that, if unverifiable, nevertheless is confirmed as it illuminates our lives. Two foci of mystery may be distinguished, although never separated, in Marcel’s thinking. The mystery of existence is dealt with in “concrete” philosophy and the mystery of being in “concrete” ontology.

## CONCRETE PHILOSOPHY

Marcel denies that the detached, disincarnate, Cartesian *cogito* provides a possible starting point for a concrete philosophy. It is with the existing subject, the incarnate being who is already in the world, that philosophy must begin. The experience of the inexhaustible concreteness of the existing world can be neither deduced, doubted, nor demonstrated. Existence is not a thing, a quality, or a discrete content of thought that can be isolated and pointed out; rather it is that in which the subject participates and from which thought begins its quest for meaning. The assurance of existence that we have is not of the intellectual order but is an outcome of our direct participation in the world via sensation and feeling. Because sensation and feeling are inseparable from the body, our knowledge of existence is tied up with our being incarnate.

Incarnation is the “central given of metaphysics,” the absolute starting point for an existential philosophy, because it is on the analogy of my experience of my body that the world is understood. I project into the world the sense of density and presence that I experience when I become aware of my own body. The world exists for me only in the measure that I am related to it in a way similar to the way in which I am related to my own body.

As I am not even ideally separable from my body, I am likewise inseparable from my situation. Those habitual surroundings and historical conditions that shape my life enter into the very fiber of what I am. Insofar as I recognize that my situation enters into the constitution of my being, and hence that I am not able to abstract myself from it completely and view it with the objective detachment of a spectator, I may speak of the family that nurtured me or of an illness that shaped me as having a mysterious character.

A concrete philosophy must also affirm the immediacy of our being with others. The principle of the intentionality of consciousness, Marcel holds, applies in our

relations both to persons and to the world. Philosophy begins not with *I am* but with *we are*.

The significance of this intersubjectivity will be determined by the type of relations that characterize one's life. The self who treats other persons as objects to be manipulated and used is condemned because of its egocentricity to live in a world lacking in ontological depth, and hence it will be prey to despair when the thrill of possession wears thin. To endeavor to allow the other person to become present as a thou is to enter into a relationship within which the assurance of fulfillment is received.

## ONTOLOGY

No word used by Marcel is more difficult to define or richer in meaning than *being*. It refers neither to the sum total of all objects that exist nor to some universal substratum underlying all particulars. Being is eternal and inexhaustible. It is "that which does not allow itself to be dissolved by the dialectics of experience" (*Metaphysical Journal*, p. 181). Only by participation in being can isolation, despair, and tragedy be overcome. The quest for being is thus identical with the quest for salvation. To deny being is to say that "all is vanity," that nothing has intrinsic worth. To affirm being is to declare that corresponding to the deepest exigency of the human spirit is a fulfillment of which an earnest is given in experiences of creativity, joy, and love.

As defined by Marcel, the question of being cannot be approached objectively and problematically. Being can be affirmed only if I can discover within experience some presence that testifies to being. Two elements in human experience seem to offer such a testimony. First, at the heart of the human condition is an "ontological exigence," an impulse to transcendence that is present in all authentic human life, the exigence to penetrate to a level of experience saturated with meaning and value. The mere existence of such an exigence is no guarantee in itself that a corresponding satisfaction exists. It could be the case, as Sartre says, that man is a "useless passion." But Marcel attempted to show, by way of a phenomenological analysis, that certain experiences of love, joy, hope, and faith, as understood from *within*, present a positive testimony to the existence of an inexhaustible presence. This assuring presence, which might be called the immanence of being in human experience, is never a possession but is constantly created anew as an I enters into relations with an empirical thou or the Absolute Thou (God). Although the assurance of being never becomes conceptually clear,

it provides the illumination making creative, open existence possible.

In what might be called Marcel's ontological personalism, the concrete approaches to being are identical with the approaches to other persons and to God. To enter into a loving relationship requires that a person exorcise the spirit of egocentricity and possession and become spiritually available (*disponible*) to others. A vow of creative fidelity is likewise necessary if the unconditional demands of love are to be satisfied. In approaching God, fidelity becomes faith and *disponibilité* becomes hope. In love, fidelity, hope, and faith man approaches the mystery of being and is overtaken with the assurance that he is accompanied by the eternal fulfilling Presence that he seeks to know.

## Bibliography

### WORKS BY MARCEL

A thorough and updated bibliography of works by Marcel, translations of his works, and works about Marcel is maintained by the Gabriel Marcel Society at <http://www.lemoyne.edu/gms>.

### Philosophical Works

- Journal métaphysique*. Paris: Gallimard, 1927. Translated by Bernard Wall as *Metaphysical Journal*. Chicago: Regnery, 1952.
- Être et avoir*. Paris: Aubier, 1935. Translated by Katharine Farrer as *Being and Having*. London: Dacre Press, 1949.
- Du refus à l'invocation*. Paris: Gallimard, 1940. Translated by Robert Rosthal as *Creative Fidelity*. New York: Noonday Press, 1964.
- Homo Viator*. Paris: Aubier, 1945. Translated by Emma Craufurd. New York, 1962.
- The Philosophy of Existence*. Translated by Manya Harari. New York: Philosophical Library, 1949. Republished as *Philosophy of Existentialism*. New York: Citadel Press, 1961. Previously uncollected essays written between 1933 and 1946. Perhaps the best short introduction to Marcel's thought.
- Le mystère de l'être*. 2 vols. Paris: Aubier, 1951. Translated by G. S. Fraser and René Hauge as *The Mystery of Being*. 2 vols. Chicago, 1950.
- Les hommes contre l'humain*. Paris: La Colombe, 1951. Translated by G. S. Fraser as *Men against Humanity*. London: Harvill Press, 1952. Republished as *Man against Mass Society*. Chicago: Regnery, 1962.
- L'homme problématique*. Paris: Aubier, 1955.
- Présence et immortalité*. Paris: Flammarion, 1959.
- The Existential Background of Human Dignity*. Cambridge, MA: Harvard University Press, 1963.

### Plays

"The Lantern." *Cross Currents* 8 (2) (1958): 129–143.

*Three Plays*. Translated by Rosalind Heywood and Marjorie Gabain. New York: Hill and Wang, 1958; 2nd ed., 1965. Contains "A Man of God," "Ariadne" (*Le chemin de Crète*), and "The Funeral Pyre" (*La chapelle ardente*; in the 2nd ed., "The Votive Candle").

### Translations

*Creative Fidelity*. Translated, with an introduction, by Robert Rosthal. New York: Farrar, Strauss, 1964.

*Presence and Immortality*. Translated by Michael A. Machado. Pittsburgh: Duquesne University Press, 1967.

*Tragic Wisdom and Beyond*. Translated by Stephen Jolin and Peter McCormick. Evanston, IL: Northwestern University Press, 1973.

### WORKS ON MARCEL

Applebaum, David. *Contact and Alienation, The Anatomy of Gabriel Marcel's Metaphysical Method*. Washington, DC: Center for Advanced Research in Phenomenology & University Press of America, 1986.

Busch, Thomas. *The Participant Perspective: A Gabriel Marcel Reader*. Lanham, MD: University Press of America, 1987.

Cain, Seymour. *Gabriel Marcel*. London: Bowes and Bowes, 1963.

Gallagher, Kenneth T. *The Philosophy of Gabriel Marcel*. New York: Fordham University Press, 1963.

Lapointe, Francis H., and Claire C. Lapointe. *Gabriel Marcel and His Critics: An International Bibliography (1928–1976)*. New York: Garland, 1977.

Pax, Clyde. *An Existentialist Approach to God: A Study of Gabriel Marcel*. The Hague: Martinus Nijhoff, 1972.

Prini, Pietro. *Gabriel Marcel et le méthodologie de l'invérifiable*. Paris, 1953.

Ricoeur, Paul. *Gabriel Marcel et Karl Jaspers*. Paris: Éditions du Temps Present, 1947.

Schilpp, Paul A., and Lewis E. Hahn. *The Philosophy of Gabriel Marcel*. Library of Living Philosophers Vol. XVII. La Salle, IL: Open Court, 1984.

Troisfontaines, Roger. *De l'existence à l'être*. 2 vols. Paris, 1953. Essentially a concordance of what Marcel has said on any subject. Contains a complete bibliography of Marcel's work until 1953.

## MARCION

(c. 85–c. 159)

Marcion was one of the most significant and, in a way, perplexing figures of the second century CE—significant both for founding the Marcionite Church and for providing the stimulus for the formation of the New Testament canon, and perplexing because of the difficulty of classifying him among contemporary thinkers. He is often called a Gnostic, and there are certainly distinct affinities

with Gnosticism in his cosmology and soteriology; but his lack of a mythical anthropology and of any syncretistic tendency sets him apart.

A native of Sinope in Pontus, he was born c. 85 and must have died c. 159, since there is no suggestion in our sources that he survived until the reign of the emperor Marcus Aurelius (161–180). According to the ecclesiastical writer Hippolytus, Marcion was the son of a bishop, and indeed there are indications that he grew up within the Christian faith. Excommunicated by his own father because of his unorthodox views, he traveled first to Asia Minor, then to Rome (c. 138–140), where he was at first closely associated with the church. In 144 he was again excommunicated, and he founded a church of his own that was for a time a serious menace to "orthodox" Christianity.

Marcion was a Bible critic and theologian rather than a philosopher; indeed, Adolf von Harnack describes him as "fundamentally a Biblicist and an opponent of all philosophy." The root of his teaching lies in the Pauline antithesis of Law and Gospel, but he exaggerated this contrast to the extent of distinguishing the Creator (the God of the Old Testament) from the true God, in himself unknown and alien to this world but manifested in the person of Jesus. This conception of the "alienness" of the true God Marcion shared with the Gnostics, but for him this concept developed from the study of the Scriptures rather than from philosophical speculation. Rejecting allegorical interpretation, he was unable to reconcile the Old Testament description of God with the New Testament portrayal of God as the father of Christ. Unlike the Gnostics as well as some of his followers, Marcion himself held that the Creator is not evil but merely just. Only the true God is good, a God of love. From this initial contrast the whole of Marcion's system follows naturally. This world, which is the work of the Creator, is imperfect. The Jewish law, and indeed all positive morality, is a means by which the Creator exercises control over humankind and is therefore to be rejected. Marcion's conclusions, however, led not to licentious antinomianism but to asceticism: Marriage and sexual intercourse, for example, were prohibited as devices for the continued procreation of subjects of the Creator. Salvation is deliverance from the world and its God and is effected at the price of Christ's blood, solely by God's grace and not because the redeemed were considered "akin" to the supreme good God, as the Gnostics believed.

The gospel brought by Jesus was misunderstood and falsified by the apostles: Only Paul had the truth of the matter. Marcion therefore rejected not only the Old Tes-

tament but also those parts of the New Testament that, according to him, were contaminated by Judaism. His canon consisted of ten letters of Paul, beginning with Galatians, and an expurgated Gospel of Luke. He also set out his teaching in his *Antitheses*, which was largely composed of contrasts between the two Gods. Marcion's works have not survived, and we are dependent on information provided by his opponents (especially Tertullian). His followers (especially Apelles) later modified his teachings so that they were in closer conformity with ordinary Gnosticism. Some of the "Gnostic" elements in his own theology have been attributed to the influence of the second-century Gnostic Cerdo.

Marcionism was at its height in the latter half of the second century. Thereafter it tended to decline in the West, and the remnants of Marcionite churches were often absorbed into Manichaeism. In the East it had a longer history, surviving down to the fifth century or later.

## MARCUS, RUTH BARCAN

Ruth Barcan Marcus, though she has published in a number of areas, is best known for her groundbreaking papers in modal and philosophical logic. In 1946 she initiated the first systematic treatment of quantified modal logic (see Barcan, 1946), therein provoking W. V. Quine's decades-long attack upon the meaningfulness of quantification into alethic modal contexts. The ensuing dispute focused attention on the phenomenon of referential opacity and led to important developments in logic, metaphysics, and philosophy of language. In subsequent papers Marcus extended the first-order formalization to second order with identity (Barcan, 1947) and to modalized set theory (Marcus, 1963, 1974). Particularly significant theses presented in these works were the axiom

$\diamond(\exists x)Fx \rightarrow (\exists x)\diamond Fx$ , known as the Barcan formula (Barcan, 1946), and the proof of the necessity of identity (Barcan, 1947; Marcus, 1961). It is of some historical interest that Marcus introduced the now standard "box" operator for necessity.

Marcus's response to criticisms of quantified modal logic took many forms and was a theme to which she returned repeatedly throughout her career. In her 1961 paper (and elsewhere) she sought to dispel certain puzzles about substitutivity of identity in modal contexts; she was an early advocate of a substitutional interpretation of the quantifiers for certain purposes (Marcus, 1961, 1962, 1972), as for example in modal and fictional discourse; she maintained that quantification into modal contexts involves no commitment to an objectionable essentialism (Marcus, 1961), and she later developed and defended a version of Aristotelian essentialism within a modal framework (Marcus, 1967, 1976). Finally, in the mid-1980s she offered an explicit defense of the metaphysical actualism that had informed her early papers in modal logic (Marcus, 1985–1986). Here once again Marcus employed an objectual interpretation of the quantifiers, construing our core modal discourse as counterfactual discourse about actual objects.

Allied doctrines of enduring significance either originated or evolved in other writings by Marcus. For example, she introduced a flexible notion of extensionality whereby languages and theories are extensional to the extent that they identify relatively stronger equivalence relations with relatively weaker ones (Marcus, 1960, 1961). She also proposed that ordinary proper names are contentless directly referential tags (Marcus, 1961). In so doing, Marcus rejected earlier "descriptivist" accounts, often associated with Gottlob Frege and Bertrand Russell, and laid the cornerstone of the so-called new theory of direct reference later elaborated by Saul Kripke, Keith Donnellan, David Kaplan, and others.

Writing in moral theory, Marcus exposed defects in the structure of standard deontic logic (Marcus, 1966). She also argued that moral dilemmas are real and, moreover, that their reality is compatible with the consistency of the moral principles from which they derive (Marcus, 1980). Reasoning from a straightforward analogue of semantic consistency, she called into question familiar arguments from the existence of moral dilemmas to ethical antirealism. The resulting account also yielded some second-order principles of conflict avoidance.

Finally, in a series of papers on the nature of belief (Marcus, 1981, 1983, 1990), Marcus rejected language-centered theories according to which beliefs are attitudes

to linguistic or quasilinguistic entities (sentences of English or “Mentalese,” for instance). Her proposal was that an agent *X* believes that *S* if and only if *X* is disposed to respond as if *S* obtains, where *S* is a possible state of affairs and what is to count as such a response is a function of environmental factors and internal states such as *X*’s needs and desires. This object-centered theory, as opposed to the language-centered views of Donald Davidson and Jerry Fodor, for example, more naturally accommodates unconscious beliefs and beliefs of infralinguals and nonlinguals. It also accommodates a more robust notion of rationality and explains, as its rivals cannot, why a fully rational agent would not believe a contradiction. In the wide sense of the term, a rational agent is one who, among other things, strives to maintain the global coherence of the behavioral—that is, verbal as well as nonverbal—indicators of his beliefs. Thus, although a rational agent might assent to a contradiction, his assent would not “go over” into a belief. Indeed, upon discovering the contradiction, he would retract his earlier (contradictory) belief claim. On Marcus’s view, just as one cannot know what is false, one cannot believe what is impossible.

Marcus was professor of philosophy and chair of the department at the University of Illinois at Chicago from 1964 to 1970, professor of philosophy at Northwestern University from 1970 to 1973, and the Reuben Post Halleck Professor of Philosophy at Yale, where she succeeded her mentor Frederick B. Fitch, from 1973 to the time of her retirement in 1992. In addition to her scholarly achievements Marcus changed the face of the philosophical profession by her efforts on behalf of women. Perhaps most noteworthy in this connection was the reform of hiring practices instituted by the American Philosophical Association during her tenure as an officer and subsequently as chairman of its National Board of Officers.

## MARCUS AURELIUS ANTONINUS (121–180 CE)

Marcus Aurelius Antoninus may have wielded more political power than any other person to have an entry in this encyclopedia. Born into a prominent Roman family in 121 CE, Marcus was adopted in 138 by Emperor Hadrian’s heir, Antoninus Pius (at Hadrian’s behest), and he succeeded Antoninus as emperor in 161. Marcus’s reign is usually judged favorably; indeed, his death in 180 is often thought to end the golden age of the Roman Empire. But it was not all wine and roses: Marcus faced troubles on the frontiers of the empire, a devastating

plague, and worst of all, persistent wars that included the first Germanic invasion of Italy in centuries, a harbinger of invasions to come.

By late antiquity, Marcus Aurelius was most famous as a philosopher. This reputation has come to rest on his Greek writings *to himself*, best known in English as the *Meditations*. In Book One, Marcus offers an idealized account of the influences on his character, acknowledging gods, family, and teachers, including several philosophers, a grammarian, and the rhetorician Fronto, part of whose correspondence with Marcus survives. The remaining eleven books manifest no obvious organization and have puzzled many scholars. Their 473 chapters vary considerably in length and style, from maxims to minitreatises, with consolations, dialogues, and harangues thrown in. These chapters commonly feature first- or second-person pronouns and the imperative mood, with the aim of recommendation or rebuke. Sometimes Marcus articulates more theoretical doctrines of philosophy or even, though much less often, arguments, but even at his most explicitly theoretical, he does not stray far from commending or censuring. Scholars have conjectured that the *Meditations* are the scraps of an intended treatise, but this does not fit well with the text. Scholars have also tried to rearrange the chapters to impose a clearer organization, but no such reorganization has commanded broad acceptance. Instead, most scholars now take the *Meditations* as they are. On the consensus view, although the whole collection is informed by philosophical reflection, Marcus writes not to theorize but to bring his thoughts, feelings, and activities in line with the philosophical commitments he accepts.

The *Meditations* are therefore not like usual philosophical writing, and this is what makes them historically significant. Philosophers in ancient Greece and Rome often encourage others to engage in meditative exercises to cultivate a philosophical way of life (especially relevant is Epictetus, *Diss.* I 1.25), and Marcus's work is the best example of such exercises. It suggests that one does not cultivate a philosophical way of life by the detailed application of philosophical theory to particular dilemmas. That is why Marcus's exercises do not shed much light on the particulars of his life. When he does make practical precepts explicit, he states them in general terms that could apply to a shopkeeper in Kansas as well as a Roman emperor and in terms that target attitudes more than actions. So it seems that one cultivates philosophy by bringing about a general outlook that one will then put into action as the circumstances demand.

The philosophical outlook that Marcus cultivates is generally thought to be Stoic though he does not call himself a Stoic. His praise for Epictetus and his use of Stoic vocabulary encourage this thought, but by no means decisively, since he also cites Plato and Epicurus favorably, and by his time philosophers of many schools used Stoic vocabulary. Still, some of the most prominent themes of the *Meditations* are genuinely Stoic: strong contrasts between the value of one's mind, a part of the divine intelligence, and what is external to one's mind and indifferent to one's happiness (II 13, III 12); concerted efforts to reduce anger at others and to control impulses (II 1, VII 22); and regular insistence that one should help other members of the human community (V 33, VIII 59, IX 1.1, IX 23). Less distinctively Stoic is the persistent theme of death (II 12, III 3, IV 5, IV 6, IV 48, VI 28; XII 36), though this is a natural obsession if the *Meditations* were written (as the evidence suggests) in the last decade of Marcus' life and some of them at military camps. So on balance the impression of Stoic commitments is hard to deny.

To call Marcus a Stoic, though, one must use an undemanding litmus. First, Marcus shows very weak adherence to two-thirds of the traditional Stoic system. He ignores the epistemology, language, and formal logic of the Stoic study of reason (or logic; *logikē*), and he belittles the need to study nature (that is, to engage physics; *physikē*). He occasionally helps himself to the Stoic thought that the cosmos is providentially ordered (II 3, X 6, XI 18.1), but he is detached enough from this thought that he also tries repeatedly to claim that the same practical precept applies whether the world is providential or, as Epicurean atomism holds, not (VII 32, VIII 17, IX 39, X 6, XII 24). In general, Marcus's philosophical commitments do not much outrun his ethic.

Even Marcus's ethical reflections are so untheoretical as to suggest a departure from traditional Stoicism. For example, Stoic ethics traditionally relies on the thought that virtuous activity alone constitutes a happy life, and Stoics support this thought either by describing the natural development of concern for virtuous activity alone (and the concomitant stripping away of obstacles to a smooth flow of life) or by engaging directly in the question of what happiness is. Marcus, though, does not motivate his Stoic aims theoretically. Presumably, he does not need to. If he already has these aims, he needs only to reshape his attitudes to improve his pursuit of them. In this way, Marcus's special purpose leads him to pass over many of the issues, distinctions, and arguments of traditional Stoicism.

The Stoicism of the *Meditations* clearly owes much to Epictetus, but in its ruthless pursuit of getting the cast of mind right without dallying in logic, physics, or the distinctions among the things that are neither good nor bad, it also resembles still more Cynicizing versions of Stoicism as that of Aristo of Chios, the renegade Stoic of the third century BCE. Marcus might have been especially influenced by Aristo's work or by the Cynic revival in imperial Rome. Or perhaps the appearance of such affinity is due to his special purpose in the *Meditations* of trying to recast his general practical attitudes.

This purpose might also explain another characteristic of Marcus's Stoicism. It is often said that Marcus shows strong Platonist leanings, especially in the starkly dualistic way in which he contrasts the intellect in the soul with the body (IV 41, VIII 37, IX 24, XII 33) and the matter of the external torrent (V 10.2, VI 15, VIII 24, IX 36). Sometimes these leanings are attributed specifically to the influence of the Platonizing Stoic Posidonius (c. 135–c. 50 BCE), and sometimes they are said to anticipate Neoplatonism. But Marcus's occasionally dualistic talk and his hostility toward the body might be understood instrumentally as part of a regimen to correct his excessive attachment to his own body and not as a commitment to any dualism.

The *Meditations* were apparently not in wide circulation for several centuries after Marcus's death, and so they exhibit no obvious influence on the immediately subsequent history of philosophy. In modern times, however, the work has been widely admired, sometimes for its fresh glimpse into ancient Stoicism but more often for its intimate picture of an aging emperor's struggle with noble yet human goals, to be a better person, and to face death without fear or regret.

## MARÉCHAL, JOSEPH

(1878–1944)

Joseph Maréchal, one of the most original and influential of Neo-Scholastic thinkers, was born at Charleroi, Belgium. He entered the Society of Jesus at the age of seventeen, and between 1895 and 1910, in spite of poor health, he not only successfully completed the long and exacting Jesuit course of studies in the humanities, philosophy, theology, and asceticism but also obtained his doctorate in the natural sciences from the University of Louvain (1905). After the completion of his Jesuit training, during the latter part of which he also taught biology to his younger confreres, he spent some time in Germany studying experimental psychology and psychotherapy. From the outset his main interest centered on the psychology of religious experience and its implications for metaphysics and the critical problem.

After the outbreak of war in 1914 he went to England with his Jesuit students. He did not begin teaching formally at the Jesuit scholasticate in Louvain until 1919. From then until 1935 he conducted courses in psychology, theodicy, and the history of modern philosophy. It was during these years that he published his most important works, the two-volume *Études sur la psychologie des mystiques* and the First, Second, Third, and Fifth Cahiers of the *Point de départ de la métaphysique* (the first three are somewhat abridged in his *Précis d'histoire de la philosophie moderne*). The Fourth Cahier, *Le système idéaliste chez Kant et les postkantians*, was published posthumously in 1947 from manuscripts left by the author.

After 1935 and until his death Maréchal ceased teaching and writing, mostly because of poor health but partly because he felt that his work was misunderstood and ineffectual. Concerning "my epistemology," he remarked, "I have never had the means of exposing, orally

or by writing, my general conception of the problem of knowledge. The Fifth Cahier states once more this problem *in terms of Kant*, which retains something artificial demanded by immediate historical antecedents. My definitive position ought to appear only at the end of the Sixth Cahier, in which there remains a new stage to overcome” (*Mélanges Maréchal*, Vol. I, p. 13; all translations are the author’s). Unfortunately, the Sixth Cahier was never published.

In an article, “À propos du Sentiment de présence chez les profanes et chez les mystiques,” published in 1908, the year he was ordained a priest, and later reproduced in the first volume of his *Études sur la psychologie des mystiques* (2nd ed., pp. 67–122), Maréchal for the first time indicated the distinctive trend of his philosophical thought. He pointed out that “the judgment of presence properly speaking affirms a spatial relation between a subject and an object,” implying their reality, which is conditioned by “(1) a certain unity of mind, realized by (2) the coordination of representations, (3) with the concurrence of feeling” (*Études*, p. 110). Because the existential judgment cannot be founded solely on sensible experience, in view of sensible illusions, or on subjective feeling, the “psychologists” arbitrarily assume the anteriority of the subjective over objective knowledge, thus creating the pseudocritical problem of the “bridge” from thought to reality, the solution of which is thus prejudiced in favor of idealism. According to Maréchal the terms of the problem should be reversed. A more simple and more logical procedure would be “to posit as a primitive fact the *real*, *affirmation*, and the *objective* and to seek how this fact, in being broken up, gives birth to the secondary notions of the *unreal*, of *doubt*, and of the *subjective*. We shall thus rediscover, with a certain number of modern psychologists and under the impulse of experience, the point of view—very clear but insufficiently analyzed—of ancient Thomistic psychology” (*ibid.*).

Maréchal’s principal work is his Fifth Cahier. The first four cahiers present a historical exposition and critical analysis of the problem of knowledge prior to Immanuel Kant, in Kant, and in post-Kantian transcendental idealism and a “historical demonstration” of the Thomistic solution. A twofold antinomy emerges, of the sensibility and understanding and of the understanding and metaphysical reason. Kant resolved the first antinomy by refuting the exaggerated claims of both the empiricists and the rationalists and by effecting a synthesis of the sensibility and understanding. However, according to Maréchal, Kant failed to resolve the second antinomy because he did not take into consideration the

role of finality and intellectual dynamism in objective knowledge, a failure revealed in his *Opus Postumum* and in Johann Gottlieb Fichte’s finalism. Maréchal held that Thomas Aquinas’s epistemology virtually contains the solution of the antinomy of the understanding and reason by their effective synthesis in terms of intellectual dynamism (though Thomas himself did not explicitly consider the modern critical problem). Hence, the Fifth Cahier, “Thomisme devant la philosophic critique,” presents the Thomistic solution of the critical problem without pretending to present an anachronistic confrontation of Kant and Thomas.

Maréchal agreed with Kant that we have no intellectual intuition of the noumenal, but he denied Kant’s conclusion that the noumenal is therefore unknowable to human reason. Even though the human mind is not intuitive, but only abstractive and constructive, in its knowledge, yet in virtue of its innate active dynamism to Absolute Being it attains the noumenal or metaphysical in its synthetic elaboration of the object of knowledge by the “active intellect.”

The Fifth Cahier has two main divisions. The first part is an examination, according to the demands of modern criticism, of “the theory of knowledge in the framework of Thomistic metaphysics,” which Maréchal aptly termed “a *metaphysical* critique of the object”; it is preceded by a “critical preamble,” in which the author explains Thomas’s “universal doubt” and refutation of skepticism. The second part is “a Thomistic critique of knowledge transposed to the transcendental plane” and therefore “a *transcendental* critique of the object,” an attempt to go beyond Kant on the basis of Kant’s point of departure and transcendental method, which seeks the a priori conditions of the possibility of the objective contents of human consciousness, viewed precisely as objective.

How does Maréchal’s metaphysical critique of the object differ from his transcendental one? Both have as their initial point of departure the object immanent in the mind, the mental content directly revealed in consciousness, what René Descartes called the “objective reality” of the idea. However, according to the metaphysical critique, the presence of the object in the mind is intentional and therefore ontological or noumenal in its signification, whereas according to the transcendental critique there is present to the mind only a phenomenon. From either viewpoint, however, there can be no question but that this immanent object presents (1) a sensible aspect, (2) a conceptual aspect (involving the notes of universality and necessity), and (3) a transcendent aspect inex-

orably pointing toward Absolute Being. Unlike Kant, scholastic Thomism accepts the objective validity of the third aspect. As we shall presently see, the two critical approaches differ not as regards their philosophical methods but only as regards their formal object. The formal object of the metaphysical critique is being, viewed as being in all its fullness, universality, and necessity—namely, Absolute Being or God; the formal object of the transcendental critique is the phenomenon.

This is not to say that the transcendental method, as understood in too narrow a sense by Kant himself, does not differ from the metaphysical method of Thomism. The transcendental method seeks to determine the a priori conditions of the possibility of the “objective” contents of consciousness. But as Maréchal contended, the most important and salient of these a priori conditions (which Kant failed to recognize) is the intellectual dynamism of the subject, its activity in constructing the immanent object. This is revealed by “transcendental reflection,” whereas “transcendental deduction” proves that the object immanent in consciousness cannot be truly “objective” except in terms of this a priori or objectivizing function of the dynamic intellect, whose formal object is Absolute Being. Needless to say, Kant himself never conceived the transcendental method in such a dynamic fashion. Thus, the most basic inconsistency of his methodology, according to Maréchal, is his stated purpose of disclosing by transcendental reflection the purely logical and static a priori conditions of knowledge, whereas, inadvertently or not, his procedure is often psychological and dynamic; he viewed the mind as constructive and synthetic, and therefore as active, but illogically concluded that the only a priori discoverable by transcendental reflection is purely logical, formal, and static. Hence, Maréchal refuted Kant in the first part of Cahier V by applying the transcendental method to the ontological object, thus legitimizing the Thomistic point of departure of metaphysics (namely, that the human mind directly attains the noumenal or intelligible in its necessary judgments), while in the second part he attempted to go beyond Kant’s agnostic conclusions by proving the necessity of metaphysics, using this same transcendental method and basing the proof on Kant’s own presupposition that the object immanent in consciousness is the phenomenal.

To constitute a noumenal “object in itself,” that which is known must be something more than an abstract essence or form in the mind; it must go beyond the domain of *form* and be related to the sphere of *act*. An abstract essence can become a possible essence and there-

fore represent a real essence only when the immanent form becomes an act of the dynamism of the intellect, necessarily relating the abstract form to Absolute Being, as a partial fulfillment of this dynamism.

Maréchal was not maintaining “the ontological parologism” that the proposition “Truth is” is intuitive or analytical; rather, he held that what the discursive and abstractive intellect apprehends is that the connection between truth and being must be affirmed under pain of contradiction, when our intellectual dynamism to Absolute Truth is also apprehended. (The objective validity of our abstractive knowledge is thus assured.) Only the divine intellect is intuitive, but an abstractive intellect is capable of apprehending and reducing an abstracted form, inherent in the potentially intelligible data of sense, to act by virtue of its active dynamical tendency to Pure Act, thus approximating the perfection of the exemplary divine knowledge. Since our intellectual knowledge is not a purely passive reception of abstract forms, the self-consciousness of the synthesizing knowing subject as an intellectual dynamism is the key to Maréchal’s doctrine on the objectivization of human knowledge.

Maréchal’s distinction between the human intellect viewed as formally cognoscitive and the same intellect viewed as a natural being or entelechy (*ut res quaedam naturae*) is very important for an understanding of his epistemology of objectivization. The strictly intentional function of the abstractive intellect, whose formal object is being as such, must be basically identified with the entitative function of the same intellect viewed as a dynamic real tendency to Absolute Being or Truth. It is only in virtue of the intellect viewed as dynamic act that the formally cognoscitive and abstractive intellect can assimilate a representative form as objective being, that is, as a partial fulfillment of the intellect’s natural dynamism to the acquisition of *all being*, the intuition of Being Itself.

Granted the sensible data, it is in the formation of the concept that the synthesizing function of the knowing subject reveals itself. Thus, metaphysical concepts present themselves in our consciousness as universal and necessary and therefore as connoting a relation to Absolute Being; though they may conceptually represent a multiplicity, they necessarily signify a universal, though analogical, unity of being that is intelligible only in terms of Absolute Being. How are we to explain these elements of universality and necessity?

In a Thomistic metaphysical critique of the object, the a priori is not simply a logical function, as in Kant. Rather, it designates, in terms of Maréchal’s intellectual dynamism, an a priori that is at once both metaphysical

and psychological; for Maréchal the formal object of the intellect as a natural entelechy, or *res quaedam naturae*, is Absolute Being. On the conscious, elicitive, and formally cognoscitive level, being is necessarily presented as an abstract being as such, but such a representation, Maréchal contended, is possible only because the intellect naturally tends to Absolute Being as its natural entelechy or end on the preconscious and preelictive level. The substantial unity of the knowing subject makes possible the “conversion to the phantasm,” without which it could not make a judgment concerning the concrete individual.

Maréchal’s transcendental critique of knowledge can be more readily understood when it is viewed in the light of his posthumously published Fourth Cahier, especially his remarks on Kant’s *Opus Postumum* (pp. 225–326) and on Fichte’s “Intellectual Intuition of Act or Dynamic Intuition” (pp. 348ff.) and his article “L’aspect dynamique de la méthode transcendentale chez Kant” (*Revue Néoscholastique* 42 [1939]: 341–384). In his analysis of Kant’s *Opus Postumum* (“The Passage from the First Foundations of the Metaphysics of Nature to Physics”)—which Kant once called his “masterpiece” but which was first published in 1920 by Erich Adickes under the title *Kants Opus Postumum, dargestellt und beurteilt*—Maréchal pointed out that Kant acknowledged that the “form” involved in human knowledge is not merely static or logical but dynamic and real in its implication. This same idea of intellectual dynamism is emphasized by Maréchal’s analysis of Fichte’s development of Kantianism, so much so that Maréchal has been accused of being too Fichtean and voluntaristic in his application of the Kantian transcendental method to the problem of knowledge. For Fichte, as for Maréchal, the self-reflecting self, the immediate intuition of the self as “a primary fact of consciousness ... is the sole solid foundation of all philosophy” (Fourth Cahier, p. 349).

## MARIANA, JUAN DE (1535–1624)

Juan de Mariana, the neo-Scholastic political philosopher, was born at Talavera de la Reina, Spain, and died at Toledo. Entering the Society of Jesus at eighteen, he completed the Jesuit course of studies in philosophy and theology and taught theology in Rome from 1561 to 1569 and at Paris from 1569 to 1574. He then retired to Toledo to work on his “History” and other writings in practical philosophy. Mariana’s *Historiae de Rebus Hispaniae* (Toledo, 1952; also published in elegant Spanish by the author, Toledo, 1601) was one of the first general histories of Spain. Also influential were his treatises *De Rege et Regis Institutione* (Toledo, 1599, translated by G. A. Moore as *The King and the Education of the King*, Washington, DC, 1948) and *De Mutatione Monetæ* (On Changing the Value of Money), one of the *Tractatus Septem* (Cologne, 1609).

Accused of attacking the sovereign power of Spain in his criticism of its fiscal policies, Mariana was tried in 1609 by the Spanish Inquisition and acquitted. His philosophy is important for its handling of political, social, and economic problems. A strong advocate of the power of the people, Mariana argued that the citizens as a whole (*communitas civium*) are superior in power to the monarch. Men lived originally in an unorganized “state of

nature,” not needing political institutions to maintain justice; all possessions were held in common, and men naturally cooperated for their common welfare (*De Rege*, Chs. 8 and 13). With advances in arts and sciences, a division of goods developed into private possession; thus arose jealousy, pride, and strife among men. Tired of the struggle for domination, men then made a pact, delegating the ruling power to certain leaders. (Note that Mariana antedates both Thomas Hobbes and Jean-Jacques Rousseau.) The basic enactments of law can be changed only by the manifest will of the people. If the king fails to rule in accord with the law, he may be deposed by the people using prudent judgment; physical force may be employed for this purpose. Mariana was accused of trying to justify tyrannicide; his views did not endear him to the Spanish monarchists.

## MARIAS, JULIÁN (1914–)

Julián Marías is the best-known and most productive of the post-Civil War philosophers in Spain who have sought to reconcile the doctrines of their teacher, José Ortega y Gasset, with traditional theism. Born in Valladolid in 1914, Marías studied under Ortega in Madrid just before the Civil War. When Ortega returned from exile in 1948, they jointly founded the Institute of Humanities in Madrid. Marías has taught at the institute and, as visiting professor, at various American universities. The bulk of his published work concerns the history of philosophy, mainly Spanish and scholastic philosophy.

His general *Historia de la filosofía* (1941), which he wrote at the age of twenty-six, emphasizes the Aristotelian and scholastic traditions and gives a prominent position to Spanish thought. In *La escuela de Madrid* (The Madrid school; Buenos Aires, 1959), Marías presented the most comprehensive study available of such contemporary Spanish thinkers as Ortega, Miguel de Unamuno, Xavier Zubiri, and Manuel García Morente.

As a Catholic disciple of Ortega, who was explicitly irreligious and anti-Catholic, Marías gave a theistic interpretation of Ortega’s “ratiovitalism” (a reconciliation of rationalism and the vitalist doctrines of the 1920s). In his major work, *Introducción a la filosofía* (1947), Marías argued that certain intellectual and spiritual “ultimates” are true biological needs of humankind. To be lived at all humanly, life requires, in addition to food and other animal necessities, “the possession of a radical and decisive certitude.” That certitude serves as the foundation for numerous “partial truths.” It harmonizes all our beliefs into a single clear perspective, and it also provides society with a ruling view that is needed for social stability. Men turn to philosophy for this certitude, so there is nothing more “practical,” vital, or socially relevant than metaphysics, which is called upon to give men a standard to live by.

Marías accepts all the pragmatist, relativist, and historicist implications of vitalism, which usually have been regarded as destructive of religious convictions, and he argues from them back to the traditional religious outlook. Truth is what answers a vital need by removing the feeling of insecurity and perplexity. It is always relative to particular life situations and historical periods. Truth fragments into a multitude of relative truths, which contain concrete concepts as distinct from general concepts, which are obtained only by an arbitrary and schematizing process of abstraction. Yet, if the quest for completely satisfying, radical certainty is pressed tenaciously enough, it will lead beyond this complete nominalism to God, who appears as the ground or basis of being. Although the ego that carries on that quest was, for Ortega, the incarnation of “vital reason,” for Marías it is the person who owns both vitality and reason. At death, that person, or soul, loses vitality and psychic activity but does not necessarily cease to exist. The mortality of the soul is a theory that remains in need of proof.

## MARITAIN, JACQUES

(1882–1973)

The French philosopher Jacques Maritain was a powerful force in twentieth-century philosophy and cultural life. The author of more than fifty philosophical works and of countless articles that appeared in the leading philosophical journals of the world, he was widely regarded as a preeminent interpreter of the thought of Thomas Aquinas and as a highly creative thinker in his own right.

Maritain, born in Paris, was reared in an atmosphere of liberal Protestantism. He attended the Sorbonne, where he fell briefly under the spell of teachers passionately convinced that science alone could provide all the answers to the questions that torment the human mind. It was at the Sorbonne that he met his wife-to-be, Raïssa Oumansoff, a young Russian-Jewish student who was to share his quest for truth and to become an intellectual and poet of real stature in her own right. She was also to collaborate with Maritain on a number of books. Soon disillusioned with the scientism of their Sorbonne masters, the two attended the lectures of Henri Bergson at the Collège de France. Bergson liberated in them “the sense of the absolute,” and, following their marriage in 1904, they were converted (1906) to the Roman Catholic faith through the influence of Léon Bloy.

The years 1907 and 1908 were spent in Heidelberg, where Maritain studied biology under Hans Driesch. He was particularly interested at the time in Driesch’s embryogenetic theory of neovitalism, a theory then little known in France. Upon returning to Paris, Maritain undertook the task of directing the compilation of a *Dictionary of Practical Life*. During the three years that he worked on this project, he also undertook a serious study of the writings of Thomas Aquinas. In 1914, he was appointed to the chair of modern philosophy at the Institut catholique de Paris.

From 1945 to 1948 Maritain was French ambassador to the Vatican. Afterward he taught at Princeton University until his retirement in 1956. He has also taught at the Pontifical Institute of Mediaeval Studies in Toronto, Columbia University, the Committee on Social Thought at the University of Chicago, and the University of Notre Dame. The Jacques Maritain Center was established at Notre Dame in 1958 for the purpose of encouraging research along the lines of his philosophy.

Maritain’s thought is based on the principles of Aristotle and Thomas Aquinas but incorporates many insights found in other philosophers, both classical and modern, and also profits greatly from data supplied by such sciences of man as anthropology, sociology, and psychology.

## THEORY OF KNOWLEDGE

The cardinal point in Maritain’s theory of knowledge is his defense and critical elucidation of different ways of knowing reality. On the one hand, Maritain sees the richness and inexhaustibility of material reality as requiring that the mind let fall on it different noetic glances, each of which reveals to the mind a different universe of intelli-

bility to be explored. There is, first of all, the universe of *mobile being*—being imbued with mutability—which constitutes the sphere of the knowledge of nature and which itself calls for both an empiriological analysis, that is, a spatiotemporal analysis oriented toward the observable and measurable as such (science of nature), and an ontological analysis, that is, an analysis oriented toward intelligible being, toward the very being and intelligible structure of things (philosophy of nature). There is, second, the universe of *quantity* as such, which constitutes much of the sphere of mathematics. And there is, finally, the universe of *being as being*, which constitutes the sphere of metaphysics.

Much of Maritain's energy was devoted to giving the philosophy of nature its epistemological charter, in contrast with many Thomists in a hurry who would have it almost totally eclipsed by metaphysics, and in contrast with the many scientists who think that the only object capable of giving rise to an exact and demonstrable science is that which is sense-perceivable and can be subjected to methods of experimental and mathematical analysis. Maritain's serious study of the work of modern physicists and biologists revealed to him that scientists are led by their science itself to discover within the mysterious universe of nature problems that go beyond the experimental and mathematical analysis of sensory phenomena. It also revealed to him that the conceptual lexicon of the scientist is radically different from the conceptual lexicon of the philosopher. For these reasons, Maritain emphasized the need for, and prerogatives of, both an ontological analysis and an empiriological analysis of the sensible real. He also worked out a theory of physicomathematical knowledge that relates this knowledge to what the Scholastics called intermediary sciences (*scientiae mediae*), sciences which straddle the physical order and the mathematical order and which have more affinity with mathematics than with physics as to their rule of explanation and yet at the same time are more physical than mathematical as to the terminus in which their judgments are verified.

On the other hand, Maritain saw the human mind as having another life than that of its conscious logical tools and manifestations: "there is not only logical reason but also, and prior to it, intuitive reason." There is indeed not only the Freudian unconscious of instincts, tendencies, complexes, repressed images and desires, and traumatic memories; there is also a spiritual unconscious or preconscious, the preconscious of the spirit in its living springs. The acts and fruits of human consciousness and the clear perceptions of the mind—in other words, the

universe of concepts, logical connections, rational discursus, and rational deliberation—emerge in the last analysis from the hidden workings of this preconscious life of the spirit; but there also emerge from them many genuine knowings, and many affective movements, which remain more or less *sur le rebord de l'inconscient*, as Bergson would have said—on the edge of the unconscious. Among such knowings we have the various kinds of knowledge by inclination (knowledge through connaturality)—notably, poetic knowledge, the "natural" or prephilosophical knowledge of moral values, and mystical experience. Maritain felt it to be most incumbent upon us to recognize not only the different kinds or degrees of conceptual and discursive knowledge but also these different nonconceptual and "immediate" forms of knowledge.

## METAPHYSICS

Maritain held the classical view that the object of metaphysics is *being as being*, and he stressed that it is in things themselves that metaphysics finds this object. It is the being of sensible and material things, the being of the world of experience, which is the immediately accessible field of investigation for metaphysics; it is this which, before seeking its cause, metaphysics discerns and scrutinizes—not as sensible and material but as being. Before rising to what may be a realm of spiritual existents, metaphysics must grasp empirical existence, the existence of material things—not as empirical and material but as existence.

For Maritain, at the starting point of metaphysics there lies an intuition, the "metaphysical intuition of being," which may be said to consist in the intellect's seeing—through an abstractive or eidetic (idea-producing) visualization—the intelligible value *being*, being in itself and in its essential properties. The word *intuition* here has caused much difficulty for some philosophers, but it seems to be demanded by the thought that Maritain was trying to express. What must somehow be preserved is, on the one hand, that it is as true to say that this "seeing" produces itself through the medium of the vital action of our intellect—of our intellect as vitally receptive and contemplative—as to say that we produce it; and, on the other hand, that it is being more than anything else that produces this "seeing."

In his scrutiny of the being of sensible and material things, Maritain presented a highly original treatment of what Thomists and others have long considered to be the first principles of speculative reason—the principles of identity, sufficient reason, finality, and causality. He

explained that the reality that is the object of the idea of being is richer than this idea, and it presses for multiplication in a manifold of notions, among them the notions of unity, of goodness, of truth: being is one, is good, is true. Each of these notions expresses to the mind nothing but being itself, to which it adds nothing but a conceptual difference. But precisely in virtue of this ideal element that differs from one to the other, these notions as such are different among themselves and are different from the notion of being; they are convertible notions but they are not identical with one another. There is thus a superabundance of being with regard to the notions in which it is objectified, and it is in terms of this superabundance that Maritain elucidated the intuitivity of the first principles.

When he turned his philosophical gaze to the problem of the “cause of being,” Maritain was attentive both to specifically philosophical ways of establishing the existence of God and to nonphilosophical or prephilosophical ways of approaching God. Under the first heading he restates the five classical ways of Thomas Aquinas, divesting them of the examples borrowed from ancient physics and formulating them in a language more appropriate to modern times; then he proposes a “sixth way.” In this “sixth way” we have first the complex primordial intuition, and later the rational and philosophical reflection, that the *I* who thinks, the *I* who is caught up in pure acts of intellect, cannot ever not have been, for both the intellect and the intelligible as such are above time: this *I* must always have existed, and in some personal existence, too, although not within the limits of its own personal being but rather in some transcendent and suprapersonal Being. Philosophical reflection can go on to establish how the *I* always existed in God, can establish that “the creature which is now *I* and which thinks, existed before itself eternally in God—not as exercising in Him the act of thinking, but as thought by Him.”

But Maritain was quick to recognize prephilosophical approaches to God—the “natural,” or instinctive and intuitive, approach proper to the first apperceptions of the human intellect, the approach through art and poetry, and the approach through moral experience. The inner dynamism of a man’s first awakening to the intelligible value of existence causes him to see that the Being-with-nothingness that is both his own being and the being of the universal whole must be preceded by transcendent Being-without-nothingness. As concerns art and poetry, the poet or artist, in following the very line of his art, tends without knowing it to pass beyond his art; just as a plant, although lacking knowledge, directs its

stem toward the sun, the artist, however sordid his life, is oriented toward the primary source of beauty. And finally, as concerns moral experience, when a man experiences, in a primary act of freedom, the impact of the moral good, and is thus awakened to moral existence and directs his life toward the good for the sake of the good, then he directs his life, without knowing it, toward the absolute Good. In this way he knows God vitally, by virtue of the inner dynamism of his choice of the good, even if he does not know God in any conscious fashion or through any conceptual knowledge.

## MORAL PHILOSOPHY

One of the most provocative sides to Maritain’s thought was his theory of “moral philosophy adequately taken.” His contention was that moral philosophy—however vast, necessary, and fundamental be the part that natural ethics plays in it—must, if it is to be adequate to its object (the direction or regulation of human acts), take into account the data of revelation and theology concerning the existential state of man. Human conduct is the conduct of an existent, not simply the conduct of a nature. Consequently, the moral philosopher must take into account all data that contribute to make the existential condition of man genuinely known to us. He must take into account the data of ethnology, sociology, and psychology. And he must also take into account theological data. For, in fact, as a result of the present state of human nature, man has more propensity to evil than the man of pure nature by reason of the original sin and of the concupiscence that remains even in the just; and, on the other hand, he has incomparably stronger weapons for good, by reason of divine grace. Maritain recognized that the moral philosopher who does take this situation into account will not be a *pure* philosopher but maintained that he will still be able to use the method proper to philosophy and advance with steps, so to speak, of philosophy, not of theology.

Maritain’s theory of natural law was elaborated against the background of anthropological data. He held that two basic elements must be recognized in natural law: the *ontological* and the *gnoseological*; and it is perhaps in considering the second of these two that Maritain made his most fecund insights. The chief point he wished to emphasize is that the genuine concept of natural law is the concept of a law that is natural not only in the sense that it is the normality of functioning of human nature or essence but also in the sense that it is naturally known, that is, known through inclination or through connaturality, not through conceptual knowledge and by way of

reasoning. The inclinations in question, even if they deal with animal instincts, are essentially human and, therefore, reason-permeated inclinations; they are inclinations refracted through the crystal of reason in its unconscious or preconscious life. And since man is a historical animal, these essential inclinations of human nature either developed or were released in the course of time; as a result, man's knowledge of natural law developed progressively and continues to develop. Thus, the fact that there is considerable relativity and variability in the particular rules, customs, and standards of different peoples is in no way an argument against natural law.

It belongs, of course, to moral philosophy to provide a scientific justification of moral values by a demonstrative determination of what is consonant with reason and of the proper finalities of the human essence and of human society.

### SOCIAL AND POLITICAL PHILOSOPHY

Much of Maritain's effort was directed to working out the character of authentically Christian politics. He lays primary emphasis on man as being both an *individual* and a *person*—an individual by reason of that in him which derives from matter, and a person by reason of that in him which derives from his subsisting spirit. Man must live in society both because of his indigence as an individual and because of his abundance or root generosity as a person. As an individual, man is only a part, and as such he bears the same relation to society as the part bears to the whole. His private good as an individual is in everything inferior to the common good of the whole, so that an individual may even be required to risk his life for the sake of the good of the community. But as a person, man is a whole; and the whole that the person is surpasses the whole that society is, because the person, by reason of the subsistence of his spiritual soul, is destined for eternal union with the transcendent Whole, whereas the particular society in which the person lives, by reason of its not having a spiritual soul, is not destined for union with the transcendent Whole, but will die in time. Man is above and superior to political society, and the political community must recognize the person's orientation to an end above time and facilitate his attainment of it.

Maritain's social and political philosophy also manifested a keen sense of history. For Maritain as for Pindar, man must become what he is—man must “win his being”; man must become, in the psychological and moral order, in the social and political order, the person he is in the ontological order. Among the many truths related to this fundamental exigency of man's being is one

that Maritain sees as of absolutely essential importance—the fact that human history is made up of periods, each of which is possessed of a particular intelligible structure, and therefore of particular basic requirements.

It is Maritain's contention that the historical climate of the modern world is quite different from that of the medieval world. For him, medieval civilization was a sacral civilization, by which he means that the historical ideal of the Middle Ages was principally controlled by two dominants: On the one hand, the idea or myth of fortitude in the service of God—the lofty aim was to build up a fortress for God on earth—and on the other hand, the concrete fact that temporal civilization had a largely ministerial role as regards the spiritual—the body politic was to a large extent a function of the sacred and imperiously demanded unity of religion. In contrast, modern civilization was for Maritain a secular civilization, by which he meant that the historical ideal of modern times is largely controlled by two other dominants: On the one hand, the idea or myth of the body politic as being by nature something of the natural order and something directly concerned, therefore, only with the temporal life of men and their temporal common good; and on the other hand, the concrete fact that in pursuing this temporal common good, modern man is most intent on the attainment of freedom and the realization of human dignity in social and political life itself.

Against the background of this view of medieval and modern civilizations, Maritain reflected at length on the nature of the democratic ideal. He saw democracy as the only way of bringing about a moral rationalization of politics, and he insisted that in order to accomplish this task democracy needs the quickening ferment of Gospel inspiration. But he also insisted, no less forcefully, that the “creed of freedom” that lies at the very basis of democracy is not a religious, but rather a civic or secular, one. Furthermore, this secular creed deals with practical tenets that depend basically on simple, “natural” apperceptions of which the human heart becomes capable with the progress of moral conscience and which can be similarly adhered to by minds that may differ greatly as to the speculative and theoretical justifications. In keeping with such a conception, Maritain repeatedly asserted that men belonging to very different philosophical or religious lineages can and should cooperate in the pursuit of the common good of political life. He also maintained that the supreme principles governing the relationship between church and state should be applied less in terms of the social power than in terms of the vivifying inspiration of the church: “the superior dignity of the Church is to find

its ways of realization in the full exercise of her *superior strength of all pervading inspiration*.” This reflects a most basic premise in all of Maritain’s thought: that immutable principles admit of, and even call for, analogical applications in different existential situations.

## PHILOSOPHY OF ART

From his earliest years Maritain was the friend and confidant of numerous artists, writers, poets, and musicians, and he was considered by many as having the finest aesthetic sensibility among the major figures of modern philosophy. His long reflection on almost every facet of the artistic process culminated in his monumental *Creative Intuition in Art and Poetry*, which grew out of six lectures given in 1952 at the National Gallery of Art, Washington, where he had been invited to deliver the initial series of the A. W. Mellon Lectures in the Fine Arts.

Maritain held, like Dante Alighieri, that human art continues in its own way the labor of divine creation. But he kept reminding the modern artist that human art cannot create out of nothing; it must first nourish itself on things, which it transforms in order to make a form divined in them shine on a bit of matter. Maritain would admit that the widespread effort toward “pure art” in the latter part of the nineteenth century may have been a beneficent phase after the exasperation of sensibility provoked by impressionism, but he affirmed that in the last analysis human art is doomed to sterility and failure if it cuts itself off from the existential world of nature and the universe of man.

The deepest concern of Maritain was with the nature of poetic knowledge and poetic intuition, that is, with the nature of the knowledge immanent in and consubstantial with poetry, poetry as distinct from art and quickening all the arts. He held that poetic knowledge is a typical instance of knowledge through connaturality. Poetic knowledge, as he saw it, is nonconceptual and nonrational knowledge; it is born in the preconscious life of the intellect, and it is essentially “an obscure revelation both of the subjectivity of the poet and of some flash of reality coming together out of sleep in one single awakening.” This unconceptualizable knowledge comes about, Maritain maintained, through the instrumentality of emotion, which, received in the preconscious life of the intellect, becomes intentional and intuitive, and causes the intellect obscurely to grasp some existential reality as *one* with the self (of the knower) reality has moved; and at the same time the knower grasps all that which this reality calls forth in the manner of a sign. In this way the self is known in the experience of the world and the world is known in

the experience of the self, through an intuition that essentially tends toward utterance and creation. Thus, in such a knowledge it is the object created—the poem, the painting, the symphony—in its own existence as a world of its own that plays the part played in ordinary knowledge by the concepts and judgments produced within the mind.

Poetic knowledge, then, is not directed toward essences, for essences are disengaged from concrete reality in a concept, a universal idea, and are an object for speculative knowledge. Poetic intuition is directed toward concrete existence as connatural to the soul pierced by a given emotion. In a passage of great beauty Maritain wrote:

This transient motion of a beloved hand—it exists an instant, and will disappear forever, and only in the memory of angels will it be preserved, above time. Poetic intuition catches it in passing, in a faint attempt to immortalize it in time. But poetic intuition does not stop at this given existent; it goes beyond, and infinitely beyond. Precisely because it has no conceptualized object, it tends and extends to the infinite, it tends toward all the reality, the infinite reality which is engaged in any singular existing thing. (*Creative Intuition in Art and Poetry*, p. 126)

Maritain was admired even by those who may be of very different philosophical convictions. He was admired not only for his lifelong zeal for truth and impassioned commitment to freedom but also for his exceptional qualities as a person—his humility, his charity, his fraternal attitude toward all that is. He came to be recognized as one of the great *spirituels* of his time.

MARITAIN, JACQUES  
[ADDENDUM]

Jacques Maritain died in Toulouse on April 28, 1973, as a professed religious of the Petits Frères de Jesus. His wife Raïssa had died in 1959 when the couple was visiting France and from that point on Maritain's center of gravity was once again Europe. In Toulouse, he taught the brothers of his community and the published works that resulted are almost exclusively theological. Thus, Maritain continued to surprise: the quintessential layman became a professed religious, the philosopher became a theologian.

His reputation with many suffered when he published *The Peasant of the Garonne* in 1966. In the immediate wake of the ecumenical council dubbed Vatican II, Maritain was severely critical of developing trends in the Catholic Church. Teilhard de Chardin and phenomenology were major targets of his criticism. Some saw in this a retrogression, remembering *Antimoderne*. It helps to distinguish Maritain's political views from his Catholic faith. He held the latter with unswerving orthodoxy from the time of his conversion. It was otherwise with his political views. His long association with *Action Française*, so difficult to reconcile with his earlier socialism, was followed by a resurgence of his natural liberalism in

political matters. The conservatism of the *Peasant* is theological, not political.

Negative reactions to the *Peasant* are eclipsed by the upsurge of interest in Maritain during the latter part of the twentieth century. The Jacques Maritain Center at Notre Dame was founded in 1958 and seemed destined to become the repository of Maritain's papers. The bulk of his papers are to be found in Kolbsheim, the home of the *Cercle d'études Jacques et Raïssa Maritain*. Under the general direction of René Mougel a magnificent sixteen volume *Oeuvres complètes* has appeared. There is another International Maritain Association centered in Rome under the aegis of Roberto Papini which has sponsored a score of publications and conferences, as well as a periodical, *Notes et Documents*. There are flourishing Maritain associations in Canada, the United States, and Latin America. Biographies have been written, collections of letters published, various monographs have appeared. A projected twenty volume set of Maritain's work in English is under way from the Jacques Maritain Center, whose web site at nd.edu can be consulted for other relevant materials.

Perhaps interest is strongest in his political, social, and aesthetic views. Given the contingency of the practical order this is surprising, perhaps, but would seem to attest to Maritain's knack of finding permanent values in the changing cultural landscape. His metaphysical views have their adherents still and there is a quickened interest on the part of physicists in Maritain's views of natural philosophy and natural science, as is evident in the institute founded by the physicist-philosopher Anthony Rizzi. Far from waning, interest in Maritain's thought seems to be increasing. For all that, it is perhaps not too much to say that it is his personality that continues to attract. Leon Bloy's line, "There is only one tragedy, not to be a saint," may seem a counter-cultural motto for a philosopher, but perhaps that is due to the all too exiguous character of recent philosophizing. In any case, as person as well as thinker, Jacques Maritain's influence is still strongly felt in the twenty-first century.

## MARKOVIĆ, SVETOZAR

(1846–1875)

Svetozar Marković was a Serbian socialist, philosopher, and publicist. After prolonged uprisings between 1804 and 1815 had liberated Serbia from Turkey, a cultural revolution took place, led by the reformer of the Serbian language and orthography Vuk Karadžich (1787–1864), and socialist ideas began to spread. The first Serbian socialist writers were the economist and philosopher Živojin Žujović (1838–1870) and Svetozar Marković.

After technical studies in Belgrade, Marković continued his education in St. Petersburg, where he attended the lectures of Dmitri Pisarev and became acquainted with the ideas of the Russian revolutionary democrats. Marković went to France in 1869 and then to Zürich, where he became acquainted with the Western revolutionary workers' movement and with the works of Karl Marx. Marković became the correspondent for Serbia and the Balkans of the Marxist First International. In 1870 he returned to Serbia, where he gathered about himself a circle of young intellectuals and workers. He published *Radenik* (The Worker; 1871–1872), the first socialist newspaper in the Balkans, and later the newspapers *Javnost* (The Public) and *Glas Javnosti* (The Public Voice). After nine months' imprisonment for violating the press law, Marković, who had become seriously ill, was set free in 1875. He began publishing a new newspaper, *Oslobodjenje* (Liberation), but shortly afterward he died in Trieste.

The basic determinant of Marković's thought and activity was the Serbian social situation. The disoriented rural paupers and the small and unorganized urban proletariat had repudiated the patriarchal social order, but

they disagreed on the means of improving their lot. In search of ways to solve the social problems of his countrymen, Marković developed a socialist ideology. This theory was greatly influenced by the Russian revolutionary democrats Nikolai Chernyshevskii, Nikolai Dobrolyubov, and Pisarev, and later by Marx, but its main sources were materialist philosophy and the natural sciences—French eighteenth-century materialism (particularly Baron d’Holbach, Denis Diderot, and Jean Le Rond d’Alembert); the vulgar materialism of Friedrich Büchner, Karl Vogt, and Jacob Moleschott; the positivism of Auguste Comte and John Stuart Mill; and the scientists Charles Darwin, Ernst Haeckel, Wilhelm Wundt, and Ivan Mikhailovich Sechenov, the Russian physiologist. There are also traces in Marković’s thought of the utopian socialists the Comte de Saint-Simon, François Marie Charles Fourier, and Étienne Cabet, as well as of other socialists such as Pierre-Joseph Proudhon and Louis Blanc.

#### ATHEISM AND MATERIALISM

Lacking a deep and systematic philosophical and sociopolitical education, Marković did not intend to become a philosopher or a literary figure but strove to be the ideologist and spiritual leader of a new trend in science and life—a publicist and propagator of new ideas. Nevertheless, his theoretical outlook was relatively original and presented an integral whole.

Marković’s ideology embraced first of all the general principles of scientific atheism and natural-philosophical materialism expressed in the study “Realni Prava u Nauci Iživotu” (The Realistic Trend in Science and Life; in the journal *Letopis Matice Srpske*, 1871–1872) and other works. From Chernyshevskii and Marx he borrowed the notion of the need for building up a philosophical theory as the basis of sociopolitical knowledge and practice. He called his view “scientific materialism and realism.” All phenomena, as well as the processes of nature, society, and spiritual life, were interpreted in terms of matter and its laws. Nature and society were integrally connected. Only by means of science was the people’s economic and political revival possible. Marković, like Marx, contrasted his view with Bakunin’s. In spite of certain elements of mechanism and agnosticism in his outlook, Marković advocated the idea of dialectical development and an evolutionistic-materialistic theory of knowledge as the basis of the social struggle of the socialist movement.

In his interpretation of man and society, Marković drew upon Darwin, Comte, the French materialists, Ludwig Feuerbach, and Chernyshevskii. Morals is founded on

knowledge and science, and the development of morals is affected by the development of man’s needs through the socialization of instincts. Moral feelings are not innate; man becomes individually moral and socially more morally minded as society develops. Only by constant labor can man raise himself to a height unreachable by any other organism. Marković condemned the morals of bourgeois society as being founded upon the exploitation of the lower classes. Because morality is the indispensable consequence of the social machine, only a socialist revolution can bring about a new socialist morality. Seeing the primary goal of the future socialist society as the morality of its members, Marković termed his ethical socialism “idealistic realism.” He did not conceive of the idea as being determined by matter, but spoke of the idea as the primary motive force in the development of society.

#### AESTHETICS

Believing that a spiritual revolution must precede the political and economic revolutions, Marković held that the social revival had to be supported by literature and art. In “Pevanje i Mišljenje” (Songs and Thought; *Matica*, 1868), “Realnost u Poeziji” (Reality in Poetry; *Matica*, 1870), and many other works, Marković expounded a materialist aesthetic modeled upon that of Chernyshevskii. Literature should be realistic and rational, expressing the genuine life, needs, and interests of the people, and should have an effect upon the general social revival. Marković’s views decisively affected the development of Serbian literature, turning it toward Russian and western European realism.

#### SOCIOPOLITICAL VIEWS

In his voluminous book *Načelo Narodne Ekonomije* (The principles of the national economy [Belgrade, 1874]), written in the vein of J. S. Mill and Chernyshevskii, Marković praised Marx for his discovery of the law of social development, but he held that these laws could not be applied to Russia, Serbia, and other economically undeveloped countries, which, in Marković’s opinion, could bypass capitalism and move from patriarchal cooperatives directly to socialism. Marković’s teachings on society, state, and revolution, in spite of some elements of utopianism and historical idealism, showed a high degree of accuracy. Although he gave too much weight to the roles of social consciousness, science, and philosophy, and consequently to the revolutionary intelligentsia, in the development of socialist society, his program was revolutionary and democratic. In a series of works, especially in his most original work, *Srbija na Istoku* (Serbia in the East

[Novi Sad, 1872]), Marković defended the Paris Commune and criticized the capitalistic social system of western Europe and the narrowness of the bourgeois democracies. Marković was convinced that the transition to socialism was possible only by means of a revolution of the whole people against foreign invaders and native capitalist exploiters. He developed a fragmentary theory of the smashing of the bourgeois state in the socialist revolution and the withering away of the socialist state in the process of building communism. Like Marx, he held that only in conjunction with revolutionary practice could revolutionary theory solve the social problem. He perceived the significance of the class struggle in the West, but in backward Serbia he thought that the revolutionary intelligentsia could play a more decisive role than the proletariat. He advocated federation and self-government for the southern Slav nations. He also advocated a system of cooperatives.

Although Marković was more a revolutionary democrat than a Marxist, his teachings nevertheless united general Marxian principles concerning revolution with theories concerning the specific national character of Serbia. Moreover, they stressed the need for joint action on the part of the revolutionary intelligentsia, the peasantry, and the workers. Thus, Marković was the founder and leader of the Serbian socialist movement, as well as its theoretician, philosopher, aesthetician, and literary critic.

## MARSILIUS OF INGHEN

(1340–1396)

Marsilius of Inghen was a scholastic theologian, writer on logical textbooks, and prolific commentator on Aristotle. He played an important role in the foundation of the University of Heidelberg. His significance rests not only on his commentaries on Aristotle—his advocacy and popularization of the new, nominalist logic and semantics—but also on an independent-minded theology that sometimes rejected post-Scotistic positions in favor of thirteenth-century positions (such as those of Thomas Aquinas or Bonaventure).

Marsilius of Inghen was a student at Paris, matriculating there in Arts in 1362, and then in Theology in 1366. At Paris, he was influenced by the thought of John Buridan, and he undertook significant administrative work, including rectorships (1367–68, 1371) as well as representation to the Papal court (1369, 1377–78). Marsilius's whereabouts are largely unknown between 1379 and the founding of the University of Heidelberg in 1386—except, that is, for a Nijmegen banquet he attended in 1382. From 1386 to 1392, he was a Master at Heidelberg—and was also an occasional Rector—up until his death in 1396 (Hoenen 1993, pp. 7–11; Santos Noya, 2000, Vol. 87, pp. 1–26).

He read the Sentences (the standard requirements to become a Master of Theology) from 1392 to 1394. Part of the preparation for this commentary was most likely done in Paris from 1367 to 1377. (Hoenen and Braakhuis 1993, pp. 39–57; Santos Noya 2000, Vol. 87, pp. 31–32).

Marsilius was a nominalist on universals. Like Ockham and Buridan he did not believe that universals exist outside the soul, and that the direct object of each science is merely the proposition in the mind. Real objects, he believed, are the objects of sciences via the signification of

the proposition. Marsilius's logic and semantics can be described reliably as Buridanist, albeit with some points of dissent and less detail. As well, he differed from Buridan on the division of supposition, the signification of chimera, his definitions of *ampliatio* and *appellatio*, and his non-adoption of *suppositio naturalis* (Bos 1983, p. 254).

Marsilius's natural philosophy is empiricist; he holds that the starting point of natural philosophy is sense data and per se known principles. From this point he then leaps from singular observations to a universal proposition if there is no expectation of a counterexample—due to the mind's inclination to truth. Thus, a causal connection can be held to be universal, though one has not experienced all its instances.

In his theology, he criticized both the Scotistic position that the Divine Ideas are formally distinct from the Divine Essence, and the Ockhamist thesis that the Ideas are identical with the objects that are known. He held the Thomistic theses that God's Ideas of created things are not distinct from his essence and that the difference between the divine attributes exists only in the human mind due to its finitude. He also held that natural reason can prove that God is the cause of all and knows created things. Marsilius brought together the critical semantico-logical tradition of the fourteenth century and the themes of thirteenth century theologians such as Aquinas and Bonaventure (Hoenen 1993, pp. 235–253).

In the fifteenth and sixteenth centuries, he was regarded as a great advocate of nominalism, and grouped with Buridan, Ockham and Gregory of Rimini. His logical treatises exist in many manuscripts, and were widely used as textbooks in the fifteenth century. His theology of grace and divine foreknowledge was well known and quoted by late-scholastic writers such as Vitoria, De Soto, Molina, and Suarez. His Aristotelian commentaries were also well known and cited up to the early-modern period. For example, both Leonardo da Vinci and Galileo Galilei refer to his commentary on Aristotle's *De Generatione et Corruptione*.

## MARSILIUS OF PADUA

(c. 1275/1280–1342)

Marsilius of Padua (Marsilio dei Mainardini), an Italian political theorist, was born between 1275 and 1280 and died in 1342. He probably studied medicine at the University of Padua. In 1313 he was rector of the University of Paris, where he met such leading Averroists as Peter of Abano and John of Jandun. He is chiefly famous for his antipapalist treatise *Defensor Pacis* (Defender of peace; 1324), a landmark in the history of political philosophy. When his authorship of this work became known in 1326, he was forced to flee to the court of Louis of Bavaria in Nuremberg; Pope John XXII thereupon branded him a heretic. Marsilius subsequently assisted Louis in various imperial ventures in Italy.

### DEFENSOR PACIS

The primary purpose of the *Defensor Pacis* was to refute the papalist claims to “plenitude of power” as these claims had been advanced by Pope Innocent IV, Egidius of Rome, and others in the thirteenth and fourteenth centuries. So crushing was the refutation produced by Marsilius that it completely reversed the papalist position. The papal position had held that secular rulers must be subject to the papacy even in “temporal” affairs, so that they must be established, judged, and, if necessary, deposed by the pope. Marsilius, in contrast, undertook to demonstrate that the papacy and the priesthood in general must be subject not only in temporal, but even in “spiritual,” affairs to the whole people and to the secular ruler acting by the people's authority. The powers of the

priesthood were to be reduced to the administration of the sacraments and the teaching of divine law, but even in these functions the priests were to be regulated and controlled by the people and its elected government. The upshot of Marsilius's doctrine was that the attempt to base human society on religious values under priestly control was decisively overthrown; instead, the way was opened for a purely secular society under the control of a popularly elected government. Hence, it is understandable that Marsilius has been hailed as a prophet of the modern world. His treatise exerted a marked influence during the period of the Reformation.

**THEORY OF THE STATE.** Equally as important as these revolutionary conclusions are the premises from which Marsilius derived them. These premises are found in his general theory of the state, which is noteworthy for its fusing of three distinct themes. The first is the Aristotelian teleological view of the state as subserving the good life. The various parts of the state, including government, are defined by the contribution they make to the rational "fulfillment" of men's natural desire for a "sufficient life." This fulfillment proceeds through the "proper proportioning" of men's actions and passions, ranging from nutritive and sensitive acts to appetitive and cognitive ones. The function of government is to regulate men's transitive acts in accordance with the law as a standard of justice. The first theme, then, stresses an affirmative and maximal utilitarianism—what is required for the attainment of the highest ends of the "sufficient life," the common benefit, and justice.

The second theme of Marsilius's political theory, in contrast, is a negative and minimal utilitarianism. It emphasizes the inevitability of conflicts among men and the consequent need for the formal instrumentalities of coercive law and government in order to regulate these conflicts. Without such regulation, Marsilius repeatedly insists, human society itself must be destroyed. In developing this theme, Marsilius presents a positivistic concept of law, which stands in contrast with his nonpositivistic conception of justice (a distinction often overlooked in discussions of his ideas). He holds that there are objective criteria of justice, which he characterizes in terms of Aristotle's analysis of rectificatory justice—moderating the excesses of men's transitive acts and "reducing them to equality or due proportion," thereby promoting the common benefit. But whereas Marsilius views law as a system of general rules concerned with the regulation of the same "excesses" and the resultant conflicts, as well as with other matters bearing on the common benefit, he emphasizes that these legal rules need not be based on "true cog-

nitions of justice." On the contrary, laws may be based on "false cognitions of the just and the beneficial," so that Marsilius, unlike most medieval political philosophers, holds that justice is not a necessary condition of law. What is necessary is that the legal rules have coercive force, such that with regard to their observance "there is given a command coercive through punishment or reward to be distributed in the present world." These rules and the government that enforces them must be unitary in the sense that, if a society is to survive, it cannot have two or more rival coercive bodies of law and government.

The third theme of Marsilius's political theory is that the people is the only legitimate source of all political authority. It is the people, the whole body of citizens or its "weightiest part," that must make the laws either by itself or through elected representatives, and it is also the people that must elect, "correct," and, if necessary, depose the government. Marsilius presents many arguments for this republican position: (1) The whole people is intellectually and emotionally superior to any of its parts, so that only from its choice will emerge the best law and government, the ones most conducive to the common benefit, as against the ones that subserve the interests of some special group; (2) self-legislation is necessary for individual freedom; (3) only if the laws and government are chosen by the people will they be obeyed; and (4) that which affects all ought to be subject to approval by all.

Although all three themes of Marsilius's general political theory were found in earlier medieval political philosophers, no other philosopher had given the second and third themes as central a position as did Marsilius. As a result of this, although Marsilius's first theme—about the ends of the "sufficient life," the common benefit, and justice—persists throughout his treatise, it is overshadowed by his emphases on coerciveness as the essence of political authority and on the republican bases of all such authority. The full consequence of these emphases emerges in the applications he makes of his general political theory to the problems of ecclesiastical politics.

**APPLICATIONS OF THE THEORY.** In keeping with his first theme, Marsilius views the Christian priesthood as one of the parts of the state dedicated to achieving the "sufficient life" for all believers. Unlike the other parts of the state, however, the priesthood subserves the "sufficient life" to be attained primarily "in the future world" rather than the present one. Like the other Averroists, Marsilius manifests skepticism about the rational demonstrability of such a future life; nevertheless, he offi-

cially accepts the Christian doctrine that the future life is superior to the present life. He also holds, however, that secular and religious values are in basic opposition; here he seems to be applying in the realm of the practical the Averroist doctrine of the contrariety of reason and faith in theoretic philosophy.

Taken in conjunction with the maximal, affirmative utilitarianism of his first theme, accepting that the priesthood subserves the highest end of man would have required Marsilius to accept also the papalist doctrine that the “secular” government, subserving the lesser end of this-worldly happiness, must be politically subordinate to the priesthood. At this point, however, Marsilius’s second and third themes have their effect. Since the essence of political authority is the coerciveness required for the minimal end of preserving society, it follows that the higher end subserved by the priesthood does not entitle it to superior political authority. The question of the order of political superiority and inferiority is thus separated from the question of the order of moral and religious values. What determines the order of political authority is not the greater excellence of one end over another but, rather, the specifically political need for unified coercive authority in order to prevent unresolved conflicts from destroying society. Hence, the secular government, as bearer of this coercive authority, must be politically superior to the priesthood. If the priests refuse to obey the government and its laws, then they must be compelled to do so, because such disobedience threatens that unity of coercive authority without which society cannot survive. Indeed, it is because of this disobedience and because of its claim to a rival, superior “plenitude of power,” that Marsilius convicts the papacy of being the gravest enemy of civil peace. In this context Marsilius presents his whole critique of the papacy as an application to fourteenth-century conditions of Aristotle’s book on revolutions (*Politics* V), dealing with the ways in which threats to civil peace may be avoided.

In addition to this political argument against diverse centers of coercive power in any society, Marsilius also stresses, from within the religious tradition itself, that religious belief, in order to be meritorious, must be purely voluntary. Hence, in order to fulfill its mission, divine law and the priesthood that teaches and administers it cannot be coercive in this world.

Marsilius’s third theme, republicanism, also plays an important role in the political subordination of the priesthood and papacy. The only rules and persons that are entitled to the status of being coercive laws and government officials are those ultimately chosen by the peo-

ple; hence, there can be no crediting the claims of divine law and the priesthood to a separate derivation of coercive political authority from God. It is true that Marsilius subsequently holds that secular rulers govern by divine right, but he views this only as a divine confirmation of the people’s ultimate electoral authority. This republicanism operates not only in the relation of the priesthood to the secular state but also in its relation to religious affairs. Because the whole people is superior in virtue to any of its parts and because freedom requires popular consent or election, the priesthood itself must be elected by the people of each community rather than being appointed by an oligarchically chosen pope, and the pope himself must be elected by the whole of Christendom. Similarly, the whole people must elect general councils to provide authoritative interpretations of the meaning of divine law. In these ways Marsilius’s general political theory leads to a republican structure for the church as against its traditional monarchic structure. In effect, this also means that the secular government, acting by the people’s authority, secures hegemony over the priesthood and papacy in all spheres.

### **Bibliography**

- The *Defensor Pacis* is available in two critical editions, one edited by C. W. Previt -Orton (Cambridge, U.K.: Cambridge University Press, 1928) and one edited by Richard Scholz, 2 vols. (Hanover: Hahn, 1932–1933), in the series *Fontes Juris Germanici Antiqui* of the series *Monumenta Germaniae Historica*. There is an English translation by Alan Gewirth, *Defensor Pacis* (New York: Columbia University Press, 1956). A comprehensive bibliography of studies published to about 1950 of Marsilius’s doctrines is contained in Alan Gewirth, *Marsilius of Padua and Medieval Political Philosophy* (New York: Columbia University Press, 1951), pp. 323–326. Bibliographical information on subsequent studies will be found in Georges de Lagarde’s important study, *Marsile de Padoue*, 2nd ed. (Paris, 1948), which is in the series *La naissance de l’esprit laique au d clin du moyen  ge*, 3rd ed. (Paris, 1959–).

**Alan Gewirth (1967)**

## MARSILIUS OF PADUA [ADDENDUM]

In order to understand Marsilius more fully, it is useful to examine both the classical influences upon his work and

the ways he applies his own principles in the minor works such as *Defensor Minor* and *De Translatione Imperii*.

### MARSILIUS AND CICERO

Most discussions of *Defensor Pacis* concentrate upon Aristotle's *Ethics* and *Politics* (which had become available in translation around 1250 and 1260, respectively). Indeed, Marsilius employs the Aristotelian distinctions of the healthy types of civil constitution: monarchy, aristocracy, and polity and their complements the diseased constitutions: tyranny, oligarchy, and extreme democracy. However, though Aristotle is certainly the primary source of many of the distinctions in Part I of *Defensor Pacis*, there are other key influences as well. Among these is Cicero's doctrine of natural duty to others from his *De officiis*. Cary Nederham has argued that this sense of natural duty is the secular analogue to theological or Christian duty. The use of parallel justifications for why a person should be committed to the community follows the general structure of the book in which Part I creates a secular justification for politics whereas Part II elaborates the foundations of ecclesiastical duty.

The secular duty to the community is a natural duty so that every person in the state must fulfill the duties of friendship and of civic society—without regard to personal welfare. This duty extends to a concern for others and a duty to rescue and assist those in need. Because the source of the duty is natural to all people, there is no national restriction on this duty. Thus, it commits each person to exhibit concern beyond his own society to others internationally.

### DEFENSOR MINOR AND DE TRANSLATIONE IMPERII

These works are more conventional and do not contain the split presentation of secular argument and theological exposition that characterized *Defensor Pacis*. These minor works are more conventional dealing with parsing the jurisdictions of theology and secular government. Though these works are not as well known as the *Defensor Pacis*, they are useful to help put Marsilius's major work into perspective. For example, one of the possible motivations for Marsilius's antipapal rhetoric (though Marsilius, himself, was a priest) might be Marsilius's alliance with the Bavarian King Ludwig IV. Ludwig wanted to expand his empire and move into Italy. (It should be remembered that at this time the Pope resided in Avignon, France.) Marsilius's writing was associated with Ludwig, who appointed Marsilius as spiritual vicar of Rome and himself as the Roman Emperor. However,

this situation was short lived and soon both fled back to Germany.

The *Defensor Minor* and *De Translatione Imperii* fit into this context. They apply principles of *Defensor Pacis* to contemporary problems. For example, papal authority is questioned in regard to Ludwig's plan to marry his daughter to a close relative in order to stabilize his political prospects. Both Marsilius and William of Ockham were to weigh in on this question as an issue of authority. In *Defensor Minor* no new positions are forged, but are fine tuned so that they might be applied to cases such as the marriage of Ludwig's daughter.

Another example concerns the bogus "Donation of Constantine." In this forged document the Roman Emperor Constantine supposedly granted the whole of the Roman Empire to the Pope who, in turn, allowed the daily duties of running the secular to fall upon the emperor. This document sought to establish a legal claim for the pope's universal secular power. Marsilius argues against the Donation in both *Defensor Pacis* and *De Translatione Imperii*.

Michael Boylan (2005)

## MARSTON, ROGER

(c. 1250–1303)

Roger Marston, the Augustinian Scholastic, was born in one of England's Marstons. He was educated at the Faculty of Arts and Theology at the University of Paris about 1270 and taught at Oxford and Cambridge between 1276 and 1285. He was the provincial of the English Franciscans between 1292 and 1298.

Marston's career may be characterized as a conscious effort to restore St. Augustine to his position as the great leader of Christian philosophers and theologians. In carrying out the proposals of his teacher, John Peckham (also an Augustinian), Marston exhibited a phenomenal knowledge of the writings of Augustine, as well as a fine sense of historical and textual criticism. He must have been attacked as an archconservative, because he defended himself by remarking that he did not cling to tradition out of mere habit, but that after a reasonable scrutiny of the evidence, he had formed opinions that harmonized the writings of the "saints" with the wisdom of the philosophers. Marston knew the Greek and Muslim philosophers, and interpreted them with a great deal of subtle skill, sometimes calling attention to fundamental ambiguities in their thought.

Marston needed all the resources at his command to counter the attacks directed against the Augustinian theory of divine illumination, which he deemed necessary to explain certitude. Since the attacks were made under the guise of Aristotle's authority, Marston attempted to reconcile Augustine's theory of knowledge with that of Aristotle, as seen through the latter's Islamic commentators. Thus, Roger claimed that the Eternal Light of Augustine is the same as the separate agent intellect of Avicenna and Averroes. However, the English friar would not allow man to be "dispossessed" of his own individual agent intellect, and hence he posits a double agent intellect: divine and human. This was one of the medieval solutions to the idealist-empiricist dilemma.

In the realm of the philosophy of nature, there was one doctrine of Thomas Aquinas to which Marston took serious exception—namely, the Thomistic contention that each individual being had but one form. Prior to Thomas, the far more common opinion had been that in material beings there was a plurality of forms. In man there were the forms of "vegetivity," "sensitivity," and "rationality," corresponding to the human functions of nutrition, sensation, and thought. Marston's solution to the question introduced a refinement that amounted to a synthesis of the Thomistic and traditional solutions,

although it favored the latter. There is one substantial form for each being, but that single form admits of various subordinate and persisting degrees, or grades. Marston's theory of the grades of the form is the first organized version of this theory that has come down to us from the Middle Ages.

With respect to the majority of his philosophico-theological tenets, Marston followed the lead of Bonaventure. With Bonaventure (and against Thomas), he considered an eternal creature an impossibility. Prime matter can exist apart from all forms by divine intervention, because God is the "Form of all things" who conserves his handiwork just as water conforms to the intricate convolutions of a mold, as long as it is contained by the mold. On the subject of God's foreknowledge of future human acts—a perennial problem in Christian philosophy—Marston remarks that since an individual's memory of a past event does not constrain his free will with regard to the past, neither does God's foreknowledge constrain his free will with regard to the future.

For a medieval, Marston has an unusually personal style, and his remarks are often a source of valuable information for the historian.

## MARTINEAU, JAMES

(1805–1900)

James Martineau, an English philosopher and religious leader, was born in Norwich. He was a brother of Harriet Martineau, the novelist and economist. James Martineau attended school in Norwich and Bristol and went on to study for the ministry under the Unitarian auspices of Manchester New College at York. He accepted a call to a congregation in Dublin in 1828 and was married later the same year. In 1832 he became minister to a dissenting congregation in Liverpool. He occupied this post for twenty-five years, but for most of that period he was also teaching philosophy and other subjects at Manchester New College, and when the college was moved to London in 1857, he moved with it. From 1869 to 1885 he served as principal of the college. Despite the criticism aroused by his views on religious and theological matters, he was regarded as the foremost spokesman of Unitarianism in England and was revered by many in other religious groups as well for his impressive contributions to the literature of hymn, private prayer, and sermon.

In accordance with the then prevailing tendency of Unitarian thought, Martineau was brought up to accept the doctrines of associationism, egoism, and necessitarianism as taught by David Hartley and Joseph Priestley. In his early teaching he used works by James Mill and Thomas Brown as texts, but the difficulties he had in defending their views, together with his own growing sense of the inadequacy of their philosophy as a basis for a Christian outlook, led him rapidly toward a new general position. By 1839 he concluded that necessitarianism was incompatible with that sense of "the personal origin and personal identity of sin" which is central to Christianity. During the next half-dozen years he worked out the implications of this point. The results were first published in 1845 and 1846 in two long reviews (reprinted in *Essays, Reviews, and Addresses*) that outlined the positions he was to develop and defend for the rest of his life. Although he learned much from a year of study in Berlin in 1848 and 1849, German philosophy did not really change his thought. He remained far more a follower of Bishop Butler and Thomas Reid than of Immanuel Kant or G. W. F. Hegel.

At the basis of all of Martineau's constructive thought is the view that we must accept as true certain deliverances of consciousness that appear to give us directly information about the external world, the self, and morality. Neither Kant nor William Hamilton nor J. S. Mill seemed to him to have given us reason to distrust the intuitions of the mind, and since these intuitions present themselves as reliable, we are entitled to have faith in them until reasons against them are produced. Martineau's intuitionism is the philosophical counterpart of the very great emphasis he placed, in interpreting religion, on personal religious experience. It is in such experience, he held, that one must look for revelation, not in messages delivered by others nor in traditions preserved by organized groups. Philosophically, both epistemology and ethics lead directly to justifications of religious belief.

From the very start of knowledge, Martineau argued, we are aware of a self and a not-self, and we are aware of these not as simply passively there but as being actively related. We thus intuit ourselves as willing and the world, in turn, as an expression of will. The former intuition is at the basis of our understanding of causality, which cannot be explained in terms of succession of phenomena, and the idea of causality finds its mature expression in the belief that God is the noumenal cause of the phenomenal order. Science, which deals only with phenomena, cannot upset our belief in God, but the increasing unity of the laws and theories that science discovers acts as a confirmation of our intuitive belief in the unity of the cause of nature.

If the "natural" attributes of God, such as omnipotence and intelligence, are revealed through our experience of the external world, the moral attributes are revealed to us primarily in our moral experience. Martineau argued very carefully that the central subject of moral judgment is motives or "springs of action," not acts or consequences. He held that whenever there is more than one motive competing to direct our action, we are intuitively aware that one of the motives is higher than the others.

"The moral faculty," he said, "is not any apprehension of invisible qualities in external actions, not any partition of them into the absolutely good and absolutely evil, not any intellectual testing of them by rules of congruity or balances of utility, but a recognition, at their very source, of a scale of *relative* values lying within ourselves," relative because a given motive may be higher in relation to one alternative, lower in relation to another. To be good is to choose to act on the relatively higher motive. Once this choice is made, consideration of consequences

comes in to aid in selecting the particular act that will best express the motive in the actual circumstances. It is the first choice only that is morally relevant, though the second is, of course, important. Since the moral value of both agent and act is wholly determined by his choice of motive, Martineau went to considerable pains to defend absolute freedom of the will. The arguments rely heavily on the concept of cause developed in his epistemology. In our own willing we learn something of the nature of God's activity; the realization that there is an authoritative demand on us to act on the relatively higher motive is the chief revelation of God within our moral experience. The authoritativeness of the demand can be explained only in theistic terms, and the content of the demand reveals to us God's moral nature.

Martineau's style is extremely florid and his exposition quite diffuse. In his epistemological and metaphysical writings he seems often to have missed the point of an opposing theory or to have been content with very weak arguments for his own. But his ethics, as an account of the ethics of motive, if not highly original, is in conception and in execution one of the finest that has ever been presented.

## MARTINETTI, PIERO (1872–1943)

Piero Martinetti, an Italian metaphysician, was professor of theoretical philosophy at the University of Milan from

1906 until 1931, when he resigned in protest against the oath imposed on university professors by the Fascist regime.

Martinetti sought to reestablish metaphysics as a valid science by a method whose validity would have to be recognized even by positivists. This project involved a refutation of positivism on its own grounds. The positivist attack on metaphysics, Martinetti claimed, is valid only against vulgar or dogmatic metaphysics. Scientific metaphysics meets all the requirements of scientific methodology. It adheres to data that all science must recognize; but it is no mere synthesis of the sciences, for it interprets scientific findings and determines their meaning rather than their mere truth. Consequently, a scientific metaphysics would achieve, on a posteriori grounds, successive unifications of empirical data until the Absolute was achieved.

The first of the successive levels in this projected unification is that of the "I" or self as a unity of sensuous consciousness. This is the constant flux of sense perception, the central point around which all perception is synthesized. At this stage no distinction is made between subject and object. The self at this level possesses a rudimentary transcendental character in the invincible conviction that its sense perceptions are identical with those of all possible subjects, but this persuasion is itself a mere datum.

This intimation of the transcendental and a priori provides a means of passage to the next level of synthesis, the logical level. But the a priori forms of synthesis are not a priori in the Kantian sense; they are "con-natural" with their empirical content. Among these forms are substance and cause, which unify respectively the coexistent and the successive. The movement from the sensible forms of unity to the logical forms is not itself a logical process; rather, it is entirely natural. Logic is the "science of the natural conformations of human thought," and logical relations are therefore empirical relations.

The third stage of synthesis, that of absolute unity, cannot be achieved in thought; it is implied in the dynamic of thought. We can have no speculative concept, but only a symbolic intuition, of it. However, it cannot be concluded, therefore, that our knowledge is limited to phenomena. The absolute unity is always present, although in an imperfect way, because it enters structurally into all levels of synthesis. This omnipresence of the Absolute Martinetti called mystical: "Our knowledge is a mystic unity with the eternal Logos."

This process of synthesis applies also to the practical order, whose transcendental principle is liberty. Morality exhibits a primary synthesis in the form of necessity freely achieved—a synthesis that is continued and extended by art and religion.

## MARTY, ANTON

(1847–1914)

Anton Marty was a professor of philosophy at the German University of Prague and for forty years a close associate of Franz Brentano. Marty's most important work is the *Untersuchungen zur Grundlegung der allgemeinen Sprachtheorie* (Halle, 1908), a treatise on the philosophy of language. His theory of meaning, or "semasiology," is based upon Brentano's descriptive psychology. From a contemporary point of view, the most interesting aspects of this theory are the distinction between categorematic and syncategorematic uses of words and the theory of emotive utterances.

Like Brentano, Marty appeals to the correctness of affirmation and rejection, and of love and hate (in a broad sense) to explicate the syncategorematic character of certain basic philosophical concepts. In the assertion "There is a horse," the words "a horse" refer to an object, but the words "there is" serve only to express the fact that the speaker is accepting or acknowledging the object. An object is said to have being if it may be correctly accepted; it has nonbeing if it may be correctly rejected; it is good if

it may be correctly loved; it is bad if it may be correctly hated; the necessary is that which may be correctly accepted a priori; the impossible is that which may be correctly rejected a priori.

Marty rejected the view of Bernard Bolzano and Alexius Meinong, according to which there are objects that may be said to “subsist” and not to “exist.” But he did contend that the objects that may be said to “exist” may be classified as being either “real” or “nonreal.” Examples of nonreal objects that exist are gaps, deficiencies, holes, space, time, and what Marty called the content of a judgment. (If the judgment “There are horses” is correct, then there exists that nonreal object that is the being of horses; if it is incorrect, then there exists that nonreal object that is the nonbeing of horses.) According to Marty, nonreal objects have no causal efficacy, and their existence is always a function of the existence of certain concomitant real objects. Brentano objected to this view on the ground that sentences ostensibly referring to such nonreal objects may be translated into sentences referring only to the real objects that Marty conceded to be their concomitants (“There is an absence of food in the larder” serves only to express the rejection of food in the larder) and that hence all such “irrealia” are superfluous. But where Marty restricted “real” to a subclass of things that exist, Brentano said that judgments about unicorns are also judgments about “real objects”; these judgments are about things that, if they were to exist, would be real (in Marty’s sense of “real”).

The word *good*, according to Marty, serves to express one’s love of an object; “bad” serves to express one’s hate of an object. Marty discussed the emotive function of ethical sentences in detail and noted the ways in which such sentences are related to commands, recommendations, questions, and optatives. However, unlike contemporary emotivists, Marty held with Brentano that the emotions expressed and incited by ethical sentences are emotions that are either correct or incorrect; his theory of ethical sentences could thus be said to be emotive and also objective. He discussed in detail the relations among emotive and nonemotive sentences and the respects in which sentences of the one type may presuppose sentences of the other (for example, a man who calls “Stop thief!” asserts implicitly that there is a thief and that he is trying to get away).

## MARULIĆ, MARKO

(1450–1524)

Marko Marulić, the Croatian poet, historian, and philosopher, was born in Split, Dalmatia. Marulić’s epic, *Istoriya Svete Udovice Judit* (The History of the Holy Widow Judith; Vinegia, 1521), is the oldest Croatian epic and the first printed Croatian literary work. Like all of Marulić’s poetry, it is both epic and didactic. Marulić’s philosophical works were written in Latin and translated into German, French, Italian, Portuguese, and other languages. His *De Institutione Bene Beateque Vivendi per Exempla Sanctorum*, first published in Venice in 1506, was reprinted, in the original or in translation, fifteen times in the sixteenth and seventeenth centuries. His *Evangelistarium* (Venice, 1516) was printed nine times.

Marulić was influenced by the Renaissance humanists and was also a student of the classical Greek philosophers, but he was at the same time an outstanding representative of then-modern Christian philosophical thought. He enriched Christian moral teaching with the abundant wealth of Stoic-Platonic moral thought and revived traditional philosophy in the spirit of humanism. Marulić regarded Epicurean and Stoic ethics as antithetically opposed and Stoic ethics as superior to Epicurean. In general, he rejected all forms of hedonism and utilitarianism, and with them ethical subjectivism and relativism.

Marulić’s exposition of a Christian ethics combined with elements of Stoicism and Platonism was enlivened by examples from life. This original synthesis of ancient elements, rejuvenated by humanism, was greatly appreciated in its day, especially for its service in the Catholic fight against the Reformation. Although ethical problems

were Marulić's main concern, he also considered the fundamental problems of philosophy.

### **Bibliography**

For additional philosophical works by Marulić, see *Quinquaginta Parabolae* (Venice, 1510); *De Humilitate et Gloria Christi* (Venice, 1519); and *Dialogus de Laudibus Herculis a Christianis Superacto* (Venice, 1524).

For works on Marulić, see *Zbornik Marka Marulića 1450–1950* (Zagreb, 1950), a commemorative volume honoring Marulić, published by the Yugoslav Academy of Arts and Sciences, with a complete bibliography of Marulić's works and of works about his life and writings.

*Vladimir Filipović (1967)*

## MARX, KARL

(1818–1883)

Karl Marx was born in 1818 in the small German city of Trier in the Rhineland, then part of Prussia. He died in 1883 in London. His life thus spanned the better part of the nineteenth century, a time of rapid and profound economic, social, and political change in Western Europe and America. Philosophically, Marx can be seen as both the culmination of the tradition of German Idealism and its end. In this latter sense, and because most of his work consists of political, economic, and historical analysis, Marx has been taken as having moved beyond purely philosophical interests and investigations into the empirical realms of the social and historical sciences.

The primary goal of Marx's life and work, of course, was to facilitate the revolutionary overthrow of the capitalist system and to help give birth to the socialist society that he believed would inevitably follow the demise of capitalism. In the broadest sense, the project was to achieve the promise of human emancipation, a theme Marx inherited from Kant and Rousseau through German Idealism. Essential to this project was the understanding of the nature and limits of human reason, particularly as embodied in social institutions, a theme of critique also derived from Kant. Marx did not truly leave philosophy behind; he remained a philosopher whose project of liberation led him to increasingly empirical analyses of capitalist society and history. His central con-

cerns are freedom, alienation, and critique, themes at the center of the tradition of German Idealism.

### LIFE

Marx came from a Jewish family with rabbinical roots on both his paternal and maternal sides. His father, however, broke with his family and converted to Lutheranism. Karl, his eldest son, was baptized in 1824. After a year studying law at the university in Bonn, Marx transferred to the university in Berlin to study philosophy. He received his doctorate from the University of Jena in 1841, but because of his close association with the radical Young Hegelians, he was unable to secure an academic appointment. Instead of pursuing a career in philosophy, he began to work as a journalist, the only career in which he ever earned any income. Increasingly engaged in the radical politics of the day, in 1843 he moved to Paris, the political heart of Europe, where he did his first serious work in the relatively new field of political economy as well as continuing his critical work on Hegel. This early work, *Economic and Philosophic Manuscripts*, unfinished and not published until 1932, is important to understanding the transformation of Marx the Young Hegelian philosopher into Marx the historical materialist. These manuscripts contain his most extended discussion of alienation, a discussion that helps shed light on how this concept was developed in his later writings, including *Capital*. It was also at this time that Marx established his lifelong friendship and collaboration with Frederick Engels.

While living in Brussels from 1845 to 1848, Marx made his final break with Hegel and the Young Hegelians, including Feuerbach. The two most important pieces of work from this period were the "Theses on Feuerbach" and *The German Ideology* (in collaboration with Engels). Neither was published in Marx's lifetime. These works are often regarded as the first statements of historical materialism and related ideas that would be further developed in Marx's mature thought. What is perhaps Marx's most famous writing, *The Communist Manifesto*, was written with Engels in 1848 at the request of the Communist League, an association of revolutionary German workers headquartered in London. Soon after its publication, revolutionary activity burst out across Europe. Eager to participate, Marx went first to Paris and then Cologne, but within a year, as it became clear that the revolution would not succeed, he settled in London. He lived there for the rest of his life.

While not absenting himself entirely from politics, Marx spent the better part of the next fifteen years

immersed in economic theory and history. In an effort to come to terms with recent events in France, he wrote *The Eighteenth Brumaire of Louis Bonaparte* in 1851–1852. Little else of note was published until the end of the decade, when he published *A Contribution to the Critique of Political Economy*. The preface to this work, often referred to as the “1859 Preface,” contains his most famous succinct statement of historical materialism. Also during this period, he worked on manuscripts never published during his lifetime that have come to be known as the *Grundrisse*. These notebooks, which did not come to light until the middle of the twentieth century, are important for a number of reasons. They include what is the broadest outline of Marx’s theoretical project, an early statement of the themes that became the focus of *Capital*, important points about Marx’s method of working on texts, and insights into how Hegelian concepts such as alienation continued to be part of Marx’s thinking.

In 1862 and 1863 Marx worked closely on the theories of political economists, Adam Smith and David Ricardo in particular, writing manuscripts later published as *Theories of Surplus Value*. This work culminated in 1867 with the publication of the first volume of his magnum opus, *Capital*. Marx continued to work on the remaining parts of this manuscript, never finishing them to his satisfaction. Engels published them only after Marx’s death: Volume 2 in 1885 and Volume 3 in 1894.

Marx returned to more active political involvements in the 1860s, becoming one of the leaders in the The International Working Men’s Association, formed in 1864. He remained politically active for the rest of his life, becoming recognized as the leading theoretician of the European working-class movement. Among his later notable writings are *The Civil War in France*, written as an address to mark the demise of the Paris Commune in 1871, and “Marginal Notes on the Program of the German Workers’ Party,” popularly known as “Critique of the Gotha Program,” written in 1875 in an attempt to help unify the two major factions of the German working-class movement. These two later works are important for comments on the nature of society and the state in postrevolutionary, socialist society, a topic about which Marx wrote very little.

## FREEDOM, ALIENATION AND CRITIQUE

Marx’s philosophical views can be understood in terms of a series of central concepts: freedom, alienation and critique; historical materialism as a dialectical theory; the

production of value and the problem of exploitation; and communism and the nature of a free society.

The chief good for Marx, as it was for Hegel, was freedom. For both, a fully free individual was autonomous, and this required rational understanding of and control over one’s actions. Both Hegel and Marx appreciated that human emancipation, understood as autonomy, was a collective project. Individuals could be autonomous in the full sense only in a rational and free society. They differed concerning the conditions of a rational society and, in particular, whether the emerging commercial bourgeois society was rational and therefore yielded the conditions for human emancipation.

Marx followed Hegel in arguing that one major impediment to autonomy was a lack of understanding of one’s self in relation to one’s social world. Such a lack of understanding results in conditions of alienation wherein the individual is dominated to her detriment by states of affairs or objects that she has helped to produce but, in her misunderstanding, treats as independent of her. Conditions of alienation, the young Marx realized, undermined not only the possibility of freedom but created human misery and a sense of meaninglessness. Whereas Hegel analyzed alienation largely as a phenomenon of consciousness, Marx stressed the objective and social roots of alienation, locating its origins in the conditions of production and the nature of labor.

Part of the project of overcoming alienation, Marx realized, involved critique—philosophical analysis that reveals the nature and sources of the alienation and that allows the individual to break through the veils of misunderstanding. Importantly, since the young Marx also realized that alienation was produced by the conditions of social existence, he grasped that until these conditions were understood and overcome, critique alone could not free the world of the destructive consequences of alienation. If the project of emancipation were to be carried to success, Marx recognized that he would have to understand the conditions that give rise to alienation and how those conditions could be changed.

## HISTORICAL MATERIALISM

Historical materialism is the theory Marx produced to explain the nature and sources of human alienation, oppression, and suffering and the possibility of attaining emancipation. In its fullest scope, historical materialism supplies an explanation of the central developments of human history, the series of stages of social development through which human societies have passed, and an account of the key dynamics determining the develop-

ment of any given social formation. Marx's theory of capitalism is the most crucial and developed part of the overall theory of historical materialism.

The starting point of historical materialism is the claim that the central project of human history is the production and reproduction of material life. Humans exist within nature as creatures of needs that can only be satisfied through interaction with nature, that is, through labor. The necessity of labor is a manifestation of the fact that the human condition has been one of scarcity. While all animals are in a similar circumstance and must interact with nature to satisfy their needs, humans are distinguished because they have the capacity to develop tools, technology in the broad sense, that allow them to better satisfy their needs. With the development of technology, new needs were created as were the possibility of satisfying them. The production of ever more powerful technology and ways of putting it to use to satisfy an ever greater array of needs and wants, that is, the growth of human productive power, is for Marx the main theme of human history.

Human productive activity involves three elements: raw materials from nature, technology, and human labor. Marx referred to the first two factors, the natural resources and technology, as the means of production. Combined together, the three elements provide the productive power or, as it is more often called, the forces of production. The forces of production, to be put to use, must be organized in terms of some set or other of social relations that determines who has access to and control over the technology, the activity of labor and the product of the labor. Marx refers to these social relations of power as the relations of production. Typically, those who dominate the relations of production appropriate a disproportionate share of the product and dominate society. Two groups of people can be designated: those who dominate the relations of production and have power over the conditions of labor and the product and those who lack control. This division is the basis of Marx's theory of class and the inherently antagonistic class relations of the dominant ruling class and the subordinate workers class.

Historical materialism claims that the forces of production tend to develop in power over time. For any given level of the forces of production, there will be a set of relations of production in terms of which the existing forces can be best utilized and developed. That is, the relations of production that exist at any give point in history will tend to be those that are best suited to the further use and development of the existing forces of production. The existing forces of production together with the set of rela-

tions of production in terms of which they are organized form an economic structure that Marx calls a mode of production. Historical development proceeds through determinant stages characterized by the prevailing mode of production. According to Marx, there have been three modes of production prior to capitalism: the ancient slave mode of production characteristic of Greece and Rome, the feudal mode of production, and the Asiatic mode of production that is found in ancient India and China and that, unlike the modes of production found in Europe, does not develop beyond itself.

Within a mode of production, the forces of production continue to develop within the constraints of the existing relations of production. At some point in the development of the forces, the existing relations are no longer optimal to the continued use and development of the forces and the relations break down, allowing a new set of relations to emerge. These points of transition between old and new relations of production are considered revolutionary periods; such periods need not be violent and swift. Marx well understood that the transition from feudalism to capitalism took several centuries. With the emergence of a new mode of production and new relations of production, the nature of power relations within the economic order changes, and a new ruling class comes into being.

All modes of production, then, are made up of a dominant and a subservient class, with the members in the latter class far out numbering those in the former. Given the obvious disparities in power and freedom class society involves, one may ask why have they been as stable for as long as they have? According to historical materialism, the economic or class relations of a society form the basic institution of that society. The other principal institutions, including the political, legal, religious, and cultural, constitute what Marx calls the superstructure of society and justify and reinforce the economic relations. The superstructural institutions that tend to exist at any given point are those that help to stabilize the base. For Marx, just as the level of development of the forces of production determines and explains the nature of the existing relations of production, so the existing relations of production determine and explain the nature of the superstructural institutions.

Part of the superstructure of a society consists of what Marx terms the realm of consciousness; that is, the prevalent ideas and values in a society. As with other aspects of the superstructure, these ideas and values are explained in terms of their role in stabilizing class relations and the base. When such beliefs and values are pro-

duced and propagated by professionals (academics, religious authorities, cultural critics, and the like), Marx refers to them as the ideology of the society. As Marx famously states it: the ruling ideas of an age are the ideas of the ruling class, and they serve the interests of that class. Morality and religion are part of the ideological superstructure, according to Marx. Hence his well-known disdain for them.

Ideological beliefs are not necessarily false, although typically they are. But even when not false, they serve to limit or mislead understanding—for instance, by suggesting that a certain condition is natural and not socially constructed. Thus ideology creates false consciousness. Insofar as the members of the subordinate class accept the ideology of their society, they are misled about the nature of their actions, their society, and the role they play in creating it. In this way, ideological mystification is a major factor in the creation of the experience of alienation and the subsequent loss of freedom. Alienated conditions of existence, conditions that involve the domination of people by the reality they have produced but do not understand, are built into the nature of class society.

## THEORY OF EXPLOITATION

In all class societies, the ruling class dominates and exploits the labor of the subordinate class. Such exploitation is fairly evident in slave societies and in feudalism. Capitalism, however, presents a far more complex case. The wage laborer (to use Marx's terms, the proletarian who is a member of the proletariat, the class of wage laborers in capitalism) appears to voluntarily accept work and to be paid for each unit of labor (typically, the hourly wage). The focus of Marx's most sustained work was to unmask this ideological appearance and expose how and why the proletarian was exploited in a way at least as bad, and perhaps worse, than was the slave or serf. By explaining the nature of capitalist exploitation, Marx believed, he could explain the nature and limits of the capitalist mode of production and why it was doomed to be replaced by a socialist society.

Marx's theory of capitalist exploitation is complex; it is grounded on the crucial distinction between labor and labor power. The proletarian, hired by the capitalist, is paid for every hour of labor he performs. What he sells to the capitalist and what the capitalist buys is the capacity of the worker to labor for an agreed upon period of time, say, a ten hour day. During that period, the capitalist owns the worker's capacity to produce goods and can use that capacity in any way he wants. He can use it effi-

ciently, making the worker work harder and produce more, or he can use it less efficiently. Since the capitalist already owns the other factors of production, the raw materials and machines and other technology, and now owns the labor that goes into producing the product, he owns all the factors of production and thus the entire product produced, which he then takes to the market to sell, hoping to return with profit.

Where does this profit come from? Marx asked. The answer resides in determining how commodities, goods produced to be sold in the market, get their prices. Marx used the labor theory of value, taken from Smith and Ricardo, to explain the nature of prices in terms of the labor necessary to produce the commodity. He extended the theory by treating labor power as a commodity that received a price, in this case called the wage, in the same way as other commodities. It is important to note here that human beings can produce under most circumstances more than they need to survive; they can produce a surplus. According to Marx's analysis, the wage (the price of labor power as a commodity) is determined by the value of what is necessary to keep the worker alive and able to work from day to day. The wage does not reflect the value of what the worker is able to produce, which includes both what is necessary and the surplus. Since in virtue of purchasing the worker's labor power and putting it to use as he wishes, the capitalist owns the entire product produced. The capitalist, that is, gets both the value of what is necessary for the worker to have in order to live and the surplus. The capitalist returns to the worker in the form of a wage, however, only the necessary value. He keeps the surplus, and it is this surplus that forms the basis of profit.

Marx noted that, according to the dominant values of capitalism, this exchange between capitalist and proletarian was neither unfair nor coercive. It is as fair and free as any other market exchange. Understanding morality as he did largely in its ideological function, Marx disdained moral critique and did not consider it important to morally condemn the exchange. What was important was to realize that through the process of exploitation, the worker produced, on the one hand, the wealth, privilege and power of the ruling class and, on the other, his own subordination, alienation and misery.

This analysis of the wage and profit is, one might say, Marx's microeconomics with a philosophical intent. His macroeconomic theory attempted to show how capitalism would, with increasing frequency, fall into various crises as the capitalists competing within the essentially anarchistic market struggled to maintain their profit. As

this process continued, the misery of the workers would only increase as well. As the proletariat struggled against worsening misery, their political consciousness would be awakened by the ideologues of their class perspective, political activists and theorists like Marx and Engels. The dual movements, of the capitalists struggling to keep the system going and the workers struggling with increased understanding to overcome it, would eventually culminate in a revolution, ending capitalism and instituting a socialist society. In accordance with the general theory of historical materialism, a successful revolution would happen at or after the point when capitalism was no longer the mode of production best suited to allow optimal use and further development of the forces of production. At that point, socialism would be the best mode.

The dialectical nature of historical materialism is illustrated in the internal dynamics of capitalism and how they are claimed to lead to the overcoming of capitalism. As Marx used the concept, appropriated from Hegel, a theory is dialectical insofar as it reflects and captures a dialectical process in the world. Dialectical processes, typically organic processes, unfold according to a logic of internal development until the present stage of the object or being is fully realized, at which point, again according to the internal logic of development of the object or being, a new stage emerges from the crises and failures of the previous stage. The conditions for the appearance of a successor stage develop in and as a result of the internal developments of the previous stage. Thus the developing nature and struggles of capitalism give rise to a unified and self-conscious proletariat able to forge a new mode of production in its class interests, which happen to be, according to Marx, universal interests.

## COMMUNISM

Marx wrote very little about the nature of the mode of production he predicted would displace capitalism. It is clear, though, that he thought human emancipation would be fully realized only in communism, the second stage of postcapitalist society. The first stage following the socialist revolution, referred to at times as socialism, would be dominated by the proletariat—hence the well known phrase, “the dictatorship of the proletariat.” Socialism would eliminate the private ownership of the means of production and the exploitation that accompanies private ownership. Technological progress would promote the accelerated development of the forces of production. At some future point, a level of productive forces would be attained that allowed humans to transcend scarcity and enter “the realm of abundance.” Abun-

dance refers to a condition in which all can satisfy their needs without depriving others of the satisfaction of needs and without having to spend the greater part of their time in undesirable, unfulfilling labor.

At this stage of human development, communism, all would be free to pursue truly human and creative activities that allowed each individual to fully realize himself or herself. Because all people would have equal access to the means of production, communism would be a classless society. Alienation and exploitation would be abolished. With conflicts over the distribution and fruits of labor eliminated or at least minimized, the primary source of social conflicts would likewise be eliminated, and there would be no need for state authority or for the distorting effects of ideology. There would be no further struggles of the sort that propelled the dialectic of history. Having provided the conditions for full human emancipation, communism would continue to allow optimal development of the forces of production. Hence, no mode of production beyond communism would be necessary or conceivable. Human life as a collective enterprise would gain a self-transparency that would allow humans for the first time to create with knowledge and intention their social fate. In this sense, Marx held that communism would be the end of history, or better perhaps, the beginning of truly human history.

## MARXISM

Marxist theories, insofar as they are of philosophical interest, are discussed in detail in the entries *Dialectical Materialism*; *Historical Materialism*; and *Marxist Philosophy*. Various Marxist ideas are also discussed in the articles *Alienation*; *Communism*; *Dialectic*; *Ideology*; and *Socialism*. See “Marxism” in the index for thinkers who are usually regarded as Marxists.

## MARXIST PHILOSOPHY

Marxist philosophy is the aggregation of philosophical ideas developed from various aspects of Karl Marx's social theory by later thinkers. Marx did not intend to write a philosophy and would have regarded “Marxist philosophy” as a contradiction in terms. He considered his work to be scientific, historical, and sociological, as opposed to “philosophical” divagations on social affairs, which he rejected as class-biased ideology. Moreover, he held that his social theory showed that philosophy was about to end. Philosophy, he said, was a symptom of social malaise and would disappear when revolution put society on a healthier foundation. The young Marx thought that this would happen because revolution would “realize” philosophy, would give solid reality to the ideal phantoms of reason, justice, and liberty that philosophers in sick societies consoled themselves with. The older Marx thought that revolution would destroy philosophy, would simply make it unnecessary, by bringing men back to the study of “the real world.” Study of that world is to philosophy “what sexual love is to onanism.” In either case Marx never varied in the opinion that the reign of philosophy over men's minds was drawing to a close. Thus, he naturally would not have contributed to its survival by writing a “Marxist philosophy.”

## MARXISM AND TRADITIONAL PHILOSOPHIES

Within a few years of Marx's death, however, there were attempts to turn Marxism into philosophy. These have continued ever since and, indeed, have gathered force since the discovery of Marx's earliest writings. There are two explanations for this posthumous transformation. First, there is the familiar paradox that efforts to get rid of philosophy by argument are themselves philosophical. Thus, Marx's antiphilosophy and the theory of historical materialism on which it is based blossomed into a veritable philosophical doctrine, to which Georg Lukács gave

consummate form. Second, after the empirical social sciences had taken from Marx's work all that was useful to them (and it was a great deal), there remained much dross—disproven prophecy, hasty generalization, and plain error. Instead of being discarded, as the errors and absurdities of Isaac Newton and Louis Pasteur were discarded in the physical and biological sciences, this non-empirical material was kept alive by a social movement committed to preserving intact the whole of Marx's legacy. It has been called Marxist philosophy.

Because Marxism is not explicitly a philosophy, those who have treated it philosophically have largely sought to find the philosophy to which it "corresponds," from which it "derives," or which it "implies." Solutions have been extremely varied and incompatible. Enrico Ferri put Marxism into the Spencerian system, and Karl Kautsky connected it with Darwinism. Eduard Bernstein and Max Adler found its philosophical complement in Immanuel Kant, and "Back to Kant!" became the slogan of the revisionists. Georgii Valentinovich Plekhanov noted Marx's Hegelian origins but preferred to ally Marxism with materialism, notably that of Ludwig Feuerbach. This opinion was widely accepted by Marxian political activists but was ardently combated by intellectuals. Otto Bauer said that Marxism could not be annexed by materialism because it was compatible with any philosophical doctrine, "including Thomism." Henri de Man essayed a combination of Marx and Freud, whereas the Marburg school of neo-Kantians made a synthesis of Kant's ethics and Marx's socialism. The Russians whom V. I. Lenin attacked in *Materialism and Empirio-Criticism* had married Marxism to the positivism of Ernst Mach and Richard Avenarius. Lenin himself followed Plekhanov in putting Marxism in the tradition of mechanist materialism, later adding a dialectical theory of development to distinguish it from classic materialism. Georges Sorel, René Berthelot, and various Italian writers found the extension of Marxism in pragmatism, and this view became influential in the United States through the writings of Sidney Hook. Antonio Gramsci and Giovanni Gentile, in their different ways, reacted against the "materialist debasement" of Marxism by coupling it with Italian neoidealism. The search for new philosophic settings for Marxism, such as existentialism, continues and is necessarily inconclusive.

The variety of opinions confirms that there is no Marxist philosophy. Nevertheless, some efforts to incorporate Marxism into philosophy are less successful than others, for Marxism is not philosophically neutral even if it does fail to define its position in respect to the major

philosophical traditions. Least successful are alliances of Marxism with materialism, from Baron d'Holbach to L. Büchner, or with positivism, whether Mach's or Herbert Spencer's. The tendency of decades of criticism has been to show that the idealist content of Marx's thought is too dominant to allow those confusions. Conversely, the alliance that has proven most fruitful and that has grown in authority over the years is that between Marxism and the Hegelian dialectic. Though Antonio Labriola had noted this, it was ignored for more than a generation until Lukács insisted that Marx belonged in the Hegelian tradition. In this Lukács has been followed by Karl Mannheim, Herbert Marcuse, Lucien Goldmann, Jean-Paul Sartre, and Maurice Merleau-Ponty. Everywhere, Marxism's principal philosophical consequence has been to stimulate the study of G. W. F. Hegel. Otherwise, it has had singularly little effect on philosophy, even on pragmatism, with which it has evident affinities.

#### ORTHODOX MARXISM

The distinction between a materialist and an idealist reading of Marx does not exactly coincide with the division between the orthodoxy of the Communist parties and the independent criticism of the so-called Western Marxists, but the history of the subject must be told in terms of the latter division. The orthodox tradition begins with Friedrich Engels, not with Marx. It uses two principal texts, Engels's *Anti-Dühring* and Lenin's *Materialism and Empirio-Criticism*. The name of Marx is very seldom mentioned in these discussions, for Marx never explicitly stated the doctrines set out by Engels, taken over and interpreted by Lenin, and then dogmatically systematized by Joseph Stalin. He sometimes appeared to hold opinions resembling those they expressed—for example, the representationist theory of knowledge—yet his early manuscripts seem far removed in spirit from the materialism of these works. That is why the early works, which are the basis of most Marxist philosophy in the West, were dismissed by Soviet writers as juvenile hangovers from Hegelianism that the mature Marx disowned.

**EPISTEMOLOGY.** Orthodox Marxist philosophy has developed very little over the years, being accepted as much by Rosa Luxemburg as by Lenin, as much by Leon Trotsky as by Stalin, as much by Mao Zedong as by Nikita Khrushchev. Its epistemology is naive representationism: The "concepts in our heads" are images, reflections, or copies of "real things." Objections to that view have been familiar since Bishop Berkeley, but they are held by orthodox Marxists to be answered by a reference to practice. We can compare mental images and the things they

copy by noting our success or failure in manipulating those things. This manipulation is primarily economic activity or is affected by it, so it must differ for each technological age and each class. There is therefore no non-partisan science. There is a contradiction here, for it is contended that the mind has exact copies of reality and yet its knowledge is historically relative. This is admitted but is circumvented by asserting that absolute knowledge is the historical goal but relative knowledge is the present plight.

**METAPHYSICS.** In metaphysics the orthodox doctrine distinguishes itself from classic materialism by insisting on dialectic process, as opposed to mechanism, in the development of things. Matter is subject to laws that are causal and determinist but not mechanist. It evolves toward the better and more complex, and it does so in a series of revolutionary jumps, in which accumulations of quantitative difference produce sudden qualitative changes after a period of tension and conflict. Matter is the unique reality. Chance does not exist, and there is no breach in this absolute monism. Mind is an epiphenomenon producing, in consciousness, reflections of matter. Matter does not determine mind directly, as the medical materialists said, but indirectly, by way of society. Society, too, develops dialectically, in revolutionary jumps that resolve its recurrent self-contradictions or internal conflicts. Human liberty consists in awareness of the necessity of social process.

**RELIGION, ETHICS, AND AESTHETICS.** Religion is doomed to disappear, being a symptom of unjust and self-negating social conditions. Ethics and aesthetics evolve as society changes, for there are no eternal, non-historical laws in either. Beauty is objective but appreciation is relative to class, so art is implicated in the class struggle.

In ethics the situation is more complex. At first the exclusion of eternal, suprahistorical laws was held to warrant amorality, ethical indifference, or at least some experimentation in new ways of living. Soviet authorities found that attitude socially inconvenient, and eventually Stalin formally condemned all applications of historical relativism that suggested that the new polity could have a new ethics (or a special new logic). Since then the position has been that Marxist philosophy substantially accepts the ethical ideals preached in other contemporary societies but adds that only a communist nation can escape hypocrisy by living up to those ideals, by practicing what it preaches. Thus, not only is ethical innovation discouraged in communist countries, but ethical criti-

cism in noncommunist countries—for instance, by existentialists—is strongly deplored as a diversion from the work of creating the social conditions for the application of the uncriticized ethical code common to all modern societies.

## WESTERN MARXISM

The Western Marxists, whose first generation, in the 1920s, comprised Lukács, Karl Korsch, Bela Fogarasi, and Josef Revai, rejected the representationist theory of knowledge, but their quarrel with orthodoxy centered on the dialectic. On this issue the orthodox followed Engels, the Westerners the young Hegelian Marx.

Engels had posited the triadic dialectic of thesis, antithesis, and synthesis as an eternal law of cosmic development, applying as much to nature as to mind and society. Everywhere, one would find constant progress from lower to higher by way of objective tensions. The tensions are caused when something engenders its own opposite or negation and are resolved when the opposites merge in a synthesis (the negation of the negation). Engels's immediate successors, whether social democrats, revisionists, Austro-Marxists, or independent students such as Benedetto Croce and Sorel, could make nothing of these ideas and simply ignored the dialectic. At first Lenin did the same, in 1894 dismissing it as a "vestige of Hegelianism." However, he later adopted Engels's dialectic as the badge that distinguished Marxist materialism from classic or vulgar materialism. This dialectic embellishment of materialism has remained a point of honor with subsequent Marxist philosophers even when the dialectic is seldom applied or evoked. The law of the negation of the negation has found little use, and the examples of it offered by Engels, August Thalheimer, and Paul Sandor have been generally rejected by philosophers and scientists. Stalin formally declared that the other law of dialectic, the law of the transformation of quantity into quality, did not have universal scope but applied only to class-divided societies. With the two laws in effect discarded, orthodox Marxist materialism no longer has a characteristic theory of development. There remains only the law of the union of opposites, which serves to reconcile contradictions (and to justify inconsistencies).

The role of the dialectic in Western Marxism is very different. It does not operate in physical nature and is not a law at all. It concerns the relation between mind and social history. That relation comes to the fore because of an evident difficulty encountered by the historical relativism of Marx. If all knowledge is partial, provisional, relative, class-biased, and historically limited, then is this

not true of Marxism itself? The answer of Engels and Lenin was that everything was relative except a small number of absolutely true propositions that included logic and Marxist theory. Seeing the impossibility of maintaining this dualism of relative and absolute knowledge, Lukács abandoned absolute (or unconditionally true) knowledge and accepted the relative and partial character of all knowledge. The relation between our knowledge and all other worldviews that constitute cultural history is a dialectical one, meaning that none is completely true or completely false. More generally, all relations between subject and history are dialectical in the sense of being ambiguous, reciprocal relations that leave room for “contrary and inseparable truths.” This is true because, on the one hand, the subject is a social and historical product and, on the other hand, because historical forces are alienated spirit, reified personality. There is conflict and tension between the two terms of that relation, and they will be removed by revolution, which will effect the synthesis of the two and will represent the triumph of the human spirit over the alienation or reification of its products. In this view the crux of historical materialism is the relation between mind and history, the dialectic relation between the personal subject and the apparently impersonal, material forces of society. In showing that those forces are really alienated personality, the theory denounces the objectification of spirit in inhuman institutions. It foresees the victory of spirit over that dehumanization.

Marxist historical materialism, said Lukács, thus criticizes itself according to its own principles. It comes to hold itself as provisional, as, at most, a progress toward a truth that is yet to be attained. Because this relativization seemed to lower Marxism from the status of a dogma to that of one ideology among others, it was no doubt the main reason for the condemnation of Western Marxist philosophy by the orthodox. Yet even the relativism of Lukács (and also of Karl Mannheim) still claims to have dogmatic knowledge of the whole of history, which is the total process into which all partial ideologies fit dialectically and which they all reflect more or less faithfully. With this notion of totality the relativists have brought back the Absolute that they first threw out in favor of the historically relative.

## COMMON FEATURES

Because of a dualism in Marx's own thinking, which he never cared to resolve, Marxist philosophy has thus divided into two broad streams. On the one side, there is emphasis on the determinist, evolutionist, materialist,

and sociological themes. On the other side, there is the idealist strain that looks forward to the deliverance of humanity from economic determinism. This idealist strain, stressing the primacy of present human activity over the solidified, alienated products of past human activity, has aptly been called titanism by Nikolai Berdyaev. It is a powerful factor in all modern Marxist thought—not only in Western Marxism, where it is explicit, but also in orthodox Soviet Marxism. After a profession of materialist faith, orthodox Marxism introduces the idealist element by attributing to matter a readiness to cooperate with progressive causes. (In other contexts such an attribution of spiritual purposes to matter is called magic.)

The two varieties of Marxist philosophy retain other common features. Both abandon the distinction between truth and falsity in favor of a relativist notion that sees truth as a historical goal and knowledge as never more than progress toward absolute truth. This relativist concept appears in all philosophical developments of Marxism, from Engels to Gramsci and Lukács. Moreover, both sorts of Marxist philosophy cling to the idea of an ultimate reality. Though this is called matter in one case and history in the other, the difference is not great wherever matter has tacitly been endowed with a purposefulness and spirituality (by evolving dialectically) that make it resemble history. Marxism started with the recognition of all things as events or processes that interact, and it emphasized, in the theory of historical materialism, some sorts of interaction that had been overlooked. In its philosophical extensions it has gone on from there to the concept of a moving totality of things to which single things are relative and within which single things have ambiguous, dialectical relations with one another. This view is as familiar to philosophers as the representationist theory of knowledge that Lenin revived and has been as thoroughly criticized. For this reason, among others, Marxist philosophy has seldom secured consideration or academic influence outside of countries where it is politically privileged.

Neil McInnes (1967)

## MARXIST PHILOSOPHY [ADDENDUM]

Post–World War II Marxist theory has been decisively shaped by historical changes: the growing irrelevance of orthodox Marxist political movements and the moral and economic decline (and eventual collapse) of the Soviet empire; the emergence of politically radical social movements based in nationalism, gender, and race rather than economic class; changes in the world capitalist economy including the emergence of globalization; and increasing environmental degradation. These developments are reflected in divergent formulations of historical materialism; the adaptation and transformation of Marxism by the new social movements and by seemingly culturally radical postmodern theories; neo-Marxist theories of contemporary capitalism; the cross-fertilization of religion and Marxism in Liberation Theology and its variants; and “eco-Marxism.”

Western Marxists such as Herbert Marcuse, the early Jürgen Habermas, and Jean-Paul Sartre resisted the dogmatic and positivist versions of historical materialism found in Marx and in the Second and Third Internationals. These writers denied that a theoretical analysis of capitalist society could provide laws of historical development. Rather, they believed that, at best, economic theory could describe certain continuing contradictions in the social order, the resolutions of which

necessarily depended on the self-awareness and political organization of contending social groups. Given the rise of fascism out of the depression and the triumph of capitalist hegemony over the industrial working classes after World War II, political revolution could no longer be thought of as a direct consequence of predictable economic collapse. It was necessary to investigate social forces that seemed to make the working class not only politically passive but also psychically attached to bourgeois authority.

These forces included not just conscious beliefs, but unconscious personality structures; not just the experience of work, but the experiences of sexuality and family life as well. Consequently, Marxist theory had to encompass psychology and cultural theory as well as economics and politics. It was further claimed that any assimilation of Marxism into a natural-science model was itself an element in political totalitarianism. Habermas (1970) developed this position into a critique of “science and technology as ideology.” When we identify social theory with natural science, he argued, we fail to distinguish between science’s goal of controlling nature and social theory’s goal of understanding and liberating human beings. As a result we end up treating people like things.

French Marxist Louis Althusser posed an influential counterview in 1969 arguing that, while different aspects of society did possess a “relative autonomy” from the economy, it was class structure that always determined historical outcomes “in the last instance.” Claiming to present the scientific view of Marxism, and in a move that anticipated later developments of postmodern thought, Althusser asserted that subjectivity was an effect of social structures and not a primary constituent of them.

There have been many subsequent attempts to connect postmodernism and Marxism, including debates about the validity of the former’s criticism of totalizing theories and grand historical narratives, about the compatibility of the two perspectives, and about the claim that postmodernism is itself simply “the cultural logic of late capitalism” (Jameson 1991).

Anglo-American philosophy has seen a sophisticated reformulation of some of Marx’s original claims about the social primacy of technological development. Analytical Marxist G. A. Cohen developed a “functional” analysis in which a universal human drive to develop forces of production conditioned social relations to change to support such development. Other analytic Marxist philosophers attempted to articulate a distinct moral perspective in Marx to ground claims about the immorality of capitalist exploitation and to critique the individualism of the

dominant liberal paradigms of writers such as John Rawls. This discussion has paralleled a rethinking of Marx’s relationship to Georg Wilhelm Friedrich Hegel, and of the place of the concept of dialectic in Marxist philosophical and economic theory.

Because of the rise of radical social movements of racial minorities and women, Marxist theory was challenged to integrate accounts of patriarchy and racism with its traditional focus on class exploitation and technological development. Theorists argued that racism and sexism were not reducible to or simple consequences of class power. They were embedded in European culture and conferred certain limited privileges on the white and/or male working class itself. Rather than depending solely on the concept of economic exploitation, or on the traditional Marxist notion that the liberation of the working class would liberate all other subject groups, socialist or Marxist-feminist theorists and black liberationists analyzed the mutually supportive, conflicting, and at times disparate elements of class, racial, and gender domination.

From the 1960s to the 1990s the structural evolution of capitalism led to new versions of Marxist economic and sociological theory. Baran and Sweezy’s analysis (1966) revealed how dominant sectors of the economy had become controlled by a small number of firms and that the classic price competition and overproduction oscillations of the nineteenth and early twentieth centuries had consequently given way to stagnation as a result of an unutilizable surplus. Other theorists (e.g., Wallerstein 1974–1980, furthered by Arrighi 1994) redefined capitalism as a capitalist “world-system” constituted by exploitative trade relations between a developed Euro-American core and an underdeveloped periphery.

Many writers claimed that the increased role of the state in the national economy mitigated the business cycle and redirected class struggles to competition over state resources. James O’Connor (1973) foresaw that contradictions between state support of capitalist accumulation and democratic legitimation would eventually cause a “fiscal crisis of the state.” Habermas (1975), writing under the shadow of the political uprisings of the 1960s and 1970s, described conflict between ideals of democracy and equality and state support of capitalist accumulation as causing a “legitimation crisis.”

Responding to the continued dominance of capitalism and the failure of almost all state-controlled communism, theorists of socialism have also raised the possibility of alternative forms of a socialist economy, especially a socialism in which consumer demand is allo-

cated by markets but is not at the same time controlled by private ownership of the forces of production. For a number of writers, the key issue is no longer the traditional idea of “socialization of the means of production,” which to some extent left open the question of the structure of that socialization, but rather that of “economic democracy,” which identifies the structure of socialization with certain fundamental political, as well as economic, changes (Schweickart 2002).

One defining aspect of contemporary society is the worsening environmental crisis, which Marxist theoreticians have responded to not only by using familiar Marxist concepts to explain it, but by positing, as did O'Connor in 1988, an “eco-Marxist” analysis in which capitalist destruction of the environment becomes the “Second Contradiction of Capital.” In this view capitalism’s tendency to destroy its own physical basis of production (through ecological devastation) now coexists with the resistance it generates from the labor force as a major source of its own undoing. While some authors, such as Andrew McLaughlin (1993) accuse Marxism of an industrialism that is a major source our environmental problems, Jonathan Hughes (2000) and others argue that Marxism is crucial to understanding how to solve them.

On a much different front, several Latin American theorists—inspired by the renewed emphasis on social justice of Vatican II (1964–1965), the spread of communist movements, and the appalling degree of poverty and repression surrounding them—created what they called “liberation theology” (Gutiérrez 1988). This was an attempt to join Christian social ethics (most importantly the “preferential option for the poor”) with Marxist social theory. Essential to liberation theology was the belief that “the poor” could only enter history as fully human beings if a fundamental social transformation—virtually a social revolution (preferably without violence)—were to occur. While the development of liberation theology would certainly have surprised Marx—and eventually prompted stiff resistance from the church hierarchy—it provided a model for the cross-fertilization of politically left ideas with religious moral concerns. The use of a quasi-Marxist vocabulary was found in Martin Luther King, who both criticized imperialism and called for a “beloved community,” and in the appearance of politically radical forms of theology focusing on women, race, gay and lesbian issues, poverty and war (see Gottlieb 2003). In the 1990s theologians’ and institutionalized religion’s dramatically sharpening response to the environmental crisis led to positions increasingly resonant with Marxism.

Frequently their criticisms of the market, capitalism, and the global economy would not be out of place in a professedly Marxist journal or socialist party. Conversely, some (e.g., Gottlieb 2002) have argued that a sustained engagement with religious values of nonviolence, universal respect, self-examination, and humility would help compensate for widely shared limitations found in politically radical, including Marxist, perspectives.

Since the last decade of the twentieth century, all of these discussions have been shaped by globalization—an economic, social, and cultural phenomenon the very definition of which is the subject of intense debate. Early on, both the monopoly capital and the world-system models were challenged by the “global capitalism” perspective (Ross and Trachte 1990), which diagnosed an international economy dominated by multinational firms, intra-national competition rather than a dominant Euro-American core, and increased power for capitalists as international mobility allows them to evade local labor movements, governments, and environmental regulations. In the twenty-first century, different accounts within a broadly Marxist paradigm include Hardt and Negri’s analysis (2001) of globalization as a new form of imperialism or “empire” and Manuel Castells’s discussion of globalization as a “network society.” For Castells traditional forms of national sovereignty have become increasingly less relevant, and the separation of decisive social power from even remotely local control causes a dramatic resurgence in the importance of ascribed social identities, especially fundamentalist religion. The importance of globalizing economic structures has also led to increased interest in multidimensional global political resistance movements, which typically involve the working class, but also include peasants, community organizations, environmentalists, students, and progressive middle class. The possibility of an alternative to globalization, and the possible forms of that alternative, are perhaps the most critical questions for contemporary Marxism.

Despite the enormous variety of Marxist and Marxist-related writings since the middle of the twentieth century, there are significant areas that remain relatively unexplored. These include the relation of disability to other forms of social marginalization; sustained and honest examination of the subjective or psychological sources of leftist political failures (for example, how the character structure or ethical orientation of activists has caused destructive intragroup conflict and unnecessary antagonism of social groups outside the left); and a willingness

to question the Marxist premise that human beings are essentially rational.

In sum, Marxism continues to evolve and mutate, with many of its basic concepts (the critique of ideology, the analysis of capitalism) still essential to socially critical perspectives such as postmodernism and feminism. If it is now virtually impossible to delineate any simple Marxist orthodoxy, or to say where Marxism ends and other left perspectives begin, one can (as in other intellectual traditions) trace the historical roots of philosophical perspective and revolutionary social intent from Marx, through enormous historical change, to the Marxisms of the present.

## MASARYK, TOMÁŠ GARRIGUE (1850–1937)

Tomáš Garrigue Masaryk, a Czech statesman and philosopher, and president of Czechoslovakia from 1918 to 1935, was born in Hodonín, Moravia. His political career belongs to history; of interest to students of philosophy is the fact that he studied philosophy at the University of Vienna from 1872 to 1876 under Franz Brentano. He spent the year 1876–1877 at Leipzig, where Wilhelm Wundt was his teacher and Edmund Husserl and Richard Avenarius were fellow students. In 1879 Masaryk became *Privatdozent* at Vienna, submitting *Der Selbstmord als sociale Massenerscheinung* (Vienna, 1881) as his habilitation thesis. In 1882 Masaryk became professor of philosophy at the Czech University in Prague, where he soon made his mark as a politician and writer in Czech. *Základové konkrétné logiky* (The foundations of concrete logic; Prague, 1885; German translation, *Versuch einer concreten Logik*, Vienna, 1887) and *Otázka sociální* (The social question; Prague, 1898; German translation, *Die philosophischen und sociologischen Grundlagen des Marxismus*, Vienna, 1899) were followed by books on Czech history and politics and by an extensive Russian

intellectual history, first published in German as *Russland und Europa* (2 vols., Jena, Germany, 1913; translated by Eden and Cedar Paul as *The Spirit of Russia*, 2 vols., London, 1919). World War I and the presidency of Czechoslovakia put an end to Masaryk's academic pursuits, but a book of memoirs, *Světová revoluce* (The world revolution; Prague, 1925; English translation, edited by H. W. Steed, *The Making of a State*, London, 1927) and *Hovory s T. G. Masarykem* (Conversations with T. G. Masaryk; 3 vols., Prague, 1931–1935) by Karel Čapek (English translations by M. and R. Weatherall, *President Masaryk Tells His Story*, London, 1934, and *Masaryk on Thought and Life*, London, 1938) reformulate his convictions impressively.

Masaryk was a practical philosopher who believed that philosophy should not only contemplate the world but also try to change it. He thus had little interest in problems of epistemology or cosmology. In his early life he reacted against German idealism and accepted British empiricism (David Hume) and French positivism (Auguste Comte). Later he argued for a type of realism that he called concretism. In every act of knowing, he believed, the whole man takes part. Concretism acknowledges not only reason but also the senses, the emotions, and the will—the whole experience of our consciousness. It is something like William James's radical empiricism

without the exceptional experiences admitted by James. But Masaryk's main interest was in sociology and philosophy of history.

Masaryk's realism was combined with a deep religious belief—Masaryk was a theist who found the Unitarianism of his American wife congenial—and a strong conviction of the immutable difference between right and wrong. Masaryk's thinking centered on the crisis of civilization caused by the decay of religion. He diagnosed the diseases of modern man (indifference, suicidal mania, violence, war, etc.) and prescribed remedies for them. He believed that sociology is the foundation of any further cultural advance but that its method must not be purely genetic and descriptive. Teleology, or explanation by purpose, is legitimate. The aim of history is the realization of the ideal of humanity. Masaryk's humanism was not, however, merely humanitarianism, although he often spoke of democracy as another term for his ideal. In spite of his sympathies for the concrete demands of socialism, Masaryk remained an individualist who disapproved of all forms of collectivism. He criticized Karl Marx as a blind worshiper of determinist science. Nevertheless, Masaryk exalted the role of the right kind of science. In *Základové konkrétné logiky*, his philosophically most ambitious book, he classified the sciences and showed how they are internally related and coordinated. The task of philosophy is to create a worldview based on the results of the sciences. Masaryk desired a new "Advancement of Learning" that would save man from intellectual and moral anarchy.

Masaryk assigned an important role in the realization of his ideal to his own nation, the Czech, and interpreted its history, remembering the Hussites and the Bohemian Brethren as a preparation for this task. He thoroughly criticized Russia for being a breeding ground for all the European diseases, particularly romanticism and materialism. Fëdor Dostoevsky, whom he both admired and rejected as a thinker, was a lifelong concern. Masaryk always expressed the deepest sympathies for the English and American tradition of empiricism and moralism and, in politics, turned his nation resolutely toward the Anglo-Saxon West. In 1918 he liberated the Czechs not only politically but also intellectually.

## MASS

The mass of a body is its inertia or resistance to change of motion. More precisely, it is a property of the body that determines the body's acceleration under the influence of a given force. Mass can therefore be measured either by the amount of force necessary to impart to the body a given motion in a given time or by the acceleration produced by a given force.

The absolute metric unit of mass is the gram, which is the mass of a body whose velocity increases by one centimeter per second each second if acted upon by a force of one dyne. Other common units are the kilogram (1,000 grams) and the pound (453.592 grams). For velocities that are small as compared with the speed of light, the mass of a body is a constant, characteristic of the body and independent of its location—in contrast to weight, which varies with the body's place on Earth or in the universe.

Although fundamental to science and, together with length and time, the basis of all measurements in physics, the concept of mass was unambiguously defined only at the end of the nineteenth century. However, its rudimentary sources, systematically employed long before by Isaac Newton and to some extent already by Johannes Kepler, can be traced back to early Neoplatonic ideas concerning the inactivity of matter as opposed to the spontaneity of mind. The ancient metaphysical antithesis of matter and spirit served as a prototype of the physical contrast of mass and force.

### CONCEPT OF INERTIAL MASS

Antiquity, and Greek science in particular, had no conception of inertial mass. Even the idea of quantity of matter (*quantitas materiae*), the antecedent of inertial or dynamic mass, was foreign to the conceptual scheme of Aristotelian natural philosophy. Paradoxically, it was Neoplatonism and its admixtures of Judeo-Christian doctrines, with their emphasis on the spiritual and immaterial nature of reality, that laid the foundations for the

inertial conception of mass, which later became the basic notion of materialistic or substantial philosophy. To accentuate the immaterial, sublime source of all force and life in the intellect or God, Neoplatonism degraded matter to impotence and endowed it with inertia in the sense of an absolute absence of spontaneous activity. For Plotinus, Proclus, Philo, Ibn Gabirol, and the Platonic patristic authors, matter was something base, inert, shapeless and “plump,” attributes that reappear in Kepler’s characterization of matter as that which is too “plump and clumsy to move itself from one place to another.”

The idea of a quantitative determination of matter different from, and ontologically prior to, spatial extension originated in scholastic philosophy in connection with the problem of the transubstantiation. The question of how accidents of condensation or rarefaction (volume changes) can persist in the consecrated *hostia* of the holy bread and wine of the Eucharist whereas the substances of the bread and the wine change into the Body and the Blood of Christ led Aegidius Romanus, a disciple of Thomas Aquinas, to the formulation of his theory of *duplex quantitas*. According to this theory matter is determined by two quantities; it is “so and so much” (*tanta et tanta*) and “occupies such and such a volume” (*et occupat tantum et tantum locum*), the former determination, the *quantitas materiae*, having ontological priority over bulk. Aegidius’s early conception of mass as quantity of matter, expounded in his *Theoremata de Corpore Christi* (1276), was soon renounced and had little influence on the subsequent development of the concept of mass. It was primarily Kepler who ascribed to matter an inherent propensity for inertia in his search for a dynamical explanation of the newly discovered elliptical orbits of planetary motion; in need of a concept expressing the opposition intrinsic in matter to motory forces, Kepler formulated the inertial concept of mass. In his *Epitome Astronomiae Copernicanae* (1618) he declared that “inertia or opposition to motion is a characteristic of matter; it is stronger the greater the quantity of matter in a given volume.”

A different approach to the same idea arose from the study of terrestrial gravitation. As soon as gravity was regarded no longer as a factor residing in the heavy body itself, as Aristotle taught, but as an interaction between an active principle, extraneous to the gravitating body, and a passive principle, inherent in matter, as Alfonso Borelli and Giovanni Baliani (author of *De Motu Gravium*, 1638) contended, the notion of inertial mass became a necessity for a dynamical explanation of free fall and other gravitational phenomena. Furthermore, Christian Huygens’s

investigations of centrifugal forces (*De Vi Centrifuga*, 1659; published in Leiden, 1703) made it clear that a quantitative determination of such forces is possible only if with each body is associated a certain characteristic property proportional to, but conceptually different from, the body’s weight. Finally, the systematic study of impact phenomena, carried out by John Wallis, Sir Christopher Wren, and Huygens, enforced the introduction of inertial mass. With Newton’s foundations of dynamics (*Principia*, 1687) these four categories of apparently disparate phenomena (planetary motion, free fall, centrifugal force, and impact phenomena) found their logical unification, through his consistent employment of the notion of inertial mass. Newton’s explicit definition of this concept, however, as “the measure of quantity of matter, arising from its density and bulk conjointly” was still unsatisfactory from both the logical and the methodological points of view. It was probably the influence of Kepler or of Robert Boyle and his famous experiments on the compressibility of air that made Newton choose the notion of density as a primary concept in his peculiar formulation of the definition of mass, a formulation that was severely criticized in modern times, especially by Ernst Mach and Paul Volkmann.

#### LEIBNIZ AND KANT

Gottfried Wilhelm Leibniz’s original conception of mass (1669), in contrast to Newton’s, defined it as that property which endows primary matter with spatial extension and antitypy, or impenetrability. In his later writings, especially in his doctrine of monads, Leibniz associated mass with secondary matter and saw in it a property of a collection of substances (monads) resulting from their being a collection. Finally, recognizing the insufficiency of purely geometric conceptions to account for the physical behavior of interacting bodies, Leibniz departed from the Cartesian approach and accepted the dynamic, or inertial, conception of mass. The trend of Leibniz’s ideas was brought to its final consequences by Immanuel Kant, with his rejection of the Newtonian *vis inertiae*, the dynamic opposition against impressed force. Refuting its legitimacy on the ground that “only motion, but not rest, can oppose motion,” Kant postulated the law of inertia as corresponding to the category of causality (“every change of the state of motion has an external cause”) and consequently defined mass as the amount of the mobile (*die Menge des Beweglichen*) in a given volume, measured by the quantity of motion (*Die metaphysischen Anfangsgründe der Naturwissenschaft*, 1786).

## DEFINITION OF MASS

Under the influence of the Kantian formulation, often incompletely understood, and primarily owing to the fact that in spite of the universal use of the concept in science as well as in philosophy no clear-cut definition of mass was available, most authors defined mass as quantity of matter without specifying how to measure it. Toward the middle of the nineteenth century, with the rise of modern foundational research and the critical study of the principles of mechanics, the logical deficiency of such definitions became obvious. It was primarily Ernst Mach, preceded by Barré de Saint-Venant and Jules Andrade, who insisted on the necessity of a clear operational definition of mass. In an essay, "Über die Definition der Masse" (1867; published in 1868 in *Carl's Repertorium der Experimentalphysik*, Vol. 4, pp. 355–359), and in the *Science of Mechanics (Die Mechanik in ihrer Entwicklung, historisch-kritisch dargestellt*, Leipzig, 1883; translated by T. J. McCormack, La Salle, IL, 1942), Mach defined the ratio of the masses of two bodies that interact with each other but are otherwise unaffected by all other bodies in the universe as the inverse ratio of their respective accelerations ( $m_1/m_2 = a_2/a_1$ ), thereby converting Newton's third law of action and reaction to a definition of mass. If a particular body is chosen as the standard unit of mass, the mass of any other body can be unambiguously determined by simple physical operations. The practical method of comparing masses by weighing is, of course, operationally still simpler but logically more complicated, since the notion of weight presupposes that of mass. Although Mach's definition is not quite unobjectionable, it has gained great popularity and is generally adopted in modern texts in science.

## INERTIAL AND GRAVITATIONAL MASS

In addition to its inertial mass, every physical body possesses gravitational mass, which determines, in its active aspect, the strength of the gravitational field produced by the body and, in its passive aspect, the amount by which the body is affected by the gravitational field produced by other bodies. According to Newton's law of universal gravitation, the force of attraction is proportional to the inertial masses of both the attracting and the attracted bodies. The resulting proportionality of inertial and gravitational masses of one and the same body, experimentally confirmed by Newton, Friedrich Bessel, Roland von Eötvös, and others, remained in classical physics a purely empirical and accidental feature, whereas the strict proportionality between the active and the passive gravitational masses is a straightforward consequence of

Newton's third law of action and reaction or, alternatively, of the very definition of inertial mass if the postulated interaction is of gravitational nature. In general relativity, however, the so-called principle of equivalence, which maintains the unrestricted equivalence between uniformly accelerated reference systems and homogeneous gravitational fields, implies the fundamental identity between inertial and passive gravitational masses. In addition, it can be shown that on the basis of general relativity the active gravitational mass of a body or dynamical system equals its inertial mass, so that in relativistic physics, in contrast to Newtonian physics, the identity of all three kinds of masses is a necessary consequence of its fundamental assumptions.

## MASS AND ENERGY

Whereas general relativity led to an important unification of the concept of mass, special relativity already, with Albert Einstein's paper *Does the Inertia of a Body Depend upon Its Energy Content?* (1905; reprinted in *The Principle of Relativity*, New York, 1923), led to a vast generalization of the concept by showing the equivalence of mass and energy insofar as a body emitting radiative energy of an amount  $E$  loses mass to an amount of  $E/c^2$ , where  $c$  is the velocity of light. Subsequent research, especially in connection with energy transformations in nuclear physics, supported the general validity of the formula  $E = mc^2$ , according to which mass and energy are interconvertible and one gram of mass yields  $9 \times 10^{20}$  ergs of energy. It also became obvious that Antoine Lavoisier's law of the conservation of mass (1789) and Robert Mayer's (or Hermann Helmholtz's) law of the conservation of energy were only approximately correct and that it was the sum total of mass and energy that was conserved in any physicochemical process.

## INFLUENCE OF THE ELECTROMAGNETIC CONCEPT

The way to these far-reaching conclusions of relativity had been prepared to some extent already by the introduction of the electromagnetic concept of mass at the end of the nineteenth century (by J. J. Thomson, Oliver Heaviside, and Max Abraham). It seemed possible on the basis of James Clerk Maxwell's electromagnetic theory to account for the inertial behavior of moving charged particles in terms of induction effects of purely electromagnetic nature. Walter Kaufmann's experiments (1902) on the deflection of electrons by simultaneous electric and magnetic fields and his determination of the slightly variable inertial mass of the electron seemed at the time to

support the hypothesis that the mass of the electron, and ultimately the mass of every elementary particle, is of purely electromagnetic nature. Although such eminent theoreticians as H. A. Lorentz, Wilhelm Wien, and Henri Poincaré accepted these ideas, according to which the whole universe of physics is but an interplay of convection currents and their radiation, with physical reality stripped of all material substantiality, the electromagnetic conception of mass had to make way for the relativistic concept as outlined above. Certain aspects of the electromagnetic conception of mass did survive, however, and reappeared in modern field theories—in particular the fundamental tenet that matter does not do what it does because it is what it is, but it is what it is because it does what it does.

## MATERIALISM

Materialism is the name given to a family of doctrines concerning the nature of the world that give to matter a primary position and accord to mind (or spirit) a secondary, dependent reality or even none at all. Extreme materialism asserts that the real world is spatiotemporal and consists of material things and nothing else, with two important qualifications: first, space and time, or space-

time, must also be included if these are realities rather than mere systems of relations, for they are not material things in any straightforward sense. Second, materialism is fundamentally a doctrine concerning the character of the concrete natural world we inhabit, and it is probably best to set to one side controversies over abstract entities such as numbers, or geometric figures, or the relations of entailment and contradiction studied in logic. A strictly extreme materialism would undertake to show that, to the extent that any of these were genuine realities, they are all material in nature, but the issues raised by abstract entities will not be pursued here. It is with extreme materialist views in the concrete realm that this entry is concerned, and in what follows, "materialist" is to be understood in that sense.

Philosophers and scientists have had various views regarding the constitution and behavior of material objects and over whether every material thing is a body, or whether forces, or waves, or fields of force are also realities in their own right. Thus, the cardinal tenet of materialism, "Everything that is, is material," covers a range of different claims.

To accommodate these differences, a material thing can be defined as a being possessing many physical properties and no other properties, or as being made up of parts all of whose properties are physical. The physical properties are position in space and time, size, shape, duration, mass, velocity, solidity, inertia, electric charge, spin, rigidity, temperature, hardness, magnetic field intensity, and the like. The phrase "and the like" is important, for it indicates that any list of physical properties is open-ended. A material thing is one composed of properties that are the object of the science of physics. And physics is a developing science, in which new properties are still being discovered. The question "What counts as a physical property?" thus has no determinate answer. In consequence, there are also no fully determinate answers for the questions "What is a material thing?" and "What does materialism claim?"

This is less serious for materialism than may at first appear, for there is a broad consensus on which properties—among those already known—are the physical ones. And new properties that emerge from research in the physical sciences are, generally speaking, readily identified as belonging among the physical ones rather than representing an anomalous, nonphysical development. It is known well enough what is involved in claiming that something is a material reality, and therefore it is understood well enough what is involved in the various ver-

sions of extreme materialism, all of which assert that everything there is, is material.

The psychological characteristics people ascribe to themselves and to one another—consciousness, purposiveness, aspiration, desire, and the ability to perceive, for example—are not considered to be physical properties. So materialism differs from panpsychism, the doctrine that everything material is also at least partly mental or spiritual. Materialism denies the world's basic entities possess these psychological properties. Materialists add that there is no second class of nonmaterial beings in possession of such psychological properties and no others; there are no incorporeal souls or spirits, no spiritual principalities or powers, no angels or devils, no demiurges and no gods (if these are conceived as immaterial entities). Hence, nothing that happens can be attributed to the action of such beings.

The second major tenet of materialism is, accordingly, "Everything that can be explained can be explained on the basis of laws involving only the relevant physical conditions." The differences among materialists over the types of effect material things can have on one another make this second tenet another slogan covering a variety of particular doctrines. Further, although materialists have traditionally been determinists, holding that there is a physical cause for everything that happens, this is not strictly required by materialism itself. Recently, the appeal of determinism has been weakened by the development and success of quantum theory, and many contemporary materialists are not committed to determinism. It should also be mentioned that metaphysical materialism in no way involves an overzealous disposition to pursue money and tangible goods, despite the popular use of "materialistic" to describe this interest.

## NATURE AND APPEAL OF MATERIALISM

The enduring appeal of materialism arises from its alliance with those sciences that have contributed most to an understanding of the world humans inhabit. Investigations in the physical sciences have a materialist methodology; that is, they attempt to explain a class of phenomena by appeal to physical conditions alone. The claim of materialists is that there is no subject matter that cannot be adequately treated with a materialist methodology. This claim cannot be established by any scientific investigation; it can be established, if at all, only by critical reflection on the whole range of human thought and experience.

Early philosophers proceeded dogmatically, aiming to prove the material nature of the world by mere reflection on what must be. Contemporary materialists are much more modest, offering the claim as a speculative but reasonable generalization from the progress of the physical sciences.

Materialism has been, traditionally, a minority view, indeed a rather daring and scandalous one, but it has made considerable progress over the past century, particularly among educated European peoples. There seem to be three main reasons for this. First, the rise of what might be called "cosmic naturalism"; there has been a decline in those aspects of religious conviction that involve appeal to providential or satanic interventions in the course of events, so that pestilence or climate change, for example, are not attributed to nonmaterial, supernatural forces. Second, the rise of "medical materialism"; the discovery of the biochemical mechanisms involved in neural functioning, and their links to psychological processes, so that it is now taken for granted that thinking, feeling, and the will are subserved by the nervous system, and can be altered by making physical changes by the use of drugs or electrodes. A malfunction of the mind is taken to be a malfunction of the brain. This is a kind of pragmatic materialism—the physical aspects are accorded primacy. Third, the rise of "electronic materialism"; recent years have witnessed an astonishing expansion in the range and sophistication of the mental tasks that digital machines can perform. Not only remembering, recalling, and calculating, but pattern recognition, estimation processes, problem solving, and learning new skills, which hitherto have been the exclusive preserve of living, conscious beings, are now routinely performed by electronic devices that, unless panpsychism is true, are purely physical structures. This has formed the background for an increasingly common assumption that mental activity is a special kind of physical process, which is one critical aspect of materialism.

Materialism remains, nonetheless, a striking and apparently paradoxical doctrine, for it insists that the only differences between human beings and grains of sand prove to be matters of energy flow and structural complexity. People have continued to embrace materialism in the face of the difficulties with which it is beset because it offers a comprehensive, unified account of the nature of reality that is economical, intelligible, and consistent with the most successful of the sciences.

## HISTORY OF MATERIALISM

**CLASSICAL PERIOD.** Materialism has been a theme in European speculative thought from the earliest periods for which there is any record.

Ionian philosophers in the tradition of Thales (sixth century BCE) attempted to account for the origin and present state of the world by appeal to changes in the state of a fundamental underlying substance (the *arche*), which in most cases was held to be of a physical nature. Parmenides of Elea (fifth century BCE) vigorously defended a thoroughgoing monism, maintaining that the world is One, unchanging, eternal, homogeneous, indivisible, indestructible, and without any interior void.

These two threads of thought are combined in the true materialism of Leucippus and his pupil Democritus, who flourished at Abdera in the fifth century BCE. Between them they worked out the first clear conception of matter, the first clear restrictions on the kinds of natural interactions in which material particles could participate, and the first clear program of explanation by appeal to these material interactions alone. The “Great Diakosmos,” a lost work written by one or the other (or both), expounded their position. Their basic idea was that the fundamental stuff was of just one kind (matter) and that the fundamental entities were material atoms that were of course by no means unique, but otherwise had all the characteristics of Parmenides’ One. These atoms are in constant motion in a void that surrounds them.

Insofar as it can be reconstructed, their doctrine embraced the following theses:

- (1) Nothing exists but atoms and empty space.
- (2) Nothing happens by chance (for no reason at all); everything occurs for a reason and of necessity. This necessity is natural and mechanical; it excludes teleological necessitation.
- (3) Nothing can arise out of nothing; nothing that is can be destroyed. All novelties are merely new combinations or separations of atoms.
- (4) The atoms are infinite in number and endlessly varied in form, but uniform in composition, being made of the same stuff. They act on one another by pressure or collision only.
- (5) The great variety of things that we encounter in the world is a consequence of the variety in number, size, shape, and arrangement of the atoms that compose them.
- (6) The atoms have been in confused random motion from all eternity. This is their natural state and

requires no explanation. (Some scholars dispute the attribution of random motion to the atoms and credit the “Great Diakosmos” with advancing the doctrine of an eternal fall through infinite space, which was later presented by Epicurus.)

- (7) The basic mechanism whereby complex bodies are formed is the collision of two atoms, setting up a vortex. In the vortex motion is communicated from the periphery toward the center. In consequence, heavy atoms move to the center, and there form a body, which is dense relative to the collection of light atoms around the periphery. The vortex continually embraces any new atoms that come near it in their random motion, and it thus begins a world.

This materialist philosophy requires a mechanical account of human sensation. The Leucippus-Democritus account seems to have been ingenious, speculative, and false. Sensation occurs in the human soul, which, like everything else, is composed of atoms. Objects perceptible by the distal senses sight, hearing, or smell, give off effluences, or images, composed of fine, smooth atoms. There are channels in the eyes, ears, and nose along which these effluent atoms pass to collide with the atoms of the soul and produce sensation. Differences of color, in the case of vision, or of pitch, in the case of sound, are due to the varying smoothness or roughness of the incoming image atoms. With the contact senses touch and taste, it is the size and shape of the atoms on the surface of the perceived object that act on soul atoms in the skin or tongue.

Sensory qualities (for example, sweetness, bitterness, temperature, and color) are thus not qualities of the object perceived, which is a collection of atoms, possessed only of physical properties such as size, shape, mass, and hardness. The sensory qualities are, rather, the effects of that collection of atoms on us, that is, on our soul atoms. Here is an early appearance of the distinction between primary and secondary qualities, a distinction every subsequent materialist has also found it necessary to make.

Empedocles (fifth century BCE) founded a medical school in Acragas (Agrigento) in Sicily. His aim was to account in a naturalistic manner for the special features of this world, particularly for the specially organized matter to be found in living creatures. The first appearance of the famous four elements—earth, air, fire, and water—is in his theory. Empedocles seems to have believed that each of these four elements comprised a different type of atom. The creation and dissolution of the macroscopic objects of this world is brought about by the combination

and separation of these atoms by two fundamental forces, love and hate, or harmony and discord.

Under the influence of love and hate the world goes through an endless cycle from complete random separation of elements (the triumph of hate), through gradually increasing order, to a complete, calm, spherical, harmonious union (the triumph of love). Hate then begins to exert itself once more. Disintegration sets in, and ultimately the world returns to the state of complete separation of elements. The present state of the world lies between these two extremes. The existence of planetary systems and the origin of animals are thus explained as the influence of love.

Empedocles can be considered a true materialist only if love and hate are either inherent forces in the elemental atoms or themselves material elements with a cementing or corrosive effect on combinations of the other elements; however, he probably thought of them as blind, powerful gods. The rest of his system is similarly ambiguous. On the one hand, he believed in the transmigration of souls and adhered to some kind of Orphic mystery religion; on the other, he gave a mechanical account of sensation, held that the soul was composed of fiery atoms, and said that the blood around the heart is the thought of men. Empedocles' philosophy thus perpetuated the materialist tradition but not in a rigorous or consistent form.

The hostile misinterpretation of his ethics as unworthily hedonistic has made Epicurus (342–270 BCE) the most famous of classical materialists. In his middle age Epicurus came to Athens and founded a school where materialism was taught as the sole foundation of a good life, at once disciplined, calm, serene, and free from superstition.

He adopted the materialist metaphysics of the "Great Diakosmos" but gave a modified account of the origin of worlds. There are an infinite number of atoms falling vertically through an infinite space. In one construction of the Epicurean system the heavier, faster atoms occasionally strike the lighter, slower ones obliquely, giving them a slight lateral velocity. In another construction all atoms fall at uniform velocity, and the original deviations from parallel downward motion are left unexplained.

However caused, the original lateral deviations result in more collisions and deviations and the establishment of vortices. From these vortices ordered arrangements of atoms arise. The number of atoms and the time available are unlimited, so every possible arrangement of atoms must occur at some time or another. This world, with its

marvelously organized living bodies, is thus just one of the infinite, inevitable arrangements into which the indestructible atoms must fall.

The only Roman author of note in the tradition of materialism is Lucretius (born c. 99 BCE), whose long didactic poem *De Rerum Natura* gives imaginative sparkle to the metaphysics of Epicurus. Lucretius adopted the second account of the fall of atoms through the void and appealed to some form of voluntary action to explain the original deviations from vertical descent. He thus introduced a nonmechanical source of motion, inconsistent with the remainder of his system.

Like Epicurus, Lucretius was motivated by a wish to free people from the burden of religious fear. He argued passionately and at length against the existence of any spiritual soul and for the mortality of humankind. These beliefs have been explicit features of materialism ever since.

SEVENTEENTH CENTURY. From the close of the classical period until the Renaissance the church and Aristotle so dominated European speculation that materialist theories virtually lapsed. The revival of materialism is attributable to the work of two seventeenth-century philosophers, Gassendi and Hobbes, who crystallized the naturalistic and skeptical movements of thought that accompanied the rediscovery of antiquity and the rise of natural science. Their most important forerunners were probably Telesio, Campanella, and Cyrano de Bergerac, all of whom attempted to combine materialistic views in physics with a psychology based on sensations.

Pierre Gassendi (1592–1655), who in the last part of his life taught astronomy at the Royal College in Paris, rejected the official Aristotelian philosophy of his time and set about the rehabilitation of Epicureanism. To bring the Epicurean system into closer conformity with Christian doctrine, he claimed that the atoms are not eternal but created. They are finite, not infinite, in number and are organized in our particular world by a providential determination of initial conditions.

Gassendi's materialism extended over physics and psychology, undertaking to account for all inanimate changes and for sensation on a materialist basis. He treated the coming into being of particular things as the accumulation of matter about a seed atom.

But his metaphysics was not, strictly speaking, materialistic, for outside the experienced world Gassendi admitted a creative and providential God and an immaterial and immortal intellect in man distinct from his corporeal soul. There are even some lapses in the physics,

too, for Gassendi spoke of gravitation as some kind of movement for self-preservation and allowed that growth from seed atoms may be controlled by formative principles other than the natural motions of atoms.

Thomas Hobbes (1588–1679) was much more consistent and uncompromising. In 1629 he discovered Euclidean geometry and was captivated by its method. During the years that followed he strove to work out a rational philosophy of nature on the Euclidean model.

Hobbes's aim was to discover by cunning analysis of experience the fundamental principles expressing the true nature of everything. The truth of these principles would be manifest to right reason and could thus serve as axioms from which a comprehensive theory of the nature of the world could be deductively derived.

The resulting system is almost pure materialism. Hobbes hoped to use the new non-Aristotelian physics of the seventeenth century as the basis for a final, complete account of reality. From definitions of space and motion he derived the laws of uniform motion. From these, together with a notion of the interaction of bodies, he hoped to proceed to an account of change, thence to an account of sensible change, thence to a theory of the senses and appetites of people, and finally to his notorious civil philosophy.

No part of the universe is not a body, said Hobbes, and no part of the universe contains no body. Hobbes was a plenist, holding all space to be filled by an intangible material ether if nothing else. This doctrine followed directly from his definition of a body as anything existing independently of human thought and having volume. Thus, Hobbes considered God to be a corporeal spirit difficult to distinguish from his eternal, immutable, omnipresent, embodied space, the pervasive ether.

All change in the universe consists in the motion of bodies, so all change reduces to change of position and velocity. Further, nothing can cause a motion but contact with another moving body. The substance of anything is body, and “incorporeal substance” is therefore a contradiction in terms. Hobbes thereby disposed of angels, the soul, and the God of orthodox theology. He departed from strict materialism, however, in his introduction of “conatus” and “impetus” (which are not physical properties) into his account of the initiation of motion and measurement of acceleration. Conatus also enters into Hobbes's account of human sensation and action. Sensations are motions in a person's body, and changes of sensation are changes of that motion. Sensory qualities are

really within the perceiver, but by conatus a “phantasm” is projected from the observer onto the observed.

Hobbes was the first to take seriously the problems that language, thought, and logic pose for materialism. He developed a nominalist theory of language and took the subject matter of thought and inference to be phantasms of sense or abstractions from these phantasms. He held, for example, that to remember is to perceive one has perceived. But Hobbes did not make clear just what contact mechanism is at work in mental operations nor whether the phantasms are genuinely corporeal. Thus, in spite of his best efforts, it is doubtful that he developed a fully consistent materialism.

The influence of Gassendi and Hobbes was diminished by the prestige of their brilliant contemporary, Rene Descartes (1596–1650), who accepted a materialist and mechanical account of the inanimate world and the brute creation but insisted that men had immaterial, immortal spirits whose essential nature lay in conscious thought undetermined by causal processes. According to Descartes, there are in the world two quite different sorts of things, extended (material) substances and thinking (spiritual) substances, which are mysteriously united in the case of humankind. He thus crystallized the tradition of dualism (the doctrine that there are just two fundamentally different kinds of substance), which was until recently materialism's chief rival.

**EIGHTEENTH CENTURY.** In Epicurus and Lucretius one motive for working out a materialist philosophy was to provide an antidote for the all too prevalent religious terror of their times. With Hobbes, and again in eighteenth-century France, the corresponding motive was opposition to religious oppression. But in addition, rapid growth in physiological knowledge had given rise to the hope that a complete doctrine of man in purely physiological terms was possible and so generated a medical materialism that made the path of the metaphysicians smoother.

Ever since the time of Democritus, materialists had held that the soul consists of fine particles within the body. In the course of the eighteenth century this suggestion was taken up and amplified, and some attempt was made to give it an experiential basis.

An anonymous manuscript, the *Ame materielle*, written between 1692 and 1704, contains many ingenious explanations of mental function along Democritean lines. Pleasure and pain consist, respectively, of the flow of finer or coarser particles through the channels of the brain. The passions are a matter of the temperature of the

heart. Reason consists in the ordering of the soul's fine particles, and the effect of wine in its course through the body is to dislodge some of these fine particles from their proper places. The manuscript is panpsychic in its expression, crediting the atoms with a rudimentary consciousness and will, but it is materialist in substance, for these qualities are not credited with any causal power. The doctrines advanced were purely hypothetical and, as we now know, false. The *Ame materielle* had successors in Dr. Maubec's *Principes physiques de la raison et les passions de l'homme* (1709), which again gave a materialist vision of man a panpsychic dress and opposed Descartes's view of the mind as a thinking substance. During the middle years of the century, Denis Diderot's many unsystematic writings took progressively a more materialistic turn. Diderot's *Le reve de d'Alembert* is a striking hypothetical account of heredity, growth, and the simpler forms of animal behavior in terms of internal motions of living bodies.

The most famous medical materialist is Jean de la Mettrie (1709–1751), a doctor with a philosophical bent whose radical views obliged him to leave a fashionable practice in Paris to live in Holland and Prussia. In *L'homme machine* (1743 [1748]) he presented a view of the human being as a self-moving machine.

After criticizing all views of the soul as a spiritual entity, La Mettrie proceeded to review all the common-sense evidence for the physical nature of mental activity. He cited the effects of bodily needs, aging, and sleep; he pointed to the analogy of the human body to much "lower" forms, which were not supposed to harbor spiritual minds. Anticipating Pavlov, he spoke of the mechanical basis of speech and of the possibilities of educating deaf-mutes and anthropoid apes. He explained learning to perceive and learning to make moral judgments by appeal to modifications of the brain. Human action is accounted for by the then new doctrine of the stimulus irritability of muscles. La Mettrie embarrassed those who held that the soul is a spiritual unity governing all vital functions by observing the continuing function of organs removed from bodies, the muscular activity of dead or decapitated animals, and the ability of a bisected polyp to grow into two complete ones. He explained conscious sensation and the mental capacities of which we are introspectively aware by means of a magic-lantern analogy, but this was unsatisfactory, for the status of the images involved was not made clear.

The details of La Mettrie's physiology, depending as they do on supposed movements of nervous filaments, are false. However, his program of seeking in neural

changes the explanation of mental activity has endured, and his claim that appeals to the actions of a spiritual soul can furnish only pseudo-explanations has gained wide support.

Jean Cabanis (1757–1808), a French doctor, continued this line of thought and in 1802 published *Rapports du physique et du moral de l'homme*, the most notable innovation of which was to treat the brain as analogous with the digestive system, making sensory impressions its aliments and thoughts its product. The great metaphysical materialist of the period is Paul Heinrich Dietrich d'Holbach (1723–1789), a German nobleman living in Paris. His work the *Systeme de la nature* was published under a false name "Mirabaud," with a false imprint "London" (Amsterdam) in 1770. This "Bible of all materialism" is speculative philosophy in the grand style; in it the antireligious motive is again uppermost. Holbach maintained that nothing is outside nature. Nature is an uninterrupted and causally determined succession of arrangements of matter in motion. Matter has always existed and always been in motion, and different worlds are formed from different distributions of matter and motion. Matter is of four basic types (earth, air, fire, and water), and changes in their proportions are responsible for all changes other than the spatiotemporal ones that motion without redistribution can accomplish.

Mechanical causes of the impact type, such as collision or compression, are the only intelligible ones, hence the only real ones. Because human beings are in nature and part of nature, all human actions spring from natural causes. The intellectual faculties, thoughts, passions, and will can all be identified with motions hidden within the body. In action outward motions of the limbs are acquired from these internal movements in ways we do not yet understand.

Holbach based the intellectual faculties on feeling and treated feelings as a consequence of certain arrangements of matter. Introspected changes are all changes in our internal material state. Thus, in remembering, we renew in ourselves a previous modification. He treated personal characteristics and temperament in terms of a person's internal structure and interpreted so-called free action not as motiveless action (an absurdity) but as action that, although seeming to flow from a free choice, actually springs from an ultimately unchosen modification of the brain. Holbach's theory of mind is also interesting because in dealing with wit and genius, it suggests the first behavioral analyses of mental concepts. As consistency required, he held the soul to be mortal. The purity of Holbach's materialism is marred only by his

admission of relations of sympathy, antipathy, and affinity among material particles, in addition to their unequivocally physical properties, the primary qualities, gravity, and inert force.

The revolution in chemistry that was effected by Joseph Priestley (1777) in England and Antoine-Laurent Lavoisier in France in the 1770s and 1780s was of importance for the later development of materialism, for it established chemistry as a strictly physical science. Since the beginning of the nineteenth century, all properly chemical explanations appeal only to material substances and their natural interactions. Such a chemistry has since been extended in biochemistry to cover all the processes of life, and the case for materialism has thereby been profoundly strengthened. Priestley himself nevertheless vigorously upheld an unorthodox version of Christianity, insisting that the existence of God and the resurrection of the body are not incompatible with a materialist and determinist view of the natural world.

**NINETEENTH CENTURY.** The philosophers of greatest influence in the nineteenth century—Kant, Fichte, Hegel, Schopenhauer, Lotze, and Mill, for example—were all of an idealist or phenomenalist bent. The dialectical materialism of Friedrich Engels and Karl Marx is not an extreme materialism of the kind discussed here.

Ludwig Buchner, a minor figure, deserves mention as the first to claim explicitly that materialism is a generalization from *a posteriori* discoveries. In *Kraft und Stoff* (1855) he claims that we have discovered (not proven *a priori*) that there is no force without matter and no matter without force.

There was during this period a continuation of inquiry and speculation on the physiological bases of mental function. Jacob Molescott (1852), Karl Vogt (1846, 1854), and Emil Du Bois-Raymond proceeded with the investigation of physiological processes along biophysical and biochemical lines. The most important developments were scientific findings that undermined the barrier between physical systems and living organisms and thus softened the natural resistances to materialistic theses.

In 1828 the synthesis of urea was achieved, and this refuted the idea that biochemistry was in some way special and distinct from chemistry. In 1847, Hermann Helmholtz established the conservation of energy in organic systems, making still less plausible any claims that living and nonliving systems could not possibly be comprehended in a single theory.

In 1859 Charles Darwin published his *Origin of Species*, in 1871 his *Descent of Man*. T. H. Huxley had produced *Man's Place in Nature* in 1863. These three works at last provided a plausible, empirically grounded case for two of the main planks of materialism, the claim that the organization of living things into forms admirably adapted for survival and reproduction can be explained without appeal to immanent or transcendent purposes, and the claim that humans are a part and product of the natural world. Since then biologists, physiologists, and pathologists have increasingly taken the truth of medical materialism for granted, couching their explanations in physicochemical terms without questioning the propriety or completeness of successful explanations in this form.

**TWENTIETH CENTURY.** The triumphant progress in the twentieth century of a materialistic biology and biochemistry has almost completely eliminated vitalist notions of living forms as governed by forces additional to, and distinct from, the purely physical forces operating on inanimate matter. The situation of earlier ages has been reversed; it now seems implausible to maintain that the vital functions of living organisms are different in kind from chemical (ultimately, physical) processes. In the attempt to demonstrate that something other than matter exists, it is on mind, rather than life, that the opponents of materialism now rely.

Early in the twentieth century, the behaviorist movement arose, in a development linked to the emergence of psychology as a distinct science in its own right, rather than a branch of the philosophy of mind. Many psychologists became disheartened by the difficulties involved in any introspective investigation of inner mental states, and turned to the study of behavior. In its analyses and explanations of human activities, behaviorist psychology relies as far as possible on publicly observable, physical phenomena of stimulus and response. Its aim was to expel the traditionally conceived inner, immaterial mind from psychology, and in this way was a profoundly materialistic development.

In the realm of the mind, a new challenge for immaterialists has also developed. The rise of cybernetics (the abstract theory of machines) and its applications in computing machinery threatens the idea of a special status for mental activity. The gathering and interpretation of information, the employment of stored information, successful and spectacular problem solving, even analogues of fatigue, overload, and confusion, hitherto all found only among complex living organisms, are now displayed by computing hardware, that is, by material structures all

of whose operations can be explained in terms of physical properties alone.

Approaching the issue from the opposite direction, experimental study of the nervous systems of animals and of ourselves is showing, in ever-increasing detail, how artificially induced physical changes in the electrochemical state of the nervous system issue in changes in the subject's mental activity. Displays of emotion, performance in perception and recall, and anxiety and tension are being tied down to brain function in this way.

During the twentieth century, there were in fact three distinct movements of a materialistic stamp in the philosophy of mind. In the 1920s and 1930s some logical positivists, led by Rudolph Carnap (1932–1933) and Otto Neurath, espoused an epistemic materialism. They held that the meaning of any statement consists in the directly testable statements deducible from it (the protocol sentences). In order for language and meaning to be public and shared, these protocol sentences must be intersubjectively testable. However, because no statement about one individual's experience or thought or other inner psychological state can be tested by anyone else, only sentences referring to the physical properties of physical entities are intersubjectively testable in the required way. Now, because most statements about minds are incontestably meaningful, they must, despite appearances to the contrary, in fact refer to physical properties and entities, even though translations of them into physical terms cannot be provided. In this way the philosophy of language led to a behaviorist materialism.

The beginnings of translation into behavioral terms was offered for some psychological expressions—for example, “is happy”—by directing attention to the way in which the use of such expressions is taught. A key element in teaching such an expression is to point to people behaving happily. In this emphasis on the conditions under which an expression can be learned, the positivists anticipated the favorite strategy of Ludwig Wittgenstein (1953) and moved away from complete dependence on their general doctrines of meaning and verification.

During the middle years of the twentieth century, the analytic behaviorists, in particular Gilbert Ryle (1949) and his followers, offered to show that descriptions of states of mind are essentially dispositional, so that attributions of intention and intelligence, choice and desire, excitement and fear, and other mental states are all to be understood as attributions of a disposition to behave in a characteristic manner in appropriate circumstances. Dispositions are held by most thinkers to issue from some standing or recurrent underlying state, and with these

analytic behaviorists the relevant states underlying human mental life were assumed to be states of the body. Their manifest intention to exorcise any spiritual soul—as Ryle would put it, any “ghost in the machine”—places them in the materialist tradition.

Wittgenstein, although he disdained the title behaviorist, belongs to the same group. He insisted that in any acceptable analysis of a mental concept the description of a person's state of mind must make reference only to publicly detectable features of the organism and its behavior. His many subtle discussions of mental concepts are all attempts to identify the patterns of behavior whose display would constitute being in a given state of mind. To attribute that state of mind to someone is to attribute a disposition to display the relevant pattern of behavior. The alternative analysis that interprets the various states of mind as states and processes in a spiritual soul is, according to Wittgenstein, not merely false, it is unintelligible.

On two key points the analytic behaviorists were not convincing. First, if mental states are dispositions to display particular patterns of behavior, they cannot be causes of the behavior in question. It cannot be that a man's anger made him shout, for the shouting is itself just an aspect of the anger. Nor can a woman's pride have made her stubborn. Yet this causal link between a mental state and the characteristic behavior pattern that springs from it, is at the heart of how we understand one another.

Second, some inner mental episodes, such as after-images, pains, sudden unsought recollections, dreams, or flashes of insight, resist any plausible dispositional analysis. The mind does seem to be a collection of categorical states, items, or events in addition to a cluster of dispositions. The effort to correct both these weaknesses, first the denial of any categorical component, and later the denial of any causal power to the mind, was a significant factor in materialism's subsequent development.

The third group of twentieth-century materialists embraced a theory of mind known as central-state physicalism, from which contemporary materialism derives. The central-state physicalists held that although it may be that some mental states can be understood dispositionally, there are many mental states, items, or events that must be accorded a straightforwardly categorical status. These categorical mental states turn out to be, as a matter of contingent fact, states of the central nervous system. To introspective awareness they do not seem to be neural states, but the explanation for this is that the nervous system is presented to itself in an opaque or covert fashion.

The mind has many aspects, and mental life underpins almost every distinctively human capacity. Most of our distinctive capacities have been pointed to as showing that a living human being must be something more than a mere assemblage of atoms. To understand ourselves, we cannot do without the concepts of perception, belief, and intelligence; action, decision, and choice; motive, drive, and need; feeling, emotion, and mood; temperament and character. We will also need to treat of consciousness and self-consciousness. The task for materialists is to explain how merely material structures could exhibit all these mental attributes. In attempting this, two basic approaches were at first adopted, the behavioral and the topic neutral.

*Behavioral strategy.* The central-state physicalists were able to appropriate the earlier work of the behaviorists and accept that the attribution to an organism of some of the mental predicates (for example intelligence, equanimity, or ambition) is in reality the attribution of a disposition to behave in a characteristic way under suitable conditions. The organism displaying the behavior, the form the behavior takes, and the conditions under which it is manifested, are all specifiable in purely physical terms. Moreover, the remarkable subtlety and complexity of human behavior, which until the twentieth century appeared to surpass anything of which a mere machine could be capable, no longer has such immaterialist implications, for now the development of electronic machines suggests that the ability to duplicate human performance is possible. In particular, the self-monitoring features of conscious behavior can be displayed by material systems.

*Topic-neutral strategy.* Many mental states resist the behavioral strategy: being in pain, seeing a color, or feeling depressed, for example. For these, a different claim was made: To attribute such a state is to assert that there is present within the organism some state or process that typically arises from a particular kind of stimulus and/or typically issues in a characteristic kind of behavior. A burning pain, for example, is a state of a person typically arising from excessive heat on the skin, and characteristically issuing in applications of soothing cream to the affected part. Mental predicates of this kind have been called *topic-neutral* because they do not specify the nature of the inner state in question. The inner state is not described either as material or as immaterial. To say that someone is in pain, the argument runs, does not of itself imply that the experience belongs to an immaterial mind. It implies only that the person is in some central state or other, arising from the states and processes in the sensory

system (input), and issuing in certain behavior patterns (output). When we attempt to identify this central state, we find that the sensory system provides inputs to the organism's central nervous system, which in turn sets in train the muscular movements required for any type of behavior. If inner states admit of the topic-neutral treatment, they, too have no immaterialist implications.

Among early central-state physicalists, some, such as Paul K. Feyerabend (1963) and Hilary Putnam, claimed only that this is the most promising line for investigation to now take. Others, such as U. T. Place (1956), J. J. C. Smart (1959, 1963), and Herbert Feigl (1958), went further and held that any alternative dualist view is already frankly incredible.

## CONTEMPORARY MATERIALISM

During the later years of the twentieth century, under the influence chiefly of David Armstrong (1968) and David Lewis (1972), the topic-neutral strategy was taken up and developed. The behavioral strategy became less prominent, as more and more mental attributions were interpreted as asserting that the organism was in an appropriate categorical state. And the role of the mental as the causal bridge between stimulus and response was taken up and emphasized. Mental states came to be regarded as theoretical constructs and assimilated to other theoretical entities more familiar from other sciences, as philosophers adopted a third strategy for accounting for mental descriptions in a material world.

*CAUSAL/THEORETICAL STRATEGY.* In a complete departure from the behaviorist viewpoint, which saw mentality as a matter of the outer effects of stimuli, the new position is that the really essential thing about any mental state is its causal role, as the crucial inner intermediary between input and response. The idea is that the activity of conscious living beings calls for explanation, and the most appropriate explanations will attribute to such organisms inner states, produced by environmental and remembered elements, and producing behavior that, in the light of the organism's beliefs, is best suited to fulfilling its purposes.

So the mind becomes an inner, theoretical entity, the that-which-best-accounts-for the phenomena of conscious behavior. The analogy was drawn with the gene in biology, that-which-best-accounts-for the phenomena of heredity, and with lightning, that-which-best-accounts-for flashes, thunder, and some kinds of storm damage.

Then, still following the analogy, the research question becomes that of finding which element in the world

turns out to fill the theoretical role in question. Structures crucially involving the DNA molecule, as it turns out, best account for heredity. Electrical discharges, as it turns out, best account for the flashes, rumbles, and damage of electrical storms. This is a matter of the contingent identification of underlying structures and processes as the causal bases for patterns of observed phenomena. So with the mind: It is the central nervous system (brain, optic nerve, spinal chord, and some other components) that, as it turns out, fulfills the mind's causal role as the intermediary and clearinghouse between the inputs, many of which we know as experience, and the outputs that consist in purposive activity.

In this way functionalism, the dominant form of contemporary materialism, developed. It has two components. The first component is a theory of the mind, which asserts that the essential feature of the mind is its causal role, and identifies the different states of mind—beliefs, fears, plans, twinges, and so forth—in terms of their particular places in the whole mental causal scheme. This theory of the nature of mind lends itself to materialism, but is not itself materialist. It is topic-neutral, allowing for any of a number of views of what it is that provides the causal bridge between inputs and responses. The second component in functionalist materialism is the theoretical identification of the mind with the central nervous system. This is a contingent assertion about what minds turn out to be in this world. As such, it is vulnerable to various empirical developments, as all substantial empirical claims should be.

## OBJECTIONS TO MATERIALISM

**THE POSSIBILITY OF SCIENTIFIC REFUTATION.** Materialism is a strong version of naturalism. It asserts that everything whatsoever that occurs in this world is the result of the operation of physical forces in accord with physical laws. So a spectacular and unequivocal divine intervention in the course of nature, such as the Apocalypse and the Day of Judgment as described in the book of Revelation, would spell the end of materialism as a credible philosophy.

Less spectacular developments could have the same impact. The firm establishing of parapsychological powers (telepathy, clairvoyance, or psychokinesis) would do so, for by definition any paranormal phenomenon involves knowledge or action by a mind in defiance of physical law. So also would developments in neural science that uncovered variations in effectual states of mind without any appropriate change in states of the central nervous system. Or changes in the central nervous system

linked to changes in mental state, such as forming a new resolution, that systematically violate the probabilities for neural change that physical laws set forth and that defy any modification to accepted physical laws.

Materialism, being vulnerable in these ways, remains to that extent speculative. But whereas a watching brief needs to be kept over the progress of scientific investigations, it is fair to say that there is at present no serious threat from these quarters. The credibility of positive paranormal results has, if anything, diminished in the course of the past half century. And we are very far indeed from being able to assert that the activity of the brain is physically anomalous. Quite the contrary; so far, no apparent violations of physical law have been found.

**THEOLOGY.** Materialism not only holds that there are no supernatural interventions in the course of nature, but that there are no divine beings of any kind. To defend materialism on these points, one must first show that there is no valid deductive argument for the existence of a necessary being, then sustain the view that this world does not call for a divine creator as the best explanation for its existence and character.

Next, one must deny that religious experience reveals a supernatural realm, as vision provides access to a physical one. Adopting the skeptical empiricists' critique, one can argue that religious experience is not sufficiently uniform, widespread, and unanimous to warrant abandoning the natural modes of explanation that have served so well in all other enquiries, especially as supernatural hypotheses face peculiar difficulties when it comes to putting them to the test. The materialist position is strengthened by the promise of continued success in finding concrete natural explanations of religious experience through developments in sociology, psychology and physiology.

If these positions can be established, claims to the existence of God and the occurrence of miracles are established neither by argument nor in experience and so must be considered as interpretative hypotheses laid upon the experienced world. The materialist must again urge that in framing hypotheses, as in seeking explanations, there is no sufficient reason for deserting the natural for the supernatural. In such circumstances as these considerations of parsimony exclude all supernatural entities from any reasonable ontology.

Materialists must show that, contrary to the claims of Spiritualists and Buddhists, there is no sufficient reason to believe in survival of bodily death or in reincarnation. And indeed there are plausible arguments that both

doctrines rest on untenable views of the self. These arguments do not impugn the possibility of bodily resurrection, but that is compatible with materialism.

**METAPHYSICS.** Materialism has in the past been assailed as incomplete. Even if, in a great advance on its predecessors, modern cosmology does provide explanations for the origin, persistence, and motion of the fundamental particles, it provides none for the initial conditions from which these derive. Nor does materialism make intelligible why each fundamental interaction has had one result and not another. The reply, now widely accepted, is that all chains of explanation must eventually come to a terminus and that to seek to go beyond contingent truths concerning the items and processes in this world is to go hunting a mare's nest.

**THE MIND AND HUMAN EXPERIENCE.** There is no doubt that our own conscious experience provides the greatest intuitive challenge to materialism. C. D. Broad in *The Mind and Its Place in Nature* (1925) formulates many people's reaction to the suggestion that mental events are physical events, such as molecular movements, taking place in our body:

About a molecular movement it is perfectly reasonable to raise the question "Is it swift or slow, straight or circular and so on?" About the awareness of a red patch it is nonsensical to ask whether it is a swift or slow awareness, a straight or circular awareness, and so on. Conversely, it is reasonable to ask whether it is a clear or a confused awareness, but it is nonsense to ask of a molecular movement whether it is a clear or a confused movement. Thus the attempt to argue that "being a sensation of so and so" and "being a bit of bodily behavior of such and such a kind" are just two names for the same characteristic is evidently hopeless. (p. 623)

Indeed, this attempt is hopeless, but it is not one a materialist must make. We need to distinguish the process of being aware from the item of which we are aware. The two "names" that materialists claim to name the same thing are "subject *S* having sensation *P*" and "subject *S* undergoing bodily changes *Q*," and it has become clear since Broad wrote that what is or is not nonsensical is not an immediate deliverance of introspection, but an issue in the fashioning of concepts to improve theories of the world. As for *P*, which is the item of which *S* is aware—what Broad calls the sensation *S* has—there would be no absurdity if this could be dealt with by a topic-neutral strategy. We are aware that something is going on in us,

which deserves the description "red patch," but according to the topic-neutral strategy, the nature of what is going on is not part of what we are conscious of. The fact of the matter, according to the materialists, is that we have a covert presentation of bodily changes *Q* to the person *S*, who is having the sensation. Nevertheless, the two main stumbling blocks for functionalist materialism both concern the character of our inner life.

**The qualia problem.** The topic-neutral or causal/theoretical strategies may well be satisfactory for those inner states that have no special "feel" about them, such as deciding. We can decide to do something, and be aware that we have decided, but that awareness carries no special feel or twinge or glow with it. We are aware that something is going on in us, something that will have an impact on how we behave by bringing a new causal factor into our life. But that state, and our awareness of that state, reveal nothing about its nature as material or immaterial. Decisions and intentions are thus favorable candidates for a topic-neutral analysis—so, too, is doing mental arithmetic, where the process leads to changes in what one will say or do, but carries no other inner characteristics that one is aware of.

The case is otherwise, however, with sensations and feelings. To see a red patch is to be aware of an inner state that has a redness about it, that sets it apart from the green and blue patches we see. This difference is not obviously a difference in how we discriminate the two items, and react to them, as is brought out by the spectrum-shift arguments, which point out that although your outward color-vision behavior may match mine, you may see reds as I see pale pinks, or blues as I see greens.

To be in love is certainly to be in a state apt to issue in a characteristic pattern of behavior. But it is more than that; there is a complex of feelings involved that do not of themselves involve behavioral differences, but differences in consciousness, by comparison with those not in love.

To be angry, or in pain, or delighted, carry special sensations or feelings with them too. All such sensations or feelings are known as *qualia*, and the qualia problem is the problem of fitting them in to a materialist world view. It is notorious that when you are seeing something green, and therefore experiencing a sensation of green, there is no green physical surface anywhere inside you. The sharp pangs of pain are similarly elusive—the neural activities have been found that occur when pain is felt, but the painfulness of pain does not seem to be present among them.

Qualia seem to be an important part of being conscious. They seem to make a difference to how we speak and act, yet they stand outside the network of physical causation, neither taking energy in their production, nor having any force to apply to change the world. They challenge the deep materialist commitment to the physical closure of the natural world. If only physical items can have physical effects, then qualia cannot even produce our awareness of them, nor our capacity to describe them, which makes them paradoxical items indeed.

There have been attempts to account for them behavioristically, as dispositions to act and react in particular ways. Perhaps the most promising materialist suggestion is that the intrinsic qualities of sensations are in reality purely schematic and enable us only to distinguish one sensation from another. Inner states notoriously elude direct characterization. Our attempts to describe them often proceed by comparison with other sensations directly or ultimately picked out by reference to their stimulus and/or response. For example, we describe smells as of cinnamon or of rotten eggs (stimulus) and as appetizing or nauseating (response); we speak of pains as jabbing, burning, or like “pins and needles.” Feelings of anger, shame, pride, and fear are all described in terms of bodily temperature.

If the sameness or difference of inner states but not their nature is given introspectively, sensations could well be states of the nervous system typically connected with stimulus and/or response, even though we are not aware of this. This strategy for dealing with qualia faces the problems of spectrum-shift arguments, because two sets of sensations, tastes for example, could be shifted relative to one another along a spectrum, yet perform equally well in informing us of the sameness or difference, and typical causes and effects, of our inner states.

The qualia problem was long emphasized by F. C. Jackson (1998) in a series of influential articles. His most recent stance is the “there must be a solution” solution: Somehow, qualia must be reconcilable with materialism, even if we cannot see how.

*The insight problem.* The second currently most acute problem for materialism concerns the nature of human insight and understanding. When we learn to speak a language, we acquire the ability to conduct a conversation satisfactorily; that is, to make appropriate responses to the speech of others, to initiate conversations using sounds the other recognizes and responds to. But to properly understand, more than linguistic competence is required. This was dramatized by John Searle (1992) in his “Chinese Room” argument: If someone who had no

understanding of Chinese but who could recognize Chinese characters were shut away in a room, and provided with pieces of Chinese—questions and so forth—through a mailbox, that person could, using a computerized dictionary for example, choose appropriate Chinese-character responses. This is a linguistic competence that does not include understanding and is clearly deficient by comparison with the capacity of a genuine Chinese speaker. The missing component, understanding or insight, proves just as elusive as do the qualia to materialist studies of the nervous system.

**PHILOSOPHY.** Materialism faces several other more general objections, for the most part of a logical kind, that must be faced.

*The argument from self-destruction.* A popular argument for disposing of materialism is this:

All doctrines concerning the nature of the world are arrived at by inference.

Thus, *a fortiori*, materialism is so reached.

But if materialism is true, inference is a causally determined process in people’s brains, and not a rational process.

Materialism is therefore a doctrine arrived at by non-rational causal processes.

Thus, if it is true, there can be no reason to think it so.

This argument has a long history, being found in Epicurus and developed and defended by J. B. S. Haldane (1932) and Karl Popper (1977). Nevertheless, it is invalid. That the course of a given process of inferring was determined by the structure of a brain does not entail that it was an unreasonable inference. Nor does it entail that there could be no ground for thinking it reasonable. We can see that this is so, by comparing reasoning in people with calculating in adding machines. The result reached is a causal consequence of the structure of the machine; it is nonetheless a correct one, and one we are entitled to rely on. Haldane later retracted his argument (1954).

*Asymmetrical knowledge of physical and mental states.* Another common argument against materialism points out that, although ordinary people can recognize thoughts and feelings and intentions, they are completely ignorant of processes in the central nervous system, and so the mental occurrences cannot be identified with any such physical events. Friedrich Paulsen, for example, argued to this effect in chapter one of his *Introduction to Philosophy* (1895 [1892]).

This argument is also, as it stands, invalid. It is like arguing that because the police know some of the characteristics of a man who committed a crime but do not know anything about John Smith, John Smith could not possibly be the man who committed the crime. A similar reply is provided by Place and Smart in articles cited in the bibliography.

The argument would be valid if another premise were added: In introspection the full nature of mental events is disclosed. But there is no good reason for thinking this premise is true.

A variation of this argument claimed that introspective knowledge of our own mental states is incorrigible, whereas no knowledge of anything physical is incorrigible, so mental states cannot be physical. This argument faded from view after Armstrong exposed its weakness: We can and do make mistakes about our own inner mental states.

*The general nature of human reason.* Keith Gunderson (1964) revived an argument of Descartes's to the effect that men are not machines, even cybernetic machines, and therefore not merely material. In all known machines the matching or surpassing of a human intellectual ability is a specific outcome of a specific structure. Each skill is a skill at some specific task and no other. But in human beings, intellectual skills are generalized and come in clusters; human reason is a tool for all circumstances. Thus, it is not proven that the human skill and that of the machine arise from a like inner structure. On the contrary, the reasonable conclusion is that the machine's skill and the human skill are to be explained in different ways—that is, a person is not any kind of machine.

The reply available to materialists is that this argument is premature. The simulation of human performance by material assemblages is in its infancy. There seems no reason to suppose a machine with generalized skills impossible.

*Intentionality.* Unlike the situation with anything physical, in the realm of the mind there are relations that can exist even in the absence of one of their terms. These are the intentional relations, which include intending, believing, hoping, fearing, and desiring. The argument from intentionality rests on this peculiarity and may be put this way:

A peculiarity of many mental states is their essential connection with an object. In intending, I must intend something, and in hoping, I must hope for something.

However, whereas when I kick something, the thing I kick must exist, the thing intended or the thing hoped for may or may not have any real existence.

In this way some mental states differ essentially from all physical states.

Thus, materialism cannot be true.

The materialist reply to this argument is that intentional "relations" are strictly speaking not relations but monadic states that are identified by reference to what would fulfill them or constitute their exercise. These are possible states or circumstances that, were they actual, would be material. It is a further question, however, whether the existence of mere, unactualized possibilities is compatible with a strict materialism.

*Logical connections between distinct existences.* The essential link between a mental state and the behavior to which it gives rise has also been seen to rule out materialism:

Where an intention is carried out, both the intention and the thing intended exist.

They are two different things.

Nevertheless, they are logically connected, because what was carried out makes the intention what it was.

But any two different physical items are only contingently connected.

Hence, mental states cannot be physical items.

Materialists urge in rebuttal that this is a consequence of the peculiarly causal character of mental states and has its counterpart in the uncontroversially physical realm.

Thus if we describe arsenic causally as a lethal poison, there is a logical connection between drinking the lethal poison arsenic and dying, even though the arsenic, the drinking, and the dying, are all distinct existences.

## NONREDUCTIVE MATERIALISM

Despite the progress made in rebutting the classical objections to materialism, and despite the current popularity, in English-speaking philosophy, of functionalist physicalism as a philosophy of mind, uneasiness remains that materialism accords insufficient recognition to consciousness and its highest expressions—music, literature, love, and fine feeling generally, as well as culture, morality, and religious aspiration. In response to this, there have been some attempts at a softer materialism that tries

to accord to the physical a primary but not exclusive place. While everything depends on the physical, it does not reduce to the physico-chemical, but rather supervenes upon it. The most thorough attempt in this direction is J. F. Post's *The Faces of Existence* (1987). A further step away from extreme materialism is taken in Nicholas Maxwell's *The Human World in the Physical Universe* (2001), which advocates a dual-aspect position while clinging to the central materialist claim that the universe is a closed system, in which the only causally effective forces are the physical ones.

## Bibliography

### GENERAL HISTORIES OF MATERIALISM

- Lange, Frederick Albert. *Geschichte des Materialismus* (1865). Translated by E. C. Thomas as *The History of Materialism*. London: Truebner, 1877–1892. This classic is by far the most important secondary source in the history of materialist theories. All English editions since the London edition of 1925 include an introduction by Bertrand Russell titled “Materialism.”
- Lewes, George Henry. *The Biographical History of Philosophy*. London: C. Knight, 1845. A lively and idiosyncratic history, with good comments on materialist philosophers.
- Vitzthum, R. *Materialism: An Affirmative History and Definition*. Amherst, NY: Prometheus, 1995. Accessible work, emphasizing the scientific aspects of the development of materialism.

### CLASSICAL PERIOD

- Aristotle. *Metaphysica*. Translated by W. D. Ross as *Metaphysics*. Oxford: Clarendon Press, 1924. Most easily accessible source for ancient world opinion on materialistic Greeks.
- Burnet, John. *Early Greek Philosophy*. 4th ed. London: A & C Black, 1930.
- Burnet, John. *Greek Philosophy; Thales to Plato*. London: Macmillan, 1914. Standard account of ancient philosophy.
- Lucretius. *De Rerum Natura*. Classic presentation, in Latin verse, expanding and occasionally modifying the doctrines of Epicurus. Translated by Rolfe Humphries as *The Way Things Are*. Bloomington: Indiana University Press, 1969. Another edition, translated by R. E. Latham. Harmondsworth, England: Penguin, 1961.

### SEVENTEENTH CENTURY

- Brandt, Frithiof. *Den mekaniske Naturopfattelse hos Thomas Hobbes*. Translated by Vaughan Maxwell and Annie Fairstoll as *Thomas Hobbes' Mechanical Conception of Nature*. London: Librairie Hachette, 1928. Detailed and definitive.
- Cyrano de Bergerac, Savinien de. *Etats et empires de la lune and Etats et empires du soleil*. 1657, 1662. Translated by Richard Aldington as *Voyages to the Moon and the Sun*. New York: Orion Press, 1962. These fictional works epitomize the seventeenth-century movement toward materialism.
- Gassendi, Pierre. *Animadversiones in Decimum Librum Diogenis Laerti*. Lyons, France, 1649.

- Gassendi, Pierre. *De Vita et Moribus Epicuri Libri Octo*. Lyons, France, 1647.
- Gassendi, Pierre. *Philosophiae Epicuri Syntagma*. Lyons, France, 1649.
- Gassendi, Pierre. *Syntagma Philosophicum*. Lyons, France, 1658. These four works appeared together in *Opera Omnia*. Lyons, France, 1658. Facsimile reprint Stuttgart-Bad-Cannstatt, frommann, 1964. In these four works Gassendi expounds and defends Epicurus (except where his views conflict with Catholic doctrine.)
- Hobbes, Thomas. *English Works*, edited by William Molesworth. London: Bohn, 1839.
- Hobbes, Thomas. *Latin Works*, edited by William Molesworth. London: Bohn, 1839.
- Mintz, Samuel I. *The Hunting of Leviathan*. Cambridge, U.K.: Cambridge University Press, 1962. Narrates contemporary reactions to Hobbes.
- Peters, Richard. *Hobbes*. Harmondsworth: Penguin, 1956. Interesting and comprehensible introduction.
- Rochot, Bernard. *Les travaux de Gassendi sur Epicure et sur l'atomisme 1619–1658*. Paris: Librairie Philosophique, 1944. Most accessible modern treatment of Gassendi.
- Spink, John S. *French Free-Thought from Gassendi to Voltaire*. London: University of London, Athlone Press, 1960.

### EIGHTEENTH CENTURY

- Cabanis, Pierre-Jean-Georges. *Rapports du physique et du moral de l'homme*. Paris, 1802. English translation by M. D. Sadi. Baltimore: Johns Hopkins Press, 1981.
- Diderot, Denis. *Oeuvres completes*. Paris: Garnier Freres, 1875.
- Holbach, Paul Heinrich Dietrich d'. *Systeme de la nature ... par Mirabaud*. 1770. Translated by H. D. Robinson as *The System of Nature*. Edited by Denis Diderot. Boston: J. P. Mendum, 1853. Classic treatise.
- La Mettrie, Julien Offray de. *L'homme machine*. 1748. Translated and edited by Ann Thom as *Machine Man*. Cambridge, U.K.: Cambridge University Press, 1996. There is also a critical edition with notes by Aram Vartanian. Princeton, 1960.
- Maubec. *Principes de la raison et les passions de l'homme*. Manuscript held in the Bibliotheque nationale in Paris (B.N. n.a.f.r.14709).
- Priestley, Joseph. *Disquisitions Relating to Matter and Spirit*. London: J. Johnson, 1777.

### NINETEENTH CENTURY

- Buchner, Ludwig. *Kraft und Stoff* (1855). Translated by J. Frederick Collingwood as *Force and Matter*. London, Truebner, 1884.
- Darwin, Charles. *The Descent of Man*. New York: Appleton, 1871.
- Darwin, Charles. *The Origin of Species*. London: John Murray, 1859. Classic treatise.
- Moleschott, Jakob. *Der Kreislauf des Lebens*. Mainz, Germany: Von Zabern, 1857.
- Passmore, John. *A Hundred Years of Philosophy*. London: Duckworth, 1957. Readable and authoritative guide.
- Vogt, Karl. *Kohlerglaube und Wissenschaft*. Giessen, Germany: Ricker, 1855.
- Vogt, Karl. *Physiologische Briefe*. Giessen, Germany, 1854.

## TWENTIETH CENTURY

- Armstrong, David M. *A Materialist Theory of the Mind*. London: Routledge and Kegan Paul, 1968. A modern classic, first systematic exposition of central-state physicalism.
- Carnap, Rudolf. "Psychologie in physikalischer Sprache" (1932–1933). Translated by Frederick Schick as "Psychology in Physical Language," in *Logical Positivism*, edited by A. J. Ayer. Glencoe, IL: Free Press, 1959. Epistemic materialism.
- Eliot, Hugh. *Modern Science and Materialism*. London: Longmans, Green, 1919.
- Feigl, Herbert. "The 'Mental' and the 'Physical.'" In *Minnesota Studies in the Philosophy of Science*. Vol. 2, edited by Herbert Feigl et al. Minneapolis: University of Minnesota Press, 1958. Identifies mental states with brain processes.
- Feyerabend, Paul K. "Materialism and the Mind-Body Problem." *Review of Metaphysics* 17 (1) (1963): 49–66. Claims materialism is the only plausible view.
- Hook, Sidney, ed. *Dimensions of Mind: A Symposium*. New York: New York University Press, 1960. Deals with the relations of mind, body, and machinery from many points of view.
- Lewis, David K. "Psychophysical and Theoretical Identifications." *Australasian Journal of Philosophy* 50 (1972): 249–258.

## MATHEMATICS, FOUNDATIONS OF

The study of the foundations of mathematics comprises investigations, though probably not all possible investigations, that consist of general reflection on mathematics. The subject naturally proceeds by singling out certain concepts and principles as “fundamental” and concentrating attention on them, but of course the identification of fundamental concepts and principles is itself based on foundational research or may be revised in the light of it.

In this entry considerable emphasis will be placed on philosophical questions about mathematics, which undoubtedly belong to foundations. However, many, perhaps most, foundational investigations are mainly mathematical. In the last hundred years an important role has been played by mathematical logic. We shall not give a detailed exposition of mathematical logic, but we hope that our discussion will give an idea of the relation between the logical problems and results and the philosophical problems and an idea of some of the results of recent work in logic.

Two of the main qualities for which mathematics has always attracted the attention of philosophers are the great degree of systematization and the rigorous development of mathematical theories. The problem of systematization seems to be the initial problem in the foundations of mathematics, both because it has been a powerful force in the history of mathematics itself and because it sets the form of further investigations by picking out the fundamental concepts and principles. Also, the systematic integration of mathematics is an important basis of another philosophically prominent feature, its high degree of clarity and certainty. In mathematics systematization has taken a characteristic and highly developed form—the axiomatic method—which has from time to time been taken as a model for systematiza-

tion in general. We shall therefore begin our main exposition with a discussion of the axiomatic method.

Foundational research has always been concerned with the problem of justifying mathematical statements and principles, with understanding why certain evident propositions are evident, with providing the justification of accepted principles that seem not quite evident, and with finding and casting off principles which are unjustified. A natural next step in our exposition, then, will be to consider mathematics from an epistemological point of view, which leads us to examine mathematics as a primary instance of what philosophers have called a priori knowledge. In this connection we shall give some logical analysis of two very basic mathematical ideas, class and natural number, and discuss the attempts of Gottlob Frege and Bertrand Russell to exploit the intimate relation between these two ideas in order to prove that mathematics is in some way a part of logic. We shall also discuss Immanuel Kant’s views on the evidence of mathematics and other conceptions of a priori knowledge. (The word *evidence* will often be used in this entry in a way that is unusual outside philosophical writings influenced by the German tradition, to mean “the property of being evident”—German, *Evidenz*.)

The growth of modern mathematics, with its abstract character and its dependence on set theory, has caused the problem of evidence to be focused on the more particular problem of platonism. It is in this development and the accompanying growth of mathematical logic that modern foundational research has centered.

Throughout the nineteenth century, mathematicians worked to make arithmetic and analysis more rigorous, which required axiomatization and an attempt to use the concepts of the theory of natural numbers as a basis for defining the further concepts of arithmetic and analysis. The manner in which this axiomatization and definition was undertaken was platonist, in the sense that both numbers and sets or sequences of numbers were treated as existing in themselves. The development of set theory by Georg Cantor provided a general framework for this work and also involved even greater abstraction and even stronger platonist assumptions.

The growth of mathematical logic introduced as further elements the axiomatization of logic (the basic step in which was completed by Frege in 1879), the effort to incorporate the axiomatization of logic into that of mathematics, and the accompanying tendency, on the part of Frege and Giuseppe Peano, to interpret rigorous axiomatization as formalization. Frege carried the development much further by undertaking to develop the whole of

arithmetic and analysis in a formal system that is essentially a system of set theory.

At the turn of the twentieth century the entire development reached a crisis with the discovery of the paradoxes of set theory, which showed that the concept of class or set as it was then being used had not been sufficiently clarified. Much of the foundational research of the early twentieth century—and not only in the axiomatization of set theory—was directed at problems posed or believed to have been posed by the paradoxes.

In that period emerged three general viewpoints, each of which had its own program based on a distinctive attitude toward the question of platonism. The most radical was intuitionism, based on L. E. J. Brouwer's critique of the whole idea of platonism. In contrast to Brouwer, David Hilbert had a firm commitment to the patronizing tendency in mathematics, but he held epistemological views that were fundamentally in accord with Brouwer's critique of platonism. Making use of the fact that no matter how platonist the mathematics formalized, questions of provability in a formal system are meaningful from a narrow constructivist point of view, Hilbert's school sought to secure the foundations of platonist mathematics by metamathematical investigation of formalized mathematics—in particular, by a proof of consistency. This viewpoint was called formalism, although the designation is misleading, since Hilbert never maintained that even platonist mathematics could be simply defined as a “meaningless” formal system.

Proponents of the third viewpoint, logicism, whose leading figure was Russell, continued to believe in Frege's program of reducing mathematics to logic. Accepting this program involved taking some platonist assumptions as intuitively evident.

A great deal of work in mathematical logic was directed toward clarifying and justifying one or another of these points of view. We might mention Brouwer's (informal) results on the impossibility of constructively proving certain theorems in analysis, Arend Heyting's formalization of intuitionist logic, the development of finitist proof theory by Hilbert and his coworkers, and Russell and A. N. Whitehead's *Principia Mathematica* as a much further development of mathematics within a system of set theory.

Nonetheless, the trichotomy of logicism, formalism, and intuitionism has probably never been the best classification of points of view in foundations. It does not take account of one of the philosophically most important problems, that of predicativity, or of some mathematical

developments—such as the development of the semantics of logic by Leopold Löwenheim, Thoralf Skolem, Kurt Gödel, and Alfred Tarski—which were crucially important for later work. At any rate the schools no longer really exist. All of them had programs that encountered serious difficulties; further experience with set theory and the axiomatizations of Ernst Zermelo and Russell deprived the paradoxes of their apparently apocalyptic character; and specialized work in mathematical logic led more and more to the consideration of problems whose significance cut across the division of the schools and to looking at the results of the schools in ways which would be independent of the basic controversies. A decisive step in this development came in the early 1930s, with the discovery of Gödel's incompleteness theorem and the coming of age of formal semantics.

Some areas of the foundations of mathematics will be passed over here—in particular, we shall not go far into the significance of the fact that mathematics has applications to the concrete world, although historically the relation between mathematics and its applications has been very close, and the present sharp distinction between pure and applied mathematics is a rather recent development. For instance, we shall omit a special consideration of geometry. If the pre-twentieth-century view that geometry is a purely mathematical theory that nonetheless deals with actual space is correct, then the omission is unjustified. However, even the question whether this view still has something to be said for it is more intimately related to the philosophy of physics than to the problems on which we shall concentrate. Geometry as understood today by the pure mathematician, as the general study of structures analogous to Euclidean space, raises no philosophical problems different from those raised by analysis and set theory.

## §1. THE AXIOMATIC METHOD

As we said, we shall begin our discussion with the axiomatic method. Consideration of the notion of an informal axiomatic system leads to the notions of formalization and formal system. Through this process, especially through the last step, mathematical theories become themselves objects of mathematical study. The exploitation of this possibility is perhaps the specifically modern move in the study of the foundations of mathematics and has led to an enormous enrichment of the subject in the last hundred years.

**1.1. AXIOMATIZATION.** Ever since Euclid, axiomatizing a theory has meant presenting it by singling out certain

propositions and deducing further ones from them; if the presentation is complete, it should be the case that all statements which could be asserted in the theory are thus deducible. Axiomatization has also come to mean a similar reduction of vocabulary, in that certain notions should be taken as primitive and all further notions which are introduced in the development of the theory should be defined in terms of the primitive ones. In essence this is the conception of an axiomatized theory that prevails today, although it has been developed in different directions.
